CONTENTS

CONTENTS

TRACK 1 - POSTGROWTH URBANISM

Varvara Toura, **From abandonment to critical conception: post-growth policies for the resilience of deindustrialised areas. The case-studies of Ile-de-Nantes and Docks-de-Seine in France**
34

Mark Groulx, Tara Clapp, Benjamin Bryce, Mikhaila Carr & Keone Gourlay, **Planning the Great Acceleration: Contributions of planning theory, ideology, and implementation to planetary transformation and social-ecological decline**
49

Abdalrahman T. Y. Alashi & Özhan Ertekin, **Deprivation Analysis in Turkey and Its Provinces: Insights for Post-Growth Urbanism**
63

Chiara Moretti, Roberto Bologna & Giulio Hasanaj, **Toward New Circular Urban Economies: Regeneration Models for the Ecological Transition of Cities. European Cases and Initiatives.**
84

Dila Toprak & Eren Kürkçüoğlu, **Post-growth Redefinition of Urban Textures: The Changing Faces of Human Scale through Eminonu and Maslak Central Business Areas in Istanbul**
100

Francesca Giangrande, Luciano De Bonis & Giovanni Ottaviano, **Alto Medio Sannio inner area between marginality, latent place knowledge and territorial heritage**
115

TRACK 2 - PLANNING AND LAW

Fanny Tremblay-Racicot, Jérôme Couture École & Léa Béliveau, **Use of New Municipal Fiscal Powers for Sustainable Urban Development: Development and Application of a Strategic Financial Planning Method in the City of Mascouche**
129

Margherita Emilia Re, **Land Take and Logistics Hubs: Castel San Giovanni, the Milan Logistic Region's Gateway to Emilia-Romagna (Italy)**
145

YaZhen Cai & Tzuyuan Stessa Chao, **Exploring the Application and Challenges of Urban Planning Legal Systems Guided by Nature-Based Solutions: A Case Study of Kaohsiung City, Taiwan**
159

Burcu Soygüzeloğlu & Tüzin Baycan, **Legal Pathways for Urban Mobility Resilience : A Content Analysis of Policy Documents for Istanbul's Transport Systems**
173

Pierpaolo Cicconi, Giorgio Caprari & Elio Trusian, **Legislative innovations in times of crisis. The proposal for a new Italian law on territorial governance and the experimentation in the Marche Region**
185

İrem Ceylan, **Public Interest or Private Profit? A Case Study of How Public Interest is Redefined Through Political Power And Land Commodification in Istanbul**
200

TRACK 3 - MOBILITY

Akkelies van Nes, **The walkability potential matrix – a new method for measuring sustainable destination configurations in town and city centres**
213

Tianxin Zhang & Mengde Zheng, **Optimisation of non-motorised facilities in urban fringe sheltered housing areas: Transport Accessibility and Equity Enhancement Based on Supply and Demand Analysis**
234

Emine Yetişkul & Metin Şenbil, **'15-minute city' in Turkey: a framework for sustainable urban planning and governance in mid-sized Turkish Cities**
245

Metin Şenbil & Emine Yetişkul, **is sump a panacea for dynamic cities? bridging ambition and reality: a case study of Istanbul**
256

Emine Yetişkul & Metin Şenbil, **Urban rail transit usage in developing countries: the case of Istanbul**
268

Omer Dogan & Sugie Lee, **Socioeconomic Disparities in Daily Activity Spaces: Insights from Smartphone Mobility Data on Non-Commuting Trips**
281

Zhoulanyi Xing, Junting Lin, enshan Chen, **Correlation Analysis Between Rail Network Nodal Attributes and Passenger Staying Rate: A Case Study of China's Yangtze River Delta Region**
301

Wendi Dong, **An Exploration of Route Synergy between Attractions in Xi'an's Main Urban Area Based on the Node-Place Model**
310

Wang Su, Wang Yuchen, Zhang Shangwu & Huang Jianzhong, **Evaluation and Optimization of Public Service Facility Accessibility in Planning Future Community Living Circles: A Case Study of Yangpu District, Shanghai, China**
318

Wang Yuchen, Chen Ge & Huang Jianzhong, **A Study on the Travel Characteristics of Rail Transit Passengers in Township Areas of Wuxi City**
333

Clément Hacquard, Maxime Hachette, Berk Celik & Alain L'Hostis, **Modelling Access Ergonomics to Daily Life Resources using Sustainable Modes within the Eurométropole de Strasbourg**
348

Yufei Qu, Yuying Zhu, Xiaoxi Zhang & Chuan Wang, **Impact of Multi-Station Aggregate Hub Redevelopment on Surrounding Urban Areas: A Case Study of London's King's Cross**
364

Jia Wei, Shangwu Zhang & Quan Yuan, **Urban freight mobility modes recognition classification and inclusive freight policy exploration based on truck trajectory data: A case study of Shanghai, China**
379

CONTENTS

Caterina Villani, Toka Fahmy Aly, **GenAI Street Experiments: A Critical Framework for Urban Design Teaching and Learning**
395

Yutong Ma, Mengyue Mei & Tongyu Sun, **Exploring Pedestrian Comfort and Urban Mobility: A Multi-Modal Assessment of Walking Experiences at Popular Restaurant Destinations in Shanghai**
408

Aydın Furkan Terzi, Ayşenur Koçyiğit, Koray Aksu & Hande Demirel, P**erformance Analysis of 15-Minute City Zones Through Spatial and Machine Learning Techniques**
427

Xinrui Guo & Yuan Zhu, **The Appropriate Intensity of Rail Transit Station Area near Historic Districts: A Case Study of Shanghai, Nanjing, Kyoto and Tokyo**
439

Ge Wan & Jianzhong Huang, **Travel Characteristic of Elderly People in Towns of Shanghai Metropolitan Area: An Urban Rural Mobility Network Analysis**
458

Jiayu Gu, Luyao Niu & Wenjia Zhang, **Why public transport interventions work or not? A meta-analysis based on the behaviour change wheel model**
467

Yanyun Mao & Jian Zhuo, **Planning amidst Planetary Crisis: Rethinking Theory and Practice through Adaptive Transformations in Public Transport**
494

Jennifer Jiang, Dayanna de Mello Sousa, Ágota Barabás, Jörg Rainer Noennig & Domokos Esztergár-Kiss, **Adapting the 15-Minute City Model for Suburban Areas: Key Performance Indicators (KPIs) and Multimodal Mobility Strategies**
509

Yuxiao Ma, Qiao Zhang, Jing Deng & Jianzhong Huang, **«Beyond Growth» in China: Coordinated Optimisation Strategies for Rail Transit Networks and Regional Spatial Structure in the Post-Urbaniastion Context**
522

Baekchan Jeon & Myounggu Kang, **Beyond Access: A Grid-Based Framework for Measuring Service Levels and Inequity in Multimodal Public Transit**
537

Elisabetta Vitale Brovarone, Francesca Blanc, Giulia Melis & Aida Shaneh, **Sustainable Urban Mobility Plans: a catalyst for transformative urban practices?**
555

Yoon Kyubin & Kang Myounggu, **Analysis of Regional Disparities in Public Transportation Accessibility: A Spatial Approach to Equal-Time Job Accessibility**
566

Kehao Li, Xiu Yang, Hu Yumin & Chao Liu, **Exploration of the Relationship between Travel Activity Chains and Self-Assessed Health of Rural Community Residents: Based on Multi-Source Data and Health Survey Questionnaire**
579

TRACK 4 - GOVERNANCE

Byeongsun Ahn & Yuri Kazepov, **Rethinking Policy Learning in Urban Policy Mobility**
602

Xin Li & Christa Reicher, **Actors in power networks: an institution framework of historic urban district renovation actors in China**
617

Han Gao, **Typologies and Dynamics of Urban Growth Projects in Ethiopia: A Discursive Analysis**
629

Bin Liu, **Institutional Supply and Practical Pathway for Self-Renewal of Old Residential Areas in Hangzhou from a Multi-Agent Collaboration Perspective: A Case Study of Zhegong New Village**
635

Gülşah Tırış & Hilal Erkuş, **Cross-Scale Transactions and Multi-Level Governance on Spatial Gains of Commons: A Comparative Study from Türkiye**
649

Zhuyang Liu & Guiqing Yang, **Pursuing total volume or efficiency? A study on the coupling pattern of rural population and space: A case study from Huangyan District, Zhejiang Province, China**
657

Lu Chenyan & Huang Yi, **Research on Demand-Side Oriented Spatial Governance in Innovation Districts: A Case Study of Hangzhou West Sci-Tech- Innovation Corridor**
670

Bilgesu Sever, **Redefinition of Urban-Rural Boundaries Under Centralized Governance: Urban Ecological Movements in the Case of a Coastal Town, Ayvalık, Turkey**
688

Guyue Sun & Hong Jiang, **Construction of Regional Multi-dimensional Proximity Network from the Perspective of Collaborative Agglomeration — Analysis of Geographical Proximity Networks in Contiguous Rural Spaces**
702

Alankrita Sarkar, **Are you a Stakeholder or Streekholder? Formal and informal planning in the Flemish-Dutch Delta**
718

Palmira Ndeshihala de Almeid**, The Bioeconomy, Experimental Governance, and Spatial Planning**
738

Yuhang Rao, **Rural Revitalization Beyond Administrative Boundaries: A Case Study of Villages Surrounding Taihu Lake, China**
753

CONTENTS

Iuliia Kozlova, Elisa Conticelli & Serena Sgallari, **Zero Net Land Take Policy Mapping: A Multi-Level Analysis in the Context of Italy and Emilia-Romagna**
765

Luqiao Zheng & Zichao Xiong, **Participatory Community Planning and Collaborative Governance in the Post-Growth Era: A Case Study of the Nanning Love-U Garden Network in China**
790

Beyza Kurt, **Participation After Disaster: Central Government Approach to Participation Planning**
799

Rola Abu Hilal, Gillian Brady, Philip Crowe & Brian Crowley, **Identifying Barriers to Compact Urban Growth in the Irish Housing Sector: Insights from Industry Experts**
813

Doriana Musaj, **Navigating Conflicts and Paradoxes: Analyzing the Interaction of Urban Regeneration, Local Governance, and Public Policy in the Tirana Riverside Project**
829

Paul van den Bragt, **Public-Private Joint Ventures in Urban Area Development: Identifying and Governing Value Tensions**
846

Stefan Lazarevski & Rudoff Gİffinger, **Designing A Comprehensive Indicator System For an Evidence-based Spatial Planning System Integration in Fringe Regions of the EU: A South Balkan Case Study**
856

Stefano Magaudda, Federica Di Pietrantonio, Serena Muccitelli & Carolina Pozzi, **Multi-Level Collaborative Governance for Environmental Protection and Climate Adaptation: Insights from EU-funded Projects**
874

Romina D'Ascanio, Elisa Avellini, Stefano Magaudda, Anna Laura Palazzo & Giancarlo Gusmaroli, **Collaborative governance through the Mediterranean. Framing a Community of Practice for Wetland Contracts**
884

Ana Escario Chust, Óscar M. Blanco, Guillermo Palau Salvador, Kawa Nazemi, Elena Correll, Uliana Eliseeva & Tanya Zerbian, **Enhancing resilience in water management agriculture: A Social Network Analysis approach to identify Leverage Points for climate adaptation**
895

Philipp Kerschbaum, **How meaningful is formal participation in environmental assessments? Examining the case of large-scale linear infrastructure projects in Germany.**
911

Céline Janssen, **Building institutional capacity for social value – reflections from the 'Back to the Neighbourhood'-project in the Netherlands**
927

Giovanni Ottaviano, Luciano De Bonis & Francesca Giangrande, **Self-government processes of the urban bioregion: insights from a study on the Metropolitan City of Rome Capital**
935

Ivan Blečić, Anna Maria Colavitti, Giulia Giliberto & Virginia Onnis, **Assessing the effectiveness of participation in urban planning processes: a dual perspective on civic engagement and process efficiency**
949

Anila Bejko, Fiona Imami & Besnik Aliaj, **The Risks of Purposive Transitions in Albania: Navigating the Just Green Transition in Light of Post-Socialist Legacies**
960

Federico Camerin & Juan Luis de las Rivas Sanz, **Redeveloping military land into affordable housing through a public-public partnership. The case of Valladolid's La Rubia barracks**
974

TRACK 5 - ENVIRONMENT AND CLIMATE

Yufei Quan, Inspiration for Pathways towards Multi-Scale Green Urban Regeneration and Planning Construction under Dual Carbon Goals
989

Zhaopeng Cheng & Chenxi Wang, **Return of Mythical Bird · Reborn of Wetland — Conservation and Restoration Planning & World Heritage Site Application Preparation for Fujian Minjiang River Estuary**
1007

Lihua Chen & Jing Gan, **The Thresholds of Urban Parks' Characteristics on Heat Mitigation Effect: Case Study of 120 Parks in Foshan, China**
1022

Lin Lin & Jin Xing, **Research on Energy-saving Renovation and Energy Consumption Correlation of Historical Residential Districts under the Background of Urban Renewal: A Case Study of Hehua Tang District in Nanjing City**
1042

Senmeng Hao, Taoling Li, Chunhui Zhang, Yanyan Xia & Zhaokui Wu, **Urban Wilderness Protection and Creation in China**
1052

Zhihan Zhang, Yuyue Huang, Xun Zhang, Qingxin Yang & Junyan Yang, **Enhancing Sustainable Cities Through Comparative Carbon Sink Benefits of Blue-Green Spaces: Evidence from Multi-Source Data**
1064

Maria Pizzorni, Irina Karaselnikova, Clotilde Havard, Amit Bhattacharya & Esra Kut Görgün, **Preserving the past or protecting the future? Harmonizing Cultural Heritage and Climate Adaptation in Siena**
1075

CONTENTS

Shumin Wang, Guoao Liu , Jianyu Li, Xinyu Lin & Mingxing Hu, **Exploring Low-Carbon Urban Development at the Plot Scale: A Study of Carbon Emission Mechanisms and Empirical Exploration of Micro-Renovation for Emission Reduction**
1087

Asli Eylem Kolbas & Oswald Devisch, **Retracing Critical Energy Fictions with Youth through a Comparative Analysis of Community-Based Interventions**
1106

Zimeng Kong, Wenjing Dong & Yanhui Wang, **Hydraulic Heritage and Community Identity: Examining Socio-Ecological Resilience and Heritage Transformation in Huaibei Area, China**
1129

Yuanhong Qiu, Ting Zhang & Yuequn Cao, **The Expansion of High-Tech Zone Development and Regional Carbon Emissions: A Synergistic Exploration of Spatial Heterogeneity and Environmental Justice**
1145

Yucel Can Severcan, Nese Aydin, Ozlem Ozden Uzmez, Eftade O. Gaga, Aybuke Balahun Coban, Gonenc Ozarli & Goksun Yildirim, **Linking outdoor particulate pollution to children's negative experiences of their neighbourhoods: Findings from an interdisciplinary research project in Ankara**
1157

Ting Zhang, Yuanhong Qiu & Jianzhong Huang, **Coordinated Development and Coupling Mechanisms of Capital Flows and Carbon Emissions from the Perspective of Environmental Justice**
1174

Tian Haoran, Jin Xing, Niu Shengnan & Ma congchao, **Research on the Outdoor Wind Environment of Buildings under the Influence of Hills: The Beigushan Hill in Nanjing**
1190

Yi Hsuan Shen & Tzuyuan Stessa Chao, **Seeking a possible Positive Energy Districts (PEDs) location choice from a local context, a case study in Tainan City, Taiwan**
1200

Shuxian Feng & Tengfei Yu, **Land suitability modelling for Integrated Mangrove Aquaculture to adapt to salinity intrusion using Machine Learning and Deep Learning approaches in southwestern Bangladesh**
1211

Kathrin Meyer, **Optimizing Decision-Making for Climate-Neutral Post-War Buildings: The Architect's Role in Sustainable Transformation**
1229

Yihuan Wang & Junyan Yang, **Investigating the impact of Urban Form Elements on carbon emissions at Different Development Stages: Based on GWR Models**
1240

Qingxin Yang, Zhihan Zhang, Yuyue Huang, Xun Zhang & Junyan Yang, **Exploring the Carbon Emission Impact of Community Life Circle Shared Clusters: A Case Study of Nanjing, China**
1254

Cemre Betul Ay & Erblin Berisha, **Toward Equitable Carbon Markets: Spatial Planning for Climate Justice in Uganda**
1265

Siying Li & Zeyin Chen, **Temporal-Spatial Distribution Characteristics of PM2.5 and Noise in the Under-Viaducts Space**
1279

Adriana Galderisi, Giada Limongi & Alessandra Scognamiglio, **Agricultural landscapes and agrivoltaic systems: the key role of landscape planning**
1302

Beyzanur Uzun & Gökçen Kılınç Ürkmez, **An Examination of the Environmental Impacts of Mega Projects on Rural Areas: A Case Study of Two Villages in the South Marmara Region of Türkiye**
1317

Havva Elmalı & Seung-Nam Kim, **Deep Learning-Based Commercial Building Energy Consumption Prediction Model Considering Occupant Density Using Mobile Network Big Data: A Case Study of Seoul**
1337

Deshayes Eloïse & Brown Will, **Accounting beyond boundaries: Exploring consumption-based carbon approaches in Paris and Gothenburg**
1347

Ana Lucia Britto, Thêmis Amorim Aragão & Jorge Nassar Fleury, **Social movements and collaborative climate adaption: the case of Campo do Bomba, in Duque de Caxias-RJ- Brazil**
1360

Ozlem Edizel Tasci, **Addressing Climate Equity Through Community Engagement on Virginia's Eastern Shore**
1371

Hualing Xu, Jing Wu & Kingsley Dogah**, Feminization of Energy Poverty in China: Contrasting Urban and Rural Experiences**
1383

Yuan Gao & Shenjing He, **Simulating Urban Green Space's Cooling Impact on School-age Children' Sleep Quality Using Diverse Planning Approaches**
1402

CONTENTS

Başak Demireş Özkul, Pınar Gökçe Kılıç, Ali Yılmaz, Fatih Uzun, Aliye Ahu Gülümser & Lara Su Baykan, **Using Participatory GIS for Sustainable Campus Planning: Insights from GreenHack Hackathon**
1420

Anna Bertolazzi, Michelangelo Fusi , Giovanni Maifredi, Michela Nota, Michela Tiboni & Claudia Zani, **Exploring the link between biodiversity, health, and climate action through the URBioPark Project**
1433

Lekha Samant, **Between Walls and Water: Technocratic planning of stormwater infrastructure and the reshaping of everyday life in flood-prone Mumba**
1444

Emanuele Garda, Gregorio Pezzoli & Marco Tononi, **The Legacy of Experience: Reflections on Climate Transition Strategies in Medium-Sized Italian Cities**
1457

Angel Burov, Angel M. Dzhambov, Donka Dimitrova, Iana Markevych, Kostadin Kostadinov, Marco Helbich & Mark J Nieuwenhuijsen, **Reintroduction of health impact assessment in Bulgarian city planning – why and how?**
1467

Carolina Giamo, Giulio Gabriele Pantaloni, Federico Farina & Andrea Nino, **SimulSoil: Ecosystem Service Modelling for Sustainability-Oriented Planning in the Metropolitan City of Turin"**
1486

Anna Kaczorowska, **Urbanization, Biodiversity, and Ecosystem Services in Norway: Challenges and Strategies for Sustainable Land Use**
1499

Marco Carlotti, **Exploring Two Interpretative Models of Eco-cities in the United Arab Emirates: Masdar City and The Sustainable City Dubai**
1502

Lia Fedele & Angelica Nanni, **From Vulnerability to Resilience: Coastal Heritage as Environmental Infrastructure**
1518

TRACK 6 - URBAN CULTURES AND LIVED HERITAGE

Asma Mehan, **Reimagining Postgrowth Urbanism: Adaptive Reuse of Industrial Heritage for Sustainable Futures**
1531

Ye Sun, Chen Chen, **Understanding the cultural potential of rural history: A conceptual framework of cultural capital development**
1539

Sijie Liu, **The inheritance mechanism of rural living heritage in China based on the model of "rural governance - policy supply - protective activation"**
1550

Sidra Khokhar, **A Critical Ethnographic of Ziddi Feminist Socio-Spatial Practices in a Modern-Mohalla of Islamabad**
1565

Hou Rui, Sun Xi-jia, **The Intersection of National Image, Urban Development, and Civic Life: A Study on the 70-Year Evolution of Large-Scale Sports Architecture Heritage in Beijing**
1595

Xin Li, Christa Reicher, **Challenges and outlooks of incremental historic urban district renovation in China – take Beijing Hutong Dongsinan case as an example**
1612

Wendy Jo Mifsud, Alexander Farrugia, **Lived Heritage through the Changing Gaze: A Views and Vistas Analysis for Valletta**
1628

Özlem Tepeli Türel, Ahmet Türel, **Measuring Cultural Participation: A Comprehensive Study in Kayseri**
1638

Antonella Contin, **Metropolitan Cities as Living Monuments: Resilient Territories between Culture, Justice and Innovation**
1653

Zhe Wang, **Study on evaluation of liveliness level and promotion strategy for Intangible Cultural Heritage in Qinghai Province**
1670

Giuseppe Fraddosio, **The Mountain of Gargano Where the Sacred Dwells in the Forms of the Earth**
1685

Neslişah Kesici, Nilgün Çolpan Erkan, **(Re)Production of Urban Space through Cultural Events: Legacy of the Bergama Festival**
1707

CONTENTS

Wenjing Dong, Zimeng Kong, Yanhui Wang, **Heritage Perception and Identity Construction Among Residents in Industrial Community Transformation: A Case Study of National Creative Park, Nanjing, China**
1717

Yanqi Chen, Yunying Ren, **Research on Cultural Adaptation Mechanisms of the Duku Heritage Corridor Based on Heritage Ecosystems**
1729

Xiaohan Zhang, Yan Wang, Wei Wu, **A Study on the Evolution Characteristics of the Spatial Layout of The Mountain Fortress System of Sichuan and Chongqing in China during the Song and Yuan Wars**
1739

Diana Amorim dos Santos da Silva, Melisa Pesoa Marcilla, **Drawn City: the effects of women's graffiti in public spaces of Rio and Barcelona through cartography**
1759

Shuyin Li, **The Dilemma of Authenticity: The Conservation and Reconstruction of Traditional Residences in China —Taking Pingyao, Shanghai and Suzhou as Examples**
1769

Jianren Zhi, Qun Zhang, **Exploring Spatial Evolution of Traditional Settlement Landscapes in the Southern Taihang Region of China: A Study on Cultural Ecosystem Dynamics and Reconstructive Strategies**
1782

Giada Limongi, Adriana Galderisi, Chiara Pisano, **Reversing cultural marginality in inner peripheries: the key role of community mapping**
1797

Ludovico Centis, **Silent evidence. On nuclear mounds, craters and caves**
1804

Zihan Ke, Yongjie Cai, **From Large-scale Modernist Planning to Small-scale Urban Blocks: Spatial Transformation Experiments in China's Large Gated Communities**
1814

Li Xin fei, Wei Qi, **The Manifestation of Patterns and the Reconstruction of Meaning: The Reproduction of Spatial Patterns and Role Interpretation Along Xi'an's Historical Urban Axis**
1835

Elena Guidetti, Adnan Pašić, Alessandro Massarente, **Overlapping urban processes: Research by design experiences in a Sarajevo city central military campus**
1841

Guangfeng Zhai, Zuyue Liu, Yan Wang, **A Study on the Identification of Historical and Cultural Resource Carriers Oriented by Value: A Case Study of the Taihu Lake Basin**
1845

Chunye Ma, Lan Wang, **Public emotions and visual perception of historic district : An AI approach using social media data**
1856

Gyuna Hwang, Jina Park, **The Spatial Dynamics of Cafés as Everyday Urban Spaces: Exploring Socialscapes through Streetscapes**
1865

Shaomin Zhang, Zimeng Kong, **Research on the Tourism Development Path of Human-Habitat World Heritage from the Perspective of Space Production: A Case Study of Pingyao Ancient City**
1892

Altea Panebianco, Alì Yaser Jafari, Barbara Caselli, **Digital Platform for Accessibility and Cultural Enhancement of Inner Areas in Italy**
1907

Ying Yuning, **The Value of Suqian Water Culture heritage from the Perspective of Cultural Landscape**
1922

Dan Ye, Yu Zhuang, Xin Li, **Research on the Revitalization Modes and Mechanisms of Historical Buildings in High-density Cities: A Case Study of Hong Kong**
1933

Paloma Guzman, Ole Fredrik Unhammer, Mesut Dinler, **Exploring Policy Frameworks for Cultural Heritage in Climate Adaptation and Disaster Risk Management: A Cross-Case Comparison**
1953

Gizem Ak, Murat Cemal Yalçıntan, **Exploring the Emotional Dynamics of Beyoğlu's Transformative Urban Atmosphere Through Music Ecosystems**
1969

POSTGROWTH URBANISM

From abandonment to critical conception: post-growth policies for the resilience of deindustrialised areas. The case-studies of Ile-de-Nantes and Docks-de-Seine in France

Varvara Toura
Affiliation: EHESS/Géographie-Cités
Email: valiatoura@gmail.com

Abstract
The appearance of the notion of sustainable development in the 1980's constituted an important step in the procedures of urban planning as its structuring elements referred to questions like growth and its limits. Considering the inequal development of urban areas in the Global North and Global South, especially places that were left neglected for several years such as deindustrialised areas, the paper tries to explore the ways through which deindustrialised areas could be developed in order to sustain both ecological balance and social equity. The choice of the case studies, the projects Ile-de-Nantes and Docks-de-Seine in France, was based on the necessity to critically think existing growth theories and concepts for the development of deindustrialised areas based on the reduction of their environmental footprint.

Key words: post-growth policies; social and environmental balance; deindustrialised areas; socio-economic inequalities, France

Introduction

The appearance of the notion of sustainable development in the 1980's and the publication of the Brundtland report constituted an important step in the procedures of urban planning of the late 20th century, especially for deindustrialised cities (Devillers, 2010). Its multifaceted nature, result of the diversity of intellectual filiations that preceded it (humanist, economist, ecologist), shows, according to some researchers like Passet, a reconciliation between limitless growth and environmental and social barriers (Passet, 1978). We can distinguish from the origins of this notion its structuring elements such as growth and its limits, conservation and preservation, as well as the place and role of natural and artificial capital in economic development procedures (UN, 1987).

A historical analysis of the issue of sustainable development carried out by Bertrand Zuindeau and Franck-Dominique Vivien in 2001 allows us to reflect on the spatial dimension of sustainable development and its role in transforming urban areas beyond modern policies of urban growth. The two authors distinguish in the intellectual framework of the concept two approaches:

- a global approach that focuses on the interactions between the environment and the economy on a global scale and
- a local approach which insists on the local characteristics (environmental, economic, cultural) for the spatial implementation of sustainable development at the local level (Vivien and Zuindeau, 2001).

It can be underlined, therefore, that even if previous works, particularly from the 1960s and 1970s, such as the Green Paper of European Commission, present a global approach to the concept of sustainable development (EU, 1990), linked to international concerns on the protection of the environment, there is also a local approach addressed particularly in reports on sustainable cities and sustainable neighbourhoods (Aalborg Charter) (EU, 1994).

The question of application of sustainable development policies at territorial level brings out the different apprehensions of space related to urban development (particularly economic). The space can take the form either of a support space, for example a space that facilitates the installation of production activities in a given territory (for example low taxes), or of a space - resource, that is to say a space that attracts the installation of production activities thanks to its natural and artificial resources (Bastié and Dézert, 1980).

It should be emphasised that there are no general rules that can function as key formulas for the implementation of sustainable development at territorial level. On the contrary, in studies of the application of sustainable development policies at territorial level, several researchers note that there are difficulties and limits in generalising local approaches and results issued from local experiences (Godard,1996). In addition, we can note that the local dimension of sustainable development, especially in small scale projects at neighbourhood level,

consists rather of a tool mobilised by local actors in order to promote mutual learning, with the collaboration of inhabitants, technicians and local elected officials for the planning of sustainable neighbourhoods.

The principles of sustainable development policies are often quite vague, particularly with regard to the simultaneous implementation of the global issues set out at the United Nations Conference on Environment and Development in 1992 in Rio de Janeiro, as these principles do not articulate with the reality of the territories (Theys, 2000). Today there are very few approaches that allow the operational implementation of the goals of sustainable development as they appeared in Agenda 21. The one that can be noted is that of the environmental footprint. This concept makes it possible to show the capacities of ecosystems to resist the pressures of human activities (Matuštík, Kočí, 2021). It mostly refers to the environmental dimension of sustainable development. However, it can be an important tool for analysing the limits of modern modes of urban growth as cities expand towards their surrounding areas and exploit their natural resources (Valderrama and al, 2024).

The difficulty of defining priorities by local authorities on the implementation of sustainable development policies both at territorial level and in public action shows the dual nature of the concept which refers, as we have already seen, at two scales: global and local (Vivien and Zuindeau, 2001). Cyria Emelianoff and Jacques Theys underline in their analysis for the sustainable city, that a sustainable city must first contribute to the solution of major global problems. This is not only a question of conflict of priorities, but of the profound difficulty in articulating several obviously different representations of territory and political action (Emelianoff and Theys, 2001). We can see that there is a dissociation between the two scales of the concept (global and local) which underlines the importance of the management of the interfaces between the two.

In regard to the subject of the scale of implementation of sustainable development policies, it is important to refer to the work of the French Institute for the Environment which highlights two aspects of the concept:

- What is sustainable on one scale may not be at another
- In problem solving there is no optimal scale in itself, there are only scales that are more useful than others for answering very specific questions (IFEN, 1999).

It is therefore obvious that there is no optimal scale of intervention. On the contrary, we can observe that there are several scales which articulate, and which must be studied in relation to their specificities and their complementarities (Eames and Abedowale, 2002). However, it should be noted that even if the implementation of sustainable development policies at different territorial scales does not allow us to talk about global sustainable development objectives, there are elements in sustainable urban development projects that reinforce the hope of a territorial implementation of sustainable development on a global scale in the future (the exemplarity of sustainable development projects at territorial level, the cooperation between the actors involved in sustainable development urban projects, the awareness of local actors around the notion of sustainable development) (Emelianoff, 2007).

By considering the inequal development of urban areas, especially those that were left neglected for several years such as deindustrialised areas which are characterised by high levels of air, water and soil pollution, the paper tries to answer the question of which ways lead to the sustainable development of deindustrialised areas in order to sustain both ecological balance and social equity. Issues related to the implementation of sustainable development policies at territorial level, the actors involved in these procedures, the different levels of decision making as well as the complementarity of these policies (at regional, municipal and neighbourhood level) are among the key points for the development of urban areas that were left neglected for several years. The purpose of the research is to critically question the appearance of new planning policies for deindustrialised areas which are considered innovative and inscribed in the sustainable development framework, such as the creation of sustainable neighbourhoods and participatory design, based on their capacity to foster regenerative relationships between society and the environment. Sustainable neighbourhoods (écoquartiers in the French context) are a form of urban design projects that try to implement environmental policies at territorial level while proposing social housing for the low-income inhabitants and participatory design actions for the involvement of inhabitants in decisions related to the form and functions of their living environments (Hamdan and al, 2021, Ministère de l'aménagement du territoire et de la décentralisation, 2024). However this type of projects seem to be rather ambitious as they are trying to respond to environmental questions that cannot be handled at local

level (for example air and water pollution) (Dessouky and al, 2023) while citizen engagement and participatory design usually refer to experimentations at neighbourhood level and not to the elaboration of concrete solutions that could be applied at different governance levels (regional, municipal) (Allen, Queen, 2018).

Methodology

The research method used was the descriptive-analytic. The descriptive method was used in order to define post-growth policies and tools for the development of deindustrialised areas and relate them to previous studies in areas facing significant socio-economic inequalities. Our main hypothesis is that the development of deindustrialised areas in a sustainable way that focuses on their particular characteristics, internal dynamics and external opportunities should be the basis for the development of such areas which struggle with the effects of deindustrialisation (socio-economic and environmental difficulties) and gentrification due to the interest for their planning by private and public investors. In several cases the former industrial cities have a significant urban past reflected on the architecture of industrial buildings such as factories and houses of industrial workers and the organisation of spaces around industrial units. At the same time, there is still present on these areas their social structure, which dates back to their industrial era, through the form of associations gathering former industrial workers and local inhabitants. These associations are interested in preserving the local character of their areas, both its tangible form (buildings and neighbourhoods) and intangible (inhabitants' relationships, areas for the low- and middle-class households), thus creating the conditions for social sustainability (Katapidi, 2023).

Deindustrialised areas, inside or outside of cities limits, face significant economic and social difficulties due to deindustrialisation, or to the closure of local enterprises, and seem to bear the effects of this negative context as they do not have sufficient funds for their environmental protection and economic development (Schindler and al, 2023). The former industrial lands are heavily polluted and struggle with economic recession. In certain cases, we observe waste in these areas either domestic or resulting from industrial activities whose presence in these areas deteriorates the existing environmental degradation, while contractors, investors and local authorities show a particular interest to build them in order to boost their local economy and those of neighbouring cities who also face social and economic difficulties. In this context the development of deindustrialised areas in a sustainable way that takes into consideration the needs of the local population and proposes economic activities in accordance with the restauration of the natural environment, offers a second life to places that were underdeveloped and neglected for several years due to socio-economic problems. Our hypothesis is that the development of neglected deindustrialised areas in a sustainable way and their subsequent integration into the regional and municipal economic channels fabric is not only a measure towards environmental and economic sustainability and resilience, but it can also serve as a measure to solve social conflicts as underdeveloped deindustrialised areas are places that gather activities of regional and municipal interest such as research hubs, tourism and cultural facilities.

Another point to underline in contemporary practices for the development of deindustrialised areas, related to technological innovations and to the need to reduce cities' environmental footprint, is the planning of these areas according to specific standards (international and national) that seems to give answers to the global dimension of sustainable development such as the reduction of carbon emissions and energy demands for cooling and heating housing units (Power, 2018). Policies such as the design of passive houses, the collection and reuse of grey water in domestic activities and the re-design of polluted former industrial lands as parks are presented as strategies for the creation of sustainable neighbourhoods (Ministère de l'aménagement du territoire et de la décentralisation, 2024). However, it is important to see whether these high-cost policies in areas historically gathering low and middle-class households are acceptable by the local population. Taking this into consideration, our third hypothesis is that the development of deindustrialised areas through the creation of sustainable neighbourhoods could act as a measure for sustainability and resilience, when these areas are developed for all (both for the local population and for new inhabitants), take into consideration the local socio-economic context (thus do not propose high-cost policies) and restore the polluted natural environment in order to bring environmental sustainability.

The analytic method was used in order to identify first the particular socio-economic characteristics of the two case studies, the relationship between the built and the natural environment as well as technical innovations which seem to foster social and environmental balance. At the same time, we took interviews with local actors (inhabitants' associations, former industrial workers associations, environmental associations, researchers, teams of architects and urban planners working on the two sustainable neighbourhood projects, local elected officials) in order to study the implementation of inclusive and equitable territorial policies which aim to foster a circular economy model than a one that exploits ecosystems. In second place based on the findings of the field research we tried to verify our initial hypotheses in order to see which policies lead to the sustainable transformation of deindustrialised areas and take into consideration the local social, economic, environmental and cultural characteristics. The research proposes an experimental approach in order to investigate the policies and tools which potentially could tackle socio-economic inequalities and reshape planning policies in deindustrialised areas. A critical point is to underline policies that seem to align with community needs, especially at neighbourhood level and which could be generalised at the level of the city. This approach (bottom-up) helps to better identify and understand cities' future in a resilient and inclusive way, as it is possible to study whether the goal of growth concerns all inhabitants, including marginalised groups, or is targeted at a limited number of people.

The analysis of the findings of the field research focuses on policies at municipal and regional level such as: 1) the revalorisation and reuse of significant buildings and neighbourhoods dating on the industrial era as a form of reminiscence of the tangible heritage, 2) the creation of community ties through the preservation of intangible heritage and the presence of active inhabitants' associations in the areas, 3) the restauration of the natural resources polluted during the industrial era of the two cities and environmental policies for reducing environmental footprint as well as 4) the development of economic activities in accordance with the local needs in order to boost municipal and regional economy as a means to reduce local unemployment rate and to lead to economic resilience and sustainability.

In our analysis of the policies that lead to the sustainable development of the two former industrial areas we took into consideration existing power dynamics of the two cities (Nantes and Saint-Ouen), their surrounding areas as well as of the regions of Loire-Atlantique and Ile-de-France in which administratively are part the cities of Nantes and Saint-Ouen. It is important to mention that both of the two regions are characterised by their industrial past with industrial activities related to energy production and shipbuilding while their deindustrialisation seems to had a different impact on the two cities as Ile-de-France, where Saint-Ouen is located, is the most developed region at national level (French) and its economy is also based on other activities such as tourism, culture, research and national administration. At the same time the funding of the two redevelopment projects in Nantes and Saint-Ouen (EU funds, public-private partnership) poses challenges regarding their growth urban planning policies as private investors (we can see it in the case study of Saint-Ouen) are more interested in economically profitable activities (office and administration buildings) and avoid taking measures for the good living conditions of the local low-income households such as the construction of social housing. A final point of our analysis is based on the political decisions taken at municipal and regional level on environmental, social and economic issues which are usually related to the political party that is affiliated the majority. While socialist and ecological parties are more interested in questions related to social cohesion and environmental protection, right and liberal parties are interested in the economic development of their areas leading in several cases in the gentrification of these spaces.

The case studies: the sustainable neighbourhood Docks-de-Seine in the city of Saint-Ouen and the industrial reconversion project Ile-de-Nantes in the city of Nantes

The choice of the case studies was based on the necessity to critically think and reshape existing growth theories and concepts for the development of deindustrialised areas based on the reduction of their environmental footprint. On one hand we have the case study of the Docks-de-Seine in Saint-Ouen, a sustainable neighbourhood project located at the north part of the Ile-de-France region not far from Paris (Figure 1). The neighbourhood was constructed on a deindustrialised brownfield by focusing on bringing eco-social balance. The project covers an area of about 100 hectares. Saint-Ouen's population in 2017 was approximately 90,000 inhabitants (INSEE a, 2018). Saint-Ouen, which is known for its industrial activities since the nineteenth century, faced a significant population decline in the late 1980s due to the departure of local industries in the periphery of the city.

Figure 1. Saint-Ouen's location on the map of France. The city is located in the Seine-Saint-Denis department in the north suburbs of Paris. The city and the Docks-de-Seine district are connected by bus and metro to Paris, thus attracting new inhabitants and enterprises who search for lower rents outside the French capital. Source: Varvara Toura

Saint-Ouen's industrial history is linked to the Docks-de-Seine district, where the city's railway station was built in 1856. The two main sectors were those of energy production and waste treatment (Figure 2). Saint-Ouen became an industrial city as a result of the infrastructure and equipment installed in the Docks-de-Seine district, where a water station was established in 1830 and a railway network in 1856. The two infrastructures created the conditions for the city's industrial development due to the good access of the site (APUR, 2006). However, this concentration of infrastructures will prevent the city from developing towards the Seine River. Only two streets of the city crossed the area of the Docks and had access to the river quay, rue Ardouin and rue des Bateliers. In the northern part of the site, a plot of 26 hectares was purchased in 1917 by the Thomson-Houston company. On the strip of land directly along the Seine, a facility was created in 1862 (Département de la Seine, Direction des affaires départementales, 1902). The departure of Total (2003) and Alstom (2004) industries from the Docks district marked the beginning of a city's renewal program for central districts, as large zones alongside the Seine River were left inactive.

Figure 2. The Docks-de-Seine district during its industrial era in 1964. The industrial activities never ceased to exist in Saint-Ouen. There are still present on the site of Docks industries related to the production of electricity and waste treatment posing restrictions to sustainable development projects in the city such as the sustainable neighbourhood project of Docks-de-Seine. Source: Historical archives of the city of Saint-Ouen

Saint-Ouen's policies towards the city's development after its industrial era focused on the sustainable reconversion of the city's urban voids and the preservation of local industrial heritage. They were established in 2000 as a measure inscribed within the regional policies of Ile-de-France region for the redevelopment of its peripheral areas. A representative project for the reconversion of industrial urban suburbs in a sustainable way is the sustainable neighbourhood project of the former industrial site Docks-de-Seine initiated in 2005. The

Docks-de-Seine project contributed to reverse Saint-Ouen's population decline that followed the closure of local industries in the late 1990s. The design team selected for the development of the project of Docks-de-Seine was the team lead by the architect Makan Rafatdjou (2005-present) while the project was planned since its beginning as a sustainable neighbourhood (écoquartier in French) focusing on the environmental dimension of the project. In the French context the écoquartiers projects receive a label from the French Ministry of Environment as projects inscribed in the field of sustainable development. We should mention that this label does not include public funds for the project but is rather an honorary title increasing the competition between architects and urban planners working on these projects.

On the other hand, we have the case study of Ile-de-Nantes, a reconversion project located in the city of Nantes at the west of France which is constructed in a deindustrialised zone (Figure 3). Compared to the first case study, in the case of Ile-de-Nantes we have a big, deindustrialised area, where an important role plays the planning and development of sustainable neighbourhoods during the third phase of the project (2017-present). The main purpose of the project was the transformation of a deindustrialised area in a sustainable way which reconciles the natural environment while revitalising the local economic and social tissue. The project covers an area of about 337 hectares. Nantes' population in 2017 was approximately 300,000 inhabitants (INSEE b, 2018).

Figure 3. Nantes' location on the map of France. The city is located in the Loire-Atlantique region at the west of France. Despite deindustrialisation Nantes' population increased after 1990 due to the development of activities based on culture, tourism and research. The city is connected by intercity buses and train to the main French cities including Paris. Source: Varvara Toura

At the beginning of the nineteenth century, industrial activities became the driving force of Nantes economy, succeeding the early manufactories of the eighteenth century. Shipowners and merchants invested in the industrial sector, particularly benefiting from European maritime trade (Guépin and Bonamy, 1835). The two areas for factory establishments were the banks of the Loire and the Erdre River. By the end of the nineteenth century, other productions emerged alongside metallurgy: sugar refineries, chemicals, and fertilizers. Companies like Amieux and Saupiquet thrived between the two wars, relying on vegetable and horticultural products or the processing of fish from the entire Brittany region. During the period of the World War I, the growing industry was that of military production as well as the construction or reconstruction of the military and civilian fleet (Bois, 1977). Till World War I, factories from all branches in the city employed over 27,000 workers. In the 1950s, reconstruction allowed a revival of the main sectors: shipbuilding (Figure 4), metallurgy, and agri-food. In the seventies, the concentration of businesses accelerated. The largest factories established themselves on the outskirts in new activity zones.

Figure 4. The Dubigeon shipbuilding industry in Nantes during its industrial era. Nantes' industrial era ended in the 1980s when shipbuilding industries located inside the city's limits moved to the neighbouring city of Saint-Nazaire. The significant industrial heritage of the city and especially shipbuilding infrastructure and equipment was part of the reconversion policies of the site of Ile-de-Nantes as they were restored and reconverted into museums and cultural spaces. Source: Musée des hommes et des techniques de Nantes

Nantes's policies towards city's development and preservation of local industrial heritage within the context of sustainable development were developed in the 1990s as part of a municipal plan for the revitalisation of urban voids. A representative project of these policies is the reconversion project of the former industrial site Ile-de-Nantes. The project is developed in three different phases since 2000 with three different design teams focusing on the sustainable development of the area by combining modern economic and environmental policies alongside citizen engagement in the urban design process as measures to preserve the local industrial heritage and to transform the deindustrialised site. These policies' primary objective was to reverse the significant population decline that the city faced after the closure of local industries in the late 1980s. The first selected design team was the team lead by the architect Alexandre Chemetoff (2000-2010) focusing on the inscription of industrial heritage in the new urban planning of Ile-de-Nantes. The next two teams started to reflect on the issue of sustainable development of the deindustrialised site through its connection with Nantes' city centre (team Marcel Smets and Anne Mie Depuyt, 2010-2017) and the creation of green-blue corridors in the site of Ile-de-Nantes alongside the planning of sustainable neighbourhoods (team Shorter and Osty, 2017-present).

Outcomes-Results

The study of the regions of Ile-de-France and Loire-Atlantique, of the cities of Saint-Ouen and Nantes and the projects of transformation of deindustrialised spaces in these cities especially the Docks-de-Seine and Ile-de-Nantes projects revealed different strategies and policies for the post-growth development of the above areas. In the case study of Docks-de-Seine the project is inscribed within the perimeter of Grand Paris, a project of transformations of former industrial cities of the Ile-de-France region based on environmental, economic and social policies, while at the same time the former industrial cities (les banlieues) are connected to Paris with a new urban railway network (Grand-Paris Express). The close proximity of the Docks-de-Seine site to the Olympic Village of 2024 Olympic Games (Seine-Denis) and the active industrial units within its perimeter make both the project of the sustainable neighbourhood Docks-de-Seine and the urban transformations inside the city of Saint-Ouen important for the development of the region of Ile-de-France as the area is considered as an energy pole providing activities of regional interest. Even though the project of Docks-de-Seine is labelled by the French Ministry of Environment as an écoquartier the planning and construction of the project are not funded by national funds, but from a public-private partnership between the Region of Ile-de-France, the Municipality of Saint-Ouen and private investors such as Nextcity, an urban development company, posing challenges regarding the social dimension of the project as the private investor is interested in profitable economic activities like office buildings and not on the preservation of the local industrial heritage and the construction of social housing for the low-income households.

At regional level the Regional Counsil is in favour of the project since its beginning, while the construction of the main building of the Ile-de-France region on the site of the Docks underline the importance of the site for the regional development. On the contrary at municipal level since the beginning of the project, the Municipal Counsil was led by three different political parties (communists, liberals, socialists) showing a different interest for the main axes of the project (environmental and social for communists and socialists, environmental and economic for the liberals).

In the case study of Ile-de-Nantes the project is located inside the city limits in proximity with Nantes historical and economic centre. Due to Nantes former socialist Mayor Jean-Marc Ayrault (who later became Prime Minister of France under the presidency of François Hollande) and his ambition to make Nantes an attractive destination for new inhabitants, tourists and public and private investors the deindustrialised area of Ile-de-Nantes, an island in the Loire River, was developed in the 1990s as part of a bigger project of urban transformations inside the city. The project was developed in three phases led by different design teams focusing since the beginning on issues related to post-growth development theories such as the social parameter of the project (a project for all), the environmental justice in a polluted industrial land and the boost of the local economy based on the internal strengths of the city of Nantes (local industrial heritage). Even though industrial activities have moved to areas outside the city of Nantes, especially the thriving shipbuilding activity who has moved in the city of Saint-Nazaire, the strategy for the development of Nantes reached to reduce the local unemployment rate through economic activities such as research labs and universities built on the site of Ile-de-Nantes, industrial museums and monuments found particularly on the Ile-de-Nantes site, as well as office and commercial activities. Inside the region of Loire-Atlantique the city of Nantes is developed as a large French city of the west side of the country while the political continuity at municipal level since the 1990s (Nantes Municipal Counsil is led by the socialist party) creates the conditions for the development of the city according to the same economic, environmental and social policies. Unlike the project of Docks-de-Seine, the Ile-de-Nantes project was funded by European Union Funds from 2000 to 2010 while the rest of the second development phase of the project and the third phase are funded by public-private funds deriving from the Region of Loire-Atlantique, the Municipality of Nantes and private investors. It is important to mention that despite the fact that the sustainable development dimension was discussed as a pillar of the project since 2000 (restauration of the natural environment of the Ile-de-Nantes and connection to the city centre of the city), this dimension of the project is more evident in the current third phase of the project with the planning and construction of sustainable neighbourhoods inside the perimeter of the project, which are also labelled écoquartier by the French Ministry of Environment.

Concerning policies for the revalorisation and reuse of significant buildings and neighbourhoods dating on the industrial era in order to inscribe the local tangible heritage within the post-growth development model (development based on local resources) the two cities followed a different strategy. In Saint-Ouen and the Docks-de-Seine site there are still active industrial units dating from the industrial era as industrial activities never ceased to exist. Due to the abandonment of several districts of the city after the closure of a certain number of local factories and to the focus on the economic regeneration of Saint-Ouen, important industrial buildings such as le garage à bennes (a space for stocking merchandise) were demolished in favour of the construction of office and commercial buildings. After 2005 and the beginning of the sustainable neighbourhood project of Docks-de-Seine we note policies for the preservation of the local industrial heritage in correspondence with the national (French) and regional framework for the conservation and restauration of historical buildings. We can note the reuse and transformation of the Halle Alstom into a recreation and office space (Figure 5) and the inscription of the gardens of the formal industrial workers on the plan of the main park of the Docks.

Figure 5. La Halle Alstom on the site of the Docks-de-Seine. A former office building of the industrial complex of Alstom, the building was transformed into an office and recreation space. Source: Varvara Toura

In Nantes and the Ile-de-Nantes site there aren't active industrial units. Even though the abandonment of several districts of the island led to the demolition of buildings dated on the industrial era such as houses of the industrial workers, the activism at city level from scholars like Jean-Louis Kerouanton and associations working on the urban and industrial heritage of Nantes created the conditions, despite oppositions at the Municipal Counsil, for the preservation and reuse of industrial heritage. These policies in favour of the preservation of the local heritage are in correspondence with the national (French) and regional framework for the conservation and restauration of historical buildings. In the shipbuilding sector at the west of the island buildings and equipment from the industrial era are still present on the site and are transformed into industrial museums, city's landmarks and recreation spaces (Figure 6).

Figure 6. Industrial building from the Dubigeon complex. The Dubigeon complex included a space for shipbuilding activities as well as office buildings and warehouses that are nowadays transformed into recreation spaces. Source: Varvara Toura

As we have previously mentioned, an important dimension of post-growth policies in the processes of transformations of former industrial cities into sustainable cities concerns the social dimension of these processes and particularly the creation of community ties between the citizens and the presence of active inhabitants' associations in the areas (development based on co-planning and co-decision). In the analysis of interviews with local elected officials and local inhabitants' associations we noted differences in the two case studies resulting from the local political and associative context. In the case study of Saint-Ouen and the Docks-de-Seine project after the deindustrialisation era many former industrial workers left the city as gentrification

processes appeared (rents' increase, construction of office and administrative buildings). The new inhabitants who were installed in the city and on the site of the Docks were young people trying to benefit from the presence of social housing in the Docks-de-Seine project and the lower housing rents compared to the Parisian housing rents. Both the region of Ile-de-France and the municipality of Saint-Ouen were favorable in the creation of inhabitants' associations working on issues like environmental protection and preservation of the local heritage. The association Mon Voisin les Docks is among the first in Saint-Ouen working with the local authorities on issues related to the quality of life on the Docks and the maintenance of the local natural resources such as the River Seine and the main park of the Docks (Figure 7).

Figure 7. Public meeting between local elected officials and inhabitants' associations in Saint-Ouen. The meeting was held in order to discuss changes in the planning of the sustainable neighbourhood Docks-de-Seine. Source: Municipality of Saint-Ouen

In the case study of Nantes and the Ile-de-Nantes project, despite the appearance of gentrification processes after the deindustrialisation era (rents' increase, construction of office buildings) the local inhabitants did not leave the city of Nantes and the Ile-de-Nantes site. With the support of the municipality of Nantes and the region of Loire-Atlantique many associations were created by local scholars and former industrial workers who were interested in the preservation and promotion of the local urban and industrial heritage. A local way of city planning focusing on the principles of co-decision and co-design was developed inside the city (l'urbanisme à la nantaise) and was used in all phases of the project of Ile-de-Nantes with the participation of local elected officials, inhabitants' associations, scholars and the teams of architects and urban planners working on the project. Public meetings, workshops and seminars were used as a means to boost citizens involvement in the processes of decision making on issues such as environmental protection, preservation and reuse of industrial heritage and design of houses and public spaces (Figure 8).

Figure 8. Workshop on the second phase of the project of Ile-de-Nantes. Local elected officials, inhabitants' associations and the team of architects and urban planners that led the project during this phase participated in the workshop. Source: Municipality of Nantes

An important parameter in the development policies of deindustrialised areas is the restauration of the natural resources polluted during the industrial era and environmental policies for reducing environmental footprint as a measure for bringing ecological and social justice to areas facing serious environmental and social difficulties

(development based on eco-social integrity). In the case study of Saint-Ouen and the Docks-de-Seine project environmental policies are inscribed in the regional environmental plan for the preservation of local natural resources such as the Seine River while inside the city are created blue and green corridors for the protection of important green spaces such as public spaces and small forests (Figure 9). The polluted industrial area inside the site of the Docks was re-designed and transformed into the main park of the neighbourhood, where vegetation acts as a natural filter in order to clean the water inside the park. Even though the project of Docks-de-Seine as an écoquartier is based on ecological and energy criteria there are doubts about its eco-social dimension as the maintenance of green public spaces of the neighbourhood and the use of smart buildings are expensive measures that do not fit with the industrial character of the city.

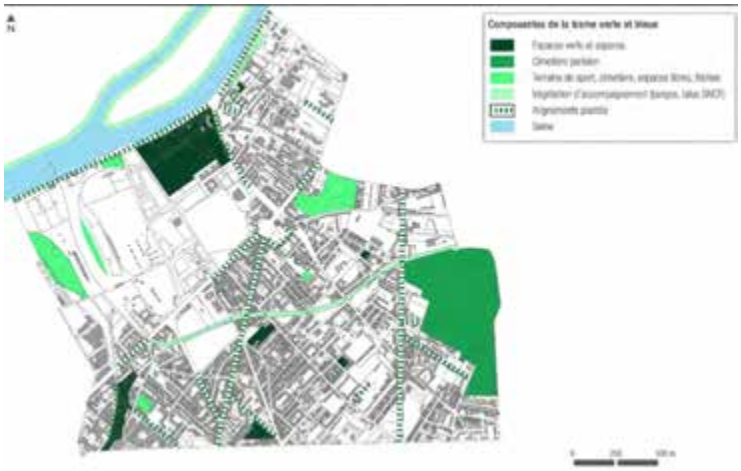

Figure 9. Blue and green corridors inside the city of Saint-Ouen. The development of blue and green infrastructures helps to restore the polluted former industrial lands. Source: Municipality of Saint-Ouen

In the case study of Nantes and the Ile-de-Nantes project environmental policies are inscribed both in the regional environmental plan for the preservation of local natural resources such as the Loire and Erdre River while the city of Nantes developed a plan for the revitalisation of the city based on green public spaces and mobility by bicycle and foot. The polluted industrial spaces inside the Ile-de-Nantes are re-designed and transformed into public spaces (parks) using vegetation as a filter for the polluted water while in the current third phase of the project the leading design team (Shorter and Osty) proposed the creation of green and blue corridors inside the island that will connect it with the public spaces of the city centre (Figure 10). As in the previous case study we should note that the planning and construction of écoquartiers on the site of Ile-de-Nantes focus on ecological and energy criteria but there are doubts about the high cost of such measures that do not fit with eco-social integrity.

Figure 10. Blue and green corridors inside the Ile-de-Nantes project. The development of blue and green infrastructures helps to restore the polluted former industrial lands and connect them to the public spaces of the city centre of Nantes. Source: Varvara Toura

Another point for the growth of deindustrialised areas in post-growth theories is related to the development of economic activities in accordance with the local needs in order to boost the municipal and regional economy as a means to reduce local unemployment rate and to lead to economic resilience and sustainability (economic development based on the local and social characteristics). In the case study of Saint-Ouen and the Docks-de-Seine project at regional level the local economy is based on existing industrial activities together with the construction of office and administrative buildings. At municipal level Saint-Ouen tries to develop its local economy based on activities related to culture and tourism using the former industrial buildings as places to host cultural and educational events (Figure 11). Even though industrial activities play a key role in the economic development strategies for the project of Docks-de-Seine, they are harmonised with the other economic activities while maintaining the industrial character of the city which seems to be gentrified as a result of the installation of office and administrative buildings.

Figure 11. Industrial, cultural and tourism activities on the site of the Docks-de-Seine. While industrial activities continue to exist in Saint-Ouen the city focuses on its industrial past as a source of development of economic activities based on local needs. Source: Varvara Toura

In the case study of Nantes and the Ile-de-Nantes project at regional level the local economy is based on industrial activities in neighbouring cities of Nantes such as Saint-Nazaire while the city of Nantes is developed as the big urban centre of the region where office and administrative buildings are found together with commercial, educational and cultural activities. At municipal level Nantes tries to develop its local economy based on activities related to culture and tourism using the former industrial buildings as places to host cultural and educational events (Figure 12). Even though the restauration and reuse of industrial buildings brings tourists to the area and together with office and administrative buildings creates gentrification conditions inside the former industrial city, they play a key role in the economic development strategies for the project of Ile-de-Nantes and maintain the industrial character of the city as they are also used by local associations of scholars, citizens and former industrial workers.

Figure 12. Educational, cultural and recreation activities in the site of Ile-de-Nantes. Even though industrial activities do not exist inside Nantes the city focuses on its industrial past as a source of development of economic activities based on local needs. Source: Varvara Toura

Discussion

The study of two real-world cases revealed the necessity to consider planning in deindustrialised areas in an interdisciplinary way that brings together members of academia, industry and local actors in order to reshape cities through bottom-up strategies while promoting eco-social integrity. The development of deindustrialised areas in the context of post-growth theories should be based on their particular characteristics, especially their tangible and intangible industrial heritage. Traces of the industrial past such as buildings, neighbourhoods, infrastructure and equipment could be restored and reused as museums, cultural spaces, research hubs and universities in order to promote the local history and boost the local economy through activities related to culture, education and tourism. Local associations of citizens and former industrial workers work on the issue of preservation of industrial heritage and in several cases reverse regional and municipal policies to demolish industrial buildings in order to built contemporary office buildings. The intangible industrial heritage relies on these social ties and on the preservation of the social character of these areas where mainly live low- and middle-class households. The funding of the projects of transformation of deindustrialised areas and especially the planning of sustainable neighbourhoods seems to attract the interest of private investors who are more interested in the development of tertiary activities that in several cases lead to the gentrification of these areas. For this reason, it is important to be developed at national, regional and municipal level policies to reverse gentrification such as a minimum number of social housing in the sustainable neighbourhoods.

Another point to consider from the above analysis for the development of sustainable conditions in former industrial areas are the policies for the environmental protection of these areas alongside the restauration of the polluted natural resources. These policies should be inscribed at a larger context (national, regional, municipal) referring to the global dimension of sustainable development in order to respond to issues such as cities' environmental footprint and reduction of gas emissions. At the same time environmental policies at neighbourhood level that are part of the development program of sustainable neighbourhoods (for example the creation of small and big public spaces such as parks) should be in accordance with the regional and municipal strategic plan for environmental protection in order to propose solutions that would not only benefit certain cities' districts but rather the entire city and region. These environmental policies should be combined with economic activities in accordance with the local communities needs (for example the creation of schools, hospitals and small shops) in order to bring ecological and social justice to areas that suffer from high unemployment rates and pollution due to being neglected for several years after their deindustrialisation. These economic activities could serve as a means to solve social conflicts as underdeveloped deindustrialised areas are places that gather activities of regional and municipal interest such as research hubs, tourism and cultural facilities.

Finally, the last point to consider are the technological innovations of the sustainable neighbourhoods' programs that are presented by politicians (in the French context by the French Ministry of Environment) and contractors as measures that bring social, economic and environmental sustainability and resilience in underdeveloped deindustrialised areas. The development of écoquartiers in France is based on certain policies and measures (Charte Ecoquartier) common for all projects of this category which mainly focus on the reduction of carbon emissions and energy demands for cooling and heating housing units. In certain cases, the cost of this policies is really high thus preventing cities to develop other local policies such as education and health care which are particularly important in areas historically gathering low and middle-class households. Technological innovations of the sustainable neighbourhoods' projects in underdeveloped urban areas such as the design of passive houses, the collection and reuse of grey water in domestic activities and the re-design and transformation of polluted lands into parks should receive national and international funding as they are part of global policies against global warming and climate change. At the same time these innovative policies should be developed for all cities' inhabitants, take into consideration the local socio-economic context (especially the difficulties related to unemployment) and restore the polluted natural environment in order to bring environmental, social and economic sustainability.

Planning the Great Acceleration: Contributions of planning theory, ideology, and implementation to planetary transformation and social-ecological decline

Abstract
In the years and decades following WWII, global energy and resource consumption were unleased on a hitherto unseen scale. The fields of earth system science, history, and planetary health continue to grapple with the causes and consequences of this 'Great Acceleration' – a proposed entry point into the Anthropocene. This paper takes its cue from recent trends in research that are 'globalizing' perspectives on the processes of suburbanization and the distinct suburbanisms these processes produce. We explore spatial and temporal scale as necessary, conjoint lenses for articulating key contributions of planning to the Great Acceleration. Taking Prince George, British Columbia, Canada as an illustrative case, we draw on archival sources and spatial analysis of historical subdivision data. These streams of analysis allow us to track and explicate how dominant planning theories were deployed between 1946 and 1981 to both rationalize and accommodate urban expansion within British Columbia's northern capital.

Keywords: Planning; Garden City; Neighbourhood Unit; Great Acceleration; Urban Development

Introduction

Across North America, the mass adoption of the suburban spatial order in the mid-twentieth century emerged in the shadow of the industrial city. While suburban settlement existed alongside the earliest cities for the wealthy and their households, urban planners at the turn of the twentieth century began to focus on the working classes as a group that should also benefit from new notions of health and order (Mumford 1961). Concepts of order, health and separation drew their power from the unprecedented mobility of labour, dispossession, tenements, and disease that had characterized the industrial cities of the late 19th Century. Ideas shaping suburban place-making emphasized orderliness, familiarity, cleanliness, health and prosperity. The separation of uses – notably domestic from industrial – and the intentional development of distinct neighbourhoods as social units became fundamental to the developing profession of planning (Aalen 1992; Grant1997; March 2004; Talen 2017; Ulmer 2018).

Across North America, auto-centric suburbs grew in the decades after the Second World War through the promulgation of a development model Filion (2015) describes as *dispersed suburbanism*. Economic growth, population growth, and household consumptivity interacted to create the culture of suburbia; planners rationalized it, cities marketed it. In Prince George, British Columbia, Canada, most of the city was developed during this period. The impacts of the growth ideology that was forged in this period are still visible in the city's present struggles to advance sustainable development around goals like decarbonization and protection of urban biodiversity. This same growth ideology is also visible in the role the City and the Province played in post WWII planning, land development, and land acquisition, as well as the resource consumptive spatial structure these processes contributed to.

Taking Prince George as an illustrative case, this article charts a historical context elucidating at a local level how dispersed suburbanism became North American cities' primary contribution to what environmental historians John McNeil and Peter Engelke have called the Great Acceleration. In the decades following 1945, accelerating energy and resource consumption became the most powerful influence on global ecology, and the entry into what is increasingly accepted as the human-induced epoch of the Anthropocene (McNeil and Engelke 2014; Steffen et al. 2015). Our goal in this paper is to examine the use of physical planning concepts that entrenched dispersed suburbanism in the structure of Prince George during a period (1946-1981) of rapid post-war growth[1]. By doing so we strengthen an empirical evidence base illustrating how the planning profession helped condition present day global challenges during the peak of the Great Acceleration.

In the post-1945 period, models of neighbourhood design in Prince George (and hundreds of other cities) borrowed from Clarence Perry's neighbourhood unit and Howard's garden city concepts. These concepts had been developed a half century before as ideal forms for work, family, and leisure (March 2004; Patricios 2002).

1 Between 1951 and 1966, the population of Prince George, British Columbia quintupled from 4,703 to 24,471 and then almost tripled by 1981 to a population of 67,559 (BC Stats 2012)

In Prince George and elsewhere, they were translated into the auto-centric spatial patterns of growth and consumption that continue to structure the city and its consequent socio-ecological impacts. In the case of the colonial settlement of Prince George, a future city began as a small number of places competing for centrality. Beyond the scope of this paper, Curry and Llewellyn (1999) review how, in the early decades of the 20th Century, the Grand Trunk Pacific Railway inserted itself and its City Beautiful inspired plan into a struggle between two existing settlement areas (Central Fort George and South Fort George) to attract development. Vogt and Gamble (2010) further problematize this struggle, illustrating a host of coercive tactics the railway deployed to secure the acquisition of property to accommodate their plan on lands wrested from the Lheildi T'enneh First Nation's Indian reserve allotment.

As the Province and resource industries sought to capitalize on the natural resources of the region, aspirations of growth following the Second World War drove the City to secure its place as the regional service centre for resource development. In British Columbia (BC), as elsewhere, there was a massive expansion of highway infrastructure and rapid investment in automobiles (Bradley 2017). Using archival sources and historical land development data, we highlight the role planners and planning thought played in shaping land consumption, growth, and automobile dependence in Prince George. Before doing so, we review two norms of spatial order that were used to rationalize auto-centric growth and design in Prince George and elsewhere. We then present first steps that entrenched a post WWII growth ideology in Prince George's planning regime before exploring the 'big picture' of boundary expansion by the City over the period. We end by examining how the spatial norms of the neighbourhood unit and garden city were deployed to extend and accommodate (both spatially and temporally) this growth ideology.

The suburban spatial order as designed and as built

Two norms of suburban spatial order were formative in realizing the spatial structure of Prince George today. Perry's neighbourhood unit shaped new neighbourhoods built between 1954 and 1981, and Howard's garden city helped to both shape and rationalize a multi-centric sprawling layout underlying planning strategies from the 1970's onward. Both concepts share many of the assumptions/certainties/ideologies of suburbia, although they operate at different scales. In the Prince George context, they were also applied at different periods through the work of different planners, as we discuss later.

The garden city concept was first presented by Ebenezer Howard in his 1898 book *To-morrow: A Peaceful Path to Real Reform.* The impact of the garden city concept on planning and urban development is well recognized, although it is worth noting that its implementation has strayed considerably from the original vision (Aalen 1992; Clark 2003; Hardy 1992; Lewis 2015; March 2004; Ulmer 2018). Influenced by reformist thinking, Howard was primarily concerned with social ideals; the spatial organization of the garden city being somewhat secondary (March 2004; Ward 1992). These social ideals included *inter alia* the collective ownership of land, reinvestment of profits from land conversion to support robust public services, and promotion of a healthy relationship between residents and their natural surroundings (Hardy 1992; Lewis 2015; Ulmer 2018).

Due in part to the growing involvement of a business class less interested in social reforms, the physical features of the garden city concept began to take priority as early as the planning for the first garden city at Letchworth (Ward 1992). Howard was a director for Letchworth but was marginalized early in the project over conflicts with other directors. As Clark (2003) describes, Howard's vision of a city created for its potential residents clashed with obligations others held toward project shareholders. Famously, the physical aspects of the first garden city were also not left for Howard to decide and were instead vested with the architects Barry Parker and Raymond Unwin (Lewis 2015; Livesey 2016; March 2004). Tensions between social goals and environmental design and quality persisted, and Aalen (1992, 28) provides a concise, if not biting, summary of the extent to which spatial planning prevailed: "[I]t is the practical dimensions of [Howard's] work that have been emphasized, while the vital socio-political ideals were barely understood, much less put into effect".

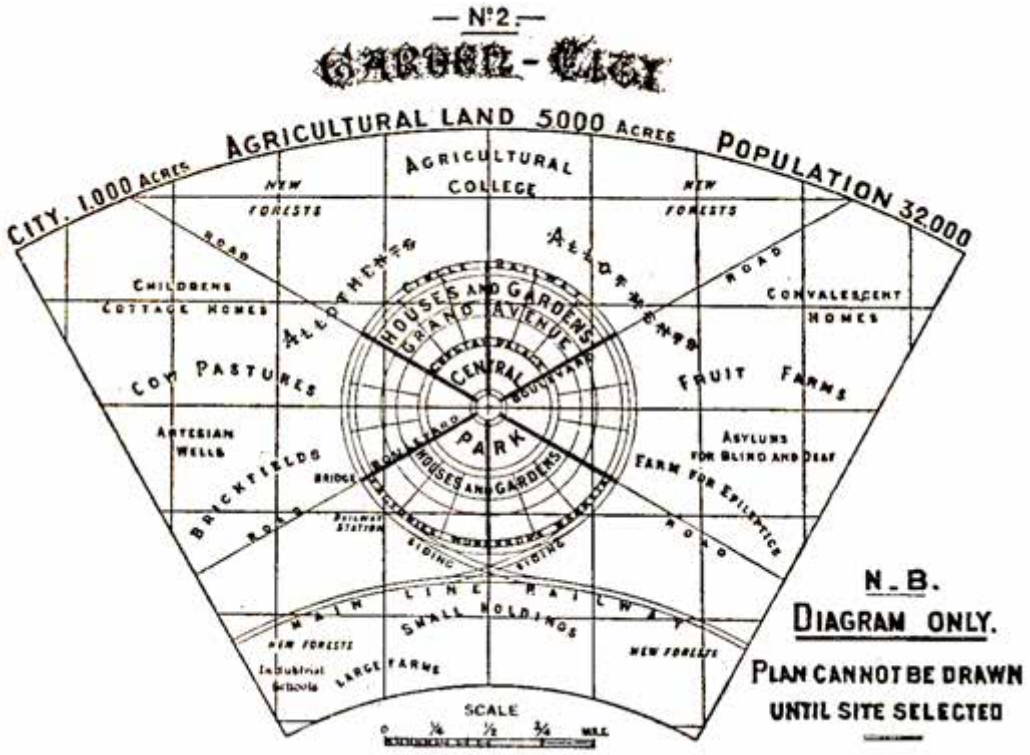

Figure 1: Garden city diagram (Source: Public Domain Wikimedia Commons).

As the garden city diagram in Figure 1 illustrates, the design of the garden city sought to connect the population to healthier natural surroundings while repopulating rural areas to ease the burden of London's population growth (Rockey 1983; March 2004). Fully realized, a 'social city' was to be a network of small scale, decentralized garden cities, each with a central settlement node housing up to twice the population of surrounding nodes. Each garden city in this network was to hold 30,000 residents in its core and 2,000 more in surrounding agricultural estates (Hardy 1992; Ward 1992). The rural agricultural landscape accommodating the network of settlements was to contribute to the livelihoods of garden city residents, a revitalized rural economy, and the sustenance needs of a growing region. Along with tree-lined streets and the provision of public gardens and parks within the settlement boundary, at the edge of the city an agricultural belt provided a space for recreation and a fixed boundary to contain outward growth of the urban area (Aalen 1992; Clark 2003).

Ogilvy (1968) discusses the implementation of the garden city concept as an aspiration to create self-contained communities. Self-containment in Ogilvy's view referred to the provision of a full suite of urban functions (e.g., employment, affordable housing, commerce, etc.) within a defined area, but also the ability for residents to pursue all aspects of a fulfilled life within the community boundary. Accordingly, land use across the wards that were defined in Howard's graphic of a circular city with six intersecting boulevards was to be carefully balanced through zoning. Public services and opportunities for commerce were afforded in a core area, surrounded by concentric belts of residential land that culminated in an outer ring of industrial use connected by a rail corridor (Aalens 1992). The relatively small scale of the garden city meant that residents would have access to the rural landscape and the clean air, pastoral views, and moral healthfulness and simplicity it was understood to provide (Ogilvy 1968).

The second norm of spatial order relevant to understanding post-WWII growth in Prince George is Clarence Perry's neighbourhood unit. The neighbourhood unit concept is typically attributed to Clarence Perry, with its most recognized form emerging in 1929 as part of New York City's regional planning process (Patricios, 2002). Although affixed within the planning cannon, both Talen (2017) and Johnson (2002) challenge the veracity of this story, recounting evidence that formulations substantially akin to Perry's concept were submitted to a design competition hosted by the City Club of Chicago in 1912.

Indeed, Johnson (2002) discusses in detail architect William E. Drummond's entry to this competition, labelled *Neighbourhood Unit*, and goes on to argue that Perry's formulation over a decade later was an appropriation of this original work.

Despite the more varied origins of the neighbourhood unit concept than are sometimes recognized, there is little doubt that Perry popularized contemporary ideas about neighbourhood planning in use by scholars and practitioners at the time (Talen 2017). As Mumford (1954, 262) notes, Perry's work "had a dramatic value in crystallizing many diffuse efforts". These efforts were influenced by social reformers like John Dewey and Robert Park and included a push to plan cities on a neighbourhood scale to address crowding, sanitation, and corruption in the industrial city. Neighbourliness, community, and safety became pillars in the foundation of new physical formulations of neighbourhood structure and function, while principles of scientific management became a counterpoint to a perceived ineffectiveness and immorality within the waning city beautiful movement (Banerjee & Baer 1984; Grant 1997).

The neighbourhood unit would become a ubiquitous model for realizing planned residential environments en masse, seeking to reinforce in physical form sociological theories of neighbourhood and community connection and identity. This included work from Roderick McKenzie identifying two *essential ingredients* of a neighbourhood: geographic proximity to a defining object and the intimate association of people living in proximity to one another. More centrally, Perry's formulation drew on Charles H. Cooley's description of a *primary group*. The primary group was a network of face-to-face interactions and exchanges among family, children, and close relations that served as a heart of a community and informed most directly one's social world and ideals (Banerjee & Baer 1984).

As a model for spatial planning, Perry's neighbourhood unit was designed to fulfill the functional needs of education, commerce, security, and identity for a population of 1000 families, or 5000 people (Grant 1997; Talen 2017). In addition to a *size* that would be defined by a population large enough to support a school, arterial roads formed *boundaries* that would direct vehicular traffic around (rather than through) the neighbourhood. An interior *open space* network served the need for recreational park space, and *institutional sites* like a school anchored the centre of the neighbourhood unit. Finally, *local shops* provided opportunities for commerce on the periphery at major transportation intersections; intentionally sited away from an *internal street system* designed to further dissuade through traffic (Banerjee & Baer 1984).

In addition to following clearly defined spatial prescriptions, neighbourhood units were to be linked together in a cellular design to plan for large areas with relative ease and efficiency (Johnson 2002). Although often understood through the motivation to provide self-containment, each neighbourhood unit can also be viewed as part of the broader function of a designed urban system that resists a centralization of urban services that might hollow out recreation, shopping, and educational opportunities at a neighbourhood level. As Mumford (1954) notes, the function of neighbourhood planning was met with a mix of welcome acceptance, and open critique regarding the potential reproduction of racial, cultural, and economic segregation. Indeed, as Erickson and Highsmith (2018, 12) document, Perry acknowledged that the use of his neighbourhood formula would likely reproduce homogenous grouping processes, "speaking more favourably than critically of separation" and the role of homogeneity as a foundations for shared community consciousness.

As Table 1 below summarizes, the garden city and neighbourhood unit are fundamental spatial concepts whose norms were translated into automobile-oriented neighbourhoods across North America. This includes a tremendous influence in accommodating growth and consumptivity in Prince George during the period of the Great Acceleration, as we now explore.

Table 1: Norms of spatial order.

	Spatial Norms as Designed	
	Garden City	*Neighbourhood Unit*
Origin	1898	1929
Tradition	Social reform	Scientific rationality
Scale	Metropolitan / organism	Neighbourhood / cell
Role of neighbourhoods	Social/educational/arts	Domestic community around a school
Pedestrian walkability	Walkable city proximate to rural landscape	Access to services within neighbourhood walking catchment
Spatial relationships	residents and nature/residents and work/services and education	residents and school/neighbourhood services
	Spatial Norms as Built	
	Garden City	*Neighbourhood Unit*
Concept + automobility	Residential-use suburbs with some services connected by highways to work and to city	Residential-use neighbourhoods without throughways and schools at the centre
Rationale	Multicentric growth and development	Scientific rationality and development
Scale	Metropolitan and suburb	Neighbourhood
Role of neighbourhoods	Residential with services	Physical community around a school
Pedestrian walkability	Access to nature	Walking routes to schools

First steps toward a post WWII growth ideology in Prince George

In Prince George, municipal policy relating urban form to growth came into place immediately following the close of the Second World War. By June of 1946, City Council approved a plan and associated zoning policy prepared by J.H. Doughty-Davies, a civil engineer with the Regional Planning Division of the Bureau of Post-war Rehabilitation and Reconstruction (Prince George Citizen, 1946). The vision of the plan was "[t]o provide healthful, safe and satisfying living environments for all individuals and families" (Doughty-Davies, 1946, 1). In this vision, Doughty-Davies reflected at a local level contemporary discourse surrounding the spatial norms of the garden city and neighbourhood unit. At a broader scale, with a population[2] of less than 5,000 at the time, his newly produced vision and supporting ideas about zoning also meshed well with a desire on the part of Provincial leaders and resource companies to capitalize on the opportunities to expand resource development and extraction in the northern half of the Province (Markey et al. 2008).

As part of the Provincial support for land privatization, the Province undertook surveys and had defined a grid of lots and road allowances in Prince George. The spatial pattern proposed was consistent with both the land layouts done by surveyors and the Crown in the period from 1875-1946, as well as the use of the grid to expedite land development in rail communities across Western Canada (Gilpin 1992; Leonard 1984). Originally, most of the lands that came to make up Prince George had been converted from Provincial to private title for agricultural development in large blocks, but some of these lands the Province had already subdivided in parcel grid. Significant areas west of the original Central Fort George settlement area would ultimately be built out according to prescriptions of the neighbourhood unit (instead of the Province's grid), but the aspirations for urban expansion were clear.

The Province's role in planning Prince George was part of a clear growth ideology evolving around the vision for the city in the postwar period. Prince George's 1946 community plan and its zoning policies were justified on

2 Rutherdale (1994) reports population data for Prince George from the 1961 Census. In 1941, the population was 2,027, and in 1951 the population was 4,703.

what Doughty-Davies (1946) described as two *important considerations*. The first was accommodating growth to a minimum population of 8,000 people. The second was accommodating, through the design of the city, the expectation that Prince George would become a freight and service hub for northern BC. This vision for a northern hub placed Prince George at the centre of not only an east-west train corridor connecting Prince Rupert to Winnipeg and Chicago, but also on a north-south axis that relied increasingly on a nascent highway network (Bradley, 2017). Reflecting on experiences from the United States, Doughty-Davies (1946, 1) described the need to allow for "[w]hat would have been regarded as monstrous vehicles and loads a few years ago".

Prince George's function as a freight and service hub for the north was rationalized in the 1946 community plan in numerous ways. A street plan called for designs that would minimize the use of right angle turns, as well as the strategic acquisition of lots along the east side of a main artery (Vancouver Street) to accommodate a widening of the street to 100'. Along with a zoning plan (see Figure 3) that established six land use designations, the community plan leveraged the rhetoric of community safety and the logic of separation to create the discursive and ultimately physical space for growth in freight and service functions. Notably, the Doughty-Davies discussed the importance of open space to afford children's play, relating preferred sites to the provision of safe family areas located away from high volume traffic corridors. While Doughty-Davies policies and vision spoke to the preferred structure and function of a future city, the most important role of his plan was to reinforce a growth ideology that would become a throughline for planning in Prince George for decades.

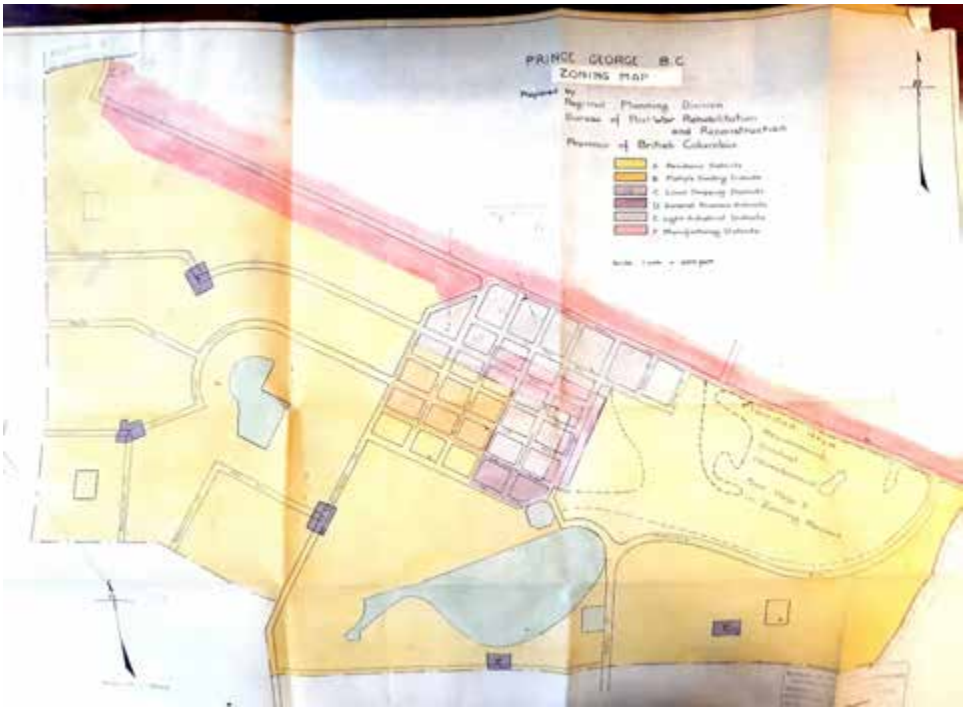

Figure 2: 1946 zoning map for the City of Prince George (Source: Northern BC Archives).

An era of boundary expansions in British Columbia's northern capital

Bolstered by the growth of a regional resource economy and its increasing function as a service hub for northern BC, a vision for post WWII urban expansion in Prince George would be largely realized by end of the 1970s. During this time, the City was an active partner with the Province in expanding its settlement boundaries. The Provincial postwar land policy for urban growth emphasized expanding the boundaries of municipal jurisdiction, and the City of Prince George seized this opportunity to grow the land area under its control.

The map shown as Figure 4 below identifies boundary expansions beginning in 1953 and ending in 1979, illustrating the extent and pattern of annexation of land into the city. The area shown in the 1946 zoning plan (see Figure 3 above) falls within central grey area depicted in Figure 4 below. Through the 1950's two boundary expansions added 1508.2 ha of land and water extending west and southwest from the area discussed by Doughty-Davies only a few years earlier in 1946.

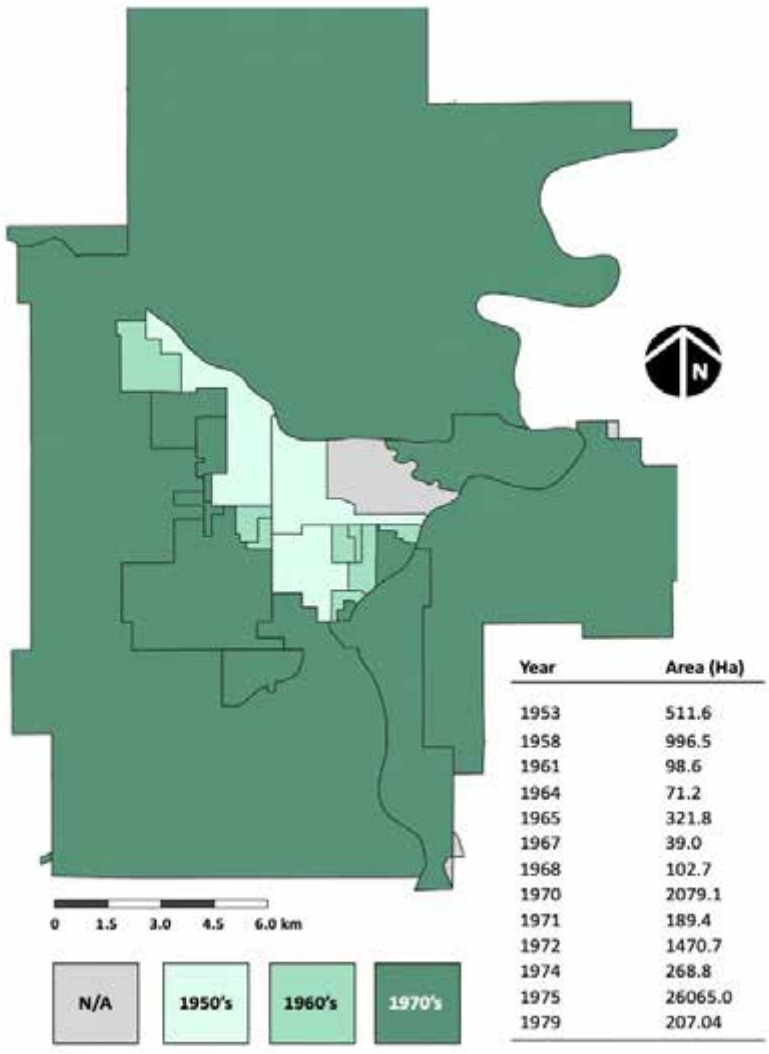

Figure 3: Boundary expansions between 1946 and 1981 in the City of Prince George (Source: City of Prince George OpenData Portal – created by lead author).

In the first boundary expansion in 1953, the City acquired responsibility for the financing and provision of utility services in the new area, placing a direct financial constraint on potential future development. Before the second boundary expansion, the City had negotiated with the Province an ownership transfer of 25% of the remaining Crown land in the expanded area (Trick 1988). While this transfer did not take place until the land met the conditions of use under Land Act regulation (BC Department of Lands, Forests, and Water 1974, 18), through this negotiation the City accessed important new tools to finance the infrastructure required to support ongoing expansion. Ultimately the City became a land developer and regulator. Each boundary expansion from 1958 onward resulted in the potential for the City to develop and sell parcels. Over the next decade an additional eleven boundary expansions would bring 26,698.3 ha of land into their jurisdiction.

As Meligrana (2003) discusses, land annexations in BC during the post-WWII period placed greater importance on the social contract with local communities than concerns for a coordinated planning vision for the spatial or governance arrangements of the province's growing regions. Up until the mid-1970s, annexation required support from a majority of landowners in the area to be annexed, but by the mid 1970s this shifted to a majority support of residents in the incorporated and unincorporated areas.

Building out Prince George's neighbourhood units

With land and financial inputs for the expansion of Prince George supported through annexation and novel financing pathways, a growing city required a spatial norm to plan for, attract, and accommodate settlers in an expanding regional resource economy. In Prince George, the neighbourhood unit served this need. Prescriptions associated with the neighbourhood unit were present in the local policy discourse as early as Doughty-Davies' 1946 community plan. While not in full or by name, Doughty-Davies drew on rhetoric familiar to the neighbourhood unit. He discussed safety at some length to support proposed siting for children's play areas within their neighbourhoods such that "no child has to go more than one quarter of a mile nor cross a main traffic street to reach it" (Doughty-Davies 1946, 3). Consistent with the scientific rationality of the neighbourhood unit, he also singled out standards for the appropriate provision of school services. Allowing for an average ratio of adults to children appropriate to the period and an expected population of 8,000 people, each child was to be afforded 100 square feet of play space proximate to their school.

Early nods to the neighbourhood unit notwithstanding, full implementation of this spatial norm would lag the sequence of boundary expansions that began in 1953. By applying the planning elements[3] summarized by Banerjee and Baer (1984) to openGIS data for Prince George's street network and zoning data (and cross referencing these against land use plans from 1969 and 1978), we identify twelve neighbourhoods that were substantially or fully built out according to the neighbourhood unit (see supplementary material). A review of all registered plans of subdivision and strata plans within these areas of the city shows the implementation of neighbourhood units through land development began between 1956 and 1960 and persisted through 1981 (BC LTSA, 2022).

The implementation of the neighbourhood unit accommodated the growth of Prince George's built-up area as the city expanded in all directions, often with new developments leapfrogging into recently incorporated areas of the city. From 1956 to 1981, over 5000 new residential parcels were established within areas that would be built out according to neighbourhood unit principles. The pace of subdivision into these residential areas peaked from 1971-1975, ultimately comprising 16.2% of the City's total parcel fabric (see Table 2).

While we were interested in the possible role the City played in processes of place branding that are increasingly scrutinized within the field of placemaking (see for instance Masuda & Bookman 2018), available archival sources revealed little evidence of this function. One caveat to this is a promotional brochure produced by the City in 1970 (City of Prince George 1970). The document features the city's high rate of growth and its industries, projecting this state into the future. For each of the main resource industries including forestry, forest products, and mining and minerals, the document paints a bright future. The emphasis is almost completely on economic prosperity and business growth, with almost no mention of the city as a place to live, with one notable exception. Affordable serviced lots available in "planned neighbourhood units".

Illustrative of the aspirations for further growth and development, the footprint of Prince George as built according to the neighbourhood unit ultimately could have been much larger if not for the fact that population growth and land subdivision began to subside by the early 1980s. As dispersed as Prince George's built-up area became, a 1978 land use plan includes a far more extensive network of arterial and collector roads expanding into the urban-rural interface (Schaber 1978). Reflective of Perry's concept, outlying areas in Prince George were to comprise neighbourhoods identified on the land use plan by a proposed set of intersecting arterial roads and a symbol representing a school at the centre of each newly bounded area.

3 Banerjee and Baer (1984) identify a combination of the following elements as characteristic of the implementation of the neighbourhood unit: *size, boundaries, open space, institutional sites, local shops, internal street networks.*

Table 2: Land subdivision within Prince George's completed neighbourhood units.

Date Range	Parcels Created	*Proportion of Parcels Created	*Area Subdivided (Ha)
1956 - 1960	312	1.0%	41.77
1961 - 1965	607	1.9%	79.88
1966 - 1970	1231	3.8%	150.60
1971 - 1975	2161	6.6%	219.46
1976 - 1981	963	2.9%	124.72

* Proportions based on total number of active parcels in City of Prince George open GIS parcel fabric layer as of June 2022. Total land and water area calculated from City of Prince George open GIS boundary layer.

Rationalizing continued growth through a garden city master plan

The post WWII growth ideology that was built in part through Doughty-Davies 1946 community plan and subsequent land transactions between the City and Province intersected with the neighbourhood unit concept as early as a the 1950s. It would be two decades later that garden city planning would play a similar role. Led by Chander Suri, then Director of Planning for the Regional District of Fraser Fort George, a Proposed Master Plan from 1971 documents a planning concept for accommodating future growth across the landscape increasing within the City's jurisdiction (see Figure 4). Reflective of Howard's vision of town and country harmony, Suri drew on surveys of the local population to support a vision that "will take advantage of the natural character of the area by combining both rural and urban elements to create urban units within rural settings" (Suri 1971, 3). To actualize this vision, the concept identified the city as a *centre of urbanity* housing a population of 175,000 to 200,000, and a network of three *satellite towns* ranging in size in size from 50,000 to 90,000 people.

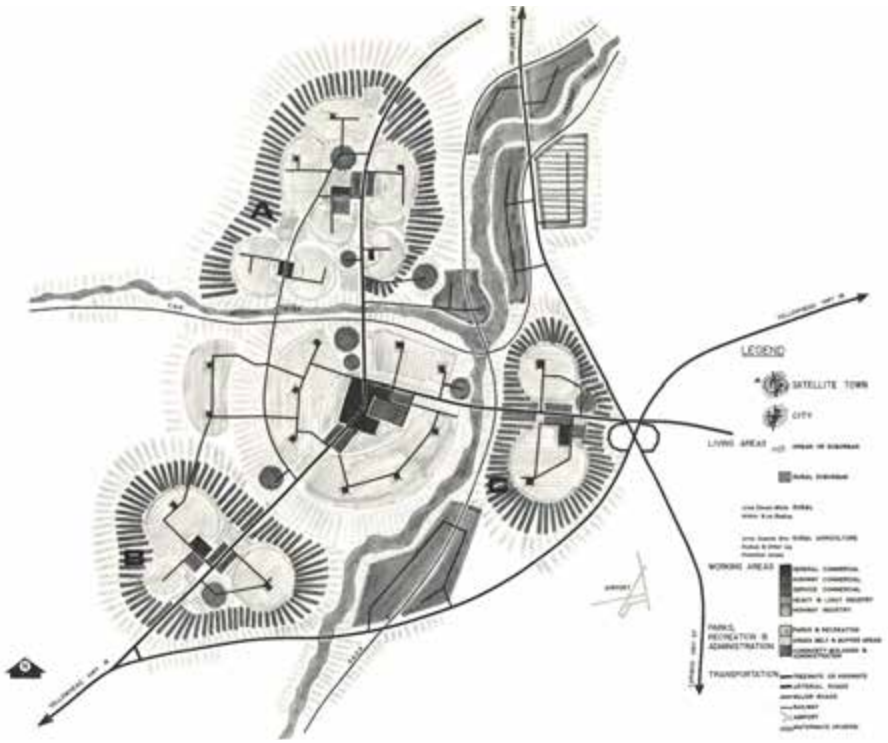

Figure 4: Greater Prince George Planning Concept from 1971 Proposed Master Plan (Source: Regional District of Fraser Fort George – Reproduced with permission)

The pace of population growth present in the two decades following the close of the Second World War would falter and ultimately stagnate by the early 1980s, but continued expectations and aspirations for growth are evident throughout the Suri plan. While focused on a detailed set of objectives and policies for building out satellite town A north of the city's original urban core, Suri articulated a broader vision for the Greater Prince George area. This vision drew directly on many of the garden city's spatial prescriptions. *The city* and each *satellite town* were to be surrounded by a green belt, with additional separation provided by the Nechako and Fraser Rivers in the case of satellite town A and C.

Within Suri's vision Greenways were to play a role as *containment areas*, while simultaneously supporting values like intensive recreation and engagement of citizens in forest reserve management. Although falling short of the collective ownership Howard envisioned (Hardy 1992; Lewis 2014; Ulmer 2018), the goal to create forest reserves managed with direct input from local citizenry sought to capture aspirations to secure an enduring public good through spatial planning and land management. The plan articulates this as the need to foster "a spirit of participation and appreciation by the local people toward preservation and management of the forest resources in the region" (Suri 1975, 25).

In addition to the function of the greenway system, an open space hierarchy was developed in response to trends in mobility, income, population, and leisure time. The sequence of open spaces would afford connection to nature, including pedestrian access from homes to private green spaces, playgrounds, local parks, and town parks. Access to regional parks was to require a vehicle. Like Doughty-Davies standards for youth play areas, planning standards for green space provision left questions of environmental quality and human health and well-being unexamined, focusing instead on quantitative relationships between population and land provision.[4]

Set within the context of two decades of economic and population growth and an era where planning thought was increasingly permissive toward growth (Chapin 2012; Filion 2009), it is perhaps not surprising that Suri would contribute to an ongoing growth ideology. Although the Proposed Master Plan and supporting summary do not address the use of common practices to address uncertainty, like building multiple scenarios with varying assumptions, Prince George's garden city concept was informed by a population projection signaling continuous, vigorous growth. Within the boundaries of the contemporary City, projections estimated population growth from 32,629 in 1971 to 150,460 in 2001. Within each of the surrounding electoral areas, population growth ranging from 21,509 to 118,670 was projected over the same period. Based on this expected growth, the planning concept for Greater Prince George depicted in Figure 4 was developed to "accommodate a population of over ½ million people (580,000)" (Suri 1975 29).

To create a plan for meeting the demand for services and consumption of such a rapidly growing population, Suri again turned to garden city principles to develop a networked hierarchy of commercial urban functions. A *downtown or central core* was to meet the specialized shopping needs of 100,000 to 250,000 people, with direct transportation connections to three outlying satellite towns. In turn, each satellite town would be serviced by three connected commercial districts: a *town centre* with at least 225,000 ft^2 of commercial space; a *town sub-centre* providing 95,000 ft^2 of space for *convenience goods and services*; and a *neighbourhood centre* of 32,000 ft^2 of space meeting *day to day* shopping needs and minor personal services (Suri 1971).

Conclusion

On May 20th, 1975, Prince George City Council was presented with a range of options for future growth. Of the four options presented, "Council approved the option of **growth in all directions"** (Suri 1975, 1 - **emphasis added**). Far from unique, this decision was one of myriad made during the decades following the Second World War that contributed to the transformation of cities across North America.

4 The open space standards in the Proposed Master Plan were related to population. Regional Parks – 2.5 to 13 acres per 1000 people; Town Parks – 2.5 to 4.5 acres per 1000 people; Community Parks – 1.5 to 2.5 acres per 1000 people; Golf Courses – 18 holes per 40,000 people; Neighbourhood Parks – 2 acres per 1000 people.

Driven by similar growth ideologies and growing affluence sparked by a massive rise in consumer goods ranging from household appliances to automobiles, cities sprawled outwards to accommodate booming populations (Belisle 2011; Bradley 2017; Filion et al., 2016; Owram 1997). Described by Filion (2015) as *dispersed suburbanism*, the postwar development pattern that accommodated this growth committed North American cities to an urban form and function dominated by low-density development, functional land-use specialization, separation of activities, and auto-dominated forms of mobility.

The negative human health (e.g., sedentary lifestyles) and environmental (e.g., greenhouse gas production) consequences that were embedded in North America's post WWII urban landscape are now well established (Chapin 2012; Girardet 2020; Rees 2018), but are often understood within a limited historical context, especially in Canada's urban north. Under the banners of resilience, sustainable development, and new urbanism (among many others), the planning profession continues to mobilize a response to address its contribution to growing global environmental issues like climate change and biodiversity loss. To succeed in this endeavour, the profession must not only advance new spatial norms for sustainable urban development. It must also take stock of the historical forces that coalesced during the period of the Great Acceleration that continue to shape present social-ecological crises (Castree 2017; O'Brien & Lousley 2017).

This research contributes to this necessary stock take by examining how planning thought, planning practitioners, development processes, and financial mechanisms coalesced from 1946 to 1981 to realize the resource consumptive urban expansion of Prince George, BC. Like a growing number of scholars (see de Baro 2022 for a recent example), we sought to situate the local and regional processes of urban planning and land development in closer proximity to global scale discourses about the Anthropocene and Great Acceleration. We did so by examining how the spatial norms of the garden city and neighbourhood unit were converted between 1946 and 1981 to facilitate growth and automobility.

Like other cities in western Canada, most of the growth in the city of Prince George took place while the spatial norms of the garden city and neighbourhood unit were dominant. The influence of other norms, namely the application city beautiful and the urban grid, have been placed within a historical context in northern cities like Prince George (Leonard 1984; Sedgwick 2010). Much of this scholarship examines the establishment of early settlements near the turn of the century, and our focus on post WWII urban planning in BC's northern capital offers new insights into the multiple waves of planning thought that were deployed to build the urban north.

Although nascent, the pattern of land annexation and the roles of the City and Province in these processes represents potential evidence of the type of urban growth coalition dynamics heavily scrutinized in metropolitan contexts, but understudied in the urban north. Further study is required to better understand these dynamics, but the present examination of Prince George helps us to understand the extent to which planning thought could lend itself to – or was mobilized in support of – a growth ideology. In this case, planners helped to promote growth, to rationalize growth, and to invest in growth. At the height of the Great Acceleration, City Council adopted a policy of unconstrained expansion within its available boundary and an urban structure designed to support a population that has yet to arrive over 50 years later.

Abstract
This paper presents a multidimensional deprivation assessment across Turkey's 81 provinces by adapting the English Indices of Deprivation (EID) to national data. It builds a Turkish Composite Deprivation Index (TCDI) using 2023 statistics from TURKSTAT, covering seven domains: income, employment, education, health, crime and social distress, housing access, and the living environment. By weighting and scaling each indicator, the study allows meaningful comparison between provinces. The results highlight a persistent east–west divide, with places like Şanlıurfa, Ağrı, and Şırnak facing deeper disadvantage. The index offers a practical lens for spotting regional gaps and guiding fairer resource allocation. It also contributes to post-growth urbanism discussions by calling attention to the structural roots of inequality and the need for more grounded, socially responsive planning.

Keywords: Deprivation Index, Deprivation Index of Turkey, Index of Multiple Deprivation, Regional Disparities, Spatial Inequality.

Introduction

This research applies English Indices of Deprivation (EID) to national data to provide a holistic evaluation of deprivation across Turkey's 81 provinces. Based on TURKSTAT data for 2023, it constructs a Turkish Composite Deprivation Index (TCDI) consisting of seven fields: income, work, health, education, social distress and crime, access to housing, and living conditions. Analysis enables comparison of provinces on a balanced basis through balancing and scaling all variables. According to the findings, there exists a long-standing east-west gap, with provinces like Şanlıurfa, Ağrı, and Şırnak being underprivileged ones. The index can be an effective instrument to find areas of inconsistency between regions and prepare for more balanced allocation of resources. By bringing to mind the structural sources of inequality and the necessity for more embedded, socially oriented development, it also helps contribute to post-growth urbanism discussions.

Such indices allow decision-makers to design financial strategies and interventions more effectively. The overarching goal of this study is fourfold: (1) to identify provinces that require more focused development strategies, (2) to generate a province-level deprivation map for Turkey that encourages a more transparent and goal-oriented planning culture among regional authorities, (3) to promote the use of systematic, data-driven evaluation tools for policy design, and (4) to emphasise the value of using official TURKSTAT data in place of survey-based samples that may be subject to bias or limited accuracy.

As this study relies on relative comparisons, the ranking of provinces is contextual—not absolute. That is, a province ranked highest in deprivation is more deprived compared to others but may not be deprived in an absolute sense. If updated regularly, the map can foster a feedback loop of improvement and accountability among provinces. It also offers a multi-layered spatial representation of how Turkish provinces relate to one another in terms of development gaps.

The central research question is as follows: What would the spatial pattern of deprivation across Turkey's provinces look like if current TURKSTAT data were structured according to the English Indices of Deprivation (EID)? Answering this requires translating nationally available datasets into domain-specific indicators, applying a multi-criterion weighted sum method, and visualising the output to better understand inter-provincial disparities.

Conceptual Framework

The study's limitations stem primarily from differences between the data used in the English Indices of Deprivation (EID) and those provided by TURKSTAT. The EID framework comprises seven domains: income, employment, education, health and disability, crime, barriers to housing and services, and the living environment.

Each domain is supported by a set of published indicators and combined using defined weights to produce domain-specific scores. These are then aggregated into an overall deprivation index.

Deprivation, as defined in this study, is a multi-dimensional condition encompassing economic insufficiency, limited access to public services, and poor living standards (Payne & Abel, 2012). At the municipal, regional, and national levels, spatial disparities have long been identified using deprivation indices. Turkey's official statistics are produced in large part by TURKSTAT (Türkiye İstatistik Kurumu). It gathers information on a variety of subjects from homes, people, and organizations and releases it on a regular basis. For this study, TURKSTAT's online database was the primary source, providing province-level data which was extracted, filtered, and assessed according to each domain. Due to the lack of a one-to-one match between English and Turkish data, alternative indicators were chosen that closely reflect the meaning and function of the original ones. Due to the fact that this directly affects both domain-level and overall deprivation outcomes, it was imperative that all indicators chosen were in good alignment with the domains they represent.

The Provincial Well-Being Index, which covered 11 dimensions and 41 variables, was first released by TURKSTAT in 2015. Although comprehensive, it integrated both objective measures and subjective survey responses. Similarly, Çağlar (2020) recalculated the index using updated sources but retained some foundational aspects. These earlier efforts leaned towards general well-being and were partially based on dated or self-reported data. In contrast, this study focuses solely on deprivation and relies only on objective and current indicators. These distinctions make direct comparisons challenging.

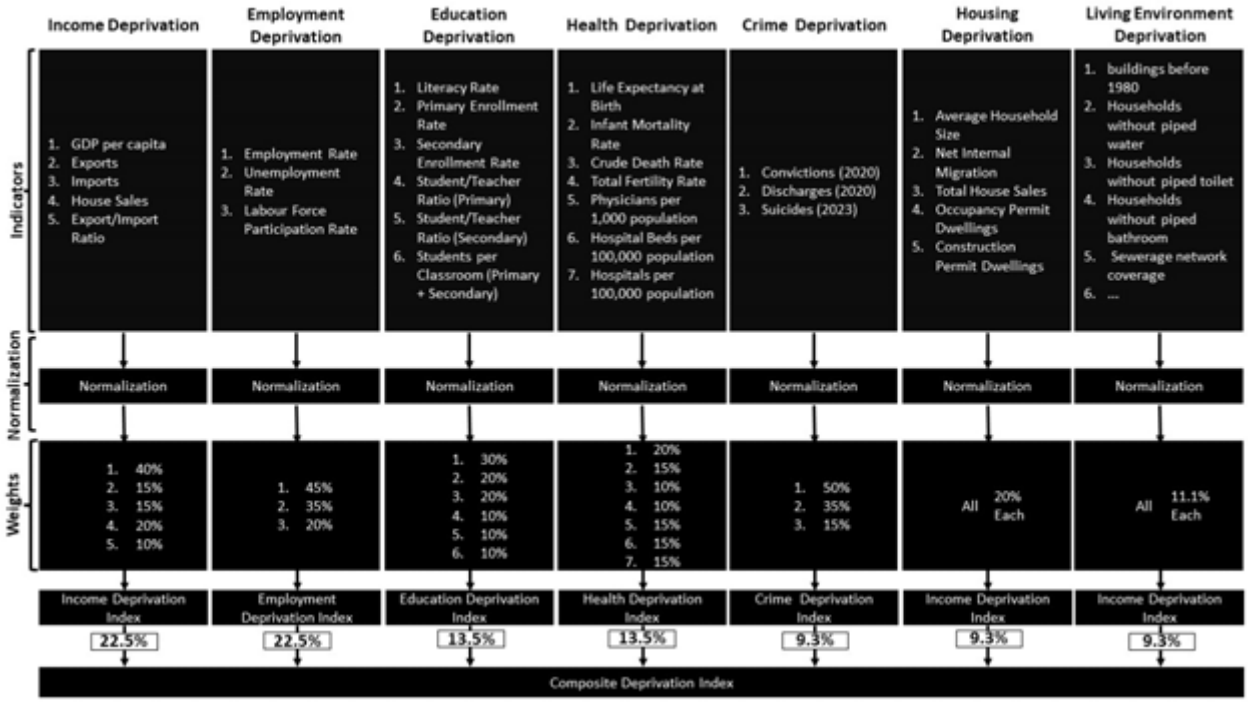

Figure 1. Framework for constructing the Turkish Composite Deprivation Index (TCDI), showing indicator selection, normalization, weighting, and aggregation into domain and composite indices across seven deprivation domains.

Income Deprivation

Captured through GDP per capita, trade volume (exports and imports), and housing market data—providing insights into regional economic capacity and household income levels. The goal of this analysis is to develop a province-level Income Deprivation Index (IDI) for Turkey by combining multiple economic indicators. The index is designed to reflect spatial disparities in economic wellbeing and to rank provinces from most to least deprived. All data used are official province-level statistics published by the Turkish Statistical Institute (TURKSTAT) for the year 2023, including:

Gross Domestic Product (GDP) per capita, Exports, Imports, Number of house sales, and Export/Import Ratio (calculated), see table 1. The reason of choosing the year 2023 is the limitations of GDP indicator's data in 2024 and 2025.

Table 1. Income Deprivation indicators and description

Indicator	Description
GDP per capita	Reflects the economic output and income potential per person.
Exports	Proxy for production capacity and global market integration.
Imports	Reflects consumption capacity but with mixed implications.
House Sales	Indicates internal economic activity and individual asset access.
Export/Import Ratio	Captures trade balance and economic self-sufficiency.

To allow meaningful comparison across different units and magnitudes, each indicator was normalized to a 0–1 scale using Min-Max scaling. This ensures that all indicators contribute proportionately to the index, regardless of their original scales, see equation (1). Higher exports usually reflect stronger economic activity, production capacity, and international market integration. It indicates more job opportunities and better industrial output thus reduces deprivation. High Imports, on the other hand, can reflect a healthy consumer market and purchasing power but if overly high relative to exports, they might indicate dependency or trade imbalance. For province-level analysis, high imports often align with urbanized, economically vibrant areas (like Istanbul or Kocaeli) so they can reduce deprivation in that context. Since the income index is based on the assumption that Higher GDP, exports, imports, and house sales equals to lower deprivation, then imports and exports have a negative contribution to deprivation in a sense.

$$Normalized_i = (X_i - X_{min}) / (X_{max} - X_{min})$$

Export/Import ratio as a separate indicator to reflect economic balance were calculated where a higher ratio (>1) indicates stronger export performance relative to imports (positive economic balance) and a lower ratio (<1) may suggest dependency on imports or a weaker production/export base. The Income Deprivation Index has been recalculated to include the Export/Import Ratio as a fifth indicator. Following the inclusion of the Export/Import Ratio, the top 5 provinces had the largest increases in rank: Hatay (46 → 30), Kırşehir (38 → 23), Tunceli (49 → 35), Edirne (50 → 38), and Zonguldak (47 → 28). These provinces have strong export/import ratios relative to their overall economic scale. Including this economic balance improves their standing, reflecting greater economic resilience or self-sufficiency. On other hand, Gümüşhane (6 → 74), Giresun (16 → 70), Rize (26 → 68), Ardahan (28 → 69), Şırnak (20 → 51). These provinces likely had low export/import ratios, suggesting weak export performance or high import reliance, this disproportionately affected their overall economic balance in the updated index.

Table 2. Income domain indicators and their weights

Indicator	Weight
GDP per capita	40%
Exports	15%
Export/Import Ratio	15%
House Sales	20%
Imports	10%

$$IDI_{(i)} = 1 - \Big(0.40 \times Normalized\ GDP\ per\ capita_i + 0.15 \times Normalized\ Exports_i + 0.15 \times Normalized \frac{Export}{Import} Ratio_i + 0.20 \times Normalized\ House\ Sales_i + 0.10 \times Normalized\ Imports_i\Big)$$

The top 5 provinces that improved most in rank after applying the custom weights are Giresun, Şırnak, Rize, Trabzon and Gümüşhane. The top 5 provinces that dropped the most in rank after applying the custom weights are Kırıkkale, Çanakkale, Zonguldak, Bolu and Düzce. These provinces likely benefited more from equal-weighted indicators (especially imports or exports) than the new GDP-dominant index. Each province received a final IDI score and was ranked from most deprived (Rank 1) to least deprived (Rank 81). The ranking directly corresponds to the descending order of the IDI score. According to the results, Gümüşhane, Hakkari, Kırıkkale, Şanlıurfa, and Edirne are the top 5 most deprived provinces. High degrees of economic deprivation were indicated by these provinces' consistently low GDP, export volume, housing activity, and economic balance numbers.

The regions of İstanbul, Ankara, Kocaeli, İzmir, and Bursa are the top five least deprived. These provinces displayed strong economic performance and trade balance, thus scoring lowest on the deprivation index.

Figure 2 illustrates the clear regional separation between the western and eastern regions in Turkey's income deprivation distribution. The eastern and northeastern provinces of the nation are the most economically deprived areas, which are represented by the darkest tones. Deprivation scores are high in provinces like Hakkari, Şırnak, Ağrı, Bitlis, and Gümüşhane. The provinces like Yozgat, Çorum, and Tokat also has a secondary cluster of high-income deprivation.

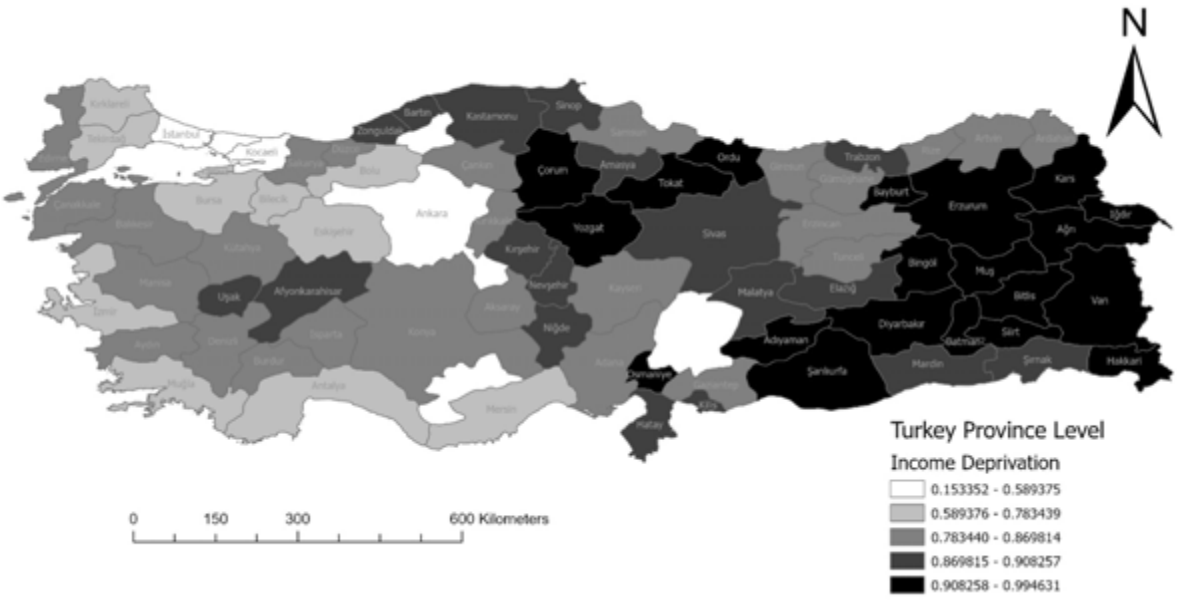

Figure 2. Income Deprivation Index by province in Turkey. Darker shades represent higher levels of income-related deprivation.

The coastal provinces of the Aegean and Mediterranean also have lower income deprivation ratings, most likely as a result of their diverse economic bases and tourism-driven economies. Despite being close to more affluent neighbors, some western interior provinces, such Afyonkarahisar and Uşak, have greater levels of deprivation, exhibiting an outlier pattern. This points to sectoral constraints impeding wider regional convergence or localized economic stagnation. Because of their varied economic bases and tourism-driven economies, the coastal provinces of the Mediterranean and Aegean also have lower income deprivation scores.

Some western interior provinces, including Afyonkarahisar and Uşak, have higher levels of deprivation while being near more prosperous neighbors; this is an outlier trend. This suggests either localized economic stagnation or sectoral restrictions preventing broader regional convergence.

Employment Deprivation

Employment Rate (the proportion of the working-age population that is employed), unemployment rate (the proportion of the labor force that is unemployed), and labor force participation rate (the proportion of the working-age population that is either employed or actively seeking employment) were chosen as indicators to aggregate the data for the Employment Deprivation Domain. These metrics offer a thorough summary of employment-related metrics for every Turkish province. Although the information provided is adequate to begin examining job deprivation, a more complete picture may be obtained by include other measures such as income inequality, gender inequalities, young unemployment, and informal work. But due to the limitations of data provided by TURKSTAT, which is the main focus of data in this study, the employment deprivation domain indicators are employment Rate, unemployment Rate, and labour Force Participation Rate. All data used are official province-level statistics published by the Turkish Statistical Institute (TURKSTAT) for the year 2023.

Table 3. Weights of employment domain indicators and their impact direction

Indicator	Weight	Impact Direction	Reasoning
Employment Rate	45%	Higher = Less Deprivation	Strongest predictor of economic inclusion
Unemployment Rate	35%	Higher = More Deprivation	Reflects labor exclusion and economic strain
Labour Force Participation Rate	20%	Higher = Less Deprivation	Signals labor market engagement, indirect

$$EDI_{(i)} = (1 - Normalized\ Employment\ Rate_i) \times 0.45 + (Normalized\ Unemployment\ Rate_i) \times 0.35 + (1 - Normalized\ Labour\ Force\ Participation\ Rate_i) \times 0.20$$

According to the job Deprivation Index, the provinces of Hakkari, Van, Diyarbakır, Hatay, and Şırnak have the worst job conditions in Turkey. The provinces have significant unemployment rates—23.3% for Hakkari and 19.1% for Van—and a consistently low employment rate, which ranges from 35.9% to 38.5%. Labour force participation is comparatively low in the provinces, particularly in Diyarbakır (40.8%) and Şırnak (42.5%). These factors, being interdependent, cause the deprivation scores to be higher, indicating low participation in formal labor markets and high economic vulnerability in these areas. At the other end of the scale, the least deprived in terms of employment are Ardahan, Tekirdağ, Antalya, Bartın, and Zonguldak. These provinces all have significantly higher employment rates—up to 58.2% in Ardahan—and relatively low unemployment rates, i.e., 5.8% for Ardahan and Balıkesir. Labour force participation is also high, especially in Ardahan (61.7%) and Tekirdağ (60.6%), indicating higher participation in the labour force. These positive figures in the three indicators reflect lower deprivation scores and place these provinces in the first rank of the employment well-being, see table (4).

Table 4. Top and least 5 deprived provinces, employment domain

Top 5 Most Deprived Provinces					
Rank	**Province**	**Employment Rate (%)**	**Unemployment Rate (%)**	**Labour Force Participation Rate (%)**	**EDI Score**
1	Hakkari	38.2	23.3	49.9	0.848
2	Van	38.5	19.1	47.5	0.783
3	Diyarbakır	35.9	11.9	40.8	0.757
4	Hatay	38.0	15.6	45.1	0.748
5	Şırnak	36.9	13.1	42.5	0.745
Top 5 Least Deprived Provinces					
Rank	**Province**	**Employment Rate (%)**	**Unemployment Rate (%)**	**Labour Force Participation Rate (%)**	**EDI Score**

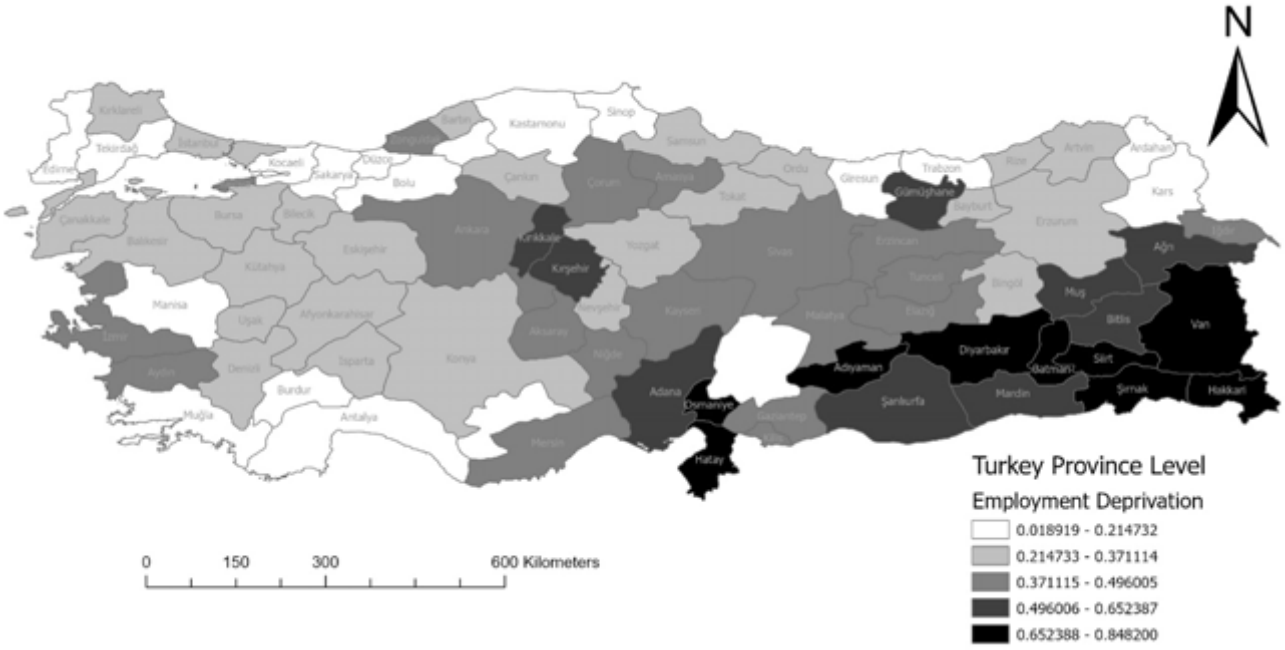

Figure 3. Employment Deprivation Index by province in Turkey. Darker shades represent higher levels of employment-related deprivation.

Education, Skills, and Training Deprivation Index (EDDI)
Quantified in terms of mean years of schooling, education attainment levels, and gender parity indices—indices of inequalities in access and attainment. The Education, Skills, and Training Deprivation domain measures geographical inequalities in access to education and educational attainment between Turkey's provinces. The domain is a key driver of long-term deprivation as educational attainment is strongly linked with labor market prospects, earnings levels, and general well-being. Statistics for this category are taken directly from the Turkish Statistical Institute (TURKSTAT) and include the following measures: literacy rate (%), primary and secondary school enrollment rate (net), student/teacher ratio for primary and secondary schools, and average number of students

per class. These measures are employed as proxies for both educational attainment and quality of educational facilities. All data used in this analysis are up to date as of 2023, and they provide temporal homogeneity for the province-level comparison.

In order to build a weighted Education, Skills, and Training Deprivation Index (EDDI), policy usefulness, data quality, and the influence of each indicator on education deprivation should be taken into account carefully. Literacy and enrollment are assigned 70% of the overall weight since they are direct indicators of the availability of and returns on education. Pupil/teacher and pupil/classroom ratios influence quality but are less direct and thus given a combined total of 30%. This allows output (literacy) and access (enrollment) to be emphasized, while infrastructural and resource indicators nevertheless weigh heavily on the deprivation index.

Table 5. Education domain indicators, impact direction and justification.

Indicator	Weight (%)	Impact Direction	Justification
Literacy Rate	30%	Higher = Less Deprivation	Literacy is the most fundamental education outcome. It reflects access to and success in basic education and influences employability and lifelong learning.
Primary Enrollment Rate (Net)	20%	Higher = Less Deprivation	Ensures foundational education access.
Secondary Enrollment Rate (Net)	20%	Higher = Less Deprivation	Indicates retention and progression in the education system. A key step toward skills training.
Student/Teacher Ratio (Primary)	10%	Lower = Less Deprivation	A proxy for learning quality. Lower ratios suggest better teacher attention and classroom interaction.
Student/Teacher Ratio (Secondary)	10%	Lower = Less Deprivation	Similarly important for quality education at later stages. Often varies more between regions due to specialization needs.
Students per Classroom (Primary + Secondary)	10%	Lower = Less Deprivation	Reflects school infrastructure and overcrowding, which affect learning conditions.

Min-Max scaling was used to normalize the chosen indicators so that they could be compared across various scales and units. The following were then weighted according to policy impact and relevance: literacy rate (30%), secondary school enrollment rate (20%), primary school enrollment rate (15%), secondary school student/teacher ratio (15%), primary school student/teacher ratio (10%), and pupils per classroom (10%). While larger classroom densities and student-teacher ratios suggest difficulties with educational accessibility and quality, higher enrollment and literacy rates suggest less disadvantage. The resulting Education Deprivation Index (EDDI) aggregates these weighted, normalized values to rank provinces from most to least deprived. This composite score captures both infrastructure strain and educational inclusion, revealing stark contrasts between regions in terms of educational opportunity and equity.

$$
\begin{aligned}

$$

Table 6. Top 5 most deprived, education domain.

Top 5 Most Deprived Provinces - Education Domain								
Rank	Province	Literacy Rate	Primary Enrollment Rate	Secondary Enrollment Rate	Student/Teacher Ratio (Primary)	Student/ Teacher Ratio (Secondary)	Students per Classroom	EDDI
1	Şanlıurfa	94.13	96.06	87.2	29	19	32	0.67
2	Mardin	93.76	95.39	88.74	21	15	25	0.53
3	Gümüşhane	96.92	81.61	76.78	13	9	13	0.51
4	Şırnak	95.11	94.37	86.14	21	15	22	0.49
5	Diyarbakır	94.97	96.17	90.35	20	15	29	0.47

Its eastern and southeastern provinces—Şırnak, Ağrı, Şanlıurfa, Muş, and Bitlis—are the five poorest in the nation. With a low secondary school enrollment rate of 86.14%, a low literacy rate of 94.85%, and a high student-teacher ratio of 21 primary and 16 secondary students per instructor, Şırnak has the lowest degree of deprivation. Comparably, Ağrı and Muş present alarming data, indicating severe infrastructure pressure with literacy rates ranging from 94.13% to 94.62% and average class sizes exceeding 30 pupils. Across all measures, the least disadvantaged provinces—Eskişehir, Rize, Trabzon, İzmir, and Ankara—show better educational achievement. With a literacy rate of 98.56%, enrollment rates for primary and secondary education above 95%, and a low average of 15 pupils per class, Eskişehir, the 81st (least disadvantaged) school, stands out. Similarly, Trabzon and Rize have low student-teacher ratios (usually less than 13 kids per teacher in primary school) and excellent literacy and enrollment rates.

Table 7. Top 5 least deprived, education domain.

Top 5 Least Deprived Provinces - Education Domain								
Rank	Province	Literacy Rate	Primary Enrollment Rate	Secondary Enrollment Rate	Student/ Teacher Ratio (Primary)	Student/ Teacher Ratio (Secondary)	Students per Classroom	EDDI
80	Edirne	98.13	95.06	92.91	13	11	16	0.1205
79	Muğla	98.79	94.76	92.43	14	11	19	0.1271
78	Balıkesir	98.43	95.01	93.19	15	11	18	0.1309
77	Amasya	97.76	95.26	93.3	13	11	16	0.1311

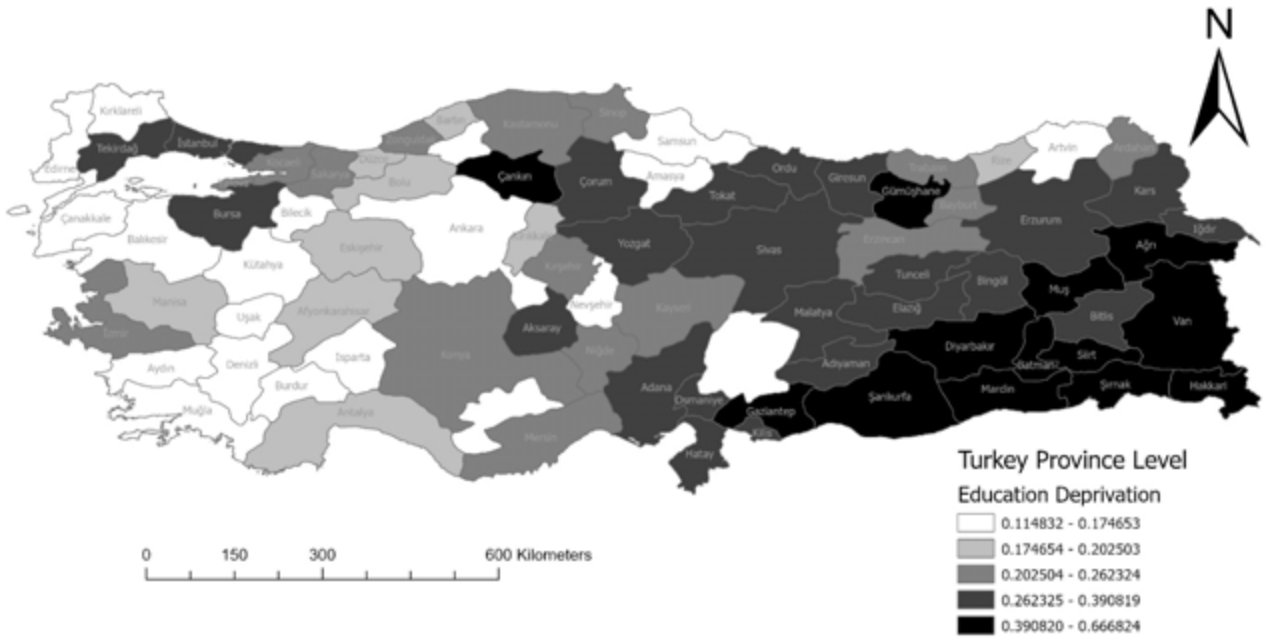

Figure 4. Education Deprivation Index by province in Turkey. Darker shades represent higher levels of education-related deprivation.

Health Deprivation

Across Turkey's 81 provinces, the Health Deprivation domain assesses regional differences in health outcomes and access to necessary medical treatments. Although some were formally published in early 2024–2025, this domain employs a set of indicators that are only taken from official 2023 datasets released by the Turkish Statistical Institute (TURKSTAT). The indicators that were selected include life expectancy at birth, hospital beds per 100,000 population, hospitals per 100,000 population, number of physicians per 1,000 population, infant mortality rate, crude death rate, and total fertility rate.

When taken as a whole, these indicators provide a comprehensive view of health-related deprivation at the provincial level by reflecting both infrastructural capacity (such as the availability of hospitals, beds, and medical professionals) and outcome-based health status (such as life expectancy, mortality, and fertility).

Each health indicator was normalized using Min-Max scaling, which converts results to a specified range between 0 and 1, in order to guarantee comparability and understandable aggregate. By doing this, the impact of several scales and measurement units is removed, enabling each indicator to make a proportionate contribution to the composite index. In order to ensure that higher normalized scores consistently reflect poorer deprivation, an inversion was used before weighting for indicators—specifically, Infant Mortality Rate, Crude Death Rate, and Total Fertility Rate—where larger values indicate worse health outcomes. By matching all indicators with the direction of well-being (greater is better), this guarantees conceptual clarity across the domain.

Even though it is less accurate, the crude death rate is useful for estimating regional mortality burdens, especially in older populations. In order to account for population dynamics and reproductive health, which can either alleviate or strain service demand, the total fertility rate was incorporated. Hospital beds per 100,000 people and hospitals per 100,000 people are used as stand-ins for the capacity and spatial distribution of medical institutions. The crude death rate is helpful for evaluating regional mortality burdens, particularly in elderly populations, despite its lower accuracy. The total fertility rate was included to take into consideration population dynamics and reproductive health, which can either reduce or increase service demand. Medical facilities' capacity and spatial distribution are represented as hospital beds per 100,000 people and hospitals per 100,000 people.

Each signal was given a unique weight according to how directly it affected health outcomes. Because it captures the combined impact of several health variables, life expectancy was given the greatest weight (20%). Because they have a significant impact on child survival and service access, respectively, the infant mortality rate (15%) and the number of physicians per 1,000 (15%) were also given priority. In order to recognize their importance and take into consideration potential demographic confounders, the crude death rate and total fertility rate were assigned somewhat lower weights (10% each). To represent their combined significance in healthcare system capacity, the three infrastructure indicators—physicians, beds, and hospitals per capita—were assigned equal weights (15 percent each), as shown in Table (7).

Table 8. Health domain indicators, weight, impact direction and justification.

Indicator	Weight (%)	Impact Direction	Justification
Life Expectancy at Birth	20	Higher = Less Deprivation	Captures overall longevity and long-term health outcomes; highly comprehensive.
Infant Mortality Rate	15	Higher = More Deprivation	Sensitive to maternal and infant care quality; reflects healthcare system performance.
Crude Death Rate	10	Higher = More Deprivation	Indicates general mortality burden; relevant in aging or high-risk regions.
Total Fertility Rate	10	Higher = More Deprivation	Reflects reproductive health and demographic pressure on health systems.
Physicians per 1,000 population	15	Higher = Less Deprivation	Measures accessibility to healthcare professionals and service availability.
Hospital Beds per 100,000 population	15	Higher = Less Deprivation	Indicates treatment capacity and readiness for inpatient care and emergencies.
Hospitals per 100,000 population	15	Higher = Less Deprivation	Represents infrastructure spread and geographic accessibility to services.

Adıyaman and Kilis both show low life expectancy (78.7 and 76.1 years), limited healthcare infrastructure (1–2 hospitals per 100,000), and high infant mortality and fertility rates—placing them at a disadvantage under a weighting scheme that emphasizes access and outcomes. Ağrı's placement is primarily driven by its low number of physicians, below-average life expectancy, and elevated fertility (2.20), which suggest regional service gaps despite a relatively low crude death rate. Under a weighting method that prioritizes access and results, Adıyaman and Kilis are at a disadvantage due to their short life expectancy (78.7 and 76.1 years), insufficient healthcare infrastructure (1–2 hospitals per 100,000), and high infant mortality and fertility rates. The main reasons for Ağrı's placing are its low physician population, below-average life expectancy, and high fertility rate (2.20), all of which point to regional service deficiencies even if the crude mortality rate is quite low.

$$
\begin{aligned}
HDI_{(i)} = {} & (1 - Normalized\ Life\ Expectancy_{(i)}) \times 0.20 \\
& + (Normalized\ Infant\ Mortality\ Rate_{(i)}) \times 0.15 \\
& + (Normalized\ Crude\ Death\ Rate_{(i)}) \times 0.10 \\
& + (Normalized\ Total\ Fertility\ Rate_{(i)}) \times 0.10 \\
& + (1 - Normalized\ Physicians\ per\ 1{,}000_{(i)}) \times 0.15 \\
& + (1 - Normalized\ Hospital\ Beds\ per\ 100{,}000_{(i)}) \times 0.15 \\
& + (1 - Normalized\ Hospitals\ per\ 100{,}000_{(i)}) \times 0.15
\end{aligned}
$$

Conversely, the five least health-deprived provinces—Tunceli, Ankara, Bolu, Isparta, and Trabzon—excelled across almost all indicators. Tunceli, the least deprived, reported the highest life expectancy (80.8 years), low infant mortality (6.4), and above-average health infrastructure, including 3 physicians per 1,000 population. Given the 20% weight assigned to life expectancy, this significantly contributed to its favorable index score. Ankara, as the capital, benefits from extensive healthcare coverage with 4 physicians per 1,000, 431 hospital beds per 100,000, and high life expectancy (79.2 years)—outperforming most provinces on service availability. Bolu, with 3 physicians per 1,000 and 425 hospital beds per 100,000, compensates for slightly less favorable fertility rates

by ranking strongly in infrastructure. Similarly, Isparta's high physician density, favorable infant mortality, and relatively low fertility help it score well despite a modest crude death rate. Last but not least, Trabzon regularly performs well on all metrics, including balanced health care delivery and an above-average life expectancy (79.0 years), which supports its classification as the least impoverished group (see table).

Top 5 Most Deprived Provinces - Health Domain		
Rank	**Province**	**HDI**
1	Şanlıurfa	0.801657
2	Hatay	0.72846
3	Adıyaman	0.726333
4	Kilis	0.685363
5	Ağrı	0.683439
Top 5 Least Deprived Provinces - Health Domain		
Rank	**Province**	**HDI**
81	Trabzon	0.35297
80	Isparta	0.338067
79	Bolu	0.304313
78	Ankara	0.297139
77	Tunceli	0.292462

The Health Deprivation map reveals a stark concentration of health-related challenges in the southeastern provinces of Turkey, where the darkest tones indicate the highest levels of deprivation. Provinces such as Şanlıurfa, Hatay, Adıyaman, Kilis, and Ağrı are among the most deprived, consistently reflecting poor outcomes across key health indicators—including high infant mortality rates, low life expectancy, limited access to physicians, and inadequate healthcare infrastructure such as hospital beds and treatment facilities. This southeastern cluster, extending into neighboring provinces like Mardin, Şırnak, and Van, highlights a persistent structural deficit in both health service delivery and health outcomes.

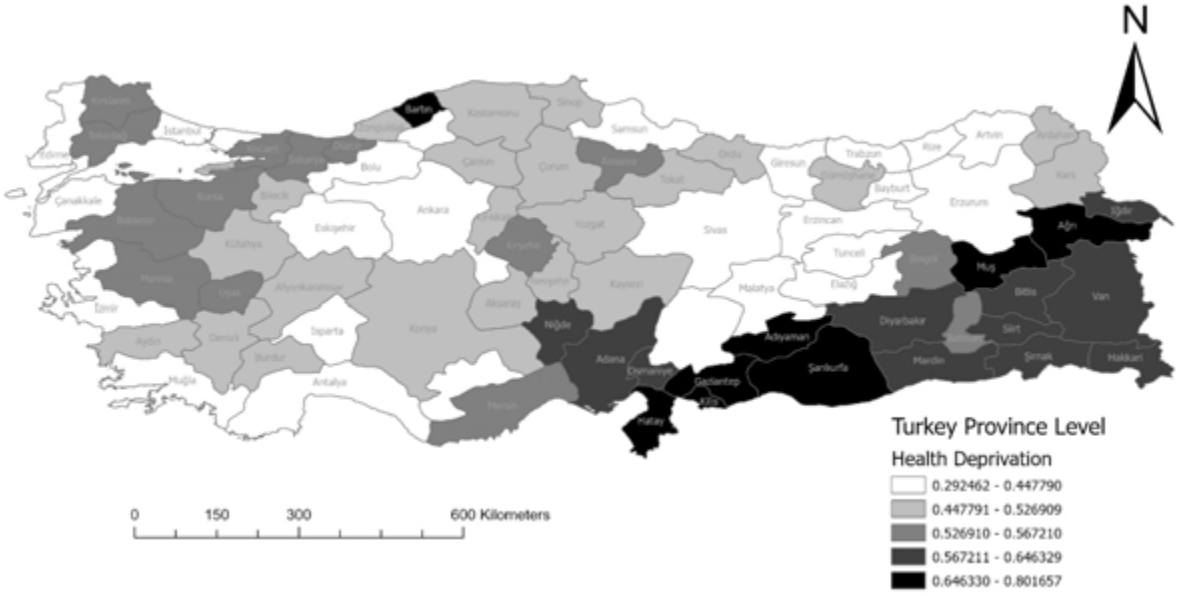

Figure 5. Health Deprivation Index by province in Turkey. Darker shades represent higher levels of health-related deprivation.

In contrast, provinces with the lowest levels of health deprivation—depicted in the lightest shades—are largely located in the central and northern parts of the country. Provinces such as Ankara, Eskişehir, Bolu, and Trabzon perform strongly across both health outcome and infrastructure metrics. These regions benefit from higher physician-to-population ratios, better hospital access, and lower mortality indicators, contributing to their favorable deprivation scores. Notably, Bartın appears as an outlier in the highest deprivation class despite its relatively peripheral location in the western Black Sea region.

Crime and Social Distress Deprivation

The Crime and Social Distress Deprivation domain evaluates regional disparities in criminal activity, justice system, and extreme social distress across Turkey's provinces. This domain integrates three core indicators: (1) the number of convicts received by penal institutions based on the province where the crime was committed, (2) the number of convicts discharged from prisons by province, and (3) the number of suicides reported per province. All data were obtained from the Turkish Statistical Institute (TURKSTAT) and correspond to the most recent available years—2020 for crime-related indicators and 2023 for suicides. These indicators jointly reflect both direct criminal activity and broader social instability. While the inclusion of suicides—legally not a crime—is conceptually distinct, it serves as a proxy for psychological and socio-economic distress. For this reason, the domain name was expanded to "Crime and Social Distress" to more accurately reflect the indicators used.

A major limitation of this domain is the scope and recency of publicly available data. Unlike economic or health indicators updated annually, crime and justice statistics from TURKSTAT are more limited in coverage and often lagged. Consequently, this domain relies on 2020 prison records and the 2023 suicide dataset, which, while still useful, may not fully capture current trends in crime or institutional burden. Nonetheless, the available indicators provide meaningful insights into spatial patterns of deprivation linked to criminality, recidivism, and societal breakdown.

Each indicator was normalized using Min-Max scaling, allowing for comparability across different magnitudes and measurement units. Since all indicators represent negative outcomes (i.e., higher values suggest worse conditions), no inversion was necessary during normalization.

To construct a composite Crime and Social Distress Deprivation Index (CSDDI), weights were assigned based on each indicator's conceptual importance. The number of convictions was assigned the highest weight (50%) as it directly measures criminal acts reported and processed through the legal system. Discharges from prison received a moderate weight (35%), representing the burden on penal institutions and potential recidivism in provinces with high release rates. Suicides were included with a lower weight (15%), acknowledging their indirect but critical connection to social distress and deprivation without equating them to crime. The final CSDDI was calculated by aggregating the weighted normalized scores of the three indicators for each province. Provinces were then ranked from most to least deprived based on their CSDDI scores. The five least deprived provinces in the Crime and Social Distress Deprivation Index—Bayburt, Tunceli, Gümüşhane, Ardahan, and Çankırı—are characterized by relatively low values across all three indicators, resulting in the lowest composite deprivation scores nationwide.

Table 9. crime domain indicators, weight, impat direction and justification.

Indicator	Weight (%)	Impact Direction	Justification
Convictions (2020)	50	Higher = More Deprivation	Represents direct measure of criminal offenses by location of crime; highest indicator of crime burden.
Discharges (2020)	35	Higher = More Deprivation	Reflects the burden on the penal system and potential re-entry of convicts into society; moderately weighted.
Suicides (2023)	15	Higher = More Deprivation	Acts as a proxy for extreme psychological and societal distress; included to capture broader deprivation but with lower weight as it is not legally categorized as a crime.

$$CSDDI_{(i)} = (Normalized\ Convictions_{(i)} \times 0.50) + (Normalized\ Discharges_{(i)} \times 0.35) + (Normalized\ Suicides_{(i)} \times 0.15)$$

Table 10 Top 5most and least deprived, crime domain.

Top 5 Most Deprived Provinces - CSDDI		
Rank	**Province**	**CSDDI**
1	İstanbul	1
2	İzmir	0.478677
3	Ankara	0.35499
4	Antalya	0.302759
5	Bursa	0.217504
Top 5 Least Deprived Provinces - CSDDI		
Rank	**Province**	**CSDDI**
82	Bayburt	0.003241
81	Tunceli	0.005252
80	Gümüşhane	0.006778
79	Ardahan	0.007452
78	Çankırı	0.009148

The Crime and Social Distress Deprivation map reveals a distinctive spatial distribution that diverges from the patterns seen in other deprivation domains. High levels of deprivation—indicated by the darkest shades—are most concentrated in major metropolitan and industrialized provinces, including İstanbul, Ankara, İzmir, Bursa, and Konya. These areas exhibit elevated levels of recorded convictions, prison discharges, and suicide rates, reflecting the complex interplay between urban density, socio-economic stressors, and institutional burden.

This urban-centric deprivation pattern suggests that crime and social distress are more acute in larger cities where population pressure, income inequality, and systemic strain may contribute to higher incidences of criminal behavior and psychosocial distress. It also underscores the challenge of balancing urban prosperity with inclusive safety and well-being.

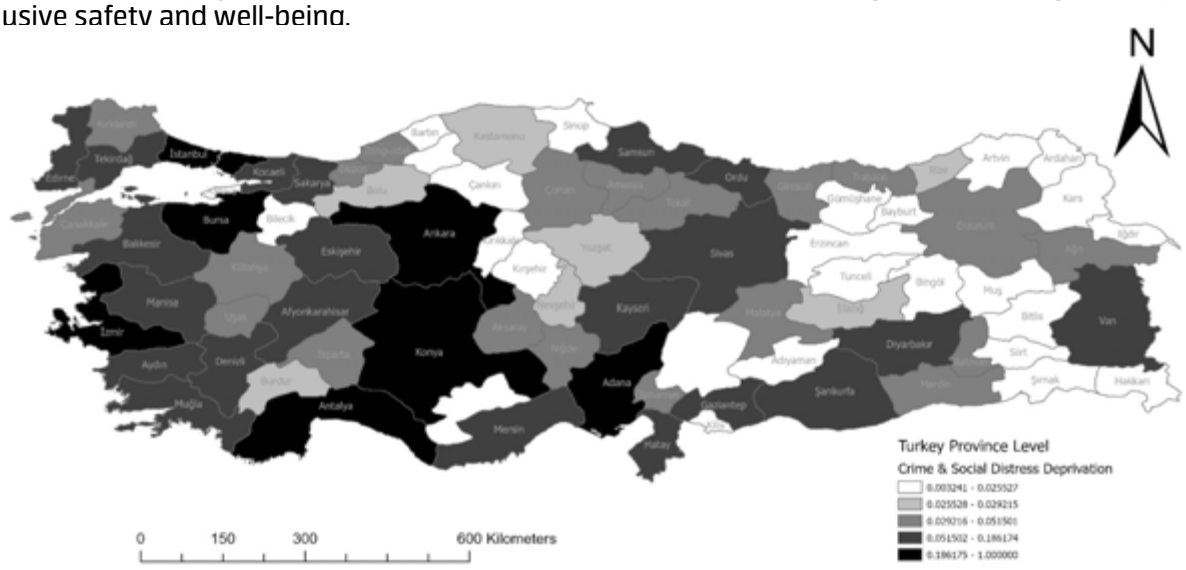

Figure 6. Crime Deprivation Index by province in Turkey. Darker shades represent higher levels of crime-related deprivation.

In contrast, the least deprived provinces are located predominantly in the northeastern and eastern parts of the country, particularly in Bartın, Ardahan, Bayburt, Tunceli, and Gümüşhane. These provinces are characterized by relatively low recorded crime rates and minimal prison system throughput. The lighter shades in these regions suggest more stable social environments with lower institutional crime burdens and fewer indicators of extreme distress.

A notable pattern is the relatively moderate-to-low levels of deprivation observed in many southeastern provinces such as Şırnak, Hakkari, and Mardin. Despite high deprivation in economic and education domains, these provinces report lower crime and social distress scores, possibly due to underreporting, demographic factors, or differing social dynamics compared to urban centers.

Barriers to Housing Deprivation

The Barriers to Housing Deprivation domain assesses spatial inequality in housing accessibility, adequacy, and supply pressure across Turkey's 81 provinces. The indicators selected aim to capture both demand-side pressures and supply-side limitations using datasets published by the Turkish Statistical Institute (TURKSTAT) for the year 2023. The final set of indicators includes average household size, internal migration (population inflow), total house sales per province, occupancy permit dwellings, construction permit dwellings. Each indicator reflects a specific challenge: larger household size implies overcrowding or under-housing; internal migration increases demand on existing stock, and high housing sales can indicate market stress or reduced affordability. On the supply side, low occupancy or construction permit approvals point to limited available or future housing stock.

This dual-perspective approach captures the tension between housing demand growth and infrastructure lag, which often results in barriers to decent housing access.

Table 11. Housing domain indicators, weight, impact direction and justification

Indicator	Weight (%)	Impact Direction	Justification
Average Household Size (2023)	20	Higher = More Deprivation	Larger household sizes often indicate overcrowding and limited housing access, especially in low-income areas.
Net Internal Migration (2023)	20	Higher = More Deprivation	High levels of in-migration increase pressure on local housing supply, leading to accessibility and affordability challenges.
Total House Sales (2023)	20	Higher = More Deprivation	Elevated housing sales may reflect overheating markets, pricing out low- and middle-income populations.
Occupancy Permit Dwellings (2023)	20	Lower = More Deprivation (inverted)	Low numbers of occupancy permits signal insufficient current housing stock; values were inverted to reflect deprivation.
Construction Permit Dwellings (2023)	20	Lower = More Deprivation (inverted)	Low issuance of construction permits indicates limited future housing provision and development; values were inverted.

$$HDI_{(i)} = (Normalized\ Household\ Size_{(i)} \times 0.20) + (Normalized\ In - Migration_{(i)} \times 0.20) + (Normalized\ Housing\ Sales_{(i)} \times 0.2) + (Normalized\ Occupancy\ Permits_{(i)} \times 0.2) + (Normalized\ Construction\ Permits_{(i)} \times 0.2)$$

The top five most deprived provinces in the HDI ranking—Şanlıurfa, Kilis, Gaziantep, İstanbul, and Mardin—demonstrated consistently high scores across multiple indicators. Şanlıurfa, ranked as the most deprived, reported both a high average household size (6.34) and a significant number of in-migrants (33,373), paired with low construction (2,696) and occupancy permits (1,685), signaling infrastructure lag amid growing demand. Kilis followed with one of the smallest housing stocks in terms of permits (384 occupancy, 245 construction) despite recording substantial in-migration (7,383), contributing to its elevated deprivation score. Gaziantep ranked third due to intense market activity—housing sales (45,139) and internal migration (39,412) were both among the highest nationally—combined with a household size above 5, stressing capacity. İstanbul and Mardin completed the top five, both reflecting extreme population pressure. İstanbul reported the highest internal migration (271,169) and house sales (240,145), while Mardin recorded high household size (5.69) and relatively low new housing provision (1,602 construction permits), reinforcing the supply-demand imbalance.

Table 12. Top 5 most and least deprived, housing domain.

Top 5 Most Deprived Provinces - HDI		
Rank	**Province**	**HDI**
1	Şırnak	0.63357
2	Kırşehir	0.627328
3	Siirt	0.586963
4	Şanlıurfa	0.5814
5	Diyarbakır	0.577848
Top 5 Least Deprived Provinces - HDI		
Rank	**Province**	**HDI**
81	İstanbul	0.264585
80	Balıkesir	0.385355
79	İzmir	0.390831
78	Çanakkale	0.396982
77	Ankara	0.408613

Conversely, the five least deprived provinces—Bartın, Karabük, Amasya, Eskişehir, and Kırklareli—ranked lowest in HDI due to a more favorable balance of demographic pressure and housing provision. Bartın and Karabük, ranked 81st and 80th respectively, had among the lowest household sizes (2.91 and 2.93), low in-migration figures (2,206 and 2,640), and modest but adequate housing permit numbers. Amasya showed moderate performance across all indicators with no extremes, which kept its deprivation low. Eskişehir and Kırklareli also maintained moderate household sizes (2.98 and 3.03) and managed a balance between sales activity and new construction, avoiding the housing market volatility seen in more deprived provinces.

The spatial distribution of housing deprivation in Turkey shows a strong concentration of high-deprivation scores across the southeastern and eastern provinces, as well as parts of Central Anatolia. Provinces such as Şırnak, Hakkari, Mardin, Adıyaman, and Gaziantep appear in the darkest shades, indicating the highest levels of deprivation. These areas are characterized by a combination of high household density, strong internal migration pressures, and insufficient housing stock as reflected by low occupancy and construction permit volumes. A secondary axis of high deprivation extends through central provinces such as Yozgat, Kırşehir, and Aksaray, where structural housing shortages and limited urban expansion contribute to constrained housing access. These provinces highlight inland challenges that differ from those found in high-growth coastal or metropolitan regions.

Unexpectedly, some industrialized or otherwise economically stronger provinces, such as Kocaeli and Antalya, also appear in the highest deprivation class. This likely reflects intense demand-side pressures—such as high internal migration and elevated housing sales—that outpace available housing supply, creating affordability and accessibility barriers. Their inclusion in this category underscores the fact that housing deprivation is not solely a function of poverty or underdevelopment but can also stem from overheating urban markets. Conversely, the least deprived provinces—represented in the lightest tones—are found in the western and northwestern regions, including Bartın, Kırklareli, and Çanakkale. These areas maintain a more balanced housing dynamic, with moderate population pressures and relatively sufficient housing stock. Similarly, select provinces in Central Anatolia and the Black Sea region—such as Çankırı and Gümüşhane—register low housing deprivation, likely due to lower in-migration rates and slower urban growth.

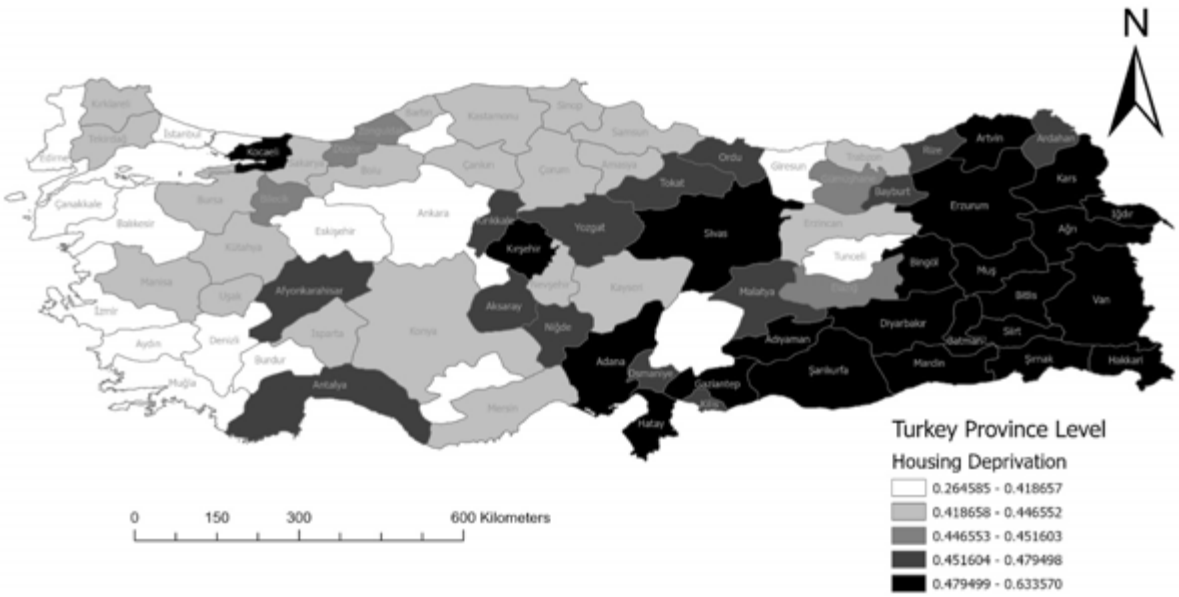

Figure 7. Housing Deprivation Index by province in Turkey. Darker shades represent higher levels of housing-related deprivation.

Living Environment Deprivation

The Living Environment Deprivation domain evaluates disparities in environmental quality, municipal infrastructure, and housing safety across Turkey's 81 provinces. This domain relies on indicators derived from official datasets provided by the Turkish Statistical Institute (TURKSTAT), reflecting both service provision and exposure to environmental or infrastructural risks. The selected indicators include traffic accident counts, the proportion of municipal populations served by sewerage networks, drinking water supply, drinking water treatment, and wastewater treatment plants, as well as the rate of electricity connections and the number of cars per 1,000 people. Additionally, three household-level indicators were incorporated: the proportion of housing stock built in or before 1980, and the share of households lacking access to piped water, toilets, or bathrooms. These indicators together offer a comprehensive view of the physical and infrastructural living conditions at the provincial level.

Each of these variables reflects a distinct dimension of deprivation. Traffic accident counts serve as a proxy for urban stress and road safety risks, while the proportions of municipal service coverage highlight regional disparities in basic infrastructure. The electricity connection rate indicates access to essential utilities, and car ownership serves as a loose proxy for mobility and transport accessibility. The absence of piped water, toilet, or bathroom facilities within dwellings reflects deeply embedded housing inadequacies that affect dignity and hygiene. Finally, the percentage of buildings constructed before 1980 acts as a proxy for outdated and potentially unsafe housing stock, particularly relevant in a country with considerable earthquake vulnerability.

To ensure comparability, all indicators were normalized using Min-Max scaling, rescaling their values between 0 and 1. For indicators where a higher raw value indicated better living conditions—such as sewerage access or water network coverage—values were inverted so that higher normalized scores consistently represented worse conditions. This allowed for a unified interpretation of deprivation across the dataset. Each indicator was assigned an equal weight of approximately 11.1%, reflecting a balanced approach to measuring deprivation across infrastructure, environmental health, and safety. The final Living Environment Deprivation Index (LEDI) for each province was calculated as the sum of all weighted normalized indicators, where higher LEDI values correspond to greater environmental deprivation.

$$LEDI_{(i)} = (\sum Normalized\ Weighted\ Indicators_{(i)}) \times 0.111$$

Table 13. Living environment domain indicator, weight, impact direction and justification.

Indicator	Weight (%)	Impact Direction	Justification
Proportion of buildings built before 1980	11.1	Higher = More Deprivation	Acts as a proxy for outdated or potentially unsafe housing, especially in earthquake-prone regions.
Households without piped water (%)	11.1	Higher = More Deprivation	Reflects inadequate access to basic in-home water infrastructure, indicating serious deprivation.
Households without toilet (%)	11.1	Higher = More Deprivation	Signals severe sanitation deprivation, affecting both dignity and public health outcomes.
Households without bathroom (%)	11.1	Higher = More Deprivation	Indicates fundamental infrastructure deficiency within the home environment.
Sewerage network coverage (%)	11.1	Lower = More Deprivation	Captures disparities in urban sanitation infrastructure and its public health implications.
Drinking water network coverage (%)	11.1	Lower = More Deprivation	Reflects accessibility of clean, piped water supply—a critical public health and welfare concern.
Water treatment plant coverage (%)	11.1	Lower = More Deprivation	Represents the quality of water service provision and regional health safeguards.
Wastewater treatment plant coverage (%)	11.1	Lower = More Deprivation	Addresses environmental and hygiene quality through wastewater management capacity.
Electricity subscription coverage (%)	11.1	Lower = More Deprivation	Measures access to electricity, a basic necessity in modern living; lower variation, but essential.
Cars per 1,000 people	11.1	Lower = More Deprivation	Used as a proxy for economic status and transport infrastructure; limited mobility can signal isolation.
Traffic accident count	11.1	Higher = More Deprivation	Indicates infrastructural stress and safety risks in the physical environment.

The five most environmentally deprived provinces—Ağrı, Şırnak, Iğdır, Ardahan, and Van—consistently scored poorly across multiple indicators. Ağrı reported one of the highest proportions of households living in buildings constructed before 1980, combined with significant percentages of homes lacking basic facilities such as piped water, toilets, and bathrooms. Similarly, Şırnak showed poor infrastructure coverage, including low rates of access to treated water and sewerage networks, alongside elevated deprivation in household-level sanitation access. Iğdır and Ardahan both exhibited critical deficiencies in basic in-home utilities and sanitation facilities, with Ardahan standing out for an exceptionally high share of households without bathrooms. These provinces also reported very low levels of car ownership per 1,000 people and limited access to wastewater and drinking water treatment systems. Van's placement was mainly driven by aging housing stock and lower than average environmental infrastructure scores, especially in treated water services, which compounded its LEDI value.

Table 14. Top 5 most and least deprived, living environment domain.

Top 5 Most Deprived Provinces - LEDI		
Rank	**Province**	**HDI**
1	Ardahan	0.597509
2	Iğdır	0.543384
3	Mardin	0.502147
4	Kars	0.458331
5	Sinop	0.434612
Top 5 Least Deprived Provinces - LEDI		
Rank	**Province**	**HDI**
5	İstanbul	0.099773
4	Yalova	0.129202
3	Kocaeli	0.132782
2	Eskişehir	0.141178
1	Ankara	0.152081

On the other hand, the five least deprived provinces—Ankara, Eskişehir, Kocaeli, Yalova, and İstanbul—ranked best due to strong performance across nearly all environmental indicators. Ankara and İstanbul, as major metropolitan areas, benefit from near-universal coverage of electricity, sewerage, water networks, and water treatment systems, along with high car ownership rates. Eskişehir also performed well, particularly in its urban infrastructure and low proportion of households lacking piped water or toilets. Kocaeli and Yalova demonstrated similarly high levels of access to urban services and modern housing stock, with minimal percentages of households in buildings built before 1980 and strong access to treated water and sanitation. These provinces consistently reported lower rates of deprivation in both household and municipal indicators, which is reflected in their low LEDI scores.

The Living Environment Deprivation map demonstrates a predominantly peripheral distribution of environmental and infrastructural challenges across Turkey. The most deprived provinces—represented in the darkest shades—are concentrated in the eastern and southeastern regions, particularly Ardahan, Iğdır, Muş, Mardin, and Şanlıurfa. These provinces face multiple deficits in basic infrastructure and environmental conditions, including aging housing stock, low access to sewerage systems, untreated water, and limited utility coverage such as piped water and electricity. This high-deprivation pattern also extends to select northern provinces such as Çankırı, Kastamonu, and Sinop, highlighting that environmental deprivation is not limited to socioeconomically underdeveloped regions but may also reflect insufficient investment in infrastructure maintenance or modernization in less urbanized northern areas.

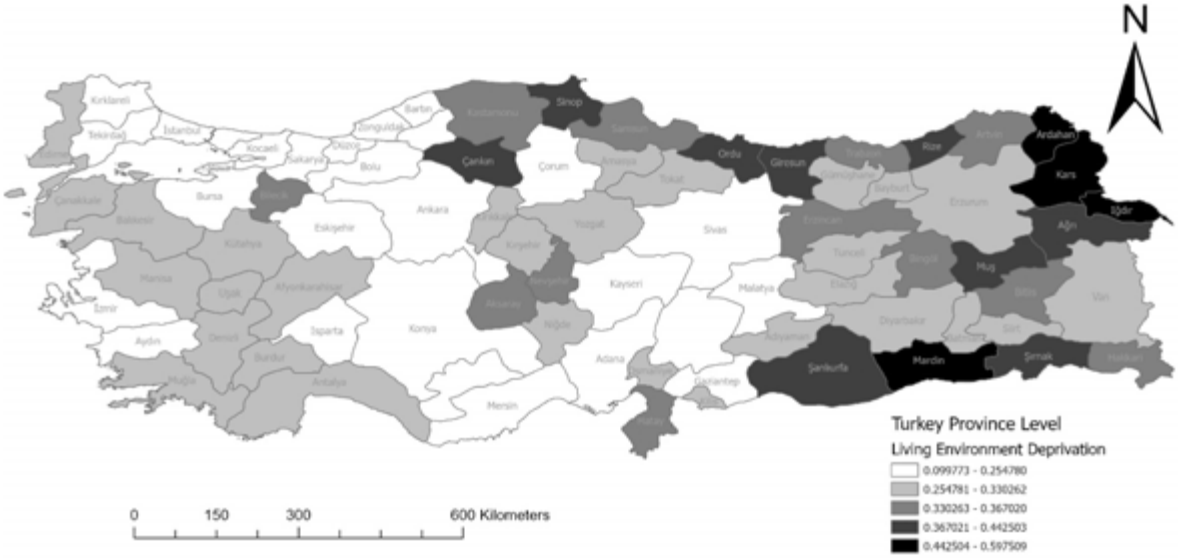

Figure 8. Living environment Deprivation Index by province in Turkey. Darker shades represent higher levels of living environment-related deprivation.

In contrast, the least deprived provinces are concentrated in the west and central-west of the country. Regions like Ankara, Eskişehir, Kocaeli, and Muğla show strong environmental conditions, marked by high access to treated water, electricity, modern housing, and municipal services. These provinces also benefit from better waste and water management systems, higher vehicle ownership, and stronger disaster-resilient infrastructure. Interestingly, several mid-performing provinces across Central Anatolia and the Aegean—such as Afyonkarahisar, Kütahya, and Aydın—display moderate levels of deprivation, indicating a relative balance between infrastructure availability and environmental pressure. These regions may have adequate municipal services but still face challenges related to older housing stock or regional population growth.

Turkish Composite Deprivation Index

The Turkish Composite Deprivation Index (TCDI) offers a multidimensional evaluation of regional deprivation across Turkey's 81 provinces. It combines seven domain-specific indices: Income, Employment, Education, Health, Crime and Social Distress, Barriers to Housing, and Living Environment. Each domain reflects a distinct dimension of socioeconomic well-being and infrastructure access, capturing both individual and structural determinants of deprivation. Weights for each domain were assigned in alignment with the English Indices of Deprivation (EID) model, emphasizing economic and labor-related domains more heavily. Specifically, Income and Employment domains each account for 22.5% of the overall index, Education and Health domains for 13.5% each, and the remaining three domains—Crime, Housing Barriers, and Living Environment—each contribute 9.3%. These weights were applied to the normalized domain scores for each province, producing a final composite index value (TCDI) and associated rank, where higher values correspond to greater deprivation.

The five most deprived provinces—Şanlıurfa, Ağrı, Şırnak, Mardin, and Iğdır—consistently exhibited high deprivation across multiple domains. Şanlıurfa, which ranked first overall, recorded elevated deprivation in health (rank 1), education (rank 1), housing (rank 4), and crime (rank 5), reflecting multidimensional structural disadvantage. Ağrı followed with top-five placements in education, health, and environmental deprivation. Şırnak also scored among the highest in deprivation across health, education, and employment, underscoring persistent developmental challenges. Mardin and Iğdır demonstrated widespread infrastructure gaps, particularly in environment and housing domains, alongside socioeconomic stress reflected in employment and crime data.

In contrast, the least deprived provinces—Istanbul, Ankara, Kocaeli, Tekirdağ, and Eskişehir—ranked consistently low on the deprivation scale due to strong performance across all seven domains. Istanbul and Ankara benefit from high income levels, extensive infrastructure, and service access, though Istanbul shows slight vulnerability in crime-related indicators. Kocaeli and Tekirdağ exhibit robust labor market and industrial metrics, with strong

educational and health outcomes. Eskişehir rounds out the least deprived group with uniformly favorable indicators across education, environment, and health, reinforcing its long-standing reputation as a well-performing mid-sized urban province.

The spatial pattern of the Composite Deprivation Index (CDI) map provides a holistic view of multidimensional deprivation across Turkey's provinces, combining all seven individual domains. The highest levels of overall deprivation—marked in the darkest shades—are concentrated in the southeastern and eastern provinces, notably Şanlıurfa, Hakkari, Şırnak, Mardin, and Ağrı. These provinces consistently scored high on multiple domain-specific indices, particularly income, education, health, and housing deprivation. Their composite scores reflect persistent structural disadvantages and underscore the cumulative effect of overlapping deprivation. This core high-deprivation zone extends westward through a belt of central and inner Anatolian provinces such as Adıyaman, Osmaniye, Niğde, and Aksaray, suggesting that deprivation is not confined to the geographical periphery but also affects provinces with constrained development trajectories and limited access to diversified economic opportunities.

Conversely, the lowest levels of composite deprivation—shown in the lightest shades—are predominantly found in the northwestern and western regions, particularly in provinces such as İstanbul, Ankara, Kocaeli, Eskişehir, and Muğla. These areas benefit from strong economic performance, well-established infrastructure, high service provision, and better education and health outcomes. Their consistently low scores across most domains place them at the opposite end of the deprivation spectrum. A noticeable mid-deprivation band cuts through western Central Anatolia and parts of the Mediterranean and Aegean regions, encompassing provinces like Afyonkarahisar, Manisa, and Denizli. While not as severely deprived as the southeastern regions, these provinces face challenges in select domains such as employment, education, or housing, which prevent them from ranking among the least deprived.

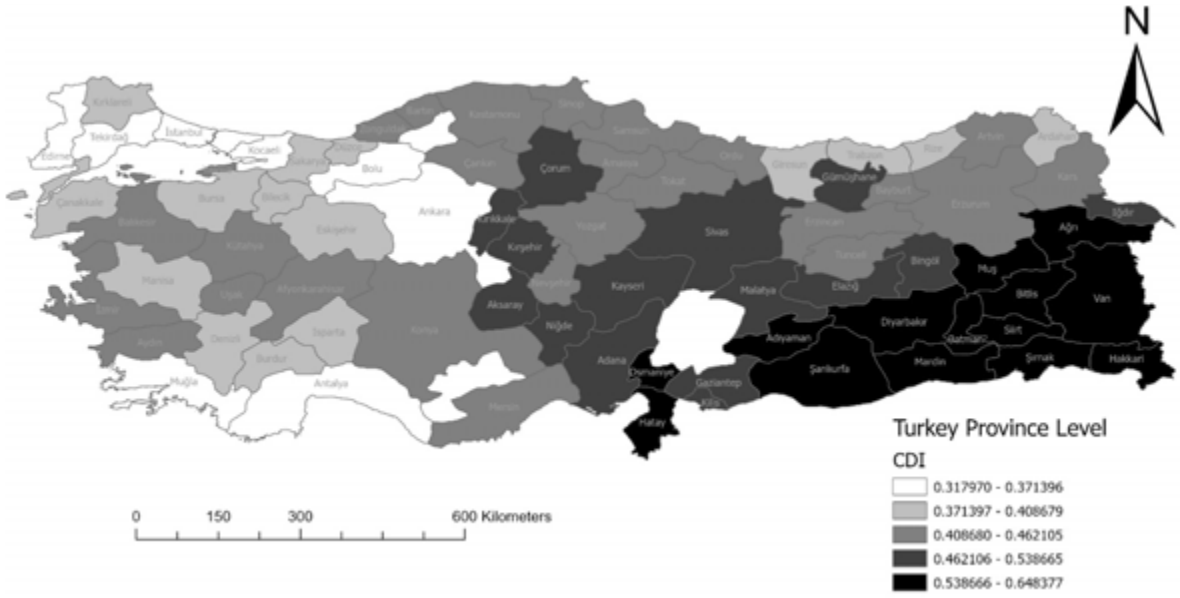

Figure 9. Turkish Composite Deprivation Index by province. Darker shades represent higher levels of composite deprivation.

Conclusion

This study presents a comprehensive, province-level analysis of multidimensional deprivation in Turkey, combining seven distinct domains—Income, Employment, Education, Health, Crime and Social Distress, Housing, and Living Environment—into a single Composite Deprivation Index (CDI). By leveraging the most recent TURKSTAT datasets and adapting the English Indices of Deprivation framework, the analysis provides a nuanced understanding of regional inequalities and spatial disparities in socio-economic and infrastructural well-being.

The results reveal a persistent and deeply embedded east–west divide, with the southeastern and eastern provinces consistently ranking among the most deprived across multiple domains. Provinces such as Şanlıurfa, Ağrı, Şırnak, and Mardin exhibit high composite deprivation scores, reflecting structural disadvantages in access to income, employment, quality education, and health services. Conversely, the least deprived provinces—including İstanbul, Ankara, Kocaeli, and Eskişehir—benefit from strong economic performance, developed infrastructure, and broader access to essential services.

It is highly recommended to agree on a specific mechanism for data collection, combination and agreement on weightings that reflect deprivation indicators that are specific to Turkey. It is also highly recommended to conduct this research at a constant annual rate in order to easily track changes in the development of the Turkish provinces and the sustainability of the spirit of competition among decision-makers in the Turkish provinces.

Toward New Circular Urban Economies: Regeneration Models for the Ecological Transition of Cities. European Cases and Initiatives.

Chiara Moretti, Roberto Bologna, Giulio Hasanaj
Affiliation:University of Florence
Email:chiara.moretti@unifi.it, roberto.bologna@unifi.it, giulio.hasanaj@unifi.it

Abstract
In response to climate change, cities must be reimagined as living organisms with sustainable urban metabolisms that efficiently manage flows. This article reviews scientific literature, policy reports, and European research to examine urban regeneration projects through the circular transition lens. It proposes new urban planning scenarios based on circular flows of both material and immaterial resources. Introducing the concept of Circular Urban Economy, the paper offers an alternative perspective in the circular cities debate by integrating circularity, nature-based solutions, climate change, well-being, and urban development to promote ecological sustainability and social equity. It explores urban transition processes grounded in regenerative design principles, emphasizing nature's role and local resource recirculation to transform degraded urban areas into ecosystems that enhance biodiversity and improve the well-being of citizens.

Keywords
Circular design; regenerative design; urban metabolism; critical urban space; ecosystem service.

Introduction

The circular economy is an increasingly emerging concept in the field of urban studies that seeks to create a more sustainable and efficient system for resource management. Contemporary cities guarantee high levels of functionality in many areas: from housing to transport, from educational to healthcare services, from employment to cultural opportunities. However, in order to provide such levels of efficiency, urban areas have been designed and built with considerable levels of sophistication, both in terms of materials and technology, making them hypertrophic and energy-intensive metabolisms that produce huge amounts of waste in the form of solid waste, water and air pollution. This factor contributes to increasing the fragility of urban areas, increasing vulnerability, reducing resilience to the effects of global warming and accelerating processes related to biodiversity loss. Ultimately, urban metabolism considers cities as complex systems that consume resources and produce waste.

During the 20th and 21st centuries, global CO2 emissions have increased from around 5 Gt to over 37 Gt per year (IEA, 2025). However, the absorption capacity of terrestrial and ocean ecosystems is limited to 19 Gt of CO2 per year, corresponding to the carbon budget available to the planet (Friedlingstein et al., 2023). Current environmental policies are consistent with a trajectory that could lead to a temperature increase of more than 3°C by the end of the century, exceeding the targets set by the Paris Agreement (IPCC, 2021). This scenario is associated with serious risks to biodiversity and human health (IPCC, 2021). (Fig.1)

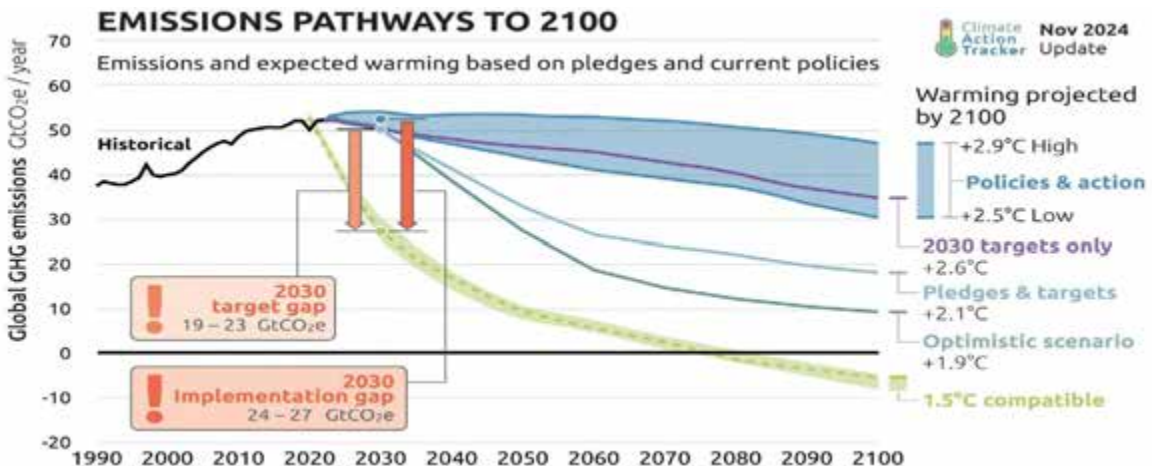

Fig. 1 – Global policies and pledges effects on greenhouse gas emissions and warming scenarios (Source: Climate Action Tracker, 2024)

Human actions have significantly altered 77% of the Earth's surface (IPBES, 2019), exploiting nature and its resources at a rate 1.75 times faster than the planet's ecosystems are able to regenerate (GFN, 2020; SCBD, 2020). The (distorted) use of natural resources is the main cause of air, water and soil pollution; waste, on the other hand, is tangible evidence of the degradation and waste that characterise the era in which we are living, the Wasteocene: an era marked by the continuous production of people, communities and places of waste, a global landfill that we must dismantle (Armiero M., 2021).

In this scenario, cities are a critical part of this mechanism as they consume 70% of the world's energy (UN-Habitat, 2022), use 75% of natural resources (Mancuso, 2023), emit 75% of CO2 into the atmosphere and produce 70% of waste (Luqman et al., 2023). In urban contexts, the linear management of resources (water, food, materials, energy) represents a development model that is no longer sustainable, as it contributes significantly to aggravating environmental problems such as resource depletion, ecosystem degradation, biodiversity crisis and loss of natural capital.

The climate crisis now requires a profound rethinking of the way we approach architecture. The year 2024 represented a critical threshold: the planet recorded its highest ever temperatures, far exceeding the +1.5°C limit set by the 2016 Paris Agreement. In just two years, global warming has accelerated to such an extent that even the most advanced scientific models are being called into question.

Until now, architecture has tried to respond through mitigation strategies, aiming to reduce the environmental impact of buildings. But this is no longer enough. The time has come to shift the focus from the goal of limiting damage to the urgent need to adapt. Adaptation means radically rethinking architectural design, imagining solutions capable of addressing the profound transformations already underway (Ratti C., 2025).

Conventional construction systems require a global flow of materials that are often untraceable. They depend on externalised and hidden spaces: copper mines, aluminium production sludge basins, and cement clinker calcination plants. The production and transport of materials require so much fossil fuel energy that the construction sector is responsible for 37% of global CO2 emissions (UNEP, 2022).

The concept of externalities was introduced in 1920 by British economist Arthur Pigou in his book "The Economics of Welfare" to describe the indirect costs that fall on individuals and territories not directly involved in the production of a good. This definition includes all the unaccounted consequences of production processes: emissions, waste, by-products and environmental impacts. Construction, in particular, is one of the sectors that generates the most externalities: every time we build, extracting resources, consuming energy, marginalising local skills and producing pollution, we contribute to a profound imbalance between the buildings we construct and the territories we transform. Taken together, these dynamics are the main cause of the environmental crisis. (Fig. 2)

Fig. 2 – Material extraction (Source: UNEP, Global Resources Outlook 2024).

Therefore, the built environment is a key lever for exploring how we can collectively engage in imagining a sustainable future. In an era marked by multiple crises, the ecological transition can no longer rely exclusively on established rules and methods: new, creative and interdisciplinary approaches are needed. Everyone's collaboration is essential. Only by integrating the social, economic and ecological dimensions can we initiate a truly circular, regenerative and sustainable transformation of our built environment.

It is possible to decouple economic growth from resource use and the environmental impacts it causes. This goal can be achieved by replacing prevailing linear growth models with regenerative and circular models for the preservation and enrichment of urban ecosystems and biodiversity. To combat climate change and reverse the current linear development model, we need to reconvert our production and consumption systems with appropriate economic, social, political and technological changes that go beyond conservation and restoration practices, towards a paradigm shift in the way we produce, use and reuse products and resources (IPBES, 2019) moving from an anthropocentric to an ecosophical vision that shifts the focus from humans to the ecosphere, integrating environmental, social and mental ecology to create communities integrated with nature.

Residues. From discarding to upcycling to reimagine cities as living organisms
"Nature produces no waste, no externalities. Every material flow is internalized in a continuous cycle. What if architecture followed the same logic? How can we balance the economies of construction with the ecologies of production?

Every time we construct a space, we deconstruct another (often in remote geographies across the planet). Buildings and the environment are therefore closely connected through a material link, and it is the responsibility of architects and planners to ensure that this link is positive." (Internalities: Architectures for Territorial Equilibrium, Spanish Pavilion at the Venice Architecture Biennale.)

Urban sites are complex, layered entities that are constantly evolving (Dovey, 2010). They can be described as an assembly of material things, flows and spatial connections that coexist. The relational understanding of sites also extends to the fact that every urban space contains a past, a present and a future (Hvattum, 2010), which means that they are dense, layered accumulations formed over time.

The challenges of circularity in urban areas call for a regeneration of cities based on circular design that brings about economic, social and environmental transformation without increasing the consumption of new resources and reducing the impact on the environment. Urban areas are characterised by a significant concentration of

material resources that accumulate over time (Gorgolewski, 2019) and, as the volume of built cities is expected to double by 2060, it is clear that the circular model will have to play a crucial role in cities in order to achieve the European Union's target of a zero-emission building stock by 2050. In order to meet these requirements and bring about a real paradigm shift in line with the principles of environmental sustainability and resource circularity, the design and management phases of interventions and the identification of the main urban challenges related to circularity play a central role (Atanasova et al., 2021;).

A fundamental aspect of this transition is understanding the key principles of the circular economy outlined by the Ellen MacArthur Foundation (EMAF, 2021) (Fig. 3):

- The first principle, "Eliminate waste and pollution", focuses on the goal of eliminating waste and pollution from the design stage onwards. This approach is not limited to managing waste at the end of the production cycle, but is based on intelligent design that prevents the creation of waste and minimises externalities. In this sense, energy efficiency, responsible use of resources and reduction of polluting emissions become an integral part of the economic system, contributing to the construction of a more equitable, resilient model that respects the ecological limits of the planet.

- The second principle, "Circulate products and materials (at their highest value)", is to keep resources in use for as long as possible. This promotes strategies such as reuse, repair, reconditioning and recycling. In this way, the aim is to improve efficiency in the extraction of new natural resources, optimise energy use and reduce losses within the system.

- The third principle, "Regenerate nature", concerns the need to regenerate the urban environment by integrating it with nature. This will ensure the long-term provision of essential ecosystem services such as clean water supply, climate regulation, soil fertility and biodiversity protection.

FIGURE 1 **THE CIRCULAR ECONOMY PLAYS A CRUCIAL ROLE IN BENDING THE CURVE ON BIODIVERSITY LOSS**

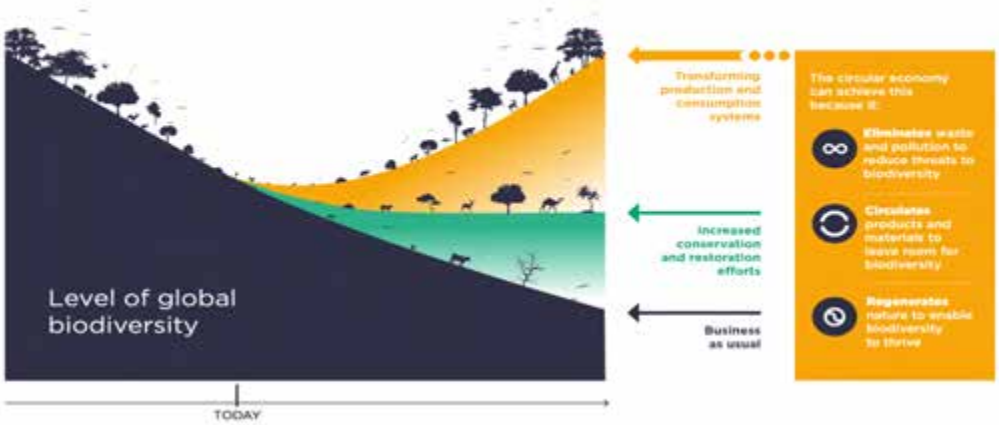

Fig. 3 - The three basic principles of the circular economy to contrast biodiversity loss (Source: Ellen MacArthur Foundation, 2021)

Resource-intensive urban lifestyles have made cities big, rich, and diverse stores of raw materials, which constantly depend on flows of goods and services to keep them running. Green and fair urban spaces can only happen if we take action that deals with urban areas as places of unsustainable consumption and socio-economic inequality at the same time. This is why urban communities characterised by regenerative design and development are desirable, as they aim to improve urban liveability while reducing the environmental footprint of cities by closing material cycles (Girardet, 2015). Increasingly circular urban economies are the means, and regenerative urban planning is the goal.

In this sense, the design of the built environment plays a decisive role, as it affects not only the quality of urban life but also society's long-term contribution to resilience to anthropogenic climate change and the depletion of

natural resources. Therefore, in order to respond effectively to the principles of the circular economy, a radical rethinking of the design and management of urban infrastructure is necessary.

At the urban level, society is transforming. As a result, there is a need to adapt the availability of spaces and buildings to new requirements. The urban regeneration process must necessarily take these changes into account, seeking to find appropriate solutions for each phase of the city's transformation. Research programmes and planning tools must recognise the vital role of cities and urban areas in the use of global economic resources, as they account for the vast majority of global consumption. This consumption puts considerable pressure on the environment, which is why the Circular Urban Economy (CUE) aims to support cities in becoming more resource-efficient and reducing their impact on the planet. The CUE encourages cities to implement circular measures that address socio-economic inequalities, promote social cohesion and improve access to urban resources, services and green spaces.

The introduction of Nature-based Solutions (NbS) in cities for resource management and to contribute holistically to the three principles of the circular economy leads to the reshaping of existing linear management into circular management. NbS play an important role in "keeping resources in use", mainly through the recovery and reuse of water and nutrients, and by giving new life to waste materials generated by other local production chains. In particular, their multifunctionality opens up a wide range of implementation possibilities: from transforming their outputs so that they fit into the value chain, to absorbing waste from other production chains to create an integrative urban supply chain.

Starting from the assumption that urban areas must be understood and addressed in relation to their use of resources and their socio-economic preconditions, the CUE aims to support the planning and design of urban places characterised by regenerative urbanism: by this term we mean liveable and green communities that are supported by circular flows of resources. Circularity should not be the ultimate goal, but rather a tool for creating healthier, more inclusive and regenerative urban communities that rely on closed material cycles to reduce their environmental footprint. We imagine cities and urban areas with restored natural resource cycles that support a high quality of life for their inhabitants, creating a transformative push towards healthy, attractive and green urban spaces. Through regenerative urban planning, we must think of cities characterised by restored natural resource cycles that support a high quality of life for their inhabitants.

The role of European policies in the circular transition: the New European Bauhaus Facility 2025-2027

In recent years, the concept of urban regeneration has evolved to become increasingly multidimensional and strategic in response to the growing complexity of urban transformation phenomena. The Urban Agenda for the EU (2023) frames urban regeneration as an integrated vision and action aimed at combating urban decay through economic, social, environmental and physical interventions, with the goal of sustainably improving the economic conditions and quality of life of residents. At the global level, UN-Habitat (2022) proposes a complementary interpretation, emphasising the participatory, inclusive and resilient nature of the process, which aims to transform declining urban areas into sustainable communities that are attentive to human well-being, social cohesion and adaptation to climate change. These definitions converge in recognising urban regeneration not only as a set of physical interventions, but as an integrated and sustainability-oriented process capable of responding to contemporary challenges related to ecological transition, spatial justice and social cohesion.

The urgency for Europe to take a leading role in global environmental governance and sustainable innovation has never been more evident. Given its significant historical carbon footprint, Europe now faces a dual and significant responsibility. Not only have European countries played a predominant role in the intensive consumption of planetary resources in the past, but in many cases they continue to do so at a rate that remains unsustainable (Dm, 2024).

Throughout Europe, profound transformations are taking place that affect both human and non-human communities. The idea that places are dynamic entities in constant flux (Dovey, 2010) is confirmed by the current reality.

In many areas, these changes are occurring particularly rapidly: buildings, infrastructure and public spaces are being rapidly constructed, modified, demolished or redeveloped. These processes have a significant impact on resident communities, as well as on future communities that will inhabit these territories.

In this context, the transition to a more circular, regenerative and systemic conception of the built environment requires a profound rethinking of decision-making practices. An integrated approach is needed that takes into account the three fundamental dimensions of sustainability: economic, environmental and social (Grupe Larsen, 2024). To effectively guide these transformations, it is crucial to activate profound levers of change capable of affecting systems at their roots. An effective green transition requires the construction of shared and imaginative visions of the future. Collective approaches to planning and storytelling are therefore essential, promoting new ways of thinking and acting in our living spaces, within societies and economies. In this perspective, it is essential to develop innovative languages, methods and tools that avoid the reproduction of unsustainable models, while promoting imagination, hope and creativity as transformative resources (Moore, 2023).

Many cities are experimenting with strategies for sustainable development and circular use of resources. A significant example of this is the "European Circular Cities Declaration", which aims to support the circular transition of municipalities, offer a shared vision of "circular cities", highlight the challenges of creating a closed-loop economy, and build a community of local authorities that share experiences, challenges and achievements. Trends show a growing number of circular initiatives at European level in support of cities and an increase in the adoption of strategies and action plans to guide the circular transition. Similarly, awareness-raising programmes on circularity for citizens and European instruments are also particularly important. In this regard, the New European Bauhaus (NEB) represents a fundamental pact as it supports actions for healthier and more resource-efficient urban environments with a particular focus on air, water, nature, biodiversity, waste and the circular economy.

The NEB is an initiative of the European Commission that aims to transform the European Green Deal into tangible change on the ground, improving everyday life through sustainable solutions for the built environment and lifestyles. It combines sustainability with good design, inclusiveness, accessibility and affordability, while respecting the diversity of places, cultural heritage and European cultures. (EC 2023). The New European Bauhaus Facility 2025-2027 (EC, 2025) is a European Commission tool designed to accelerate the transformation of neighbourhoods through sustainable and inclusive design, focusing on promoting innovation, circularity and the use of biological materials. By prioritising the use of circular economy principles and resource-efficient materials, the NEB contributes to the Clean Industrial Deal's goal of reducing carbon emissions and improving the sustainability of industrial processes. By embedding its vision in local and regional contexts, the NEB aims to bring Europe closer to its inhabitants, strengthening ties and bridging disparities to create prosperous and inclusive communities. The Tool addresses the transformation of the built environment at the neighbourhood scale, understood as complete systems where people live, socialise and find services. The main objectives are:

- Transforming places with communities by enhancing public spaces and buildings and empowering local communities through greater involvement.
- Promoting a sustainable, circular and regenerative European building ecosystem that is inclusive, accessible, affordable, resilient and promotes health and well-being. It focuses on innovation in materials, products and methods and seeks to make the built environment and materials more adaptable and reusable.
- Developing new business and financing models to rethink the way projects are conceived, planned, executed and invested in.

The tool invites cities to use planning strategies aimed at rethinking urban metabolisms to support both ecological balance and social equity by promoting regenerative relationships between society and the environment. These are the themes of the second objective of the NEB Facility, which promotes projects and strategies to make neighbourhoods more sustainable, circular, accessible and regenerative, improving their climate resilience through the restoration of nature and biodiversity. It will do so by helping to rethink the way we design, build and use the spaces around us. Particular attention will be paid to the reuse of existing infrastructure and materials and to renovation. New technologies will also be explored to optimise construction methods and the resources used and reduce costs, while ensuring user-centred and place-based solutions that take into account cultural heritage, local and vernacular knowledge, reflect local cultural identity and meet people's needs. It will take a

more systemic and holistic approach to neighbourhoods, looking at energy or mobility systems, for example. Under this specific objective, the NEB Instrument will promote environments where nature can thrive, helping to restore biodiversity, reduce pollution and improve the health and well-being of all living beings. The choices and actions implemented by European strategies (Fig. 4) should serve as concrete and replicable examples, helping to set benchmarks for collective action in the fight against climate change and environmental degradation.

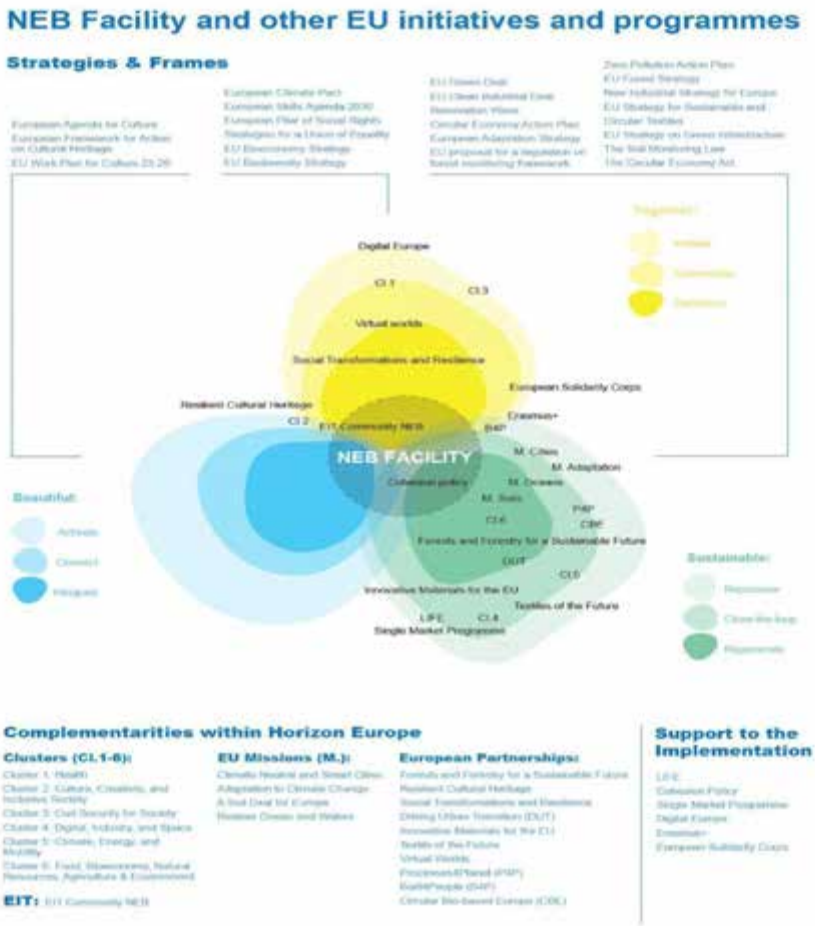

Fig. 4 - European Programmes and initiatives that support New European Bauhaus (Source: New European Bauhaus Facility 2025-2027)

European experiences in regenerating existing abandoned spaces through circular economy processes.
In order to address the various urban challenges and prepare cities for new development based on the recovery, reuse and recycling of materials and resources, starting from the design phase, but also in the management and maintenance phases, it is essential to adopt a holistic and systemic approach that carefully assesses flows. An initial survey of scientific literature, urban governance and European policy guidelines has highlighted the importance of promoting a systemic and innovative architectural model capable of contextualising individual interventions within a broad framework of transformation, taking into account the complexity of urban contexts. Although all urban challenges related to the circular economy can make a concrete contribution in the field of architecture, those related to the recovery of the built environment and construction waste and the protection and enrichment of urban ecosystems and biodiversity are of particular interest for the future urban development of cities as they deal, on the one hand, with waste from construction and demolition work and, on the other, with the transformation of impermeable urban surfaces into resilient and biodiverse natural infrastructure systems (IPBES, 2019; EC, 2020). and, on the other hand, the transformation of impermeable urban surfaces into resilient and biodiverse natural infrastructure systems (IPBES, 2019; EC, 2020). In order to identify some significant strategies,

solutions and tools adopted in experiments to regenerate existing abandoned spaces through circular economy processes, a survey of case studies was carried out (Table 1 shows the most relevant projects) according to four fundamental axes for decarbonisation: waste, materials, inclusion and biodiversity.

(1) The built environment as a resource mine. The Waste axis focuses on optimising the use of resources in urban areas, which are seen as complex systems containing buildings, infrastructure, technologies and material flows. This approach promotes interventions aimed at extending the useful life of resources through maintenance, renovation and repair activities, in order to interrupt linear flows and reduce waste production, thus increasing the efficiency of urban resource use. The built environment represents a resource of materials for the transformation of buildings and open space, offering great opportunities for circularity. In this sense, the design of the built environment plays a decisive role as it affects not only the quality of urban life but also society's long-term contribution to resilience to anthropogenic climate change and the depletion of natural resources. Therefore, in order to respond effectively to the principles of the circular economy, a radical rethinking of the design and management of urban infrastructure is necessary. In this regard, urban mining offers the opportunity to reshape our cities by converting waste into valuable resources.

(2) Circularity as an enabling tool for the transition of urban resources. The Materials axis analyses the value chains of natural and regenerative materials. In the case studies analysed, circularity is not conceived as an end goal, but rather as a set of tools for developing more resilient, inclusive and regenerative urban communities, characterised by closed material cycles that contribute to reducing environmental impact. The approach is based on closing material cycles, reducing environmental impact and restoring vitality to urban ecosystems, benefiting the quality of life of inhabitants. Conventional construction systems require a global flow of materials that are often untraceable. The transition to materials produced using regenerative methods allows for the use of materials or the production of resources with low greenhouse gas emissions, promoting biodiversity and the climate and avoiding damage to ecosystems (Filho et al., 2021).

(3) Social cohesion and integration of socio-economic dimensions in circular approaches. The Inclusion axis recognises the crucial importance of social dynamics in pursuing a circular economy. Therefore, measures aimed at mitigating socio-economic inequalities, promoting social cohesion and ensuring equitable access to resources, services and urban green spaces are encouraged. Urban areas are also considered privileged contexts for the application of new urban design principles geared towards inclusive regeneration.

(4) Towards regenerative urban planning: The Biodiversity axis promotes the adoption of regenerative design principles aimed at restoring natural resource cycles and creating sustainable, inclusive urban spaces capable of improving quality of life. This approach aims to generate green, resilient and socially cohesive urban environments capable of responding effectively to contemporary environmental and social challenges. Contributing to paradigm shifts in urban planning, design and architecture towards a biocentric perspective, in which urban areas and communities are further integrated into nature for a sustainable socio-ecological balance across urban-rural gradients.Table 1: most relevant experiments to regenerate existing abandoned spaces through circular economy processes analised.

Table 1: most relevant experiments to regenerate existing abandoned spaces through circular economy processes analised.

Project	Description	Axes				Pillars of the circular economy
		Was.	Mat.	Incl.	Biod.	
Kopfbau Halle 118 (Winterthur, Switzerland)	A concrete example of the recovery of an abandoned building is represented by the work carried out by the Swiss architecture firm Bauburo in situ and its partner company Zirkular, which, with the K118 pilot project, demonstrated how urban mining can be integrated into a modern building context, promoting the adoption of sustainable and circular practices. This case study highlights how, through innovative design and the use of recycled materials, it is possible to reduce the environmental impact of construction while maintaining the high quality and functionality of buildings.	•	•	•		Recovery of abandoned infrastructure Maximisation of the use Reversed planning process Reuse of materials Design for disassembly Strengthening community development Promoting social cohesion
Frank Areal (Basel, Switzerland)	Franck Areal, a new centre for social innovation, circularity and art, is a place where new connections are created: a centre for contemporary and urban dance, inclusive and cultural projects for young people, gastronomy and nightlife, as well as a space for regenerative and circular economy projects and an intergenerational housing project built with recycled construction materials and innovative energy technologies.	•	•	•		Recovery of abandoned infrastructure Maximisation of the use Reversed planning process Reuse of materials Strengthening community development Promoting social cohesion
La Ferme du Rail (Paris, France)	Located in the dense urban fabric of Paris's 19th arrondissement, on Rue de l'Ourcq, the urban farm and green oasis La Ferme du Rail provides an excellent example of possible circular approaches to the regeneration, reuse, protection and conservation of urban space for biodiversity through the active involvement of stakeholders. Developed over four years, this block creates an oasis of circular urban economy: it promotes a value chain that combines commercial activities with social and cooperative initiatives that benefit those who live there.	•	•	•	•	Recovery of abandoned infrastructure Maximisation of the use Reuse of materials Experimentation with natural solutions Urban renaturalisation Strengthening community development Promoting social cohesion

LUMEN - Laboratorio Urbano Mensola (Florence, Italy)	This is a culturally-based urban regeneration project that redevelops municipal real estate, creates social interaction in an abandoned public space and aims to create a new cultural hub next to the newly created Mensola Park. LUMEN's mission is to create a space where people can independently build opportunities to actively participate in their community. Through participation and individual empowerment, LUMEN is committed to promoting creativity, civic engagement and urban regeneration, encouraging the creation of an environment in which every individual can contribute to positive change.	•		•	•	Recovery of abandoned infrastructure Management of disused public properties Maximisation of the use Temporary and flexible use of space Reuse of materials Urban renaturalisation Strengthening community development Promoting social cohesion
Buiksloterham (AmsterdamNetherlands)	Buiksloterham is a typical post-industrial district, just a short ferry from the center of Amsterdam. The development of Buiksloterham as a living lab for circularity has led to a significant strengthening of the local economy and a transformation of what could previously have been deemed 'unusable land' into a thriving neighbourhood. Currently, Buiksloterham is undergoing transformation from an industrial area to a mixed living and working area. With local stakeholders, Metabolic developed a set of interventions for improving the current situation through waste minimization, high levels of source separation, and improved recycling techniques.	•	•	•	•	Recovery of abandoned infrastructure Maximisation of the use Reuse of materials Promoting responsible consumption Urban renaturalisation Optimise water use Strengthening community development Promoting social cohesion
Bluecity (Rotterdam, Netherlands)	Since 2015, BlueCity has developed from a vacant swimming pool into a circular economy hub for the city and region. In 2025, BlueCity is a model city for the circular and blue economy and home to 55 entrepreneurs. It is a meeting place for pioneers and enterprising minds, where they develop a framework for action, whether to grow their impact, live a zero waste life, or develop a future-proof material. BlueCity's mission is to accelerate the transition from the linear to the circular economy through entrepreneurship. BlueCity is designed as a prototype circular city to be replicated on a large scale.	•	•	•	•	Recovery of abandoned infrastructure Maximisation of the use Develop a future-proof material Experimentation with natural solutions Optimise water use Strengthening community development Supporting entrepreneurs with knowledge about circular economy

Oosteroever Circulair District (Oostend, Belgium)	For the Oosteroever site, a comprehensive hypothesis for a circular district was developed, addressing all key dimensions: materials, water, biodiversity, and programme. The proposal emphasises the importance of systems research and the creation of an urban planning model to support the economic transition of the area. This approach aims to avoid fragmented developments lacking mutual interaction. Furthermore, sustainable solutions require an integrated strategy at the scale of the entire district.	•	•	•	•	Recovery of abandoned infrastructure Reuse of materials Promoting responsible consumption Urban renaturalisation Optimise water use Strengthening community development Promoting social cohesion
Darwin Eco-system (Bordeaux, France)	Darwin aims to regenerate an abandoned urban space while promoting a social, green and creative economy. It is a place where new models are explored to reconcile economy and ecology, based on cooperative and sharing principles. The initiative focused on the preservation and renovation of the original buildings while providing workspace for over 100 enterprises and (social and cultural) associations, as well as co-working facilities. The ecological transition is an important theme in the redevelopment of the area, both in the renovation of buildings and in the wider activities developed. The area has for example become a living lab for new (urban) farming techniques like aquaponics and micro-gardening.	•	•	•	•	Recovery of abandoned infrastructure Promoting responsible consumption Develop a future-proof material Experimentation with natural solutions Strengthening community development Promoting social cohesion

Strategies for circular urban regeneration. Systemic processes for the cities of the future.

We already have everything we need. The point is not to continue producing, but to learn to read what exists more carefully, to recognise its latent value and reactivate it. The built environment is not an exhausted resource, but a reservoir of potential: every building, every material used has a residual value that can be regenerated. This approach opens up a new aesthetic of architecture, in which reuse is not only an environmental necessity, but also a design language capable of expressing beauty, memory and innovation. From a systemic perspective, architecture takes on the role of mediator between ecologies and economies, becoming an active tool in decarbonisation and the reactivation of local economies. The transition from a linear to a circular model requires a profound transformation of design methodologies: it is not just a matter of changing materials, but of radically rethinking processes, value metrics and decision-making models. We must move beyond the logic of initial cost to embrace a holistic view of value throughout the entire life cycle of the work.

We are accustomed to considering demolition and disposal as inevitable stages of the building cycle. But today it is possible to overturn this paradigm: designing architecture and neighbourhoods that generate minimal waste, facilitating disassembly, reuse and recovery of materials. This means intervening not only on the built environment, but also on design habits, supply chains and regulatory tools, in order to build urban contexts that reduce waste production and maximise regeneration.

Circular urban regeneration is based on a compact, biodiverse and zero-land approach, where the useful life of buildings and materials is extended through reuse strategies and the use of materials produced according to regenerative criteria (EMAF, 2021).

The urban transformation projects analysed aim to promote and accelerate progress towards inclusive, regenerative and transformative urban futures and highlight the importance of collaborative efforts between policymakers, urban planners, environmentalists and communities to implement effective strategies to preserve and restore urban biodiversity. Based on the results obtained through the analysis of the state of the art and the observation of case studies, it emerges that the main strategies for circular transition through the creation of interacting and replicable models concern:

- Recovery of critical or abandoned infrastructure or urban areas;
- Maximisation of the use of existing building heritage through models of sharing and flexible use of space;
- Reversed planning process: form follows availability, the project develops constantly as the search for components progresses;
- Adaptive reuse of materials from existing infrastructure, through a detailed analysis of residual and reusable materials;
- Mapping of local surpluses, in collaboration with companies and local networks for the reuse of resources within projects;
- New internal balance of relations between ecologies and economies;
- Experimentation with natural solutions to increase the presence of urban greenery, promote biodiversity and create resilient ecological infrastructure;
- Dematerialising public space infrastructure and focusing on nature as infrastructure;
- Promoting social cohesion and a participatory approach ensuring that urban regeneration aligns with the needs and characteristics of local populations;
- Strengthening community development and civic awareness.

Measuring the effectiveness of the projects analysed is the priority challenge that requires constant refinement of tools, continuous updating and improvement of results, and progressive deepening of evaluation methods, in awareness of the complexity and variability of reference parameters and the need to build a system for predicting effects throughout the entire life cycle for a regenerative and accessible urban system by design. The experiences studied show that the circular transition, with a view to climate neutrality, lays the foundations for an innovative vision of regenerative intervention, which aims to eliminate the concept of waste and refuse in the short to medium term (8-10 years, according to the European average) and invests, over the longer useful life phase, the entire range of material and immaterial resources in a perpetual self-sufficient cyclical process of decommissioning and regeneration.

Urban space can be configured as a regenerative ecosystem, guided by a zero waste approach that involves all resource flows, from design to management. Designing according to the useful life cycle of elements allows for the creation of self-sufficient and adaptive environments capable of resiliently addressing environmental, economic and social challenges. Circular design radically reformulates the relationship between construction and materials, focusing on the continuity of value over time and space. Reuse is no longer just a technical practice, but an evolving architectural narrative, where even buildings that can no longer be recovered become urban quarries, rich in materials that, as part of the existing heritage, acquire a cultural and environmental value greater than that of virgin materials.

CUE therefore proposes itself as an integrated, adaptive design model rooted in the territories, capable of generating environmental, social and economic value from what already exists. An approach based on proximity, nature and the enhancement of local resources, towards more equitable, resilient and regenerative cities.

If we look at this type of approach, NbS can be seen as a concrete application of the principles of circularity on an urban and architectural scale, through the mimicry of natural processes and the closure of ecological cycles (EEA, 2021). Artificial wetlands, vegetated channels, detention and infiltration basins, rain gardens, bioswales, renaturalised riparian strips and many other solutions act as decentralised biophysical systems, capable of filtering, storing and returning water to the natural hydrological cycle. These systems reduce pollutant loads,

mitigate flow peaks and recover resources (such as nutrients and biomass), in line with circular strategies for wastewater recovery (Li et al., 2020; EEA, 2021). NbS applied in urban areas to buildings and open spaces support the metabolic efficiency of urban systems, reducing energy consumption for cooling, greenhouse gas emissions and promoting passive ecosystem service flows (Pauleit et al., 2017). These results contribute directly to a circular reconfiguration of urban infrastructure without consuming new land (Pomponi & Moncaster, 2016).

Practices aimed at regenerating degraded soils increase carbon sequestration, improve soil fertility and promote biodiversity in urban and peri-urban areas. Such approaches are consistent with the principles of the circular bioeconomy, as they transform organic waste into productive inputs, contributing to the restoration of ecosystem functionality and increasing resource productivity in the long term (Lal, 2020; IUCN, 2020).

The integration of NbS into the theoretical and operational frameworks of the circular economy is not merely functional, but systemic. Both approaches emphasise resource cyclicality, multifunctionality and decentralisation, opposing linear and sectoral development models. The adaptive and feedback-based nature of NbS reflects the cyclical flows inherent in circular systems, reinforcing the need for their integration into sustainable territorial development strategies (Fischer & Newig, 2016; Kirchherr et al., 2017).

Fig.5 - 'Structure and flow' channels (efficiency) and 'network and exchange' (resilience) within a mycelial system (Source: National Institutes of Health)

The long-term future of our materials economy is regenerative. This transition requires a deep understanding of the impacts of systems, avoiding further degeneration of global biodiversity and land through green growth. Therefore, to imagine a post-capitalist future, it is important to promote circular, green and inclusive governance models. The CUE theme, through a proactive approach, encourages cities to implement circular measures that address socio-economic inequalities, promote social cohesion and improve access to urban resources, services and green and blue spaces. For this reason, new government tools must deepen urban transition processes according to the principles of regenerative design, strengthening the role of nature and the recycling of local resources to transform degraded urban areas into ecosystems that enhance biodiversity, combat climate change and improve the well-being and health of citizens.

Conclusions

The regeneration of degraded urban spaces according to the principles of the circular economy represents an urgent challenge but also a strategic opportunity to radically rethink our relationship with the built environment. The hegemony of the extractive economy over design culture has consolidated production chains so effective that they block the possibility of considering pre-existing materials on site as a valuable resource, improperly reducing them to waste. A paradigm shift, on the other hand, invites us to view these materials as a new form of urban stratification, an urban and anthropogenic mine from which to draw in order to promote infinite andregenerative production cycles. From this perspective, architecture should no longer be an act of replacement but a process of transformation, supporting a creative rebirth of our relationship with the built environment through an approach that prioritises reuse, regeneration and reintegration of materials on site, rather than demolition and disposal.

The adaptive reuse and regeneration of existing urban resources are the foundations of a new culture of urban renewal, which should guide all city operational plans according to the principles of "zero volume" and "no net land take". Unused or underused spaces represent a strategic potential for activating targeted urban policies

and strategies capable of responding sustainably to contemporary needs. It is therefore essential that local administrators recognise the social, economic and environmental impact that these places can generate and equip themselves with appropriate visions and tools to rethink urban planning logic in a regenerative and circular way. The temporary activation of abandoned buildings and areas can trigger participatory processes of active citizenship and local activism, offering citizens concrete tools to contribute to urban development. If systematised, this approach can lead to a more inclusive and resilient urban transformation.

The transition to regenerative cities therefore requires deep integration between spatial innovation, social inclusion and the protection of urban biodiversity. This is not simply a matter of adding up good practices, but of a structural change in the vision of the city: from an entity that consumes land and resources to an integrated ecosystem capable of self-regeneration. The promotion of biocentric planning, which reintegrates the built environment with natural processes, is one of the most effective levers for a just ecological transition.

For these changes to be effective and scalable, it is necessary to build a model consisting of policies, financial instruments, design regulations and collaborative mechanisms. The simultaneous development of tools such as material registers and passports, together with the creation of alliances between public and private actors and local communities, is essential to enable a truly circular institutional urban economy.

Through the implementation of the CUE, the goal is to create a cohesive ecosystem that not only anticipates future needs but also collectively guides the transition of cities towards systemic, equitable and transformative governance models capable of internally rebalancing the relationship between ecologies and economies.

The paradigm shift presented in the paper is not easy, but it is necessary and requires a joint effort that cannot be postponed and can provide policymakers with the tools and knowledge needed to expand related interventions in other urban contexts.

Post-growth Redefinition of Urban Textures: The Changing Faces of Human Scale through Eminonu and Maslak Central Business Areas in Istanbul

Dila Toprak[1], Eren Kürkçüoğlu[2]
[1]Istanbul Technical University, toprak17@itu.edu.tr
[2]Istanbul Technical University, ekurkcuoglu@itu.edu.tr

Abstract
As cities move beyond growth-driven models, the relationship between urban texture and human scale becomes essential for designing people-centered environments. Historically, economic expansion has produced dense, vehicle-oriented urban forms, often at the expense of spatial intimacy and human comfort. This paper explores how contrasting urban forms along Istanbul's Central Business District axis—Eminonu and Maslak—reveal the impacts of urban morphology on social experience. Through spatial analysis of building height, street width, and enclosure, the study highlights how Eminonu fosters walkability, social interaction, and a sense of place, while Maslak reflects the spatial fragmentation of growth-focused development. The paper proposes a post-growth urban framework grounded in human-scale design, advocating for inclusive, livable, and resilient cities shaped by morphological balance rather than expansion.

Keywords: post-growth urbanism, human scale, morphology, central business area, Istanbul

Introduction

Urban growth has long been equated with progress, prosperity, and modernity (Harvey, 2005). However, this growth has also led to social alienation, spatial fragmentation, and environmental degradation, prompting increasing criticism of the traditional growth-driven urbanism model (Sachs, 2015). In response, post-growth urbanism has emerged as a critical framework that not only questions the relentless pursuit of growth but also calls for a fundamental reorientation of urban development priorities. Rather than focusing on quantitative metrics such as GDP, urban sprawl, and consumption, post-growth urbanism emphasizes spatial quality, ecological integrity, and the well-being of individuals and communities (Latouche, 2009; Raworth, 2017; D'Alisa, Demaria & Kallis, 2015). This shift invites a profound rethinking of urban design, with a focus on creating environments that are both sustainable and human-centered, fostering more inclusive, resilient, and livable cities (Sennett, 2018; Gehl, 2010).

Central to this rethinking is the concept of the human scale, which underscores the importance of designing urban spaces in alignment with human needs and experiences. It promotes environments that are accessible, navigable, and conducive to social interaction (Gehl, 2010; Sennett, 2018). Human scale extends beyond physical size and proportion; it embodies an experiential and social relationship between urban form and the human body, encouraging legibility, comfort, and inclusivity (Gehl, 2010). Scholars such as Lynch (1981) and Alexander (1977) argue that human-scale environments enhance coherence, orientation, and meaningful engagement among inhabitants. Within the post-growth paradigm, the human scale is not merely a design guideline but a vital lens for evaluating the inclusivity, accessibility, and resilience of urban life (Carmona et al., 2003; Sennett, 2018). Urban spaces shaped through this lens foster a deeper sense of connection, both to place and to community, thereby strengthening social cohesion and overall well-being.

The human-centered approach is also closely linked to urban texture, understood as the spatial arrangement of streets, buildings, and open spaces. Urban texture includes the voids and patterns that shape everyday urban experiences (Mehaffy, Porta & Romice, 2010). Dense and layered urban textures support walkability, spatial intimacy, and mixed land uses, thereby nurturing vibrant social life and a heightened sense of place (Jacobs, 1961; Gehl, 2010). In contrast, growth-oriented design often prioritizes car infrastructure and high-rise, functionally segregated development. These conditions disrupt the spatial continuity and social cohesion essential for livable environments and tend to alienate individuals from their surroundings (Gehl, 2010). The relevance of this discussion becomes particularly evident in metropolitan cities like Istanbul, which embodies both historical continuity and rapid modernization.

Istanbul's Central Business District (CBD) axis, stretching from the organically developed historic texture of Eminonu to the modern district of Maslak, presents a striking contrast in spatial and experiential perspective (Keyder, 1999; Aksoy & Robins, 2011). These two business districts, which differ physically and functionally, have been selected as case areas due to their distinctive urban forms. While Eminonu maintains a dense, fine-grained

structure that promotes pedestrian activity, visual coherence, and spontaneous social exchange, Maslak reflects the spatial consequences of late 20th-century neoliberal urbanism, characterized by fragmentation, vertical expansion, and a loss of public life (Erkip, 2000). The contrast between these two commercial districts highlights how different urban textures can significantly influence both physical space and social dynamics, particularly in terms of post-growth urbanism and human scale.

This paper investigates how the contrasting urban forms of Eminonu and Maslak shape not only the physical space but also the social experience and sense of place, qualities essential to post-growth urban environments (Carmona et al., 2003; Gehl, 2010). Adopting a comparative morphological approach, the study focuses on three key indicators: street width, building height, and street enclosure. These parameters are analyzed not only in formal terms but also as spatial conditions that influence human comfort, inclusivity, and the vitality of urban life. By bridging morphological analysis with post-growth theory, this paper aims to contribute to contemporary urban debates on how spatial form can support human-centered, sustainable, and socially inclusive futures (Latouche, 2009; Raworth, 2017).

Spatial Development of Istanbul's Central Business District (CBD) Axis

The urban development of Istanbul's CBD axis has been crucial to the city's history, characterized by changes influenced by urban planning and socio-economic conditions (Göksu & Pilehvarian, 2019). Understanding this formation is essential for contextualizing the historical background of the selected case areas, as the axis reflects significant changes from the city's traditional commercial core to its contemporary business districts.

In the 1950s, Istanbul's commercial center was the Eminonu area of the Historical Peninsula, functioning as the main trading location of the city for the import, export, and sale of many commodities (Göksu & Pilehvarian, 2019). From 1956 to 1958, a significant development in the city's planning was going on with the construction of Barbaros Boulevard, which connects Beşiktaş to Zincirlikuyu. This development served as a pivotal axis for the spread of the city's primary commercial centers into other regions. This shift marked the beginning of a new phase for Istanbul's CBD, which would later see the rise of modern commercial areas beyond the historical core (Çelik, 1993). In the late 1960s, the city subsidized skyscraper construction in Maslak, the city's development area. This development signaled a notable transition towards vertical development and modernity.

In the 1970s, the evolution of the city's commercial landscape continued to grow, as the merging of the Taksim-Şişli-Büyükdere axis and the Mecidiyeköy-Gayrettepe axis facilitated the northern region of Istanbul's development as an extension of the Historical Peninsula's commercial center (Kubat et al., 2012). The simultaneous reduction of military zones in the northern part of the city, especially in the Sarıyer district, resulted in a cluster of multi-storey projects in Maslak after the 1970s. These improvements positioned the area as a modern business district, highlighting vertical expansion. This period also experienced a notable transformation in commercial architecture, as enterprises progressively preferred contemporary office buildings to maintain market competitiveness (Kıray, 1998).

During the 1990s and early 2000s, the evolution of Maslak coincided with the expansion of the entire CBD axis, characterized by the establishment of industrial zones, business hubs, and upscale residential districts. In this period, initiatives were undertaken to maintain the identity of the 'Old City' in the Historical Peninsula, transforming it into a tourism and commerce-focused district (Aydemir, 2019) (Figure 1).

In the present day, Eminonu and Maslak represent two critical points along Istanbul's CBD axis, embodying different historical backgrounds, urban textures, and planning paradigms. While Eminonu, located in the Historical Peninsula, has served as the city's core commercial and cultural hub for centuries, its dense streets maintain a strong connection to human activities and daily life (Tüfekçi, 2017). In contrast, Maslak, which spatially developed in the second half of the 20th century, symbolizes Istanbul's modern expansion, characterized by vertical growth, office spaces, and infrastructural integration (Karaca, 2020). The comparison of these two business district areas illustrates the broader tension between preserving historical urban character and accommodating contemporary economic and spatial demands.

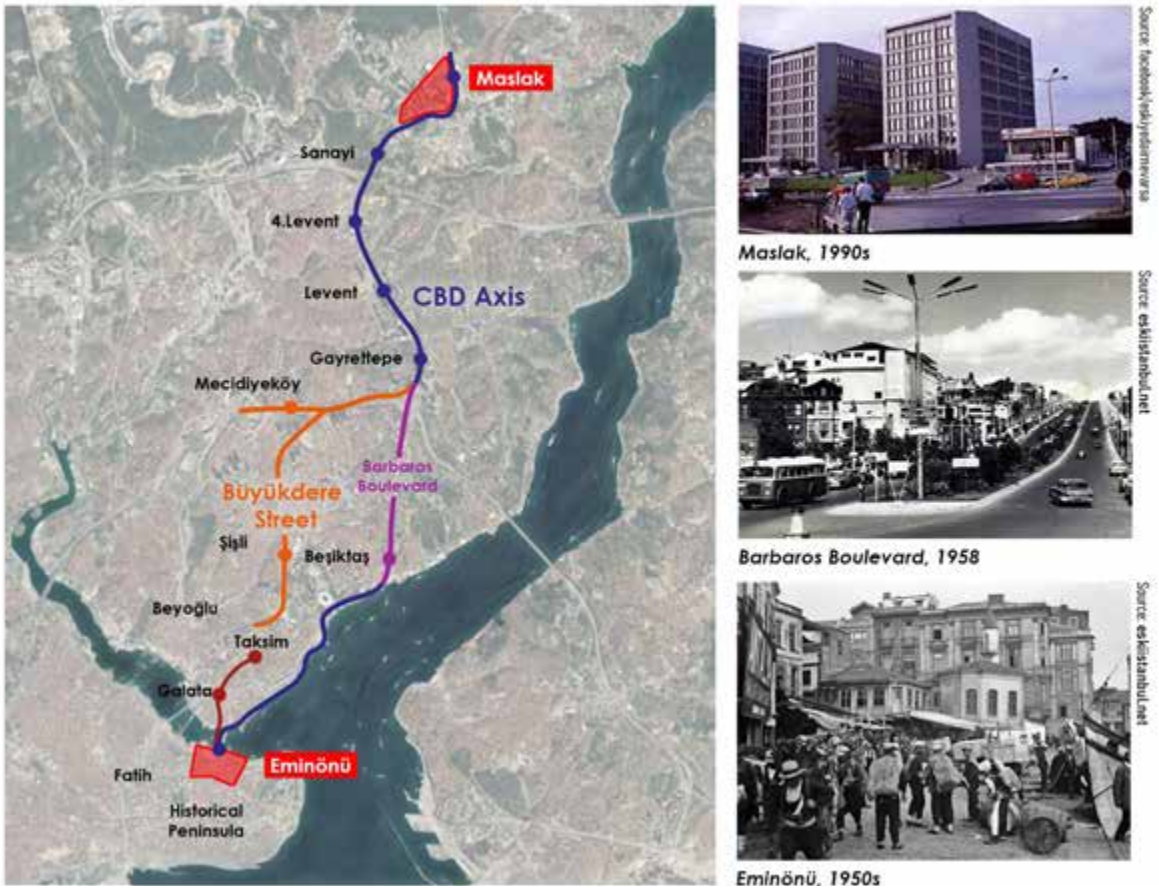

Figure 1. Development of Istanbul's Central Business District (CBD) Axis

Morphological Comparison of Eminonu and Maslak Case Areas

This section systematically analyzes the morphological characteristics of Eminonu and Maslak through essential spatial parameters, seeking to explain how distinct planning approaches, particularly those shaped by human scale and post-growth thinking, have influenced their urban forms. By contrasting these two areas, the analysis highlights the spatial implications of different urban development models, one based on historical continuity and social proximity, the other on modern economic imperatives, and raises critical thinking about how cities can transition to post-growth futures that prioritize human well-being over expansion.

Environmental Relations

Eminöonu serves as a highly connected urban node, influenced by its historical layers and dense transportation networks. Surrounded by significant areas including Golden Horn, Vezneciler, Sirkeci, and Unkapanı-Vefa, it acts as a central connection in Istanbul's urban texture. Three major streets and two iconic bridges (Galata and Haliç) provide strong east-west and trans-Golden Horn connectivity, connecting the district to both old and modern city regions. Eminonu's multimodal infrastructure, which includes the M2 metro, the T1 and T5 tram lines, and a rearranged bus network, improves its accessibility and spatial planning. Its maritime function strengthens both intercontinental and local links, with eight ferry lines anchored in Istanbul's water-based transportation. Green and cultural icons, including Gülhane Park and Istanbul University's Beyazıt Campus, contribute to the city's environmental and historical identity. Overall, Eminonu illustrates environmental urban integration by combining natural, infrastructure, and socio-cultural systems into a multilayered urban network (Figure 2).

Maslak, on the other hand, is a vast northern district defined by its strategic placement along Büyükdere Street, a major urban axis that connects it to the surrounding districts. The M2 metro line connects Maslak directly to Eminonu, increasing its connectivity to Istanbul's transportation network. Istanbul Technical University's Ayazaga Campus is a significant educational and research construct in the region. The Atatürk Auto Industrial Zone reflects

the district's industrial background, however, it is currently facing issues as a result of urbanization. Maslak is a dynamic urban neighborhood where transportation, sectoral clusters, and changing land uses all contribute to its position in the city (Figure 2).

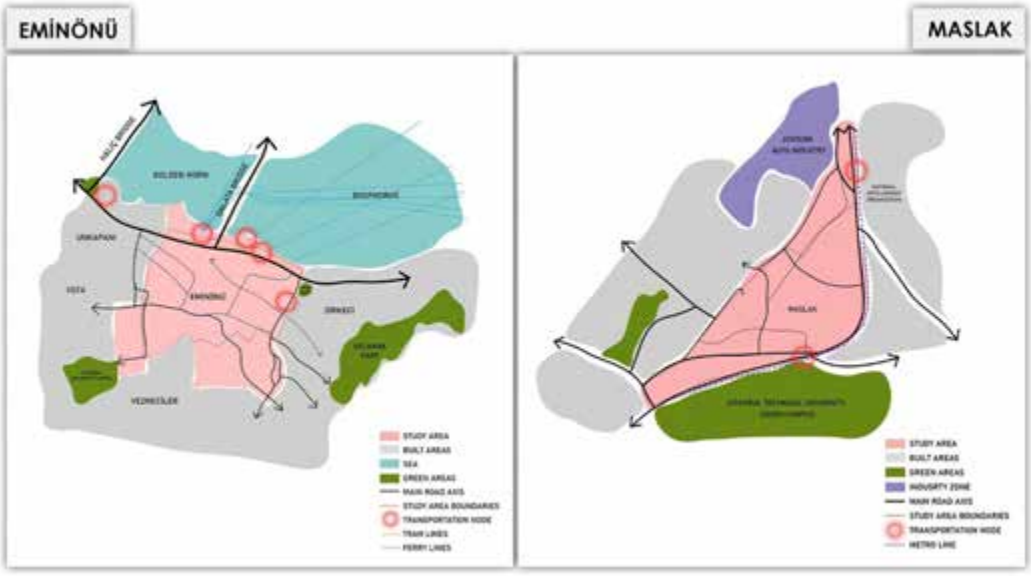

Figure 2. Environmental Relations Analyses of Eminonu and Maslak Areas

Eminonu demonstrates environmental integration through historical continuity and multimodal connectivity, whereas Maslak stands out with its vibrant and modern sector of commerce. Together, they represent distinct urban processes at various spatial scales.

Land Use

Eminonu exhibits a more complicated and layered land use pattern within a smaller space. In addition to its primary commercial purpose, Eminonu incorporates a diverse range of uses, including tourism, religious facilities, public services, and technical infrastructure. This multifunctional structure is integrated into a historical urban texture, where dense building stock and fine-grained parcelization allow for the cohabitation of many activities within walking distance. In contrast to Maslak's single mosque, Eminonu has a high concentration of mosques and religious institutions (Figure 3).

Maslak is a large-scale, contemporary business district, with land use primarily monofunctional. Commercial activity is primarily centered in high-rise office buildings and luxury plazas, with little integration of different land use functions. While the region has designated green spaces and a single religious facility, the general land use composition is simplified to support business and corporate services, representing a planned and vertical urban structure common in modern development models (Figure 3).

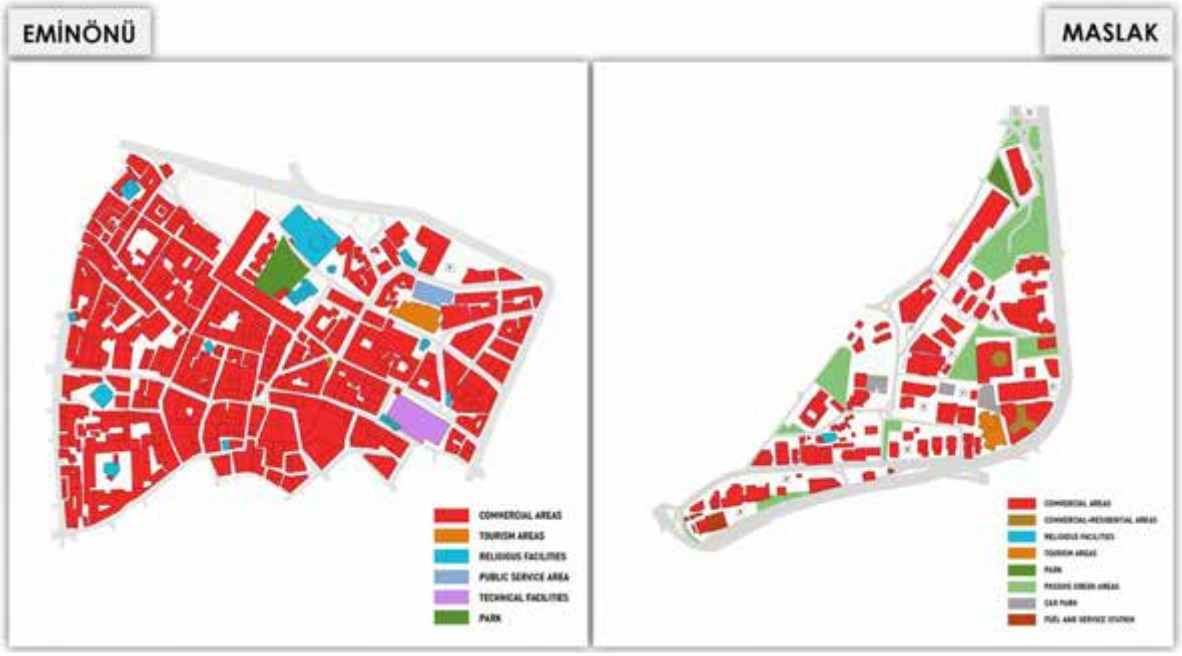

Figure 3. Land Use Analyses of Eminonu and Maslak Areas

Eminonu represents a tight, historically evolved, and multipurpose urban center, whereas Maslak displays a planned, monofunctional, and geographically large business area because of modern commercial demands.

Figure-Ground

Eminonu is characterized by a dense and closely knit urban texture in which buildings are primarily linked, resulting in continuous street frontages and enclosed block constructions. This creates a figure-ground connection in which architectural forms dominate, leaving open spaces fragmented, small in scale, and irregularly distributed. The built environment's compactness helps to create a readable and well-defined street network, with restricted yet coherent circulation paths that have evolved organically over time (Figure 4).

In contrast, Maslak's figure-ground composition is more dispersed and broken. Buildings are typically independent, standing alone on larger building blocks and surrounded by open space. This division causes a lack of continuity of the urban texture, resulting in a less coherent streetscape. Maslak's open spaces are larger in scale and more evenly distributed. The road network is also less prominent, with wider but more scattered roadways (Figure 4).

Eminonu and Maslak provide two distinct urban morphologies defined by spatial organization, construction patterns, and open space distribution. While both areas have open spaces, the scale, distribution, and connection of built and unbuilt environments differ significantly, reflecting the underlying urban logic.

Figure 4. Figure-Ground Analyses of Eminonu and Maslak Areas

Urban Elements

Eminonu offers a layered urban experience through Kevin Lynch's elements, which are paths, edges, districts, nodes, and landmarks. Its narrow, continuous streets create a dense pedestrian network shaped by the organic structure of the area. Districts in the area blend commerce, religion, tourism, and public services, forming micro-zones rooted in historical-commercial uses. Numerous nodes, such as squares and marketplaces, serve as vibrant social anchors. Historical landmarks such as mosques, bazaars, and monuments stand out in the area. The landscape in the area is concentrated in the middle parts of the building blocks (Figure 5).

Maslak reflects a modern, functionally pre-zoned urban model. Broad, vehicle-oriented streets form a legible but less human-scaled path system. Edges like Büyükdere Street act as rigid physical boundaries. Nodes are fewer and primarily serve functional roles, like plazas at business buildings' entries. Landmarks are mostly high-rise office buildings, offering visibility through scale rather than historical or cultural significance. The landscape is concentrated in the idle spaces (Figure 5).

Eminonu and Maslak represent two contrasting urban typologies. Eminonu's organic, fine-grained structure fosters a rich and immersive urban experience grounded in historical continuity and human-scale complexity. Maslak, in contrast, embodies a modern, planned environment focused on function, scale, and accessibility. Analyzing these two areas through Lynch's framework highlights the spatial, social, and experiential divides between traditional and contemporary urban forms.

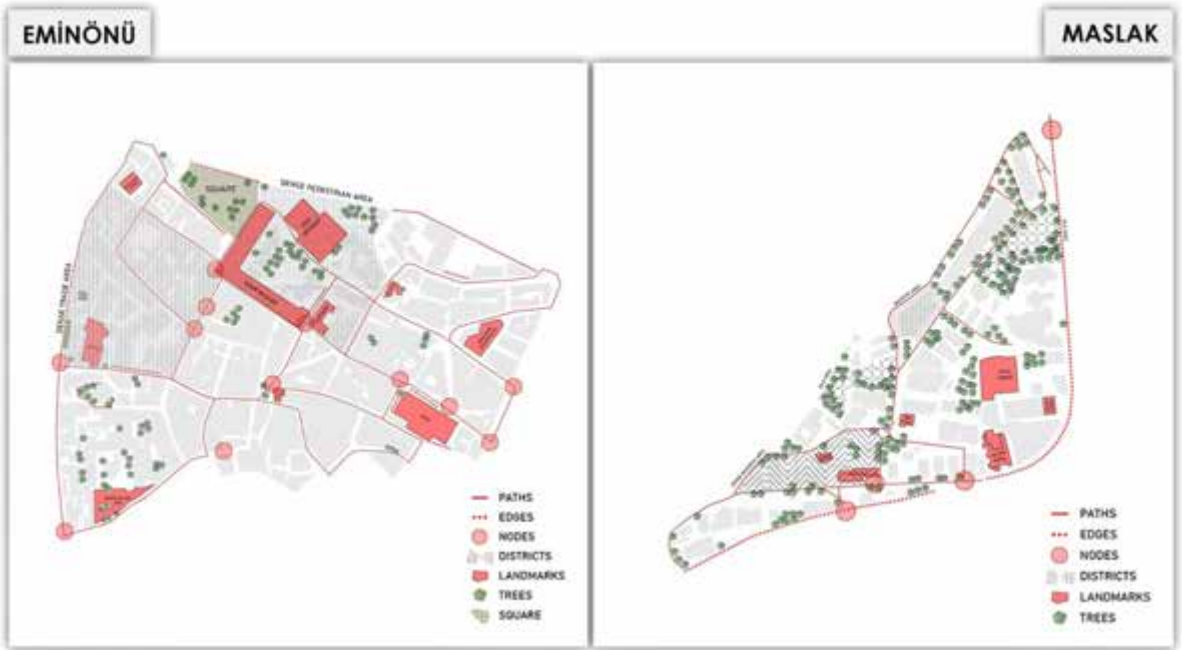

Figure 5. Urban Elements Analyses of Eminonu and Maslak Areas

Street Width

Eminonu's historic urban texture creates a narrower and enclosed street network, which includes mostly streets measuring 2 to 3.9 meters. This compactness brings buildings closer together, making visible boundaries, and encouraging and prioritizing pedestrian activity. These narrow paths promote intimacy, social connection, and accessibility. The built environment encourages walking, with street life smoothly transitioning between commerce, culture, and daily activities (Figure 6).

In Maslak, the rarest street width range in the area is 2 to 3.9 meters. The area is defined by wider streets, primarily designed to accommodate vehicular traffic. The scale of streets and buildings reflects a modernist planning approach, prioritizing efficiency, car access, and the separation of functions. This leads to a spatial environment that often overwhelms the pedestrian, where distances are longer, street crossings are broader, and public life is more dispersed. The human scale in Maslak is diminished by the verticality of high-rise buildings and the vastness of road corridors, creating an experience that feels more formal, distant, and controlled (Figure 6).

Street width in both of these areas has a significant impact not only on physical accessibility but also on urban behavior, daily rhythms, and perceived relationships between human and place. Eminonu aligns with human-scaled, walkable characteristics, while Maslak represents a more vehicle-oriented, large-scale urban paradigm.

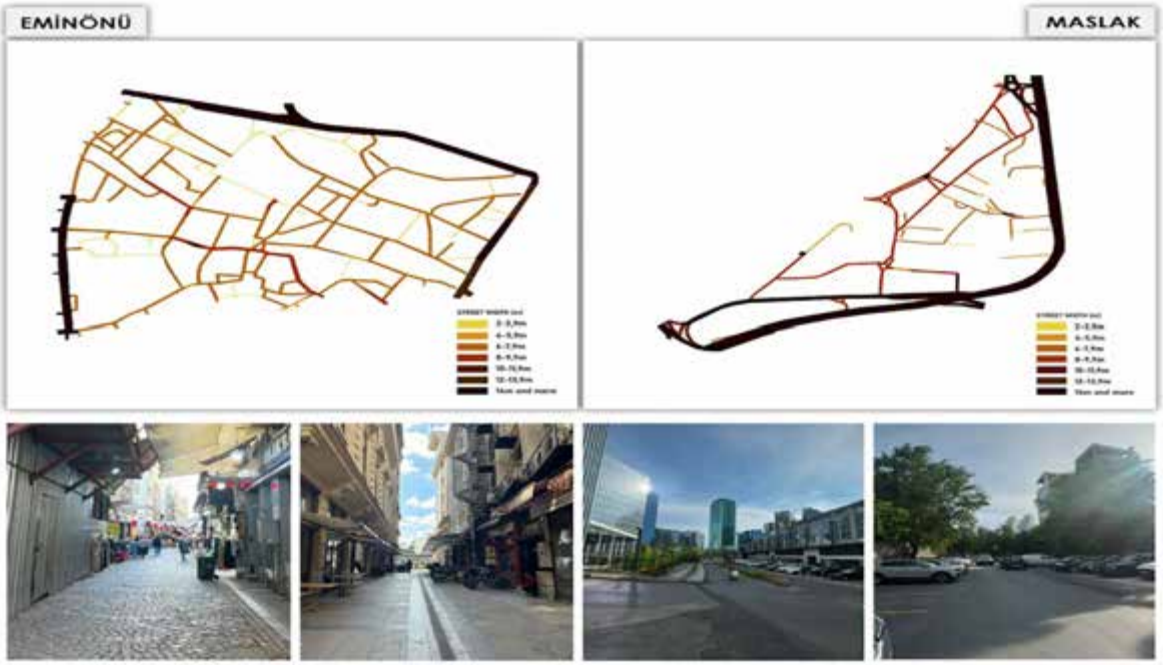

Figure 6. Street Width Analyses of Eminonu and Maslak Areas

Building Height

Eminonu represents a historically evolved urban texture defined by human-scale interactions, walkability, and spatial intimacy. Its mid-rise building stock, typically 3 to 4 storeys, supports a consistent skyline aligned with a dense street network and enclosed blocks. The compact figure-ground relationship fosters direct connections between buildings and public space, creating a layered, legible environment. Streets, squares, and built forms transition organically, shaped by centuries of incremental development. The gradual east-west height transition enhances visual harmony. Eminonu's form prioritizes connectivity, enclosure, and architectural coherence rooted in tradition and urban memory (Figure 7).

Maslak, in contrast, illustrates a modern, planned business district defined by verticality and fragmented urban form. With a wide range of building heights, from low-rises to skyscrapers, often in isolated clusters, the skyline is less cohesive in the area. Buildings are typically separated and surrounded by open space, reducing spatial continuity and pedestrian permeability. The wide roads and scattered paths prioritize vehicles, while nodes and landmarks serve functional roles rather than creating social or spatial anchors. Maslak emphasizes visibility and economic identity, but often at the cost of accessibility and urban richness (Figure 7).

The contrast between Eminonu and Maslak reveals two opposing urban models—one shaped by organic growth and human-scale design, the other by modern planning and functional zoning. Eminonu offers a compact, coherent, and pedestrian-oriented space fostering interaction and place identity. Maslak reflects contemporary urbanism focused on visibility, zoning, and monumentality, often with limited cohesion. These differences impact how space is used and experienced. Future planning can draw from both approaches, combining the experiential richness of traditional districts with the flexibility and efficiency of modern development to create more inclusive and resilient urban environments.

Figure 7. Building Height Analyses of Eminonu and Maslak Areas

Street Enclosure

Street enclosure is crucial for defining the quality of pedestrian space and influencing how individuals perceive and navigate the urban landscape. This understanding is essential for creating pedestrian-friendly environments that promote walking and social engagement (Gehl, 2011). Moreover, studies on street enclosures may assist with decisions on street design, land use planning, and public space development, leading to more vibrant and livable urban environments (Whyte, 1988). The ratio of enclosure, defined as the spatial relationship between building height and street width (Ewing & Handy, 2009), varies notably between these areas, leading to different levels of urban intimacy and openness.

Eminonu is an example of a historically complex urban setting where street enclosure is a key factor in shaping the experience of pedestrians and the character of the space. Narrow streets with mid-rise buildings, which are usually three to four stories high, interact closely to produce the area's high enclosure ratio. The average ratio in the area is 1:1 and above. This implies the field has great and high placemaking potential. Because of the intimacy and continuity created by this spatial arrangement, pedestrians can fully immerse themselves in the constructed environment. Because of its distinct boundaries and well-defined paths, the enclosure at Eminonu helps people feel safe and oriented. However, in some areas, particularly where large and continuous facades are on the narrow streets, this intensity can become overwhelming, resulting in a sense of spatial compression or visual overload (Figure 8).

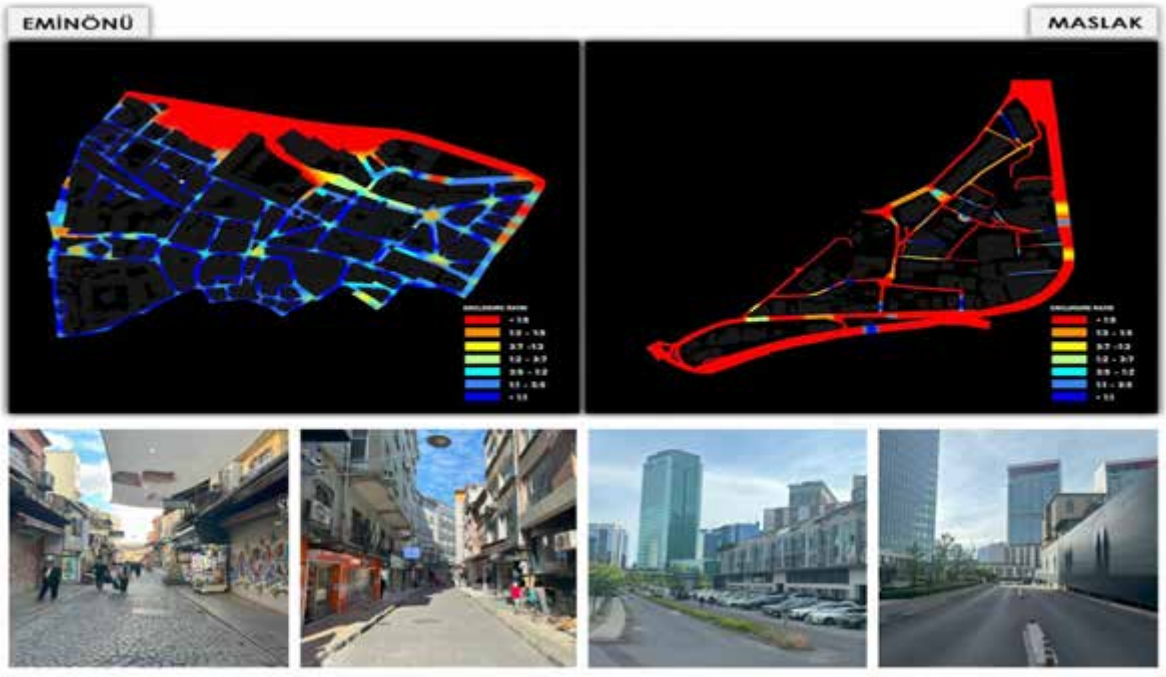

Figure 8. Street Enclosure Analyses of Eminonu and Maslak

Maslak, on the other hand, exemplifies a modern urban paradigm focusing on openness and visual permeability over its built environment. The area's street enclosure ratios are significantly lower, due to wide paths, large building setbacks, and a variety of building heights, which frequently range from low-rises to skyscrapers. As a result, many of Maslak's streets are large and exposed, which decreases the sense of place. It is observed that the prevailing ratio in the area is 1:5 and lower. This means that there is a weak and low placemaking potential in the field. Pedestrians feel disconnected from the surrounding built space, as large-scale shapes and dispersed layouts undermine the interaction between buildings and the streets. While certain parts of the area are pedestrian-centered and have more defined proportions, the area is predominantly car-oriented and fragmented (Figure 8).

Eminonu and Maslak demonstrate how street enclosure shapes urban atmosphere and user experience. Eminönü's narrow, well-defined streets foster pedestrian comfort, social interaction, and spatial coherence rooted in historical patterns. Maslak, shaped by zoning and large-scale planning, prioritizes openness and visibility but often lacks human-scale engagement. While both areas vary internally, Eminonu offers a more cohesive and emotionally resonant public realm. These contrasts highlight the role of proportion, enclosure, and building-street relationships in creating inclusive and walkable urban spaces.

The Erosion of Human Scale in Vertical Growth

The shift from historical, human-scaled urban textures to vertically extended business districts in the case areas brings out the broader phenomenon of losing human proportions in modern cities. This phenomenon, exemplified by the different development patterns in Istanbul's Eminonu and Maslak districts, demonstrates the physical and social effects of promoting vertical growth above intimate proportions, which encourages human comfort and social interaction.

Historically, urban settings like Eminonu evolved organically, with thick urban textures, building heights, and street widths that strongly resemble human proportions. These types of areas encourage walking, stimulate spontaneous social interactions, and maintain a strong feeling of place (Gehl, 2010; Jacobs, 1961). The length of streets and buildings' heights creates an enclosure that visually and physically connects people to their surroundings, promoting direction and social cohesiveness (Lynch, 1981). These features, according to Lynch (1981), are critical for legibility and psychological comfort among urban dwellers.

Maslak, on the other hand, illustrates the late twentieth-century trend toward vertical expansion and sprawling office buildings, which has radically transformed urban shape and distorted human scale. High-rise skyscrapers on large building blocks can disrupt urban continuity and limit spatial intimacy (Erkip, 2000; Kıray, 1998). This type of growth emphasizes economic efficiency while excluding pedestrian experience and reducing potential for dynamic street life (Montgomery, 1998).

The vertical expansion concept, while representing modernization and economic advancement, frequently creates spatial conditions that are alienating human interactions. Higher structures cause microclimatic effects such as wind tunnels and large shadows, which reduce outdoor comfort (Solecki et al., 2004). Furthermore, greater scale and spacing between buildings reduce the intelligibility and cohesion of urban environments, complicating navigation and lowering the sense of safety (Carmona et al., 2003).

Modern central business districts around the world have followed a similar trajectory, with a focus on automobile-oriented infrastructure and high-density vertical building (Graham and Healey, 1999). The resulting urban surroundings frequently fail to support cities' social functions, such as communal activities and cultural expression (Whyte 1980). The challenge of post-growth urbanism is to balance the needs of economic progress with the preservation and restoration of human dimensions. This includes reconsidering zoning restrictions, promoting mid-rise, mixed-use complexes, and emphasizing pedestrian-friendly street networks (Dovey, 2016). Cities can establish environments that are not only economically productive but also socially inclusive and environmentally sustainable by focusing on morphological balance and spatial quality rather than just height and density (Alexander, 1977; Gehl, 2010).

Pathways to Human-Centric Urbanism

In response to the alienating effects of vertical urban growth and the loss of human scale, urban theorists and practitioners have increasingly argued for a return to human-centric principles in urban planning. Human-centric urbanism focuses on spatial, social, and sensory elements that improve daily life. This strategy challenges growth-driven paradigms and instead promotes inclusivity, livability, and sustainability—core principles shared by post-growth urbanism (Latouche, 2009; D'Alisa et al., 2015).

Rescaling cities is an important step toward human-centric urbanism. This entails reactivating human-scale spatial proportions and ensuring that buildings, streets, and public spaces promote pedestrian mobility and interaction between individuals. According to Jan Gehl (2010), designing for "the human dimension" necessitates an awareness of people's physiological and psychological capabilities—how far we can see, walk, and gather comfortably. Mid-rise, mixed-use complexes, fine-grained urban blocks, and narrow streets with busy frontages are practical alternatives to the spatial fragmentation created by megastructures and superblocks (Carmona et al., 2003).

Another critical pathway is reclaiming and reactivating public space. The quality, accessibility, and programming of public spaces significantly shape the social life of cities. William H. Whyte (1980) famously demonstrated how small design choices, like movable chairs, sun exposure, or food kiosks, can foster spontaneous social engagement. In contemporary urban discourse, reclaiming public space also involves confronting its commodification and promoting spatial justice, ensuring that all social groups, especially those marginalized, have the right to the city (Lefebvre, 1996; Mitchell, 2003).

Another crucial approach is to reclaim and reactivate public spaces. The quality, accessibility, and management of public places all have significant effects on urban social life. William H. Whyte (1980) notably illustrated how minor design elements, such as movable seats, sun exposure, and food kiosks, can encourage spontaneous social contact. In modern urban discourse, reclaiming public space entails opposing its commodification and advocating spatial justice, ensuring that all social groups, particularly those oppressed, have the right to the city (Lefebvre, 1996; Mitchell, 2003).

Redefining the criteria for creating sustainable, safe, and pedestrian-friendly environments is required to promote human-scale concepts. Dominant planning paradigms frequently use growth measures like GDP or square meters of developed land to judge success. In contrast, post-growth urbanism emphasizes criteria like well-being, accessibility, ecological balance, and social equality (Raworth, 2017; Banister, 2008).

This paradigm change highlights the need for new planning tools and evaluative frameworks that value quality over quantity and focus on long-term resilience.

Human-centric urbanism is not a nostalgic return to pre-modern cities, but rather a forward-thinking synthesis of social, ecological, and morphological understanding. It acknowledges the city as a living organism that must be created with compassion, humility, and common sense. While the pressures of global capitalism and population expansion persist, rethinking cities at the human scale opens up new avenues for urban justice and sustainability.

Conclusion

As urban societies face the limitations of growth-driven planning approaches, the demand for spatial strategies based on human scale and experiential enrichment becomes more essential. This study indicated that the contrasting morphological layouts of Eminonu and Maslak—two different commercial hubs along Istanbul's CBD axis—provide important insights into the effects of urban form on social life, environmental integration, and pedestrian experience.

Eminonu, with its organically evolved, fine-grained urban fabric, exemplifies the enduring value of human-scale environments. Its compact street network, moderate building heights, and dense land use pattern foster a spatial intimacy that supports walkability, spontaneous social interaction, and emotional attachment to place. These characteristics align with Gehl's (2010) advocacy for "life between buildings," as well as Lynch's (1981) argument that spatial legibility and coherence enhance urban dwellers' psychological comfort. Eminonu's success in maintaining a functional and inclusive urban landscape is also a testament to the resilience of historical urban textures, where the layering of functions and diversity of uses encourage multisensory engagement and community-oriented life (Jacobs, 1961; Pallasmaa, 2005).

In contrast, Maslak demonstrates the effects of vertical expansion patterns that favor economic efficiency over physical scale. Its spatial configuration, which includes large vehicle roadways, detached towers, and monofunctional zoning, shows a modernist planning tradition that frequently ignores the human scale (Erkip, 2000; Montgomery, 1998). Although Maslak represents Istanbul's global integration and neoliberal urban agenda (Aksoy & Robins, 2011), its fragmented urban texture, reduced pedestrian connectivity, and lack of social anchors highlight the limitations of a development model that prioritizes expansion over spatial quality (Graham & Healey, 1999; Fainstein, 2010).

This study's comparative morphological analysis focuses on street width, building height, figure-ground interactions, and street enclosure (Figure 9). Eminonu's high enclosure ratios and narrow streets generate a rhythm of spatial interaction and intimacy that encourages informal interactions and promotes a sense of place (Gehl, 2010; Carmona et al., 2003). In contrast, Maslak's low enclosure ratios and building setbacks add to spatial alienation and weaken the cognitive connection with the built environment (Alexander, 1977; Whyte, 1980).

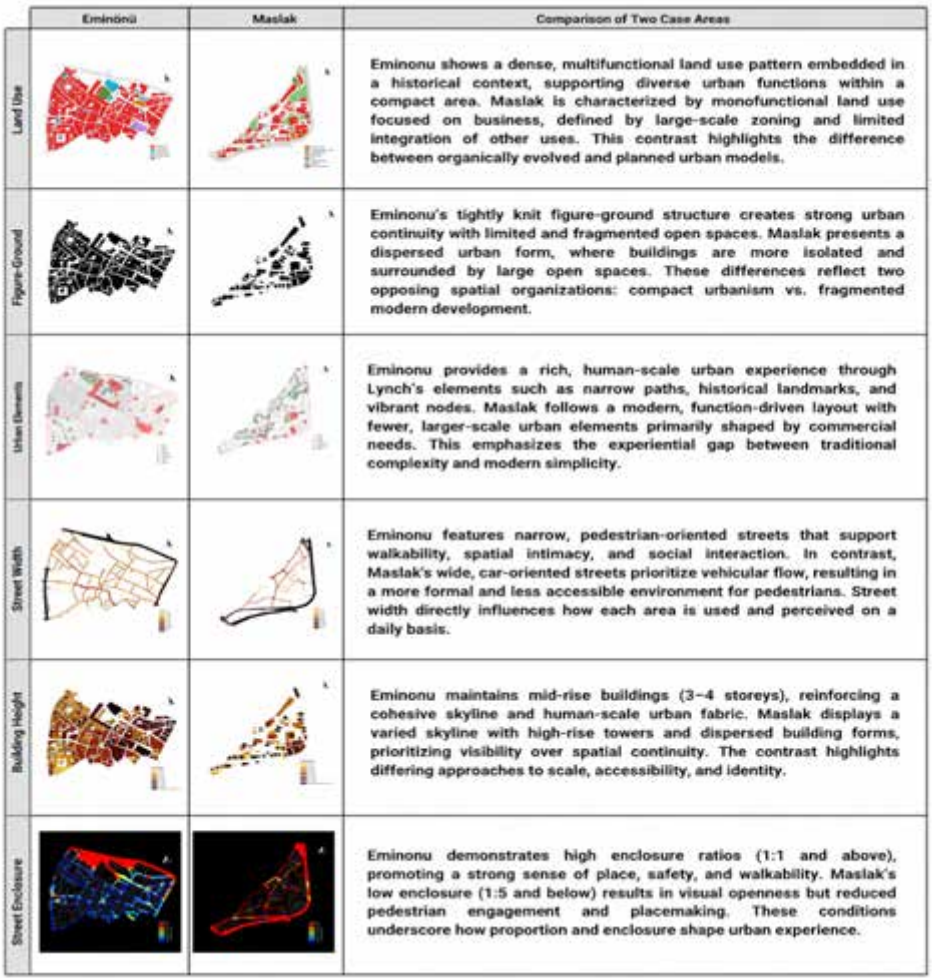

Figure 9. Comparison of Two Case Areas

From a post-growth urbanism viewpoint, these insights highlight the need to shift planning objectives away from verticality and toward ecological integrity, social inclusion, and spatial justice (Latouche, 2009; Raworth, 2017). The human scale is more than just a throwback to ancient urban forms; it is an essential design guideline for creating places that promote well-being, accessibility, and resilience. As Dovey (2016) points out, geographical complexity and morphological variation are critical for adaptive, habitable cities in a post-growth period.

The legislative consequences of this study suggest that future urban development in Istanbul and other metropolitan locations should not aim to imitate the vertical expansion of places like Maslak without critical thinking. Instead, a hybrid planning approach that draws on the morphological complexity of historical cores like Eminonu while adapting to modern infrastructure and economic needs could result in a more balanced and humane urban future. This would entail encouraging mid-rise, mixed-use projects, improving pedestrian infrastructure, preserving cultural assets, and implementing participatory design methods incorporating local knowledge (Sanoff, 2000; Healey, 1997).

Finally, reestablishing human scale in urban design entails redefining progress rather than opposing it. A city that is readable, inclusive, walkable, and emotionally engaging is more likely to be socially cohesive and environmentally responsible.

Abstract
The paper examines some results from the ongoing PRIN (Research Project of Significant National Interest) "RE-PLACE. Reframing the Place-Based Approach through Cultural Ecosystem Services of "inner areas," aimed at strengthening local communities' role in building "place knowledge". Among the three Italian inner areas addressed in the PRIN (Alta Marmilla and Gennargentu-Mandrolisai in Sardinia, Alto Medio Sannio in Molise, Madonie in Sicily), it focuses on the case study of Alto Medio Sannio, also assessing the effectiveness/ineffectiveness of tools used to date to overcome gaps and poor integration of these contexts. Particular attention is given to a current topic in these areas: the transhumance routes ("tratturi"), considered here as generating elements of a rich territorial heritage to be valorized and reproduced through autonomous local development practices.

Keywords
Inner areas, autonomous local development, territorial heritage, tratturi

Introduction

This contribution regards a reflection on the planning of the so-called inner areas, in which depopulation, emigration, social and productive rarefaction, abandonment of the land, are distinctive phenomena. Shaping a new role for inner areas requires forms of community and the arising of new subjectivities that rely on forms of direct democracy (Magnaghi, 2020), reconstructing the places of living and promoting the synergic connection between local economies (Bruni, Zamagni, 2015).

In particular, we analyse the first results of the ongoing PRIN (Research Project of Significant National Interest) "RE-PLACE. REframing PLace-based Approach through the Cultural Ecosystem services of inner areas"[1]. It aims to strengthen the role of local communities in building "place knowledge" and territorial heritage also through the innovative lens of Cultural Ecosystem Services (CES), which represent non-material and/or socio-ecological benefits that people gain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, aesthetic experiences, and cultural and educational values (Chan *et al.*, 2012; Andersson *et al.*, 2015).

The project investigates three Italian inner areas (Alta Marmilla and Gennargentu-Mandrolisai in Sardinia, Alto Medio Sannio in Molise, Madonie in Sicily) and promotes a multi-scalar approach, based on a co-evolutionary perspective on the interplay between human settlement and the environment. It is oriented to understand and maximise the resilience of marginalised territories, to build alliances and collaborative processes and to promote place-making developed by communities.

In detail, the contribution focuses on the case study of Alto Medio Sannio inner area, made up of 33 small municipalities (many of which with less than 1,000 inhabitants) between the Molise provinces of Isernia and Campobasso, some of which border the Abruzzo region. The research path is designed to support the expression of the autonomous local development practices based on the continuous reproduction of territorial heritage. It

1 The PRIN "RE-PLACE", funded by the Italian Ministry of University and Research, is coordinated by the Research Unit of the University of Cagliari (PI prof. Anna Maria Colavitti), and involves the Research Units of the University of Palermo (Associated PI prof. Annalisa Giampino) and of the University of Molise (Associated PI prof. Luciano De Bonis) to which all the authors are affiliated.

is intended to capture the critical issues of some ongoing experiences in the area which are aimed at reducing the fragility of marginalised contexts, also identifying the ineffectiveness of the tools that until today have perpetuated the gap and the poor integration of these contexts.

First of all (see section 1), we position our research within the EU "place-based" approach, which in the Italian context is fully articulated through the SNAI (National Strategy for Inner Areas). However, our approach diverges significantly from the EU and national frameworks by embracing a self-organising paradigm. This paradigm is rooted in some key findings from resilience studies within ecological and socio-ecological disciplines, as well as the fundamental concept of territorial heritage, a cornerstone of the Italian territorialist school.

Then (see sections 2 and 3), in alignment with the objectives of the PRIN "RE-PLACE", we identify the key components of the territorial heritage within the study area, combining the non-sectoral nature of the territorialist approach to heritage with the notion of Cultural Ecosystem Service. Emphasising the critical role of CES in environmental planning, we additionally outline the envisaged participatory mapping activities in the area, designed to progressively and self-organisingly shape appropriate actions for the preservation and enhancement of territorial heritage.

Finally (see section 4), we dedicate particular attention to a very popular and current topic in these areas: the "tratturi system" (territorial system of sheep tracks), ancient transhumance routes which today are considered important elements of the heritage to be valorised. These elements, from a multifunctional perspective, are considered by us to be latent resources for self-sustainable development that takes into account the benefits that ecosystems provide to the inhabitants of the area.

1. Inner Areas between marginality, fragility and resilience

The Territorial Agenda 2030 (Aa.Vv., 2020) emphasises the importance of the "place-based" concept (De Bonis, 2021). However, unlike the term territorial cohesion, it does not offer a clear or explicit definition. It is reasonable and logical to infer (De Bonis, 2021) that the interpretation of "place-based" frequently mentioned in the Territorial Agenda aligns with the framework developed by Barca (2009) for the EU and thoroughly taken up in the EU's place-based approach (Barca *et al.*, 2012). This approach highlights the critical role of a place's social, cultural, and institutional characteristics while also acknowledging the need for external political interventions. The latter aim to address underutilized endogenous potential and social exclusion caused by the unwillingness or incapacity of local elites. In essence, it incorporates top-down measures as a vital component of territorial cohesion policies (De Bonis, 2021), in order to overcome internal barriers that obstruct territorial development and innovation processes (Barca, 2009).

The National Strategy for Inner Areas (SNAI in Italian), established in 2013 at the conclusion of Barca's tenure as Italy's Minister for Territorial Cohesion, is inherently a direct extension of the EU's place-based approach, which Barca himself pioneered in 2009. As a result, it also incorporates the use of top-down initiatives. Moreover, its primary objective is to recognise the vulnerability of places and communities while enhancing the delivery of essential citizenship services to address depopulation effectively (Lucatelli *et al.*, 2022).

Beyond an "indirect" limitation — which aligns with the same "deficiency" Ugo Giusti (1938) identified in the INEA research on the depopulation of Italian mountain areas — namely the attempt to address the anorexia of peripheral regions without simultaneously tackling the bulimia of central areas (Giacchè, 2019:41) — we believe that a more "direct" evaluation of the Strategy is needed. Specifically, this pertains to the effectiveness of the partially top-down, place-based approach of the SNAI to areas considered as "fragile" (De Bonis, 2021).

It is clear, however, that in order to conduct a more direct assessment, we first need a reference definition of "fragility". The latter is often regarded as the opposite of resilience, in turn a term which, although belonging to a relatively defined semantic field, assumes markedly different meanings depending on the context in which it is applied. In an ecological or socio-ecological context, resilience, as defined by Holling (1973), refers to the ability of a system to persist by absorbing changes and disturbances while maintaining consistent relationships between populations or state variables.

With specific reference to socio-ecological systems, resilience refers to the system's ability to absorb disturbances, adapt, and reorganise while undergoing change, ensuring it retains its core functions, structure, identity, and feedback mechanisms (Walker *et al.*, 2004).

Considering that we are discussing territorial systems, which we align with socio-ecological systems (SES) (De Bonis 2023a; De Bonis, Ottaviano 2024a), precisely to specific subsets of social systems where certain interdependent relationships among humans are mediated through interactions with non-human entities (Anderies *et al.*, 2004), we regard the previously mentioned definitions of resilience as equally applicable to territorial SES. Highlighting that the potential fragility (lack of resilience) of the latter, as with all SES, can be particularly critical due to their state of "perpetual dynamism" and "continuous adaptation" (Gunderson, Holling, 2002), driven by the complex interactions between the human species and the environment that define them (De Bonis, 2021). With specific reference to such a criticality, it is also worth highlighting that Gunderson (2000) associates resilience with an emergent property of ecosystems, stemming from their self-organising behaviours over time.

In other words, the more territorial SES exhibit self-organisation, the more they behave in a "non-fragile" way. We can consequently posit that the effectiveness and relevance of policies concerning these systems can be assessed by their ability to promote and enhance the emergence of self-organising properties within such systems (De Bonis, 2021).

Without hastily concluding that the SNAI is entirely ineffective in reducing the fragility of the territorial systems it targets — which is one of its primary goals — it can nonetheless also be asserted that its risk of ineffectiveness increases significantly when its inherent top-down component becomes dominant (De Bonis, 2021).

In contrast, such a risk tends to disappear within the territorialist approach, due to its focus on the concept of territorial heritage. This heritage is understood as the result of long-term co-evolutionary processes involving a wide range of social actors and their interactions with the environment (Magnaghi, 2017). It includes not only the particularly significant portion of resources that constitute it, and also embraces the socio-cultural environment, the *milieu* (Dematteis, Governa, 2005), as well as productive knowledge, the arts, and more (Magnaghi, 1998).

2. Territorial heritage and CES

The process of reconstituting virtuous co-evolutionary relationships between communities and environments is necessarily linked to a more general reconsideration of the way of understanding the relationality between the human and non-human components of socio-ecological systems.

The recent trend towards forms of "ecologically oriented" economy brings with it utilitarian and extractivist visions of non-human biological and biophysical elements, which materialise in market approaches (pure or in some way assimilable to them) to the relationship between human societies and ecological systems (De Bonis, Ottaviano, 2024b).

Among the objectives of the "RE-PLACE" research project is the identification of elements of territorial heritage through tools other than those that guide market approaches in order to be able to use them as a key to critically reading the actions and governance planned for these territories within the National Strategy for Internal Areas. The ultimate aim is to outline new approaches to a new shared knowledge of Inner Areas, capable of enabling processes of territorial reproduction of systems.

The "RE-PLACE" project, through a range of territorial and ethnographic analysis methods, analyses the different "knowledges of place" and territorial heritage as a key factor for local development of the subjects (local communities, inhabitants, local associations, public actors, etc.), allowing to explore territorial heritage as a key factor for local development from different points of view.

The non-sectoral nature that is the foundation of the territorialist approach to heritage can also be profitably integrated by the notion of Cultural Ecosystem Service.

As a paradigmatic class of service, Cultural Ecosystem Services have emerged as a concept around which researchers and policy makers can understand ecosystems in terms of their life-enriching and life-affirming

contributions to human well-being, and represent a salient example of how culture is more generally accepted as an important "variable" in the work of environmental managers and planners (Satterfield *et al.*, 2013 in Fish *et al.* 2016). The idea that the ecosystem approach can improve and innovate traditional methods of planning collective services is gaining consensus in the scientific debate. The introduction of new performance criteria in terms of ecological-environmental, social and cultural supply would allow us to evaluate the multiple benefits that ecosystem components and urban biodiversity can bring to local communities (Colavitti *et al.* 2024).

CES can be a source of "deep attachment" in communities (Chan *et al.* 2012) and access points for public engagement and concern in environmental issues, thus helping to build broader public support for ecosystem protection (Daniel *et al.*, 2012 in Fish *et al.* 2016) and, potentially, to support those processes of reconstitution of co-evolutionary relationships between communities and environments based on virtuous forms of relationality. Moreover, recognising the intrinsic link between territorial heritage and the concept of cultural landscape as provided by UNESCO[2], but overcoming the UNESCO exclusive focus on the "outstanding universal value" (De Bonis *et al.* 2024), it can be considered that, among the benefits that ecosystems generate for human societies, their cultural value cannot be ignored, even in the dimension of «ecosystems' contributions to the non-material benefits (e.g. capabilities and experiences) that arise from human-ecosystems relationships» (Chan *et al.*, 2012:9).

Although their value in the assessment of ecosystem services is generally less recognised, it should be noted that while «locally degraded provisioning and regulating services may be substituted by socio-economic means (e.g. drinking water from a polluted well can be replaced by bottled water), [...] the cultural values of an ecosystem or a landscape are irreplaceable» (Plieninger *et al.*, 2013:118).

Some authors (Plieninger *et al.*, 2013) argue that definitions of most categories of cultural services are vague, and it is therefore difficult to rigorously establish significant relationships between ecosystem structures and functions and the satisfaction of human needs and wants (Daniel *et al.*, 2012 in Plieninger *et al.*, 2013), having to also consider that cultural services do not represent purely ecological phenomena, but rather are the outcome of complex and dynamic relationships between ecosystems and humans in landscapes over long time spans (Fagerholm *et al.*, 2012 in Plieninger *et al.*, 2013).

According to Plieninger (2013), a greater awareness of cultural ecosystem services can be relevant for nature conservation and sustainable land management — and therefore to support those territorial reproductive processes based on virtuous co-evolutionary relationships between local communities and the environment, the importance of which we have underlined — because they are directly experienced and intuitively appreciated by people, unlike what often happens with regulation and support services (Daniel *et al.*, 2012; Schaich *et al.*, 2010), and because they are generally enjoyed in "packages", thus potentially helping to overcome the tendency to design in relation to single ecosystem services.

The "RE-PLACE" project aims to fill some of the gaps identified in the literature through a participatory mapping of the entire range of cultural ecosystem services perceived by local populations in the inner areas under study[3]. The challenge is to understand whether CES can be integrated into the planning processes of inner areas through the active involvement of settled communities that have developed an "adaptive resilience" (Davoudi, 2012) towards a context of progressive abandonment and who with their daily practices reinvent these spaces through a co-evolutionary nature-culture process.

The "RE-PLACE" project then aims to investigate, analyse and map informal local development practices promoted by inhabitants. The ongoing results derive from a combination of mapping exercises, semi-structured interviews and questionnaires, also analysed with statistical and GIS-based techniques. On the one hand, we are advancing the detailed definition of the investigation tools for the Alto Medio Sannio area, on the other we are

2 Particularly the "continuing landscape" where evolutionary processes remain ongoing, while simultaneously displaying significant material evidence of their historical development over time (UNESCO, 1992).

3 Mapping CES requires connecting local communities' perceptions of place. This goal can be achieved by collecting data from interviews and mapping conducted on representative samples of the settled community. CES mapping has been extensively studied in recent years. However, methodologies for spatial analysis of CES are still weak due to problems related to data quality and evaluation, which make it difficult to accurately determine their catchment area (Colavitti et al. 2024).

experimenting with the investigation tools refined on the basis of prior experiences. Notably, in the workshops in Sorgono (Sardinia, Gennargentu-Mandrolisai area), where in March 2025 the entire RE-PLACE research group convened with the local communities. By posing targeted questions rooted in the CES framework a community map was created, where each participant identified the places he considered most significant.

Similarly, through some questions that are starting to be submitted to the communities of Alto Medio Sannio, the aim is to build over time a patrimonial base to understand which actions can be activated for the self-sustainable development of the territory.

3. Alto Medio Sannio, the hinge of biodiversity

Figure 1 - The Verrino Valley afrom a viewpoint in Agnone. Ph. Francesca Giangrande, 2024.

Alto Medio Sannio is the largest inner area in Molise. It extends in the central-northern sector of the Molise Region, south of the provinces of Chieti and L'Aquila and is made up of 33 municipalities[4] belonging to the two provinces of Campobasso and Isernia, with Agnone as the lead municipality of the area. The Alto Medio Sannio area has a total population of 28,835 inhabitants (2023) with a population density of 30.62 inhabitants/km^2. The most populous municipalities are Agnone (4,679 inhab.), Frosolone (2,830 inhab.) and Trivento (4,360 inhab.), while the smallest one — not only of the area but of the whole Molise — is Castelverrino with only 98 inhabitants. The area is affected by significant demographic problems: population data by Istat indicate that between 1994 and 2023, the area has overall lost 28.1% of its resident population, presenting an average annual decrease rate of

4 For the province of Campobasso, the municipalities of Castelbottaccio, Duronia, Lucito, Molise, Montefalcone nel Sannio, Montemitro, Roccavivara, Salcito, San Biase, Sant'Angelo Limosano, Torella del Sannio, Trivento are included; for the province of Isernia the municipalities of Agnone, Bagnoli del Trigno, Belmonte del Sannio, Capracotta, Carovilli, Castel del Giudice, Castelverrino, Chiauci, Civitanova del Sannio, Frosolone, Macchiagodena, Pescolanciano, Pescopennataro, Pietrabbondante, Poggio Sannita, Roccasicura, San Pietro Avellana, Sant'Angelo del Pesco, Sant'Elena Sannita, Sessano del Molise, Vastogirardi are included. In the programming cycle 2021-2027, compared to the cycle 2014-2020, the composition of the area has changed as it has seen the municipalities of Civitacampomarano, Limosano, Montagano, Petrella Tifernina, San Felice del Molise leave and those of Molise, Montemitro, Sant'Angelo Limosano, San Biase, Torella del Sannio join.

1.1%. During the period above, the municipalities that recorded a greater average annual loss are San Biase (with -58.7% in 29 years) and Castelbottaccio (with -56.3%). People aged over 80 represent 11.4% of the total residents of the Area, while those under 14 represent 9.3%. The high presence of the population over 80 clearly photographs the incidence of aging within the area.

The lowest percentage is in Pescolanciano (8.6%) while the highest is in Castelbottaccio (23.2%). Demographic data also confirm that the Municipalities of Agnone, Frosolone and Trivento, in addition to having the largest number of residents, have an economic and social dynamism that makes them the major centers providing district services.

Alto Medio Sannio is a naturalistic and historical "hinge" territory between the Sannio Collinare (hilly) and the Abruzzo Apennines with great potential for territorial development offered by a landscape rich in biodiversity and the presence of historical values. It goes from 300 m of sinuous panoramas drawn by the Trigno river up to the 1,730 m of Monte Campo. As part of an historical-cultural heritage, the area features several remains of the Samnite territorial civilisation , first of all the Italic site of Pietrabbondante. Furthermore, there is a rich museum heritage, almost a single still visible trace of what has crossed the territory for years, and the cultural events are also numerous. Certainly, to date, a weakness that emerges from the analysis is that there is a poor recognition and valorisation of the aforementioned territorial heritage.This area also presents geomorphological and hydrogeological degradation despite having good agricultural potential demonstrated by current production.

It is a fact that this territory has undergone, like most of the Italian inner areas, a process of marginalisation that has lasted more than a century with all the consequences that this entails (delayed development, reduction in the use of the very rich natural-cultural heritage, reduction in job opportunities, de-anthropisation, partial reduction of cultural identity). The depopulation of young people and families and the consequent process of population aging, associated with low population density, determines a strong impact on the fixed costs for the provision of services and infrastructures. The Alto Medio Sannio Area Strategy (fund FESR and FSE+ programming cycle of 2014-2020) focused on welfare interventions; however, it emerges that this policy have little effect on reducing fragility if it does not take into account some specific local experiences – current or latent – of heritage valorisation, which demonstrate the virtual capacity to create favourable conditions for the generation of CES and self-organising processes of more intimate and strong interconnection between local communities and territorial resources (Ottaviano, De Bonis, 2023), for a process of land care, which however lack a systemic vision. What could this vision be?

4. The system of sheep tracks ("tratturi")

Figure 2 - Shepherd on the Lucera-Castel di Sangro sheep track in the municipality of Pescolanciano. Ph. Francesca Giangrande, 2024.

As regards the deepening of this contribution with respect to the whole of the territorial heritage and the CES, a relevant sub-theme that is emerging from the mapping is that of the system sheep tracks ("tratturi"), recognised and perceived by the people who live in the cultural landscape of the Alto Medio Sannio as territorial elements that can potentially provide intangible cultural benefits. The network of so-called "tratturi" constituted the link for the summer-winter movement of flocks that moved from mountain pastures to those in the plains and vice versa, making the economy of the Abruzzo-Molise Apennines interdependent and complementary with that of the Apulian plain.

Plausibly, transhumance was the generator, or one of the main co-generators of the territorial, and therefore also landscape, structure of Mediterranean Europe (De Bonis, 2023b). The civilisation of transhumance allowed the development of agriculture, trade and craftsmanship, which flourished in the area. In Agnone, for example, the copper tradition was carried on for centuries, linked above all to the presence of the rivers, which lasted from the Middle Ages until 1970, the year in which the San Quirico Ramera (artisanal copper company) was closed. In 1400 there was a coppersmith for every three houses, dense workshops that reached 171 in 1700, and as many as 8 foundries that employed over 500 people. Today the only remaining trace of this activity is the Ramera Gerbasi in Agnone, where the seventh generation works the copper; a symptom that craftsmanship is little appreciated among young people who, for various reasons, no longer dedicate themselves to this profession. The survival of Ramera Gerbasi is paradoxically linked to the digital world, since they have a strong connection to the foreign import-export market. A similar fate has befallen agriculture, where it is even more difficult to innovate; this sector still has a high relevance but has difficulty in reconverting and raising the quality of products and/or innovating in well-defined sectors (including supply chain sectors).

Forestry is also at risk from modern and contemporary development processes in inner areas. In general, a co-evolutionary approach between human settlement and environment, aimed at understanding and maximising the resilience of inner and marginalised territories, has diminished and weakened. Let's observe this phenomenon from a particular point of view: the system of "tratturi".

In environmental and naturalistic terms, the system of sheep tracks is inserted within two other elements of the landscape of significant importance such as agricultural crops and woods. For centuries, the transhumance routes have represented the only infrastructures for communication and economic and social exchange between populations, so much so that some more recent inhabited centres still show their dependence on the course of the sheep tracks. This ecosystem is a unique and rare example of the strong bond between traditions, people and territory (Cicoira, 2016). The infrastructures of the transhumance landscapes do not coincide with the wider set of transhumance landscapes, to which they primarily belong; in addition to the infrastructural elements, landscapes also include further elements of the built environment – like taverns, fountains, churches (Meini *et al.*, 2018), but also small urban agglomerations, watering holes, boundary markers and milestones built along the network (Di Martino *et. al.*, 2006) – and above all they are constituted by the agro-forestry and settlement structures co-generated by the transhumant practice, well beyond the lands directly occupied by it (De Bonis, 2023b). The castles in Molise, for example, are arranged orthogonally to the path of the tratturi, with major centres supported along the ridge path of the reliefs emerging between the two main watercourses (Trigno and Biferno) and with the smaller centres (of promontory) arranged in clusters, in a geologically and morphologically suitable position but reachable from the first (Cerasoli, Cordoni, 1998 in De Bonis, 2023b). This is a settlement structure that can simultaneously take into account the constraints imposed by the need to easily reach the tratturi on the one hand, and the need to place the settlements in sufficiently safe areas on the other (Cerasoli, Cordoni, 1998 in De Bonis, 2023b).

Summarizing the history of the evolution of the tratturi, it has to be said that the Romans were the first to institutionalise transhumance (Meini *et al.*, 2018 in De Bonis 2023b), by imposing the payment of a certain fee to the tax authorities. But the phenomenon of transhumance, and the territorial civilisation connected to it, has much more distant origins; according to Salmon (1967 in De Bonis 2023b) the *calles* that crossed Roman Sannio were not only used in pre-Roman times by the Samnites and the Sabellian peoples of central Italy, who in the winter months drove their animals (especially sheep) long distances towards the pastures of the plains, but they also date back to the Iron Age if not the Bronze Age, as archaeology has demonstrated. It is highly probable that the basis of the tratturi development was a model of seasonal nomadism of human groups which, already in the prehistoric phase, they had exploited those characteristics to activate a "hunting nomadism", which

would later transform into pastoral nomadism, due to the progressive climate warming that determined the vegetation transformation of valley and mountain environments starting from 15,000 years ago (Minelli, 2015 in De Bonis 2023b). On the other hand, it is certain that, after the acquisition of large portions of *ager publicus* by the Romans following the Samnite, Pyrrhic and Punic wars, pastoral activities in Samnium increased in comparison to agricultural ones. At the "price" however of having to pay from then on for the use of pastures that were previously freely available (De Bonis, 2023b). The Normans, after the early medieval pause caused by the barbarian invasions, contributed to the flourishing rebirth of pastoral activity, generally recreating political unity and re-establishing the necessary conditions of security (Meini *et al.*, 2018 in De Bonis 2023b). The Angevin rulers established the so-called Dogana della Mena delle pecore, with significant contextual expansions of the pastures, with the aim of stabilising and increasing the tax revenue that derived from it (Musto, 1964:10 in De Bonis, 2023b). The institutionalization process reached its peak with Alfonso V of Aragon, until 1806 when the Dogana was suppressed with the law promulgated by G. Buonaparte of dissolution of all the constraints and easements of the Tavoliere (De Bonis, 2023b).

The pasture was then closely linked to the culture of transhumance and denigrated specially in the era of the affirmation of private property, as reported by the historical scholar Mattia Iorillo (2025)[5] that stated that the construction of a strongly negative imaginary of the transhumant world was imposed with the spirit of the Enlightenment, which has produced the demonisation of civic uses, of common lands and obviously of those tratturi, which with their spatial transversality were natural enemies of private property, of field closures and agricultural rationality. Thus, although transhumance continued in other forms even after the Second World War, the breaking of the routes of the "sheep kingdom" decreed a marginalisation of territories ancestrally suited to that type of exploitation. First with the Bourbons, with the Fascism (with the battle for grain and the construction of a "very rural" Molise) then, until the modernisation processes a secular world, cultural and natural together, was broken. And also, as Potito d'Arcangelo noted, the "cosmovision" of the transhumant shepherd modeled on the "phasic movement of natural cycles and movements along the sheep tracks", in return, it gave it "the ability to leave a mark, to transform places profoundly". Herein lies, once again, the most emblematic and real character of the tratturo throughout the modern age and on the borders of contemporaneity. Its contextual nature, of evolution and transformation in an environmental continuity made up of human and animal relationships. Those that practically disappeared at the dawn of the twentieth century, leaving the great void of Molise (Iorillo, 2025).

The Alto Medio Sannio area is crossed by the Celano-Foggia, Castel di Sangro-Lucera, Sant'Andrea-Biferno-Ateleta "tratturi", and by the Pescolanciano-Sprondasino-Castel del Giudice "tratturello". As described in the Wide Area Environmental Landscape Plan of Alto Molise, the landscape is characterised by roads, fortifications, villages, hill areas whose environmental characteristics are determined by different groups of houses and agricultural agglomerations, by the land division, by the compromised hydrogeological situation and by the network determined by the torrential channels, and from the intensive use of cultural and natural resources of the territory concentrated in the municipalities of Agnone, Belmonte del Sannio, Poggio Sannita, Castelverrino.

Since, as previously mentioned, one of the objectives of the "RE-PLACE" project is the analysis of the ways in which SNAI has been implemented in the study areas, also with specific reference to its relations with planning and governance, an in-depth study was carried out regarding actions and tools that have as their object the sub-theme of the "tratturi" system. We have therefore taken into consideration a current area planning tool that is considered complementary and synergic to the Alto Medio Sannio Area Strategy, *i.e.* the project "Sviluppo turistico lungo i tratturi - recupero e valorizzazione del percorso tratturale; incentivazione e potenziamento dell'offerta turistica" (Tourism development along the sheep tracks - recovery and enhancement of the sheep track; promotion and enhancement of the tourist offer) foreseen in the "Contratto Istituzionale di Sviluppo" (Institutional Development Contract) and financed by the Development and Cohesion Fund 2014-2020, which is included among the context measures of the Area Strategy for the programming period 2014-2020. Analysing this tool allows us to corroborate the idea that the Strategy has limitations in capturing the regenerative practices of self-government of inner areas, still focusing too much on single-sector interventions imposed from above that do not take into account the landscape evolution of Molise.

In this context, in March 2024 the Masterplan for the recovery of the Molise sheep tracks was presented by the Stefano Boeri Architetti studio, involving 59 municipalities (Campodipietra is the lead municipality) and the Land

5 https://www.iltascabile.com/letterature/vie-erba-vuoto/

Reclamation Consortium "Sud Bacino Moro-Sangro-Sinello e Trigno" with the aim of recovering, protecting and enhancing the tratturi and the events related to them, with specific actions aimed at the tourist development of the territory through the historical-cultural and artistic recovery of the villages crossed by the "tratturi". As stated in the intervention planning document of "Contratto Istituzionale di Sviluppo", the intention is to launch joint actions aimed at safeguarding the landscape and the "tratturi" heritage, focusing attention on dedicated tourist-cultural itineraries, with particular attention to minor destinations and the recovery of public assets attributable both to the "minor heritage" – typical local traditional buildings (villages, farmhouses, refuges, etc.) and artefacts related to local network systems (shepherd's houses, watering holes, crossings, etc.) – that to the "valuable cultural heritage" – historical-artistic emergencies (monasteries, castles, villas), all divided into two axes of intervention; axis 1 – tratturi; axis 2 – villages.

The Alto Medio Sannio area, as delimited by SNAI, is not mentioned in the Institutional Development Contract but is addressed by the project with interventions of both axis 1 and axis 2. For axis 1, a variety of interventions are planned, from marking the tratturi path by installing adequate trail signs and new wooden fences, to the restoration of equipped rest areas, to the reconversion of cultivations to tratturi soil (meadow), to clearing, deforestation, reclamation, restoration of rows, to the creation of horse/cycle paths equipped with various aids such as adapted tandems and electric wheelchairs (*buggy bike*), to the arrangement of the former loan quarry of the Chiauci dam, to the restoration of connecting roads with the villages, to the interactive tourist signage and signage equipped with QR-Codes for sites of interest etc. Interestingly, for the municipality of Civitanova del Sannio the project envisages allowing the maintenance of the tratturi by entrusting it to farmers who have located their agricultural-livestock businesses in the same areas crossed by the "tratturo", practicing grazing of their animals aimed at promoting the cleaning of the tratturi area. While for the maintenance of the structures (equipped rest areas, tourist boards, wooden bridges, etc.) that have been located mainly in the vicinity of homes, the use of the so-called "Administrative Barter" is proposed, which provides for interventions entrusted on a project basis to citizens who request to compensate the tax burden with their own performance through interventions of urban decorum, recovery and reuse, with purposes of general interest, of unusable areas and real estate.

Another intervention that we consider relevant is in the Fonte le Frassi district where there is a village of 8 wooden houses built in 2002 following the earthquake and currently used by a single family unit that occupies one of the structures. With small restoration and adaptation interventions, the project foresees a tourist accommodation function or the creation of small points of sale of local products and a possible support point for demonstrations and events along the "tratturi" axis. For axis 2, the architectural redevelopment and urban recovery of some villages and hamlets is planned, promoting the existing historical-cultural and environmental-landscape heritage, the restoration of the Transhumance house of Frosolone to create a refreshment point and museum, the creation of an artistic path that uses the exhibition of elements of traditional copper art of Agnone etc., the redevelopment of a building in Pietrabbondante to be used as a Multipurpose/Cultural Centre, the redevelopment of the San Basilio staircase and the recovery for recreational and cultural purposes of the municipal building, former ERP (public residential construction) building in Salcito, the redevelopment of the former ECA (Municipal Welfare Agency) building in the historic centre of Lucito for rural tourism accommodation purposes, the recovery of the properties available to the municipality of Trivento for hospitality purposes and the adaptation of their accessibility, the adaptation of the former school of Poggio Sannita to Casa della Salute (House of Health), and so on.

Of considerable interest is the securing of a municipal building in Montagano for the creation of a socio-cultural center for which attention will be paid by the operators and the Municipality in continuous and interactive reference with the responsible subject, to integrate and improve the offer in relation to the relationships already in place with national and foreign tour operators, and to the forms of collaboration and cooperation with the help of various subjects, such as schools and universities, including institutional ones such as the Superintendency, the Molise Region, etc. The intervention of the Masterplan appears impressive to us, it involves 236 km of "tratturi", 38 km of "tratturelli" and 39 km of "bracci" (secondary routes), it includes the creation of 7 starting and finishing gates (Castel del Giudice, San Pietro Avellana, Montalto, Rionero Sannitico, Sepino, Gambatesa, Santa Croce di Magliano), to then be divided into 36 intermediate stages.

The ambition of the Masterplan is to equate the tratturo to an ecological corridor, as a result of a rigorous application of topographic rules that give it a specific configuration and geometry, recognisable in the pattern of ancient and modern signs of the landscape. Therefore, this proposal, although it is the first of such a global

nature that concerns the tratturi, seems to ignore the current state of the tratturi system and does not question enough the self-reproducibility of the system, imposing from above a series of specific interventions that do not involve local agents, with the exception of the municipalities. In February 2024, there was an autonomous initiative by scholars and citizens to meet in Sepino to create a civic committee that would work alongside the institutional control room, but the proposal for discussion remains evanescent to date, considering that the project is still in the embryonic stage.

It is implied that slow tourism acts as a driving force for increasing employment and against demographic impoverishment but, as Nunzio Marcelli, a breeder-entrepreneur who practices transhumance, claims in an interview (14 March 2024)[6], there is concern that it will turn into the usual opportunity to announce a title, and that the funds will then be used without contextualisation, which happens when the planners insert a single component that leads to the decontextualisation and nullification of a useful opportunity to bring these territories back to playing a leading role in sustainable development. On the other hand, there is an interesting phrase repeated several times within the "Contratto Istituzionale di Sviluppo" programming document that would suggest an attention to the theme of coevolution, that is that the "path of the ancient tratturo" can therefore offer visitors unique landscapes, colours and atmospheres, in which the "evident man-nature binomial becomes evidence of the measured use of the territory and its resources". Another interesting aspect is present among the objectives of the Masterplan, namely the definition of guidelines for the management of the "tratturi", with new methods

of public-private co-management with the relaunch of the role of the agricultural operator as a central figure for the maintenance of the characteristics of the "tratturo" over time. The Masterplan documents do not specify how this objective can be achieved.

Conclusions

Figure 3 - Evidence of tratturo Celano-Foggia in Alto Medio Sannio. Ph. Francesca Giangrande, 2024.

There is no doubt that signs of innovation are emerging in Italy; a multi-scalar, co-evolutionary approach between human settlement and environment, aimed at understanding and maximising the resilience of internal and marginalised territories, at building alliances and collaborative processes and at promoting place-making developed with communities, animates practices and processes initiated at different scales and in different

6 https://www.amolivenews.it/2024/03/14/progetto-cis-tratturi-molisani-nunzio-marcelli-opportunita-imperdibile-per-rendere-attrattivo-il-territorio/#google_vignette

territorial contexts, not only within the SNAI (De Vita *et al.*, 2021). The approach of the "RE-PLACE" project implies the need to support the (re)discovery of ancient and new forms of local knowledge which allow the continuous adaptation to the mutability of environmental contexts and whose loss undermines the effectiveness of interventions implemented in more recent times. It also encourages the establishment of new relations between human societies and non-human environmental elements that allow the continuous generation of innovative local knowledge (De Bonis, Ottaviano, 2024a). The matching between the growth of "place awareness" of local communities and the identity characteristics of the heritage make possible to produce "territorial added value" (Magnaghi, Dematteis 2018) based on visions, strategies and tools and on new forms of self-government of territorial commons, namely place-specific values and resources, sedimented over time.

In this contribution we have analysed the critical issues of the SNAI and the EU place-based approach, suggesting to pay particular attention to the interpretation of territories as socio-ecological systems, and consequently to the importance of the concept of fragility/resilience and of self-organising properties in "marginal" territorial SES. We have also put forward a hypothesis for triggering a multifunctional regeneration process of the transhumance landscapes (De Bonis, 2023b) in the inner area studied in the PRIN "RE-PLACE", in particular through the valorisation of the heritage system of the tratturi, considered not in isolation but as a whole, and according to more collaborative and cooperative trajectories than those currently dominant. In recent decades, globalisation and socio-economic forces have affected not only production dynamics but also the co-evolutionary relationship between communities and territories, leading to important changes in the ways of working, consuming and socialising. The weakening of relationships, which had consolidated the process of community place attachment and the formation of civic consciousness and sense, influences citizenship practices and the production of places. It is therefore essential to restart, especially in areas that suffer the marginalising effects of the aforementioned globalising dynamics, processes of retro-innovative re-establishment of self-organising relationships between human and non-human entities of territorial SES, intrinsically and simultaneously conservative and regenerative of territorial heritages.

With reference to the Molise case study of the PRIN "RE-PLACE", and in particular to one of its most relevant heritage elements, it can be concluded that if there must exist a system of sheep tracks, made up of paths, stops, mown meadows, natural areas, villages, pastoralism, agriculture, civic uses, which also have a value (at different intensity) such as CES, that is, as a producer of biodiversity, bearer of aesthetic values, sense of place, cultural heritage values, recreation and ecotourism, spiritual values, educational values, places of social relations, places of inspiration, cultural heritage values for communities, should be recognised by the local communities themselves, according to a true place-based approach, restoring the autonomous initiative of all local and translocal subjects who wish to participate in the self-government of sustainable development.

Lastly, the "RE-PLACE" project attempts to build new languages, the result of the dialogue between expert knowledge and contextual knowledge, for which experts should be able to get involved in the construction of "co-knowledge". The evaluation approach of the CES is not objective, but rather related to that of a "socially constructed value practice" (Ernstson, Sorlin 2012). We believe that knowledge of CES is relevant and allows us to have a sufficiently clear picture to set up a truly sustainable and fair policy that aims at restoring eco-social balance. The growing reference to the local dimension of well-being has opened the horizon of the subjective investigation of its perception and its construction (Magnaghi, 2020). Starting from participant observation and design interaction with social practices, it is possible to develop an adequate evaluation tool that has as its objective the maintenance and regeneration of territorial SES.

Abstract
Over time, the Québec government has granted municipalities broad monetary levy powers. While these do not ensure full financial autonomy, they enable revenue diversification, reduce reliance on property taxes, and support policy goals like combatting climate change and land speculation.

However, many cities hesitate to use these powers, often keeping tax rates low and depending on new developments for growth. To address this, the City of Mascouche sought the services of our team, resulting in a 2025–2030 Strategic Revenue Plan.

This paper outlines the methodology used to prioritize over 25 fiscal tools. It presents evaluation criteria and details the municipality's selected measures. While these decisions reflect trade-offs between fiscal potential and environmental efficiency, administrative simplicity and legal risk played a dominant role in decision-making.

Keywords: local finances, cities, ecological taxation, municipalities, Québec

Introduction

Over the years, the Government of Québec has granted Québec municipalities extensive monetary levy powers. Aiming to enhance their autonomy and recognize their role as proximity governments, the provincial government provided municipalities with general taxation and regulatory charges powers in 2018 (Tremblay-Racicot et al., 2023). In 2023, additional powers were introduced, enabling municipalities to vary property tax rates based on different sectors or any characteristic of the property assessment roll, excluding the property's value.

Although these new powers do not render municipalities fully financially autonomous, they allow diversification of revenue sources and reduce dependence on property taxes (Federation of Canadian Municipalities, 2024). They also offer opportunities to achieve various public policy objectives, such as mitigating or adapting to climate change, combating land speculation, or promoting a circular economy, through ecofiscal measures or by making property taxes more progressive. For instance, municipalities can impose regulatory charges targeting major traffic generators to encourage transportation management plans, tax vacant land or buildings, address underdensity through floor area ratio taxes, or impose higher tax rates on luxury properties ("monster houses") and lower rates on denser housing or areas with vulnerable populations.

In a pre-electoral context, many municipal officials and managers are questioning how to prudently use these new legislative powers, particularly as cities have historically tended to keep tax rates low while relying on new property assessments to grow their tax base. To address this, the City of Mascouche, located in Quebec, sought the services of our research team to assist in identifying and planning fiscal measures to prioritize over the next five years. This collaboration resulted in the December 2024 submission of a 2025–2030 Strategic Revenue Plan, offering recommendations to guide the City in prioritizing and phasing the deployment of fiscal tools (Tremblay-Racicot et al., 2024).

This paper aims to showcase the novel methodology developed to identify priority measures among over 25 documented fiscal tools. It is divided into five sections: 1) Presentation of the approach and methodology; 2)

Mascouche's fiscal and financial profile; 3) Eco-tax measures; 4) Measures enabled by the new powers of Bill 39; 5) Summary of recommendations and timetable; 6) Conclusion.

Presentation of the approach

In the spring of 2024, the City of Mascouche debuted a process aimed at diversifying its revenue sources and making use of under-utilized monetary levies, particularly in the area of eco-taxation. Drawing on its expertise in municipal taxation, and more specifically in the innovative use of new monetary powers by Quebec municipalities, a team from the Centre de recherche sur la gouvernance (CERGO) of the École nationale d'administration publique (ENAP), led by Professor Fanny Tremblay-Racicot, was commissioned to support the town in identifying and planning the fiscal measures to be prioritized over the next five years.

The resulting Strategic Revenue Plan makes recommendations to enable the city to document the prioritization and phasing of the fiscal tools to be deployed. As the analysis of the various measures, their prioritization and the timetable were carried out in collaboration with representatives of the town's various departments. Because the decision of adopting a strategic revenue plan was based on the need of diversifying the municipalities' revenue sources, our team validated this perceived issue by first carrying out an analysis of its fiscal and financial profile, which is presented in the next section.

As for the recommendations included in the plan, they were based on a co-construction process (3 work meetings and e-mail exchanges over a period of 6 months) conducted with the city representatives. This process allowed for the identification, prioritization and phasing of measures to be implemented under two areas of intervention: eco-taxation and new taxation powers arising from Bill 39 (B39) on municipal taxation.

Prioritization criteria

The choices were made jointly by the research team and representatives of the municipality's departments on the basis of the four dimensions explained in the following paragraphs: fiscal potential, sound administrative management, acceptability and equity, and environmental performance.

Fiscal potential

The purpose of this dimension is to evaluate the growth and sustainability of a financing tool's net revenues. To be able to generate net revenue growth that ensures the sustainability of financing, the tool must be able to rely on a sufficiently broad tax base, have growth potential on this base, and have some leeway on the levy rate, without undermining the city's fiscal competitiveness. This dimension is assessed on the basis of the criteria listed below. It should be noted that a preliminary assessment presenting a range of potential revenues is also included in the analysis of this criterion. This range has been estimated by the units responsible for the Town of Mascouche.

Evaluation criteria

- Does the tax base involve a number of taxpayers or a monetary flow or stock large enough to ensure short-term revenues that can be considered significant? (Tax base width);
- Does the tax base have a reasonably foreseeable growth potential in the medium and long term? (Growth potential);
- Considering Ville de Mascouche's tax competitiveness, can the current levy rate on this tax base be considered as already high? (Margin for manoeuvre on the levy rate).

Sound administrative management

This dimension relates to the technical and legal issues that can influence the applicability and efficiency of implementing a financing tool.

Choices regarding the selection and phasing of a measure will be made on the basis of its administrative simplicity and the savings in human and technical resources it entails, its efficiency, the principle of "the right levy for the right service", and the user-pays principle, which can help optimize resource allocation. In addition, coherence with other measures and objectives of the City is taken into account. This dimension is assessed on the basis of the following criteria.

Evaluation criteria
• Would an additional levy on this tax base require resources, whether in terms of fixed assets, operations or tax compliance, the cost of which can be considered high or even prohibitive? For example, is the collection process compatible with the current method of managing the tax account? (Administration costs);

• Is the measure based on the user-pays principle? In particular, does the measure make it possible to increase the financial participation of certain categories of taxpayers whose consumption of public services exceeds the municipality's production costs? (User-pay);

• In the short term, are the data or technology required to implement the measure available and applicable according to current practices at Ville de Mascouche? (Applicability);

• Does the measure contradict any regulations or policies currently in force at Ville de Mascouche? Does the measure require the creation of a new regulatory regime or a modification of existing regulations? (Coherence)

• Does the measure present a risk of legal challenge?
Does the measure reinforce the provisions of the Ville de Mascouche's Strategic Plan for Sustainable Development (Strategic Plan).

Acceptability and equity
The purpose of this dimension is to assess the social acceptability and equity issues of financing tools, particularly with regard to the ability of businesses and residential taxpayers to pay. This dimension was assessed on the basis of the following criteria.

Evaluation criteria
• Would the measure receive a higher level of approval from the population than could be expected from a tax levy? (Perception);
• In principle, can a taxpayer reduce or even avoid the levy by modifying his or her behavior? (Availability of alternatives);
• Does the measure have a greater financial impact on vulnerable people? (Vulnerable population)
• Does the measure make it possible to reasonably increase the financial participation of legal entities or individuals with a greater ability to pay? (Ability to pay);
• Does the measure make it possible to target certain categories of taxpayers who have benefited in recent years from a favorable tax transfer? (Temporal equity);
• Does the measure potentially have a greater impact on taxpayers in certain sectors of the municipality?
• Where applicable, does the measure have an effect on housing affordability (Affordability).

Environmental efficiency
This dimension aims to assess the potential of measures in terms of dissuading or encouraging those subject to them to change their habits to adopt environmentally-friendly behaviors. Where applicable, this dimension is evaluated on the basis of the following criteria.

Evaluation criteria
• Is the measure the most appropriate means of achieving the environmental objective? (Relevance);
• In principle, does the measure offer the potential to optimize land use or favor compact forms of land development? (Land use);
• In principle, does the measure offer the potential to enhance the area's attractiveness or direct growth towards already more urbanized areas to curb urban sprawl? (Attractiveness);
• In principle, does the measure have the potential to contribute to the resilience of ecosystems (Resilience);
• In principle, is the measure likely to encourage land use that is conducive to sustainable mobility (Sustainable mobility);
• In principle, does the measure make it possible to internalize negative environmental externalities, or to involve the generators of nuisance financially? (Polluter pays).

Methodology
The financing tools identified for each of the two axes (eco-taxes and measures arising from PL39) were analyzed on the basis of the criteria presented above. The relevant information for each tool was collated in an analytical sheet (found a Supplementary Document), and the results were grouped together in a summary table (Appendix A) and a phasing grid for measures to be prioritized (example presented in Appendix B).

The purpose of analytical framework is to analyze the main advantages and disadvantages of the financing tools identified in the following sections. To do this, an evaluation was carried out for each measure on each of the criteria, which means that the potential subjectivity inherent in such a process must be taken into account. The analysis framework generally used to limit this type of bias is the multicoder method, in which several people carry out an independent evaluation on the basis of a pre-defined analysis grid (example presented in Appendix C). This method achieves a level of inter-coder reliability, a criterion that enables the analysis grid to be validated. This method then enables a conciliation process between coders based on a deliberative process to determine which codes are not unanimously supported by the coders. This method does not completely eliminate subjectivity, but it does greatly reduce its risks. Following the analysis carried out by the two principal investigators from the CERGO team, a working session was held with the Mascouche team to validate the results obtained.

Mascouche's fiscal and financial profile
On January 21, 2021, Amyot Gélinas Conseils inc. presented the Town of Mascouche with a report analyzing the municipality's fiscal and financial situation. The Amyot Gélinas Conseils team made two main observations: 1) a lack of revenue diversification, resulting in a property tax overcharge, particularly for residential units; and 2) little room for manoeuvre with regard to property tax rates to remain competitive with rival towns.

Against this backdrop, the Town of Mascouche has undertaken to diversify its sources of revenue in order to strengthen its financial stability and share the tax burden more equitably among the various categories of taxpayers. The Town has implemented the following measures:

- A 3% increase in real estate transfer tax for all taxable income in excess of $500,000;
- A contribution to infrastructure and equipment during the construction of real estate projects, also known as a "development levy". The city also has agreements with real estate developers for the infrastructure required for development, a contribution for park purposes, and a contribution for affordable social housing.
- A special general property tax rate for buildings with six or more units;
- A special property tax rate for industrial and non-residential buildings;
- Special property taxes for debt servicing, social or family housing funds, regional files and public transit and rail;
- Fees for waste collection, water and sanitary sewer services;
- Compensation for snow removal in certain sectors;
- A special property tax for sanitation in certain sectors.

The tax picture shows that the Town makes effective use of the powers at its disposal in urban planning matters. It is even in the vanguard when it comes to developers' contributions to the financing of municipal infrastructure and strategies for financing social and family housing. What's more, no value-for-money issues have been identified.

The purpose of this report is to analyze other possibilities for diversifying the Town of Mascouche's sources of revenue in order to share the tax burden even more equitably and achieve certain environmental objectives.
Financial profile

The Ministère des Affaires municipales et de l'Habitation (MAMH) publishes an annual financial profile of municipalities. This profile provides financial and fiscal data, ratios calculated from this data, and comparisons with different groups of municipalities. Indexes are also presented, enabling comparisons between municipalities for a given year. Among the various indicators published, three appear to be relevant for analyzing Mascouche's fiscal situation:

• Non-residential standardized taxable assessment, which establishes the share of property wealth occupied by businesses and industries;
• The overall tax rate (TGT), which measures tax pressure, i.e., the percentage ratio of tax levies applied to taxable properties over the total value of these properties; and
• The proportion of operating expenses financed by the general property value tax. This last indicator measures dependence on property taxes.
Table 1 shows the distribution of these three indicators for Mascouche, the municipalities in its population class, its MRC and its administrative region, as well as the results for Quebec as a whole.

Table 1: Ville de Mascouche compared with its peers on three financial indicators

	Nb.	Standardized taxable assessment non-residential (%)	Overall tax rate (TGT) Per $100 of assessment (%)	Financing of operations by property value tax %
Mascouche	1	9,7	0,9681	65,0
Population class	35	15,4	0,9095	59,4
RCM	2	11,3	1,014	61,4
Administrative region	57	10,0	0,9550	57,6
All of Quebec	1104	14,6	0,8994	52,3

Source: MAMH, Financial Profile 2023.

Analysis of this data reveals three main findings:
• The tax base for non-residential buildings is much lower in Mascouche than elsewhere.
• The overall tax rate (TGT) is higher in Mascouche than in municipalities of comparable size, but fairly similar to the average for the administrative region.
• Property tax financing is higher in Mascouche than elsewhere, accounting for 65% of operating revenues. This observation justifies the pursuit of revenue diversification and an analysis of the various possibilities open to the Town.

Comparison with neighboring towns
In order to take into account the context of fiscal competitiveness in which budget planning takes place, Mascouche should also be compared with neighbouring towns. The table below includes the towns of Blainville, Terrebonne, Saint-Eustache, Repentigny, Varennes and Mirabel. Four indicators are presented: the ratio of residential to non-residential property wealth, property tax revenues from residential to non-residential properties, the average tax burden of dwellings and the ratio of non-residential to residential tax rates.

Table 2: Ville de Mascouche compared with its neighbors on four financial indicators

	Residential vs. non-residential property wealth (%)	Residential vs. non-residential property tax revenues (%)	Average tax burden on housing ($)	Average non-residential vs. residential tax rate ratio (no. of times)
Mascouche	90	73	2 750	3,2
Average	84	61	2 378	3,5
Blainville	89	71	2 767	3,3
Terrebonne	88	72	3 019	2,8
Saint-Eustache	80	56	2 182	3,1
Repentigny	90	73	2 828	3,3
Varennes	74	37	1 997	4,7
Mirabel	83	54	1 472	4,0

Source: MAMH, Financial Profile 2023; Municipal budgets

An analysis of these data reveals five main findings:
• The share of property wealth derived from residential assessment units (90%) versus non-residential units (10%) is greater in Mascouche than in comparable neighboring towns. Only Repentigny has a similar share.
• The ratio of residential property taxes (73%) to non-residential taxes (27%) is higher in Mascouche than in comparable neighboring towns, with the exception of Repentigny (73%), Terrebonne (72%) and Blainville (71%), where the level is similar. As a result, property tax revenues are heavily dependent on residential properties.
• The share of property wealth generated by residential properties (90%) is greater than the share of tax revenues that the city derives from them (73%). It is possible to observe a tax transfer from residential to non-residential properties, which helps to alleviate some of the burden on Mascouche residents.

• At $2,750, the average tax burden per dwelling is higher in Mascouche than in most comparable neighboring towns, but lower than its direct neighbors Blainville ($2,767), Repentigny ($2,828) and Terrebonne ($3,019). Taking into account the context of tax competitiveness, the level of taxation on housing is close to the threshold.
• At 3.2 times the average residential rate, Mascouche's average non-residential tax rate is slightly below the average of comparable neighboring towns (3.5 times). Only Varennes (4.7 times) and Mirabel (4 times) have a significantly higher level. Considering the context of tax competitiveness, the level of taxation of non-residential buildings is also close to the threshold.

Implications for the Strategic Revenue Plan
The above findings suggest a number of implications for the present Strategic Revenue Plan:
• The scope for increasing property tax revenues remains limited, since it already occupies a significant share of revenues, the level of tax burden on residential assessment units is close to the threshold limit, and high rates are already applicable to non-residential properties.
• To establish a strategy for diversifying the municipality's revenues, the search for a fairer distribution of the tax burden is to be favoured.
This search for balance can be achieved through the following principles:
• Making greater use of the user-pays principle wherever possible, in particular so that taxation better reflects the intensity of use of municipal services.
• Involve the generators of nuisance and other negative externalities to a greater extent in financing the city.
• Optimize the value of properties already served by municipal infrastructure.
• Target certain categories of taxpayers who have benefited from favorable tax transfers in recent years.
• Modulate tax effort according to ability to pay.

Definition of Eco-fiscal measures
The eco-fiscal measures analyzed in this Strategic Revenue Plan represent a municipal levy based on a pollutant, product or service that deteriorates the environment or results in a levy on natural resources (Tremblay-Racicot et al., 2023). Ecofiscal measures dissuade or encourage those subject to them to modify their habits, unlike more coercive measures that force certain changes in behavior or usage. Thus, other types of instruments, including regulation or prohibition, subsidies, standards and awareness programs, can be addressed, but only within regulatory regimes financed by a tax or charge. The three categories of levy analyzed in eco-taxation are pricing, general power to tax and general power to levy regulatory charges.

Pricing
In the economic sense, pricing is the establishment of a contribution related to the production costs of a service, based on the user-pays principle. It should be pointed out at the outset that the Act respecting municipal taxation (LFM) presents a specific definition of pricing that departs from the classic economic definition. In fact, the MTA also considers a property tax based on a characteristic of the building other than its value, such as its surface area, its frontage or any other of its dimensions, to be a tariff. The MLA also broadens the concept of user-pay, since a fee must be related to the benefit received. This notion of benefit received includes not only the benefits derived from the use of a service, but also those arising from its availability, regardless of its consumption. For the purposes of this report, we focus on defining two forms of pricing permitted by the LFM, but distinct from a property tax:

1) The first form is a fee charged to the owner or occupant of a building for the use of a service. For example, a fee could be linked to the number of lifts of a residual materials bin, or the total weight of residual materials disposed of by a property assessment unit. Another example could be the number of cubic meters of drinking water consumed by the assessment unit. In this case, to set a rate, the municipality must be able to accurately establish the cost of a service and the consumption of this service by the various assessment units on its territory. The tariff will be the price which, once multiplied by consumption, will balance revenues with the costs of the service.

2) The second form is a one-off or subscription-based compensation for the use of a good or service, or for the benefit derived from an activity. For example, this could be an annual fee for water or waste billed to the municipal tax bill. In this case, the municipality must be able to establish precisely the costs of a service and the number of assessment units where the service is available. The fee will be set by dividing the costs by the number of units. It will then be equivalent to the average cost of the service per unit served.

General taxing power
The general taxing power (GTP) allows local municipalities to impose any direct tax on their territory, and to provide for any exemption or criteria under which the amount or rate of this tax may vary. Unlike the General Regulatory Levy Power (GRP), which is intended to fund a regulatory regime, taxes adopted under the TMP are primarily intended to generate general revenues to be paid into a municipality's general fund, although they may also be dedicated to a service. Municipalities must, however, respect a number of exclusions, including the main tax fields already occupied by the governments of Quebec and Canada. In addition, municipal taxes cannot be applied to the State, its agents and public and parapublic organizations, thus excluding hospitals, schools and national museums, for example. Insofar as the rate and amount levied can vary according to certain criteria, in addition to being accompanied by exemptions, the tax can send a price signal that encourages or discourages certain behaviors or uses by those subject to it, whether legal entities (businesses) or individuals (citizens). Taxes therefore also have the potential to help achieve environmental objectives. GTP could, for example, be used to levy a tax on the use of, or the right to use, an asset. For example, a TMP could be used to levy a tax on paved surfaces, a tax on land use coefficients, or a tax on vehicle registration.

General Regulatory Levy Power
In contrast to a tax, which is used to raise general revenues for the municipality, the main purpose of a General Regulatory Levy Power (GRP) is to finance a regulatory regime under municipal jurisdiction. Thus, although it may resemble a tax, a regulatory levy is different in nature from a tax; it must serve to finance a regulatory regime (a program, a service, an infrastructure, etc.) or, through the level of the levy, it must aim to encourage or dissuade certain behaviours on the part of those subject to it (Tremblay-Racicot et al., 2020 : 30). Whether it is intended to finance a service or influence behaviour, a regulatory fee must be linked to a complete and

detailed regulatory regime. The person subject to the charge, whether a legal entity or an individual, may be the beneficiary of the regime, or the person whose activities make it necessary. In Quebec, a special fund must be set up to hold exclusively the sums collected through the levy. Moreover, since the sole purpose of a regulatory royalty regime must never be to raise general revenues, the associated fund must not generate significant or permanent surpluses, unless the regime is intended to influence behaviour.

The GRP shares a number of exclusions with the GTP, including the inability to apply to the State, its agents and public and parapublic organizations. On the other hand, the distinct nature of the royalty gives it the advantage of being similar to an indirect tax. As a result, the three exclusions provided for in the GTP do not apply to the GRP. It is therefore possible to levy a charge: 1) in respect of the supply of a good or service; 2) on the presence of an individual on the territory of the municipality; and 3) on a person using a public road, within the meaning of article 4 of Code de la sécurité routière (chapter C-24.2) or in respect of equipment placed under, on or over the public road to provide a public service.

The measures under consideration for the eco-fiscal intervention axis are divided into five areas of activity, depending on the objective pursued:
- Urban planning and development
- Reducing drinking water consumption and improving soil permeability
- Sustainable mobility
- Reducing the quantity of residual materials sent to landfill
- Air quality and GHG reduction

New taxes arising from Bill 39's new powers
In addition to eco-fiscal measures, a series of new possibilities were also included in the analysis. The Act to amend the Act respecting municipal taxation and other legislative provisions, Bill 39, was assented to on December 8, 2023. It is part of the new partnership between the Québec government and local governments. The resulting measures are intended to help modernize municipal taxation by giving municipalities new fiscal powers and greater flexibility in the use of existing fiscal powers.

Varied property tax rates by sector/areas of the municipality
It is now possible to apply differentiated taxation by sector. This system can be used to encourage densification in certain sectors, or to support other economic situations (e.g., downtown revitalization or major work on a commercial artery). Sector prime rates must not deviate by more than 33.3% from a uniform rate, which must correspond to the average of sector rates weighted in proportion to the total assessed value of each sector. In concrete terms, the uniform rate corresponds to the base rate that would apply if the local municipality did not use sector-based taxation. The sectors concerned must be defined when a new assessment roll is filed. However, to enable a greater number of municipalities to apply this new power, a transitional measure allows the municipal territory to be divided into sectors for any roll in effect on January 1, 2024.

Extend the use of varied property tax rates to residential properties and remove constraints limiting the number of non-residential sub-categories

To encourage sustainable land development through targeted tax rates, municipalities may now determine separate rates applicable to residential properties, or to sub-categories chosen by the municipality. Separate rates must fall within a range of 66.6% to 133.3% of the prime rate. For example, such a measure could encourage densification by allowing a lower tax rate for buildings with more than one dwelling unit. For the sake of concordance, certain adjustments have been made to the provisions relating to non-residential buildings. For example, there is no longer a limit on the number of non-residential sub-categories that may be established by municipalities. These sub-categories must be defined prior to the filing of a new assessment roll. It should be noted that the preliminary roll, which was previously mandatory for the creation of non-residential sub-categories, now becomes optional.

Increase the maximum tax rate applicable to serviced vacant lots
Since 2001, a municipality has been able to set a rate of up to twice the prime rate (residential rate) for properties in the vacant land category served by water and sanitary sewer services. Local municipalities may now set a special rate for serviced lots of up to four times the prime rate.

Allowing the imposition of a property value tax on vacant residential units
Municipalities may now impose a tax on the property value of buildings containing a vacant or underutilized housing units for residential purposes. The tax rate applicable to vacant or underutilized dwellings may not exceed :
• 1% when the municipality begins imposing the tax;
• 2% when the municipality has been imposing the tax for at least one year;
• 3% when the municipality has imposed the tax for at least two consecutive years.

This power applies to buildings containing at least one dwelling unit that is not occupied for a minimum of 180 days a year by the owner, a relative or another occupant, in the latter case by virtue of a lease, including a sublease. In addition, to be subject to the tax, a dwelling must have certain characteristics. In addition, exemptions from the tax are provided for social and affordable housing.

Public transit regulatory charge
This new power enables all local municipalities to finance the costs of public transit infrastructure, equipment and operations through a dedicated development charge. The fee could be charged in a variety of ways, including when a permit is issued for construction or renovation work. Municipalities are empowered to define, by bylaw, the various parameters for implementing the charge, such as the calculation method, the rate and the sectors that would be subject to it. To ensure consistency with the development charge, the Minister of Municipal Affairs has the regulatory authority to exempt persons from payment of the transportation charge and to specify the types of work subject to it. Also, until such time as this regulation is enacted, the Act provides that a transportation charge cannot be levied in respect of social and affordable housing.

Allow local municipalities and MRCs to impose a vehicle registration tax to finance public transit, and empower the Société de l'assurance automobile du Québec (SAAQ) to enter into collection agreements.

Municipal laws have been amended to allow local municipalities in whose territory a public transit corporation has jurisdiction under the Act respecting public transit corporations, and RCMs that declare jurisdiction over public transit, to impose, by bylaw, a tax on the registration of any passenger vehicle in the name of a person whose address entered in the SAAQ register corresponds to a location within their territory. This tax must be earmarked for financing public transit. The by-law of the municipality or MRC must indicate the amount payable. Such a tax cannot be imposed on the territory of a local municipality that is part of the Communauté métropolitaine de Montréal (CMM), nor on the territory of Saint-Jérôme, since the CMM already has such a power on the territory of the Autorité régionale de transport métropolitain.

Summary of recommendations
As discussed earlier, these tools were selected based on a diagnostic assessment of the City's financial profile and four prioritization criteria: (1) fiscal potential; (2) sound administrative management, including legal risks; (3) social acceptability and equity; and (4) environmental efficiency.

The report puts forward three types of proposals:
• Measures **to be prioritized**, the design and deployment of which should be undertaken in the short term;
• Measures **under study** between 2026 and 2030, which could eventually be implemented, but which should not be prioritized due to strategic or management imperatives; and
• **Non-recommended measures** that have been discarded, as others are preferred to them based on the analysis of results.
Recommendations are described in the next paragraphs. For the sake of this paper, only the measures to be prioritized or under study are presented (excepted for Sustainable mobility). They are grouped under 8 categories:
• Urban planning and development
• Reducing drinking water consumption and improving soil permeability

• Sustainable mobility
• Reducing the quantify of landfill waste
• Air quality and greenhouse gas (GHG) reduction
• Varied rates by building category
• Varied property tax rates by sector
• Other provisions of Bill 39

Urban planning and development
Recommended measures
- Analyze the introduction of a **tax on the floor-area ratio** (FAR).
The purpose of this tool is to increase the financial contribution of businesses and industries whose buildings occupy a land area below a certain threshold, in order to maximize their use. A tax on the floor area ratio could be applied to any owner of an assessment unit belonging to the non-residential building category or the industrial building category that is served by a municipal water and sewer service and has a floor area ratio of less than 20%. The results of the analysis show that the measure receives a very favourable or favourable evaluation on all four dimensions studied. In addition, Mascouche estimates a 30% loss of revenue resulting from under-occupation of the ground for buildings that could be affected by the measure. Particular attention, both financial and administrative, will need to be paid to the geomatics tools required for deployment and annual data updating.
- Analyze the introduction of a **tax on non-vegetated surfaces**
This tool could target businesses and industries whose property exceeds a certain threshold of mineralization or soil sealing. The measure is designed to increase revenues from buildings that constitute heat islands and major generators of surface water in municipal infrastructures. It also aims to internalize environmental costs for the city, reinforce best practices and reward the greening of the territory. The results of the analysis show that the measure receives a very favourable or favourable assessment on the four dimensions under study. Particular attention will need to be paid, both financially and administratively, to the geomatic tools required for deployment and annual data updating.

Reducing drinking water consumption and improving soil permeability
Recommended measures
- Examine the possibility of increasing **pool fees**
Pool fees are currently set at $25. This rate has never been revised since it was introduced. According to the city, there are some 7,000 pools on the territory. However, the results of the analysis show that the measure could give rise to an acceptability issue. The measure could require an in-depth analysis to determine an increase in the current rate, or its transformation into a tax adopted under the TMP. Fees could also be modulated according to pool type.
- Analyze the implementation of a **drinking water use and treatment rate** for industrial, commercial and institutional **(ICI) users.**

This measure stems from a government obligation under the Quebec Strategy for Drinking Water Conservation. Pay-per-use pricing requires water meters. The installation of water meters will improve the accuracy of the municipality's water balances. Once the volume of water consumed is known, building owners can be given the tools they need to target abnormal consumption, and thus better select the actions to be taken to promote drinking water savings. The results of the analysis show that the measure receives a very favourable assessment for three of the four dimensions of the analysis. However, from the point of view of sound administrative management, short-term challenges remain in adjusting municipal bylaws, supplying and installing meters, and monitoring user consumption. Detailed deployment planning may be required.

Measures under consideration
- Investigate and document the elements required for the implementation of **user-based pricing and drinking water treatment** for the **residential sector.**

This measure is consistent with the government's obligation to estimate residential water consumption under the Stratégie québécoise d'économie d'eau potable. However, pay-per-use pricing requires the presence of water meters in all residences, whereas the obligation requires an estimate based on sampling only. The measure could

be kept under review to ensure that the municipality is ready and sufficiently equipped to deploy it, should it be deemed necessary. A pilot project could be considered, given the scope of such a project for the residential sector.

- Investigate and document the elements required to **implement a wastewater discharge charge.**
The purpose of a wastewater discharge charge is to levy an amount to be determined according to the quantity of wastewater and the level of contamination discharged by industries over a given period. The levy thus serves to finance a regulatory regime set up by the city, and to influence a reduction in discharges, particularly of contaminants, on the part of the industry or company targeted by the levy. The measure could be kept under review in order to detail the issues involved in its application, particularly for older buildings, and to assess the effects of implementing a user charge on industrial and commercial wastewater discharges.

Sustainable mobility
In the case of sustainable mobility, no measures were recommended. Below is the rationale explaining the reason they were excluded.

Measures not recommended
- Levy on major trip generators
This tool consists of a fee levied on major trip generators, such as large employers and organizers of major events, who do not have a travel management program in place. This measure has little potential, as there are few major trip generators in Mascouche.
- Pricing or on-street parking stickers
On-street parking pricing or parking stickers correspond to the implementation of a rate to control and manage certain parking-related issues in a given city or sector. In Mascouche's current context, analysis shows that on-street parking pricing has little potential in terms of revenue, and poses a number of challenges in terms of sound administrative management and acceptability.

Given Mascouche's poor public transit service, heavy dependence on the automobile and the metropolitan context in which transportation planning is taking place, it is recommended that the Town of Mascouche not immediately rely on eco-taxes to achieve its sustainable mobility objectives, but rather on increasing public transit supply and prioritizing active mobility corridors through greater investment in this area, which is beyond the scope of the mandate.

Reducing the amount of landfill waste
Measure under study
- Investigate and document the implementation of a **fee for Construction, Renovation and Demolition (CRD) waste;**

This tool consists of introducing a levy on construction, renovation and demolition permits to divert residual materials from disposal. Applicants subject to the fee who have a materials management plan in place, or who have improved source separation of certain materials, could be exempted from the fee. The revenues collected could be allocated to assistance and support programs promoting the circular economy in the construction sector and reducing the quantities of materials disposed of. As the city does not currently have an ecocenter, this measure may be difficult to apply. The measure could be kept under review in order to detail the issues involved.
- Investigate and document the implementation of **incentive-based pricing for the collection and processing of residual materials** (smart collection).

The costs associated with waste collection and disposal services are currently covered by a fixed fee of $167 per year per dwelling or business. Incentive pricing, based on the number of lifts and the size of the bin, for example, could help reduce the amount of material going to landfill. However, the implementation of incentive-based pricing is complex, given the heterogeneity of buildings, types of collection and equity between multi-unit buildings and single-family homes. Challenges in processing the data required for pricing are also to be expected. However, in view of its effectiveness and the anticipated renewal of the residual materials collection contract, its analysis is desirable with a view to deployment.

Air quality and greenhouse gas (GHG) reduction
Recommended measure
- Examine the possibility of introducing a **tax on homes without a tree in the front yard.**
The tool targets the absence of a tree in the front yard of residential, commercial and industrial buildings. The presence of a tree in the front yard is mandatory under current regulations. The presence of a tree can be determined using the Jakarto survey. According to the city, some 2,200 properties do not comply. According to the analysis, the measure has a strong potential to influence compliance with the regulations. The analysis also shows that the measure scores favourably on all four dimensions under consideration.

Measure under consideration
- Investigate and document the introduction of a tax on oil-fired systems or dual-energy systems using oil.
The tool consists in imposing a tax on owners of residential buildings with oil-fired heating appliances or a dual-energy system with oil. Since the analysis highlights the presence of an acceptability issue, it may be necessary to analyze in greater detail the data concerning the number of taxpayers targeted, the rate that could be imposed and the phasing of the measure, in particular to ensure predictability for those subject to the measure.

According to information obtained by the City's appraiser, the data are not totally reliable. An administrative effort will be required upstream of the measure's deployment to validate properties with this type of equipment.

Varied rates by building category
Recommended measures
- Analyze the option of introducing a **variable rate based on living area** for single-family dwellings exceeding a certain threshold.
The aim is to implement a higher property tax rate for very large single-family homes. Since many municipal services are currently financed by compensation and not by property tax, these properties benefit to some extent from a tax transfer on these services. Moreover, the analysis shows that the measure scores favourably on all four dimensions under study.

It should be noted, however, that prior to implementing this measure, particular attention will need to be paid to the criteria for tax liability. It should be noted that a minimum property value per square metre cannot be used as a threshold or criterion for tax liability. The additional rate that could be imposed, as well as the phasing, will need to be considered in order to ensure a certain level of predictability for the taxpayers concerned, and to ensure that the measure reaches the buildings and citizens that meet the underlying objectives.

- Analyze the option of establishing tax subcategories by **value bracket** for **non-residential buildings**.
The tool consists of creating a property tax system with varying rates per value bracket for non-residential buildings. Two separate property tax brackets for non-residential or industrial buildings, based on assessed value, could be envisaged. Analysis shows that the tool is favorably evaluated for its fiscal potential, sound administrative management, acceptability and fairness. However, there are no environmental benefits to be anticipated from this measure.

Measures under consideration
- Investigate and document the option of establishing higher tax subcategories for buildings whose **land use code (LUC)** is related to the production of **nuisance or negative environmental externalities or** to **a higher intensity of use of municipal services**, and a lower tax subcategory for buildings whose **LUC** is related to the **production of environmental benefits and is to favor businesses working in the circular economy**.

Although the analysis was carried out separately for each type of CUBF, since different effects were noted for certain criteria, it is recommended that they be merged at the time of implementation for reasons of administrative simplicity and consistency in application. When the results are combined, the analysis shows a favorable assessment for one or other of the CUBF code categories on the four dimensions under study. In this sense, in the first instance, a higher rate for buildings generating nuisances or negative externalities is recommended in a first phase of deployment.

- Investigate and document the option of a **varied property tax rate** for **additional categories of number of dwellings in multi-unit rental buildings**.

The tool consists of increasing the number of dwelling categories where a varied property tax rate is applied, compared with what currently exists. The analysis shows potential impacts on equity and acceptability of the measure, as well as on environmental efficiency. Before introducing an additional number of categories, it may be necessary to study in greater detail the effects on affordability and the municipality's densification efforts, particularly if the objective is to apply a higher rate for buildings with a larger number of units.
- Investigate and document the option of a **varied property tax rate** based on the physical link for **condominium-type residential buildings.**

The tool consists of implementing a higher property tax rate for assessment units integrated with a condominium-type residential building. The analysis shows potential impacts on equity, particularly in terms of mitigating assessment roll effects, and the acceptability of the measure, as well as on environmental efficiency. Before implementation, it may be necessary to study in greater detail the effects on affordability and the municipality's densification efforts.

Varied property tax rates by sector
Measure under study
- Investigate and document the option of using the **five sectors** set out in Bylaw **1286** on contributions to municipal infrastructure and equipment, currently in force, to establish **a varied rate for these sectors.**

The aim of this tool is to implement a varied property tax rate for five sectors of Mascouche identified by the by-law on contributions to municipal infrastructure and equipment. Analysis shows that the measure could pose a challenge in terms of acceptability and fairness. Before its implementation, it may be necessary to study in greater detail the additional funding requirements for each sector, particularly in relation to the level of service received. It should be noted that the measure could also help to balance, in part, the impact of the new assessment roll on taxpayers, thus addressing the equity issue.

Other provisions of Bill 39
Recommended action
- Analyze the option of **increasing the special rate for vacant lots served** at four times the basic rate.
Ville de Mascouche already uses this financing tool. The measure consists in increasing the special rate according to the new parameters allowed by law. The analysis shows that the tool receives a favorable or very favorable evaluation on the four dimensions under study.

Conclusion
While these decisions reflect difficult trade-offs between fiscal potential and environmental efficiency, administrative simplicity and legal risk emerged as dominant factors guiding the choices. The co-development process and exploration of new possibilities also led to the prioritization of innovative, progressive fiscal measures that are environmentally sustainable, such as the floor-area ratio tax or the increased property tax rate on "monster houses". Combined with measures adopted in other Quebec municipalities, these advancements suggest a paradigm shift in the financial planning approaches of Quebec municipalities, where the practice of keeping tax rates low and relying solely on real estate development growth to balance the short-term budget is replaced by a longer-term, more integrated and coherent approach to diversify revenue sources and align service and infrastructure needs with revenue sources that both can fund these needs and support other policy objectives.

Land Take and Logistics Hubs: Castel San Giovanni, the Milan Logistic Region's Gateway to Emilia-Romagna (Italy)

Margherita Emilia Re
Politecnico di Milano – Zhejiang University
margheritaemiliare@gmail.com

Abstract
This research examines the impact of logistics infrastructure on land take in Castel San Giovanni, a municipality hosting one of Italy's largest logistics hubs. Situated on the southern edge of the Milan Logistic Region, the town has undergone rapid transformation due to fragmented planning and the large-scale expansion of its Logistic Park. By analysing development documents and measuring land take over time, the study illustrates the consequences of insufficient planning coordination. These are assessed in light of regional directives, focusing on Emilia-Romagna's Regional Law No. 24/2017. In the absence of a national regulatory framework, this law reflects the ongoing tension between strategic environmental goals, such as the EU's Net Zero Land Take target by 2050, and local dynamics marked by deregulated growth and limited institutional oversight.

Key words: Land Take, Logistic platforms, E-commerce, Emilia-Romagna region

1. Introduction

1.1. The role of logistics platforms in land take growth

In recent decades, land take in Italy has undergone a significant acceleration, driven by the growing expansion of logistics settlements linked to the strengthening of distribution networks and the explosion of e-commerce (ISPRA, 2024). This phenomenon has particularly affected Northern Italy, where the pressure from logistics and e-commerce has led to the radical transformation of entire territories. The consequences of this model include the degradation of ecosystem services, the reduction of landscape quality, and increased pressure on private mobility and natural resources (Artmann, 2016; Dupras et al., 2016; Ursić et al., 2016). According to ISPRA data (The Italian Institute for Environmental Protection and Research), the phenomenon currently affects more than 7.16% of the national territory, with an estimated average annual loss of 456–501 million euros in ecosystem services such as water regulation, carbon sequestration, and biodiversity habitats (ISPRA, 2024). Land use changes entail not only the removal of highly fertile agricultural areas but also a reduction in the natural services essential to environmental quality and community well-being. Moreover, the transformation of agricultural and rural areas also results in a profound redefinition of cultural heritage and place identity, marking a rupture with historical settlement traditions (EEA, 2013).

In this context, the urgency for more conscious territorial governance is tied to the need for regulatory and planning tools capable of integrating environmental, social, and landscape dimensions in land use regulation. At the European level, a comprehensive soil directive has not yet been adopted, but the "Soil Monitoring Law," recently proposed by the European Commission, incorporates the principle of "Healthy Soil" into the Green Deal to ensure the preservation and restoration of soil ecosystem functions. This kind of proactivity, together with the goal of No Net Land Take (NNLT) (European Commission, 2023), represents an important sign of attention, although the most significant actions to limit land consumption and promote regeneration practices remain at the national and regional levels. These policies not only address soil protection and urban sprawl but are also consistent with broader EU environmental strategies, such as biodiversity conservation goals outlined in the EU Biodiversity Strategy for 2030. It is therefore of fundamental interest to examine the regulatory frameworks that govern logistics settlement development, to understand how their application, and often limited enforceability, influences actual territorial transformation processes on the ground.

1.2. The significance of Castel San Giovanni as a representative case study

The logistics hub of Castel San Giovanni, located in the province of Piacenza, stands out for the exceptional speed and scale of its development, making it an emblematic case in the Italian logistics landscape. The analysis of its chronological process highlights how the synergy between regulatory flexibility, local political will, and significant private capital has prevailed over an integrated vision of territorial transformation. This predominance has led to significant consequences not only on the environmental and ecological level but also on the social, economic, and urban structure of the area. Castel San Giovanni thus represents a paradigmatic and accentuated example

of a phenomenon that is spreading widely across Northern Italy: the rapid and fragmented expansion of logistics settlements, often carried out in the absence of effective supra-local coordination and the safeguarding of the social fabric of the affected contexts.

The province of Piacenza, moreover, has long been characterised by an explicit logistics vocation, recognised in the strategic objectives of the main planning tools (Gabellini et al. 2010) from the Regional Territorial Plan (PTR) to the Provincial Territorial Coordination Plan (PTAV) and further formalised in the Simplified Logistics Zones (ZLS) documents, developed from national directives and subsequently adapted at the regional level. However, this vocation is realised through a settlement process that is often not fully recognisable in official planning documents due to its incremental, ad hoc, and fragmented nature.

1.3. Objectives and methodology of analysis

This research aims to critically investigate the relationship between the development of logistics platforms and land consumption, with particular attention to the regional regulatory framework and, primarily, to Regional Law No. 24/2017[1] of Emilia-Romagna, which governs the protection and use of the territory. The analysis focuses on the case study of the Logistic Park of Castel San Giovanni, intending to reconstruct its development process and highlight the central role played by planning and implementation tools, which have constituted the normative and procedural backbone of this development. In particular, the main instruments at the municipal, provincial, and regional levels are examined, from structural plans to territorial agreements and procedural plan amendments, which have enabled the progressive realisation of the hub through an incremental and exceptional approach.

The regulatory component is integrated with a quantitative analysis of land consumption, carried out using GIS tools applied to land use data provided by the Emilia-Romagna Region, relating to the period 2003–2020. This analysis allows for a precise mapping of the territorial transformations that have occurred, outlining their spatial extent and temporal dynamics. The methodology adopted, therefore combines a documentary and regulatory review with a territorial investigation at the municipal scale, aimed at measuring the impact of planning decisions.

The multi-level approach makes it possible to identify the critical issues that have enabled a development markedly inconsistent with the guiding principles of the regional legislation itself and the European directives on the sustainable use of land.

2. General context: Italian land take by the logistic framework

2.1. Development of the logistics sector in Italy and Europe: the role of the RLM

In recent decades, the logistics sector has experienced exponential growth throughout Europe, driven by the globalisation of production chains and the integration of markets. In this context, Italy has become a key node in continental goods flows thanks to its strategic geographical position at the centre of the Mediterranean and the convergence of major trans-European corridors. Lombardy in particular stands out as a national and European logistics hub: from a transport perspective, it lies at the centre of a macro-area defined as the Milan Logistic Region (RLM). This territory transcends regional administrative boundaries and also includes neighbouring areas of Piedmont (Novara) and Emilia-Romagna (Piacenza). This functional region, with Milan at its centre, is characterised by an economic connective tissue represented precisely by logistics flows (Dallari and Curi, 2020) and has been described as equivalent to the circulatory system of an organism, an essential network ensuring the distribution of resources necessary for economic functioning.

According to a study by the LIUC Logistics Research Centre, Milan and its logistics region handle around 140 billion euros in goods annually, involving over 35 million people, including operators, employees, and service users (Dallari and Curi, 2020). The RLM covers an area of approximately 27,770 km² with 10.7 million inhabitants (a density of 385 inhabitants/km²) and contributes around 18% of Italy's GDP, confirming itself as one of the country's and Europe's leading economic engines.

At the national level, logistics real estate has become one of the most dynamic sectors in the market. Since 2017, the logistics segment, once marginal, has seen extraordinary growth, establishing itself as the leading asset class in the Italian property market (Marchesini 2024). In 2023, investments in logistics properties reached approximately 1.7 billion euros, accounting for over a quarter (27%) of the total national real estate market

1 Emilia-Romagna Regional Law of 21 December 2017, No. 24, "Regulations on the protection and use of the territory".

volume (ISTAT, 2024). This represents an unprecedented level of capital for the sector and highlights the strategic importance logistics has assumed in the economic landscape. In terms of physical volumes, 2023 marked the fifth consecutive year with over 2 million m² of new warehouses leased or purchased (take-up), and forecasts for 2024 indicate a further increase of 1.7 million m² to be occupied by the end of the year (ISTAT, 2024). Overall, the logistics sector in Italy currently employs 1.16 million people and generates a value of 92.7 billion euros, equivalent to 5.4% of national GDP (Tecnocasa, 2024). These figures confirm that logistics, from being an ancillary function, has become a primary economic driver for the country.

Within the RLM, the province of Piacenza plays a particularly significant role as a hinge area. Piacenza is, in fact, the first Emilia-Romagna territory immediately south of Milan and benefits from a favourable geographical position at the intersection of several communication routes. Traditionally, Piacenza lies along the Via Emilia (east-west axis), which connects the main centres of Emilia-Romagna, but in recent years its importance has extended to transversal links between north-western and north-eastern Italy. In perspective, the Piacenza area connects, on one side, Liguria, Piedmont, and south-eastern France, and on the other, Verona, north-eastern Italy, and eastern Europe. This central position along multiple routes, combined with its relative proximity to a major international seaport such as Genoa, has favoured the development of a strong local logistics hub: already in 2010, the Provincial Territorial Coordination Plan indicated that around 50% of new productive areas developed in the province of Piacenza between 2000 and 2010 were destined for logistics (PTCP, 2012). The area's infrastructure supports this vocation: Piacenza features a strong intermodal character, with navigable waterways (the River Po), an extensive railway network (with both passenger and freight links on the Milan-Bologna line and secondary routes), as well as a primary motorway network. At the A1 Motorway (Milan–Bologna) intersection with the A21 (Turin–Brescia), the Piacenza area offers excellent road accessibility for freight transport. Several nearby motorways exit, and the possibility of activating rail links to logistics hubs (such as Castel San Giovanni, already equipped with dedicated tracks awaiting use) makes this area extremely attractive to national and international logistics operators.

2.2. The increase in demand: e-commerce, just-in-time, and the transformation of logistics

The reasons behind the boom in contemporary logistics are multiple and linked to structural changes in economic and consumption models. Firstly, the explosion of e-commerce has redefined distribution needs: the widespread diffusion of online shopping, further accelerated by the Covid-19 pandemic (Casaleggio Associati, 2021), has generated unprecedented demand for sorting centres, proximity warehouses, and delivery platforms. E-commerce and retail companies require advanced logistics bases to ensure fast and reliable deliveries across the territory, increasing the demand for modern logistics spaces. Secondly, the adoption of the just-in-time (JIT) model and, more generally, of Lean Management practices in production chains has led companies to minimise warehouse stock at production sites, relying instead on frequent and timely supplies. This reorganisation implies that logistics is no longer seen as a mere transport service downstream of production, but rather as an integral and decisive part of the production process itself. What was once considered a phase of transport is now in all respects an autonomous and crucial production segment: efficient logistics management can generate savings of between 5% and 15% of a company's profits by optimising production, storage, and distribution (Farioli, 2019). In other words, global competition is pushing companies to reorganise their supply chains, often outsourcing logistics to specialised operators and investing in logistics innovation to improve delivery times and costs (Panfilo, 2018).

The consequence of these dynamics is that logistics has become an independent industrial sector, with its actors, capital, and spatial requirements. The phenomena that we can detect in the logistic spots of the territory of Piacenza province highlights how large contract logistics companies and 3PL (third-party logistics) operators have emerged, managing the entire flow of goods on behalf of producers and distributors, thus promoting the rise of increasingly large and technologically advanced logistics hubs (Alfieri,2023). Contemporary warehouses differ greatly from traditional industrial sheds: large single-storey surfaces of tens (if not hundreds) of thousands of square metres, high internal clear heights to maximise vertical storage, and extensive fully impermeable yards for manoeuvring and loading/unloading, allowing easy access for articulated lorries and heavy vehicles. This building typology, the mega-warehouse or big box, is designed to meet the market's continuous demand for flexibility (Marchesi,2023), such as rapid reconfiguration of interior spaces and the ability to manage variable goods flows. At the same time, however, it exerts strong pressure on the territory, given its out-of-scale dimensions to the traditional urban fabric. Entire peri-urban agricultural areas have been rapidly converted into logistics districts, with particular concentration in flat areas near major metropolitan hubs – contexts where

the availability of relatively cheap land, combined with proximity to consumer markets, creates ideal conditions for logistics settlements (Dallari & Curi, 2020). The Italian landscape, especially in the Po Valley, has thus seen a multiplication of large warehouses with standardised architecture, often located near motorway junctions.

2.3. Logistics and land take: the scale of the phenomenon

Land consumption driven by the growth of logistics represents one of the most critical aspects in terms of territorial sustainability. In Italy, land consumption has reached alarming levels in recent years: according to ISPRA data, in 2023, new artificial land cover affected 72.5 km², with net consumption amounting to 64.4 km², equivalent to approximately 17.6 hectares per day, or 2.3 square metres of land per second. Between 2006 and 2023, the country lost a total of 1,289 km² of natural or agricultural surfaces. In 2023 alone, more than 72 km² of new land were sealed (ISPRA 2024). These transformations are due to various factors (residential urbanisation, infrastructure, industrial sites, etc.), but the logistics sector has contributed increasingly, especially in Northern Italy.

Precisely quantifying the land consumption attributable to logistics is not straightforward, as official land use databases and municipal urban plans lack a specific category for logistics settlements. These are generally included under industrial or commercial zones, making it difficult to isolate and monitor the phenomenon. Recent studies provide useful strategies to address this methodological gap, highlighting how the absence of an ad hoc classification in land use data hinders the implementation of targeted policies to contain land consumption linked to logistics hubs. To address this limitation, research is currently experimenting with innovative mapping methodologies, combining photointerpretation from aerial images and auxiliary data, to allow the quantification of the phenomenon through in-depth studies (Ronchi et al., 2023).

Although not ranking first at the national level, the Emilia-Romagna Region is also among the territories most affected by land consumption. The percentage of regional land now sealed reached approximately 8.91% in 2023 (ISPRA, 2024), placing Emilia-Romagna fourth in Italy after Lombardy (12.1%), Veneto (11.86%), and Campania (10.57%).

Although this figure is lower than that of the leading regions, it reflects significant anthropic pressure, particularly concentrated along the foothill belt and the plain crossed by the Via Emilia. In this context, the province of Piacenza stands out for the speed with which logistics areas have expanded in recent years. In addition to the emblematic case of Castel San Giovanni, where an area of about 200 hectares has been urbanised to make way for one of the largest logistics hubs in the country, the entire provincial territory has seen a proliferation of storage and distribution facilities, including in smaller municipalities, often near motorway exits. Land consumption in the province of Piacenza has increased significantly, contributing to the regional figure. According to ISPRA, in 2023, the province of Piacenza recorded land consumption of 128.9 hectares (ISPRA 2024), with previously agricultural areas being covered by warehouses, yards, and new access infrastructure.

3. The regulatory framework

3.1. National and regional regulation

In Italy, the regulation of land consumption and territorial transformations is entrusted to a complex, multi-level system involving national, regional, provincial, and municipal regulations. Although in recent years public decision-makers have shown increasing intention to address the phenomenon of land consumption by attempting to activate policies and programmes aimed at responding to this issue (Ronchi et al., 2018), at the national level the absence of a specific framework law on soil has created a regulatory vacuum, leaving ample room for intervention by regions and local authorities. Among the main environmental and urban planning regulations, Legislative Decree No. 152/2006 (Environmental Code) sets out the general principles of environmental protection, but does not address the phenomenon of land consumption in a systemic way. In particular, it does not provide an explicit definition of "land consumption", leaving room for heterogeneous interpretations and applications at the regional level.

The environmental management of logistics areas and transformations is complex. On the one hand, there are national plans and programmes aimed at strategically strengthening the logistics sector; on the other, regional regulations are introduced in very different ways into the landscape of territorial governance. This heterogeneity is accentuated by the absence of a specific urban planning category for logistics, which is often assimilated

into general productive functions, despite having distinct characteristics and impacts. At the national level, the intense market pressure and the growing demand for territorial areas that meet specific requirements, such as adequate infrastructure, efficient connections with highly specialised supply chains, and integration with tertiary and administrative sectors, have led public decision-makers to reconsider the issue of land consumption with greater attention, recognising the need to counter the phenomenon of "logistics sprawl" (Aljohani & Thompson, 2016). This strategic direction is accompanied by the need to rationalise spending on new road and rail infrastructure, as well as to govern the location processes of logistics functions. In this context, policies such as the Simplified Logistics Zones[2] (ZLS) emerge as tools to incorporate these needs and provide national-level guidance (Bonfantini et al., 2022). The ZLS are indeed configured as strategic areas for regional economic development, where the infrastructure system supports coordinated growth of the productive fabric. Companies located in these zones benefit from economic and financial incentives and procedural simplifications. Considered from a national perspective, the ZLS, together with the Special Economic Zones (ZES), are intended to identify growth-driving areas, catalysts for small, medium, and large enterprises intercon

nected within an integrated infrastructure system operating on a European scale (Bonfantini et al., 2022).
Despite these references, a unified national regulatory framework capable of systemically addressing the phenomenon of land consumption is still lacking. Territorial management is largely entrusted to the Regions, which have developed differentiated and often uncoordinated legislative tools. Some Regions, such as Lombardy, with the recent Regional Law No. 15/2024[3], have adopted specific regulations to govern logistics settlements and their territorial impacts, while others, such as Emilia-Romagna, have integrated these issues within general land governance laws. This legislative asymmetry produces uneven effects, with direct consequences on the spatial distribution of logistics functions and the ability to manage their environmental impact.

The Emilia-Romagna Region has adopted advanced regulatory and planning tools for soil protection and sustainable territorial development. At the heart of this system is Regional Law No. 24/2017, which promotes urban regeneration and places strict limits on new land consumption, giving priority to the reuse of existing areas through municipal-level General Urban Plans (PUG). Supporting this, PRIT 2025 guides the location of infrastructure in a way consistent with territorial planning, while the Pact for Labour and Climate sets out ambitious programme goals, such as net-zero land consumption by 2050. More broadly, instruments such as the Regional Territorial Plan (PTR) and the Landscape Plan contribute to ensuring coherence between economic development, environmental protection, and landscape quality.

3.2. Regional Law Emilia-Romagna 24/2017: governing transformations between controversies and prospects
Regional Law 24/2017 "Regional rules on the protection and use of territory" represents an ambitious attempt by the Emilia-Romagna Region to combine economic growth, environmental protection, and urban quality. The law was introduced in a context marked by growing concerns over land consumption and aims to steer territorial transformations towards goals of sustainability, resilience, and regeneration. However, despite its integrated vision, the law does not include a specific regulatory tool for logistics settlements, which continue to be treated in the same way as generic productive functions. Among the central objectives of LR 24/2017 are: the limitation of irreversible land consumption; urban regeneration as the priority principle of transformation; the introduction of environmental, ecological, and landscape criteria into planning processes; and the obligation for implementing parties, including logistics operators, to provide ecological compensation and mitigation measures.

The law also adopts a multi-level governance model and promotes tools such as the General Urban Plan (PUG) – a new integrated tool replacing the former Structural Plan (PSC) and Operational Plan (POC) – and the Programme Agreement for supra-municipal projects. In support of the emphasis the law seeks to place on the containment of land consumption, it states: "Territorial and urban planning may provide, for the entire period, an overall land consumption limit of no more than 3 per cent of the urbanised territory surface area" (LR 24/2017).

Despite its advanced theoretical framework, the implementation of LR 24/2017 has revealed several critical issues.

2 The Simplified Logistics Zones (ZLS) were introduced by the 2018 Budget Law (Law of 27 December 2017, No. 205, "State Budget for the financial year 2018 and multi-year budget for the three-year period 2018–2020").
3 Lombardy Regional Law of 8 August 2024, No. 15, Regulation of logistics settlements of supra-municipal relevance.

In particular, the law has struggled to curb the uncontrolled development of logistics platforms, often authorised through urban planning amendments, as will be demonstrated in the documentary analysis of the case study examined in this research. Furthermore, it should be noted that the law includes a list of categories exempt from the calculation of net land consumption, meaning that certain areas are not counted in the containment calculation. Among these are precisely those areas that "Are not counted for the purposes of calculating the maximum share of land consumption: new productive settlements of regional strategic interest that are subject to settlement and development agreements [...]" (LR 24/2017). Thus emerges a side of the law that controversially responds to the declared aim of containing land consumption while, conversely, allowing for a rather broad list of exceptions. The lack of a specific urban planning category for the logistics sector has also made it difficult to distinguish between traditional productive settlements and large logistics hubs, hindering any ex-ante assessment of environmental and landscape impacts. The absence of sector-specific regulatory tools has led to fragmented local policies, where municipal administrations, often under pressure from economic operators, are left to manage complex projects without adequate technical and regulatory support.

One of the most problematic aspects in the management of territorial transformations, finally, is the systematic use of urban planning amendments, as evidenced in the results of the analysis conducted on the case study considered in this research. These instruments allow for modifications to current urban planning tools to approve new developments, often as exceptions to the goals of limiting land take. Their use has been particularly frequent in the logistics sector, where investors' tight timelines and economic pressure push for rapid and simplified solutions.

4. The Logistic Park of Castel San Giovanni: one of the largest logistics hubs in Italy

4.1. Castel San Giovanni: territorial context and strategic role

Castel San Giovanni, located at the westernmost edge of the province of Piacenza, is today one of the most significant logistics nodes in Northern Italy. With fewer than 15,000 inhabitants, the municipality lies in a highly connected geographical position, strategically located at the intersection of the Via Emilia, the A21 (Turin–Brescia) and the A1 (Milan–Bologna) motorways, near the border with Lombardy and only 70 km from the Milan node. This infrastructural configuration makes it a key junction between the western Po Valley and the Milan metropolitan system, effectively positioning it as the logistical gateway of Emilia-Romagna to the Milan Logistic Region (RLM). Functionally, over the past twenty years, Castel San Giovanni has assumed the role of a territorial gateway, supported not only by road accessibility but also by the availability of large, flat agricultural surfaces that were easily convertible. Before its transformation, the area was characterised by extensive agricultural use, strong landscape continuity, and a local ecological network linked to major waterways, particularly the Tidone Valley and the River Po, just a few kilometres north of the site. This setting facilitated a rapid shift toward logistics development (Figure 1), which began in the early 2000s, supported by supra-municipal planning instruments and an active local political willingness. Castel San Giovanni is, in fact, one of the first cases in Emilia-Romagna of systematic conversion of agricultural land to logistics use, carried out in the absence of a truly organic programme, through a sequence of specific agreements and planning amendments.

In just over a decade, the municipality transitioned from a compact urban structure, surrounded by agricultural fields, to a functionally dual landscape, polarised between the historical town centre and the new logistics development, which now extends over more than 200 hectares (2 km²), nearly equaling the area of the historical centre (2.9 km²). The Logistic Park currently employs approximately 2,500 workers and is organised under a condominium management model divided into two main blocks (Condomini A and B). Its principal logistics typology is third-party logistics (Gazzola, 2022), and it hosts major companies such as AMAZON ITALIA, LEROY MERLIN, FIEGE – ZARA, CLOSE2YOU, GEODIS, VAILOG, and GXO Logistics. This expansion has resulted in significant soil sealing and has intensified infrastructural, environmental, and social pressures on the existing territory.

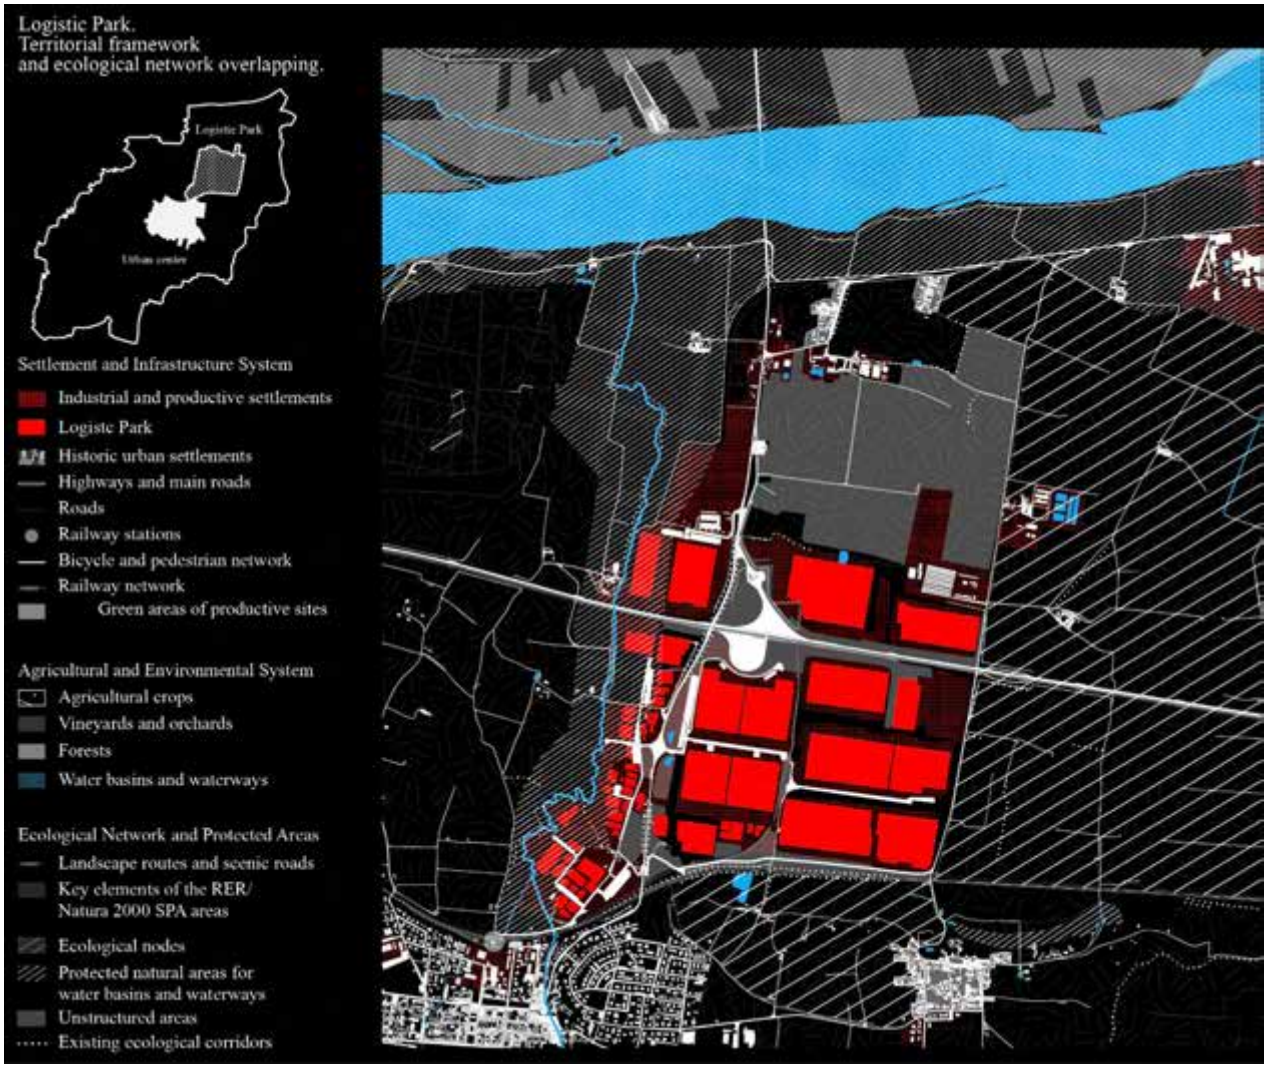

Figure 1: Territorial framework and ecological network overlapping of the Logistic Park.

This image represents the current state of the logistics hub's expansion as of 2023. As can be seen, during the various phases of expansion, the additive planning approach repeatedly intersected areas belonging to the ecological network. Author's elaboration based on data from the Emilia-Romagna Geoportal. (Appendix Figure 1)
4.2. Timeline and instruments: the development of the logistics hub

The Castel San Giovanni Logistic Park represents one of the most significant examples of territorial transformation driven by the growth of the logistics sector in Emilia-Romagna. The development of the hub has an intriguing origin, rooted in what was once locally known as the "Fallimento Speranza" (Speranza Bankruptcy) lands (Gazzola, 2022). The idea to establish one of the region's most important Territorial Development Production Hubs in Castel San Giovanni emerged from a strategic decision to revitalise a large industrial area within the municipality, an area that would be reoriented toward the growing logistics and freight movement sector. This strategic direction began to take shape in the 1990s, when a local private investor acquired extensive plots of land, previously occupied by a major pig farm near the highway, following the bankruptcy of the former enterprise. Although the vision was ambitious, it initially raised concerns, particularly within the local administration, which feared it might not be equipped to manage the implications of hosting such a large-scale logistics development within its jurisdiction. These concerns were especially evident during the early stages, as the municipality worked to define the types of functions and activities that could be allowed in the area. In this context, PTCP formally designated Castel San Giovanni as a Territorial Development Production Hub (PPST), thereby reinforcing its logistical vocation, a direction that was later confirmed and operationalised through subsequent municipal planning instruments.

The first formal local act dates back to 2002, with the approval of the then-current General Regulatory Plan (PRG), which already included provisions for new productive settlements south of the town, although not yet explicitly designated for logistics. The new Municipal Structural Plan (PSC), approved in 2007, incorporated these provisions, identifying that area as a potential zone for productive expansion. The scale shift occurred shortly thereafter, in 2007, when the site was formally designated as the future "Logistic Park" through a planning amendment under the SUAP procedure (One-Stop Shop for Productive Activities), promoted by a group of private investors and approved by the municipal administration with a view to supporting local economic development. This exceptional intervention via SUAP effectively bypassed the standard Operational Plan (POC), avoiding unified planning for the logistics park as a whole: subsequent expansions were thus implemented through ad hoc amendments rather than within an overarching framework. However, SUAP, designed to streamline procedures for initiating specific productive activities, appears ill-suited for managing large-scale, structural transformations. In the case of Castel San Giovanni, the procedure was used as a shortcut to initiate planning amendments and fast-track approvals, undermining the coherence and strategic evaluation required by comprehensive planning.

In 2008, a Programme Agreement was signed between the Municipality, the Province, and private operators, legitimising the start of the first developments and providing for the construction of primary and secondary infrastructure (new access roads, utility connections, environmental mitigation measures). Despite the lack of supra-municipal coordination or an integrated territorial vision, this agreement enabled construction work to begin quickly: by 2010, the first logistics platforms were already operational, including those for Zara and Geodis. Between 2011 and 2015, the logistics park expanded further east and south, through new sectors implemented via successive amendments that bypassed existing planning instruments. During this phase, global operators such as Amazon established a presence, with a platform of approximately 100,000 m² active since 2015. Amazon's arrival marked another scale leap: in addition to attracting further investors, it triggered increased pressure on municipal services, a sharp rise in local housing demand, and an acceleration in landscape transformation.

During this period, in 2012, a Territorial Development Agreement was signed between the Province of Piacenza and the Municipality of Castel San Giovanni. This agreement provided the institutional and regulatory framework for consolidating the logistics hub and its future expansions. It defined the characteristics of the Territorial Development Production Hub (PPST), including implementation methods, mitigation and compensation measures, ecological infrastructure, and mobility networks, in accordance with the PTCP and urban planning regulations.
At the regional level, Regional Law No. 24/2017 on land governance introduced stricter requirements for sustainable planning. However, by the time it came into force, most of the Logistic Park had already been developed. From 2014 to 2021, successive expansions were implemented through SUAP planning amendments within the "possible expansion" zones outlined in the Territorial Agreement (Figure 2). These allowed for the rapid construction of new sectors — Lotti P–R (2016), S (2017), Z (2018), Y–T (2020) —based on operators' requests.

The SUAP process, designed to simplify procedures for production-related developments, bypassed more structured urban planning assessments and all procedures required to ensure appropriate compensation measures for the impact of the logistics complex considered as a whole. By 2020, all designated expansion areas had been built out, with new logistics players, such as Leroy Merlin, joining Amazon, Geodis, and Zara. The hub reached full build-out despite growing concerns over traffic, land consumption, housing pressure, and habitat fragmentation—issues that underscore the regulatory tensions between strategic environmental objectives and local implementation practices.

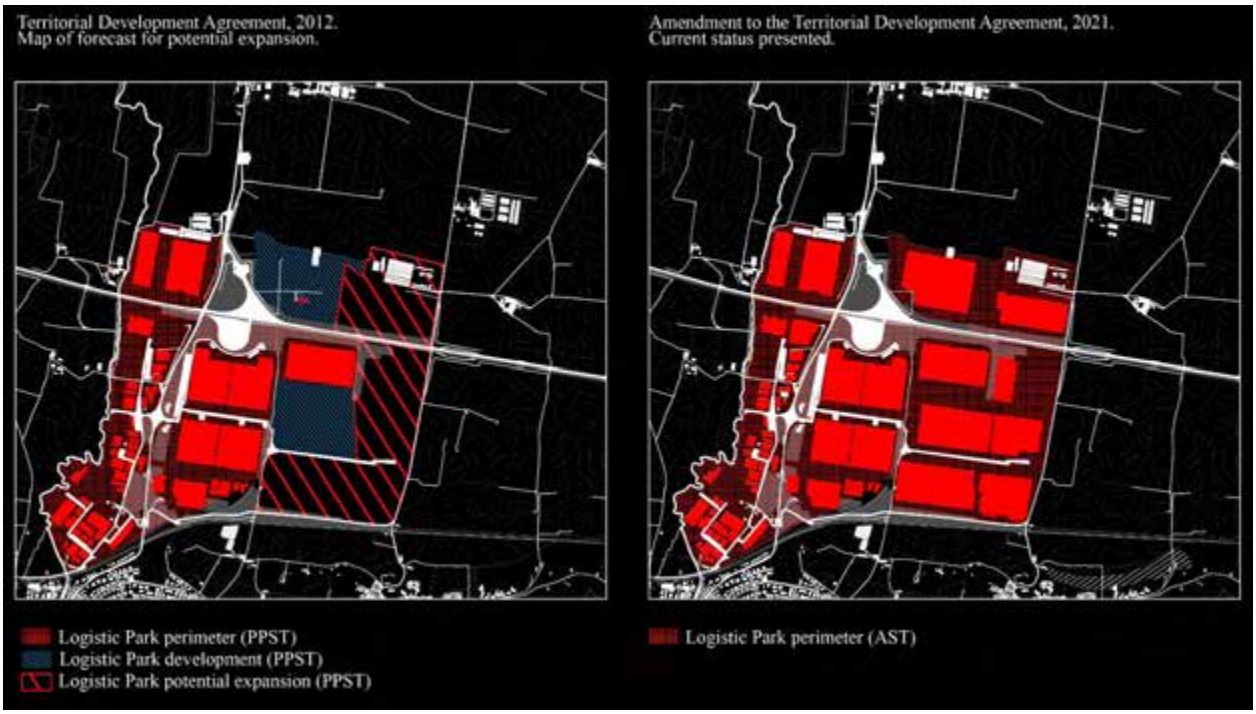

Figure 2: Comparison between potential expansion and final layout in 2021.

The data are processed using the information contained in the documents supporting the approval of the completion of the logistics hub, and refer to the potential expansion scenario outlined in the development agreement signed between the municipality and the province in 2012, and its subsequent update in 2021. (Valsat, 2020). Author's elaboration on Valsat document. (Appendix Figure 2)

4.3. Territorial transformations: land take analysis

The development of the logistics hub in Castel San Giovanni has led to a significant transformation of the local territorial structure, with extensive effects on the agricultural landscape, land use, and the urban morphology of the municipality. The settlement has substantially altered the traditional relationship between town and countryside, creating a new functional centrality that goes beyond the boundaries of the historical urban core and reshapes priorities in terms of accessibility and infrastructure at the municipal scale. To investigate the impact of the logistics hub's integration into the pre-existing agricultural fabric, this research includes a land use change study based on regional data from the Emilia-Romagna geoportal. This dataset provides percentage indicators for urbanised areas, agricultural zones, natural areas, and wetlands from 2003 to 2020. A further analytical step involved quantifying the percentage variation in consumed and renaturalised land—elements of direct relevance to Regional Law 24/2017. The data confirm a drastic change in land use (Figure 3). In just 17 years (2003–2020), urbanised surface area increased by approximately 387 hectares, while the municipality lost around 531 hectares of agricultural land. This brought the municipal land consumption rate to 18.22%, one of the highest figures in the province of Piacenza. For comparison, the entire province of Piacenza recorded, in 2023 alone, an increase of 128.9 hectares of consumed land, largely due to the expansion of new logistics settlements. Analysing the direct proportionality between the urban centre and the logistics sector, the current urbanised territory of Castel San Giovanni reveals the rapid and unbalanced settlement growth that occurred in just over a decade.

The logistics hub grew in a modular and additive fashion, with sectors progressively added without integrated planning for the remaining open spaces or urban edges. Each new intervention was conceived independently, lacking an overall coordinated design. This has resulted in a fragmented and polarised configuration of the local landscape: the municipal territory is now clearly divided between the traditional urban core and the new productive zone, while the remaining green areas appear fragmented, marginal, and unintegrated into the pre-existing ecological network.

Visual and functional connections between the urban centre and the surrounding countryside have been disrupted, and the internal infrastructure of the logistics hub has assumed an autonomous character, poorly connected to the existing urban fabric.

The urbanisation methods adopted, lacking environmental mitigation or ecological compensation measures, have exacerbated the impacts on the territory. The constructed warehouses are characterised by their monofunctional scale and standardised architecture: single-storey platforms reach surface areas of 30,000–70,000 m², with heights of 12–15 metres. The vast asphalted yards surrounding them, dedicated to heavy vehicle movement and parking, form extensive additional impermeable surfaces, increasing rainwater runoff and local flood risk.

Overall, large-scale soil sealing has compromised the land's ability to absorb stormwater, raising the likelihood of flooding and altering the natural hydrological regime. Simultaneously, territorial fragmentation has reduced ecological continuity between agricultural and natural areas, with negative effects on biodiversity and the local microclimate. No green infrastructure or adequate vegetated buffer zones were planned to mitigate the impact, nor are there public functions or communal spaces within the logistics complex: the logistics hub thus appears as an autonomous element, poorly integrated into the broader urban system.

From a settlement perspective, the expansion did not follow a principle of urban compactness but instead produced an external body, a 'twin city' with a logistics character. The new built lots developed in succession along the road infrastructure built for the hub, prioritising heavy vehicle functionality but proving inefficient in landscape and ecological terms. The large scale and uniform appearance of the buildings, combined with the absence of green transitions, have accentuated the visual rupture with the rural context, creating a landscape impact perceptible even from a distance. Ultimately, the territorial transformations induced by the logistics hub have replaced the former agricultural landscape with a continuous built and asphalted environment, marking the territory irreversibly from both ecological and morphological perspectives.

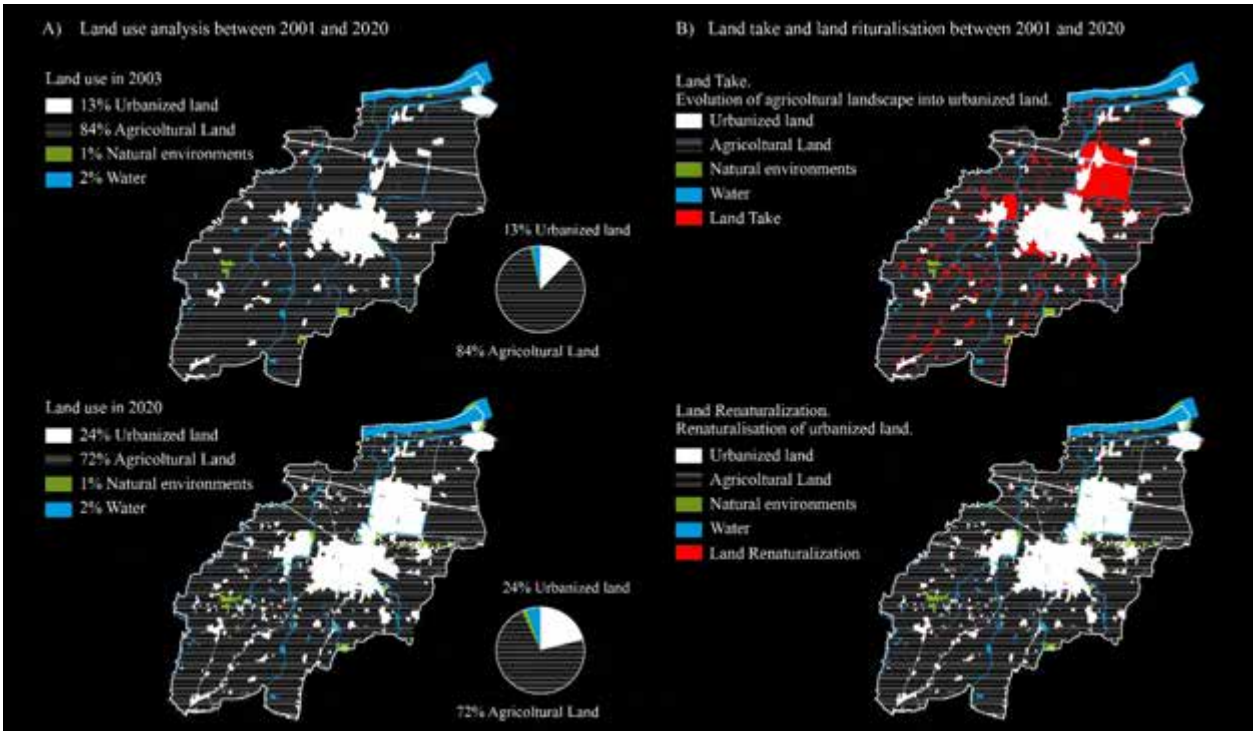

Figure 3: Land use analysis and land take, and land renaturalisation process analysis. Study conducted within data from 2003 and 2020.

A) Land use in the municipality of Castel San Giovanni in 2003 (above) and in 2020 (below). The map and pie charts show the expansion of artificial surfaces (grey areas) at the expense of agricultural land (yellow areas) between 2003 and 2020. In 2003, urbanised land accounted for 13% of the municipal surface, while by 2020 it had reached 21%.

B) Land consumption (in red) and minor renaturalisation phenomena (in dark green) in the municipal territory of Castel San Giovanni between 2003 and 2020. The red areas indicate agricultural or natural surfaces converted into urbanised land during the period, mostly concentrated in the logistics hub quadrant, while the limited renaturalisation efforts appear as isolated fragments within an increasingly artificialised landscape. Author's elaboration based on data from the Emilia-Romagna Geoportal. (Appendix Figure 3)

5. Conclusions

The case study of Castel San Giovanni offers a critical lens through which to interpret the complex interplay between logistics-driven territorial development and regional planning frameworks in contemporary Italy. The findings reveal a dissonance between the objectives of sustainable land governance, such as those outlined in Emilia-Romagna's Regional Law No. 24/2017, and the mechanisms through which large-scale logistics settlements have been realised in practice.

The logistic transformation of Castel San Giovanni occurred through an incremental and ad hoc process, heavily reliant on SUAP amendments, which permitted bypassing standard urban planning instruments and, crucially, the systematic assessment of environmental and cumulative territorial impacts. While such procedures have facilitated the rapid deployment of logistics infrastructure, they have simultaneously undermined the integrative principles of land-use regulation, resulting in the fragmentation of the local ecological network, the erosion of agricultural land, and a significant landscape discontinuity between the historic urban core and the logistics enclave.

This empirical evidence corroborates broader criticisms raised in recent discourse surrounding the implementation of LR 24/2017. As highlighted by investigative analyses (Pileri, 2023; Rosano, 2023), the exemption of strategic productive settlements from soil consumption calculations, coupled with the delayed adoption of General Urban Plans (PUGs) by the majority of municipalities, has significantly weakened the law's regulatory efficacy. In the absence of a national framework law, regional initiatives risk being rendered ineffectual by institutional fragmentation and political-economic pressures at the local scale.

These dynamics have repercussions beyond the regional context, aligning with broader European concerns about soil sealing and the unsustainable expansion of settlement areas. The European Commission's Soil Strategy for 2030 acknowledges the centrality of land as a non-renewable resource, setting the target of No Net Land Take by 2050 as a guiding principle for Member States. This target is grounded in recognition that artificial soil cover causes irreversible losses of ecosystem functions, such as water regulation, carbon storage, and biodiversity support, and imposes long-term socio-environmental costs (European Commission, 2021; EEA, 2019).

Considering such findings, it becomes imperative to reconsider the instruments governing territorial development. A shift is required toward a governance model that transcends market-driven logic and embraces the intrinsic value of soil, cultural landscapes, and the well-being of communities. This highlights the need for a supra-local and possibly national governance scale to effectively regulate logistics-driven development, overcoming the current fragmentation and enabling coordinated, strategic planning across administrative boundaries. Future planning strategies should embrace adaptive and environmentally conscious frameworks capable of responding to emerging pressures. These frameworks must aim to mitigate environmental degradation and address the spatial fragmentation produced by uncoordinated development. In the case of Castel San Giovanni, overcoming the current disconnection between urban growth and territorial coherence requires a rethinking of planning priorities. However, any future intervention must be embedded in a long-term, coordinated vision that recognises the complexity of territorial transformations and ensures that land-use governance aligns with both ecological sustainability and social equity.

The original Territorial Development Agreement document is not available; however, relevant maps are included in the Valsat document (environmental legitimacy procedure), which was drafted to support the future expansion of the logistics hub.

Figure 3:
Author's GIS elaboration on regional data available at: https://geoportale.regione.emilia-romagna.it/. Due to differences in the data acquisition methods used by the region to detect land use across different years, some inconsistencies may be observed. However, the data remain broadly consistent with the results obtained and accurately reflect the overall transformation trends.

Exploring the Application and Challenges of Urban Planning Legal Systems Guided by Nature-Based Solutions: A Case Study of Kaohsiung City, Taiwan

YaZhen Cai, Tzuyuan Stessa Chao
Affiliation: Department of Urban Planning, National Cheng Kung University, Tainan, Taiwan
Email:t900916@gmail.com

Abstract
This study focuses on examining Nature-Based Solutions (NbS) within urban planning across different spatial scales in Kaohsiung City, Taiwan, particularly evaluating the content of planning regulations and their implementation strength. By constructing an NbS relevance matrix and integrating the Strategic Environmental Assessment (SEA) framework, the study conducts regional risk and potential analyses to assess the feasibility of planning strategies in each area. The findings indicate that the incorporation of NbS in spatial planning regulations remains insufficiently systematic. Therefore, the study recommends promoting the mainstreaming of NbS through institutional reforms and enhancing climate adaptation and sustainable urban transformation by referencing international case studies and strengthening multi-level governance.

Keywords: Nature-based Solutions (NbS), Urban Planning, Climate Adaptation, Sustainable Urban Development

1. Introduction

1.1 Global Context and the Importance of the Issue

In recent years, as global warming intensifies, the frequency of extreme weather events increases, and ecosystems continue to degrade, urban areas worldwide are facing unprecedented pressure on sustainability and resource availability, particularly in terms of land, water, and infrastructure. According to the United Nations Environment Programme (UNEP, 2024), countries must commit, in the next round of Nationally Determined Contributions (NDCs), to reducing emissions by 42% by 2030 and 57% by 2035; otherwise, the Paris Agreement's 1.5°C target will be unattainable, with global temperatures potentially rising to between 2.6°C and 3.1°C(United Nations Environment Programme, 2024), leading to severe impacts on human society, ecosystems, and the global economy. The IPCC (2023) similarly highlights that cities are not only major sources of carbon emissions but also at the frontline of climate impacts, particularly vulnerable to risks such as biodiversity loss. Future climate scenarios must incorporate irreversible risks such as ecosystem collapse, limits to species adaptation, and social tipping points, while also addressing the unequal impacts of climate change across different social groups. The report further calls for interdisciplinary and multi-level cooperation to develop adaptation strategies that are inclusive and locally grounded, in order to effectively respond to increasingly complex environmental challenges.

1.2 The Rise and Multiple Benefits of Nature-based Solutions (NbS)

Drawing on insights from both international reports, it is increasingly evident that traditional engineering-dominated solutions are reaching their limitations and are no longer sufficient to address today's complex environmental and social challenges alone. This has prompted cities around the world to shift towards more sustainable and resilient strategies. In recent years, Nature-based Solutions (NbS)—offering multiple co-benefits in climate adaptation, carbon reduction, ecological restoration, and human well-being—have gained significant global attention.

NbS has been formally integrated into international frameworks such as the United Nations Framework Convention on Climate Change (UNFCCC) and the Convention on Biological Diversity (CBD), and is closely aligned with Natural Climate Solutions (NCS), the Sustainable Development Goals (SDGs), and net-zero strategies. Overall, NbS has evolved from a traditional ecological tool into a multi-level, multi-objective governance strategy, playing an increasingly important role across environmental, social, and economic dimensions.

Environmentally, NbS contributes to carbon sequestration, alleviates the urban heat island effect, regulates the water cycle, and reduces flood risks. Socially, urban green spaces enhance mental well-being, strengthen community interaction, and build resilience. Economically, NbS stimulates green investment, creates employment opportunities, and reduces infrastructure maintenance costs (Raymond et al., 2017; UNEP, 2024).

2. Theoretical Background

2.1 The Importance of NbS for Cities and Urban Planning

Nature-based Solutions (NbS) are increasingly recognised as context-specific and adaptive urban policy tools that can respond to particular societal needs while delivering multiple co-benefits. Cities such as Rotterdam, Copenhagen, and Singapore have already incorporated NbS into spatial planning, climate risk management, and urban design frameworks (Frantzeskaki, 2019).

Recent research also highlights the close relationship between NbS and urban planning and land-use systems, demonstrating their potential to enhance urban resilience, public health, and social inclusion (de Luca et al., 2021). Practical applications such as permeable green spaces, green walls, and green roofs serve as illustrative examples. NbS has also been embedded within the Sustainable Development Goals (SDGs), no longer serving solely as a conservation tool but evolving into a comprehensive strategy that integrates spatial planning, social policy, and infrastructure development.

For urban planners, NbS represents not only a means for adaptation and carbon reduction, but also a critical strategy for ecological restoration, social equity, and sustainable development. It enables the integration of multiple urban challenges and supports transformative change in cities (Liu, Jay & Chen, 2021).

2.2 Practical Applications and Classifications of NbS in Urban Spaces

The European Union has actively promoted Nature-based Solutions (NbS) through major initiatives such as Horizon 2020 and Horizon Europe, applying them widely across urban renewal domains including green corridor development, water system integration, biodiversity enhancement, and brownfield regeneration. Among these efforts, the Naturvation project's development of the Urban Nature Atlas (UNA) stands out for systematically collecting empirical NbS cases from European cities, serving as a key reference for public authorities and planners worldwide (Almassy, Maia & Pinter, 2022).

Bona et al. (2023) analysed 24 NbS projects across European cities, categorising them by spatial scale into micro (buildings and plots), meso (communities and neighbourhoods), and macro (cities and regions), thus facilitating multi-level integration. Liu, Jay, and Chen (2021) classified NbS based on urban planning terminology, including interventions such as green roofs, vertical greening, and river restoration. Pirouz et al. (2024) further emphasised that systematically embedding NbS into planning frameworks helps reduce dependence on natural resource consumption while promoting the integration of ecological services and social well-being.

NbS can achieve multiple objectives—including climate adaptation and resource circularity—by combining green infrastructure interventions such as urban forests and rain gardens across different spatial scales. Its advancement also depends on cross-sectoral collaboration, policy incentives, and financial instruments to transition from pilot initiatives to institutionalised models. As such, NbS should not be viewed merely as a spatial intervention tool, but rather as a core institutional strategy for urban development (Pirouz et al., 2024).

2.3 Challenges in Implementing NbS in Urban Planning Policies

According to the UNDP Ukraine (2021) report, although certain policy documents in Ukraine have begun to reference Nature-based Solutions (NbS), the term is still largely absent from most urban planning, environmental protection, and climate adaptation legislation. While the current legal framework offers potential support, it lacks specific provisions and implementation guidelines. The report calls for the urgent formal integration of NbS into legal statutes, planning documents, and technical standards, alongside the enhancement of institutional, financial, and educational support systems to meet the demands of sustainable urban governance.

Even in countries where NbS has reached a more advanced stage of development, its application in urban planning often encounters conceptual stagnation, a lack of operational frameworks, and the absence of monitoring mechanisms. Moreover, the role of urban planning departments remains unclear, highlighting the persistent gap between academic discourse and practical implementation (Dumitru et al., 2020). As a result, effectively integrating NbS into urban plans and infrastructure strategies has become a key priority for many nations seeking to advance sustainable and climate-resilient development (Xie & Bulkeley, 2020; Wickenberg et al., 2021).

2.4 Development Trends and Research Gaps in Taiwan

Taiwan's complex spatial characteristics and governance structures differ significantly from those of European countries, resulting in a comparatively late start in developing and applying Nature-based Solutions (NbS). Relevant research has only recently gained traction, initially assessing ecological impacts and effectiveness in rural contexts to establish localised guidelines and models. Responding to the NbS principle of triple social, environmental, and economic benefits, studies emphasised enhancing urban resilience (Chen, 2020; Chiu et al., 2024). Subsequently, Taiwan's academia and policymakers clarified and deepened NbS definitions, core concepts, and practical frameworks (Li, 2022), increasingly focusing on urban spatial governance and climate change adaptation through policy frameworks that emphasise spatial re-naturalisation and integrated multi-benefit approaches (Chou et al., 2023). Further studies explored opportunities from spaces released by building setbacks for NbS implementation, such as green infrastructure, permeable pavements, and tree canopy expansion, noting green infrastructure design as key to urban effectiveness (Tsai, Hsu & Lin, 2023).

Policy-wise, Taiwan initiated action through drafting the 2012 "National Climate Change Adaptation Policy Framework" (Shih, 2024). Responding to growing global emphasis on NbS, the National Development Council in 2022 led cross-ministerial meetings, resulting in consensus to integrate NbS into climate adaptation policies, with the Forestry and Nature Conservation Agency of the Ministry of Agriculture coordinating cross-sectoral implementation. Recently, the Executive Yuan formally approved the "National Climate Change Adaptation Action Plan (2023–2026)", embedding NbS strategically within national climate governance and promoting cross-departmental collaboration. This plan positions NbS as a pivotal tool and core policy philosophy.

Despite active promotion, a gap remains between NbS theory and practice. While individual case studies have yielded valuable insights, comparative analyses across urban or regional contexts remain limited, confining applications to specific scenarios (Chou et al., 2023). Public and professional awareness of NbS remains vague, with institutionalised planning methods and technical guidelines still lacking. Moreover, NbS has yet to be systematically integrated into urban planning and building regulations, restricting effective implementation. At the local government level particularly, improvements in technical capacity, budgets, and access to reference cases are urgently needed.

2.5 Kaohsiung City as a Case Study: Opportunities and Challenges

Against this backdrop, Kaohsiung City—one of Taiwan's six special municipalities—stands out as a potential demonstration site for implementing Nature-based Solutions (NbS), owing to its industrial transformation and high-density urban development. However, it also faces distinct challenges compared to other international contexts. In recent years, Kaohsiung has actively sought to transition from a heavy industrial city to a smart, low-carbon, and sustainable green metropolis, developing locally adaptive strategies to address climate risks, enhance ecological resilience, promote social equity, and drive green economic development.

According to the 2024 Kaohsiung Voluntary Local Review, the city government has aligned its policy framework with the Sustainable Development Goals (SDGs) and has actively advanced sponge city initiatives and green infrastructure construction. To date, 36 stormwater retention ponds have been completed within development sites, along with 25 publicly constructed retention ponds. The total area of urban green space has reached 2,536 hectares. Furthermore, the Kaohsiung House 4.0 programme promotes vertical greening and energy-efficient building design. A dedicated Sustainable Development and Climate Change Response Council has been established to coordinate cross-departmental resources, strengthen urban resilience, and expand the deployment of nature-based infrastructure.

Nonetheless, current discussions and policy initiatives remain fragmented. The key challenge now lies in how to systematically incorporate NbS into urban planning frameworks and effectively integrate natural elements into spatial strategies.Accordingly, this study adopts an urban planning perspective to examine the feasibility and obstacles of integrating NbS in Taiwan, using Kaohsiung City as a case study. It focuses on two distinct areas: Aozihdi, a newly developed zone transitioning from agricultural use; and Gushan, an older district vulnerable to flooding. By reviewing planning documents and spatial strategies, the study assesses the potential and limitations of NbS implementation in these contexts and offers locally grounded integration proposals.

Drawing on international experience, it aims to provide concrete strategies to strengthen Kaohsiung's resilience and guide its sustainable transformation, while also serving as a policy reference for other cities seeking to pursue NbS as a dual pathway toward climate adaptation and long-term sustainability.

3. Methodology

3.1 Research Design

Many studies have employed NbS matrix systems to examine relevant indicators and the approaches and status of policy integration (Goličnik Marušić, Dremel and Ravnikar, 2023), viewing them as strategies tailored for different urban contexts (Zwierzchowska et al., 2019). Researchers have combined matrix systems with Strategic Environmental Assessment (SEA) frameworks to promote the legal integration of NbS into urban planning, enabling comprehensive environmental and regulatory assessments at early policy stages, thereby reducing future implementation risks and improving environmental outcomes (Figueiredo Gallardo et al., 2022). Consequently, this research aims to develop an integrated conceptual framework, systematically embedding NbS into each primary stage of SEA to enhance the overall resilience of urban land-use planning in response to climate change. By systematically aligning diverse NbS strategies with SEA planning phases corresponding to climate impacts, the study seeks to facilitate climate adaptation-oriented urban planning practices (San Jose et al., 2025).

This research uses Kaohsiung City, Taiwan, as a demonstration case, selecting detailed plans corresponding to primary urban plans for analysis. This approach allows a consistent and clear analytical framework and comparative benchmarks, as detailed plans typically reflect the spatial strategies and land-use implementation from primary plans. By excluding specific, case-oriented detailed plans such as redevelopment or special development zones, the study avoids heterogeneity issues arising from differences in regulations and planning objectives, ensuring more generalisable and representative results.

To further assess NbS applicability and challenges in varying urban contexts, the research focuses on two representative spatial types: (A) Gushan District's detailed plan, an early-developed urban area with high flood risk, whose drainage systems and topography are sensitive to climate impacts, suitable for exploring NbS resilience strategies in built environments; and (B) Aozihdi area's detailed plan, transformed recently from agricultural land to urban uses, representing one of Kaohsiung's key urban expansion zones(Table 1). Its recent development and planning flexibility facilitate examining NbS as a proactive development tool. These two areas reflect different phases of Kaohsiung's urban development, addressing diverse climate risks and governance needs, thus providing valuable comparative insights and policy implications.

Table 1: Strategic Environmental Assessment Matrix

region	Assessment Aspects (Key Risks/Challenges)	
A	Key Risks	• Located near the mouth of the Love River, the area faces dual flood risks from tidal surges and heavy rainfall. • Dense development has resulted in a lack of green space connectivity, undermining ecosystem functions and urban resilience.
	challenge	• Hydrological Risks – Water Resource Management • Ecological Conservation – Green Spaces, Habitats and Biodiversity, Climate Adaptation and Restoration, and Mitigation Actions.
B	Key Risks	• The area was formerly rezoned from agricultural land and has undergone extensive residential and commercial development, resulting in high development pressure and population concentration. • The area is low-lying and prone to flooding during heavy rainfall.
	challenge	• Hydrological Risks – Water Resource Management • Warming Risks – Climate Adaptation and Restoration, Mitigation Actions, and Environmental Quality

3.2 Data Collection

Literature indicates that Taiwan has actively explored and developed NbS primarily within the last five years Systematic promotion of Nature-based Solutions (NbS) in Taiwan only began to take shape in the past five years, approximately since 2020 (Lin, Chan, and Hsu, 2021). This study uses detailed urban plans completed in Kaohsiung between 2020 and 2025 as its core dataset, with a particular focus on cases from the most recent two years that contain NbS-related provisions or spatial strategies. Selected samples include three detailed plans from the Gushan District and eight from the Aozihdi area. All materials are sourced from officially published planning documents and maps by the Kaohsiung Urban Development Bureau, encompassing a wide range of spatial typologies and enabling analysis of NbS application potential.

3.3 Analytical Process and Methods

This study adopts a mixed-methods approach, combining qualitative and quantitative techniques to systematically assess the representation and spatial appropriateness of NbS within urban planning texts (Sarabi et al., 2022). The process begins with a literature-based compilation of keywords related to NbS and green infrastructure, as well as the corresponding environmental and social challenges they address, forming the basis of an evaluation indicator list. The NbS matrix method is then applied to conduct clause-by-clause analyses of the Gushan and Aozihdi plans, identifying the frequency and proportion of relevant keywords to quantify the extent of NbS integration.

Further analysis is carried out using the Strategic Environmental Assessment (SEA) framework to evaluate each area's capacity to respond to key challenges such as hydrological risks and the urban heat island effect. From a regulatory perspective, the study assesses the potential environmental impacts of the plans and the depth of NbS integration. A scoring system is employed to identify implementation gaps, based on which targeted recommendations for improvement are proposed.

3.4 NbS Typologies and Scope of Analysis

This study draws on the policy framework "Building a Resilient Greater Bay Area through Nature-based Solutions", along with other scholarly sources (Debele et al., 2019), to adapt the classification of NbS for urban environments in Asian cities. The classification is structured into three main categories:

(1) **Blue Infrastructure:** Centred on water resource management, this includes riverside and waterfront systems and coastal wetland systems. Key functions encompass flood adaptation, water purification, and aquatic habitat maintenance.

(2) **Green Infrastructure:** Focused on terrestrial ecosystems and urban greening, it includes open spaces (e.g., parks, greenbelts) and ecological spaces (e.g., protected areas, habitats), providing recreational services and enhancing biodiversity.

(3) **Hybrid Infrastructure:** Combining green infrastructure and grey engineering to create synergistic benefits, this category includes detention ponds, permeable pavements, vertical greening on buildings, and ecological corridors.

To ensure statistical accuracy and analytical consistency, the study applies a set of exclusion criteria: repeated mentions from the same source are counted only once; interventions lacking ecological functionality or those that are purely engineering-oriented are excluded; vague or non-specific terms (e.g. references to "greening" without classification) are not included; existing infrastructure that has not undergone retrofitting is excluded; and appendices or procedural documents are disregarded unless they contain specific NbS design descriptions.

4. Results

4.1 Distribution of NbS Types

From the distribution of NbS types in urban planning documents over the past five years, both Gushan and Aozihdi districts primarily emphasise green open spaces (e.g., urban parks, greenery), representing the most frequently mentioned NbS measures. Gushan had 17 occurrences(Table 2), while Aozihdi had 56(Table 3), highlighting urban greening as the current priority NbS strategy. In mixed NbS categories, Aozihdi notably shows greater diversity and frequency of application compared to Gushan. Although Gushan also mentions permeable paving and

green corridors, these appear less frequently, and ecological conservation-oriented NbS are entirely absent, indicating a stronger emphasis on landscape enhancement and spatial reuse. However, the frequency of NbS mentions, while indicative of strategic preferences, is insufficient to reflect actual implementation effectiveness or institutionalisation.

Table 2: Quantification of Frequencies in the NbS Relevance Matrix -Gushan District

Location	Nature-based Solution (NbS) Categories Based on Nature as the Solution frequency Proportion of NbS-related provisions			Documents from Gushan District within the past five years	
city	blue	River, Riverbank	Riverside and waterfront parks	1	1. Riverbank restoration transformed into a riverside park. (100%)
		coast	Coastal wetland	0	
	green	Open space	*Urban Park, Greening (planting, tunnels)	*17	1. The establishment or expansion of parks and green spaces (an increase in quantity)(59%) 2. Land Resource Integration and Conversion (including support for greening (strategies)(29%) 3. Disaster Prevention, Evacuation, and Resilience Functions(12%)
		Ecological space	Nature/Ecological Reserve	0	
	Hybrid	Open space	Flood retention function	0	
			Permeable pavements and waterways (natural water management)	1	1. Pavement permeability improvement (basic pavement renewal)(100%)
		Architectural space	Building Greening (Green Roofs, Green Walls, etc.)	0	
		semi-open space	Atrium and Rain Garden	0	
		ecological space	Green infrastructure network, Pedestrian trail, Green corridor	10	1. Utilization of the Green Corridor after Railway Undergrounding(70%) 2. Integration of Blue-Green Infrastructure Network(30%)

Table 3: Quantification of Frequencies in the NbS Relevance Matrix-Aozihdi District

Location	Nature-based Solution (NbS) Categories Based on Nature as the Solution frequency Proportion of NbS-related provisions			Documents from **Aozihdi District** within the past five years	
city	blue	River, Riverbank	Riverside and waterfront parks	1	1. Construct a waterfront park and recreation area.(100%)
		coast	Coastal wetland	0	
	green	Open space	***Urban Park, Greening (planting, tunnels)**	***56**	1. **Establishment or expansion of parks and green spaces (quantitative increase)(50%)** 2. Ecological education and multifunctional greening (qualitative enhancement) (30%) 3. Disaster prevention, evacuation and resilience functions(13%) 4. Greening aesthetics of blocks and boundaries.(7%)
		Ecological space	Nature/Ecological Reserve	0	
	Hybrid	Open space	Flood retention function	5	1. Detention basins and stormwater retention facilities(100%)
			Permeable pavements and waterways (natural water management)	9	1. Permeable Pavement Installation (Base Pavement Upgrading)(56%) 2. Stormwater Retention and Natural Drainage Facilities(44%)
		Architectural space	Building Greening (Green Roofs, Green Walls, etc.)	3	1. Building setback greenbelt and site green coverage ratio(100%)
		semi-open space	Atrium and Rain Garden	0	
		ecological space	Green infrastructure network, Pedestrian trail, Green corridor	116	1. Utilization of the Green Corridor after Railway Undergrounding (62.5%) 2. Linking Ecological Corridors and Species Habitats(37.5%)

4.2 NbS Application Intensity and Clause Proportions

The NbS matrix analysis reveals that both areas have included a considerable proportion of NbS-related clauses in their urban planning documents, reflecting their respective emphasis and priorities at the planning stage.

In Gushan district, NbS clauses focus predominantly on 'green open spaces' (17 clauses), with new or expanded public green spaces comprising 59%, highlighting an aim to increase overall greenery. Land consolidation and adjustments to green spaces account for 29%, indicating an attempt to identify greening opportunities through spatial reorganisation in high-density settings. Greening combined with disaster prevention accounts for only 12%, suggesting a supplementary role. Mixed-type NbS mainly involve green corridors and reuse of underground spaces (70%), emphasising regeneration and spatial revitalisation, with permeable paving and waterway design at 30% (Table 2).

In Aozihdi, 'green open spaces' are central (56 clauses), reflecting a strong emphasis on green infrastructure and ecological integration during urban development. New or expanded parks and green spaces constitute the primary policy direction (50%), while multifunctional green areas combining ecological education and aesthetic landscaping comprise 30%, underlining educational and landscape values. Disaster prevention facilities represent 13%, with urban visual greening at 7%. Mixed-type NbS (16 clauses) predominantly focus on green corridors and underground space reuse (62.5%), highlighting spatial connectivity; permeable paving and rainwater management systems represent 37.5% (Table 3).

4.3. SEA Analysis: Spatial Potential and Strategic Evaluation for NbS Integration

The evaluation mainly covers three core dimensions: strategic focus, implementation strength, and site-specific identification. The scoring criteria reference Fischer & Gazzola's (2006) SEA implementation study, which employs a three-level rating (high, medium, low) to compare institutional effectiveness, as well as the IPCC Fourth Assessment Report (AR4), which uses likelihood scales such as 'very likely (>66%)', 'likely (33–66%)', and 'unlikely (<33%)' for quantifying scientific evidence strength. This approach, recognised internationally for semantic grading, continues to be applied in IPCC's Sixth Assessment Report (AR6), thereby forming a combined assessment standard(Table 4).

When assessing the focus of urban-plan provisions or design elements, one judges whether a clause explicitly addresses a specific risk or challenge—such as flooding or ecological crises. If the wording directly and concretely corresponds to such challenges, it is deemed "high focus," indicating a clear, purpose-driven strategy. If it only partially addresses the challenge, leaving ambiguity or lacking full implementation detail, it is classified as "medium focus," showing that policy intent is emerging but still open to refinement. Conversely, if a clause makes no explicit reference to any risk or response and remains at the level of abstract vision, it is regarded as "low focus," signifying that the strategy lacks specificity and actionable guidance.

When evaluating implementation strength, clauses with high strength (≥ 66 %) are typically expressed in unequivocal, legally binding language—common terms include "shall," "must," "may not," "in accordance with...," or "only if," for example: "New buildings shall incorporate permeable paving over at least 30 % of the site." Medium strength clauses (33–66 %) combine mandatory and encouraging language—terms such as "encourage," "recommend," "should" or "may" appear, some with legal effect and others merely advisory, for instance: "The site may include an ecological detention basin" or "Developments should retain native planting." Low-strength clauses (≤ 33 %) are largely optional, lacking legal compulsion and reliant on developer discretion; wording such as "may," "encourage," "recommend" or "subject to conditions" is used, for example: "It is encouraged to adopt low-impact development principles" or "The site may consider a retention basin to improve runoff."

Site-specific identification is judged by whether a clause clearly specifies applicable locations and spatial design requirements. High identification (≥ 66 %) occurs when clauses explicitly name districts, plots or zoning categories and provide concrete spatial standards. Medium identification (33–66 %) applies where clauses mention applicable types or spatial approaches but remain vague or lack detailed criteria (e.g. "applicable to development zones" or "may include ecological spaces"). Low identification (≤ 33 %) is when clauses are purely conceptual—merely referring to "enhancing green amenity" or "developing green spaces" without specifying any location, type or method—indicating low site specificity.

By applying these criteria, one can systematically gauge a planning policy's strategic focus, enforcement efficacy and on-the-ground feasibility, thereby informing subsequent policy diagnosis and optimisation.

Table 4: SEA Scoring Criteria

Evaluation Dimension	Definition	Evaluation Criteria
Priority Dimension (Strategic Focus)	Assess whether the urban planning regulations or designs explicitly address this risk or challenge.	1. Fully addresses the challenge with appropriate and clearly defined measures → High 2. Partially addresses the challenge, but with room for improvement. → Medium 3. Fails to address any challenges → Low
Implementation strength (Legal Mandate of Provisions)	Assess whether the provisions in the planning documents are 'optional' or 'mandatory'.	1. ≥ 66 % of clauses are explicit and mandatory with non-compliance affecting planning approval → High implementation strength 2. 33 - 66 % of clauses blend compulsory and encouraging language, indicating a middle-age of enforcement → Medium implementation strength 3. ≤ 33 % of clauses are framed as encouragement, guidance or optional, relying on developer discretion → Low implementation strength
Site-specific Identification (Implementation Potential)	Assess whether the applicable location is clearly specified and whether spatial design conditions are provided.	1. ≥ 66 % of clauses explicitly specify applicable locations and operational conditions → High site specificity 2. 33 - 66 % of clauses mention locations or spatial conditions but remain partly vague → Medium site specificity 3. ≤ 33 % of clauses make no concrete reference to locations or conditions → Low site specificity

Justification and indicative references

1. **Priority Dimension (Strategic Focus):**
   Frantzeskaki (2019): Explores whether Nature-based Solutions (NbS) serve as a core strategy for urban transformation and identifies how they explicitly correspond to specific challenges for evaluation.
2. **Implementation Intensity (Legal Mandate of Provisions)**
   Kabisch et al. (2016): pointed out that many urban Nature-based Solutions (NbS) measures are merely recommendatory provisions, resulting in low implementation rates.
   Gómez Martín et al. (2020): encouraged planning documents to include clearly action-oriented clauses corresponding to specific risks.
3. **Site-specific Identification (Implementation Potential)**
   In the study by Xie, L. and Bulkeley, H. (2020) within the Urban Nature Atlas (UNA), it is suggested that assessing the spatial specificity of NbS design holds a certain level of importance.
   San Jose et al., (2025) and Figueiredo Cardenia et al. (2022), when applying the SEA framework, emphasize that aligning Nature-based Solutions (NbS) with specific spatial locations leads to higher implementation potential. If the spatial areas are not explicitly defined, the likelihood of effective strategy implementation is reduced.

The analysis indicates that Gushan's NbS clauses concentrate on expanding urban green spaces. While this partly addresses ecological conservation, provisions for water management, blue–green corridor connectivity and biodiversity remain underdeveloped. Only 31% of clauses explicitly tackle climate risks, and most are advisory rather than legally binding. Although 70% specify particular locations, the overall profile is "moderate focus, low enforceability, high site specificity."

In Aozihdi, green space expansion also predominates, with additional clauses on water management reflecting stronger support for both total green cover and adaptive reuse of vacant sites. However, references to hydrological or heat risk measures are still few. About 58% of its clauses address climate challenges with moderate enforceability, and 85% name exact locations, yielding a "moderate focus, moderate enforceability, high site specificity" profile.

Overall, despite Kaohsiung's green energy ambitions, regulatory and local context responses need strengthening. The gap between Gushan and Aozihdi stems largely from differing legal enforceability: Aozihdi's higher proportion of mandatory, location specific clauses establishes a firmer implementation basis, whereas Gushan's advisory approach limits its potential. Accordingly, this study stresses that successful NbS adoption depends not only on spatial suitability but also on clear, enforceable institutional design. To this end, a comparative case analysis framework will examine clause types, implementation responsibilities, spatial clarity and strategic integration to pinpoint institutional bottlenecks and inform future policy refinements.

Table 5: Strategic Environmental Assessment Matrix

region	Assessment Dimensions of NbS Implementation (Regulatory Provisions)			General Description
A	Focus area	Project Intensity	regional identification	Although the location is clearly specified, the overall legal provisions lack sufficient enforceability, and there is still room for improvement in strategic focus.
	Actively expanding green spaces, but still insufficient in flood prevention and blue-green infrastructure integration.	Only about 31% of the provisions are legally binding regulations, resulting in relatively limited enforceability.	Only 69% of the provisions explicitly specify applicable locations (such as along the Love River, Shoushan, etc.).	
	◈ Moderate potential	◈ Low potential	◈ High Potential	
B	Emphasizes the enhancement of green spaces and considers stormwater retention, but still requires improvement in addressing hydrological risks.	Approximately 58% of the provisions are legally binding regulations, but there is still room for improvement in enforcement capacity.	85% of the regulations explicitly specify applicable locations (such as Aozihdi Forest Park).	The location is clearly specified, and the regulation has a moderate level of enforceability, but there is still room for improvement in strategic focus.
	◈ Moderate potential	◈ Moderate potential	◈ High Potential	

5. Discussion

5.1 International Case-Comparison Methodology

This study uses the Urban Nature Atlas (UNA) to identify an international city—Hamburg, Germany—with spatial characteristics and climate risks akin to those of Kaohsiung. Employing a case-comparison framework, it contrasts the two contexts to pinpoint local challenges in climate adaptation and urban resilience, extract policy-implementation lessons from Hamburg's successes, and reveal gaps in Kaohsiung's spatial planning, regulatory application, inter-agency collaboration and implementation resources, thereby bolstering the prospects for institutionalising NbS locally (Dignum et al., 2020).

5.2 International Case-Comparison Methodology

Hamburg's HafenCity, situated on the banks of the Elbe and formerly an industrial and port district, has been transformed into a high density, mixed use urban quarter. Its low lying topography and extensive impermeable surfaces have long exposed it to flooding and the threats posed by extreme rainfall under climate change, while ecological restoration and infrastructure renewal remain challenging.

The proliferation of dense housing and infrastructure has dramatically increased surface runoff, overwhelming the city's drainage systems; coupled with increasingly frequent and intense downpours, this exacerbates urban inundation, surface water flooding and water pollution risks. In response, in 2009 the City of Hamburg and the municipal water utility, HAMBURG WASSER, launched the RISA (RegenInfraStrukturAnpassung) programme to establish an integrated, nature based stormwater management system. RISA's objectives are to restore the city's natural hydrological balance, boost on site rainwater retention and infiltration, enhance flood resilience, protect aquatic ecosystems and incorporate rainwater as a key element of urban design and green infrastructure. The initiative unfolded in four phases: in 2010, comprehensive risk analysis and climate scenario modelling; in 2011, the development of guiding principles to align stormwater policy with land use planning; pilot demonstrations of permeable pavements, green roofs and retention landscapes; and, in 2015, the publication of the Regenwasser 2030 Structural Plan, fully integrating stormwater policy into urban governance. A cross departmental framework brought together experts in urban planning, water engineering, transport and landscape architecture, supported by GIS based vulnerability mapping and site assessment tools to inform spatial prioritisation and policy design. Despite regulatory ambiguities, overlapping departmental responsibilities, varied site conditions and limited public engagement, RISA overcame implementation barriers through regulatory reinforcement and institutional transformation. Ultimately, the Regenwasser 2030 Plan became a milestone in Hamburg's evolution into a water sensitive city, demonstrating a systematic approach—from technical innovation and governance integration to regulatory reform and public education—that not only enhances urban climate resilience and spatial quality but also offers a highly replicable nature based water management model for other port and high density cities.

6. Institutional Comparison and Conclusions

Contrasts two institutional models for integrating NbS, focusing on governance integration, legal mandates and interdepartmental cooperation rather than spatial scale or project count. In Hamburg, the RISA system explicitly designates climate adaptation and water management as statutory, cross-departmental objectives, integrating land use, building regulations and drainage via the HafenCity Masterplan so that resilience underpins rather than merely embellishes urban planning(Table 6).

Table 6: Comparative Analysis of International Case Studies

Analytical dimension	(Aozihdi + GushanDistrict) (2019–2024)	Case: Germany RISA – Hamburg (2005-2015)
Major Types of Implemented Nature-based Solutions (NbS)	Urban parks and greening, greenway trails and corridors, permeable pavements, detention and stormwater management facilities, and building greening	Water Resource Management Green Spaces and Sustainable Urban Drainage Systems.
Implementation Instruments (Initial Institutional Arrangement)	Urban planning, urban renewal, and BOT implementation have not yet established an integrated stormwater management tool.	Project-Oriented Climate Adaptation Plan and Spatial Integration HafenCity Masterplan + RISA System (Rainwater Adaptation Platform).
Regulatory and Planning Integration	Although the concept has been incorporated into detailed plans, there is a lack of legally established NbS indicators and institutionalized financial support.	Explicitly incorporate into the Urban Planning Act and Building Act, establish a stormwater management fund and development obligation mechanism.
Implementation approach	Low level of departmental integration, primarily driven by urban development agencies; community participation is preliminary or unclear.	Establish the RISA coordination platform to enable cross-sectoral integration (including environmental protection, water resources, urban planning, real estate developers, and communities).
Key Development Priorities	Some spaces show potential (such as green buildings), but all are implemented through general green infrastructure.	Integrate data-driven engineering and land policies, and provide pilot implementations as models for other cities to follow.

In Kaohsiung, by contrast, NbS measures such as greening, retention basins and permeable paving remain at case-by-case or advocacy stages, lacking clear legal status, mandatory standards or defined responsibilities; departmental collaboration platforms (e.g. urban development, water, environment and construction) are undeveloped and agencies largely act independently, preventing systemic benefits. Kaohsiung's planning framework also lacks the technical integration and task-oriented governance exemplified by Hamburg's institutional platforms and pilot mechanisms. This analysis not only exposes Kaohsiung's governance bottlenecks but also offers transferrable lessons from international practice to inform policy innovation and deepen institutional capacity. Success will require elevating NbS from planning tool to statutory core by setting explicit targets and tasks, establishing cross-departmental governance structures, enacting regulatory frameworks and spatial instruments, and involving stakeholders at all levels, thereby enabling Taiwan's urban planning system to achieve a truly nature-based, sustainable and climate-adaptive transformation.

Abstract
Urban transport systems face escalating disruption risks by challenging resilience in megacities like Istanbul. This study systematically evaluates the presence and coherence of resilience-related strategies across multiple policy levels within Istanbul's transportation policy and legislative frameworks. Employing content analysis on 14 national and 21 local policy documents, main policy themes and granular sub-themes were first identified. Benchmarks for urban mobility resilience were then developed. Subsequently, these benchmarks were applied to assess gaps within each identified main policy theme across both national and local documents. The analysis reveals critical policy gaps which highlight inconsistencies. Our findings pinpoint areas for legal and policy reform to strengthen Istanbul's transport resilience against increasing threats, which ensures system continuity and public safety.

Keywords: content analysis, disaster preparedness, Istanbul's transportation system, policy frameworks, urban mobility resilience

Introduction

The increasing vulnerability of urban transport systems to both natural hazards and human-induced disruptions poses a critical challenge for modern cities. Urban areas, as hubs of economic, social, and infrastructural complexity, rely heavily on effective and resilient transport systems to maintain their functionality during and after disruptive events. As climate change intensifies the frequency and severity of extreme weather events, such as floods and earthquakes, ensuring the resilience of transport systems becomes a key priority in urban sustainability efforts (Priolo et al., 2023).

The problem addressed by this research is the insufficient integration of disaster risk preparedness within the existing legislative and policy frameworks for urban transport planning. Despite the importance of resilience in maintaining urban functionality, many transport systems remain vulnerable to cascading failures due to inadequate coordination between policy frameworks, infrastructure design, and disaster risk management strategies (Mattsson and Jenelius, 2015). This gap poses significant risks, especially in highly urbanized regions such as Istanbul, which faces both seismic threats and climate-related hazards (Priolo et al., 2023). Transport network disruptions can paralyze entire regions, which leads to severe economic losses, compromised public safety, and disruptions in essential services.

Transport networks are interconnected with other critical infrastructure systems which amplify the consequences of their failure (Yang et al., 2022). As cities continue to grow and densify, particularly in hazard-prone regions, addressing these vulnerabilities by assessing the content and structure of current policies at various governance levels becomes essential for sustainable urban development and public safety.

This paper aims to answer the following questions:
1. Which governance strategies and interventions are most effective for enhancing disaster resilience in urban transport systems?
2. How are disaster preparedness and resilience integrated into Istanbul's transport policy and legislative frameworks by examining the distribution of efforts across different policy levels and key thematic areas?

The primary objectives of this research are to systematically map and analyze the extent to which Istanbul's transport policies address disaster preparedness and resilience, including a detailed thematic breakdown of policy provisions at national and local scales. This study also seeks to identify critical gaps and areas for improvement in existing policies based on this internal analysis while proposing strategic recommendations for

enhancing Istanbul's transport resilience through integrated planning and policy adjustments. Ultimately, this research contributes to the broader discourse on resilient urban systems by emphasizing the role of transport infrastructure in disaster risk reduction and by providing a detailed examination of a major city's policy landscape by offering insights for policymakers aiming to enhance urban resilience. Interpretations regarding international perspectives are also discussed in the conclusion to contextualize the findings. The following section will focus on establishing a theoretical foundation by exploring key concepts, metrics, and international frameworks for transport system resilience within policy frameworks.

Understanding Transport System Resilience: Key Theories and Metrics

Transport resilience theory provides a conceptual basis for understanding how urban transport systems can withstand and recover from disruptions caused by natural disasters, climate events, and human-induced crises. Resilience, in this context, refers to the capacity of a system to resist, absorb, adapt to, and recover from external shocks while continuing to provide essential services (Bešinović, 2020). The resilience of this underlying transport system is a critical determinant of broader mobility resilience, which concerns the ability of individuals and goods to maintain necessary movement and access during and after such events.

The concept has evolved from ecological and systems theory, with Holling (1973) introducing resilience as a system's ability to absorb disturbances without shifting to a different functional state. Bruneau et al. (2003) expanded this understanding in infrastructure systems by defining the "4R" framework of robustness, redundancy, resourcefulness, and rapidity as key attributes of resilience in critical infrastructure.

Robustness refers to a transport system's ability to endure disruptions without significant performance degradation while redundancy involves the availability of alternative routes and transport modes to ensure service continuity during disruptions. Resourcefulness captures the capacity to mobilize resources and implement strategies for crisis response, and rapidity highlights the system's ability to restore normal operations quickly following disruptions (Bruneau et al., 2003; Bešinović, 2020). These dimensions together define the structural and operational stability of transport networks under stress, which directly impacts the continuity of mobility for the urban population.

Resilience indicators are essential tools for measuring and evaluating how effectively a transport system manages disruptions and, consequently, supports sustained mobility. These indicators can be categorized across three critical phases of disruption management: pre-event, during-event, and post-event capacities. Pre-event indicators assess proactive measures like risk assessments, disaster mitigation strategies, and infrastructure design for hazard resistance (Yang et al., 2022). During-event indicators evaluate absorptive capacity, focusing on network capacity, travel delays, and the availability of alternative routes while a disruption occurs (Murray-Tuite, 2006; Leobons et al., 2019). Post-event indicators measure recovery effectiveness by examining how quickly and efficiently normal operations are restored and whether long-term disruptions to overall mobility are minimized (Yang et al., 2022).

Transport resilience also operates across multiple dimensions that reflect the diverse aspects of urban mobility systems. Physical resilience pertains to the structural integrity and durability of infrastructure against hazards like floods and earthquakes. Operational resilience deals with maintaining service functionality and minimizing disruptions during crises. Social resilience ensures equitable access to mobility and protection for vulnerable populations, while economic resilience focuses on minimizing financial losses and ensuring recovery funding. Governance and policy resilience, though explored separately in the next section of the literature review, plays a crucial role in supporting effective resilience planning and implementation that ultimately enhances mobility for all users (Yang et al., 2022; Mattsson and Jenelius, 2015).

The theoretical principles of transport resilience, including the "4R" framework, resilience indicators, and multi-dimensional analysis, will form the foundation for the content analysis of Istanbul's transport policy documents in this study. This theoretical basis will assist in developing coding categories for assessing how well disaster preparedness and strategies for achieving mobility resilience are integrated into the city's transport policies and will contribute to identifying existing gaps and areas for improvement.

International Policy Frameworks for Transport Resilience: Implications for Istanbul, Türkiye

In response to growing challenges posed by climate change, rapid urbanization, and increasing natural and man-made disasters, various international frameworks have been developed to guide cities in enhancing the resilience of their transport systems. These frameworks emphasize proactive risk reduction, sustainability, and equitable urban mobility, recognizing that resilient transport systems are essential for maintaining the functionality of urban areas during and after disruptive events. This section reviews key international frameworks and strategies that serve as foundational references for operationalizing transport resilience strategies in urban mobility planning.

The Sendai Framework for Disaster Risk Reduction (2015-2030) is a global standard emphasizing proactive disaster risk management. It outlines four key priorities for action: understanding disaster risk, strengthening disaster risk governance, investing in disaster risk reduction, and enhancing disaster preparedness for effective response and recovery. Within transport resilience, the framework calls for the integration of risk reduction principles into infrastructure planning and the reinforcement of critical infrastructure such as transportation networks to withstand extreme events. The Sendai Framework stresses the importance of multi-level governance and coordination among policymakers, planners, and emergency responders (UNDRR, 2015).

Complementing the Sendai Framework, the European Green Deal (2019) provides a comprehensive policy roadmap aimed at achieving climate neutrality by 2050. A core component is the reduction of transport-related emissions by 90% while promoting sustainable and resilient mobility systems. The Green Deal underscores the dual need for both climate change mitigation—through emission reductions—and adaptation, ensuring urban infrastructure, including transport systems, can withstand climate impacts such as floods and heatwaves. It also emphasizes multimodal and low-emission transport networks, urging the adoption of clean energy technologies and digitalization to support sustainable urban mobility (European Commission, 2019).

Building on these climate resilience goals, the EU Urban Agenda and its associated Transport Resilience Guidelines further operationalize resilience by providing detailed frameworks for city-level transport planning. The Urban Agenda fosters cooperation among member states, cities, and stakeholders to improve the quality of life in urban areas through integrated planning processes. The guidelines encourage cities to adopt Sustainable Urban Mobility Plans (SUMPs) that integrate disaster risk reduction measures into their transport strategies. They emphasize risk-informed decision-making, stakeholder engagement, and the need for cities to align transport resilience efforts with broader sustainability goals, such as those outlined in the Sustainable Development Goals (European Commission, 2021).

A significant contribution to the resilience planning discourse is the 100 Resilient Cities Initiative (100RC), which introduced seven key principles for urban resilience: reflectiveness, robustness, redundancy, flexibility, resourcefulness, inclusiveness, and integration. Applied to urban mobility, these principles guide the development of systems that can withstand and recover from shocks while maintaining essential services. Cities like Rotterdam and Singapore have implemented these principles by investing in modular infrastructure, data-driven flood management systems, and flexible public transit networks that can adapt during crises (100 Resilient Cities, 2015).

The CIVITAS Initiative and its publication Planning for More Resilient and Robust Urban Mobility offers further strategic guidance by integrating resilience principles into Sustainable Urban Mobility Planning (SUMP) processes. The guide emphasizes the importance of preparedness, risk assessment, and policy coherence across multiple governance levels. It also promotes measures such as multimodal networks, improved public transport integration, and the use of climate-resilient materials in infrastructure development (POLIS & Rupprecht Consult, 2021).

Finally, the Sustainable and Smart Mobility Strategy by the European Commission presents a forward-looking roadmap for the transport sector, aligning with the European Green Deal's goals. It emphasizes digital transformation, climate adaptation, and crisis preparedness. Key strategies include promoting multimodal transport hubs, expanding low-emission zones, and incorporating climate risk assessment tools into infrastructure planning processes. The strategy highlights the need for both long-term systemic transformation and short-term adaptive measures in urban mobility planning (European Commission, 2021).

While these global frameworks provide a cohesive set of principles and strategies for operationalizing transport resilience and emphasize integrated governance, proactive risk management, sustainability, and equitable mobility access, their application must be contextualized for local challenges. The Turkish context, in particular, underscores the importance of aligning these international principles with local disaster risk profiles. Türkiye faces unique vulnerabilities due to rapid urbanization, geographical exposure to seismic activity, and an ageing infrastructure system. Istanbul, as one of Türkiye's most densely populated urban centers, is highly exposed to disasters such as earthquakes and flash floods. Its location along the North Anatolian Fault, combined with increasing extreme weather events, creates complex challenges for its urban transport systems. Historical disasters such as the 1999 Marmara earthquake and recurrent flooding events have revealed systemic vulnerabilities in Istanbul's transport infrastructure, emphasizing the urgent need for a more resilient and adaptive mobility strategy (POLIS & Rupprecht Consult, 2021).

In recent years, Istanbul has initiated critical efforts to improve transport resilience, including seismic retrofitting of key infrastructures and the adoption of GIS-based disaster monitoring tools. However, significant gaps may still exist when considering comprehensive approaches to resilience, such as fully integrating principles like inclusiveness, ensuring vulnerable populations are prioritized in emergency transport planning, and flexibility, which involves creating alternative routes and modes of transport to maintain mobility under extreme conditions. The principles established in the international frameworks discussed above provide valuable insights that can help contextualize and inform the assessment of Istanbul's transport policies.

This review of theoretical background and international policy frameworks sets the stage for a detailed examination of Istanbul's own policy landscape. The insights gleaned from these global perspectives, combined with the theoretical understanding of resilience, will help frame the subsequent content analysis of Istanbul's transport policy documents. The next section will delve into Istanbul's current policy framework while the methodology will outline how its legislative frameworks will be analyzed to identify policy gaps and areas for strategic improvement in disaster risk reduction and resilient urban mobility planning based on its inherent characteristics and stated goals.

Istanbul's Current Policy Framework for Resilient Mobility: Opportunities, Gaps, and Limitations

Istanbul's urban mobility systems are critical not only for ensuring the city's daily operations but also for maintaining public safety and economic stability during and after crises. As a megacity located on the North Anatolian Fault and exposed to significant climate-related risks such as flooding and landslides, Istanbul faces unique challenges that make disaster resilience an essential focus. Rapid urbanization, aging infrastructure, and high population density further compound these risks, which places immense pressure on its transportation networks. These vulnerabilities highlight the importance of developing an integrated mobility resilience framework, as the ability to ensure the continuity of transport networks during disruptions is fundamental to safeguarding lives and enabling recovery efforts.

The policy framework governing Istanbul's mobility resilience is shaped by a combination of national and local strategies. At the national level, directives such as the National Earthquake Strategy and Action Plan (NESAP) and the Türkiye Disaster Risk Reduction Plan (TDRRP) provide overarching guidelines for disaster preparedness and risk reduction. These documents emphasize critical measures such as retrofitting transport infrastructure by establishing emergency logistics hubs, and integrating disaster response protocols into urban planning (IMM, 2024). Locally, the Istanbul Metropolitan Municipality (IMM) plays a pivotal role in implementing these strategies through initiatives like the Istanbul Provincial Disaster Risk Reduction Plan (IPDRRP) and the Istanbul Climate Change Action Plan (CCAP). IMM's Disaster Coordination Centre (AKOM) has key efforts to retrofit key transport structures, develop emergency evacuation routes, and deploy Geographic Information Systems (GIS) for real-time disaster monitoring (AKOM, 2024).

Despite these initiatives, Istanbul's mobility resilience framework faces significant gaps and limitations. Coordination between national and local entities, though formalized, is often fragmented. Overlapping responsibilities between institutions like IMM, the Disaster and Emergency Management Presidency (AFAD),

and district municipalities have led to delays in the implementation of resilience measures (IMM, 2024). Informal settlements, which house a large portion of Istanbul's vulnerable populations, remain inadequately integrated into disaster planning.

These settlements are frequently located in flood-prone or seismically vulnerable areas and lack access to critical infrastructure and emergency resources, leaving residents disproportionately exposed to risks (IPDRRP, 2024).

Technological advancements have introduced opportunities to enhance Istanbul's disaster preparedness. For example, the adoption of GIS and Intelligent Transport Systems (ITS) has improved real-time monitoring and enabled better emergency traffic management. However, the lack of centralized data-sharing platforms limits the integration of these tools across institutions, which impeds effective decision-making (IMM, 2024). While Early Warning Systems for earthquakes and floods are under development, their implementation remains inconsistent, with significant room for improvement. Additionally, partnerships with international organizations, such as the World Bank and the European Bank for Reconstruction and Development (EBRD), have supported projects like the Istanbul Seismic Risk Mitigation and Emergency Preparedness (ISMEP) initiative, which has funded retrofitting and resilience measures for key public and transport infrastructure. Yet, these efforts have not been sufficient to address long-term funding needs, particularly for underserved areas (ISMEP, 2024).

The challenges faced by Istanbul's mobility resilience framework are symbolic of the broader issues encountered by rapidly urbanizing cities with high disaster risk profiles. In the context of this paper, In the context of this study, Istanbul serves as an essential example of how disaster preparedness and resilience can be integrated into mobility systems. Its experiences demonstrate that while technological advancements and international partnerships can support progress, sustainable resilience requires a cohesive policy framework that bridges gaps between national and local strategies. By analyzing Istanbul's mobility resilience framework, this research contributes to broader efforts to improve disaster preparedness in urban contexts, offering policymakers actionable recommendations for creating more adaptive and inclusive cities.

Methodology

This study employs a qualitative content analysis approach to analyze Istanbul's transport policy landscape by focusing on how disaster preparedness and mobility resilience are addressed across different policy levels and thematic areas. The aim is to map the presence and distribution of key resilience-related themes within selected national and local policy documents, ultimately visualizing these relationships to understand current policy emphases and potential gaps.

The dataset for this research comprises a comprehensive collection of 35 policy documents including 14 national-level (coded N1-N14) and 21 local-level (coded L1-L21) texts, selected for their direct relevance to disaster resilience, mobility preparedness, urban planning, and transport strategies pertinent to Istanbul. The initial identification of this collection of documents was based on two key deliverables of the Istanbul SUMP Stage II project: the Inception Report and the Analysis of Current Planning Practices. These documents, sourced from official government portals and institutional repositories, span a wide temporal range and cover both strategic frameworks and operational plans to ensure a comprehensive overview of governance approaches (Table 1). As acknowledged within the source project, this foundational list may be further enriched during related pilot initiatives such as the one focused on Istanbul's earthquake and flood risks (Pilot Project 5.5.1), which the first author is involved in.

Table 1. The list of selected policy documents

Document Code	Document Title	Year
N1	The Twelfth Development Plan	2024-2028
N2	Annual Presidential Programme 2025	2025

L21	Istanbul Green City Action Plan (GCAP) (Draft)	2025-2030

MAXQDA software was utilized primarily for efficient document management, facilitating navigation through the extensive dataset, searching for specific keywords and concepts related to resilience, and annotating relevant sections within the policy texts to support the thematic analysis. The core analytical process was developed through a two-stage process. First, a hybrid inductive-deductive thematic analysis was conducted, which results in featured main themes and granular sub-themes. To move beyond thematic identification to a critical evaluation, a five-point ordinal scale was then developed to serve as a benchmark for assessing policy gaps.

This scale utilizes a graduated color scheme to visually represent the strength of policy articulation for each main theme. The color intensity progresses across the five-point scale, where the lightest indicates no relevant or only an indirect strategy, and the darkest signifies the highest level of policy actionability and strenght with an identifiable strategy supported by a defined performance indicator. The findings from this thematic mapping and visualization are then interpreted to identify patterns, current priorities, and potential areas for strengthening Istanbul's overall approach to resilient mobility.

Findings and Results

The policy landscape governing Istanbul's urban mobility resilience is a complex interplay of national directives and local implementation. The flow of policy focus, which provides a comprehensive visualization of the relationships between the two policy levels, 8 main themes identified in this study, and 30 granular sub-themes are mapped out with an alluvial diagram (Figure 1). The width of each flow is proportional to the intensity of policy attention, which allows for a visual assessment of strategic priorities, areas of convergence, and critical gaps.

The diagram immediately reveals a clear division of labor between the national and local policy levels. The national level predominantly focuses on establishing high-level frameworks and standards. A significant portion of its policy output streams into the themes of "National Strategic Frameworks & Standards" and "Disaster Specific Operations & Local Resilience". This flow further breaks down into granular sub-themes such as "NatDisasterFrameworks" (e.g., TDRP, TDRRP), "LongTermTransportVision" (e.g., Vision 2053), and setting national "TransportSafetyStandards" and "EvacRouteDesignStds". This pattern underscores the national role in setting the overarching strategic direction and legal foundation for disaster management and transport planning across the country.

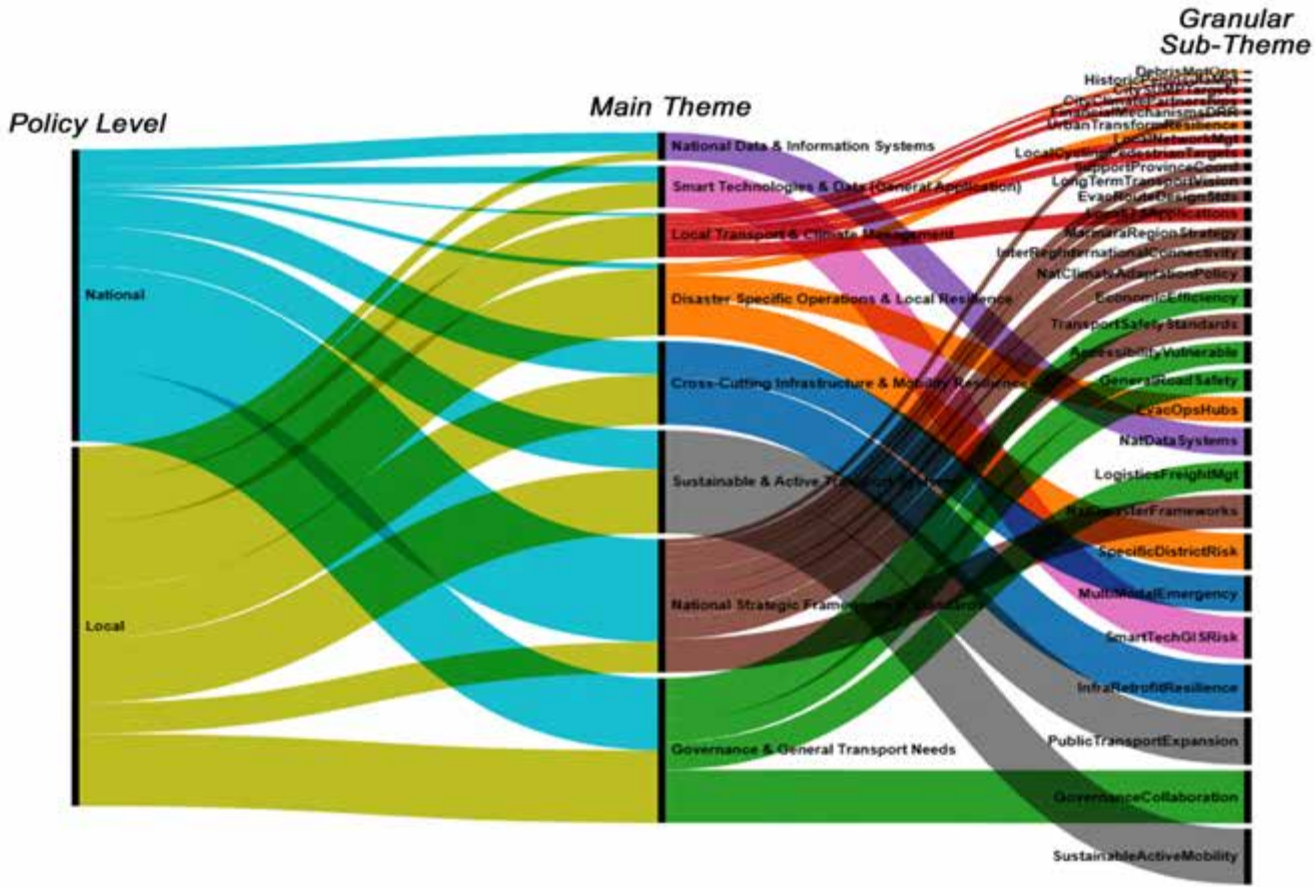

Figure 1. Alluvial diagram of main themes and granular sub-themes of national and local level policy documents (created by authors)

Conversely, the local policy level is overwhelmingly focused on governance, service delivery, and on-the-ground implementation specific to Istanbul. The two largest streams originating from the local level are directed toward "Governance & General Transport Needs" and "Sustainable & Active Transport Systems". These flows are linked to highly operational sub-themes like "PublicTransportExpansion," "GovernanceCollaboration," and "SustainableActiveMobility," which reflects the municipality's direct responsibility for managing and expanding public transport by engaging with stakeholders, and promoting green mobility. Furthermore, the local level's focus on place-based solutions is evident in sub-themes such as "CitySUMPTargets" and "LocalCyclingPedestrianTargets," which are fed exclusively by the local policy stream.

While there is a clear divergence in primary roles, the diagram also highlights crucial areas of convergence. The 'Disaster Specific Operations & Local Resilience' theme is a key area of shared responsibility, receiving significant policy attention from both national and local levels. This combined flow addresses a wide array of sub-themes, including "MultiModalEmergency" operations, identifying "SpecificDistrictRisk," and establishing "EvacOpsHubs," indicating a necessary collaboration in crisis management. Similarly, "Cross-Cutting Infrastructure & Mobility Resilience" is another area of mutual focus, channeling policy effort into the critical sub-theme of "InfraRetrofitResilience" for key transport assets.

Most importantly, the diagram provides a stark visualization of the strategic gaps identified in this research. A critical disconnect is visible between disaster planning and sustainability. There are no significant flows connecting the main theme of "Disaster Specific Operations" with sustainability-oriented sub-themes like "LocalCyclingPedestrianTargets." Likewise, the massive policy stream dedicated to "Sustainable & Active Transport Systems" does not meaningfully connect with disaster-related sub-themes, visually confirming that these two powerful policy agendas operate in parallel rather than in an integrated manner. This lack of integration represents a significant vulnerability in the overall resilience framework for Istanbul's transport system.

Investigating the source of this vulnerability requires a deeper analysis of the documents themselves, beginning at the national level. The analysis of 14 national policy documents reveals a foundational, yet incomplete, legal and strategic framework for strengthening the resilience of Istanbul's transport systems. The findings show a clear national trend toward data-driven governance and a dual focus on disaster resilience and sustainability. However, critical inconsistencies and gaps exist, which have direct consequences for a megacity like Istanbul (Figure 2).

A primary finding is the national shift towards measurable, evidence-based policymaking, which provides an essential foundation for Istanbul's resilience efforts. Recent cornerstone documents like the Twelfth Development Plan (N1) and the Annual Presidential Programme (N2) mandate the creation of national data systems such as the Infrastructure Information System (see Article 605.6) and the Disaster Management and Decision Support System (DMDS). These national systems provide the essential data landscape upon which Istanbul's municipal agencies must build their own resilience monitoring and decision-making tools. However, a significant gap is noted in TDRP (N7), which lacks a clear data analytics component by creating a potential challenge for Istanbul's integrated emergency management.

The national policy landscape is strongly shaped by two parallel strategic pillars: disaster resilience and sustainable mobility. The resilience pillar offers direct legal pathways for action in Istanbul. N1 includes a specific mandate to increase the resilience of critical infrastructure in the Marmara Region (see Article 838.1), directly targeting Istanbul. This is reinforced by the TDRRP (N5), which calls for making urban infrastructure earthquake resistant (see Action D.6.3), a core task for the city. Similarly, the sustainability pillar with its national goals for reduced emissions (Green Deal Action Plan, N13) and a 6000 kilometre expansion of bicycle routes (Bicycle Route Network Master Plan, N11), provides the strategic backing for Istanbul to advance its own green transport initiatives.

Despite the individual strength of these two areas, a critical inconsistency emerges where they fail to connect, a gap that creates a direct vulnerability for Istanbul. The analysis shows that national disaster response frameworks, particularly the TDRP (N7) and the NESAP (N4), do not integrate sustainable transport modes into their operational plans. This national-level oversight is highly problematic for a densely populated megacity like Istanbul, where alternative transport modes like bicycles could be vital for maintaining mobility and delivering aid when primary road networks are compromised during a disaster.

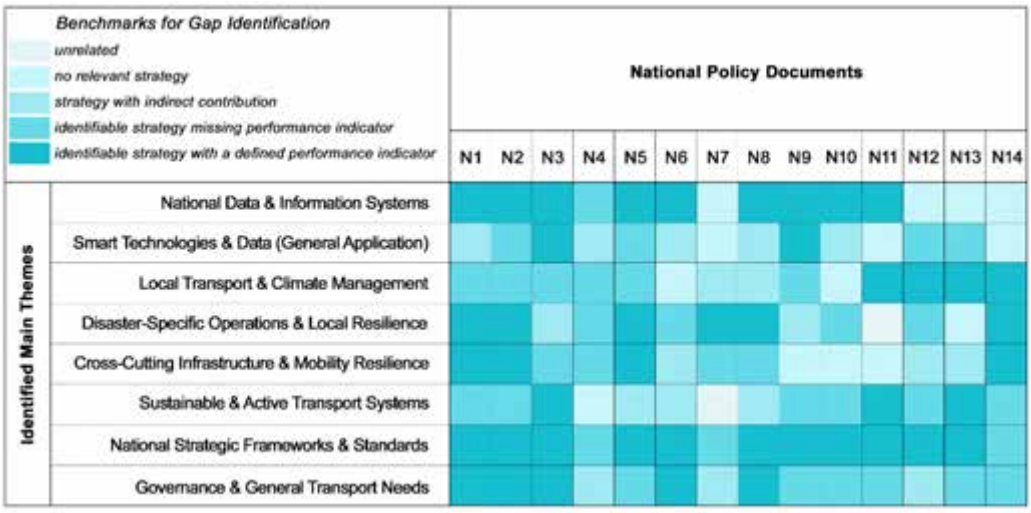

Figure 2. Assessment matrix for gap identification across national policy documents (created by authors)

The findings also highlight that while a clear policy evolution is underway, from older, non-metricized strategies like the NESAP to newer, key performance indicator-driven plans like the Twelfth Development Plan, the effectiveness of this national framework in protecting Istanbul hinges entirely on its translation into coherent local policy. National documents provide the top-down mandate, but their success depends on the creation of legally-binding, adequately funded, and technically sound municipal plans and actions. This points to the need for a deeper analysis of Istanbul's local documents to determine if these national strategies are being effectively implemented or if significant gaps in local legislation are undermining the city's transport resilience.

On the other hand, the analysis of 21 local policy and planning documents for Istanbul reveals a dynamic, ambitious, and highly operational policy environment. At this municipal level, strategic objectives are translated into actionable plans, which provide concrete legal pathways for enhancing urban mobility resilience. However, the analysis also uncovers significant inconsistencies, particularly in the integration of parallel policy streams, which creates vulnerabilities in the city's overall resilience framework. A defining characteristic of this local policy landscape is its robust and detailed approach to disaster operations (Figure 3).

The theme of 'Disaster-Specific Operations & Local Resilience' is exceptionally strong in the key operational plans. For instance, the IPDRRP (L4) moves beyond strategy to define measurable key performance indicators such as reduction in travel time during evacuation scenarios. This is further operationalized by the Istanbul Local Level Disaster Evacuation Operational Plan (L15), which provides granular detail on 204 transferring areas and additional 46 potential areas registered in DMDS for use during emergencies. Plans like the Istanbul Provincial Disaster Logistic Plan (L5), the Debris Management Plan (L6), and the Fleet Management Emergency Action Plan (L7) provide a comprehensive, multi-faceted framework for response and recovery, which indicates that Istanbul's legal and administrative capacity for managing a crisis is well-established and highly structured.

In parallel, the local documents demonstrate a powerful and measurable commitment to sustainable and active transport. This is a clear policy priority for the Istanbul Metropolitan Municipality (IMM). The IMM Strategic Plan (L1) sets ambitious, quantifiable targets such as increasing the total cycling infrastructure length from 266 km to 1,050 km and raising the share of rail transport in public transit from 20.6% to 30%. This vision is reinforced by dedicated documents like the Istanbul SUMP I (L3), the Istanbul Cycling Master Plan (L8), and the Pedestrian Master Plan (L9), all of which have identifiable strategies with a defined performance indicators for their core sustainability objectives.

However, a critical policy gap emerges where these two priorities should intersect. The city's strong sustainability agenda operates largely in isolation from its disaster resilience framework. While documents like the Bicycle Master Plan (L17) and Pedestrian Master Plan (L16) excel in promoting active transport, their summaries contain little to no mention of how these networks could be leveraged during an emergency. For disaster-related

themes, these plans either offer only an indirect contribution or have no relevant strategy at all, which creates a significant inconsistency. This failure to integrate the two pillars means that the legal and operational potential of Istanbul's growing active transport network as a resilient mobility option during a crisis remains unrealized.

Beyond these core themes, Istanbul's local governance is data-rich. Many key documents including L1, L4, and IPDRP (L13) demonstrate exceptional strategic maturity by defining clear, measurable performance indicators for their focus on creating and integrating data systems such as performance monitoring platforms and GIS-based risk maps. However, the application of this data through smart technologies is less mature. While many plans mention leveraging technology, they often lack specific, measurable outcomes. For example, the Vision 2050 Strategy (L2) and L5 refer to integrating smart technologies and advanced analytics systems, but do not define how the success of these implementations will be measured. This suggests a gap between the city's capacity for data collection and its ability to systematically deploy that data for smart, resilient operations.

Furthermore, the analysis reveals a mixed approach to vertical policy coherence. The city's disaster-specific plans (L4, L13, L15) show strong alignment with national frameworks by explicitly referencing documents like the TDRP. This formal, documented alignment provides a clear and measurable legal pathway for coordinated national-local disaster response. In contrast, most other local strategic documents including L1, L3, and various master plans, do not explicitly reference their alignment with corresponding national strategies. They operate in parallel with national goals rather than being formally nested within them, which results in what this study classifies as an indirect contribution. This suggests a potential gap in legal and administrative coherence, where ambitious local initiatives may not be fully harmonized with the broader national strategic direction, potentially leading to inconsistencies in long-term implementation. In summary, Istanbul's local policy landscape provides strong legal pathways for operational disaster response and sustainable transport. However, the findings pinpoint a critical need for policy reform to bridge the gap between sustainability and resilience planning. Integrating these two domains and ensuring greater vertical coherence between local and national frameworks are essential next steps to strengthen the resilience of Istanbul's transport systems against future disruptions.

Figure 3. Assessment matrix for gap identification across local policy documents (created by authors)

Conclusion

This study embarked on a thematic content analysis to evaluate the legal and strategic pathways for urban mobility resilience within the complex policy landscape governing Istanbul. By examining 35 national and local documents, the research aimed to map the coherence of resilience-related strategies, identify critical policy gaps, and pinpoint areas. The analysis confirms that while Istanbul possesses a sophisticated and highly operational policy environment for both disaster management and sustainable transport, significant vulnerabilities arise from the lack of integration between these two powerful, yet parallel, policy agendas.

The findings reveal a clear division of responsibility: national policies provide the foundational legal frameworks while local policies focus on operationalization. National documents such as the NESAP and the TDRRP establish

a strong mandate for resilience by emphasizing the retrofitting of critical transport infrastructure. At the local level, this translates into exceptionally robust and detailed operational plans such as the IPDRRP, which defines measurable key performance indicators like reduction in travel time during evacuation scenarios, and the Debris Management Plan, which outlines post-disaster logistics. Simultaneously, both policy levels demonstrate a powerful commitment to sustainable mobility. National documents like the Green Deal Action Plan and the Bicycle Route Network Master Plan set ambitious targets for emissions reduction and a 6,000-kilometre expansion of cycling routes. This is mirrored locally by the IMM Strategic Plan, which aims to increase cycling infrastructure from 266 km to 1,050 km, and by a suite of dedicated master plans for active transport. However, the most critical finding is the systemic failure to connect these two agendas. National disaster frameworks, particularly the TDRP, do not integrate sustainable transport modes into operational plans and assign municipalities limited direct responsibility. This national-level oversight is replicated locally, where active transport plans for cycling and pedestrians show little to no consideration for their potential role during emergencies.

These findings hold significant implications when contextualized within the international frameworks and theoretical principles of resilience. The strong multi-level governance structure for disaster planning in Istanbul aligns well with the priorities of the Sendai Framework for Disaster Risk Reduction, which emphasizes coordinated action across administrative levels. The city's detailed operational plans also reflect key attributes of the "4R" framework, particularly in building robustness through infrastructure retrofitting and ensuring resourcefulness through pre-planned crisis management. However, the lack of integration of active transport highlights a critical weakness in achieving redundancy and flexibility. Furthermore, while Istanbul's ambitious sustainability goals are consistent with the European Green Deal and SUMP principles, the analysis reveals that the city has not yet fully realized the integrated approach these frameworks advocate, where disaster risk reduction is a core component of sustainable mobility planning, not a separate activity.

To bridge these identified gaps and strengthen the legal pathways for resilience, this study proposes several key policy recommendations. This requires amending national frameworks like the TDRP to explicitly include roles for non-motorized transport in emergency response and mandating that local active transport plans incorporate disaster preparedness scenarios. Second, vertical policy coherence must be strengthened. While local disaster plans show strong alignment with national directives, other strategic documents like the IMM Strategic Plan operate in parallel, formalizing the alignment of all local strategies with national goals is essential. Finally, to bridge the gap between data collection and action, investment is needed in integrated smart city platforms that can utilize real-time data for both daily traffic management and dynamic crisis response.

While this study provides a comprehensive analysis of the policy landscape, it is limited to the content of the documents themselves and does not assess their on-the-ground implementation. Future research should therefore focus on evaluating the effectiveness of these policies through case studies and assessing the allocation of financial and human resources. Further studies could also explore the perceptions and preparedness of vulnerable communities to determine if these top-down strategies are effectively reaching those most at risk.

In brief, this research demonstrates that building urban mobility resilience in a megacity like Istanbul is not merely a technical or infrastructural challenge, but a profound issue of policy integration and governance. Closing the documented gaps between disaster planning and sustainable mobility is essential for creating a transport system that can not only withstand future shocks but also continue to serve the needs of all its citizens by providing system continuity and public safety against increasing threats.

Abstract
Within the current framework of territorial governance, new planning models are emerging, focused on urban regeneration, the reduction of soil consumption, and regulatory simplification. The legislative proposal put forward by INU and its implementation in the Marche Region represent a key step in the redefinition of Italian urban planning. These legislative instruments respond to the need to move beyond the traditional system and to address contemporary challenges, marking the beginning of a new phase oriented towards flexibility, sustainability, and the revitalisation of urban planning.This article reconstructs the historical, regulatory, and scientific development that led to the new proposal, examining the contributions that have emerged within the national and regional debate, and assessing the innovative scope of the Marche law as the first concrete experimentation of the INU model.

Keywords: territorial governance – urban planning – national reform – urban planning legislation – Marche Region;

1-Introduction

Through the reconstruction of a historical-critical account of the evolution of planning in Italy and of the main phases of territorial transformation, the aim is to highlight the discontinuities and persistences that continue to shape the institutional and planning framework of the country. This process culminates in the recent reform proposal, the "Law of Fundamental Principles and General Norms for Territorial Governance", drafted by the National Institute of Urban Planning (INU) in 2024.The INU's proposal has reactivated a significant area of reflection within the urban planning community, which, however, has never ceased to show concern for the need for a reform of territorial governance. Since 2022, a large part of the INU's efforts has been devoted to a systematic in-depth process, carried out through publications, public discussions, and conferences, leading to the presentation of the draft law in the Senate in July 2024. These activities have contributed to rekindling—and to some extent consolidating—the debate within the field of urban planning on the urgency of a new national law.

In the current context of debate—marked by a widespread consensus on the obsolescence of Urban Planning Law No. 1150/1942—a consolidated practice has emerged among various Italian regions, aimed at updating their planning systems through autonomous regional legislation. In this scenario, the significant legislative development of the Marche Region has adopted a regulatory framework explicitly inspired by the proposal developed by the INU through Regional Law No. 19/2023[1]. Rooted in the principles promoted by the Institute, the Marche law opens up a further and significant field of inquiry, while also representing the first testing ground for the concrete implementation of the contents and guidelines set out in the national proposal.

The current interpretation of the Italian framework—characterised by autonomous regional legislative initiatives and by a new national reform proposal—does not represent an isolated process, but rather fits within a broader European context.In this scenario, European policy has gradually embraced urban regeneration, within the wider framework of sustainability, as a structural paradigm of its strategy, recognising its central role in processes of cohesion and competitiveness. It is with the Toledo Declaration of 2010 that the concept of integrated urban regeneration was introduced, based on a multidimensional and cross-cutting approach.

1 Regional Law No. 19 of 30 November 2023, Marche Region, Provisions on Planning for Territorial Governance.

Although it emerged in response to an economic and financial crisis affecting Europe, urban regeneration was proposed not only as a driver of development, but also as a tool to strengthen social cohesion and environmental sustainability (Giaimo, 2025a).

While the issue of urban planning appears to have "disappeared from the horizon of both politics and society" (Brenna, 2021, p. 61), a scientific community has gradually built a complex and substantial wealth of knowledge. This extensive body of thought and material highlights the innovations that have taken place in the field of planning and critically examines the progressive marginalisation of the discipline within public, political, and social debate.

Alongside the well-established contribution of the broad community of urban planners and architects—who have long been engaged in developing new instruments for territorial governance, experimenting with innovative planning models, and analysing regional legislation aimed at moving beyond the framework of Law No. 1150/1942—a significant contribution has also come from the legal community. The latter has addressed major issues such as the reform of Title V[2] of the Constitution and the current project for differentiated autonomy[3] for the Regions. Today, however, its focus is increasingly directed towards urban regeneration, conceived as "a set of actions, if not a true function, through which to guarantee both the right to the city and the tools necessary for urban life" (Giusti, 2021, p. 441).

In today's crisis scenario, marked by structural fragilities and ongoing uncertainties, the contribution evaluates the innovation within the ongoing debate both inside and outside the relevant scientific communities. It reflects on the role and potential revitalisation of urban planning within an institutional and social system undergoing profound transition.

2-Data And Methods

2.1 Methodology: Acquisition And Study Of Sources

For the definition of the state of the art and the reconstruction of the process that has accompanied the debate on territorial governance, the study began with an in-depth analysis of the two most recent regulatory references. These constitute the central core around which the proposal for a "*Law of fundamental principles and general rules for territorial governance and planning*,"[4] developed by INU, revolves, alongside the regional law of Marche, LR No. 19/2023.

The examination of the two texts allowed for the identification of the conceptual pillars and the paradigms that support them, as well as for the detection of convergences. In particular, even in an initial review, it was possible to recognise significant structural and substantive affinities, including:

- the redesign of planning instruments, notably with the introduction of the General Urban Plan (PUG) as a municipal tool structured around three functions: structural, regulatory, and operational;
- the adoption of inter-institutional co-planning as a collaborative method aimed at ensuring coherence and simplification across different planning levels;
- the adoption of the principle of coherence as a methodological criterion for the vertical and horizontal integration of planning content, understood as a relationship of functionality, efficiency, effectiveness, compatibility, consistency, and absence of contradictions among the various components;
- a redefinition of the concept of infrastructure and services, moving beyond an exclusively quantitative interpretation to also include qualitative and performance-based criteria;
- the enhancement of public-private partnership in planning processes;

2 The reform of Title V, Part II, of the Italian Constitution, implemented through Constitutional Law No. 3 of 2001, established territorial governance as a matter of concurrent competence between the State and the Regions.

3 Law No. 86 of 26 June 2024, containing provisions for the implementation of differentiated autonomy for Regions with ordinary statute, pursuant to Article 116, third paragraph, of the Constitution.

4 The draft law of the National Institute of Urban Planning, presented to the Senate on 16 July 2024, aims to replace Law No. 1150 of 1942.

- the establishment of an integrated knowledge framework, conceived as a shared and dynamic territorial database, serving as a technical-operational tool for planning and interoperability between entities;

- a broader definition of the concepts of soil consumption reduction and urban regeneration, considered foundational principles of contemporary urban planning.

Following the analysis of the two most recent legislative references and their evident and declared interconnection, the investigation focused on an in-depth study of the materials constituting the current debate surrounding them. In particular, it was considered essential to examine the sources reflecting the process of constructing the reform proposal, as well as the reflections and experiments associated with it.

Following the analysis of the two regulatory references and their evident and declared interconnection, the investigation focused on an in-depth examination of the working materials and sources related to them, which contributed to the process of developing the reform proposal. A large portion of these materials originates from the INU scientific community, specifically from the journal *Urbanistica Informazioni*. This journal has played a fundamental role in documenting and spreading the debate since 2022, the year in which, following the Bologna Congress, INU formally initiated the process of drafting the new legislative proposal.

Through a systematic analysis of the issues published, it has been possible to reconstruct the structure of the reasoning that accompanied the process of defining the national proposal, as well as the main contributions that have increased the reflection on regional planning. This collection of materials represents the most significant knowledge base to identify the principal conceptual trajectories and to highlight the structural weaknesses of the current planning system. These contributions have made it possible to identify the unresolved challenges and priority issues that the draft law aims to address and overcome through a renewed regulatory framework, while simultaneously offering an interpretative key to the elements characterising both the INU text and the Marche regional law. In particular, the following themes emerge:

- the intention to confer unity upon the national planning system, at the threshold of a new urban planning era;
- the updated, broad, and detailed definition of the concept of territorial governance, in line with contemporary needs;
- the development of planning instruments capable of effectively integrating the principles of urban regeneration and the reduction of land consumption;
- the overcoming of the obsolete regulatory framework of Urban Planning Law No. 1150/1942 and of the hierarchical-vertical model of territorial governance generated;
- the repeal of Ministerial Decree 1444/1968, particularly with regard to the regulation of urban standards;
- the resolution of the predictive rigidities inherent in traditional General Urban Plans (PRG), in favour of more flexible and adaptive planning.
-

Having identified the main themes emerging from the debate and their regulatory translation in the two aforementioned references (the INU proposal and the regional law of Marche), a more extensive review of the literature was undertaken. This review aimed to reconstruct, through a retrospective method, the evolution of the process that led to the current configuration of the debate. The investigation was conducted by selecting specific keywords: i) some relating to broad themes and general issues ("planning," "regional planning," "territorial governance," "regional laws," "urban reform," "planning tools"); ii) others more specific and linked to the current concerns of contemporary debate ("urban regeneration," "combating soil consumption," "structural plan," "urban equalisation").

Among the identified materials, contributions published in the last 15–20 years were considered. The subsequent selection was carried out through a preliminary reading of the abstracts, aimed at verifying their relevance to the research objectives and ensuring thematic coherence with the interpretative lines that had emerged.

From the contributions thus filtered, open access texts deemed most significant for reconstructing the main developments of the debate and the conceptual challenges leading to the current phase of proposal and regulatory experimentation were further explored and analysed.

2.2 Summary And Discussion Of The Issues Emerging

The in-depth study conducted on materials pertaining to the first area of investigation (i), related to territorial governance and planning in a general sense, enabled the reconstruction of a broad and complex evolutionary framework. The selected contributions, often focusing also on the genesis and analysis of regional laws, proved fundamental for identifying the main chronological sequences and outlining the normative and conceptual transformations that have affected the national planning system.Simultaneously, the investigation carried out in the second area (ii), centred on specific topics emerging from the current debate and identified through targeted keywords, produced more sectoral contributions which, although limited in scope, proved essential for integrating and completing the general framework reconstructed in the first field of investigation. This, in turn, contributed to the definition of a coherent, multi-level interpretative system.

The analysis of the collected scientific contributions highlighted a close correspondence between the phases of intensification in the disciplinary debate and certain significant historical and institutional turning points that shaped its content and interpretative directions. In particular, it was possible to identify four main time periods, each characterised by specific thematic focuses:

- **2000–2005:** In this initial phase, the focus of scientific output was predominantly on the INU's 1995 legislative proposal, which introduced elements of discontinuity compared to the traditional framework and stimulated significant reflections on the future of territorial governance. The debate took place within the broader context of institutional reform processes, culminating in the reform of Title V of the Constitution (2001), which redefined territorial governance as a concurrent matter between the State and the Regions. This encouraged the Regions to initiate autonomous legislative processes, incorporating some of the innovations proposed by the INU.
- **2005-2015:** This decade is marked by an intense scientific output focused on the analysis of the first new-generation regional laws and the experimentation with the planning models derived from them, with particular reference to the municipal scale. The innovations introduced during this phase represent the initial concrete experiences of reform, constituting a break from the traditional regulatory framework. The differences that emerged in the various approaches adopted at the regional level gave rise to a plurality of planning models, which the scientific community has considered important to examine.
- **2015-2020:** In this phase, a progressive sectorialisation of scientific interest can be observed, with growing attention towards new planning paradigms: urban regeneration, the containment of land consumption, and urban equalisation[5]. These themes are increasingly recognised as foundational to the so-called "fourth generation of urban planning". At the same time, the contribution of the legal community is gaining strength, initiating a structured reflection on the legal framing of these concepts and their systematic integration into the broader framework of territorial governance.
- **2020-2025:** The final identified time period is marked by a strong concentration of contributions attributable to the INU, following its commitment to draft a new national legislative proposal. The materials produced focus on the development of the fundamental principles of the reform, the analysis of the current system's critical issues, and the necessity to overcome its now obsolete legacies. During this period, visions oriented towards the comprehensive renewal of the regulatory framework are consolidated, increasingly clarifying the coordinates of the emerging new phase in urban planning.

Within the broader context of these publications, five main topics and research foci have been identified. These structure the following paragraphs with the aim of providing a critical synthesis of the state of the art:

i) The origins of the reform: territorial governance between the State and the Regions, and the INU legislative proposal of 1995.
ii) Initial reform experiences: regional models in Italy within the renewed planning system.
iii) Urban regeneration and the fight against soil consumption: paradigms of fourth-generation urban planning.
iv) Towards a new urban planning era? The contemporary scenario.
v) The INU proposal within Regional Law Marche 19/2023.

5 A tool for the fair distribution of development rights among landowners involved in urban transformation, overcoming the strict divide between buildable and non-buildable areas. It allocates proportional rights even to unaffected properties, preventing disparities and supporting the creation of the public city. Today, it plays a key role in urban regeneration strategies.

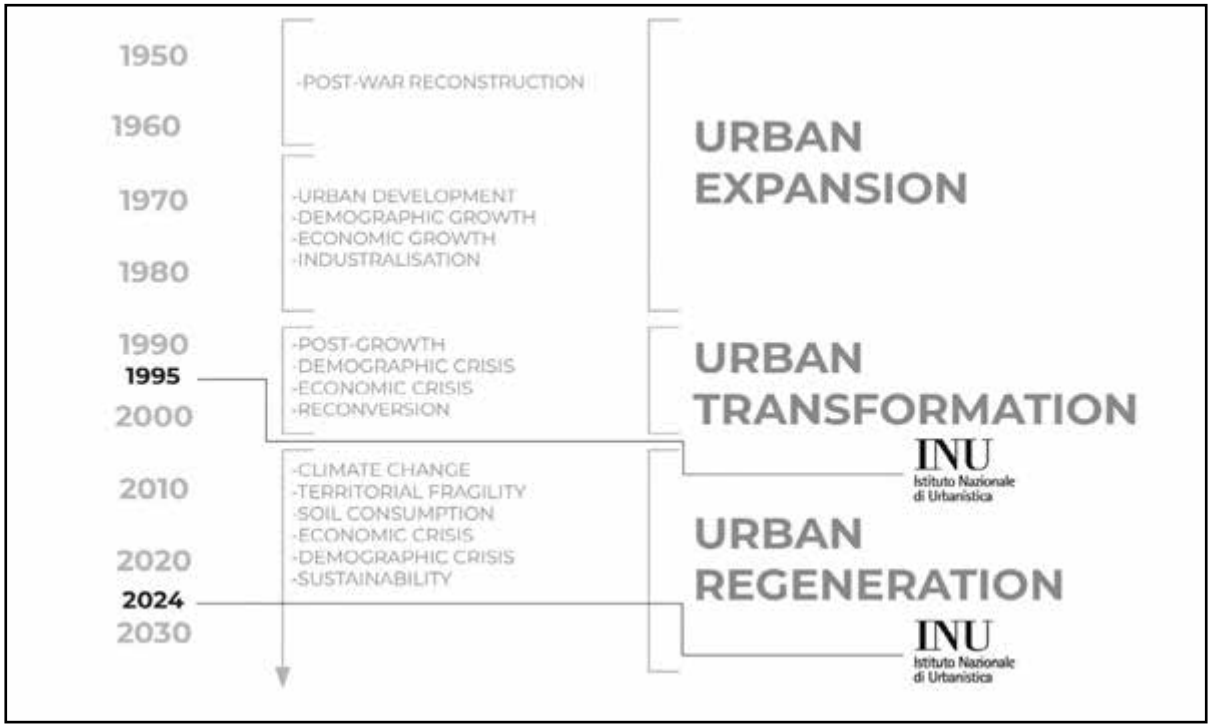

Fig.1 Main urban planning phases in the Italian context and the historical placement of the most significant INU reform proposals.

2.2.1- The origins of the reform: territorial governance between the State and the Regions, and the INU legislative proposal of 1995.

The 1990s mark a crucial turning point for territorial governance in Italy. This period is characterised by two main, parallel factors:

- The State's normative and institutional system, which expands the content of urban planning regulations and implements a gradual process of administrative decentralisation.
- A substantial shift in the needs and paradigms of urban planning, marked by a transition from "urban expansion" to "urban transformation."

Between 1970, the year of the establishment of the Regions[6], and the 1990s, the first regional laws on urban planning were developed. These are defined as "first-generation" laws because they merely paraphrased the contents of Law no. 1150/1942, without altering its conceptual and hierarchical framework. In the 1990s, however, a second cycle of reform began, marked by the emergence of "second-generation" regional laws that started introducing the first innovations in urban planning. Two key national legislative milestones facilitated this process. On one hand, Law no. 142/1990 on local autonomies, which acted as a framework law for the organisation of territorial authorities, assigning a central role to the Province, understood as an intermediate level of coordination between Municipalities and the Region.

On the other hand, a package of environmental laws contributed to this process, including Law no. 431/1985 (the Galasso Law), which, beyond protecting areas of particular environmental interest, introduced landscape planning; and Laws no. 183/1989 and no. 394/1991, which established, respectively, basin authorities and national parks, providing for the creation of entities endowed with managerial autonomy and their own planning instruments.

It is clear that, as a result of these processes, both the content and the very form and nature of urban planning instruments have been expanded, "significantly broadening the scope of action of the Regions and local

6 D.P.R. January 15, 1972, No. 8, Article 1: The administrative functions exercised by the central and peripheral bodies of the State concerning urban planning are transferred, for the respective territories, to the ordinary statute Regions.

autonomies to the point of integrating, within the same instruments—both at the territorial and urban planning levels—provisions for the territory, provisions for the landscape, and provisions for the environment" (De Luca, 2015, p.7).

This regulatory process is accompanied by a broader shift in national socio-economic conditions. During this phase, a progressive crisis of the General Regulatory Plan (PRG) becomes apparent—an instrument introduced by Law No. 1150/1942, which had governed and managed the urban expansion of cities in the post-war period. Faced with a new scenario transitioning from a phase of expansion to one of transformation, the PRG "appeared inadequate to address the new situations emerging, such as the increasing availability of disused industrial areas for reuse, the opportunities for the reconversion of old railway zones, historic port systems, and large public services, which had become central in the urban context but now obsolete" (Oliva, 2012, p.136). Indeed, the PRG showed clear signs of ineffectiveness, proving insufficient to respond to emerging situations. Critical elements were partly due to its excessive predictive rigidity and strong prescriptive character, a result of zoning. At the same time, to meet the growing needs for urban transformation, the approach of "derogatory interventions" was established in those years.

This was introduced by laws that created Urban Recovery Programs (Programmi di Recupero Urbano, PRU) with Law No. 493/1993 and Urban Redevelopment and Sustainable Territorial Development Programs (Programmi di Riqualificazione Urbana e di Sviluppo Sostenibile del Territorio, (PRUSST) (Ministerial Decree of 8 October 1998), following a logic where the project takes precedence over the plan.

Within a decade marked by significant institutional transformations and new territorial needs, the INU proposal of 1995 is situated. The main innovation of this proposal lies in the attempt to overcome the crisis of the PRG by proposing a new type of municipal plan structured into three distinct components:

- a structural component, which is a planning document of a non-binding and non-prescriptive nature, but aimed at defining the future layout of the city;
- a regulatory component, which deals with the management of the existing city;
- an operational component, of a binding and prescriptive nature, intended to manage the main transformations, with a temporal validity of five years.

Additional innovative elements concern the introduction of instruments such as urban equalization and compensation, designed to overcome the long-term difficulties associated with expropriation. These tools are conceived with the aim of acquiring areas intended for public use through the attribution of building rights that can be freely traded.

The INU proposal was immediately embraced by the Tuscany Region, which, through Regional Law No. 5/1995[7], introduced the structural component within municipal planning. In doing so, Tuscany paved the way for subsequent regulatory developments in other regions, within a future landscape of differentiated regional models—a process that would become fully evident with the amendment to Title V of the Constitution in 2001.

2.2.2 Initial reform experiences: regional models in Italy within the renewed planning system

The reform in 2001, which marked the culmination of a process of administrative decentralisation initiated in previous years, represented a turning point for the Regions in matters of spatial planning. Within this new institutional framework, several Regions launched innovative legislative initiatives, effectively becoming the first experimental field. On the other hand, it can be observed that the constitutional reform itself proved to be of limited practical relevance. Rather, it served to legitimise innovation processes that were already underway (De Petris & Stefani, 2005). The regulatory experiences initiated during this phase are commonly classified as belonging to the "third generation" and played a central role—as well as serving as a testing ground—in the urban planning debate between 2005 and 2015. They were particularly significant for analysing the differences and similarities between regional models and the first observable effects on the territory.

The main feature shared by the new regional legislations is a common intent to revise the municipal urban plan according to new criteria of innovation and flexibility. Based on this need, the Regions, through their renewed

7 Regional Law of 16 January 1995, No. 5, Region of Tuscany, Provisions for Territorial Governance.

regulatory frameworks, gave rise to two main reference models: the Tuscan model and the Lombard model. The Tuscan model (initiated with Regional Law No. 5/1995 and revised by Regional Law No. 1/2005[8]), characterised by a primacy of public authority in the field of urban and territorial transformations (De Luca, 2015), introduced an internal distinction within the municipal urban plan between a structural component—which includes general development guidelines and medium- to long-term strategic choices—and an operational component—which implements structural objectives by addressing the actionable operational contents and detailing specific transformations (Cappelletti, 2012). This model, to which Emilia-Romagna largely adheres, identifies the Structural Plan as the main hallmark of regulatory evolution. It also includes an initial attempt to address land consumption through a policy whereby "new land commitments for settlement and infrastructure purposes are permitted only if there are no alternatives for the reuse and reorganisation of existing settlements and infrastructures[9]."

By contrast, Lombardy (Regional Law No. 12/2005[10]) adopts a regulatory framework that diverges from the structural/operational logic. Instead, it bases the municipal plan on a strategic-political planning document, in which urban transformation areas are identified without establishing rigid quantitative rules or altering the legal status of land.

From this document, the process moves directly to the implementation plans, which enjoy a high degree of flexibility and are assessed on a case-by-case basis by the Regional Executive, without requiring approval by the Municipal Council (Cappelletti, 2012).

In this context, it is important to emphasise that, despite the reformist momentum demonstrated by certain Regions, a national framework law on territorial governance has never been enacted. This absence has contributed to the consolidation of a highly heterogeneous dynamic among the various regional systems. The failure to approve a framework law has led to what has been described as a form of "runaway urban federalism" (Oliva, 2012, p. 89), in which the lack of a unified national direction has fuelled regulatory fragmentation, thereby preventing the development of a coherent and shared vision for reforming the national planning system.

Within the context of the first reformist wave, there was also an initial attempt to introduce a national reform of territorial governance through a framework law. This was Bill No. 3519 Mantini & Lupi, approved by the Chamber of Deputies on 28 June 2005 but never enacted into law due to the end of the legislature and the consequent failure to obtain approval from the Senate. The draft law essentially adopted the Lombard planning model but sparked extensive debate and received opposition from much of the urban planning scientific community, including INU. In particular, the law would have unjustifiably introduced numerous specific deregulation procedures, which implicitly reflected a project aimed at dismantling public territorial governance (Magnaghi & Marson, 2005).

2.2.3 Urban regeneration and the fight against soil consumption: paradigms of fourth-generation urban planning

With the conclusion of the era of so-called "third-generation" laws, the last decade has been characterised by a renewed debate surrounding planning, driven by the emergence of new socio-economic demands within the country as well as new requirements in urban planning. Among the central issues, the need to contain soil consumption has increasingly asserted itself with urgency, closely linked to the demand for the redevelopment of the existing built environment. During this phase, urban planning consolidates a paradigm shift that had already begun, also guiding new regional policies.

Although urban regeneration has become a central paradigm of a new phase in urban planning, it lacks a consolidated definition due to the complexity and multiplicity of the contexts in which it can be applied. This difficulty stems from the heterogeneous nature of the interventions encompassed by this category and the heightened interest in transversal topics, ranging from the broader issue of territorial governance to the sphere of individual rights (Giusti, 2018).

8 Regional Law of 3 January 2005, No. 1, Region of Tuscany, Provisions for Territorial Governance.

9 Article 3, paragraph 4, Regional Law 1/2005, Region of Tuscany. In Article 3, "The Essential Resources of the Territory," this law promotes and guarantees the protection of the essential resources of the territory as common goods that constitute the heritage of the community.

10 Regional Law of 11 March 2005, No. 12, Region of Lombardy, Law on Territorial Governance.

The regional experiences of the last decade have served as the initial field of observation to verify whether urban regeneration and the related objective of containing soil consumption found expression in a shared regulatory lexicon, sufficient to legitimise the hypothesis of a fourth generation of urban planning laws.

In the absence of a national framework law, regional experiences present a diverse landscape. However, an initial survey reveals recurring elements, such as the direct correlation between urban regeneration and the containment of soil consumption. There is also a well-established distinction between regeneration—which refers to a cluster of models and techniques integrated with actions on the social front (urban welfare) and environmental front (remediation, renaturalisation, etc.)—and redevelopment, which concerns individual building elements (Boscolo, 2017).

Among the most significant regional models to emerge in this phase are those of Tuscany (Regional Law 65/2014[11]) and Veneto (Regional Law 14/2017[12]). In both cases, the areas subject to urban regeneration interventions are identified within the operational component of their respective planning instruments: the Operational Plan in Tuscany and the Intervention Plan in Veneto.

Also noteworthy is the experience of Emilia-Romagna (Regional Law 24/2017[13]), which partially diverges from this approach. Although it does not explicitly define specific areas or detailed prescriptions for urban regeneration[14], the law establishes, within the General Urban Plan (PUG), the criteria for urban expansion—permitted up to a limit of 3% of the urbanised territory[15]—and for significant transformations within the urban boundary, to be assessed through operational agreements.

The challenges posed by urban regeneration reflect a broader crisis within urban planning, largely due to its excessive prescriptiveness. The debate and the so-called fourth-generation laws thus initiate a new approach aimed at rethinking the entire discipline, promoting a more active, interactive, and strategic form of planning (Dipace, 2014). This latter approach is reaffirmed as the guiding logic within which the municipal plan must operate, in light of new needs—not seeking to interpret the future through rigid prescriptions that immobilise situations, but rather adopting greater flexibility and directives capable of facilitating public-private agreements (Urbani, 2017).

2.2.4 Towards a new urban planning era? The contemporary scenario

Urban planning can draw upon a vast body of past experience and is currently facing a historically significant transition in light of new contemporary challenges. The path initiated by the "fourth generation" laws, focused on urban regeneration and combating land consumption, now encounters new factors of relevance that further influence its evolution. Events such as the Covid-19 pandemic, geopolitical instability, increasing international conflicts, and the climate emergency have profoundly affected society and the political landscape. This series of events has deeply impacted the country's socio-economic stability, reflecting in territorial governance as a growing crisis of predictive capacity. The speed at which contemporary dynamics unfold, alongside the urgency to accelerate public policy responses, has progressively weakened the role of planning as an instrument capable of envisaging and guiding the future scenarios of communities and territories (Giaimo, 2025b). As a consequence, there is significant disorientation and a profound crisis of public and institutional legitimacy, expressed through the increasing marginalisation from decision-making processes.

Alongside the development of the new regulatory framework, a renewed recognition of the central role of the plan has emerged, notably during the most recent INU Congress held in May 2025 with the theme "The Useful Plan." The plan is conceived as the instrument that must address current crises and evolve in response to

11 Regional Law of 10 November 2014, No. 65, Region of Tuscany, Provisions for Territorial Governance.

12 Regional Law of 6 June 2017, No. 14, Region of Veneto, containing provisions for the containment of soil consumption and amendments to Regional Law of 23 April 2004, No. 11, "Provisions for Territorial Governance and Landscape Matters."

13 Regional Law of 21 December 2017, No. 24, Region of Emilia-Romagna, Regional Regulation on the Protection and Use of Soil.

14 As provided by Article 33 of Regional Law 24/2017 of Emilia-Romagna, "the General Urban Plan (PUG) may not establish the building capacity, including potential capacity, of areas within the urbanised territory, nor may it set out detailed regulations for interventions whose implementation is subject to an operational agreement or a public initiative implementation plan."

15 As stipulated by Article 6 of Regional Law 24/2017 of Emilia-Romagna, "territorial and urban planning may provide, for the entire period, for a total soil consumption not exceeding the maximum limit of 3 percent of the surface area of the urbanised territory."

changing economic, social, and environmental conditions. In a scenario characterised by a gradual decline in the resident population, the obsolescence of the building stock, and the growing need to respond to the effects of climate change, the urban plan is called upon to interpret the demands of urban regeneration in relation to the specificities of each context, while simultaneously outlining the contributions that public and private actors can offer to the transformation process (Stanghellini, 2025).

Essentially, the contemporary debate recognises the shortcomings of the urban plan in its predictive function. It is now widely accepted that the plan should no longer be based on forecasts but should be conceived as an innovative tool for the discipline itself. It must respond flexibly and adaptively to ongoing transformations, enabling decision-making that remains coherent with changing conditions.

2.2.4.1 The INU proposal within Marche Regional Law 19/2023

The proposed "Law of Principles for Territorial Governance" promoted by INU represents a definitive overcoming of the legacies of past urban planning. In parallel, the Regional Law of Marche No. 19/2023 marks a comprehensive and profound change in its regulatory framework, clearly departing from a legislative model considered among the most canonical and faithful to the structure of Law No. 1150/1942.

The INU proposal, which aims to establish a unified framework in response to excessive regional fragmentation, begins by adopting the notion of territorial governance as a "broad set of interrelated functions[16]," and is based on a series of innovative principles and concepts, such as:

i) urban and territorial regeneration and the fight against soil consumption are identified as central and cross-cutting objectives of territorial governance[17]. The aim is to overcome the traditional concept linking planning to urban expansion by adopting a paradigm shift that positions regeneration as part of a circular economy.
ii) A redesign of competences in territorial governance is proposed within a multilevel framework based on co-planning and participation, in which: a) the State assumes a strategic role and outlines development objectives consistent with those of the EU; b) the Regions adopt principles according to specific territorial needs; c) Municipalities, Provinces, Metropolitan Cities, and Unions plan territorial arrangements and define sustainable development strategies within their respective competences[18]. The objective is to overcome fragmentation and the lack of coordination among the different levels of territorial governance.
iii) The method of Interinstitutional Co-planning[19] is proposed as a multilevel horizontal governance approach to be implemented through Interinstitutional Conferences. Simultaneously, the planning instruments and the respective roles of Regions, metropolitan areas, provinces, and municipalities are redefined[20]. The objectives are to overcome the traditional planning system based on hierarchical conformity and the "cascade" model of plans under Law 1150/42, aiming instead for a collaborative and integrated method.
iv) A new model of municipal urban planning is proposed through the General Urban Plan (PUG)[21], structured into three functions: a) structural-strategic component (objectives, strategies, and future configuration of the city, non-prescriptive); b) regulatory component (management and regulation of the existing city and consolidated areas, assigning building rights); c) operational component (relating to areas of transformation, to be implemented through agreements between public and private initiatives).

The objective is to abandon the vision of the plan as a static and purely prescriptive instrument, adopting instead a dynamic, flexible, and continuously updated approach.
v) Planning centred on the principle of coherence[22], understood in terms of efficiency, compatibility, consistency,

16 Definition provided in Article 1, "Scope of Application and Notion of Territorial Governance", of the draft law.
17 Draft Law, Title II: Fundamental Principles and Objectives of Territorial Governance. Article 2: Fundamental Principles and Objectives - Article 3: Territorial and Urban Regeneration - Article 4: Delegation in Matters of Urban Regeneration - Article 5: Containment of Soil Consumption and Territorial Risk Mitigation.
18 Draft Bill, Title III: Actors, Competences, Levels, and Functions of Territorial Governance. Article 6 Duties and Functions of the State - Article 7 Duties and Functions of the Regions - Article 8 Duties and Functions of Local Territorial Entities.
19 Article 10 – Co-Planning and Interinstitutional Evaluation.
20 Article 12 – Instruments of Territorial Planning.
21 Article 14 – Functions and Instruments of Urban Planning.
22 The principle of coherence is reiterated throughout the entire legislative proposal, particularly regarding the relationship between the different levels of planning. Its clearest articulation is found in Article 14, where it is presented as a criterion aimed at avoiding the systematic recourse to amendments: "In application of the principle of coherence and

and the absence of contradictions between plans and plan functions. The objective is to plan effectively in uncertain contexts and to overcome the rigid, prescriptive, and all-encompassing nature of traditional plans, promoting adaptability in place of strict "conformity" and the frequent recourse to variations.
vi) Introduction of Essential Levels of Performance (LEP)[23] for urban standards, with uniform quantitative and qualitative criteria for public facilities and services across the entire national territory. The objective is to overcome the concept of urban standards derived from Ministerial Decree 1444/68 and the resulting fragmentation and heterogeneity of current standards, ensuring not only quantitative but also qualitative levels.
vii) Introduction of urban and territorial equalisation as tools to encourage regeneration, allow the free transfer of land for public facilities, and increase the flexibility of the plan[24]. The objective is to overcome the rigidity of traditional urban planning instruments in order to promote regeneration policies.

Regional Law No. 19/2023 of the Marche Region currently represents the most comprehensive normative expression at the regional level of the proposal developed by INU. The foundational principles of the proposal, articulated across various articles, find direct reflection both in the general structure and in the specific provisions of the new Marche urban planning law. The Marche Region was previously governed by Regional Law No. 34/1992[25], which can be classified as a "second-generation" law model, primarily focused on control but also on supporting urban expansion. This was adopted during a phase of building growth and territorial transformation that lasted until the crisis of 2008–2010. In this context, the new normative framework places the Region, for the first time, in front of the challenges of planning that must offer a vision of the territory not only as a space for construction, but as a complex ecosystem in which sustainability, environmental coherence, resilience to climate change, and quality of life prevail (Centanni, Vitali & Veschi, 2025).

It is important to highlight that the innovativeness of the Marche regional regulation lies not only in its alignment with the principles of the INU proposal but also in the introduction of elements that represent a discontinuity with respect to the previous regional regulatory framework. In particular, the law incorporates and updates those reform initiatives that have already been tested by other regions within the framework of the so-called "fourth generation" laws, outlining a more advanced and effective model of territorial governance.

the principle of simplification, amendments are limited to cases where they are not consistent with the objectives and the structural-strategic contents of the General Urban Plan" (Article 14, paragraph 12).

23 Article 17 – Minimum and Non-Derogable Urban and Territorial Provisions.

24 Article 18, "Urban and territorial equalisation, compensations, and incentives".

25 Regional Law of 5 August 1992, No. 34, Marche Region, Regulations on urban planning, landscape, and territorial organisation.

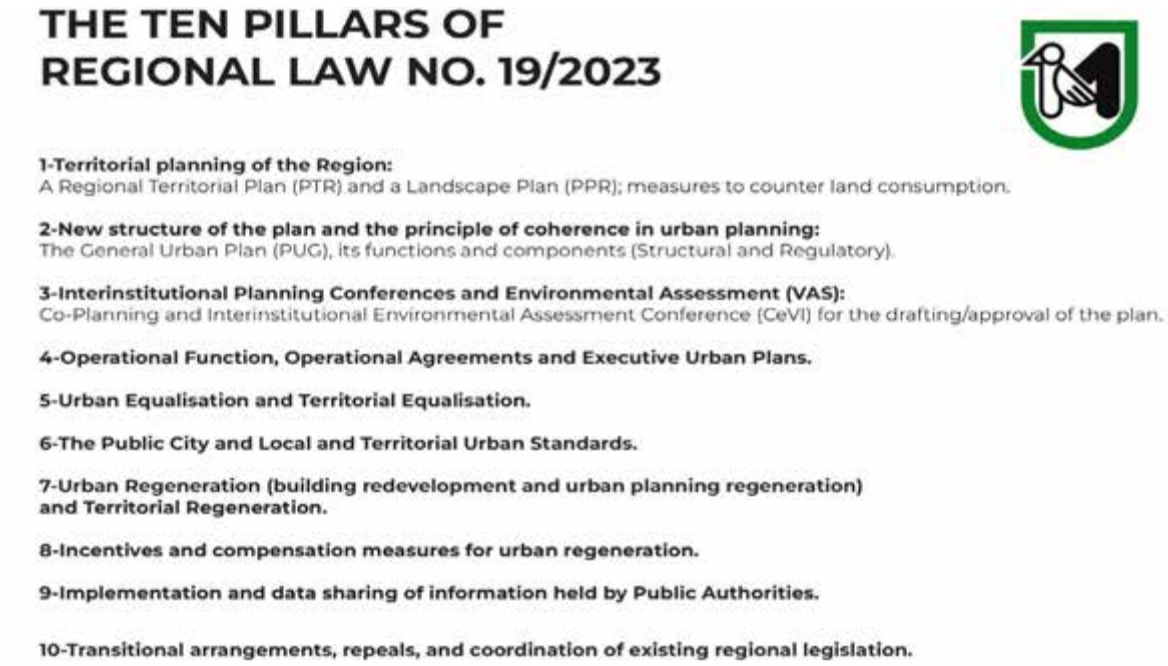

Fig.2 The Pillars of Regional Law No.19/2023. Reworking by Pierpaolo Cicconi of an image from the presentation by the Marche Region entitled "*THE NEW REGIONAL LAW ON TERRITORIAL GOVERNANCE. Regional Law No. 19/2023 – Planning Provisions for Territorial Governance. First implementation*", held in Civitanova Marche (MC) on 4 May 2024.

A significant element is represented by the comprehensive redesign of the planning instruments system[26], which is profoundly reorganised from the regional to the municipal level. While the previous legislation was based on a hierarchical-vertical structure, with a descending sequence of plans — from the Regional Environmental and Landscape Plan (PPAR, approved in 1989), to the Provincial Coordination Territorial Plans (PTCP), and finally to the municipal General Regulatory Plans (PRG) — following a logic of adjustment and conformity, the new law introduces a framework founded on principles of coherence and joint planning.

At regional level, two main instruments have been introduced and reformulated:

- **The Regional Landscape Plan (PPR)**[27], which must be prepared in accordance with the European Landscape Convention (2001) and in compliance with the Cultural Heritage and Landscape Code (Legislative Decree 42/2004). The Regional Landscape Plan (PPR) is responsible for identifying the landscape systems and the elements deserving protection, defining and delimiting the landscape areas, and establishing specific usage regulations for each of them.

- **The Regional Territorial Plan (PTR)**[28], introduced anew with a structural and strategic function, it defines the general guidelines, medium- to long-term strategies, and objectives for the sustainable development of the regional territory. It constitutes the framework of reference for economic planning and for the integration of regional sectoral policies.

At provincial level, the central role of the **Provincial Coordination Territorial Plan (PTCP)**[29] is maintained, serving as an intermediate instrument between regional and municipal planning. The PTCP defines strategic objectives, spatial frameworks, and development guidelines for the provincial territory, with a view to ensuring multi-level coherence and inter-institutional coordination.

26 The new structure of the planning instruments is defined in Article 3, "Planning Instruments," of LR 19/2023.
27 Article 8 of Regional Law 19/2023 (LR 19/2023, art. 8).
28 Article 10 of Regional Law 19/2023 (LR 19/2023, art.10).
29 Article 12 of Regional Law (LR 19/2023, art.12).

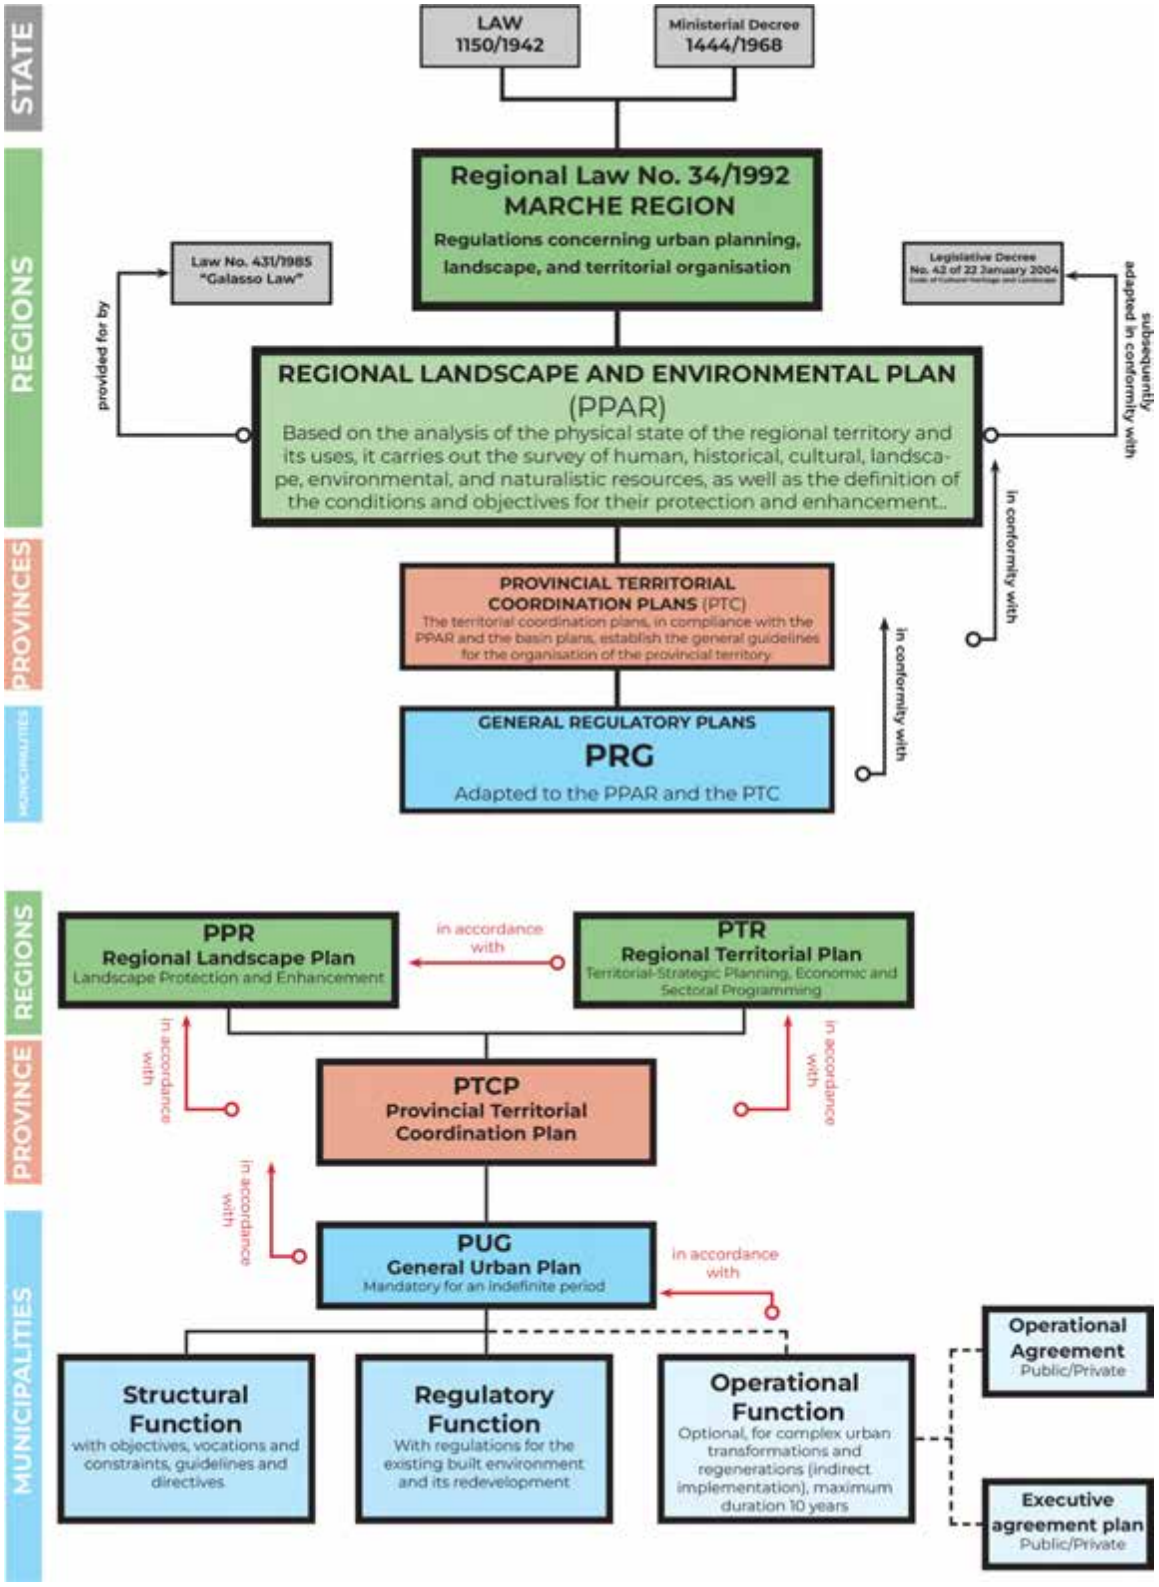

Fig.3 Comparison between the previous hierarchical-vertical model of territorial governance (above), established by Regional Law 34/1992, and the new "horizontal" model of planning instruments (below).

At municipal level, Regional Law no. 19/2023 introduces a new general planning instrument: the **General Urban Plan (PUG)**[30], which represents the focus of municipal planning actions in accordance with the principles of sustainability, regeneration, and containment of soil consumption. The PUG is structured into **three functional components**, each with a specific role in the territorial governance process:

- **Structural component: performative and strategic** in nature, it serves as a guiding and orienting tool for territorial transformations over the long term. It does not grant building rights but it outlines the strategic vision of the municipal territory, translating general sustainable development objectives into expected outcomes in terms of landscape, environmental, socio-economic, and cultural performance. It establishes the distinction between urbanised territory and rural or agricultural land, guiding decisions towards **urban and territorial regeneration**, resource enhancement, and the **containment of soil consumption**.
- **Regulatory component:** it concerns areas not subject to complex urban transformations, such as **agricultural zones, natural areas, parts of the existing settlement system**, and **consolidated infrastructural networks**. It establishes the urban and building regulations governing permissible interventions in these areas, determining **building rights** and thus allowing implementation through **direct intervention**.
- **Operational function**: it is aimed at the planning and implementation of complex urban regeneration and territorial regeneration interventions, in line with the choices set out in the structural component. It constitutes the implementing part of the strategies of the General Urban Plan (PUG) and is carried out through **Executive Urban Plans (PUE)** and **Programme Agreements (AO)**, initiated by **public and/or private actors**.

The law assigns a strategic role to **urban regeneration**[31], defining it as the set of interventions—both on buildings and on public and private spaces—aimed at the recovery and redevelopment of existing areas through operations such as demolition and reconstruction, new construction, and densification, with the objective of **raising environmental, architectural, and functional quality standards**.

The regulation also introduces a significant and potentially effective distinction between two levels of intervention, which has already emerged in other advanced regional experiences and in the scientific debate:

- **Building rehabilitation:** falling within the **regulatory** component of the General Urban Plan (PUG), it includes operations such as reuse, renovation with extension, demolition and reconstruction with extension, and building replacement. These interventions aim to improve the **seismic, energy, hygienic-sanitary, and environmental performance** of the existing building stock.

- **Urban regeneration:** pertaining instead to the **operational** component of the PUG, it qualifies as a process of **complex and integrated** transformation of marginal, degraded, or disused urban areas. This process is implemented through **Programme Agreements** and **Executive Urban Plans**, promoted by public and/or private entities.

For such interventions, the law introduces a further element of innovation through the explicit recognition of **urban equalization**[32] as a technical-operational tool, functional to the implementation of the objectives of territorial transformation and redevelopment.

30 As established by Article 14, "Municipal urban planning is exercised through acts with structural and strategic-forecasting, regulatory, and operational functions."

31 According to Article 25, paragraph 1 of Law no. 19/2023, "The planning instruments referred to in this law are primarily aimed at urban and territorial regeneration, as an integrated mode of territorial governance to counter soil consumption, to redevelop existing settlement and infrastructure systems, and to eliminate situations of degradation."

32 According to Article 20 of Law no. 19/2023, urban equalization, in addition to being a preferred tool for urban regeneration operations, becomes an operational technique aimed at avoiding disparities in treatment between real estate properties and at ensuring the development and enhancement of the public city.

Finally, with regard to soil consumption, the law provides a precise definition as "a change from a non-artificial land cover to an artificial land cover," allowing for a further distinction into:

- **Consumed soil,** expressed as an absolute quantity;
- **Degree of artificialization,** expressed as a percentage of the total territorial surface area.

The approach adopted by the law is aimed at achieving a **zero soil consumption balance** through the introduction of **mandatory compensatory measures**. These measures are to be implemented in cases of new soil sealing and include interventions such as **renaturalisation, soil de-sealing, and ecological restoration**.

The operational implementation of these objectives is entrusted to the **Regional Territorial Plan (PTR)**, which is tasked with defining **criteria, guidelines, and qualitative and quantitative parameters** to monitor and regulate the impact of transformative interventions on soil consumption.

3.Conclusions

The research has highlighted the growing and consolidated perception of a discipline in structural and identity crisis, caught between, on the one hand, a regulatory framework regarded as excessively restrictive, bureaucratic, and prescriptive; and, on the other, an increasing demand for greater flexibility, adaptability, and promptness in territorial governance processes. Within this context—often amplified by reductive and overly simplified narratives, at times populist or technocratic—urban planning is frequently accused of being an obstacle rather than a resource.

However, a fundamental element is often overlooked: the intrinsic complexity of urban planning, which cannot be reduced to a mere technical tool, but must be understood as a political, strategic, and cultural practice of territorial design. Hence the need—repeatedly emphasised in recent debate—for a reformulation of the discipline not only in operational terms but also in conceptual ones, so that it may acknowledge its multidimensional, interdisciplinary and complex nature, without resorting to excuses or justifications.

From this perspective, it is legitimate to ask whether the current crisis is attributable solely to internal limitations of the discipline, or rather to external factors: economic stagnation, demographic decline, and the changing dynamics of settlement and production. It is, therefore, also a contextual crisis, which imposes objective constraints on the effectiveness of planning instruments and their capacity to guide territorial transformations in accordance with the objectives of equity, sustainability, and resilience.

It is within this context that the new regulatory phase must be interpreted, as represented by the INU's legislative proposal and, concretely, by Regional Law no. 19/2023 of the Marche Region. Both aim to radically redefine the system of planning instruments, particularly at the municipal scale. As highlighted by the central themes addressed in the present work, the debate has been most intensely focused on the form and function of the municipal plan—particularly on the need to move beyond the traditional rigid framework and to introduce more performance-based, integrated, and strategic models, which have already been tested by many Regions over the past two decades.

This element, amplified by the INU's own initiative regarding the "Useful Plan," which seeks to reflect on the meaning, function, and effectiveness of urban planning today, raises significant questions: Why is urban planning considered to be in crisis today, if many Regions have long adopted advanced models? Why do the INU proposal and the Marche law resume certain well-established solutions? And finally, why does the three-function plan model (structural, regulatory, operational) continue to be proposed, despite already being widespread and consolidated in various regional experiences?

Are the currently proposed regulatory and methodological innovations (which the debate continues to define as such) genuinely innovative, or do they instead represent an attempt to reiterate already established solutions, without managing to address the systemic limitations afflicting the discipline? In other words, is there a risk of falling into a condition of self-referentiality and operational ineffectiveness, not due to intrinsic shortcomings, but because of the inability to influence processes of economic, social, and territorial crisis that lie beyond its scope of action? At this point, the task of the discipline is not only to formally reinvent itself but also to legitimize

its role as the orchestrator of territorial transformations, demonstrating the capacity to confront contemporary challenges and the uncertainties of our time.

Public Interest or Private Profit?
A Case Study of How Public Interest is Redefined Through Political Power And Land Commodification in Istanbul

İrem CEYLAN
Istanbul Technical University
iremmceyllaan@gmail.com

Abstract
This study examines how public interest is defined and applied in Turkish urban planning through the case of the Etiler Police School site in Istanbul. Using Robert K. Yin's explanatory case study method, it explores the legal and institutional processes that enabled the site's transformation from a public educational facility into a high-rise private development. The findings show that public interest was strategically invoked to justify zoning changes and shift planning authority to central government, despite no disaster risk or public input. Though legally framed, the process contradicted planning principles of equity, transparency and spatial justice. The study argues that public interest was used more as rhetorical justification than ethical guidance, highlighting the need to restore its normative function in planning systems.

Keywords: Public interest; urban planning; land transformation; spatial justice; planning law.

1. Introduction

The concept of public interest has long served as a normative and guiding principle in urban planning theory and practice. Rooted in classical democratic ideals, public interest is expected to balance individual and collective needs while legitimising spatial interventions (Mumford, 1938). Yet, in practice, particularly in contexts with centralised governance traditions, it is frequently instrumentalised to justify top-down, profit-oriented urban transformation projects. In Turkey, while public interest is repeatedly cited in legal and planning documents, it often lacks critical scrutiny in terms of whose interests it truly represents and what spatial and socio-political consequences it produces.

This paper investigates the transformation of the former Etiler Police School site in Beşiktaş, Istanbul, which was sold and redeveloped under the pretext of public interest. Despite its initial educational function and public ownership, the site was rezoned for commercial and tourism purposes, replaced by high-rise towers, and ultimately privatised. This controversial case provides a rich context to examine the shifting meaning and use of public interest in Turkish planning processes, especially within the frameworks of constitutional law, spatial planning legislation, and institutional policy dynamics.

The case is analysed through an embedded case study design, following Yin's (2018) methodology, where the macro-level discourse of public interest is examined through the micro-level planning decisions, legal instruments, and implementation strategies applied to a single site. Multiple layers of analysis are adopted: (1) the normative legal basis as defined in the Turkish Constitution and administrative court decisions; (2) the planning rationale as framed by the Spatial Plans Regulation and zoning reports; (3) the policy instruments that enabled the central government to override local planning authority (such as disaster-risk area declarations); and (4) the spatial and social outcomes, including the erosion of public services and the commodification of land.

The Etiler case was selected for its exemplary demonstration of how public land can be transformed into a speculative asset through legal and institutional manoeuvres. Moreover, the project's scale, location within a protected area, and direct contradiction with planning principles make it a compelling case to question the operational meaning of public interest in Turkey's contemporary urban planning system.

In doing so, this study aims to answer the following research question: How is the notion of public interest defined, interpreted, and operationalised in the transformation of public land in Istanbul? The study adopts a qualitative case study approach, based on document analysis, policy review, planning legislation, and media reports, using pattern-matching logic to explore the gap between declared objectives and actual outcomes.

2. Theoretical Background

Public interest has long been considered a foundational principle in urban planning, yet its definition remains fluid, context-dependent, and often politically contested. The concept is generally assumed to represent the collective needs of society, as opposed to individual or corporate interests (Mumford, 1938; Bozeman, 2007). However, despite its normative appeal, public interest is rarely neutral in practice. Instead, it frequently becomes a rhetorical and strategic tool employed by political and economic actors to legitimise decisions that may otherwise lack democratic or ethical grounding (Campbell & Marshall, 2002).

In Turkey, the term "public interest" (kamu yararı) is deeply embedded in legal and planning discourse, yet its invocation often lacks substantive scrutiny. Article 5 of the Turkish Constitution frames public interest as a central function of the state, while spatial planning regulations mandate adherence to public interest as one of the guiding principles in plan-making. However, the discretionary power of central government institutions, particularly in the post-2010 period, has increasingly led to top-down decision-making in which public interest is equated with state-defined priorities, often without public consultation or transparent justification. In this sense, the term functions less as an ethical commitment and more as an instrument of governance—frequently aligned with market logics and private capital flows.

Beyond legal and political frameworks, the public interest is also a key subject of debate in planning ethics. Scholars have argued that planning is no longer a purely technical domain but a profoundly normative one, requiring practitioners to make explicit value-based judgments (Upton, 2002; Taylor, 1992; Campbell, 2002). Campbell (2002) argues that planning must be seen as a "moral endeavour", in which planners consider the long-term implications of their decisions on justice, equity and sustainability. Public interest, within this frame, is not simply a policy aim, but a moral compass guiding spatial decisions in line with social fairness and intergenerational responsibility.

Yet ethical consensus on the meaning of public interest is difficult to achieve. Diverse philosophical frameworks—such as deontological and teleological ethics—suggest different ways to evaluate planning actions (Howe, 1994). While deontological approaches emphasise rights, duties and procedural integrity, teleological perspectives are concerned with the consequences of actions, often measured in terms of social welfare or utility. The tension between these perspectives is particularly pronounced in planning decisions involving land ownership, displacement, and redevelopment—areas where outcomes can be deeply unequal despite formal procedural compliance.

Recent decades have witnessed a shift in planning rationalities towards more entrepreneurial and neoliberal modes of governance. In this context, the public interest is often reduced to fiscal efficiency or economic growth, as cities compete globally for investment and prestige (Harvey, 1989; Taşan-Kok & Oranje, 2017). The commodification of public goods—especially land and infrastructure—has become increasingly normalised, and planning has in many cases become a facilitator of speculative urban development. As noted by Allmendinger and Haughton (2012), the rise of "soft spaces" of planning and informal governance arrangements often bypass democratic processes and blur the boundaries between public and private interest.

In the Turkish context, the centralisation of planning authority and the expansion of emergency legal instruments—such as the declaration of disaster-risk areas (Law No. 6306)—have enabled the state to bypass standard planning procedures. These mechanisms are frequently justified on the grounds of public interest, yet their application often leads to the concentration of power, the weakening of local authorities, and the displacement of communities. Şengül (2002) refers to this process as the "depoliticisation of planning through technocracy", where technocratic justifications mask underlying political and economic motivations.

A critical distinction must be made between procedural legality and substantive justice. In many cases, planning decisions are made within the bounds of formal legal frameworks but fail to deliver equitable or sustainable outcomes. Legal instruments are frequently stretched or reinterpreted to accommodate political priorities, while the language of public interest provides an aura of legitimacy. This is particularly evident in the manipulation of zoning regulations, the redefinition of land uses, and the transfer of public land to private entities.

Professional bodies such as the Union of Chambers of Turkish Engineers and Architects (TMMOB) have repeatedly contested such practices, arguing that they undermine the integrity of planning and erode public trust. Judicial rulings, including those by the Council of State, have on occasion annulled plans for failing to meet basic planning principles despite their formal legality. These tensions highlight the urgent need to evaluate public interest not merely as a legal condition, but as a multidimensional concept encompassing ethical, social and spatial considerations.

3. Methodology

This research adopts a qualitative case study methodology, following Robert K. Yin's (2018) explanatory approach to investigate how the notion of public interest is framed, interpreted and operationalised within a concrete planning case. The study is designed as a single-case inquiry, focusing on the transformation of the former Etiler Police School site in Istanbul. The site was chosen not only for its spatial and institutional complexity, but also for its significance in reflecting wider dynamics of centralised planning, legal manipulation, and the instrumentalisation of public interest discourse in Turkey.

As Yin suggests, explanatory case studies are particularly suitable for exploring causality in complex socio-political environments where the researcher does not have control over events. This approach allows for the systematic tracing of how planning decisions unfold over time, and how actors use legal and discursive tools to justify their interventions. The case is structured as an embedded design, incorporating several units of analysis—including legal decisions, planning documents, zoning changes, institutional reports, and media narratives—all of which contribute to understanding how public interest was invoked and implemented across different phases of the project.

Data collection relied primarily on document analysis, drawing from a wide range of sources. These include official spatial plans and plan modification notes, national legislation and regulations (such as Law No. 6306 on disaster-risk area transformation), court rulings, policy documents from local and central government agencies, media reports, and technical assessments such as geological surveys and planning justifications. The use of multiple sources enabled data triangulation, enhancing the reliability and construct validity of the research.

The analytical process employed pattern matching as the principal strategy, where theoretical expectations derived from planning ethics, legal norms, and professional standards were compared with the actual development trajectory of the site. Specifically, the study examined whether the justification of public interest in official documents aligned with the observed outcomes in terms of land use, institutional authority, social benefit, and spatial justice. Through this approach, the research aimed not only to reconstruct the sequence of events, but also to expose the gaps between normative principles and practical implementation.

Importantly, this case study does not seek generalisation in the statistical sense, but rather aims to contribute to analytical generalisation, where findings from a well-documented case inform theoretical understanding of how public interest is contested and negotiated in planning practice. In doing so, the study foregrounds the complex interplay between planning law, political authority, ethical judgement, and public accountability within the evolving landscape of urban governance in Turkey.

4. Case Study: The Etiler Police School Site Transformation

The Bosphorus Law No. 2960 was enacted to protect and develop the cultural and historical values and natural beauties of the Bosphorus Area of Istanbul in the public interest and to determine and regulate the zoning legislation to be applied in order to limit the construction that will increase the population density in this area. According to this law, the Bosphorus Area is divided into zones and different construction and protection categories are defined. The land of Etiler Police School is located in the Bosphorus Backsight Area within the scope of the Bosphorus Law enacted in 1983. In terms of authority, Istanbul Metropolitan Municipality's Bosphorus Zoning Directorate has the authority over the Bosphorus Foresight Zone, while district municipalities have the authority over the Bosphorus Backsight Zone.

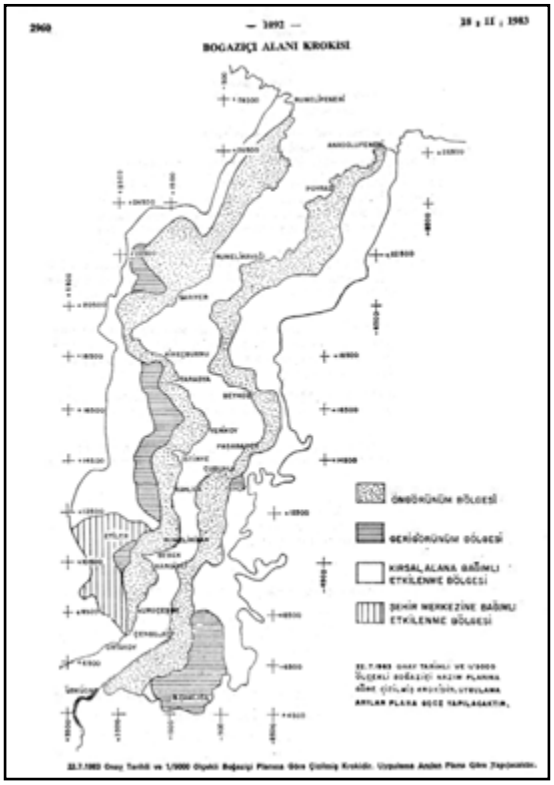

Figure 1. Bosphorus Area

In 1966, the Etiler Police School was opened in the area located in the Bosphorus Backsight Zone. In the December 10, 1993 dated Conservation Revision Implementation Zoning Plan, the parcel where the Etiler Police School is located is marked as "police college" in the plan.

Figure 2. Conservation Development Plan Approved on December 10, 1993

On January 20, 2010, the Istanbul Project Coordination Unit of the Special Provincial Administration of the Governorship of Istanbul decided to reconstruct some of the buildings belonging to the Etiler Police School as they did not meet the needs of the Istanbul Etiler Police Training Center Directorate and the Provincial Directorate of National Education and as the retrofitting of the existing buildings was not economically feasible. This reconstruction process was financed by the European Investment Bank (EIB). The value of services received from the EIB for the Etiler Police School and 40 other school buildings or dormitories was documented as EUR 4,312,900.

The decision taken in 2010, which covers reconstruction and retrofitting projects, was completed in 2012, according to the annual report of the Istanbul Seismic Risk Mitigation and Emergency Preparedness Project (ISMEP), which was established under the Governorship of Istanbul in 2006.

Again in 2012, the Etiler Police School land was transferred from the Treasury of Finance to the Istanbul Metropolitan Municipality in accordance with the protocol signed between the Istanbul Metropolitan Municipality and the General Directorate of Security on April 07, 2012. This transfer was followed by an amendment to the Implementation Zoning Plan dated December 26, 2012.

Şekil 10 : Planlama Alanının İptal Edilen 26.12.2012 t.t.'li Uygulama İmar Planındaki Durumu

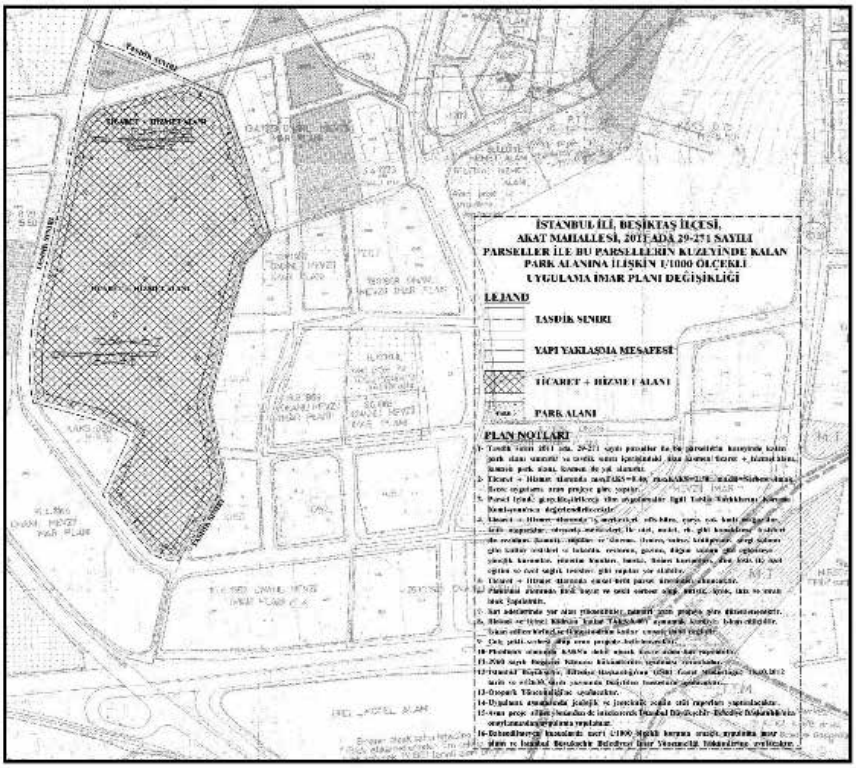

Figure 3. Zoning Plan Amendment dated 26 December 2012

According to this Implementation Zoning Plan amendment, it is seen that the area, whose function appears as an educational facility (police college) in the old plan, has been functionalized as a trade + service area in the new plan.

When the construction conditions of the Etiler Police School land, where all buildings including the administrative building, dormitory and school buildings are currently 5 storeys, are examined according to the new plan; it is seen that the maximum height is left free, the building coverage ratio is processed as 2.50, and a construction permit is given as a trade + service area and 100 thousand square meters of construction right is provided on the land.

According to the Council of Ministers' Decision No. 2013/5118, published in the Official Gazette on July 24, 2013, the area located within the boundaries of Rumeli Hisarı Neighborhood, Beşiktaş District, Istanbul Province, as

delineated by the attached map and list indicating its boundaries and coordinates, has been designated as a "risky area" pursuant to Article 2 of Law No. 6306 on the Transformation of Areas at Risk of Natural Disasters. This decision was adopted by the Council of Ministers on July 8, 2013.

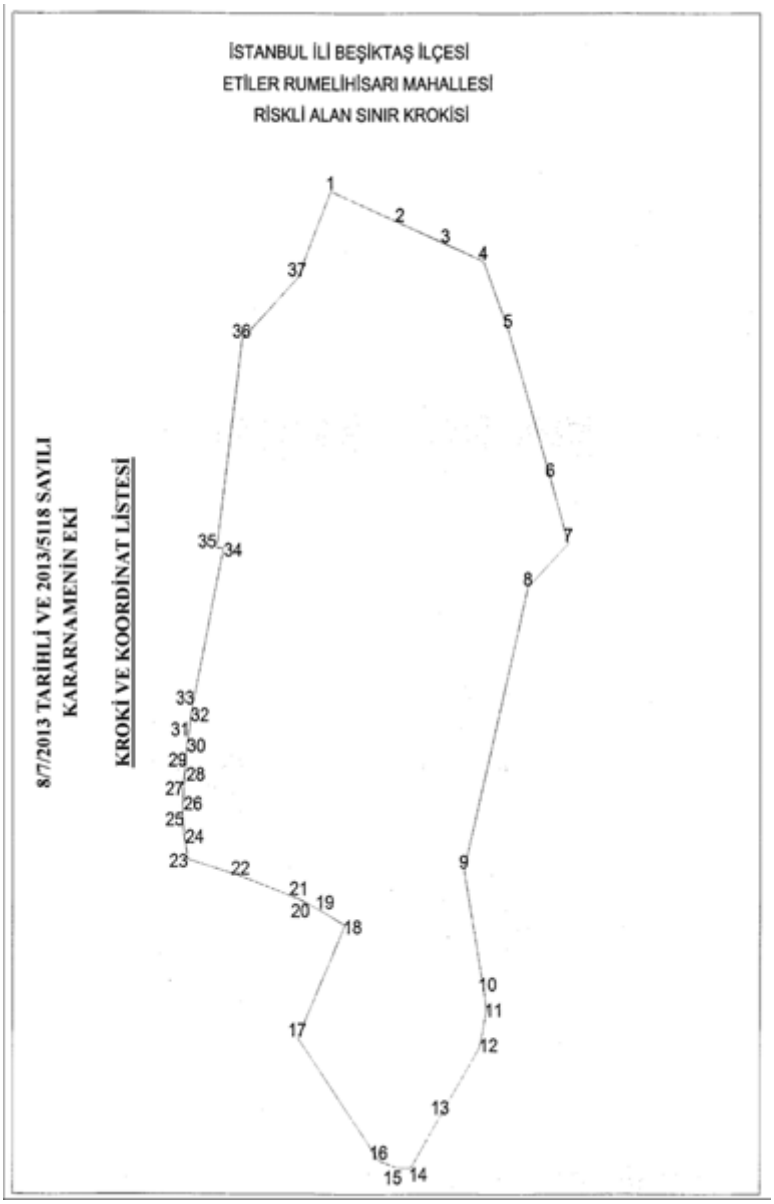

Figure 4. Etiler Rumeli Hisarı Neighborhood Risky Area Boundary

Law No. 6306 on the Transformation of Areas Under Disaster Risk, in force since May 31, 2012, aims to reduce disaster risks. The law states that in order for an area to be declared a risky area, the ground structure or the building stock on it must have a risk of collapse in a possible earthquake, and the analyses to be made in determining this risk are explained step by step.

According to the data obtained from the geological-geotechnical survey report of the zoning plan prepared by the Ministry of Environment, Urbanization and Climate Change in 2022 for the study area, it has been determined that the area is located in "suitable areas" and "rock environments" and that there is no risk element that carries a disaster risk in this context. At the same time, according to the letter prepared by the Disaster and Emergency Management Presidency (AFAD), there is no "Disaster-Prone Zone" decision for the study area.

In this context, the designation of an area classified as having stable ground conditions in official Ministry reports as a "risky area" in a city like Istanbul, which is highly susceptible to earthquakes, is open to debate in terms of public interest. This is particularly significant given the existence of regions in Istanbul that are far more critical in terms of disaster risk. Moreover, the selection of this area and the fact that its building stock had already been renewed with funding from the European Investment Bank in 2012—one year prior to this decision—necessitate a thorough evaluation of the entire process from a public interest perspective.

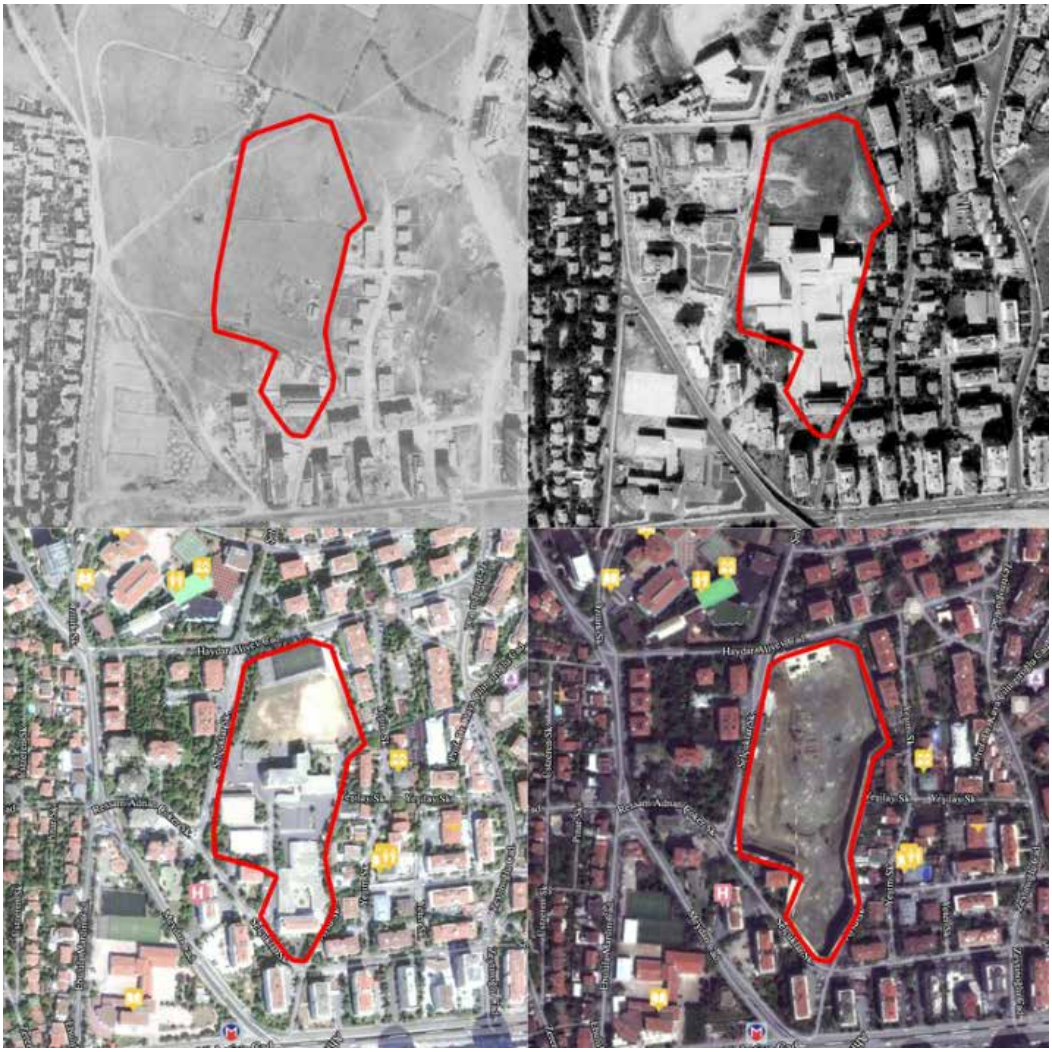

Figure 5. Aerial Photographs of Etiler Police School in 1966, 1987, 2011 and 2021

With the declaration of the area as a disaster risk area, the authority to make all kinds of plans in the area was transferred to the Ministry of Environment, Urbanization and Climate Change.
UCTEA Chamber of Architects and UCTEA Chamber of Urban Planners filed a lawsuit against these plan amendments on May 6, 2013, and two expert reports obtained within the scope of the file found that the plans were contrary to the principles of urbanism and the law.

In 2014, Etiler Police School was closed by the Council of Ministers' Decision No. 2014/6831. In 2018, the demolition of the Etiler Police School began. In the same year, the Istanbul Metropolitan Municipality put the land up for sale, and the tender was won by Istanbul Konut İmar Plan Sanayi ve Ticaret A.Ş. (KİPTAŞ), a subsidiary of the municipality, for 1,388,520,000 TL. Subsequently, KİPTAŞ organized a selective bidding process for the construction project, which was won by the partnership of Yapı ve Yapı Sanayi Ticaret A.Ş. + ASTAŞ Gayrimenkul Yatırım A.Ş. The winning partnership developed a project consisting of three skyscrapers with a height of 36 stories. The project includes 251 residential units in two blocks, while the third block will be operated as a hotel by the renowned hotel and

residence operator, Mandarin Oriental Group. The hotel will feature 156 rooms, 16 suites, and three restaurants. Following these developments and tender processes, a retaining wall construction permit was issued on July 27, 2018, and new building permits were granted on November 1, 2018. On November 7, 2018, the establishment of floor ownership was registered, creating 536 independent units within the project.

In a 2018 court decision, the project was deemed to serve the public interest. However, the Istanbul Regional Administrative Court's 4th Administrative Litigation Chamber overturned this ruling on September 20, 2019, under Decision No. 2019/1568, annulling the zoning plan in question. This decision was definitively upheld by the 6th Chamber of the Council of State on June 28, 2021. The court's ruling emphasized that the zoning plans granted construction rights significantly exceeding the environmental building conditions.

In a joint statement, the Istanbul Branch of the Chamber of City Planners and the Istanbul Metropolitan Branch of the Chamber of Architects, affiliated with UCTEA, expressed their stance on the matter, stating, "What belongs to the public should be returned to the public without further delay." In 2021, the Istanbul Metropolitan Municipality annulled the construction permits issued in 2018. In 2022, the Ministry of Environment, Urbanization, and Climate Change, the sole authority responsible for planning the area, prepared a new plan. This plan adhered to the existing project, designating two blocks with ground floor + 32 stories and one block with ground floor + 36 stories. The land use, previously classified as commerce + service, was revised to commerce + tourism. In 2023, following the new plan, the company obtained a construction permit from the Ministry and resumed construction. That same year, professional chambers once again filed lawsuits against the plan and the construction permit.

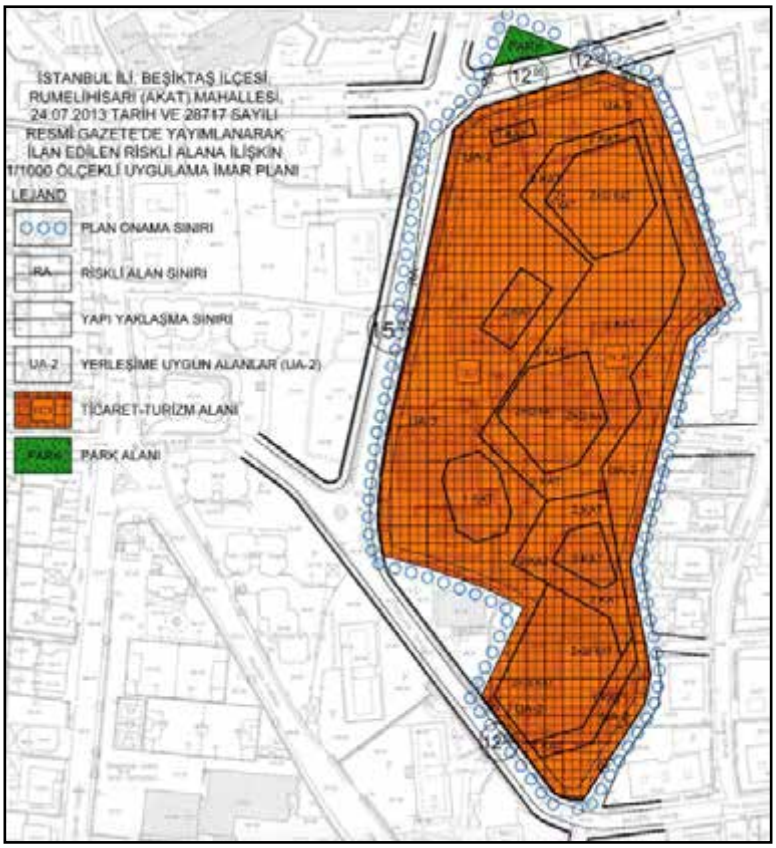

Figure 6. Zoning Plan Prepared by the Ministry of Environment, Urbanization and Climate Change

5. Findings and Discussion

The case of the Etiler Police School illustrates a complex interplay between formal planning mechanisms, legal frameworks, and political strategies that ultimately facilitated the transformation of a public educational site into a luxury mixed-use development. While each procedural step was framed within legal instruments—such as zoning amendments, disaster-risk legislation, and institutional protocols—the cumulative effect of these decisions reveals a pattern of instrumentalising the concept of public interest to legitimise a highly profit-oriented project.

One of the most striking findings concerns the strategic use of Law No. 6306, which permits central government intervention in areas designated as disaster-prone. Despite the lack of geological or structural evidence supporting such a designation, the area was declared "risky" just one year after its reconstruction was completed with international funding. This decision effectively bypassed local planning authority and transferred all regulatory power to the Ministry of Environment, Urbanisation and Climate Change. As highlighted in the theoretical framework, this shift represents a textbook case of policy-based depoliticisation, where risk is mobilised as a neutral technical category to enable centralised planning and high-density development (Allmendinger & Haughton, 2012; Şengül, 2002).

The pattern of actions observed in this case also exemplifies what Bozeman (2007) describes as the erosion of substantive public interest. While officials claimed the project would bring urban value through tourism and economic development, the outcomes contradicted fundamental planning principles such as transparency, social equity, and sustainability. The rezoning process, conducted with limited public engagement, prioritised maximum construction rights over considerations of infrastructure capacity, environmental impact, or spatial justice. This aligns with critiques in planning theory that warn of "public interest" being reduced to economic utility, thereby marginalising ethical obligations to the broader community (Campbell & Marshall, 2000; Campbell, 2002).

From a legal standpoint, the annulment of the zoning plans by the Council of State in 2021 reaffirms that the process violated not only planning ethics but also the principles enshrined in Turkish legislation. The court's recognition that the new density "exceeded surrounding urban conditions" serves as a rare but critical institutional acknowledgment of the misuse of legal tools for political-economic gain. This also reveals the fragility of procedural legitimacy: even when decisions are technically legal, they may still be overturned if they fail to fulfil the broader mandate of the planning system, which includes safeguarding public interest in a meaningful sense.

Ethically, the case further problematises the role of planners and public institutions. The transition from a publicly funded educational facility to a privatised luxury enclave raises profound questions about the ethics of land use decisions in neoliberal governance contexts. The use of public resources for reconstruction, followed by rapid reclassification and sale, underscores what many scholars term the commodification of public assets (Harvey, 1989). Here, public interest was invoked not as a moral commitment but as a discursive shield—deployed to rationalise a sequence of decisions that ultimately undermined social equity and public trust.

Finally, the resistance mounted by professional chambers, supported by expert reports and legal actions, illustrates the contested nature of public interest in practice. Their emphasis on planning integrity and social accountability signals the importance of maintaining institutional counterbalances to state-led commodification. However, their limited success in halting the project reflects the structural imbalance of power in Turkey's planning system, where central authority increasingly dominates local governance, often with limited channels for participatory input or ethical scrutiny.

In sum, the Etiler case exemplifies how public interest can be selectively interpreted, politically instrumentalised, and legally stretched to accommodate speculative urban agendas. While formally legal, the process deviated from ethical planning standards, undermined democratic oversight, and privileged private gain over public benefit. It thus calls for a critical reassessment of how public interest is defined and operationalised in planning—particularly in contexts marked by strong centralisation and market-oriented urban policy.

6. Conclusion and Recommendations

This study has examined how the notion of public interest is defined, negotiated, and operationalised in the transformation of public land within the Turkish urban planning context. Through an explanatory case study of the Etiler Police School site in Istanbul, the research has demonstrated that while public interest remains a central term in both planning law and political discourse, its meaning in practice is far from fixed. Rather, it is subject to reinterpretation by institutional actors, often in ways that align with market-oriented development agendas.

The findings indicate that the transformation process was shaped by a combination of legal mechanisms, institutional restructuring, and strategic discourse, all of which facilitated the commodification of a formerly public educational facility. Despite the procedural legality of the actions taken, the process violated substantive planning principles, undermined local governance, and prioritised private profit over collective benefit. This case illustrates a broader tendency within contemporary urban governance to instrumentalise public interest as a justificatory narrative, rather than uphold it as an ethical or constitutional obligation.

Moreover, the research contributes to planning theory by reaffirming the importance of distinguishing between formal legality and ethical legitimacy. While laws and regulations provide the procedural framework for decision-making, they do not necessarily guarantee just or equitable outcomes. In contexts of strong centralisation and limited public participation, the invocation of public interest must be critically scrutinised—particularly when used to justify the transfer of public land to private capital.

In light of these findings, several recommendations are proposed for both policy and practice:

Reconceptualising public interest: Planning authorities and practitioners must adopt a more inclusive and deliberative understanding of public interest, one that foregrounds social equity, environmental sustainability, and long-term collective well-being rather than short-term economic gains.

Reinforcing institutional checks and transparency: The roles of professional chambers, judicial review, and civil society must be strengthened to ensure accountability in plan-making processes. Legal frameworks should incorporate clearer criteria for risk designations and land use changes, supported by independent assessments.

Restoring the ethical foundation of planning: Planning education and practice must place greater emphasis on ethics, particularly in contexts where the boundaries between public and private interests are increasingly blurred. Planners should be empowered to act not only as technicians but as ethical agents responsible for upholding public values.

Rebalancing planning authority: There is a need to re-empower local governments and communities in planning decisions. Centralised interventions should be limited to exceptional circumstances and must be accompanied by transparent justification, participatory mechanisms, and rigorous impact assessments.

The transformation of the Etiler Police School is not an isolated case, but rather a manifestation of systemic shifts in the governance of urban space. As such, it serves as a cautionary example of how the language of public interest can be co-opted to enable spatial injustice. Reclaiming the integrity of this concept—both legally and ethically—is essential for building more democratic, just, and sustainable cities.

MOBILITY

The walkability potential matrix – a new method for measuring sustainable destination configurations in town and city centres

Akkelies van Nes
Western Norway University of Applied Sciences
avn@hvl.no

Abstract
The object of this present study is to reveal the spatial configuration of 55 Norwegian towns and cities related to degree of walkability potentials. The aim is to investigate to what extent the street or road profile affect the walkability potentials in the town centres based on the distribution of roads in comparison of streets based on street names. The focus is on the town centres, because they tend to have the largest walkability potentials. For this, the last part of the street or road names is used to identifying whether it is a balanced street or a road encouraging car use. Likewise, the number of X and T junctions is counted in the town centre. Correlations between T and X junctions were made, and correlations between road and streets were made for the town centre of all 55 Norwegian towns and cities.

The results show that the higher number of X-junctions in correlation with T-junctions, the shorter urban blocks, implying higher degree of walkability potentials in the town centres. Likewise, the higher numbers of streets in correlation with roads in a town centre, the higher degree of facilitation of pedestrian friendly pathways. Three different clusters are identified in the statistical analyses, in which comply with the reputations the various town and city centres have regards walking attractiveness or private car dependency. The higher number of X-junctions in correlation with T-junctions, the more integrated the town centre is on a local as well as global scale. Likewise, the higher number of streets in correlation with roads, the more integrated the town centre is. Finally, the more the town or city centres have an orthogonal grid structure consisting of streets, the higher integration and thus higher walkability potentials.

The method is a first step to have an operational and easy applicable tool to measure degrees of walkability potentials in town and city centres.

Keywords: walkability potentials, street names, street profiles, junction type, urban centres.

Introduction – measuring attractive walkable town and city centres

Town and city centres are regional attractors and attractive destinations where a diversity of functions is clustered, and the building densities are higher than the surroundings. During the last 30 years, town and city centres are perceived to be beneficial for encouraging sustainable transport means such as providing an efficient public transport and facilities for walking (Banister 2008, Murgante et al 2023, van Nes 2021a). But how can the physical and spatial framework of walking friendliness be measured? Often it is believed that high building density and high degree of land use diversity encourage short walking distances and hence more people in streets (Ewing and Cervero 2010). Therefore, densification of the built mass and intensification of land use diversity if often used as a strategy for making sustainable town and city centres. However, the spatial configuration of the mobility network is often forgotten in the sustainable city debate (van Nes 2021a). The application of various space syntax analyses on a wide range of cities world-wide highlight that town and city centres have high spatial to- and through movement in relation to the whole town or city (Hillier et al 2007). However, the degree of walkability of the mobility network is difficult to identify with only the space syntax method. Therefor the aim of this contribution is to present a different approach to measure walkability potentials in town and city centres, based on street profiles and junction type. To what extend play street profiles and junction type for the walkability potential in town and city centres? How can street profiles be measured or quantified?

Most Norwegian towns and cities have small urban centres surrounded by many single-family houses. Oslo, the largest city of Norway, has three large local centres (van Nes 2003) and they are surrounded by sub-urban neighbourhoods consisting of flats, row houses and single-family homes. Bergen is the second and Trondheim is the third largest city in Norway, and both cities have one small urban centre surrounded by sub-urban neighbourhoods consisting of mostly single-family homes, and some flats and row houses. Since the 1960s, urban growth in Norway has been much planned around the private car. The effects are the emergence of low-density urban sprawl, location of large out of town car-based shopping malls, and acceptance of new land use plans facilitating single-family houses in the countryside and into the forest (Aarsæther, Falleth, Nyseth, & Kristiansen 2012).

There exist several reports where researchers have been trying to measure various sustainability indicators for Norwegian towns and cities. The sustainability indicators have been to measure the populations' distance to nature or parks, population density on build up land, distance to kindergarten, primary school, grocery shops and daily travel behaviour. What is missing are various means for identifying the spatial framework for making walking attractive instead of using the private car for distances lesser than 1,5 km.

As space syntax research has shown, streets with high to- as well as through movement potentials on a local scale, combined with well-integrated main routes running through them tend to be lively neighbourhoods with high walkability potentials (Kråkenes et al 2022, Bolset et al 2022, van Nes 2021 a and b). Often these neighbourhoods have short urban blocks, tend to have high building densities and a large variation of functions inside buildings (Ye and van Nes 2014, van Nes 2021c, Berge et al 2022). Often town and city centres score high on these spatial analyses. Therefore, space syntax analyses are conducted of all 55 Norwegian cities and towns. The results from the space syntax analyses in the town and city centres are tested on junction type, based on Stephen Marshall's work (2005), and path type, based on Job Eldijk's method (2014) on classifying streets regards their functions or users. The number of X and T junctions is counted and correlated with one another. Furthermore, the total number of roads and highways in correlation to all other streets is investigated in the city and town centres based on pathnames. The reason for focusing on the centres, is that the walkability potentials are largest there and the various spatial structures of these centres gives an indication of the degree of private car dependency.

The first part of this paper will present the state of the art of current sustainability policies and practice in Norway. The second part will present the scope of this inquiry with the method used, whereas the third part present the results from the various spatial analyses and the statistics. An outline for a walkability potential matrix is presented. The fourth part discuss the findings, and the fifth part reflects over the usefulness of the walkability potential matrix.

Sustainability parameters, planning policies, and practice

Norway has a short urban history. Before the industrial revolution, Norway had a strong farming culture (van Nes 2022). There were a few towns along the coastal areas with small urban centres. These centres are still existing. During the industrial revolution, around 1850 in Norway, some new towns grew up where the large factories were located whereas others expanded around the old historic cores. In general, most Norwegian towns up to 1960 were small and compact, and developed according to the pedestrian, bus and in some cases trams.

After 1961, everyone was allowed to buy a private car in Norway. Since then, Norwegian built environments are transformed and planned around the private car. Except from the large cities, Norwegian towns are extremely private car dependent. During the last decade, there exist national policies to make towns and cities more sustainable by improving public transport, implement high parking fees, reduce parking facilities, implementing bicycle lanes, implement road payments etc. However, little of this can be seen in Norwegian small and medium sized towns (Kråkenes et al 2022).

During the last 30 years, the consideration of the environment has put some influence on the planning of Norwegian towns and cities. The focus is on finding good solutions for pedestrians and cyclists, increasing the building density within existing built-up land, and providing large investments in new solutions for public transport in the large cities in Norway. The concept of sustainability was first incorporated in planning in the national policy documents in 1993 and then substituted by governmental planning guidelines in 2014.

The problem of measuring sustainability parameters in Norway

So far, it seems that the large cities are better at implementing sustainable planning measurements than the smaller towns of Norway (Kråkenes et al 2022). This problem is revealed by comparative case studies of large as well as small sized Norwegian towns and cities the last decades. The report 'Byer og Miljø' (Cities and Environment) focus on the state of the environment and sustainable development in the 13 largest municipalities in Norway. The total population in these 13 municipalities represents 36% of Norway's total population (Kommunal- og Moderniseringsdepartementet 2016).

Based on their parameters, the results in this report show that the largest cities in Norway score higher on environmental status and sustainable development than the average values for all towns in Norway. For example, the report shows that smaller towns have a larger built-up area per inhabitant compared to the larger cities. In 2012, Oslo had the lowest built-up area with 224 m2 per inhabitant but has the highest density of buildings within the built-up area. Conversely, Tromsø city, with a significantly high density of buildings per inhabitant, had the lowest density of buildings in the period 2011-2012 with 50%. Overall, the density of buildings within the conurbation boundary of these 13 municipalities was 72%, while it was on a national average 43%. The results in this report clearly show that cities with high density of buildings are also the cities that are most able to live up to the authorities' targets for densification. Densification refers to the part of new housing that is established within existing urban boundaries (Haagensen 2015, p.20-22).

The report's indictor of walkability potentials is based on metrical distances from homes to grocery shops, schools, and kindergartens. Oslo scores highest with 90% on the indicator 'residents living with less than 500 meters away from a grocery store' in the municipality. Stavanger city is second on this list where 75% of the residents is living close to a grocery store. Most inhabitants in the largest cities have a short distance from home to a grocery store. These distances seem to increase the lower the population is in a town. This trend can also be seen by comparing the average from these 13 towns and cities with the average for the country (Haagensen, 2015, p.51). Likewise, regards distance from home to primary school, Oslo has the largest number of children living lesser than 500 meters betweeen their homes and primary school. In 2014, 96 % of the children had a short distance between home and primary school. The national average is lower than the average of these 13 cities, which is 63% versus 85%. Thus, the lower population density in a city, the longer distances between home and primary schools (Haagensen, 2015, p.55).

A report from the Institute of Transport Economics about land use and transport development for climate-friendly and attractive cities shows that there are clear correlations between densification and car dependence. Densifying in and around the existing town and city centre reduce private car dependency, reduces urban sprawl into the countryside, gives positive impact on the attractiveness of cities by contributing to high variation of services and land uses, contributing to lively and vibrant urban areas. Improved public transport services results in reduced car use. Furthermore, densification and transformation in the city centre contribute to increased accessibility, a provision of a variation of jobs, and increased attractiveness for the establishment of advanced businesses that requires highly skilled and specialized employees (Tennøy, Øksenholt, Tønnesen and Hagen 2017, p. 19).

Another important finding from this report was that the compact urban centres in the large cities provided at least as good access to public outdoor areas as the low-density towns. Arrangements for public transport, cycling and walking in combination with restrictive measures to regulate car traffic contributed to many of the same effects. At the same time, the report shows that restrictions on car traffic in heavily car-based cities are experienced as a significant disadvantage for those who work or live in areas where one is heavily dependent on the private car for daily activities (Tennøy, Øksenholt, Tønnesen, and Hagen 2017, p. 19).

Current trend in Norwegian towns and cities

Through restrictive municipal plans and strong agreements with governmental institutions, the large cities have shown ability to act in line with national policies and guidelines. Since 2014, the objective of the national transport plan is zero growth in private car transport. However, the small and medium-sized cities in Norway are lagging behind regards enhancing compact town centres and avoiding urban sprawl (Kråkenes et al 2022). For example, the town Notodden decided to reduce 180 acres of virgin land in favour of one hundred new detached residential plots in 2015. This is happening at the same time as state planning guidelines emphasize densification and transformation in already built-up areas. Four years later, Notodden's out of town shopping centre was granted permission to expand for car-based retail. At the same time, the regional plans discourage these kinds of developments for preventing deterioration of existing old town centres and increased passenger car traffic (Kråkenes et al 2022). The following features is taking place in most Norwegian towns during the last 20 years (Kråkenes et al 2022):

- Large car-based shopping centres are established outside the city and town centres,
- Agriculture and natural resources are being demolished through implementing new buildings on nature land,
- Important urban functions, such as homes, workplaces, etc. are established far from each other,
- The proportion of dwellings that require space, energy and resources is high, such as for the establishment of detached single-family houses,
- The car is given high priority as a means of transport in the cityscape despite increased government investment in more climate- and environment-friendly modes of transport such as walking, cycling and public transport,
- Important downtown streets and main squares are dominated by car parking spaces,
- Large new residential areas are established at a long distance from the city centre, which contributes to increased private car dependency and long travel journeys between work, school, leisure activities and shopping.

Thus, there is a large gap between national and regional planning policies and local implementation practice.

Relevant writings on walkability in an international context

It is believed that a town centre with good walkability facilities can contribute to lesser use of the private car and encourage densification strategies inside and around the existing town centre. The recent used concept 'the 15 minutes cities' indicated that everything should be accessible within 15 minutes walking within the city centres and from public transport stops. The concepts short travel time, high building density, high land use diversity and proximity of everything are used to describe the '15 minutes city' (Murgante et al 2023). Except from Oslo, most Norwegian town centres can be crossed within 15 minutes of walking.

There exist a large body of literature on measuring walkability potentials. In the study of Cervero and Kockelman (1997) the authors found out that compact neighbourhoods with a synergy of high building density, mixture of functions and pedestrian friendly design encourage reduction of vehicle trips. The authors propose a concept of 3Ds (density, diversity, and design), where the definitions of density and diversity is well defined. However, when it comes to the definition of design, it is defined to consist of sidewalks, tree rows, and providing facilities for pedestrian and cyclists. The study is slightly touching upon street profiles. However, the underlying spatial configuration of the mobility network is lacking. The authors are aware of that short block lengths encourage walking.

Later, Erwing and Cervero (2010) changed the 3Ds to 5Ds, now standing for density, diversity of land use, design, distance to transit, and destination accessibility. Still the concept of design is vague, and the issue of street profiles and street network configuration is lacking. The distances between homes and transit are now considered. In research on evaluating the state of transit-oriented development in the InterCity-Triangle of the Oslo fjord region, density and degree of function mixture was considered and correlated with space syntax analyses and strong correlations between them were found (Myklebust et al 2022). However, the street profiles were not considered in this research.

In another research, Moudon et al (2006) attempt to make operational definitions of walkable neighbourhoods. The authors also claim that higher residential density, smaller street blocks, presence of sidewalks, and finer mixes of uses promote high degree of neighbourhood walkability. Closeness of shops and retail have the largest impact of walking.

The concept 'walking the last mile' is used for understanding the various parameters for making walking attractive from the public transport stop to a destination (Braun et al 2022). However, what kind of spatial structure can enhance the initiative that people choose to move on foot or by car? There must be something more the built environment can offer rather than short metric distances or good pavement surfaces. Does the spatial structure and profile on the path network really matter? How can they be combined in one method?

In 2014 Job van Eldijk developed a method for street profiles based on street functions or street or road users (Eldijk 2014). He divides the mobility network in the following four categories: 1) pedestrian and bicycle streets, 2) balanced streets, 3) vehicle dominated roads, and 4) vehicle only roads. The purpose of the analysis is to examine how the street and road network is used by the various road user groups, and who dominates street use.

As research has shown, traditional town centres and neighbourhoods tend to have a high number of balanced streets. These streets are constituted by buildings entrances adjacent to the pavements and the buildings tend to have 'active frontages' oriented towards the pavements (Olsen et al 2022, Berge et al 2022, Meinert et al 2019). Modern neighbourhoods tend to have mostly vehicle dominated roads and separate pedestrian and bicycle paths (Stedal et al 2022, Kråkenes et al 2022). Buildings tend to lack entrances and windows on ground floor level along the roads.

Based on earlier space syntax research, urban centres with both high local and global integration, and the main routes need to be well connected to the neighbourhood seems to be well frequented by pedestrians (de Koning et al 2020a,b, van Nes & Yamu 2020, van Nes 2021a,b,c). Seemingly, urban environments with short urban blocks and a high number of X-junctions tend to have high spatial integration values (Shi and van Nes 2009). On a micro scale level, the street profiles seem to enhance walking (Meinert et al 2019). That means that buildings need to face streets with active frontages (Rønneberg Nordhov et al 2019), and a balanced street with both access for cars and pedestrians, or spatially well-integrated streets for pedestrians only (Berge et al 2022). Seemingly, encouraging sustainable mobility means that it is not enough to have high building density and high degree of land use diversity. It is the structure of the street and road network that influence the degree of density and land use diversity (van Nes et al 2012, Ye and van Nes 2014, de Koning et al 2021a,b, van Nes 2021b).

Method for developing the walkability potential matrix

For the town and city centres, the total number of T and X junctions are counted based on Stephen Marchall's work from 2005 (p.96-98). For junctions consisting of five arms and more, are registered as X-junction. A correlation is made between the total number of T and X junctions in relation to the total number of junctions. When the value is close to 1, the higher number of X junctions.

A correlation is made between roads and streets versus the total number of paths. For this, the last part of the street or road names is used to identify whether it is a balanced street that enhance walkability or a road encouraging car use. Based on Eldijk's classification system on street function, a separation of category 1) and 2) from category 3) and 4) is made based on the last part of path names. The first two categories are pedestrian friendly streets, whereas the last two part are roads designed for vehicles.

A path's name consists of mostly two parts. One part is a particular name given to the specific path for identification of a particular place and wayfinding, whereas the other part indicates the type of path (street, road, avenue etc). The 'particular name' part can be named after persons, things, animals, objects from the nature, unique shapes, places, or hierarchy of pathways (for example: Main Street, or in Norwegian 'Storgata'). The focus on this inquiry concerns the second part of the name, which often indicates for the type of users and the type of path.

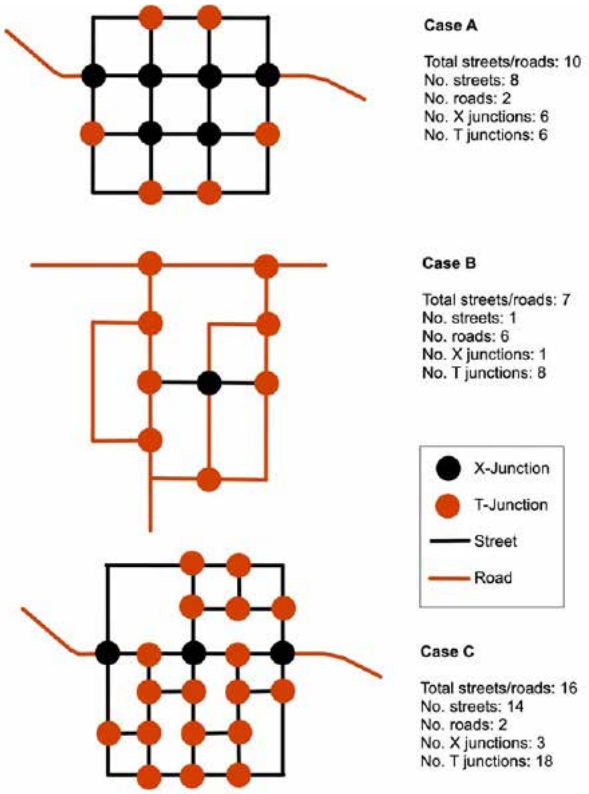

Figure 1: Three types of town centres based on path type and junction type.

In many northern European build environments, the balanced streets tend to have names ending on 'street' whereas the vehicle dominated roads ends on 'road'. In Norway the word 'gate' is used for 'street' and 'vei' for road. In this inquiry, all the paths with the name ending on 'vei, veg, veien, and vegen are registered as 'roads' in all 55 town and city centres. The names of the motor- and highways in Norway tend also to end on road ('vei', 'veg', 'veien' or 'vegen'). The remaining streets we classify as balanced or pedestrianized. A check was made with google street view. There are some exceptions, but the number is very low. For example, one of Oslo's main shopping streets is named 'Bogstadveien'. In the past it was a road leading from Oslo's city centre towards Bogstad farm. Through city growth, the road was urbanised and have today a balanced street profile.

In historic city centres, there exist a small number of paths with names that not always are ending on street (gate in Norwegian). Examples are 'smau' (pedestrian dominated path), 'almenning' (balanced street), 'aveny' (balanced street) or 'kroken' (balanced street). Therefore, they are all put into the category 'street' because they are pedestrian friendly streets. A correlation is made between the categories 'roads' and 'streets.' When the value is close to 1, the higher number of streets in correlations to road a city or town centre has.

Space syntax analyses are conducted of all 55 Norwegian towns and cities in 2022 with purpose to ascertain how various Norwegian towns and cities perform spatially. In sum, all these analyses indicate to some extend walkability potentials in these centres. All axial maps are hand drawn. It was possible to correlate the spatial data with data regards car ownership and building activities from the CBS of Norway for 47 towns and cities. For the larger cities, data about travel behaviour for public transport was gained for 6 cities. However, the resolution of all these data is too rough for correlations with the space syntax variables.

Regards the space syntax analyses, various normalised angular integration (NAIN), and normalised angular choice (NACH) analyses with both 500 (local) and 5000 (global) radii are conducted. The NAIN analyses show the to-movement potentials, whereas the NACH analyses show the trough-movement potentials of the street and road network. In addition, the angular step depth analyses taken from all the main routes are used for revealing how the main routes are connected to the local streets of the various neighbourhoods (van Nes 2021c).

These space syntax variables are used to test the results from the walkability potential matrix.

Hypotheses

As world-wide space syntax research has shown, streets with high through- and to- movement potentials on a local scale has the highest number of pedestrians in and along streets. Regards the theory of the natural movement (Hillier et al 1993), the higher level of through movement potentials on a local scale, the higher walkability potentials. At the same time, these locally integrated streets need to be well-connected to the main route network, in which is identified by calculating the through movement potentials on a city scale (de Koning and van Nes 2019).

On the scale of the town and city centres, one hypothesis is that the higher number of X-junctions in correlation with T-junctions, the shorter urban blocks, the more locally integrated the neighbourhood is, and the higher walkability potentials. Seemingly, the more the town or city centres have an orthogonal path network structure, the higher integration and thus higher walkability potentials. Another hypothesis is that the higher numbers of streets in correlation with roads in a town centre, the more integrated the urban area is and the higher walkability friendliness. Streets tend to have pavements and buildings located in a row with active frontages faces towards the pavements and streets. Conversely, roads tend to have free standing buildings that have frontages that are turned away from the streets. The entrances are often located on the side or the back side of the buildings.

Most town centres in Norway tend either to have an orthogonal street grid structure with a high number of streets and X junctions, or a road network structure consisting of mostly roads and T-junctions. The hybrid variant is a town centre having a street network with high number of streets with a high number of T-junctions. Figure 1 shows a diagram of three types of town centre.

Case A has an orthogonal grid structure with a high number of X-Junctions and high number of streets. Examples of these types of town centres are Kristiansand and Sarpsborg centres. Case B has a high number of T-junctions and roads. Examples on these kinds of town centres are Alta, Sandvika and Karasjok. Case C has high number of streets and seems to have an orthogonal grid structure but has a high number of T-junctions. Examples of this case are Arendal and Kragerø centre.

Developing the walkability potential matrix and statistical testing

The walkability potential matrix consists of identifying the degree of walkability potentials of town and city centres based on correlating junction and path type. The 4-star diagrams are used to visualise how each town scores. In the regression analyses, the mean values for all space syntax analyses are used for the whole city or town, and for only the town centre. The reason for correlating the findings from junction and path type with space syntax analyses is to reveal how the walkability potential matrix affects the degree of to- and through movement potentials in town and city centres.

Findings

The space syntax analyses of all 55 cities shows that the main centre appears to have the highest degree of through as well as to-movement potentials on town or city level. Figure 2 shows the to-movement potentials (NAIN) of twelve towns and cities centres of different sizes in Norway. Often it is difficult to see on a space syntax map to what extend a city centre is vehicle dominated or pedestrian friendly. The six cases on the top are towns with a high degree of private car dependency. The centres consist of car-based shopping centres surrounded by parking lots. Likewise, these town centres consist of mostly roads and has a high number of T-junctions, in line with case B in figure 1.

The six cases below have an orthogonal street network consisting of a high number of X-junctions and high number of streets, in line with case A in figure 1. These town and city centres have linear shopping streets with a high variation of individual shops easily accessible on foot. However, nothing can be said about the degree of walking friendliness of the streets of these towns based on the various space syntax analyses.

If it is so that local integration matters for enhancing walkability, figure 3 shows the NAIN and NACH analyses with a low metrical radius (500 meters), and street function analyses of three different Norwegian town centres. Trondheim centre has a high number of T-junctions but consists of mostly streets. The local to-movement as

well as through-movement potentials are high. Moreover, most of the streets are balanced. Trondheim centre is known to have a high number of people frequenting streets and is also very bicycle friendly. Conversely, Alta centre consists of roads and has a high number of T-junctions. These roads are vehicle dominated. The local to-movement potentials are low, and it has average values on the local through movement potentials. The shopping centre is turned away from the roads and is surrounded by large parking lots. Kristiansand has a high number of X-junctions and a high number of streets. It has a high number of balanced streets, with a high number of pedestrians frequenting the streets.

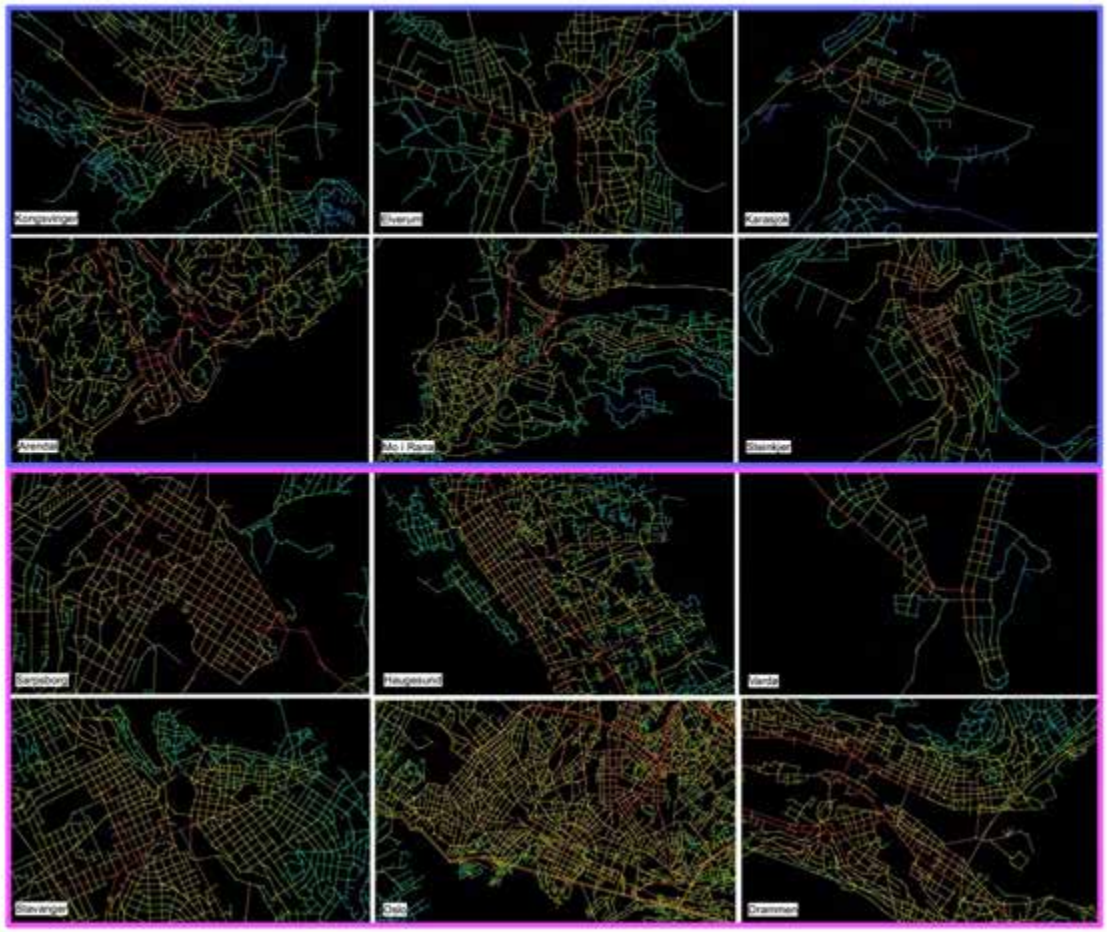

Figure 2: NAIN analyses with high radius of 12 Norwegian town and city centre. The six cases on the top have high number of T-junctions and consist of mostly roads, whereas the six cases below have high number of X-junctions and consists mostly of streets.

From the space syntax and the street function analyses it is not clear to what extend the level of the walkability potentials are in the town and city centres. Therefore, a closer view on junction and path type is revealed in the next chapter.

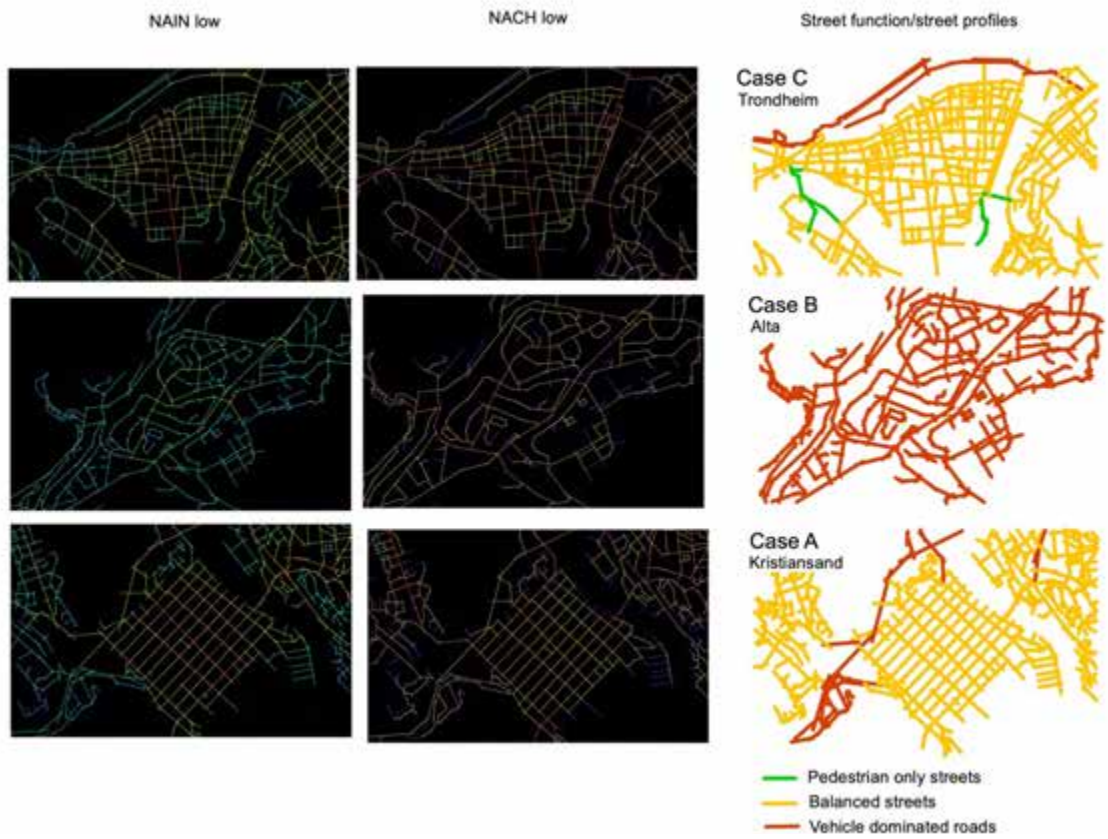

Figure 3: Space syntax and street function analyses of Trondheim (top), Alta (middle) and Kristiansand (below).

The correlation between path and junction types

A 4-star diagram can visualise how each town and city perform in relation to others regards the junction and path types. First, the correlation is shown between T-junctions and X junctions in relation to the total number of junctions, and the correlation between street and roads in relation to the total number of paths. The centres are grouped into large, medium, and small sized cities or towns.

Figure 4 shows a 4-star diagram of Norway's 6 largest cities. Kristiansand (green line) has the lowest number of T junctions due to that the centre consist of a strict orthogonal street network with mostly X-junctions. Trondheim's centre (blue line) consists of mostly streets with mostly T-junctions. Oslo (red line) scores average on all analyses.

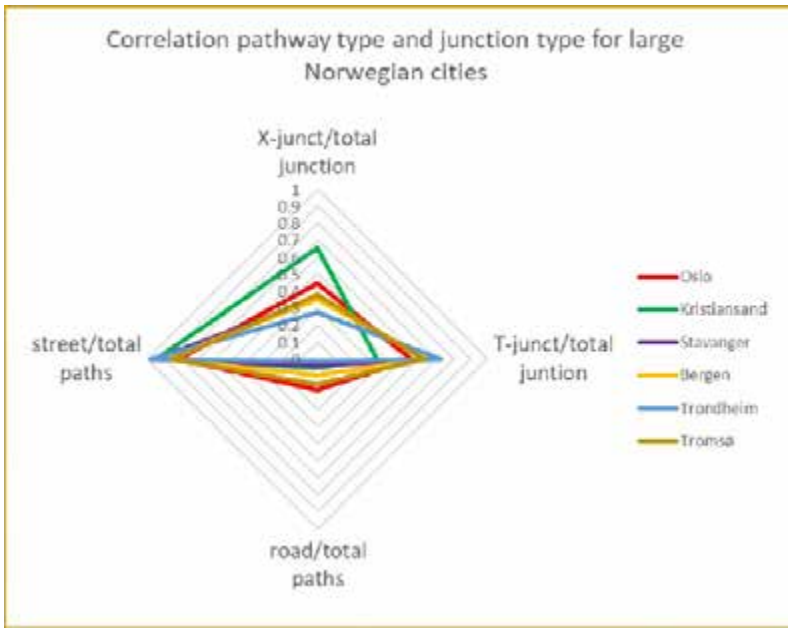

Figure 4: a 4-star diagram of Norway's 6 largest cities showing the correlation between streets, roads, X-junctions, and T-junctions.

Figure 5 shows a 4-star diagram of the medium sized town centres. Alta centre (red line) scores high on the number of T-junctions and roads, whereas Halden centre (blue line) scores high on the number of streets, and Sarpsborg centre (dark purple line) high on the number of X-junctions.

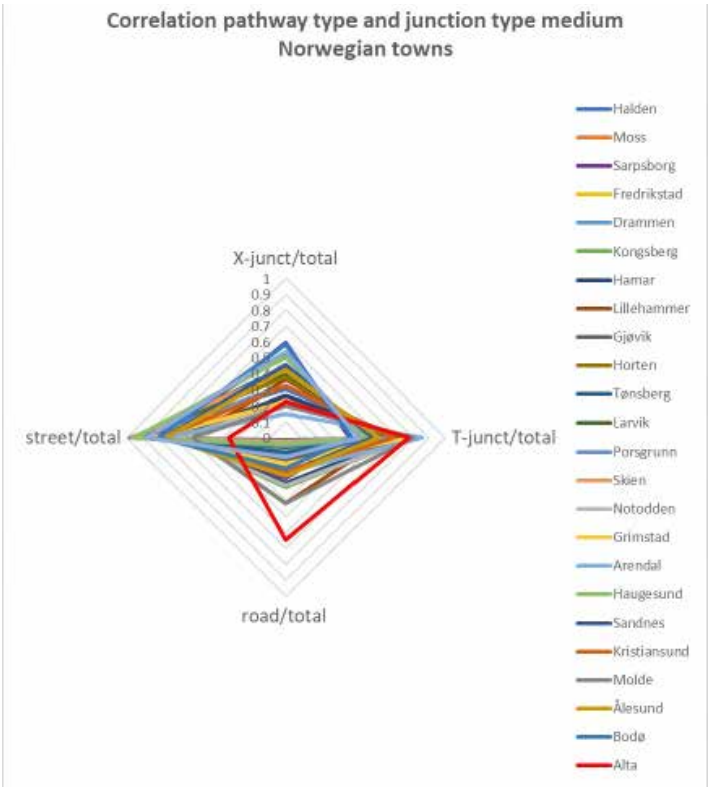

Figure 5: a 4-star diagram of Norway's medium sized towns showing the correlation between streets, roads, X-junctions, and T-junctions.

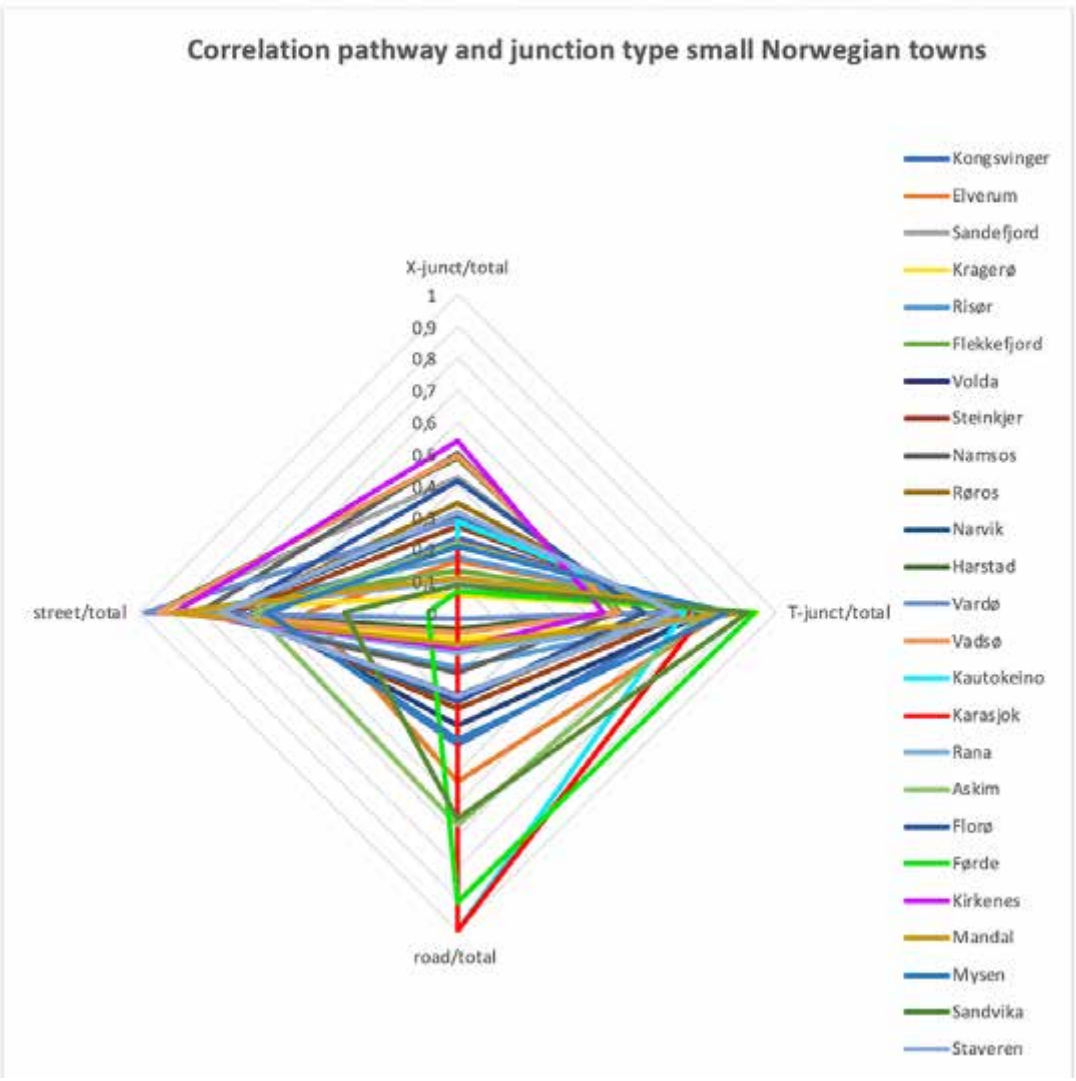

Figure 6: a 4-star diagram of Norway's small sized towns showing the correlation between streets, roads, X-junctions, and T-junctions.

Figure 6 shows the correlations of the centres of small Norwegian towns. The old coastal towns with an orthogonal street grid structure scores high on the X-junction and the percentage of streets. Conversely, the two Sami towns Karasjok (red line) and Kautokeino (turquoise line) consists of only roads. Likewise, the centres of the new towns, such as Førde (green line) and Sandvika (dark green line) have high number of roads and T-junctions. The small southern Norwegian town Kragerø (Yellow line) has a high number of streets and high number of T-junctions. The northern Norwegian coastal town Kirkenes (purple line) and Vadsø (orange line) has the highest number of X-junctions.

Figure 7 shows a scatterplot with the correlation between junction type and path type, and three different examples of town centres. The scatterplot represents the walkability potential matrix. On the Y axis, the closer a centre is to number 1, the higher percentage of streets in correlation to total number of paths. On the X axis, the close a centre is to number 1, the higher percentage of X-junctions in relation to the total number of junctions in a centre.

Three clusters can be seen in the scatterplot, in which comply with the three cases shown in figure 1. The town and city centres with orthogonal street grid are clustered together on the upper right corner in the scatterplot. Kristiansand centre has the highest number of X-junctions and streets. In the other cluster, town centres that has a small orthogonal grid in it centres, high number of streets, but has a high number of T-junctions in relation

to X-junctions. The towns Kragerø, Rana and Flekkefjord are examples of this. On the lower right part of the scatterplot the towns Elverum, Alta, Sandvika, Førde, Karasjok and Kautokeino are located. These towns have mostly roads and T-junctions.

The town centres that are located on the upper right in the scatterplot are case A towns, whereas towns centres located on the lower left in the scatterplot are case B towns. The case C towns are those who are located on the upper right in the scatterplot.

In many ways the scatterplot shown in figure 7 is a walkability potential matrix based on only junction and path type. The three clusters shown in the scatterplot comply with the reputation these towns have. Town centres in cluster A are known to be pedestrian friendly, town centres in cluster C are car-based, whereas towns in case B are also pedestrian friendly due to the high number of balanced streets. These streets are constituted by buildings that are oriented towards the streets with entrances and windows.

Below in figure 7 a four-star diagram is shown with the three most extreme cases representing each cluster. The shape and the location of the diamond indicate the type of town. The green diamond is on located on the upper left and consist of a high number of streets and T-junctions. These towns have robust centres enhancing pedestrian-based shopping streets and has a high level of walkability, in which indicate high level of sustainable transportation modes.

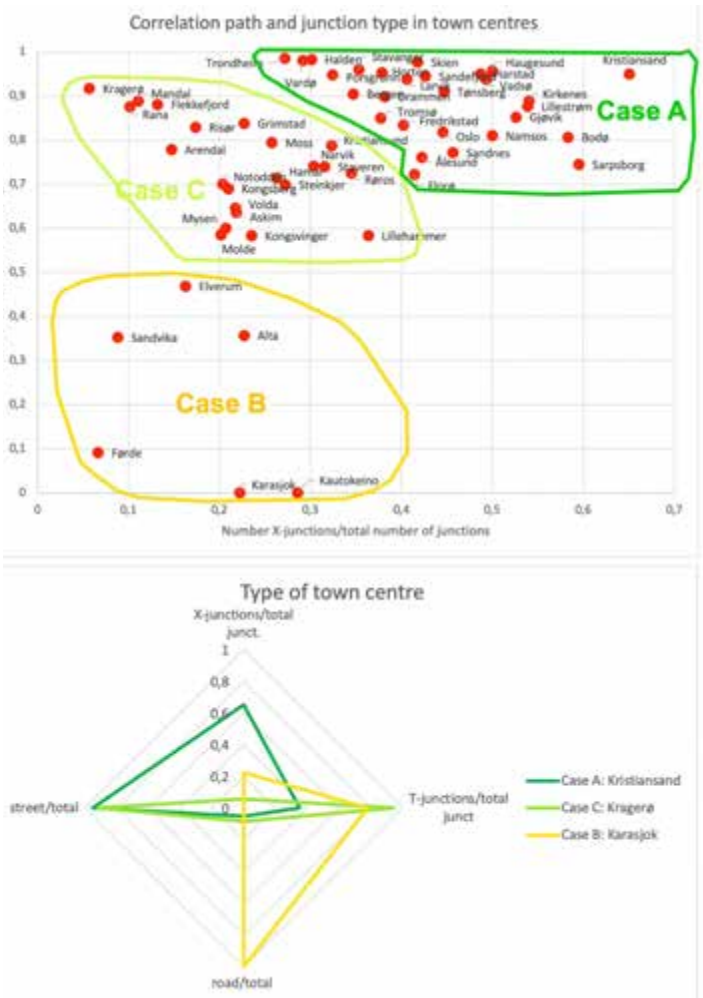

Figure 7: Top: The walkability potential matrix - Scatterplot showing the correlation between junction and path type. Bottom: 4-star diagram showing examples of three different towns representative for each cluster.

The light green diamond is flat and stretched out on the horizontal levels. The towns belonging to this category are small old town centres that either are squeezed between small hills or narrow valleys or along a coastal line. The biggest threat of these towns are the establishment and expansions of out-of-town shopping malls. Often these shopping malls are causing town centre decline due to that shops move out to these car-based shopping malls. Therefore, these town centres are very woundable when expanding due to population growth.

The yellow diamond is located on the lover right in the diagram. Towns belonging to this category are villages that recently got the status as town due to their regional position or population growth, or they are new towns. Their centres are developed around a T-junction, and everything is dimensioned around private car usage. Traffic safety, road capacity rules from the road engineer handbooks have steered the development of these town centres.

The next is to reveal to what extend the number of various junction and path types correlates with space syntax variables through regression analyses.

Regression analyses between junction type and space syntax
To what extend do these three types of town and city centres score on the spatial configuration of the street and road network? The axial map does not make any difference between path as well as junction type. Scatterplots were made for revealing the regression (R2) between space syntax analyses and path and junction types for all 55 town and city centres. The strongest correlations were found with the local NAIN and NACH analyses with a radius of 500 meters.

The correlation coefficient between the junction type and local NACH is R2 = 0,3701 and local NAIN is R2 = 0,3325 for all town and city centres. Thus, high number of X-junctions matters for generating high integration with high local to- and through-movement potentials. As research has shown, central urban areas with high local integration are attractive for pedestrians and contributes to low energy use for transport (de Koning et al 2020b).

Figure 8 shows a scatterplot with a differentiation between the size of the cities and towns. Regards the local to-movement potentials (mean NAIN low), the medium sized towns have the highest correlation with the percentage of X-junctions. Conversely, the larger the town or city, the stronger the correlation is between the percentage of X-junctions and local through movement potentials (mean NACH low). Seemingly, large towns and cities has a well-integrated main route network well-connected to adjacent larger neighbourhoods than the medium and small towns. Many of the small towns that just got the town status have a centre that is consisting of mostly roads with several T-junctions. Most of them are small villages that has expanded.

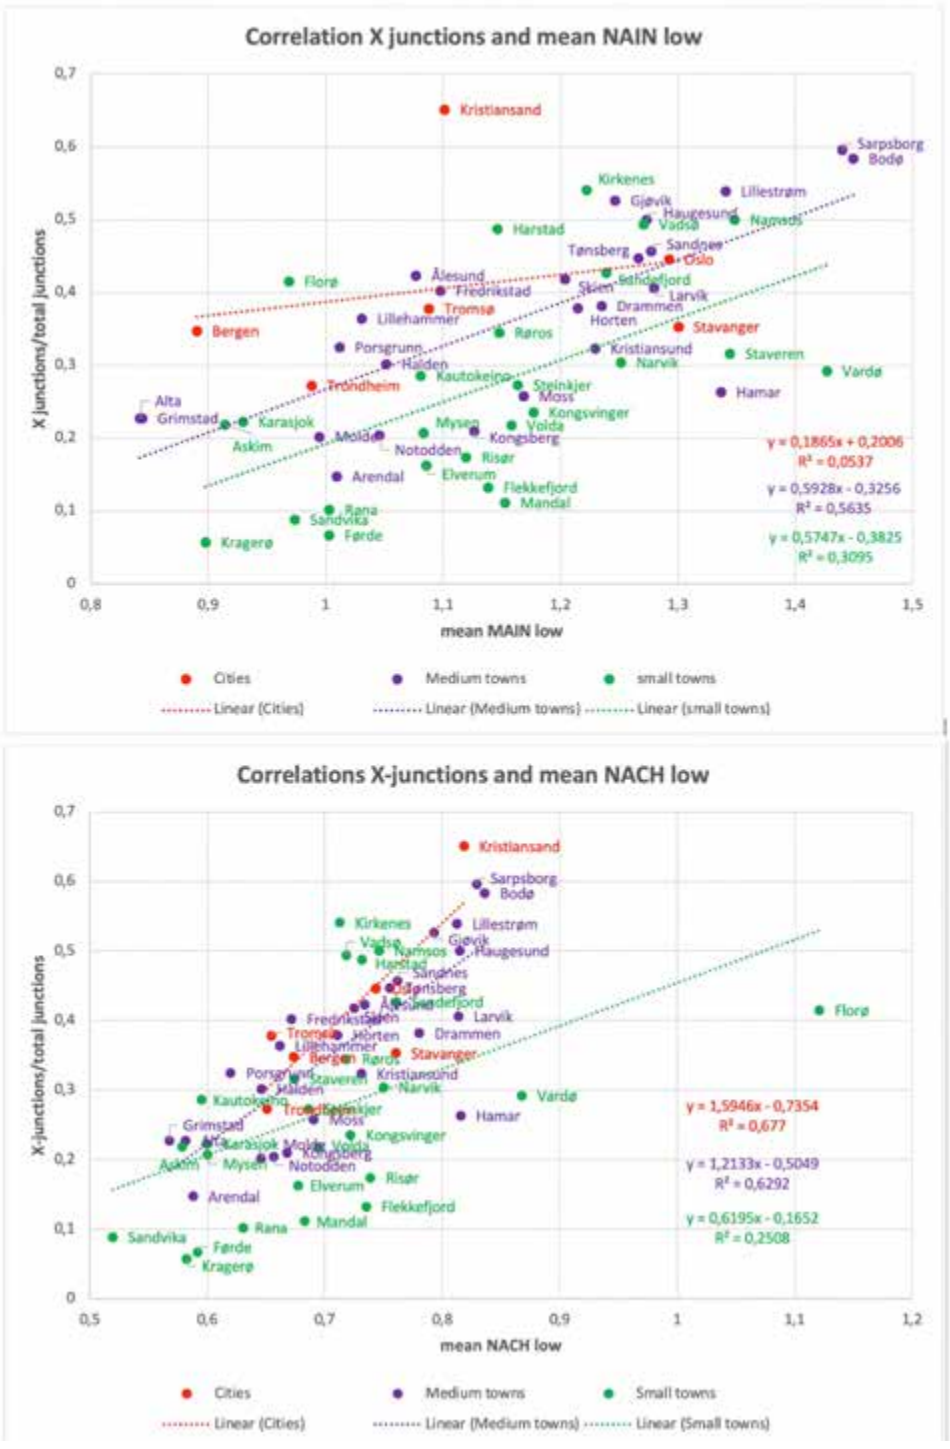

Figure 8: Regression analyses of X junctions and local mean NAIN and NACH with a differentiation of the town and city size.

Regression analyses between path type and space syntax

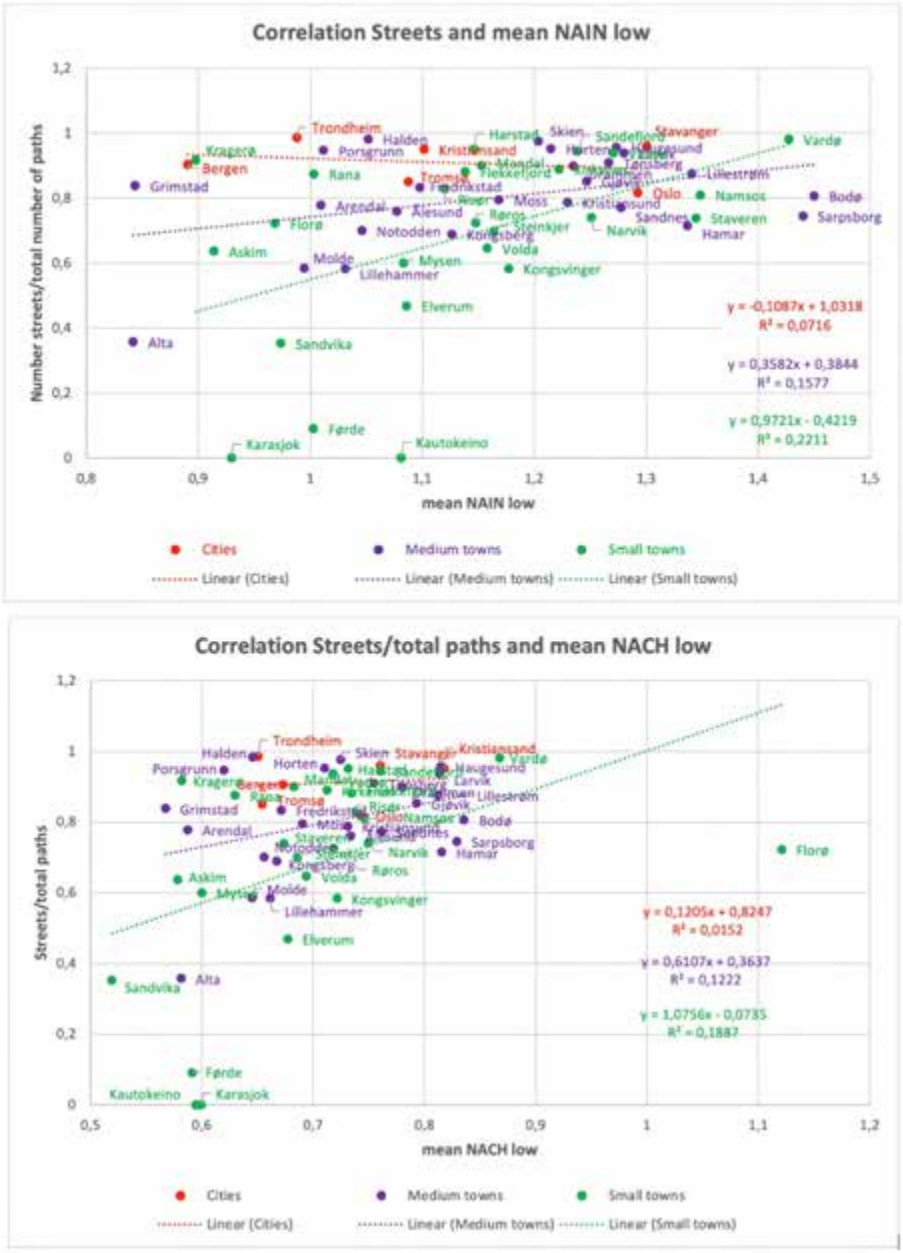

Figure 9: Regression analyses of percentage of streets and local mean NAIN and NACH with a differentiation of the town and city size.

Regards the correlation coefficient between the percentage of streets in relation to roads with local to- and through movement potentials for all towns and cities, they are slightly lower than the X-junctions. The correlation coefficient between the path type and local NACH is R2 = 0,1627 and local NAIN is R2 = 0,13 for all town and city centres. When making a differentiation between the sizes of the city and towns, as shown in figure 9, the small towns show the strongest correlation between the percentage of streets and local to- and through movement. The smallest towns have the largest variation of all three cases. Thus, the percentages of streets in relation to roads seems to matter to some extend in the various local integration analyses.

Discussion

As the results of all the 55 Norwegian town and city centres show, a high number of X-Junctions in correlation with T-junctions combined with a high number of streets in correlation to roads contribute to high degree of walkability potentials. Often town centres with an orthogonal street grid, have many X-junctions and tend to have short urban blocks. All streets in these towns and cities have pavements or are pedestrianised. In the streets with car accessibility, there is a balanced use between pedestrians and car drivers. In most cases, the buildings tend to be faced towards the streets with active frontages.

Conversely, town centres with high number of roads in relation to streets tend to be dominated by T-junctions. The urban blocks tend to be large, in which increase walking distances. Even though most of the roads have pavements, it is still vehicles dominating these roads. Buildings are mostly turned away from roads, in which makes walking as a boring experience. Town centres with these spatial features tend to have a car-based shopping centre and few people frequenting streets on foot. Often a random chosen small area is reserved for a square with some benches to sit, often named 'torget' (the square).

Figure 10 shows some google street view images of four different town and city centres. The two cases on the top are car dominated towns with a car-based shopping centre surrounded by parking lots. The buildings are turned away from the roads, in which reduce the perception of safety and attractiveness for walking. The two cases below are from city centres that are dominated by streets. Whereas Kristiansand centre consists of mostly X-junctions and Trondheim centre consists of mostly T-junctions, the centres consist of mostly streets with pavements. All buildings have active frontages oriented towards the streets.

Figure 10: Google Street view images of the car dominated roads in the centres in Alta and Mo i Rana, and the balanced streets in the centres of Kristiansand and Trondheim.

The percentage of X-junctions have the strongest correlation with the degree of local to- and through movement potentials. High number of X-junctions contributes to short urban blocks and high local integration, in which creates short movement routes and high degree of land use mixture. A high percentage of streets in relation to roads contribute to make the path network attractive for walking, due to that the buildings along streets tend to have active frontages with many entrances orientated towards the streets. This stimulates the senses and gives a nice walking experience. Moreover, the location pattern of shops tends to have a linear pattern. The variation of shops tends to be high in these kinds of centre, in relation to the centres that are dominated by roads and T-junctions. Conversely, the location pattern of shops tends to be clustered in a car-based shopping centre in towns dominated by roads and T-junctions. Most shops are from branches and offers few opportunities for individual shops.

Conclusions – the walkability potential matrix measures the destiny configuration
A first step to enhance sustainable mobility means is to focus on the path network in city and town centres. It is not enough with high density of buildings and high degree of land use diversity. The spatial structure and the profile of the path network also matters. Metric or topological distances do to some extend matters for enhancing walkability but must be seen together with the path type and the junction type. The first one is about making walking is comfortable, safe, and enjoyable (stimulating the senses during walking), whereas the second one is about the degree of routes choices (dealing with monotony versus variation). Seemingly, the spatial framework for the so-called '15 minutes cities' or for 'walking the last mile' indicates the following spatial parameters:

- High number of X junctions in relation to T Junctions,
- High number of streets in relation to roads,
- High global as well as local to- and through movement potentials regards the spatial configuration.

All these parameters together contribute to enhancing potentials for walking friendly town and city centres. A street with buildings faced towards it, short urban blocks and large choice of routes makes walking far more attractive than a road with adjacent building turned away from it and large urban blocks with few route choices. These parameters needed to be incorporated into the 'design' part of the 5Ds proposed by Ewing and Cervero (2010). Or a 6th 'D' needs to be added, such as for example 'destination configuration'.

How can the walkability potential matrix be applied into current planning and urban design practice? In general, all present urban planning and design activities must start from to build on information about the town or city where the intervention takes place. Those responsible for planning must be able to obtain this information. A regrettable fact is that many planners and urban designers do not distinguish between qualifications for preparing plans and qualifications for obtaining relevant information and analysing such information for planning. The aim of this contribution focus on the latter.

Over the past decades, knowledge has been developed both for obtaining and analysing information that has given both planners and urban designers far better tools than before to carry out analyses of urban structure and its characteristics for space use than before. However, it is still a long way to go from research into planning practice.

The use of the walkability potential matrix will give indications of how attractive it is to be a pedestrian in the various street profiles. This attractiveness is also affected by light, sunlight etc. This is probably one of the reasons why small urban blocks are more attractive than large urban blocks. Large parts of Norway lie at the same latitude as Greenland, where several streets have shade with snow and ice on the ground for about 6 months per year. When implementing high density of houses in central urban areas in line with the central authorities' recommendations in neighbourhoods consisting of large urban blocks with new roads with buildings turned away from it, contribute to pedestrian unfriendly streets.

The walkability potential matrix is needed to assess the formulation of policies at a higher level than at a municipality level. This is needed to make policies for a good street network suitable and attractive for pedestrians. Moreover, this method can be used to make a screening for new planning proposal for neighbourhoods to test to what extend the path network contributes to high degree of walkability. The biggest challenge is to upgrade and change the road engineer's path network dimension 'bible' containing rigid road standards requirements

mostly suitable for vehicle dominated roads in the Norwegian countryside. Requirements for street dimensions in an urban context is lacking in this book. Likewise, requirements must be set for new buildings in land use plans, such as enhancing active frontages with windows and doors facing towards streets on ground floor level.

Even though the focus in this inquiry focused only on junction and path types, the next step is to obtain information about the characteristics of streetscapes and buildings in terms of attractive pedestrian movement routes and its relation to shadow and sunlight analyses. Likewise, the next challenge is to obtain detailed travel behaviour data from each town and city for correlating the results with the walkability potential matrix. What is clear is that the weather conditions do not influence a town or city's walkability potentials. Some of the towns are in areas with rough climate and weather conditions. Moreover, the walkability potential matrix needs also to be tested on town and city centres from other countries.

Most streets in Norwegian town and city centres came into being before the explosion of private car ownership. Therefore, most building entrances and windows on ground floor level are oriented towards the streets. Therefore, a note of warning must be given to current urban planners and designers: When giving a new pathway a name ending on 'street', it is not a guarantee for that it will facilitate pedestrian movement. Seemingly, the path needs pavements, building with entrances and windows (active frontages) oriented towards the path on ground floor level for making walking attractive, safe, and enjoyable.

For generating walking friendly and sustainable town and city centres in Norway, the largest challenges need to be put on the road engineers. The current road planning manuals need updates regards requirements for street profiles with good urban qualities. The road engineer needs to look further outside the road or street's boarder and incorporate the adjacent buildings to a street when intervening in built environments (van Nes 2021b). Likewise, the rigid planning standards on maximum noise is based on models based on origin and destination traffic models. All these requirements create anti-urban urban centres, in which make walking boring. In addition, the challenge for urban planners is to put requirements on building facades and street profiles in land use plans. The adjacent buildings to streets need active frontages with doors and windows on the ground floor facing streets for making walking safe and enjoyable. Streets with blind walls and buildings turned away from streets are perceived as boring, dull, and unsafe.

At present, villages with a regional central position are expanding in Norway. Recently, many of them are getting a town status. Often these village have a tiny old centre consisting of one or two streets. When the number of inhabitants is growing, often large new neighbourhoods containing single-family houses are spread out into the countryside around these small centres. This creates long travelling distances along roads that are boring to walk on, which again are contributing to that these centres are planned around the private car. Again, this contributes to the establishment of car-based shopping centres adjacent to these tiny old centres. Therefore, the largest challenge is to introduce street planning and traditional balanced street profiles for creating short and attractive walking distances in town and city centres.

The next step is to try out the walkability potential matrix on other cities outside Norway. The historic and the local context need to be considered regards identifying the path type from path names. In Norway the last part of street names correlates with Eldijk's street profiles classification. Hopefully, the walkability potential matrix can contribute to refine the 'design' concept from the 5Ds or to add a 6th D named 'destination configuration.'

Optimisation of non-motorised facilities in urban fringe sheltered housing areas: Transport Accessibility and Equity Enhancement Based on Supply and Demand Analysis

Tianxin Zhang (Xi'an University of Architecture and Technology)
Mengde Zheng (Xi'an University of Architecture and Technology)

Abstract:
As affordable housing developments continue to expand toward the urban fringe, limited public transportation connections and extended commuting distances have intensified mobility challenges for residents. Owing to their affordability and flexibility, non-motorized vehicles have become a key solution for bridging the "last mile." However, the current supply of parking facilities for such vehicles is inadequate, leading to reduced travel efficiency and increased inequality in the distribution of transportation resources. This study examines 13 affordable housing communities on the outskirts of Xi'an, utilizing 473 valid survey responses to develop a supply-demand assessment and travel behavior model. Findings reveal that demand for non-motorized vehicle parking is 1.8 times the current capacity, particularly among low-income and long-distance commuters. In response, the study proposes a set of optimization strategies: dynamic adjustment of parking layouts, implementation of intelligent management systems, enhancement of public transit connectivity, and repurposing of underutilised motor vehicle spaces. The results offer practical insights for promoting transportation equity in peripheral urban areas.

Keywords: Affordable Housing; Urban Fringe; Non-motorized Vehicle Facilities; Transportation Equity; Supply-Demand Analysis

I. Introduction

With the continuous enhancement of China's urban housing security system, the spatial distribution of affordable housing has increasingly extended to the urban periphery (Vinda et al., 2023). While these emerging areas have helped alleviate residential pressure in central urban districts, they are also confronted with underdeveloped transportation infrastructure and inadequate public service systems (Chen, 2023). In particular, factors such as limited rail transit coverage, sparse distribution of bus stops, and generally long commuting distances have significantly increased both the travel costs and time burdens for residents. Against this backdrop, non-motorized vehicles—valued for their flexibility, affordability, and adaptability—have gradually become the primary mode of transport for last-mile commuting in affordable housing communities.

However, the growing share of non-motorized travel has not been matched by corresponding improvements in supporting infrastructure. In many peripheral affordable housing areas, insufficient parking space for non-motorized vehicles, imbalanced facility distribution, and outdated management practices have led to frequent issues of "parking difficulty and disorder" during peak commuting hours. These challenges not only reduce travel efficiency but also disrupt the order of shared community spaces, further exacerbating inequalities in transportation resource allocation and reinforcing the stratification of urban social space.
Moreover, the high usage rate of non-motorized vehicles reflects the income sensitivity of residents in their travel mode choices. Due to financial constraints, this population often lacks access to private vehicles (Zhao and Zou, 2025), while inadequate public transportation coverage fails to provide viable alternatives—rendering non-motorized vehicles a form of "passive adaptation." This structural disparity in access to transportation resources reveals the essence of transport equity issues: not in the vehicles themselves, but in the unequal rights to mobility (Currans et al., 2020).

Therefore, optimizing the non-motorized vehicle facility system is both a practical necessity for improving commuting efficiency and a strategic approach to promoting transportation equity and spatial justice in peripheral affordable housing areas (Linlin et al., 2022). A systematic analysis of facility imbalances from the threefold perspective of "infrastructure supply–resident behavioral response–spatial equity" helps address the structural oversight of "prioritizing housing over mobility" in current urban planning, and advances a people-oriented, green, and low-carbon transition in urban transportation systems.

This study selects 13 typical affordable housing communities located in five districts of Xi'an—High-Tech Zone, Qujiang, Xincheng, Lianhu, and Weiyang—as empirical cases. Through questionnaire surveys and field observations, a total of 473 valid samples were collected. A facility supply-demand ratio model is employed to assess configuration tension, and a binary Logit model is used to analyze the determinants of non-motorized commuting behavior. Based on the empirical findings, this paper proposes an optimization strategy for non-

motorized vehicle facilities that targets both "livability" and "equity," focusing on total capacity expansion, spatial layout refinement, smart management mechanisms, and public transport system enhancement. The study aims to provide empirical support and policy recommendations for transportation planning and resource allocation in peripheral affordable housing areas.

The structure of the paper is as follows: Section II reviews the relevant literature and theoretical foundations; Section III introduces the study area, data sources, and model specifications; Section IV presents the empirical results and diagnostic analysis; and Section V offers countermeasures and planning implications.

II. Literature Review

2.1 Commuting Challenges Faced by Residents of Affordable Housing in Urban Peripheries

The siting of affordable housing projects in urban peripheries often places them far from city centres, leading to limited public transportation coverage and significantly extended commuting distances (Deng, 2021). These areas are mainly inhabited by young people and low-income groups, whose travel behavior shows a high dependence on non-motorized vehicles (Han, 2022). Cheng pointed out that even when housing projects are located near rail transit stations, the absence of continuous connecting routes and pedestrian infrastructure results in relatively low actual accessibility (Cheng, 2024). These studies collectively indicate that the commuting disadvantage faced by residents in peripheral affordable housing areas is both widespread and structural.

2.2 Supply-Demand Imbalance and Facility Allocation Issues of Non-Motorized Vehicles

With the rising frequency of non-motorized vehicle use, the mismatch between supply and demand for related facilities in affordable housing communities has become increasingly prominent. Han found that many youth-oriented public rental housing projects in Xi'an face challenges such as a shortage of parking spaces, poor nighttime lighting, and lack of management, all of which negatively impact commuting experience and safety (Han, 2022). Lu Yuan et al. highlighted frequent conflicts between non-motorized and motorized vehicles in Shunyi District, Beijing, which reflect spatial mismatches in parking resource allocation (Lu et al., 2023). Notably, some affordable housing communities exhibit a phenomenon of facility mismatch: although the proportion of residents using private vehicles is low, the number of motor vehicle parking spaces often exceeds those for non-motorized vehicles. This reflects the continued application of commercial housing standards without due consideration of the travel needs of affordable housing residents. International studies have also shown that the travel intensity of motor vehicle use among low-income populations is significantly lower than that of the general public, and a lack of differentiation in development evaluations may lead to misallocation of resources (Amanda et al., 2018).

2.3 Theoretical Approaches to Accessibility and Transportation Equity

Recent research has gradually shifted from a narrow focus on individual travel behavior to more systematic investigations into infrastructure provision and transportation equity. Scholars widely agree that transportation equity involves not only freedom of mode choice but also travel capability, accessibility efficiency, and balanced spatial resource allocation (Geurs and van Wee, 2004). However, most of the relevant literature remains centreed on urban core areas and lacks systematic assessments of the equity of non-motorized vehicle facility allocation in peripheral affordable housing zones. Although some studies have attempted to measure equity through indicators such as supply-demand ratios, service radius, and facility density, there is still a notable absence of integrated application in the field of non-motorized transportation (Sun et al., 2021).

III. Research Design and Methods

3.1 Study Area and Sample Selection

As the affordable housing supply system in Xi'an has gradually improved, the spatial distribution of affordable housing communities has extended to the urban periphery. This has led to the formation of typical affordable housing clusters in areas such as the High-Tech Zone, Qujiang New District, Weiyang District, Xincheng District, and Lianhu District. During the site selection process, the planning orientation often followed the principle of "locating away from the core of the main urban area and closer to emerging industrial zones." While this approach has contributed to relatively high land-use efficiency, it has also brought about increasingly prominent issues related to lagging transportation infrastructure.

This study selected 13 representative affordable housing communities from the five aforementioned districts as the survey samples, covering various types of affordable housing, including public rental housing, housing coordinated through the housing provident fund, and resettlement housing. Specifically, the selected communities include:

Figure 1. Distribution of Sample Affordable Housing Communities in Xi'an

District	Community Name	Housing Type
Qujiang New District	Gongzuo I Public Rental Housing, Gongzuo II Public Rental Housing	Public Rental Housing
High-Tech Zone	Lanbo Apartment, Jinye Apartment, Software Apartment	Public Rental Housing
Xincheng District	Tianlun George Mansion, Qujiang Mingfu Jiayuan	Resettlement / Provident Fund Coordinated Housing (Mixed)
Lianhu District	Fenghefang, Vanke Golden Joy City, Yirun Garden	Provident Fund Coordinated Housing
Weiyang District	Xipu Tuozhai, Zhongpu Tuozhai, Xiaoli Provident Fund Community, Poly Wutongyu	Resettlement / Public Rental Housing (Mixed)

The selected communities are situated within the transitional zone between the central urban area and industrial new districts, typically exhibiting a pattern of "peripheral distribution along major rail corridors." Although some housing projects are located near rail transit nodes or arterial roads, their actual accessibility remains limited due to the absence of continuous pedestrian networks and convenient transfer pathways. This is particularly evident in the generally excessive walking distances to subway stations (often exceeding 2 kilometers), low-frequency bus services, and expansive service radii—factors that have significantly increased residents' reliance on non-motorized modes of transport.

From a spatial planning perspective, these affordable housing developments are commonly located beyond the control boundaries of rail-related land use and at the fringe of urban functional zones. While such locations benefit from low land costs and favorable policy support, they are often designated in higher-level planning documents as "development reserves" or "ecological control zones." Consequently, they lack adequate urban-scale public service infrastructure, resulting in mismatches in the provision of transportation, education, and healthcare services. In some cases, despite their proximity to transit corridors, barriers such as the lack of pedestrian crossings, indirect or fragmented walking paths, and steep elevation differences give rise to a planning paradox: **spatial proximity but functional disconnection**.

Regarding sample composition, a total of 500 questionnaires were distributed, yielding 473 valid responses—an effective response rate of 94.6%. Stratified random sampling was conducted based on housing unit quantity, population density, and administrative divisions. GIS verification was employed to ensure spatial coverage was evenly distributed, housing types were diverse, and commuting characteristics were representative.

3.2 Data Sources and Indicator Construction

(1) Data Sources and Collection Methods

The data for this study were primarily obtained through two channels: in-person questionnaire surveys and on-site observations conducted in selected residential communities. The survey was carried out between January and February 2025, covering both weekdays and weekends. Researchers visited 13 affordable housing communities to conduct face-to-face interviews and distribute paper questionnaires, supplemented by an online version. Respondents were permanent residents aged 18 or older who had lived in the community for at least six months. The survey focused on their daily commuting patterns, usage of transportation facilities, and perceptions of mobility and access.

Simultaneously, using a combination of street-view image analysis and field inspections, researchers recorded the quantity, spatial distribution, and saturation level of non-motorized vehicle parking facilities in each community. In some cases, video surveillance coverage was also used as a supplementary validation tool to enhance data accuracy and timeliness.

To ensure the scientific rigor and effectiveness of the questionnaire design, this study referenced the *Urban Residential Area Traffic Survey Manual* (Ministry of Housing and Urban-Rural Development, 2020) and the indicator framework of the Place Pulse 2.0 perception model. Based on these sources and aligned with the study's objectives, a multi-dimensional structured questionnaire was developed, encompassing residents' demographic characteristics, commuting behavior, satisfaction with transportation facilities, and travel preferences.

(2) Questionnaire Structure and Variable Distribution

The questionnaire is composed of four core modules and 22 variable items. The main components are detailed in the table below:

Figure 2. Questionnaire Structure and Variable Types for Residents of Affordable Housing in Xi'an

Module	Example Variables	Sample Questions	Variable Type
Resident Demographic Information	Age, Gender, Household Income	What is your current total monthly household income?	Single choice / Interval
Commuting Behavior Characteristics	Commuting Distance, Primary Mode of Transport	What is your primary mode of transport for commuting to work or daily activities?	Single choice
Usage of Non-Motorized Facilities	Frequency of Use, Parking Space Shortage	Do you often find it difficult to find a non-motorized vehicle parking spot?	5-point Likert scale
Perception of Travel Environment	Nighttime Lighting, Sense of Safety, Transfer Convenience	Do you find the route from your community to the nearest metro station convenient?	Subjective perception variable

The facilities usage section employs a 5-point Likert scale (ranging from "very dissatisfied" to "very satisfied") to assess residents' perception of the rationality of the configuration, management, and distribution of non-motorized vehicle parking spaces; the behavioral preference section sets multiple-choice questions based on the frequency and substitutability of travel modes to identify the degree of residents' reliance on non-motorized vehicles.

(3) Estimation Method for the Supply and Demand of Non-Motorized Vehicle Facilities
To objectively assess the actual supply-demand balance of non-motorized vehicle parking facilities, this study adopts a combined approach using both theoretical demand estimation and on-site capacity verification, and constructs the following model:

Facility Supply-Demand Ratio = Actual Number of Parking Spaces ÷ Estimated Number of Required Spaces
The estimated number of required parking spaces is calculated using the formula below:

Estimated Demand = Ownership Rate × High-Frequency Usage Rate × Per Capita Demand Coefficient × Residential Population

Where:
Ownership Rate refers to the proportion of households owning non-motorized vehicles per 100 households;
High-Frequency Usage Rate refers to the proportion of residents who use non-motorized vehicles five or more times per week;
Per Capita Demand Coefficient is set at 1.1, taking into account spare spaces and rotation needs;
Residential Population refers to the actual total number of residents in each community.
Based on survey results, the average facility supply-demand ratio across the 13 sample communities is only 0.56, indicating that the demand is approximately 1.8 times the current capacity. This finding aligns closely with residents' subjective perceptions of facility shortages. Particularly in communities located in Weiyang District and Qujiang New District, parking saturation during morning and evening peak hours approaches 100%. As a result, some residents are forced to park in informal areas such as greenbelts, building corners, and fire access lanes—raising concerns over safety and spatial order.

3.3 Model Construction and Variable Specification

(1) Model Selection and Theoretical Foundation
To explore the factors that significantly influence the likelihood of residents choosing non-motorized vehicles as their commuting mode, this study employs a **binary Logit model** for empirical analysis. This model is suitable for cases where the dependent variable is dichotomous, and it can estimate the marginal effects of various independent variables on the probability of choice.

The Logit model is grounded in the **Random Utility Maximization (RUM)** theory, which assumes that individuals tend to select the travel mode that offers the **highest net utility** among all available alternatives. The decision to commute by non-motorized vehicle is jointly influenced by travel behavior characteristics, facility supply conditions, and socioeconomic attributes.

The basic form of the Logit model is as follows:

$$Pr(Y = 1) = 1 / [1 + \exp(-(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_n X_n))]$$

Where:
Pr(Y = 1) represents the probability that a resident chooses non-motorized commuting;
X ,X ,...,X are the explanatory variables (e.g., commuting distance, facility satisfaction, etc.);
are the parameters to be estimated.
In this model, one of the core explanatory variables is the **facility supply-demand ratio**, calculated as:

$$\text{Facility Supply-Demand Ratio} = \text{Actual Parking Spaces} / \text{Estimated Demand}$$

With the estimated demand computed as:

$$\text{Estimated Demand} = \text{Ownership Rate} \times \text{High-Frequency Usage Rate} \times \text{Per Capita Coefficient} \times \text{Residential Population}$$

Where:
Ownership Rate: the proportion of non-motorized vehicle ownership per 100 households;
High-Frequency Usage Rate: the proportion of residents who use non-motorized vehicles five or more times per week;
Per Capita Demand Coefficient: set to 1.1 to account for spare capacity and turnover needs;
Residential Population: the estimated total number of residents in each community.
(2) Variable Settings and Index Explanations
The dependent and independent variables selected for this study are listed in the table below.

Figure 3 Variable Definitions and Descriptions Used in This Study

Variable Name	Type	Description	Coding
Use of Non-motorized Vehicle	Dependent Var.	Whether the resident primarily uses a non-motorized vehicle (e-bike/ bicycle) for commuting	Yes = 1, No = 0
Commuting Distance (km)	Continuous	One-way distance from residence to regular commuting destination	Numeric
Monthly Household Income)	Continuous	Total household income, reflecting economic capacity and transport preferences	Numeric
Proximity to Subway Station	Dummy Variable	Whether the residence is within 15-minute walking distance to a metro station	Yes = 1, No = 0
Satisfaction with Parking Facilities	Continuous	Satisfaction level with non-motorized vehicle parking (5-point Likert scale)	1 to 5 Likert scale
Ownership of Private Car	Dummy Variable	Whether the household owns a private motor vehicle	Yes = 1, No = 0
Youth Group Indicator	Dummy Variable	Whether the resident is aged between 18 and 35, indicating travel activity level	Yes = 1, No = 0

(3) Basis for Variable Selection
This study constructs an explanatory model of non-motorized commuting behavior based on three key dimensions: *travel capacity*, *travel environment*, and *facility conditions*. The objective is to establish a logically coherent analytical framework that supports subsequent policy simulations and spatial planning with theoretical justification and empirical data.

In terms of variable selection, commuting distance serves as one of the most critical determinants, as it directly reflects whether non-motorized vehicles are viable for actual travel routes. Monthly household income captures the residents' financial capacity to afford transportation and is closely linked to their sensitivity to travel cost and

flexibility. Proximity to metro stations is used to assess the availability of rail transit as a supplementary mode; a lack of metro access often increases reliance on non-motorized vehicles. Satisfaction with non-motorized parking facilities reflects the residents' subjective evaluation of infrastructure quality and functions as an important mediating variable influencing behavioral choices. Private car ownership represents the availability of alternative travel modes and poses a practical constraint on non-motorized vehicle usage. Lastly, a youth group indicator is included to control for demographic structure, acknowledging that younger residents tend to have higher levels of cycling acceptance and commuting frequency.

4.Empirical Results and Problem Analysis

4.1 Residents' Travel Structure and Mode Preferences

Through a survey of 13 low-income housing communities located on the outskirts of Xi'an, a total of 473 valid questionnaires were collected. The results showed that residents in these communities were more inclined to use non-motorized vehicles (electric bikes and bicycles) for commuting. This mode accounted for 42.5%, which was much higher than the average level of residents in the city centre. Among them, the usage rate of electric bikes was 31.3%, and bicycles accounted for 11.2%; followed by public transportation (28.6%), subway (14.1%), walking (12.4%), and private cars (10.5%).

This trend indicates that in these suburban areas, non-motorized vehicles have gradually become the preferred mode of transportation for residents' commutes due to their flexibility, economy and convenience. The majority of the respondents' commuting distances fall within the range of 2 to 5 kilometers (accounting for 54.7%), which is exactly the optimal range for the efficiency of non-motorized vehicles. Under this distance condition, the efficiency of walking is low, the coverage of the bus network is limited, and subway stations are often quite far apart (mostly more than 2 kilometers), thus non-motorized vehicles play a crucial role in connecting residential areas with transportation nodes and employment locations in the "last mile" of the journey.

When divided by age groups, there are significant differences in travel preferences. Among the young and middle-aged group aged 20 to 45, the usage rate of non-motorized vehicles is as high as 58.3%, significantly higher than that of other age groups. Moreover, even in households with private cars, over 35% of the respondents prefer to choose electric bicycles for daily travel, which also indicates that non-motorized vehicles are not only alternative transportation methods but have also formed a structural reliance in these areas.

It is worth noting that the use of non-motorized vehicles is not limited to commuting purposes. The research results indicate that 62.8% of the residents stated that they would choose electric vehicles or bicycles for daily travel, such as shopping, picking up children, commuting for transfers, etc. Due to the high usage frequency and dense travel demands, the requirements for community internal supporting facilities have also been continuously increasing. However, the current facility supply clearly does not match the actual usage intensity.

Overall, the travel patterns of these residents of edge-served affordable housing show a typical pattern of "short distances, high frequencies, and low costs". Non-motorized vehicles have become an important part of their daily transportation. This behavioral characteristic not only reflects the guiding role of urban spatial layout in travel choices, but also reveals the real dilemmas faced by residents in terms of travel fairness and efficiency in the context of infrastructure deficiencies.

4.2 Income Levels and Constraints on Transportation Choices

Survey data reveal that residents of affordable housing communities on the outskirts of Xi'an generally have low household incomes. Specifically, 37.6% of households report a monthly income below RMB 3,000, while 41.2% fall within the RMB 3,000–5,000 range. Combined, these groups account for over three-quarters of the total sample, indicating a significant concentration of low-income households and a marginal presence of middle- and high-income earners. This underscores the role of such housing developments in accommodating economically disadvantaged populations.

Income levels strongly influence residents' sensitivity to transportation costs. The findings indicate that the lower a household's income, the higher the likelihood of using non-motorized modes of transport. Among households earning less than RMB 3,000 per month, 59.2% rely on non-motorized vehicles—primarily electric bikes and bicycles—for daily commuting. In contrast, this proportion drops to 27.4% among those earning over RMB

5,000. Respondents widely reported that non-motorized transport offers a low-cost, low-maintenance solution that circumvents the limitations of infrequent bus routes, distant metro stations, and long walking distances—making it the most cost-effective commuting option under current living conditions.

Further analysis suggests that low-income groups tend to bear more family caregiving responsibilities, such as escorting children to school, shopping for groceries, or accompanying family members to medical appointments. These activities are characterised by high frequency, irregular timing, and dispersed destinations, necessitating a flexible and readily available mode of transportation. In this context, public transit and metro systems—which depend on fixed schedules and require transfers or walking connections—fall short. Meanwhile, private cars remain out of reach for many due to prohibitive costs associated with purchase and upkeep.
However, the higher the reliance on non-motorized transport, the greater the dependency on supporting infrastructure. In many affordable housing areas, the availability and quality of such facilities are inadequate. Common issues include insufficient parking shelters, poor spatial planning, and disorganized management. Due to limited financial means, many residents are unable to rent or purchase formal parking spaces and must instead rely on improvised open spaces within the community. This leads to the encroachment of green areas, blocked access points, and heightened fire safety risks.

From the perspective of transport equity, the lack of infrastructure for non-motorized vehicles exacerbates existing inequalities in mobility conditions. Given the same commuting routes, higher-income individuals are able to access more comfortable and efficient transport options such as private cars or ride-hailing services. In contrast, those choosing environmentally friendly and space-efficient modes are often left with no designated parking, inadequate lighting, and a lack of secure storage.

In sum, the lag in non-motorized transport infrastructure in affordable housing communities is not merely a technical oversight, but a central issue in the broader discourse on transportation equity and just urban governance.

4.3 Manifestations of Supply–Demand Imbalance in Non-Motorized Vehicle Facilities
In affordable housing communities located on the urban periphery, non-motorized vehicles have become the primary mode of transportation for both commuting and everyday mobility. However, this high frequency of use stands in stark contrast to the inadequate provision of supporting infrastructure, resulting in a structural imbalance characterised by high demand and low supply.

According to combined field observations and questionnaire-based estimates, the average supply-to-demand ratio for non-motorized vehicle parking facilities across 13 sampled communities is only 0.56—indicating that existing facilities can accommodate just 56% of estimated usage. The Pi Tuozhai West Community in Weiyang District has the lowest ratio, at 0.39, while Jinye Apartments in the High-Tech Development Zone also perform poorly, with a ratio of 0.44. These figures suggest that even newly developed projects in economic and technological zones have failed to keep pace with the rapid growth in cycling demand.

Field observations further corroborate the survey findings. During peak hours, many communities experience fully occupied parking sheds, disorganized parking near entrances, and electric bicycles obstructing stairwells. Some 73.2% of residents reported regularly being unable to find legal parking spaces during rush periods, while 45.6% admitted to parking in "informal" areas such as greenbelt edges, stair landings, or beside waste collection points. Although some communities are equipped with underground garages, low utilization rates persist due to inadequate lighting, the absence of charging stations, and lack of surveillance, leading to a spatial mismatch in which surface-level areas are overcrowded while underground spaces remain underused.

From a spatial planning perspective, current non-motorized vehicle infrastructure suffers from three typical deficiencies:

Insufficient quantity of parking spaces: Most communities lack independently planned parking areas for non-motorized vehicles. Temporary sheds are often installed in vacant plots or at the edges of green spaces, without systemic design or integration.

Fragmented spatial layout and poor circulation design: Parking locations are frequently disconnected from main entrances or pedestrian flow paths, forcing residents to detour or pass through vehicular areas, which reduces usability and convenience.

Weak management mechanisms: Property managers rarely assign staff for supervision. Access control to sheds is often inoperative, unified charging systems are lacking, and nighttime lighting and basic security are insufficient.

Additionally, some older affordable housing communities face functional misuse of space, with bicycle sheds being repurposed as storage rooms or electric vehicles occupying car parking spaces, further compressing already limited parking capacity. In the context of spatial scarcity, parking availability has gradually become a contested resource, leading to informal competition that disrupts community order and exacerbates tensions among residents.

4.4 Spatial Disparities and Equity in Non-Motorized Transport Infrastructure

In the affordable housing communities of Xi'an, spatial inequality in the distribution of non-motorized transport (NMT) facilities has become a critical factor influencing both commuting efficiency and transportation equity. Based on field research and cross-sectional comparisons across five administrative districts—Qujiang New District, High-Tech Zone, Weiyang District, Lianhu District, and Xincheng District—this study identifies significant variations in facility quantity, spatial layout, management quality, and resident satisfaction. These findings reveal a pronounced regional imbalance in the allocation of NMT infrastructure.

The current landscape of NMT facility provision can be categorized into four typical patterns:
High-Demand, Low-Supply Zones: Exemplified by Qujiang New District, where residential and employment functions are densely integrated, resulting in concentrated commuting demand. In Qujiang's public rental housing (Yiyuan and Eryuan), the average supply-to-demand ratio is only 0.42, and resident satisfaction scores fall below 2.3 (on a 5-point scale). Over half of respondents report having to detour or park in traffic lanes, reflecting a structural mismatch between growing demand and lagging supply.

Well-Equipped but Underutilised Zones: Found in recently developed communities within the High-Tech Zone (e.g., Lanbo and Jinye Apartments), where a relatively adequate amount of NMT parking was included during initial construction. However, more than 30% of parking spots remain unused long-term. The main reasons include poor management, absence of signage, insufficient lighting, and lack of theft protection—all of which discourage resident use. This reflects a common issue of quantity without quality.

High Usage, Weak Governance Zones: Characteristic of suburban fringe areas in Weiyang District, where the resident population is predominantly young and commuting by non-motorized modes is frequent. Yet, infrastructure is seriously underdeveloped, with the lowest supply-demand ratio of 0.39. Many neighborhoods feature makeshift sheds built by residents, green spaces converted into parking, and blocked pathways. The lack of formal management and mixed land use creates both spatial disorder and safety risks.

Centrally Located, Aging Infrastructure Zones: Seen in older affordable housing projects in Lianhu and Xincheng Districts, which benefit from proximity to public transit nodes (bus and metro). Despite relatively lower NMT dependence, existing facilities are outdated and insufficient. For instance, Fenghefang community faces parking shortages and limited capacity for upgrades due to unclear property rights and tight land availability.

From a broader spatial perspective, the distribution of NMT facilities in Xi'an displays a dual structure of "planned-priority zones" versus "neglected-demand zones." While some newly developed areas have formally reserved space for such infrastructure, the lack of adaptive planning mechanisms results in low utilization rates. Conversely, areas with the most urgent demand often lack systematic provision and everyday oversight, leading to an inverse mismatch between supply and actual usage patterns.

5.Optimization Strategies and Policy Recommendations

Based on the preceding empirical analysis of non-motorized travel behaviors, facility supply-demand dynamics, and transportation equity issues in affordable housing communities on the urban fringe of Xi'an, it is evident

that these areas commonly face challenges such as insufficient facility supply, imbalanced spatial distribution, weak management mechanisms, and inequitable allocation of transportation resources. In response, this paper proposes an optimization strategy for non-motorized vehicle (NMT) facilities, guided by the dual goals of livability and equity. The strategy encompasses five key areas: facility expansion, spatial restructuring, smart management, multimodal connectivity, and institutional safeguards.

In terms of infrastructure supply, a dynamic planning mechanism based on behavioral data should be established. During the housing design phase, indicators such as NMT usage intensity, commuting distance, and demographic composition should be incorporated to more accurately forecast demand and avoid immediate oversaturation upon project completion. A two-pronged approach is recommended—combining incremental expansion with flexible adjustments. For existing communities, additional parking spaces can be created by repurposing unused land or converting idle areas. For new developments, regulatory oversight should be enforced in accordance with the *Technical Guidelines for Non-Motorized Facilities in Residential Areas of Xi'an*, ensuring minimum provisioning standards and dynamic monitoring mechanisms. Priority should be given to high-demand areas such as Weiyang and Qujiang, where commuting frequencies are high and metro access is limited, in order to establish a more function-oriented resource allocation framework.

With regard to spatial integration, efforts should be made to align NMT parking with key nodes such as metro stations, bus stops, and community entrances, thereby building a continuous "cycle–transit–walk" travel network. Micro-level layout should avoid poorly lit, inconvenient, or underutilised areas in order to improve facility visibility and usability. GIS-based simulations may be employed to model facility placement in relation to actual resident travel paths, enhancing the logic and efficiency of spatial design.

On the management front, the implementation of intelligent operation systems is recommended. These should include digital tools for real-time space monitoring and reservation, as well as integrated modules offering charging, lighting, and security features to increase the utilization of underground garages and centralized sheds. Community co-governance should also be encouraged, such as the formation of NMT user associations or volunteer-based riding order monitors, in order to strengthen grassroots-level oversight and participation.
As NMT serves a vital role in last-mile connectivity, its infrastructure must be integrated into the broader urban transport system. This includes optimizing micro-circulation bus routes in peripheral areas to enhance short-distance accessibility, establishing high-capacity transfer hubs near metro stations, and embedding cycling lanes and parking facilities into the design of transit infrastructure. Such integration helps reduce private vehicle dependency and improves mobility for underserved populations on the urban fringe.

Finally, institutional support is essential. The planning and operation of NMT facilities should be incorporated into the performance evaluation and acceptance criteria for affordable housing projects to ensure traceability and accountability. A public funding mechanism should also be established to incentivize communities that demonstrate high-quality facility construction and strong user satisfaction. Furthermore, underutilised motor vehicle parking spaces can be converted—via functional reallocation and physical separation—into areas designated for NMT parking and charging, promoting a more equitable redistribution of spatial resources.

6.Conclusions and Outlook

This study focuses on affordable housing communities located on the urban periphery of Xi'an, using questionnaire surveys, spatial analysis, and field observations to investigate non-motorized travel behavior, infrastructure supply-demand imbalance, and transportation equity. The results indicate that electric bikes and bicycles have become the dominant travel modes among residents, particularly under conditions of short-to-medium commuting distances, low household income, and limited metro connectivity. However, supporting infrastructure in most communities remains inadequate, with an average supply-demand ratio of just 0.56 and even lower figures in some areas. Common issues include severe parking shortages, mismatched spatial layouts, and ineffective facility management. Travel choices are significantly influenced by commuting distance, income level, and satisfaction with infrastructure. A structural mismatch is evident between facility provision and usage intensity across different districts, revealing a lack of behavior-oriented and dynamically adjustable planning mechanisms.

To address these issues, the study proposes an optimization strategy guided by the dual goals of livability and equity. Key directions include expanding facility supply, improving spatial integration, promoting smart management, enhancing connections to public transit, and strengthening institutional support. Specific recommendations include establishing behavior-data-driven allocation models, repurposing underutilised spaces, reinforcing intelligent operations and community participation, and fully integrating non-motorized systems into the broader urban transport network.

This research broadens the perspective on non-motorized travel in peripheral urban areas and introduces a transportation equity-based evaluation framework for facility planning, filling a gap in empirical studies at the intersection of transport and housing policy. Future research could incorporate dynamic mobility data to further analyze travel behavior, compare travel patterns across different types of affordable housing, and develop more adaptive policy tools to support green mobility and equitable governance in urban fringe areas.

'15-MINUTE CITY' IN TURKEY: A FRAMEWORK FOR SUSTAINABLE URBAN PLANNING AND GOVERNANCE IN MID-SIZED TURKISH CITIES

Emine Yetişkul

e-mail: senbil@gazi.edu.tr

Abstract
This paper examines the feasibility of applying the 15-minute city model in Turkey's mid-sized cities, where compact form and walkability offer an existing foundation for proximity-based planning. Despite this potential, rising car use, fragmented governance, and weak coordination between land use and transport planning constrain progress. Emphasizing the principles of proximity, diversity, density, and ubiquity, the study highlights the need for integrated transport systems, pedestrian-friendly design, and mixed-use development to improve daily life quality. Using tools like the Next Proximity Index (NEXI) and drawing from international experiences and localized urban contexts, the authors call for participatory governance and adaptive reforms. The study concludes that meaningful implementation of the 15-minute city in Turkey depends on restructured planning and governance frameworks responsive to local needs, spatial equity, and the evolving dynamics of urban mobility and accessibility.

Keywords: 15-minute city; sustainable urban planning; public transportation; mid-sized cities; Turkey.

Introduction

This study explores the potential of Turkey's mid-sized cities to align with the "15-minute city" concept, emphasizing proximity, inclusivity, and sustainability. These cities, characterized by compact urban areas where most residents live within a 3-km radius, inherently support walkable, proximity-based urban planning. However, rising automobilization and minimal car use restrictions along with uncoordinated transportation policies in Turkey pose significant risks to the realization of this concept. This study underscores the need for integrated transportation strategies, pedestrian-focused urban planning, and stringent parking policies to support 15-minute city while mitigating car dependence and fostering sustainable urban environments.

Central to the "15-minute city" framework is the reorganization of urban functions to ensure proximity within neighborhoods, necessitating systemic changes in resource allocation patterns and governance schemes (Pozoukidou and Chatziyiannaki, 2021). The concept also emphasizes principles of proximity, diversity, density, and ubiquity, aiming to reduce reliance on motorized transport while promoting sustainable and equitable urban living (Moreno et al., 2021). Practical frameworks for neighborhood-level transformations and multimodal connectivity with an emphasis on public engagement and behavioral shifts in Moreno (2024) are particularly relevant for Turkish cities in transition.

For Turkish cities, rethinking public transportation as the backbone of urban mobility is essential. Developing trunk transit systems free from regular traffic conditions can increase reliability and encourage shifts from private vehicle use. Public transport nodes, such as rail and bus stations, should be integrated into neighborhoods to support seamless multimodal connectivity while reducing car travel.

Pedestrian-friendly design is another critical component. Enhancing walkability through well-maintained sidewalks, safe crossings, and traffic-free inviting public spaces can significantly encourage active mobility. Walkable neighborhoods not only promote physical health but also contribute to cognitive well-being and social interaction, particularly among vulnerable populations like the elderly (Zhang et al., 2023). Moreover, pedestrian infrastructure must account for inclusivity, addressing the "last millimeter" challenges to ensure accessibility for all (Buliung, 2024).

Parking policies play a pivotal role in reducing car dependency. Stringent regulations, such as limiting parking availability in central areas and imposing higher fees, discourage car use and reclaim urban space for pedestrian and community activities (Núñez et al., 2024).

Mixed land-use planning further supports proximity by ensuring essential services, amenities, and recreational spaces are distributed across neighborhoods, thereby fostering local economies and social cohesion (Pozoukidou and Chatziyiannaki, 2021).

While the theoretical underpinnings of the "15-minute city" are rooted in principles of proximity and inclusivity, practical implementation requires data-driven approaches. Tools like the Next Proximity Index (NEXI) can assess accessibility levels and identify gaps in urban planning, guiding tailored interventions (Olivari et al., 2023). Besides, the experiences of cities worldwide provide valuable insights. For instance, European cities with high pedestrian accessibility and diverse land use demonstrate reduced car reliance and enhanced urban equity (Vale and Lopes, 2023). Similarly, compact neighborhoods in ultra-dense cities like Shanghai showcase how mixed-use planning and walkability can foster cognitive and physical health (Zhang et al., 2023). These examples underscore the importance of adopting integrated urban design principles that prioritize human-centric planning over car-oriented development.

Although Turkey's mid-sized cities possess unique opportunities to lead by example in movement, transitioning to the "15-minute city" in these cities requires addressing existing challenges, including societal car dependency and fragmented urban governance. The study explores different traits of collaboration across for sustainable urban planning goals. Moreover, community engagement in planning processes ensures that interventions reflect local needs and aspirations, fostering public support and long-term success (Pozoukidou and Chatziyiannaki, 2021).

The '15 Minute City' Paradigm

The concept of the 15-minute city has rapidly emerged as a transformative paradigm in contemporary urban planning, addressing the critical issues of environmental degradation, socio-spatial inequality, traffic congestion, and the erosion of community life. Its intellectual roots trace back to historical planning movements such as Clarence Perry's neighborhood unit, the garden city movement, and compact city theories. What distinguishes the 15-minute city is its shift from spatial to temporal framing of accessibility, ensuring that essential services—housing, employment, education, healthcare, commerce, and leisure—are accessible within a 15-minute walk or bike ride. The COVID-19 pandemic acted as a catalyst for re-centering urban discourse around these principles. Moreno et al. (2021) redefined urban planning by emphasizing accessibility over mobility, repositioning neighborhoods as the nucleus of urban resilience. Expanding this understanding, Whittle (2024) situates the 15-minute city within a broader critique of 20th-century planning ideologies, arguing that the model is not merely a design response, but a shift toward human-centric governance that reclaims the neighborhood as a democratic, semi-autonomous unit of everyday life. This interpretation underlines the 15-minute city as both a spatial strategy and a socio-political agenda aimed at reviving local urban agency in an age of globalization and centralized planning inertia.

The 15-minute city is structured around four foundational principles: proximity, diversity, density, and ubiquity (Moreno et al., 2021). Proximity ensures that daily needs are within a short walking or biking distance, promoting a high quality of life and reducing reliance on motorized transport. Diversity introduces a functional and social mix that sustains inclusive and vibrant communities. Density, reconceptualized from sheer population concentration to efficient land use, underpins both economic viability and the infrastructure necessary for active mobility. Ubiquity ensures that these attributes are not confined to affluent areas, but equitably extended across all neighborhoods, fostering spatial justice. This framework promotes polycentricity, envisioning urban regions as interconnected networks of semi-autonomous, self-sufficient neighborhoods. Echoing this vision, Whittle (2024) articulates that such neighborhoods must not only support daily functions, but also be empowered units of democratic and cultural life, capable of nurturing local identity, adaptability, and resilience. In doing so, the 15-minute city model diverges from 20th-century doctrines of speed and spatial expansion, instead cultivating a human-scaled, time-sensitive geography that invites deeper civic participation and localized governance.

Pozoukidou and Chatziyiannaki (2021) offered a vital critical perspective that builds on the conceptual optimism of 15-minute city framework by addressing its institutional blind spots. They contend that while spatial reconfiguration is a necessary condition for realizing the 15-minute city, it is insufficient without complementary institutional transformation. Specifically, they underscore that the success of this paradigm hinges on localized service delivery supported by adaptive governance, cross-sector collaboration, and participatory mechanisms that reflect the diverse needs of urban populations. Their critique highlights the danger of reducing the 15-minute city to a technocratic or aesthetic endeavor, warning that such interpretations risk rendering the model a symbolic gesture rather than a functional reality. By calling attention to the political, procedural, and resource dimensions of urban reform, Pozoukidou and Chatziyiannaki deepen the discourse, insisting that proximity must be institutionalized not only spatially, but structurally and democratically.

Empirical work by Olivari et al. (2023) introduced the Next Proximity Index (NEXI), a tool for quantifying access to essential services within 15-minute radii. Positioned as a response to critiques such as those raised by Pozoukidou and Chatziyiannaki (2021), NEXI operationalizes the abstract ambitions of the 15-minute city into measurable and actionable indicators. The index is calculated by identifying and mapping key urban functions—such as education, healthcare, retail, green space, and public transport—and assessing their presence within a 15-minute walking radius from residential areas. Each function is weighted based on its essentiality and frequency of use, and the index aggregates these weighted scores to produce an overall proximity measure for each neighborhood. Their studies across Italian cities revealed wide disparities influenced by urban form and historical development, highlighting the importance of context-sensitive planning. Crucially, NEXI extends beyond mapping spatial proximity to integrate dimensions of social inclusion, climate resilience, and mobility justice. This transformation from a technical metric to a normative planning instrument marks a significant step in addressing the procedural and distributive shortcomings emphasized in earlier critiques. By enabling planners to diagnose accessibility gaps and tailor interventions, NEXI exemplifies how empirical tools can support equitable urban transformation and embed the principles of the 15-minute city into grounded governance practices.

Building on the empirical rigor introduced by NEXI, which translates the abstract ideals of the 15-minute city into actionable planning metrics, subsequent studies has further expanded the paradigm's operational and normative dimensions. For instance, Núñez et al. (2024) questioned whether reductions in car usage are primarily driven by modal shifts or by the simple act of shortening travel distances. Their findings underscored that while investments in sustainable mobility infrastructure are important, the most transformative outcomes stem from co-locating services and residences. This reinforces the notion, already embedded in NEXI's design, that land-use planning must be foregrounded in sustainable urban transformation—thereby validating Pozoukidou and Chatziyiannaki's (2021) call for procedural and distributive reforms. Zhang et al. (2023) contributed a public health dimension, revealing how 15-minute neighborhoods in Shanghai foster cognitive and emotional well-being among aging populations. They demonstrated that walkable access to diverse urban amenities reduces isolation and bolsters autonomy, extending the paradigm beyond logistical convenience into the realm of social health and cohesion. Likewise, Vale and Lopes (2023) mapped pedestrian accessibility across over 100 European cities and exposed systemic disparities, where affluent neighborhoods benefited disproportionately. Their research warned that without explicit redistributive planning, the 15-minute city could exacerbate spatial injustice. They also highlighted the specter of "green gentrification," urging integration of equity and participatory governance into urban design. Finally, Buliung (2024) expanded the discourse by introducing the concept of "last millimeter" barriers—micro-scale urban design flaws that significantly hinder access for individuals with disabilities. He argued that while macro-level walkability metrics are often celebrated, they overlook the experiential and embodied dimensions of mobility. His critique strengthens the paradigm's commitment to spatial justice by insisting that true accessibility must be measured not just by distance, but by the ease, dignity, and autonomy with which urban space is navigated. Together, these works illustrate how the paradigm of the 15-minute city continues to evolve—anchored not just in visionary theory, but in inclusive, context-sensitive, and empirically grounded planning practice.

Lately, Moreno (2024) has recast the 15-minute city not merely as a spatial model, but as a profound philosophical and cultural response to the crises of contemporary urban life—namely, speed, fragmentation, and commodification. Accordingly, the 15-minute city is conceptualized as a temporal revolution—an urban condition that values slowness, synchronicity, and an enriched experiential engagement with place. This approach challenges prevailing urban paradigms that prioritize acceleration and efficiency. By positioning the

15-minute city as a multidimensional framework encompassing climate action, public health, and governance innovation, Moreno (2024) calls for a redefinition of urban rhythms and relationships. Central to this vision is the neighborhood as a "complete habitat," where decentralization and human-scale urbanism become catalysts for inclusivity, resilience, and civic engagement. In this formulation, the 15-minute city transcends traditional planning logic to become a vehicle for reimagining urban time, social proximity, and collective futures.

Cumulatively, the literature has progressed from foundational theory to the development of operational tools, empirical validation, and normative elaboration, offering a comprehensive framework for the 15-minute city. Rather than positioning it as a universal or static solution, the discourse affirms the model as a flexible and evolving paradigm of holistic urban transformation. A critical thread running through this body of work warns against the pitfalls of technocratic overreach, superficial implementation that neglects local contexts, and the perpetuation of socio-spatial exclusion. Success in realizing the 15-minute city, as emphasized across multiple studies, depends fundamentally on inclusive and transparent governance structures, iterative and reflexive planning mechanisms, and strategies that are grounded in the cultural, institutional, and spatial particularities of place. This expanded understanding reinforces that the paradigm's long-term viability hinges not merely on infrastructure or design interventions, but on the depth of institutional commitment to equity, participation, and contextual sensitivity.

For mid-sized Turkish cities, the rapidly expanding 15-minute city literature offers a dual perspective—serving as both a source of inspiration and a framework for critical reflection. These cities often display inherently compact morphologies and localized social cohesion, which could form a promising basis for implementing proximity-based urban strategies. However, the rapid motorization observed across Turkey—where vehicle ownership continues to rise despite being far from saturation levels—has compounded the challenges of spatial equity and environmental sustainability (see Şenbil and Yetişkul, 2020). Compounding this issue is the widespread inadequacy of public transit systems in mid-sized cities, which are frequently characterized by fragmented service coverage, irregular scheduling, and limited multimodal integration. The predominance of centralized governance and institutional inertia further impedes transformative urban action. As such, the realization of the 15-minute city in Turkey must be envisioned not as a superficial adoption of global trends, but as a profound transformation that responds to the nation's unique socio-political, infrastructural, and spatial conditions. This necessitates the decentralization of urban governance, a targeted redistribution of public investment toward marginalized neighborhoods, and the institutionalization of participatory planning mechanisms that amplify community voices. In this context, investments in walkable public realms, socially inclusive services, and responsive governance structures are not supplementary but essential. Only through such a multidimensional and locally grounded approach can Turkish mid-sized cities fully embody the principles of the 15-minute city and deliver meaningful outcomes in accessibility, social equity, and urban resilience.

Reframing Urban Planning for 15-Minute City

The 15-minute city, as conceptualized by Moreno (2024) and elaborated throughout contemporary urban planning literature, represents a transformative break from conventional paradigms of city-making. By shifting the primary focus of planning from spatial hierarchies and mobility efficiency to temporal proximity and everyday accessibility, this model reorients urban policy toward a more human-scaled, equitable, and inclusive logic of spatial organization. Unlike earlier approaches that emphasized expansion, zoning rigidities, and centralized nodes of urban activity, the 15-minute city emphasizes integrated, decentralized neighborhoods that embed urban functions within a walkable or bikeable radius. Rather than merely pursuing environmental metrics or sustainability benchmarks, this model urges a reconfiguration of how cities are experienced and governed—placing daily life, local autonomy, and temporal dignity at the center of urban transformation. The 15-minute city is not merely a design proposition, but a cultural and political reclamation of local agency—a response to the alienation and fragmentation produced by twentieth-century planning orthodoxy (Whittle,2024). In this light, the planning system must be gauged anew, not simply adjusted, to accommodate a neighborhood-oriented urbanism that values inclusivity, accessibility, and autonomy.

Despite the compact morphology and latent proximity potential of many Turkish mid-sized cities, the prevailing planning system remains ill-suited to realize the ambitions of the 15-minute city paradigm. In the face of rapid motorization—which continues to accelerate despite Turkey's relatively low car ownership levels compared to developed nations—urban infrastructure remains overwhelmingly designed to accommodate growing vehicular

demand rather than to foster a modal shift toward active mobility and short-distance accessibility. The current planning approach privileges high-capacity roads and automobile-centric development, sidelining investments in walkable, bikeable, and transit-supportive urban forms. Compounding the issue, while modifications for single-plot developments are often processed with relative ease, comprehensive area-wide changes face severe institutional and procedural constraints.

Plan changes that require the reorganization of plots, reallocation of public or community spaces, and realignment of shared infrastructure demand cumbersome legal navigation, tax obligations, and inter-agency coordination.

These hurdles are particularly acute in already built-up neighborhoods, where fragmented land ownership, outdated cadastral alignments, and an absence of operative neighborhood-scale planning mechanisms render transformational interventions practically unfeasible. A reframed planning approach must thus reorient public investment and legislative design toward neighborhood-scale and city-wide accessibility solutions—such as short transit route circulators, protected cycling corridors, pedestrian-first streetscapes, and multimodal feeder systems—while simultaneously streamlining regulatory pathways for retrofitting established urban areas. Current practices are dominated by rigid, centrally imposed master plans and a heavily top-down governance architecture that inhibits local adaptation and hinders organic neighborhood evolution. Plan modifications—particularly those aiming to introduce mixed-use zoning or reallocate services to enhance daily accessibility—are often stalled by bureaucratic inertia. The process is burdened by convoluted approval mechanisms, complex legal scrutiny, and considerable taxation burdens, especially for modifications involving broader land reorganizations in already built areas. These are particularly complex because they often require the adjustment of parcel boundaries, the provision or redesign of public and community spaces, and the integration of common goods into a new spatial logic compatible with proximity-based planning. Apart from reorganization of informal housing areas—which more or less face similar institutional and procedural bottlenecks—there is next to no planning agency in Turkey currently capable of undertaking neighborhood-based reorganization or transformation projects aimed at retrofitting already built-up urban areas into more sustainable, proximity-oriented forms.

Notably, while single-plot amendments are somewhat easier to process and more commonly approved, area-wide changes that necessitate the reconfiguration of multiple plots, the realignment of public and communal spaces, or adjustments to shared infrastructure are met with substantial institutional resistance. These comprehensive transformations, essential for enabling integrated neighborhood-level accessibility, often encounter insurmountable procedural barriers unless channeled through large-scale urban transformation projects. Yet even these projects are primarily aimed at housing reconstruction and disaster resilience, rarely contributing to the diversification of urban functions or the realization of complete neighborhoods. This rigidity undermines the capacity for incremental, context-sensitive interventions vital for achieving spatial justice and temporal proximity. Turkish urban planning remains entrenched in functionally segregated zoning and infrastructure priorities that favor high-speed, motorized mobility over fine-grained, pedestrian-oriented accessibility. As a result, neighborhoods remain disconnected from daily needs and incapable of supporting self-reliant urban life, thereby contravening the fundamental logic of the 15-minute city model.

This institutional void mentioned above severely limits the possibility of adapting existing neighborhoods to meet the spatial and functional requirements of the 15-minute city paradigm. While plan amendments for individual plots are relatively more feasible, area-wide modifications—particularly those involving the reorganization of already developed urban zones—encounter substantial procedural obstacles. These difficulties stem from strict legal requirements, high taxation, and the need for consensus among multiple landowners, especially where public spaces, communal facilities, and infrastructure must be reconfigured to meet proximity-based planning goals. Such interventions demand collective coordination, legal harmonization, and public consent—all of which are administratively cumbersome and procedurally opaque under the current regulatory regime. To reframe urban planning for the 15-minute city, it is essential to transition toward planning tools and institutional frameworks that prioritize flexible and adaptive instruments for retrofitting existing urban areas. This shift involves enabling fine-grained, incremental changes at the neighborhood scale that accommodate diverse local conditions and promote temporal proximity, rather than enforcing large-scale, top-down spatial reorganizations. This entails redefining neighborhood units as semi-autonomous, self-reliant territories where residents can access essential services, employment, education, and leisure within a short walking or cycling distance.

Achieving this transformation necessitates mainstreaming mixed-use zoning within Turkish land-use legislation, accompanied by support for incremental and context-sensitive development rather than the enforcement of rigid, large-scale masterplans. To do so, the planning system must be diametrically transformed to foster area-based planning and enable comprehensive urban retrofitting aimed at sustainable and proximity-based outcomes. Current regulatory structures tend to facilitate changes on individual plots, while rendering broader area-based interventions—those requiring coordinated reorganization of plots, reallocation of communal spaces, and integration of public amenities—exceptionally difficult. Without fundamental reform, the capacity to recalibrate existing urban fabric in alignment with 15-minute city goals remains structurally constrained. Such flexibility is key to cultivating resilient, self-sufficient neighborhoods. Whittle (2024) emphasizes that mid-sized urban territories hold significant potential to spearhead this shift by embracing agile, human-scale planning practices. These cities, rather than mimicking the infrastructure-heavy and centralized models of major metropolises, can become exemplars of localized governance and proximity-based urbanism, aligning closely with the ethos of the 15-minute city.

Quantitative tools like the Next Proximity Index (NEXI) introduced by Olivari et al. (2023) offer critical insights into how proximity can be operationalized through spatial analysis. By mapping the availability and diversity of essential services within a 15-minute walking radius, NEXI helps planners diagnose service gaps and prioritize interventions at a granular level. Crucially, this index accounts for both spatial coverage and the qualitative utility of services, integrating considerations of usage frequency and community importance. Pozoukidou and Chatziyiannaki (2021) emphasize that without such tools—and without integrating them into institutional processes—15-minute city initiatives risk becoming superficial or unevenly distributed. Indeed, NEXI embodies a procedural response to their critique, translating normative goals into technical diagnostics that can guide context-sensitive interventions in Turkish cities. In addition, Marquet et al. (2025) have revealed that the widespread adoption of the 15-minute city concept has incited political backlash, conspiracy narratives, and polarized reactions, particularly in the post-COVID planning climate. This skepticism, sometimes grounded in ideological opposition to centralized planning, at other times fuelled by misinformation, challenges planners to reconceptualize how participatory legitimacy and public trust are secured. Their study calls attention to the necessity of transparent, inclusive, and dialogic planning processes that not only inform but also engage communities in shaping their urban environments. The authors categorize critiques from baseless conspiracy theories to legitimate equity concerns, urging planners to discern and respond with sensitivity to context.

However, most Turkish mid-sized cities suffer from poor and insufficient planning units. This institutional weakness is not merely a matter of capacity but also of legal and procedural design. To meet the spatial demands of the 15-minute city, planning departments must be structurally enhanced through targeted capacity building. This includes mandating, by law, the employment of certified city planners in all municipal planning offices and equipping them with the legal authority and technical resources to initiate neighborhood-based retrofitting projects. Furthermore, these units must be supported by a set of model frameworks and toolkits for urban retrofitting—flexible yet enforceable templates that can be adapted to local socio-spatial conditions. Compulsory area-based planning practices, centered around 15-minute city metrics, should be embedded into national planning regulations, ensuring that all plot arrangements, public space configurations, and communal services are strategically designed to maximize proximity. Mixed-use densification and pedestrian-centered public realm design should be codified through new legislation to ensure that neighborhoods evolve as cohesive, accessible, and self-sufficient territories.

Fundamentally, reframing Turkish urban planning for the 15-minute city means dismantling its static, top-down blueprinting tradition and replacing it with adaptive, participatory, and neighborhood-responsive mechanisms. It requires a regulatory architecture that promotes mixed-use overlays, flexible zoning, and simplified plan amendments. Planning offices must be transformed from enforcement units into platforms for co-creation and public engagement. As Whittle (2024), Moreno (2024), and Marquet et al. (2025) assert, this transformation is as much about governance as it is about spatial design—it is about restoring time, agency, and dignity to everyday urban life. Training a new generation of planners equipped with the skills for equity-driven, participatory planning is paramount. Only through this deep institutional renewal—supported by empirical tools like NEXI and grounded in the lived geographies of Turkish cities—can planning systems evolve to meet the demands and opportunities of the 15-minute city model.

Enforcing and Enabling Mid-Size Cities for 15-Minute City in Turkey

To complement these reforms, it is crucial to establish advanced monitoring frameworks that ensure accountability, performance benchmarking, and feedback loops in the implementation of 15-minute planning. This necessitates integrating tools like the NEXI (Olivari et al., 2023) into the routine planning workflow, accompanied by open data policies that allow citizens and stakeholders to track progress in real-time. In addition, legal instruments must be revisited to introduce enforceable thresholds and measurable indicators for service accessibility, walkability, and land-use mix within Planning Zones (PZ). For instance, municipalities should be required to provide yearly audits evaluating whether each PZ meets designated proximity and inclusivity metrics, triggering corrective measures in case of persistent gaps.

Mid-size cities in Turkey represent a critical scale for operationalizing the principles of the 15-minute city, balancing human-scale urban form with regional development needs. Despite their latent potential, these cities are increasingly at risk of following the sprawling, car-dependent trajectories of metropolitan counterparts unless significant legislative and institutional reforms are introduced. As highlighted in Özdemir Sarı et al. (2019), Turkey's existing urban planning framework remains largely reactive, fragmented, and unfit for promoting integrated neighborhood-scale transformations. Therefore, to realize the promise of the 15-minute city model, a recalibration of planning legislation, spatial governance, and urban design practice is imperative.

A key strategic reform must involve the legal demarcation of Urban Settlement Areas (USAs), beyond which suburban and peri-urban expansion should be tightly controlled. These USAs should serve as statutory growth boundaries, akin to urban containment strategies seen in the UK and parts of Northern Europe, to focus investment, planning attention, and infrastructural development within a defined, optimally compact urban envelope. As Moreno (2024) argues, the 15-minute city is incompatible with low-density sprawl because it fragments service provision, increases travel distances, and undermines efforts to build cohesive, self-reliant neighborhoods. Therefore, USAs should be embedded within national and regional legislation, accompanied by clear development guidelines and enforcement mechanisms to prevent encroachment on agricultural land, ecological zones, or disaster-prone areas.

In the Turkish context, however, the definition and scope of USAs in current upper-level plans—particularly Territorial Plans—are often far too expansive relative to realistic future settlement needs. These designations frequently stem from inflated population projections that lack robust demographic analysis and ignore ongoing trends such as stagnating urban growth and accelerated aging in mid-size cities. This tendency is largely inherited from a planning culture forged during Turkey's rapid urbanization years, when population growth and urban expansion were seen as inevitable. However, Turkey now finds itself in a post-urbanization phase, where population growth is either negligible or negative in many mid-sized cities, and where demographic aging is a dominant trend (e.g., Senbil and Yetiskul, 2022). Consequently, existing settlement areas can accommodate most of the anticipated demand, making further expansion both unnecessary and inefficient. The pressing challenge, therefore, is not how to manage outward urban growth, but how to retrofit and revitalize already built-up areas to align with sustainable, proximity-based planning principles. Despite this, existing USAs assume expansive urbanization trajectories, implicitly endorsing urban sprawl through land reserves that exceed actual development demands. This disconnect results in low-density, fragmented urban expansion incompatible with compact, walkable, and service-rich neighborhoods envisaged in the 15-minute city paradigm. A recalibration is urgently required—one that realigns USA definitions with principles of urban compactness, land efficiency, and proximity-based planning. These redefined USAs should reflect current and projected demographic realities, explicitly prioritizing retrofitting and densification within existing built-up areas rather than speculative outward growth.

Within these designated settlement areas, cities must be subdivided into Planning Zones (PZs) that become the primary units for implementing the 15-minute city paradigm. Each PZ should encompass a population size, urban footprint, and service threshold appropriate for the realization of temporal proximity goals—meaning that residents can access essential services, jobs, education, public spaces, and mobility options within a 15-minute walk or bike ride. These zones should not be conceptualized as static units but as dynamic, semi-autonomous neighborhoods with tailored retrofitting plans. As emphasized in Whittle (2024), each urban context requires flexible adaptation of the 15-minute framework; thus, zoning must allow for local specificities, historical development patterns, and community needs.

Operationalizing this framework demands that each Planning Zone be governed through an integrated tripartite approach encompassing planning, design, and infrastructure development. The planning component must involve the preparation of neighborhood-scale development plans that align land use with proximity metrics, prioritizing mixed-use development, densification, and functional integration. These plans must also be legally enforceable and nested within higher-scale municipal plans, ensuring vertical coherence across planning levels. According to Pozoukidou and Chatziyiannaki (2021), one of the most common pitfalls of 15-minute city initiatives lies in the failure to link morphological transformations with institutional change, thereby resulting in fragmented or tokenistic interventions.

The design element should focus on human-centered urban form—walkable block structures, interconnected street networks, well-distributed public spaces, and universal design principles. As Buliung (2024) warns, pedestrian-friendly designs are often undermined by micro-barriers that inhibit access for the elderly, disabled, or those with mobility impairments. Therefore, design standards must be informed by inclusive design guidelines and be co-produced with community input. Participatory design workshops, citizen audits, and tactical urbanism can all serve as tools to ground spatial transformation in local realities while maintaining alignment with 15-minute city principles.

Infrastructure development is the final and perhaps most capital-intensive pillar. Within each PZ, infrastructural upgrades must prioritize multimodal mobility, green and blue networks, and digital connectivity. In particular, neighborhood-level investments in public transit circulators, bike lanes, stormwater management, and renewable energy micro-grids can reinforce spatial resilience and sustainability. The findings of Olivari et al. (2023) through the Next Proximity Index (NEXI) show that accessibility must be both physical and qualitative, measuring not only distance but also frequency, diversity, and the usability of services. NEXI-like metrics should be institutionalized into municipal planning offices as diagnostic and monitoring tools.

Planning departments should be at the core of this effort, with new legislative mandates to conduct compulsory areal plans for each PZ. These units must be capacitated through professionalization policies—requiring that every municipality with more than 10,000 residents employ at least one certified planner, with an additional certified planner mandated for every subsequent 25,000 residents. According to data from the Turkish Statistical Institute, there are 664 such municipalities in Turkey exceeding this population threshold, indicating the wide-reaching implications and feasibility of such a policy framework. This approach fosters a neighborhood-level, holistic planning perspective, enabling municipalities to engage in detailed spatial analysis, proactive retrofitting, and integrated service delivery aligned with the principles of the 15-minute city. Furthermore, planning departments should operate as proactive coordinators, monitoring the consistency of planning, design, and infrastructure projects, and ensuring that all interventions are evaluated through the lens of proximity, accessibility, and inclusivity. As emphasized in the urban governance frameworks articulated by Pierre (2011) and Healey (2006), local institutional capacity is the linchpin of sustainable urban transformation. Without embedded, empowered, and well-resourced local planning units, even the most visionary reforms risk stalling at the level of rhetoric.

In addition to statutory enforcement, enabling mechanisms are essential to translate legal provisions into built reality. This includes fiscal incentives for mixed-use development, subsidies for adaptive reuse and infill housing, and technical assistance programs for small-scale developers and cooperatives. Drawing from the work of Jessop (2002), urban policy must be seen as a multi-level governance challenge, requiring coordination between local, regional, and national actors. Therefore, Turkey must adopt a planning governance model that incentivizes cross-sector collaboration, reduces bureaucratic inertia, and foregrounds place-based innovation. Moreover, Turkish planning legislation must recognize retrofitting—not greenfield development—as the core strategy for spatial transformation. most mid-size cities are already largely built up, and meaningful 15-minute city implementation hinges on adapting existing neighborhoods rather than constructing new ones. Retrofits must include parcel reorganization, communal facility integration, and mobility recalibration, and should be guided by flexible but enforceable planning codes. These codes must mandate minimum service thresholds per PZ, specify mixed-use quotas, and enforce building design standards that enhance accessibility and reduce carbon footprints.

Turkey's new planning vision must also embed democratic and participatory practices. As Marquet et al. (2025) reveal, backlash against 15-minute city initiatives often stems from perceived top-down imposition and lack of transparency. To mitigate these risks, public deliberation should be embedded into the DNA of the

planning process, including participatory budgeting, neighborhood councils, and inclusive design charrettes. Only then can spatial proximity be translated into social proximity, nurturing the civic trust essential for long-term sustainability. To further elaborate on these strategies, it is critical to design monitoring frameworks with clear accountability lines and publicly accessible benchmarks. These systems must go beyond simple audits and incorporate layered data reporting mechanisms tied to annual municipal performance reviews. Legal instruments must be complemented with compliance indices that are transparently tracked through centralized digital dashboards, enabling civic oversight and targeted funding. International examples, such as France's Quartiers Prioritaires de la Politique de la Ville (QPV) and Spain's Barrios en Riesgo programs, show how legal precision, transparent criteria, and community involvement can mutually reinforce urban proximity planning. By studying Italy's use of NEXI in cities like Bologna, Turkish mid-sized cities can refine data granularity and develop tailored proximity indices. Applying these insights will support the translation of 15-minute planning concepts into localized and enforceable frameworks, while anchoring implementation in institutional learning and peer benchmarking across municipalities.

Conclusions

This study underscores that the 15-minute city paradigm, far from being merely a planning slogan or fleeting policy trend, represents a multidimensional and transformative framework that aligns with the specific conditions and evolving aspirations of mid-sized Turkish cities. Mid-sized cities in Turkey present unique opportunities to integrate the principles of proximity, accessibility, and equity, owing to their inherently compact urban forms, walkable neighborhood structures, and manageable urban scale. These settlements, while less burdened by the spatial complexities of large metropolitan regions, offer fertile ground for retrofitting urban spaces in line with the 15-minute city ideal. Yet, their planning potential remains underutilized due to fragmented governance, under-resourced local planning units, and a lack of participatory frameworks. Recognizing these characteristics, mid-sized cities could serve as pilot grounds for implementing neighborhood-based planning initiatives that prioritize short-distance access to key services and amenities. Moreover, their scale allows for more direct citizen engagement, enabling planners to co-create solutions in real-time with community members. Such localized and iterative approaches are essential for embedding the values of the 15-minute city in urban practice, especially in contexts where formal planning instruments often fail to capture everyday spatial and temporal needs.

However, these opportunities remain largely untapped in the face of rapidly increasing motorization, ineffective and underfunded public transit systems, and entrenched bureaucratic rigidity in planning procedures. A key challenge lies in the disjunction between spatial proximity—often achievable given the compactness of mid-sized cities—and actual operational accessibility, which is hindered by systemic inefficiencies and uneven resource distribution. This gap becomes more pronounced due to a planning regime that, while allowing for frequent plot-level changes, imposes significant legal and financial barriers to area-based transformations involving the reorganization of parcels, communal facilities, and shared infrastructure. Moreover, apart from interventions limited to the rehabilitation of informal housing areas, there is a conspicuous absence of institutional mechanisms or planning agencies capable of orchestrating neighborhood-scale retrofitting initiatives. Consequently, spatial inequalities persist, and the transformative potential of mid-sized cities to implement the 15-minute city paradigm remains unrealized, hindered by fragmented institutional support and the lack of cohesive planning mechanisms capable of executing neighborhood-scale, integrated interventions.

Through extensive engagement with contemporary literature and international best practices, the research highlights how the 15-minute city calls for a fundamental recalibration of urban planning and governance models in Turkey. Moreno (2024) and Pozoukidou and Chatziyiannaki (2021) frame the paradigm not only as a spatial design logic but also as a governance philosophy that values local autonomy, decentralized decision-making, and democratic inclusivity. These values are especially relevant in Turkish urban contexts, where top-down master planning and regulatory rigidity stifle innovation at the neighborhood scale. In this regard, the 15-minute city paradigm serves as both a corrective lens and a strategic tool for reframing Turkish urbanism toward a more human-scaled, temporally sensitive, and equity-centered model of development. It provides a much-needed counterbalance to the prevailing top-down, regulation-heavy planning approach, which often prioritizes standardized land use efficiency over everyday human experiences. By emphasizing the quality and immediacy of access to services within neighborhoods, the paradigm invites a restructuring of planning priorities around lived realities and localized needs.

Its implementation would encourage urban planning to shift from abstract, long-range projections to immediate, people-focused practices, thus embedding flexibility, inclusiveness, and responsiveness at the core of policy and spatial decision-making.

The research reinforces the imperative to redefine urban governance structures by aligning them with flexible planning tools, adaptive zoning frameworks, and area-based retrofitting strategies that can respond to localized socio-spatial dynamics. It proposes the formal subdivision of strictly demarcated urban settlement areas (USAs) into Planning Zones (PZs), each of which should operate as a semi-autonomous and self-sufficient neighborhood unit. The boundaries of USAs must be carefully defined and strictly enforced to prevent unplanned sprawl, which has long been fueled by inflated population projections and outdated assumptions of perpetual urban expansion. These expansive territorial designations—often inherited from the rapid urbanization era—no longer reflect current demographic trends, which show stagnation or decline in many mid-sized cities across Turkey. Therefore, spatial containment and urban compaction must underpin any attempt to retrofit urban areas for proximity-based living. Within these redefined and realistically bounded USAs, PZs must be governed through integrative processes that fuse spatial planning, urban design, and infrastructure development in a synergistic manner. The objective is to ensure that PZs function as complete urban habitats capable of fulfilling daily life needs—such as access to employment, education, healthcare, and recreation—within a short walking or cycling distance. Drawing on the Italian implementation of the Next Proximity Index (Olivari et al., 2023), which provides a scalable tool for evaluating proximity-based service delivery, and incorporating the "last millimeter" design considerations detailed by Buliung (2024), the study highlights the necessity for inclusive and accessible urban design. This must be supported by robust participatory planning mechanisms, dynamic data-driven monitoring systems, and iterative feedback loops that enable continuous refinement of interventions to match evolving community needs and preferences.

As Marquet et al. (2025) highlight, backlash and misinformation regarding the 15-minute city concept make participatory legitimacy crucial. Therefore, governance frameworks must be constructed not solely on legal mandates but on sustained civic engagement, transparency, and accountability. This necessitates an expanded role for professional city planners—not only as technical experts but as facilitators of community dialogue and co-design. Planners must be embedded in local governance structures with the mandate and capacity to engage residents, mediate conflicting interests, and translate proximity-based planning ideals into locally resonant strategies. Equally critical is capacity-building within municipal planning departments: municipalities must be legally required to employ professional planners at proportional scales to population, thereby fostering a neighborhood-level, holistic planning approach. This structural reform ensures that context-sensitive, neighborhood-scale plans are not only drafted with community input but also effectively implemented and monitored.

This study ultimately calls for a comprehensive and systemic transformation of Turkey's planning apparatus, one that is deeply rooted in democratic co-production, context-sensitive urban retrofitting, and a steadfast commitment to spatial justice. The entrenched rigidity of the current planning system must give way to mechanisms that facilitate adaptable, area-based strategies capable of responding to diverse neighborhood needs. Central to this transformation is the institutionalization of the core values of the 15-minute city—proximity, diversity, density, and ubiquity—within legal and procedural planning frameworks. These principles must be operationalized not as abstract ideals but as actionable criteria embedded in zoning regulations, design standards, and administrative practices. Only through such integrative and enforceable reforms can Turkish mid-sized cities evolve beyond mere functionality and efficiency, and become truly inclusive, resilient, and livable urban environments.

Abstract
Sustainable Urban Mobility Plans (SUMPs) aim to improve urban transport by integrating land use, public transit, and active mobility in an equitable and sustainable way. Initially designed for European cities, SUMPs face challenges in fast-developing urban contexts in the Global South. This paper reflects on Istanbul—a fast-growing, car-dependent developing megacity with complex governance structures. Istanbul's evolving landscape offers a lens to explore how SUMP strategies can adapt to rapid urban growth, institutional fragmentation, and shifts from flexible bus networks to fixed rail systems. The study emphasizes integrating land use, institutional capacity, and multimodal systems, while recognizing informal transport and expanding stakeholder engagement. Rather than critiquing SUMPs, it seeks to amend and localize them to better suit dynamic metropolitan realities in developing regions.

Keywords: SUMP; Istanbul; Sustainable Transport; Dynamic Cities; Mobility Planning

Introduction

Sustainable Urban Mobility Plans (SUMPs) have emerged as a key framework for addressing transportation challenges in urban areas by emphasizing sustainability, inclusivity, and environmental responsibility. Developed within the European Commission's broader policy landscape, SUMPs aim to integrate public transport, active mobility options such as walking and cycling, and land-use planning into a unified strategy to reduce greenhouse gas emissions and ensure equitable access to urban opportunities (Rupprecht Consult, 2019; Werland, 2020). While adaptability is one of the core principles guiding SUMPs, their implementation in fast-growing and complex cities reveals notable deficiencies.

This shortcoming becomes especially visible in Istanbul, where the city's official SUMP highlights the struggle of a rigid planning framework to respond to the rapidly shifting urban landscape and fragmented institutional terrain. Istanbul's soaring car ownership, its spatial sprawl, and the disjointed expansion of its rail transit system all underscore the limited adaptability of a framework originally designed for more stable and regulated urban environments. SUMPs, when not meaningfully tailored to local dynamics, fail to keep pace with the urgency and scale of urban change in cities like Istanbul.

Although Istanbul's SUMP aspires to promote sustainable modes of transportation, it falls short in integrating land-use strategies and urban design principles. The city's disjointed pedestrian and cycling networks illustrate this disconnect, diminishing the effectiveness of active mobility initiatives. Furthermore, while the SUMP includes measures such as congestion pricing, low-emission zones, and parking constraints, their limited scope and weak enforcement significantly undermine their capacity to meaningfully curb private car use. This gap reveals a deeper contradiction: while SUMPs declare adaptability as a founding value, their real-world performance in cities like Istanbul illustrates how this principle remains underdeveloped in practice (Przybylowski, 2018; Spadaro and Pirlone, 2021).

Additionally, Istanbul's significant investments in rail transit expansion reveal a missed opportunity to integrate new infrastructure into a broader land-use and urban transformation strategy. Rather than aligning new metro and rail lines with transit-oriented development principles, the expansion has largely occurred in isolation from policies that could steer urban growth patterns, reshape spatial hierarchies, or prevent car-dependent sprawl. The inadequate integration between metro, tram, bus, and ferry systems further compounds inefficiencies, weakening the effectiveness of multimodal connectivity and undermining the return on infrastructure investment (Yaoundé SUMP Summary, 2019; Kiba-Janiak and Witkowski, 2019). These missed opportunities

highlight the urgent need for SUMPs to move beyond static infrastructure delivery and incorporate dynamic urban development considerations. Integrating real-time data analytics and scenario-based planning tools could better align mobility interventions with ongoing transformations in land use and demographic patterns, allowing policies to evolve alongside the city's rapid changes (Wołek, 2014; Rutka et al., 2024).

Central to overcoming these challenges is the need for institutional changes in Istanbul's administrative structure. The existing framework, characterized by fragmented and distributed decision-making across various agencies, compromises the coordination necessary for effective land use and transportation planning. This disjointedness hinders the alignment of transit infrastructure with evolving urban form, missing opportunities to guide urban transformation through strategic land-use policies. A restructured governance model that consolidates authority under a unified institutional body is therefore essential. This centralized body should not only oversee transportation planning but also ensure its integration with broader spatial development strategies. Without such institutional reforms, the successful implementation of SUMP initiatives will remain out of reach, and their transformative potential will be stifled by bureaucratic inefficiencies and contradictory policy agendas.

Urban mobility cannot be effectively addressed in isolation; it requires close collaboration with urban design and development strategies. Above all, the rail transit system should be recognized as a strategic driver of urban transformation, with station areas serving as focal points for transit-oriented development and densification. This targeted approach not only strengthens multimodal integration but also leverages infrastructure investment to reshape urban form in a more sustainable and efficient manner. Furthermore, aligning station-area development with disaster-resilient urban renewal initiatives offers an opportunity to meet immediate needs for safer and more adaptable urban environments. A governance framework that formalizes the relationship between these domains can enable more cohesive policies, facilitating the creation of mixed-use developments, resilient transit-oriented neighborhoods, and pedestrian-friendly public spaces. Such alignment would not only enhance the feasibility of sustainable mobility solutions but also strengthen urban resilience, support climate adaptation efforts, and contribute significantly to improving the overall quality of urban life.

This study proposes a reimagined SUMP framework for Istanbul, emphasizing land-use integration and transit-oriented development. Policies such as enhancing public spaces for pedestrians, expanding non-motorized transport networks, and introducing innovative car-use restrictions are essential to fostering a sustainable mobility culture. Moreover, effective stakeholder engagement, including citizens, policymakers, and private entities, is crucial for implementing inclusive and responsive strategies (Lindenaua and Böhler-Baedeker, 2014; Andréi and Papuc, 2021). Istanbul's experience offers valuable lessons for cities facing similar challenges, underscoring the necessity of adapting SUMPs to local contexts. By aligning long-term urban development goals with flexible, innovative mobility strategies, and implementing critical institutional changes, SUMPs can transcend their current limitations, providing transformative solutions for the cities of tomorrow. This paper aims to contribute to propose a vision for advancing SUMPs in rapidly changing urban contexts, offering a roadmap for sustainable and inclusive mobility planning.

A Critical Look into Sustainable Urban Mobility Plans

Sustainable Urban Mobility Plans (SUMPs) have emerged as a significant response to the persistent limitations of traditional transport planning, which historically emphasized vehicle flow and infrastructure over sustainability, equity, and multimodal integration (Banister, 2008; Rupprecht Consult, 2014). In contrast, SUMPs promote long-term, inclusive mobility strategies that center people over cars and support broader goals of urban development and climate responsibility (Rupprecht Consult, 2014, 2019). Originating from European policy shifts in the early 2000s, SUMPs developed through initiatives like the EU's Green Paper on Urban Mobility.[1] Grounded in sustainability, inclusivity, and systemic integration, SUMPs embrace systems thinking—addressing mobility not just as movement, but as embedded in social, spatial, and environmental systems (Curtis and Low, 2012; Bertolini et al., 2005).

A careful reading of SUMP documents reveals an institutionalized planning framework grounded in eight core principles: transparency, participation, integration, cooperation, comprehensiveness, evaluation, adaptability, and sustainability (Table 1). These principles were clearly outlined and operationalized in the first and second

1 https://eur-lex.europa.eu/EN/legal-content/summary/green-paper-towards-a-new-culture-for-urban-mobility.html?fromSummary=32 (Accessed on May 16, 2025)

editions of the SUMP Guidelines (Rupprecht Consult, 2014, 2019). SUMPs advocate participatory planning and emphasize goal-oriented evaluation, data-informed decisions, and resilience to shocks. What differentiates SUMPs from conventional transport plans is their redefinition of success through accessibility and urban equity (Curtis and Scheurer, 2016). They encourage integrated governance that aligns transport and land use, inclusive stakeholder involvement, and modal shifts from cars to public and active transport for better health, safety, and environmental outcomes (Werland, 2020; Spadaro and Pirlone, 2021).

Tablo 1. SUMP Principles and Their Basic Tenets

SUMP Principle	Basic Tenet
Transparency	Planning process should be open and accessible to all stakeholders, thereby fostering trust and legitimacy.
Participation	the active involvement of citizens, local authorities, businesses, and civil society is critical for grounding decisions in lived experiences and building consensus.
Integration	Alignment of policies across sectors and transport modes should facilitate coordinated and cohesive planning.
Cooperation	Planning process should extend beyond local actors to include regional, national, and international institutions, enabling multi-level governance and resource sharing.
Comprehensiveness	Planning process should address all aspects of urban mobility—such as public transport, walking, cycling, freight, and private vehicles—within one strategic framework.
Evaluation	Planning process should include evidence-based planning by embedding monitoring tools and performance indicators throughout the planning cycle.
Adaptability	Cities should be able to respond to changing circumstances, emerging challenges, and new opportunities, ensuring the plan remains relevant over time.
Sustainability	The entire approach should focus on long-term environmental, social, and economic objectives, making SUMP a cornerstone of broader urban development strategies.

SUMPs follow a structured yet flexible process that unfolds through four key stages: (1) Preparation and analysis, (2) Vision development and strategy formulation, (3) Measure planning, and (4) Implementation accompanied by continuous monitoring and evaluation. Each phase is designed to foster collaboration, support evidence-based decision-making, and encourage local adaptation. Performance indicators, such as those tracking greenhouse gas emissions, modal shares, and accessibility, are central to evaluating progress and informing iterative improvement (Rutka et al., 2024).

Numerous case studies highlight the practical value of SUMPs. Gdynia, Poland, an early adopter, achieved success through strong political leadership, stakeholder involvement, and targeted initiatives like bus network reorganization and pedestrian-friendly infrastructure (Przybylowski, 2018). Similarly, cities such as Tallinn and Brno utilized SUMPs to drive institutional reform and build planning capacity. EU programs like CIVITAS have been instrumental in facilitating knowledge exchange and scaling best practices.However, SUMPs are not universally applicable in their standard form. Scholars such as Werland (2020) warn against overly rigid applications, emphasizing that rapidly evolving urban environments require adaptable strategies. In regions where governance is fragmented or coordination is weak, applying a one-size-fits-all model can undermine planning effectiveness and limit impact.

To succeed, SUMPs must genuinely reflect their core principle of adaptability by operating as flexible toolkits deeply grounded in local realities. However, current implementations often fall short in translating this principle into actionable strategies, particularly in complex and rapidly evolving contexts like Istanbul. The rigid application of SUMP frameworks risks overlooking informal transport modes, entrenched governance fragmentation, and distinct socio-cultural conditions. For SUMPs to be truly effective, they must be recalibrated to include adaptive

governance structures, integration of paratransit and informal systems, and planning processes that are continuously responsive to shifting urban dynamics. This requires more than inclusivity in principle—it demands context-sensitive approaches that prioritize local agency, political structures, and community-led insights. In cities like Istanbul, where transport challenges evolve rapidly, the transformative potential of SUMPs depends on this deeper institutional flexibility and operational responsiveness.

Transportation in the Developing World: A Misfit for SUMP?

Urban mobility systems in the Global South operate within markedly different socio-political, economic, and spatial contexts than those in the Global North, where Sustainable Urban Mobility Plans (SUMPs) were initially conceived. As Vasconcellos (2001) explains, transportation in developing countries is deeply entangled with institutional fragility and social inequality. While cities in the Global North typically enjoy stable governance, robust land-use regulation, and established public services, many urban centers in the Global South contend with rapid population growth, informal settlement expansion or uncontrolled urban sprawl, and fragmented institutions.

In these settings, transportation reflects power hierarchies and socio-economic disparities. Infrastructure investments often prioritize central areas and affluent populations, reinforcing spatial inequities. Peripheral and informal neighborhoods remain underserved, and public transit, when available, is frequently unreliable and underfunded—conditions that primarily impact low-income residents. Despite low car ownership rates, urban development continues to favor automobile infrastructure, fueled by policy inertia, aspirational consumer behavior, and the symbolic appeal of modernity. The institutional landscape in many Global South cities complicates planning further. Fragmented responsibilities and weak coordination between agencies hinder coherent mobility strategies. This often results in transportation policies that perpetuate exclusion rather than mitigate it. SUMPs, though well-intentioned, tend to be based on assumptions that rarely align with local realities—such as readily available data, established participatory mechanisms, and effective multi-level governance (Spadaro and Pirlone, 2021).

Paratransit systems—minibuses, motorcycle taxis, shared vans—are central to urban mobility in many Global South cities, especially where formal transit falls short. These informal systems are adaptable, affordable, and responsive to demand. While SUMPs do acknowledge paratransit to some extent, it is often framed narrowly, typically relegated to a feeder role for formal networks like rail or BRT systems. This limited recognition, although a positive step, fails to account for the full potential of paratransit as a backbone of everyday mobility for millions. The omission reflects a formalist bias that equates modernity with regulation and informality with dysfunction (Vasconcellos, 2001; Schipper et al., 2020). Moreover, efforts to replace or formalize paratransit often lack transition strategies, leading to service disruptions and resistance from communities and operators. A more inclusive and pragmatic approach would acknowledge paratransit's broader function and integrate it meaningfully through supportive regulation, infrastructure investments, and participatory reform processes. Sustainable mobility in the Global South depends not on the elimination of informality but on recognizing and empowering systems that already serve vast segments of the population.

A critical and often overlooked reality is that urban transportation systems in these regions are in a state of continuous flux. Infrastructure investments, such as new rail lines, can rapidly alter demand patterns and land use, potentially leading to gentrification or displacement. Simultaneously, urban sprawl—largely driven by increased car ownership—further undermines long-term transport planning. In response, SUMPs must evolve into genuinely reflexive and adaptive frameworks that can respond to these unpredictable dynamics. Istanbul exemplifies these challenges acutely. The city's sprawling geography, uneven development, and income disparities contribute to profound mobility inequalities. Peripheral districts often lack reliable public transit options, while a surge in car ownership among the middle class intensifies congestion and emissions. Although the city adopted a formal SUMP in 2022, it continues to struggle with entrenched car dependency, fragmented multimodal integration, and institutional fragmentation. Between 2019 and 2024, while the population increased by only 1%, the number of private vehicles surged by 32%, underscoring the disconnect between policy ambitions and actual mobility outcomes. The SUMP's treatment of paratransit further reflects this misalignment. Although paratransit is acknowledged, it is limited to a feeder role for the rail network—a framing that, while a positive step, fails to capture the full potential of services like the minibus/dolmuş system. These systems provide vital, flexible, and demand-responsive connectivity, particularly in underserved and peripheral areas. By reducing

them to a subordinate status, the plan overlooks their strategic role in addressing Istanbul's broader mobility challenges. A truly adaptive and inclusive SUMP would integrate paratransit more holistically into the city's transport ecosystem, leveraging its capacity to fill systemic gaps left by formal infrastructure.

Indeed, the cultural symbolism of car ownership adds another layer of complexity. As Gwilliam (2003) and Pojani and Stead (2015) observe, cars are often perceived as symbols of autonomy, modernity, and upward mobility—particularly in contexts where public transport is stigmatized or unreliable. Consequently, policies such as congestion pricing or vehicle quotas, effective in many European settings, often encounter resistance in cities of the Global South. These cultural and perceptual dynamics further expose the limitations of SUMPs when transposed without critical adaptation. For SUMPs to succeed in such contexts, they must go beyond rigid templates and evolve into genuinely flexible toolkits. This requires co-development with local actors and responsiveness to the institutional, cultural, and socio-economic specificities of each setting. Engaging informal operators, inclusively upgrading infrastructure, and investing in collaborative governance are all essential strategies. Only under such conditions can mobility planning transcend technocratic control and emerge as a catalyst for spatial justice and urban dignity. As Vasconcellos (2001) reminds us, mobility constitutes a core dimension of citizenship—integral not only to freedom of movement, but also to equitable access to public life. Sustainable mobility in the Global South will not emerge through replication of Northern models, but through the construction of grounded, pluralistic, and inclusive alternatives rooted in lived realities.

Compounding these challenges are the persistent issues of governance fragmentation and limited community engagement, which significantly undermine the effectiveness of mobility planning. In many Global South cities, decision-making remains highly centralized and technocratic, often excluding informal transport operators, residents of peripheral neighborhoods, and civil society organizations from meaningful participation. This top-down orientation reveals the difficulty of directly transplanting Northern planning models—rooted in stable governance and institutional coherence—into dynamic, diverse, and often politically fragmented Southern urban environments. As Cervero (2013) and Dimitriou (2013) argue, effective transport planning in such contexts must be deeply embedded within broader developmental agendas, encompassing poverty alleviation, livelihood support, and inclusive governance mechanisms. Mobility, in this perspective, is not merely a logistical or infrastructural issue but a fundamental right that connects people to opportunities in education, employment, healthcare, and civic life.

SUMP in Developing Cities: A Reflexive Proposal

In order to transcend the limitations of conventional Sustainable Urban Mobility Plans (SUMPs) when applied to complex, fast-growing cities in the Global South, a reflexive approach is required—one that does not merely adapt European practices to local contexts but reconfigures the planning paradigm itself. Drawing from the works of Vasconcellos (2001) and Dimitriou (2013), this proposal outlines the contours of a rearticulated SUMP framework that is responsive to the political, spatial, and institutional contingencies of cities such as Istanbul. Vasconcellos (2001) asserts that transport planning in developing countries must start not from abstract, imported objectives but from deeply situated understandings of structural inequality, pervasive informality, and unequal access to urban opportunities. Transportation in these contexts is not merely a logistical issue but a dynamic social contract—one that reflects and reinforces patterns of privilege, marginalization, and spatial exclusion. Planning must therefore be attentive to the lived realities of the majority, particularly those relegated to informal settlements or peripheral areas. Similarly, Dimitriou (2013) emphasizes the need for cultivating an "appropriate planning culture"—a concept that demands planners engage with the political economy of local institutions, recognize the historical trajectories of urban development, and co-create mobility strategies through inclusive and participatory mechanisms. Rather than treating planning as a one-way transfer of best practices, this approach calls for a dialogical, adaptive process grounded in stakeholder empowerment and cultural sensitivity.

Within this reframed paradigm, SUMPs must reposition themselves as facilitators of socio-spatial justice. This means reorienting the planning process away from technocratic idealism and toward political and institutional realism. Horizontal integration of diverse actors—from municipal planners and informal operators to community leaders and transit users—must be treated as an essential design principle, not a peripheral engagement strategy. The goal is not to achieve universal best-fit models but to foster locally negotiated, collectively stewarded mobility systems that enhance equity, dignity, and sustainability. To achieve this, a reflexive SUMP must begin with a diagnostic phase that acknowledges the co-existence and interdependence of multiple mobility systems within a city—not only formal infrastructure like buses and rail lines but also paratransit services, informal

transport networks, non-motorized pathways, and even seasonal or event-driven mobility patterns. This stage must move beyond traditional planning assumptions that privilege measurable technical indicators to embrace methodologies that uncover the deeper socio-spatial dynamics of movement. Rather than relying exclusively on modal split, congestion metrics, or emissions data, the diagnostics should incorporate ethnographic observation, participatory mapping, and spatial storytelling to surface the textures of everyday mobility, especially among marginalized and underserved communities.

In practice, this could involve community-led audits of access barriers, mobile interviews with commuters across class and gender lines, and the use of digital tools to document experiential geographies such as zones of fear, waiting, or exclusion. Such approaches not only broaden the evidentiary base of planning but also reframe mobility as a lived and contested experience. This deeper diagnostic insight reveals where formal networks fail, how paratransit fills systemic voids, and why certain routes, modes, or practices persist despite being institutionally invisible. Ultimately, the goal is to generate a holistic and inclusive mobility portrait that identifies not only gaps in infrastructure but also structural exclusions and power asymmetries that shape how, where, and for whom the city moves.

From this basis, the visioning phase must foreground mobility as a human right and as a fundamental pillar of social citizenship, shaping not only how individuals move but how they participate in the economic, cultural, and political life of the city. This requires a deliberate and sustained inclusion of marginalized voices—particularly women, the urban poor, disabled individuals, informal transport workers, and users of non-motorized modes—who are often excluded from formal planning discourses despite their deep experiential knowledge of the mobility landscape. Vernacular expertise must be brought to the center of deliberative processes, with planning spaces structured to facilitate not just consultation but co-creation. This could involve neighborhood assemblies, mobile town halls, or storytelling workshops that draw out latent mobility aspirations, anxieties, and place-based knowledge. Through these engagements, the visioning phase becomes not a normative projection from planners but a shared construction of future mobility imaginaries.

Vision statements should thus emerge from iterative dialogue and collective deliberation that extend beyond technocratic or environmental benchmarks. These statements must reflect a pluralistic synthesis of values—articulating goals that transcend narrow, efficiency-based definitions of sustainability to embrace a deeper normative agenda of urban dignity, intergenerational equity, spatial inclusion, and collective belonging. In a context marked by institutional fragility and spatial inequality, such visioning must function not only as aspirational rhetoric but as a strategic, co-produced claim on urban futures. In this reflexive frame, mobility transforms into an emancipatory space through which urban residents assert their right to the city—a right not just to access but to shape and inhabit public space, economic opportunity, and civic life on just and equitable terms. Mobility, thus conceived, becomes a catalyst for democratizing urban governance and redistributing spatial power.

Strategic goals in a rearticulated SUMP must be structured around equity-driven imperatives rather than conventional modal or infrastructure-based categorizations. The planning framework should explicitly ask: who is currently excluded from mobility systems, who stands to gain in terms of reduced travel time, improved safety, or increased opportunity, and who disproportionately absorbs the social and environmental costs of urban transport? This reframing positions equity not as a peripheral concern but as a core organizing logic of the entire planning apparatus.

By anchoring strategic priorities in redistributive justice, planning interventions can be aligned to directly redress historical exclusions, elevate the needs of peripheral and vulnerable communities, and reconfigure the spatial allocation of public investment. This may include prioritizing last-mile connectivity for informal settlements, enhancing pedestrian infrastructure in underserved areas, or subsidizing informal transport operators who serve essential routes. Ultimately, strategic goal-setting must function as a political act—deliberately tilting the balance of mobility benefits toward those who have been structurally disadvantaged by previous planning regimes. At the level of measures, SUMPs must adopt a flexible, modular approach capable of navigating institutional fragmentation, fiscal limitations, and infrastructural unevenness typical of many Global South cities. This flexibility is not only a logistical necessity but a strategic response to the plural mobility ecosystems that define such urban contexts.

While formal interventions—such as the development of dedicated bus corridors, transit-oriented development, or pedestrianization schemes—can play a vital role, they must be conceived as part of a broader integrative strategy that includes and elevates informal systems rather than displacing them.

A reflexive SUMP must treat informal transport—such as minibus/dolmuş services—not as a problem to be solved but as a vital asset to be supported, regulated, and incrementally improved. While current SUMP frameworks sometimes acknowledge the role of paratransit as a feeder to high-capacity rail corridors, this limited framing underestimates its broader significance in the mobility ecosystem. Informal modes often serve as primary transport solutions in peripheral neighborhoods, act as critical connectors between fragmented formal services, and embody community-responsive systems that adjust flexibly to shifting spatial and temporal needs. Planning should identify and enhance the complementarities between formal and informal systems through the design of shared nodes, integrated ticketing schemes, corridor coordination, and non-punitive regulation. Additionally, measures must address the labor conditions, safety norms, and environmental performance of informal transport to ensure these systems are not only functional but also dignified and sustainable. Such an approach recognizes that informal systems are often the outcome of adaptive problem-solving in environments where the state has failed to provide adequate services. Therefore, measures should be embedded in an ethos of collaborative governance, where planners act not as enforcers of top-down standards but as facilitators of negotiated arrangements that improve efficiency, accountability, and equity across the entire mobility system.
The implementation phase should be viewed as a multi-scalar and iterative governance process, wherein national ministries, municipal agencies, metropolitan authorities, and neighborhood-level organizations collaboratively co-create, pilot, and adapt mobility initiatives over time. This polycentric governance structure must be deliberately cultivated to accommodate varying capacities, political interests, and jurisdictional overlaps, which are often pronounced in the context of developing cities. Effective implementation demands a redefinition of roles—not merely top-down enforcement or bottom-up advocacy, but shared responsibility and mutual accountability across levels.

Capacity building within this phase must go beyond technical training or institutional restructuring; it must encompass political negotiation, relational trust-building, and mechanisms for ongoing conflict mediation. This involves developing facilitative leadership, transparent communication channels, and participatory budgeting mechanisms to ensure that diverse stakeholders remain engaged and empowered throughout the process. Importantly, implementation should not be treated as a linear execution of predetermined plans but as a dynamic, feedback-driven learning cycle that accommodates shifts in social, economic, and political conditions. Only through this reflexive, inclusive implementation architecture can SUMPs in developing cities begin to generate meaningful and durable mobility transformations.

Monitoring and evaluation must be reframed as dynamic, participatory processes that go beyond conventional performance indicators and embrace reflexive, socially grounded metrics (Peters and Reisch, 2023). Rather than solely emphasizing quantitative outputs such as kilometers of track laid, ridership growth, or modal shift percentages, evaluative frameworks must also scrutinize qualitative dimensions of equity, inclusion, and empowerment. Questions like: Has physical and economic access improved for women, children, and people with disabilities? Are informal transport operators more secure in terms of income, labor rights, and institutional recognition? Have commute times and cost burdens been reduced for residents in peripheral and underserved areas?—must become central to the assessment matrix. To support this, monitoring systems should incorporate community-led evaluation tools, participatory feedback loops, and context-sensitive indicators that are co-defined by stakeholders during earlier planning phases. Mixed-method approaches, including ethnographic fieldwork, user experience diaries, and real-time digital platforms for commuter reporting, can enrich the evaluative process and foster ongoing civic engagement. Importantly, evaluation must be adaptive and recursive—feeding insights back into the planning and implementation pipeline to refine goals, modify interventions, and maintain accountability. In a reflexive SUMP, monitoring becomes not an endpoint but a learning architecture that sustains continuous transformation toward greater urban mobility justice.

What about Istanbul?

In the case of Istanbul, where the population has remained relatively stable over the past five years, the dramatic 32% increase in motorized vehicle ownership during the same period underscores a deepening reliance on private

cars and a stark misalignment with the aims of sustainable mobility. This accelerating automobilization, unmatched by population growth, signals not only policy inertia but also the inadequacy of current planning paradigms to influence transport behavior meaningfully. A reflexive SUMP would necessitate a fundamental departure from the existing technocratic and infrastructure-heavy orientation that dominates Istanbul's mobility strategy. While the SUMP report for Istanbul demonstrates commendable alignment with EU-defined planning procedures and sustainability language (Canitez et al., 2020), it ultimately mirrors a prescriptive framework developed for mature European cities. It emphasizes quantitative metrics, modal efficiency, and high-cost infrastructure projects—such as metro expansions and congestion pricing—without adequately responding to the lived experiences, socio-spatial inequalities, and plural mobility practices that define Istanbul's dynamic urban fabric.

One of the major risks in Istanbul's current approach stems from its insufficient capacity to anticipate and adapt to the shifting equilibrium conditions that inevitably follow significant mobility and land use interventions. The introduction of new metro lines and transit extensions—while ostensibly aimed at promoting modal shift and reducing congestion—has led to a spatial reconfiguration of travel demand and intensified land speculation in proximity to these new transit nodes. In several cases, this has catalyzed urban transformation processes such as gentrification, displacing lower-income populations and altering the socio-economic fabric of these districts. Simultaneously, urban sprawl continues to expand Istanbul's peripheries, driven in part by rising car ownership and auto-oriented development paradigms that remain insufficiently challenged by the current policy framework.

These concurrent phenomena have created a fluid, often volatile landscape of mobility behaviors and spatial patterns. Modal preferences, trip lengths, and travel times fluctuate as new corridors emerge, housing markets shift, and job centers decentralize. In this dynamic context, SUMP strategies that rely on static baselines or pre-defined mode targets risk obsolescence and misalignment. Without adaptive feedback loops and real-time monitoring mechanisms, infrastructure investments can inadvertently generate induced demand or reinforce existing spatial disparities. A truly reflexive SUMP must therefore integrate scenario planning, continuous impact assessment, and responsive institutional coordination to remain aligned with the evolving urban metabolism. It must move beyond infrastructure provision as a deterministic force and recognize its catalytic role in shaping, and being shaped by, broader urban transformations.

A reflexive SUMP for Istanbul would begin by acknowledging the city's complex and plural mobility ecologies that encompass formal transit lines, informal systems like dolmuş and minibuses, ferry routes shaped by the city's geography, and the daily pedestrian flows that characterize many lower-income districts. The current SUMP process has only marginally addressed the social logic of these systems, treating informal transport as a residual phenomenon rather than as a strategic component of the urban mobility network.

Furthermore, Istanbul's SUMP underutilizes participatory methods. Public engagement has been limited to consultation rounds rather than constituting a co-productive planning process. A reflexive model would invert this logic—planning would begin with ethnographic inquiry, spatial storytelling, and neighborhood-level assemblies to co-diagnose problems and formulate contextually meaningful interventions.

Institutional fragmentation and jurisdictional overlaps continue to impede mobility coherence in Istanbul. The current SUMP does little to resolve these governance issues beyond recommending coordination. A reflexive SUMP would treat governance integration not as an administrative fix but as a political process that requires cross-level negotiation, interdepartmental trust-building, and shared accountability.

To improve Istanbul's SUMP, it must move toward a deliberative framework that emphasizes procedural justice and localized knowledge. This includes formalizing the role of informal actors in planning councils, adopting community-based evaluation indicators, and reframing infrastructure decisions around distributive equity. Rather than deploying standardized tools like congestion pricing without adaptation, Istanbul should develop hybrid solutions that balance demand management with improved access for peripheral and low-income areas. In sum, Istanbul's mobility planning must transition from a compliance-driven blueprint to a reflexive, adaptive, and locally resonant transformation process.

Such a framework, while grounded in the values of the original SUMP model—sustainability, inclusiveness, and integration—must diverge methodologically and politically. It must embrace uncertainty, foreground local agency, and frame mobility not as a matter of control, but as a collective negotiation over space, access, and rights.

In doing so, SUMPs in the Global South can evolve from prescriptive models into emancipatory processes, capable of reshaping the urban future from below.

Conclusions for Istanbul, The Biggest (Developing) City in Europe

Sustainable Urban Mobility Plans (SUMPs) have emerged as a transformative framework for urban transport planning, emphasizing sustainability, inclusivity, and environmental stewardship. Developed by the European Commission, SUMPs aim to reconfigure urban mobility systems to prioritize public transport, active modes of transport such as walking and cycling, and the integration of land-use planning with transport infrastructure. Unlike traditional strategies focused on vehicular flow, SUMPs align mobility planning with broader socio-economic and environmental objectives. Their adoption addresses urban challenges like congestion, greenhouse gas emissions, and social inequality (Rupprecht et al., 2019; May, 2015). SUMPs are built on principles of participatory planning and integrated development, tailoring policies to each urban area. Key goals include reducing the environmental impact of transportation, improving public health through active mobility, and fostering equitable access. They contribute to the European Union's climate goals and align urban development with the United Nations' Sustainable Development Goals (Werland, 2020; Spadaro and Pirlone, 2021). A key feature of SUMPs is their focus on short- to mid-term interventions that can be scaled and adapted. These include enhancing public transport efficiency, expanding cycling and pedestrian infrastructure, and integrating multimodal networks. Such strategies mitigate the negative externalities of high car usage, like air pollution and congestion (Lindenaua and Böhler-Baedeker, 2014; Broseta, 2015). Adaptability is crucial for accommodating evolving urban dynamics.
However, implementing SUMPs in rapidly growing cities like Istanbul reveals critical limitations. Istanbul's context—marked by sprawling urban development and rising car ownership—presents challenges that conventional SUMPs, originally tailored for stable European settings, are not fully equipped to manage. One fundamental issue is the failure to adequately address the city's systemic transition from a bus-based to a rail-based transit system. Over the past two decades, Istanbul has shifted from a flexible, point-to-point bus network—valued for its economies of scope, thick market and adaptable routing properties—to a more rigid, hub-and-spoke rail system dependent on economies of scale. This transition signifies both a structural and cultural transformation. Bus systems often feature movable stops and adaptable service paths, while rail systems are anchored by fixed stations that serve as enduring spatial nodes. These nodes have significant implications for surrounding land use in terms of densification, economic clustering, and shifts in real estate dynamics. Despite these changes, the current SUMP does not sufficiently account for the spatial repercussions of this shift. It reiterates observations of spatial transformation but stops short of embedding them in actionable strategies. This oversight reflects a broader pattern in which the planning system remains passive—adopting a laissez-faire approach instead of strategically engaging with the systemic transition. To achieve meaningful sustainability outcomes, planning institutions must go beyond merely acknowledging change and take an active role in shaping development. This requires a proactive integration of land use and transit planning that leverages the transformative power of fixed rail infrastructure. Only through such engagement can the full potential of costly transit investments be realized and sustainability targets met.

Although SUMP documents reference integration and multimodal coordination, they lack a comprehensive grasp of the systemic change that is reshaping urban mobility in Istanbul. Without explicitly addressing the full implications of this rail-centric transition—and its interdependence with land use and service delivery—SUMP initiatives risk remaining fragmented and ineffective. The lack of a holistic view inhibits progress toward meaningful sustainability goals. To address this gap, a revised SUMP must prioritize this structural transition at its core, proposing a cohesive, forward-looking framework that aligns land use, accessibility, and multimodal connectivity with Istanbul's evolving rail-based urban form (Torrisi et al., 2020). A notable issue is the inadequate support for sustainable modes like walking and cycling, which remains disconnected from a broader spatial vision. Aspirational goals are undermined by the absence of a flexible land-use strategy, particularly one centered on urban transformation around high-capacity rail transit stations. Pedestrian infrastructure is not systematically linked to multimodal hubs, reducing its utility, while cycling paths are fragmented and insufficiently embedded into daily mobility networks. To realize the full potential of costly transit investments, a grand urban transformation strategy based on transit-oriented development (TOD) is essential—one that balances density and diversity of

land uses in both newly built and already developed urban areas. Without such an approach, SUMP risks failing to curb car ownership and the growing demand for road and parking space, ultimately weakening its capacity to deliver sustainable mobility outcomes (Przybylowski, 2018; Vujadinović et al., 2021).

Another shortcoming is the limited adaptability of the current SUMP to Istanbul's evolving transport landscape. While rail transit investments such as metro and tram expansions are underway, these high-capacity systems are not integrated into a broader land-use and transit strategy. To maximize the value of such investments, the existing bus-based transit topology must be comprehensively restructured. This reconfiguration should involve redefining the metropolitan area into coherent transit zones aligned with transit-oriented development (TOD) principles. These zones should support a hierarchical, polycentric urban model, in which multiple centers are interconnected by a unified and strategically layered transit system. Such a system would ensure seamless integration between modes—including rail, bus, and ferry—while enabling flexible land-use responses in both new and established urban areas. Without this level of coordination and adaptive planning, the SUMP will be unable to fully leverage its infrastructure investments or meaningfully reduce car dependency and its attendant demands for road and parking space (Yaoundé SUMP Summary, 2019; Kiba-Janiak and Witkowski, 2019).

Addressing these challenges requires a reimagined SUMP framework tailored to dynamic cities—one that goes beyond technical fixes and embraces strategic planning engagement. While adaptive tools like real-time data analytics are essential to identify shifting mobility patterns and anticipate intervention impacts, they are not sufficient on their own. Without an overarching vision anchored in institutional responsibility and proactive policy-making, even the most sophisticated data-driven tools may fall short. A genuinely effective SUMP must not only adapt to evolving conditions but also shape them by deliberately guiding urban growth, land use, and mobility behavior. This means abandoning the current laissez-faire attitude, where systemic transitions are acknowledged but not strategically acted upon, in favor of a planning culture that leads rather than follows urban change. In this paradigm, data serves not just as a mirror to urban trends but as a catalyst for visionary, sustainability-oriented decision-making (Wołek, 2014).

Institutional changes are also essential to realizing SUMP initiatives in Istanbul. The current administrative structure, characterized by fragmented decision-making, hinders effective coordination. Without a centralized governance model that consolidates transportation planning and aligns it with land-use policies, the implementation of SUMP will likely fail. Effective integration demands a governance framework that establishes clear relationships between land use and transportation planning, ensuring decisions are made with a holistic view of urban development. Only by restructuring institutional frameworks can Istanbul overcome the challenges of siloed operations and fragmented accountability, paving the way for successful SUMP execution (Rupprecht et al., 2019). Sustainable initiatives in Istanbul must pair land-use policies with context-driven urban design strategies to achieve meaningful results. While mixed-use developments integrating residential, commercial, and recreational spaces can reduce commute needs, these alone are insufficient without a parallel emphasis on urban design. Transit-oriented development (TOD) should not only enhance accessibility but must also be anchored in complete street design principles that prioritize inclusive, safe, and legible public spaces. Urban transformation around transit hubs must include pedestrian-friendly streetscapes, protected cycling infrastructure, accessible transit stops, and vibrant public realms that accommodate all transport modes equitably. These urban design interventions must be tailored to varied neighborhood contexts—densely built historical cores, new development areas, and informal settlements alike. Without such targeted and comprehensive design efforts, even well-conceived land-use strategies may fail to deliver sustainable mobility outcomes or foster the modal shift necessary for reducing car dependency (Andréi and Papuc, 2021; Salazar Deza et al., 2021).

Curbing private car usage is critical. Policies such as congestion pricing, low-emission zones, and parking management are vital tools to discourage automobile dependence and redirect funding toward sustainable projects. However, these measures must extend beyond boutique or pilot applications confined to limited districts like historical peninsula in Istanbul. To be effective, they should be scaled across the entire metropolitan built-up area and consistently engage private mobility in all urban settings. Comprehensive application ensures that car use is managed holistically, not just in selected city centers. At the same time, these measures must be coupled with substantial improvements in public transport—particularly in terms of coverage, frequency, and reliability—to offer credible and attractive alternatives to car use (MobiliseYourCity, 2023).

Expanding non-motorized transport networks, such as bike lanes and pedestrian zones, also remains essential to building an inclusive and balanced mobility system (Kiba-Janiak and Witkowski, 2019).

Stakeholder engagement is another critical SUMP component. Truly inclusive planning must involve a wide spectrum of stakeholders, ranging from neighborhood councils and local civic organizations to metropolitan-scale construction firms, mobility providers, and transport unions. Ensuring that citizens, businesses, and policymakers are actively included allows policies to more accurately reflect localized needs, values, and challenges. Beyond that, integrating private-sector stakeholders—especially those involved in large-scale construction, transit operations, and urban development—can support both the acceptance and implementation of mobility strategies. A multi-scalar and cross-sectoral engagement process strengthens social legitimacy and enhances the responsiveness of the SUMP to Istanbul's complex metropolitan dynamics (Lindenaua and Böhler-Baedeker, 2014).

Istanbul's experience underscores the need to adapt SUMPs for fast-growing cities. While sustainability and inclusivity remain central, practical applications must reflect local challenges. Without recalibration, SUMPs risk becoming aspirational documents with limited impact. By adopting innovation and context-sensitive approaches, cities like Istanbul can realize SUMPs' full potential and set benchmarks for addressing urban complexities (Rupprecht et al., 2019; Spadaro and Pirlone, 2021). Lessons from Istanbul highlight the importance of aligning mobility strategies with long-term goals and institutional capacity. As the primate city of Turkey, Istanbul not only holds the largest population and economic weight but also possesses the highest institutional capacity for urban and transport planning. This leadership role makes Istanbul a reference point for other Turkish metropolitan areas, which frequently adopt its policies, institutional frameworks, and operational models. As such, the development and refinement of a robust, context-sensitive SUMP in Istanbul carries significant potential for transferability and scaling. Even the specific policy and operational proposals outlined in Istanbul's SUMP could serve as a blueprint for institutional and legal revisions in municipal governance and local service delivery. A carefully reiterated and effectively implemented SUMP in Istanbul could thus function as a national model, offering tested frameworks and adaptable strategies that reflect both ambition and practicality. Achieving this outcome will require technical expertise, investment, political will, and sustained public engagement. As cities across Turkey grapple with rapid urbanization and climate change, a resilient and well-localized SUMP in Istanbul can inform a scalable, nation-wide shift toward sustainable urban mobility planning (Werland, 2020).

ABSTRACT
This study examines urban rail transit usage in Istanbul to shed light on broader challenges faced by developing countries. Using models based on node and place characteristics of stations, it evaluates their impact on passenger volumes across the rail network. Despite major investments and rapid urbanization since the 1960s, only a fraction of station areas saw concurrent increases in passenger and population figures between 2017 and 2022. While node and place variables showed some significance, the regression models could not fully explain usage variability, suggesting that institutional, socio-economic, and spatial dynamics play a disruptive role. The findings indicate that stations have been treated more as isolated nodes than integrated components of the urban fabric. The study calls for a planning approach that combines rail transit with broader urban development, tailored to the complex realities of developing cities for maximizing the transformative potential of rail investments and promote sustainable urban growth.

Keywords: Urban Rail Transit, Developing Country, Istanbul, Node and Place Characteristics

Introduction

Investments in urban rail systems have increased significantly on a global scale, encompassing both developing and developed nations (Newman & Kenworthy, 2015). This trend underscores the growing recognition of urban rail as a crucial solution to contemporary urban challenges. However, is urban rail exclusively concerned with enhancing public transportation efficiency? Certainly not. Scholars assert that rail stations have the potential to serve as dynamic urban hubs, fostering economic development by attracting businesses and residents to the surrounding areas (Yang, Zhong, & Gao, 2022). While this proposition appears promising, its applicability in developing countries remains an open question.

Developing cities are constantly evolving, driven by both urbanization and natural population growth. As a result, these cities undergo significant expansion, extending both horizontally through suburban sprawl and vertically through high-density development (Mahtta et al., 2022). However, urbanization in these regions is often chaotic, characterized by fragmented investments and weak urban planning (McGill, 1998; Abdi & Daudén, 2021). The rapid pace of urban growth often outstrips the capacity of local governments to implement effective infrastructure and regulatory frameworks. This lack of coordination leads to inefficient land use, inadequate transportation networks, and increasing socio-economic disparities. As a result, many urban rail projects face challenges in integrating seamlessly with the surrounding urban fabric, limiting their overall effectiveness. So, what happens when urban rail is introduced? The results vary—some areas attract more people, while others remain unchanged or even see decline. Why? The dynamic nature of developing cities plays a huge role. In this study, we dive into Istanbul—a city that perfectly captures these trends.

As the most populous city in Europe, Istanbul has embraced the global "railization" movement (Gökçe, 2024). This shift has been driven by increasing urban congestion, environmental concerns, and the need for sustainable mobility solutions. Consequently, the city has prioritized expanding its rail network to enhance connectivity and reduce reliance on automobile transport. These efforts align with broader global trends that seek to integrate public transportation more effectively into urban planning. Since 2000, the city has invested heavily in suburban, metro, and light rail lines. By 2017, almost 57% of the population had a rail station within a kilometer (Gökçe, 2024, p. 8). However, the presence of a nearby station has not consistently resulted in increased ridership or population growth. This discrepancy raises an important question: what underlying factors contribute to this unexpected outcome?

Building upon these observations, a comprehensive analysis was conducted on 137 station areas within a one-kilometer radius to evaluate changes in population and passenger usage between 2017 and 2022. The results

indicated that only 27 stations (19.71%) experienced simultaneous increases in both population and passenger numbers. In contrast, 57 areas (41.61%) saw an increase in ridership despite a decline in population, while 53 stations (38.69%) experienced a reduction in passenger numbers. Notably, 20 stations with growing populations reported a decrease in transit users. These findings suggest that factors such as rail type, capacity, and land use significantly influence transit trends. However, they also highlight broader structural challenges in the development and integration of urban transit networks within rapidly evolving cities.

From these findings, valuable insights can be drawn regarding urban rail transit in rapidly evolving cities. This study provides an in-depth examination of urban rail transit in Istanbul, utilizing models based on node and place characteristics (Bertolini, 1996). Furthermore, it identifies inefficiencies within the system and proposes strategies to better integrate "transportation transformation" with "urban transformation." The study is structured as follows: Section 2 reviews transport trends in developing countries, Section 3 examines Istanbul's rail expansion, and Section 4 presents three analytical models—the Node model, the Restricted Node-Place model, and the Node-Place model—employing data from 2013, 2015, 2017, and 2019.

Nevertheless, a key challenge remains—while the models confirmed the significance of node and place characteristics, they did not fully account for the misalignment between ridership and population trends across the 137 stations. No statistically significant patterns were observed, suggesting that Istanbul's rapid urban transformation and shifting demographic patterns may have disrupted the anticipated relationship between transit usage and population density. This finding underscores an important consideration: rather than functioning as integral components of the urban fabric, Istanbul's rail stations have primarily been treated as isolated network nodes.

To effectively address these challenges, cities, particularly in developing regions, must integrate public transit—especially rail—as a core element of urban planning. This integration should emphasize accessibility, efficiency, and sustainability to ensure long-term viability. Moreover, seamless coordination between transportation policies and urban development strategies is crucial to maximizing the socio-economic benefits of rail transit investments. Engaging the public and ensuring equitable access to rail services can further enhance the effectiveness and acceptance of these initiatives. Given that these concerns extend beyond Istanbul, they are equally relevant to cities worldwide. A well-structured planning framework that prioritizes transit in urban development is essential for optimizing rail investments. The fifth section provides key recommendations for addressing these issues and enhancing the role of rail transit in rapidly evolving urban environments.

The Background: Transportation In Developing Countries

Urban transportation in developing countries presents a complex and multifaceted challenge. The transportation systems in these regions often reflect a hybrid of modern and traditional elements, resulting in inefficiencies unique to the developing world context. Rapid urbanization, economic constraints, and evolving social dynamics necessitate a nuanced understanding of urban mobility. Despite the global trend of "railization," transportation networks in developing nations continue to grapple with mobility issues like those identified by Gakenheimer (1999).

One of the most pressing challenges is the rapid pace of motorization, which often outstrips the capacity of existing transportation infrastructure. This imbalance leads to severe congestion, with cities such as Istanbul experiencing higher congestion levels despite lower vehicle ownership rates compared to many developed cities. Moreover, excessive travel demand further exacerbates congestion, as transportation networks fail to keep pace with the growing number of private vehicles on the road.

Public transit remains a crucial component of urban mobility in developing countries, carrying a significant share of urban trips. However, the effectiveness of public transportation is frequently hampered by political and institutional challenges, including inadequate funding, fragmented governance, and policy inconsistencies (Cervero, 2013). The dominance of bus systems, which often suffer from congestion-related delays, underscores the need for strategic investments in dedicated transit lanes and signal prioritization.

Disparities in transportation access further complicate urban mobility, leading to inequitable distribution of resources and services. In many developing cities, marginalized communities face longer commute times

and limited transit options, exacerbating socio-economic divides (Gakenheimer, 1999). Addressing these issues requires targeted policy interventions and infrastructure investments that prioritize inclusive and equitable transportation solutions. The decentralization of urban functions, often driven by motorization, tends to relocate employment opportunities to suburban areas, making access difficult for lower-income, non-motorized populations.

Additionally, the urban structures of many developing cities are not conducive to high levels of motorization. Narrow roads, often inherited from historical urban layouts, limit the space available for expanding vehicular infrastructure. The high density of both residential and commercial establishments further restricts the feasibility of large-scale road expansions. As a result, transportation planners must seek alternative mobility solutions that align with the existing urban fabric and prioritize sustainable transport options. Limited street space, high population densities, and mixed land-use patterns contribute to infrastructure inadequacies, further straining transportation networks (Bertolini, 2008). These constraints make it challenging to develop large-scale road expansion, leading to congestion and inefficiencies. Furthermore, mixed land-use patterns result in complex travel behaviors, as people need to navigate between residential, commercial, and industrial areas within short distances. The combination of these factors necessitates the adoption of innovative urban mobility solutions, such as improved public transit networks and non-motorized transport infrastructure, to enhance overall accessibility.

A significant factor fueling motorization is the strong desire for private vehicle ownership. Economic growth and aspirations for a modern lifestyle drive an increasing demand for automobiles, which, in turn, exacerbates congestion and environmental concerns. The introduction of new road systems often has a more pronounced impact on urban development in developing countries compared to their developed counterparts. The construction of highways, for example, tends to accelerate urban sprawl and alter existing urban structures, sometimes to the detriment of sustainable mobility (Cervero et al., 2009).

Furthermore, the diversity of vehicle types on the streets of developing cities presents unique challenges in traffic management. A mix of human-powered vehicles, motorcycles, minibuses, and high-speed cars complicates the efficiency and safety of urban transport. While informal transit options such as tuk-tuks in Thailand and minibuses in Turkey offer flexible mobility solutions, they also contribute to congestion and regulatory challenges.

Despite the increasing adoption of urban rail systems as a potential solution to congestion, rail transit alone cannot resolve the mobility crisis in rapidly growing urban environments. The success of such systems hinges on comprehensive planning, robust policy frameworks, and sustained political commitment (Cervero, 2013). Cities that fail to integrate rail investments with broader urban planning efforts risk underutilization and continued congestion.

Many developing cities also face institutional inefficiencies and social inequities that further complicate transportation management. Limited political will, insufficient administrative capacity, and corruption hinder the development of cohesive land-use and transportation strategies. In several cases, the influx of second-hand vehicles from high-income countries exacerbates congestion and contributes to higher greenhouse gas emissions. The fragmentation of urban services and a reactive rather than proactive approach to transportation planning often result in disjointed and ineffective mobility solutions.

The expansion of transportation infrastructure frequently leads to urban sprawl, marked by a “flattening of the density gradient” (Cervero, 2013, p. 14). This phenomenon is particularly evident in megacities like Istanbul, where transit investments can inadvertently contribute to socio-spatial segregation. Lower-income populations are often displaced to peripheral areas, while central urban districts undergo modernization catering to wealthier residents. However, successful cases from Bogotá and Curitiba demonstrate that well-integrated transportation and urban development strategies can lead to more sustainable and equitable mobility solutions. Investments in Bus Rapid Transit (BRT) systems and cycling networks have helped these cities accommodate growing mobility needs while promoting compact urban development.

Sustainable urban mobility in developing cities necessitates a strategic integration of land-use planning and transportation policies that emphasize accessibility and operational efficiency. The implementation of smart

growth principles can significantly contribute to lowering emissions, improving air quality, and fostering overall urban livability. A comprehensive and resilient mobility framework must incorporate a diversified array of transportation modes, targeted infrastructure investments, and systematic institutional reforms. Among these, rail investments hold paramount importance as they mitigate congestion, enhance urban connectivity, and provide an environmentally sustainable alternative to road-based transport. When seamlessly integrated with land-use planning, rail systems have the potential to reduce reliance on private automobiles and facilitate transit-oriented development. Consequently, a clear strategic vision and sustained commitment from policymakers are essential for developing nations to not only alleviate congestion but also stimulate economic growth and promote social inclusivity.

The Backdrop: İstanbul's Changing Face Of Public Transit

Istanbul, with an estimated population approaching 16 million, is the largest metropolitan region in Europe—when considered alongside the adjacent Gebze region to the east, the total population nears 17 million. Since the 1960s, the city has undergone rapid urbanization, with its population expanding from approximately one million to its current scale. This unprecedented demographic surge, primarily driven by migration, necessitated extensive northward (inland) expansion, resulting in the proliferation of informal settlements, commonly referred to as squatter housing. By the 1980s, these initially low-rise, one- to two-story structures underwent significant transformations into multi-story apartment complexes to accommodate the escalating population density. Consequently, the urbanization of Istanbul has been characterized by a dual process of internal densification and peripheral sprawl, reshaping the city's spatial and infrastructural landscape (Figure 1).

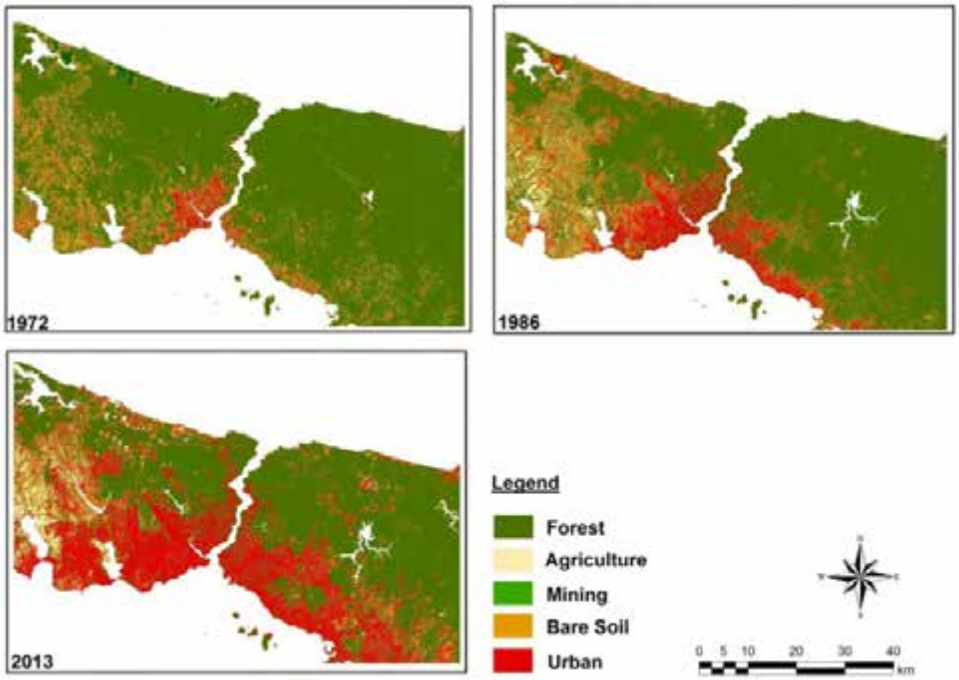

Figure 1 Urban expansion of İstanbul from 1972 to 2013 (Source: Akın et al., 2015, p. 506)

This densification, however, has left Istanbul grappling with inadequate infrastructure on multiple fronts. The swift population growth and the shift from squatters to apartments have placed immense pressure on the city's infrastructure, which has struggled to keep pace with the demands of such rapid urban development. Essential services and facilities, including transportation, sanitation, and public utilities, have often been overwhelmed, leading to significant challenges in terms of quality of life for residents. The city's infrastructure, originally designed for a much smaller population, has not been adequately upgraded to meet the needs of its current size, resulting in persistent issues with congestion, housing, and basic urban services.

To address these challenges more comprehensively, the municipal system for metropolitan areas was transformed into a two-tier system in the early 1980s. This new structure features an upper tier known as

the metropolitan municipality and a lower tier consisting of district municipalities. The aim was to enhance effectiveness and efficiency by leveraging economies of scale through metropolitan-wide investments in transportation, water supply, wastewater management, and other essential services. This restructuring intended to streamline administration and improve service delivery across the rapidly growing urban landscape.

Recently, the concept of the metropolitan municipality has evolved into what is now termed the "greater municipality," with jurisdictional areas extending to provincial borders while maintaining the two-tier system. Provinces with populations exceeding 750,000 are designated as greater municipalities. This latest iteration of the municipal system has integrated rural areas into urban governance, placing them under the same administrative umbrella as their urban counterparts. This change aims to ensure more cohesive and unified management of resources and services, addressing both urban and rural needs within the same administrative framework (Tekeli & Okyay, 2014).

Before the 1990s, Istanbul's public transportation infrastructure was relatively underdeveloped. Apart from a century-old two-stop rubber-tired funicular, locally known as the "Tunnel," which connected the seashore to a higher point in the city center on a very short line, the city had two old suburban rail lines. These lines terminated at Sirkeci on the European side and Haydarpaşa on the Asian side, both located at the southern tips of the Bosporus. These suburban rail lines formed the backbone of public transit, running through legally established housing strips parallel to the Sea of Marmara, an inland sea that connects the Black Sea to the Mediterranean Sea. To the north of both suburban lines, towards the inner areas of Istanbul, a state highway (namely E5, which was later recoded as D100, connecting Turkey's interior regions to Europe) served as the main urban artery (Tekeli, 2009). In these northern areas, illegal housing settlements were linked to this backbone by small entrepreneur-operated minibuses and public buses operated by the Istanbul Electric Tram and Tunnel Company (İETT). The minibus transit system has evolved flexibly with urban expansion and, in many cases, has supported urban expansion in the form of squatter housing (Tekeli & Okyay, 1981).

The establishment of a metropolitan municipality brought significant changes to Istanbul's transportation landscape. In the 1990s, financially empowered metropolitan administrations began investing in rail transit lines. This period marked the beginning of an incipient "railization," although efforts to expand the rail network were initially hampered by economic downturns in the Turkish economy. Despite these challenges, the trend towards rail transit steadily increased after 2000, with new metro and tramway lines extending from the city center to densely populated inner areas. The central government further spurred these developments by taking charge of the rail construction phase, boosting the expansion of rail infrastructure. A significant milestone was the recent completion of a high-tech, driverless metro line connecting the newly built Istanbul Airport, one of the three largest airports in Europe, to the city center. Today, two of the main airports, bus terminals, and intercity rail terminals, as well as main activity centers, are interconnected via the urban rail network, highlighting the substantial progress made since the 1990s.

Recently, the Bosporus has been underpassed by two tunnels: one for the suburban rail line (Marmaray Tunnel inaugurated in 2013), which connected independent lines on the European and Asian sides, and the other for motor vehicles (Eurasia Tunnel inaugurated in 2016). The addition of a third bridge on the northern frontier of the Bosporus has further increased urban mobility, which seems to be driving further urban expansion in the northern regions. Today, a seamless trunk suburban line, Marmaray, runs from Gebze, the westernmost district of the neighboring Kocaeli province, to Halkalı, the terminal station of the suburban line on the European side, covering a stretch of 86.6 km with 43 stations (Figure 2).

Figure 2. Main road corridors and Marmaray suburban line (highlighted in solid red line) in İstanbul (Source: Canitez et al. , 2020)

Over nearly three decades, the sustained effort in "railization" has transformed Istanbul's transportation system from a predominantly rubber-tired network to a more sophisticated rail network based on a node-place topology. Historically, the metropolitan administration's organizational structure was not designed to support such a network; it was geared towards a rubber-tired system. This necessitated significant changes to adapt to the new rail-based system. However, these changes required not only extensive physical infrastructure investments but also a thorough organizational restructuring to manage and operate the new node-place topology effectively (Cervero, 2013).

The main issue is that the rail network in Istanbul is designed for nodes without adequately developed station areas (i.e., places). This is a serious problem that needs to be addressed through capacity building. Developing station areas into functional, vibrant places is essential for maximizing the benefits of rail transit. Enhancing the integration of these nodes into the urban fabric will require strategic urban planning, improved land use policies, and the creation of amenities and services that make these areas attractive and accessible to residents (Bertolini, 1996, 2008; Cervero, 2008, 2013). By focusing on building capacity in these areas, Istanbul can ensure that its rail network not only serves as a means of transportation but also contributes to the overall livability and functionality of the city.

Especially after 2010, rigorous investments in rail transit has turned disconnected rail lines into a highly connected rail network as depicted in Figure 3a. As of 2024 number of transfer stations has increased to more than 40 stations (including with BRT system, the Metrobüs). In the next ten years the network is likely to increase another 250 km reaching the network depicted in Figure 3b.

-a-

-b-

Figure 3. The 2024 rail network (a) and the expected rail network at 2030(b) in İstanbul (Source: Metro Istanbul Accessed: October 15, 2024)

To support this transformation, Istanbul had to build new capacities within its administrative framework. This included developing specialized skills and capabilities within the city's transport authorities and restructuring existing organizations to better manage the integrated rail network. The transition also necessitated the implementation of new technologies and management practices to ensure the efficient operation of the expanded rail system. As Istanbul continues to grow, the ongoing development of its rail infrastructure remains a critical priority. The city plans to further expand the network, particularly along the south-north axis, to meet the needs of its burgeoning population and to maintain its position as a major metropolitan hub in Europe.

Urban Rail Transit Usage And Population Interaction Around Station Areas In Istanbul

Between 2017 and 2022, Istanbul experienced a 5.85% increase in population, expanding from 15,029,231 to 15,907,951. In parallel, Turkey's total population grew by 5.53%, rising from 80,810,525 to 85,279,553. Simultaneously, Istanbul's urban rail transit system recorded a substantial 47.95% increase in weekly ridership, surging from 14,408,882 to 20,844,589. This expansion was primarily attributed to the introduction of new lines and stations. Notably, when using 2013 as a baseline instead of 2017, the increase in weekly trips reaches 116.26%, underscoring the rapid growth and utilization of rail transit over the past decade.

For the 137 stations that were operational in both 2017 and 2022, weekly passenger numbers increased by 9.20%, a rate surpassing the overall population growth during the same timeframe. Analyzing these stations in terms of passenger volume and station area populations—where 103 of the stations are on the European side—reveals no significant difference in passenger usage between the European and Asian sides of the city.

Among the 137 stations examined, 84 stations (61.31%) registered an increase in weekly passenger numbers. A paired t-test shows an average increase of 9,561 weekly passengers per station between 2017 and 2022 (p=0.063, d.f.=136), adding to an average weekly ridership of 103,894 passengers per station. As discussed in the introduction, the stations have been categorized into four groups based on changes in passenger volumes and surrounding population between 2017 and 2022 (Figure 5).

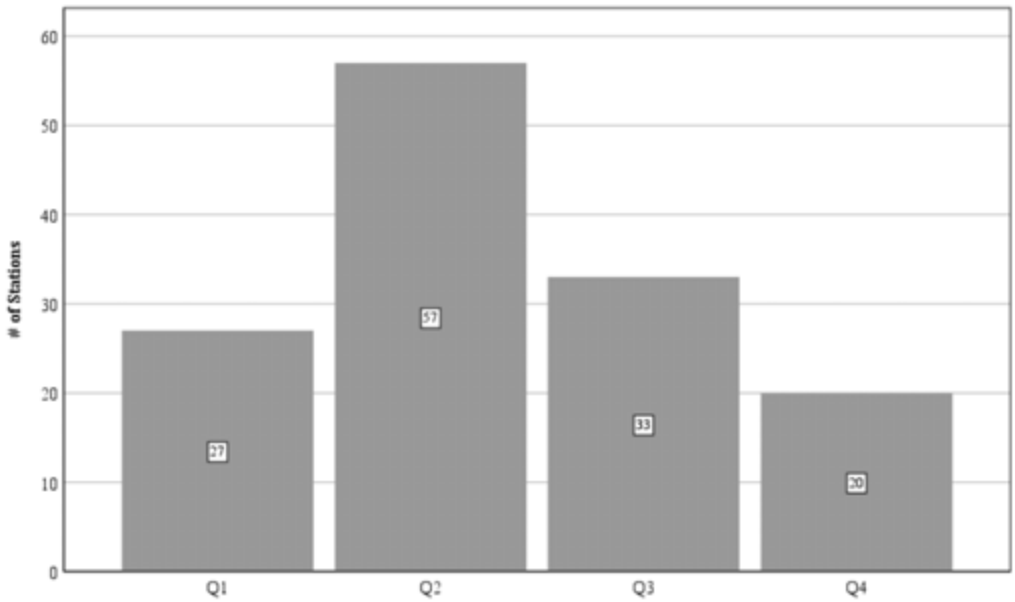

Figure 4. Changes in passenger values of rail stations and population of station areas (1 km radius) between 2017 and 2022

The first group (Q1) consists of stations where both population and passenger numbers increased. The second group (Q2) includes stations where passenger numbers rose while population figures declined. The third group (Q3) represents stations where both population and passenger values declined. Lastly, the fourth group (Q4) encompasses stations where the station-area population increased while passenger usage decreased. Figure 4 illustrates the distribution of stations across these four groups.

A general trend of population decline is observed in station areas categorized as Q2 and Q3, representing 65.69% of the total stations. The number of stations experiencing population loss (Q2 and Q3) surpasses those witnessing passenger growth (Q1 and Q2). Additionally, more stations recorded simultaneous declines in both population and ridership (Q3) than those where both increased (Q1). The mixed findings in Figure 4 suggest a strong intra-metropolitan shift of both population and commercial activities, facilitated by increased motorization. A detailed examination of land use patterns and their changes in different station groups offers explanations for these shifts.

Stations in Q1, where both passenger numbers and population increased, are predominantly residential areas near the city center. Conversely, Q2 stations, situated in central locations or urban transformation zones, have seen a decline in population due to redevelopment activities. Stations in Q3, which primarily serve mixed land-use areas dominated by retail businesses, appear to have suffered from both population relocation to outer areas and widespread business closures, particularly during the COVID-19 pandemic. Q4 stations, which primarily belong to metro lines running parallel to the D100 highway, seem to have lost passengers to private vehicle usage.

A more comprehensive analysis is conducted using a panel regression model, incorporating weekly passenger data from the second week of December in 2013, 2017, 2019, and 2022 as the dependent variable. The Random Effects Panel Regression model employed in this study is structured as follows:

(1) $$y_{it}=\beta_1+\boldsymbol{\beta}'\mathbf{x}+(e_{it}+u_i)$$

where,
y = natural logarithm of passenger values
x = the column vector of independent variables
β = the row vector of parameters
t = years of observation (2013, 2015, 2017, 2019, 2022)
i = rail transit station
e = station based temporal error term
u = station based error term
In this system a generic error term is defined as

(2) $$v_{it}=(u_i+e_{it})$$

Variance of the generic error term is as

(3) $$\sigma_v^2 = \mathrm{var}(v_{it}) = \mathrm{var}(u_i + e_{it}) = \sigma_u^2 + \sigma_e^2$$

In the model provided above, the covariance between the measurements of a station at two different times is assumed to be the same for all stations, while the covariance between two stations at the same time is set to zero. Using these assumptions, the correlation of the number of passengers served by a station between two time periods is calculated as follows:

(4) $$\rho = corr(v_{it}, v_{is}) = \frac{cov(v_{it},v_{is})}{\sqrt{var(v_{it})var(v_{is})}} = \frac{\sigma_u^2}{\sigma_u^2+\sigma_e^2}$$

In the model structure presented above, two groups of independent variables are used. The first group represents node characteristics, while the second group consists of place variables that characterize the station areas. However, not all independent variables are available for all years. Station area populations are available for 2017 and 2022, while the number of work locations is available only for 2022. Therefore, place variables are not usable for all years. Table 1 provides the dependent and independent variables along with summary statistics. Variables are categorized according to Bertolini's scheme (12, 13).

There are five node variables and two place variables. Note that the population variable restricts the panels to only two time points, 2017 and 2022. The number of work locations reduces the analysis to multiple linear regression as it is only observed in 2022.

Table 1. Descriptive Statistics of Regression Variables

Variable	# of Observations	Mean	Std. Deviation	Min.	Max.
N. of Passengers (ln) / dependent variable	762	11.01	0 .89	6.93	13.358
N1: Indicator for suburban rail, MARMARAY	762	0,13	0,34	0	1
N2: Indicator for light rail transit	762	0.35	0,48	0	1
N3: Indicator for European side rail	762	0,73	0,44	0	1
N4: Number of transfers to other lines at the station	762	0,16	0,41	0	2
N5: Number of stations to go on the line to reach the city center	762	9,95	6,44	1	29
P1: Resident population in 1 km radius of the station (ln)	324	10,64	1,15	3,14	12,30
P2: Number of work locations in 1 km radius of the station (ln)	180	7,87	1,38	3,91	10,91

Based on the dataset depicted in Table 1, three regression models were devised and named according to the variables included. For all the available years in the dataset, i.e., 2013, 2015, 2017, 2019, and 2022, since we only have node variables, the model is named **the Node Model** (Table 2). There are two regression models based on panel data, i.e., ***Model 1***, and ***Model 2***. While ***Model 1*** is named as the Node model, ***Model 2*** is named as **the Restricted Node-Place Model** as it includes only resident population around 1 km of stations (***P1***) without including data on work locations (***P2***)—data about work locations were only available for 2022. ***Model 2*** reveals insignificant coefficient value for the place variable (***P1***). However when we turn to a linear regression model conducted for a single year, 2022 (***Model 3***), both place variables (***P1***, ***P2***) attain significant positive coefficient values. Estimation of the regression coefficients are presented in Table 2.

In all models, we have negative coefficients for Marmaray (***N1***) and LRT (***N2***). Unlike metro rail stations, which are actively used throughout the week, both LRT and Marmaray stations serve fewer passengers on average. Weekly passenger levels at Marmaray and LRT stations are approximately 10% and 40% lower, respectively, than those at metro stations, respectively. Therefore, we have negative coefficients for Marmaray (***N1***) and LRT (***N2***) stations. The regression based on panel data does not reveal significant coefficients for the European side rail, ***N3***. However, the regression model conducted for a single year (2022) reveals a significant, but negative, value. Consistent negative results lead us to conclude that the Anatolian side population is more reliant on the rail system than the European side population. This is closely related to the development patterns on both sides of the Bosporus, as shown in Figure 1. The number of transfers (***N4***) available at a station increases weekly passenger levels to more than twice the average values. Although its effect decreases in models that include place variables, it still retains its importance as a node feature.

The southern tips of the Bosporus on both the European and Asian sides resemble city centers in terms of the rail network. Nearly all rail trips use these two locations as reference points in daily journeys. A station's relative position on the network, denoted by ***N5***, is determined with respect to intermediate stations and the city center. The models reveal significant and consistent values for the ***N5*** variable, which remain unaffected by the inclusion of place variables. The relative position is relatively immune to additional explanatory variables in the models. City centers on both sides of the Bosporus are important hubs for all rail trips. There is always an increasing trend of passengers at stations toward the city center, regardless of the rail type. We do not expect changes in this pattern in the future, even with the ongoing relocation of the population.

Table 2. Regression Results

Variable	The Node Model (Model 1)		The Restricted Node-Place Model (Model 2)		The Model 3: The Node-Place Model (Model 3)	
	Linear Regression with Random Effects (Years of The Panel Dataset: 2013, 2015, 2017, 2019, 2022)		Linear Regression with Random Effects (Years of The Panel Dataset: 2017, 2022)		Linear Regression (Year of The Dataset: 2022)	
	Coefficient	z-statistic	Coefficient	z-statistic	Coefficient	t-statistic
Constant	11.26**	78,50	10,58**	21,34	8,64**	12,87
N1	-0,33*	-2,27	-0,05	-0,31	-0,07	-0,51
N2	-0,22	-1,59	-0,20	-1,49	-0,30*	-2,16
N3	-0,05	-0,40	-0,05	-0,41	-0,26*	-2,05
N4	0,99**	10,56	0,87**	6,78	0,71**	5,45

	0,84		0,66		NA	
R^2	0,21		0,22		0,35	

** = significance <0,01, * = significance <0,05

The results presented above suggest that the impact of node and place characteristics on rail station usage is mixed and insufficient to explain more complex relationships. This could be due to the unique characteristics and inherent dynamism of developing countries, a phenomenon elaborated in the second section. Additionally, each developing country has its specific backdrop, as detailed in the third section for Istanbul. Although the regression analyses provided intuitive results, further investigation is needed to explain the mixed outcomes observed for the 137 stations (see Figure 4).

We believe Figure 4 reflects the unique context and dynamism of developing countries, in contrast to the regression results. Since none of the regression analyses conducted on the 137 stations yielded significant coefficients for population change on changes in passenger values, there must be other intervening factors, such as institutional and administrative dynamics, as well as ongoing socio-economic and demographic processes. In an urban setting that is still evolving, as seen in developing countries, should rail transit planning adopt a different approach? This question highlights the need for a new planning paradigm that considers these unique challenges.

Conclusions

In the context of developing countries, urban transportation systems often face unique challenges and exhibit specific characteristics. Rapid urbanization in developing countries results in a mismatch between old and new infrastructures, which creates inefficiencies and ineffectiveness. Moreover, the specific backdrop of each developing country adds another layer of complexity. In Istanbul, significant investments in the rail network began in the 1990s, marking the start of an "incipient railization." Despite economic downturns, this trend continued, leading to a substantial expansion of the rail network in the post-2000 era.

The central government's support further accelerated "railization", with notable achievements such as undersea tunnels over the Bosporus, driverless metro line connecting Istanbul Airport to the city center. However, the mixed results from the 137 stations between 2017 and 2022 underscore the varied impact of these investments. While some stations saw increased passenger values and populations, others did not, reflecting the city's complex urban dynamics and the multifaceted nature of urban transportation challenges in developing contexts.

The regression models, although they provide insights into rail transit usage, do not fully capture the complexity of the observed patterns, necessitating further exploration of the interplay between urban dynamics, socio-economic factors, and transportation infrastructure in developing countries. Addressing these challenges requires a multifaceted approach. Developing countries need to prioritize integrated urban planning, ensuring coordination between transportation and land use policies. Strengthening regulatory frameworks and institutional capacities is essential to create an environment conducive to investment and sustainable development.

In this framework, each rail station should be viewed as an asset to foster policies that enhance both node and place characteristics. Accordingly, each station should be considered a reference point for developing an urban fabric conducive to sustainable transportation modes such as walking, bicycling, and transit altogether, rather than merely a node for transit access (Newman & Kenworthy, 2015; Cervero et al., 2009; Cervero & Murakami, 2009). In conclusion, while urban rail investments have the potential to transform land use and promote sustainable development, realizing these benefits in developing countries requires addressing them in a broader context. By adopting integrated planning approaches, strengthening institutional capacities, and fostering inclusive development, developing countries can unlock the full potential of urban rail investments and create vibrant, equitable, and sustainable urban environments.

Socioeconomic Disparities in Daily Activity Spaces: Insights from Smartphone Mobility Data on Non-Commuting Trips

Omer Dogan[1], Sugie Lee[2]*
Hanyang University, Seoul, Korea
omerdogan@hanyang.ac.kr
Hanyang University, Seoul, Korea
sugielee@hanyang.ac.kr

Abstract
Urban mobility significantly influences accessibility, social cohesion, and equity; however, non-commuting travel remains understudied. This study investigates the impact of income, age, and gender on non-commuting mobility in Seoul, utilizing large-scale smartphone data. We measure activity space distance and destination diversity to assess disparities in leisure-related movement in four different time periods of the day. Results show that higher-income groups travel farther and to more diverse destinations, while lower-income, middle-aged women, and older adults are more spatially constrained. Importantly, Gini coefficient analysis reveals significant intra-group disparities, indicating that individuals from the same demographic group but different neighbourhoods experience unequal access to mobility. These findings underscore the need for inclusive, place-sensitive mobility policies that address both intergroup and intragroup inequalities in daily urban life.

Keywords: Non-commuting mobility, activity space distance, destination diversity, socioeconomic disparities, Gini coefficient

1. Introduction

Contemporary cities face mounting pressures to ensure equitable access to urban life as mobility patterns evolve beyond routine commuting. Non-commuting travel, comprising over half of urban trips in developed economies (Miyauchi et al., 2021), includes leisure, social visits, caregiving, and errands, and plays a vital role in shaping individual physical well-being, social cohesion, and vitality (Sulis et al., 2018; Jin et al., 2024; Wang et al., 2024). The more a group of people travels to various parts of the city, the more opportunities they have for social exchange and interaction, which benefits both individual well-being and collective urban life (Mouratidis & Poortinga, 2020). Especially, the diversity in the pattern of mobility makes the catalytic impact for local economic vitality (Chong et al., 2020; Pentland, 2020). Economically, discretionary trips drive patronage of small businesses, accounting a significant part of retail spending in walkable neighbourhoods (Moyano et al., 2020). Physically, active travel modes during these trips contribute to meeting WHO-recommended daily exercise thresholds, reducing chronic disease risks (Sahlqvist et al., 2012). However, unequal access to mobility-enabling infrastructure may exacerbate socioeconomic disparities in these benefits. Cities must address inequalities in accessing vibrant areas for different socioeconomic groups, as disparities can impact physical activity and social interaction (Zhang & Warner, 2023). Barriers like safety concerns, lack of transportation, and inadequate amenities in lower-income areas often limit access for women, the elderly, and other vulnerable groups (Gauvin et al., 2020; Shoval et al., 2010).

Yet, despite its growing significance, non-commuting mobility remains underexplored in urban research. Unlike commuting, which is often fixed and purpose-driven, non-commuting mobility reflects deeper layers of spatial preference, lifestyle, and access to opportunity (Mouratidis & Poortinga, 2020; Nilforoshan et al., 2023). Disparities in such mobility, driven by income, age, gender, and neighbourhood infrastructure, can limit physical activity, social interaction, and access to vibrant areas, particularly for vulnerable groups such as women and the elderly (Shoval et al., 2010; Gauvin et al., 2020). Understanding how diverse populations navigate cities beyond the workplace is crucial for addressing spatial inequality and designing inclusive urban policies, particularly in highly stratified contexts such as Seoul (Han, 2022; Jin et al., 2024).

The primary objective of this study is to investigate how income, gender, and age influence non-commuting mobility patterns in Seoul, with a particular focus on both inter-group and intra-group disparities in access to urban spaces. Using large-scale smartphone mobility data, the study quantifies differences in activity space distance and destination diversity across four distinct time periods of the day: morning, daytime, evening, and nighttime. By applying entropy measures and Gini coefficients, it captures both spatial and temporal variation in non-commuting travel behaviour across demographic and socioeconomic lines. Through this approach, the

research aims to uncover structural inequalities in daily mobility beyond work-related travel, informing the development of inclusive, time-sensitive urban policies that support equitable access to leisure, caregiving, and social opportunities for diverse population groups.

2. Literature Review

Urban mobility contributes significantly to urban sustainability by fostering social cohesion, stimulating economic activity, and reducing segregation (Xu et al., 2018; Bettencourt, 2013; Barbosa et al., 2021). It enables encounters among diverse social groups, breaks down barriers, and supports local economies by facilitating movement across neighborhoods (Chong et al., 2020; Pentland, 2020). As Jacobs (1961) noted, such everyday interactions in public spaces build community and contribute to a more inclusive urban fabric.

Mobility also plays a crucial role in mitigating urban segregation. Studies show that the places people visit for daily activities are often more socially diverse than their residential neighbourhoods (Jones & Pebley, 2014; Pinchak et al., 2021). This exposure to diversity through movement, particularly non-commuting travel, can help offset spatial isolation at home (Boterman & Musterd, 2016; Wang & Li, 2016; Lin & Ta, 2023). For example, Silm et al. (2018) found, using mobile phone data, that activity spaces beyond home and work locations tend to show lower levels of segregation. These findings highlight how everyday mobility fosters social interaction across groups.
Patterns of mobility-based segregation reveal how social divides are mirrored in travel behaviour. In U.S. cities, studies have shown significant racial segregation in mobility patterns (Hilman et al., 2022). Likewise, in Colombian cities, Lotero et al. (2016) found that individuals largely frequented places associated with their own socioeconomic class, indicating a high level of stratification. Dong et al. (2017) further demonstrated how segregation in mobility can reinforce social boundaries rather than build bridges. While South Korea is more ethnically homogeneous, it faces distinct mobility challenges, particularly disparities related to gender, age, and income, which influence who can access which parts of the city.

Built environment research frequently emphasises transport networks as mechanisms for fostering interaction across social groups (Netto et al., 2015; Carpio-Pinedo, 2021). Network centrality analyses, particularly within space syntax, are commonly used to identify highly accessible areas via walking, driving, or public transit (Rokem & Vaughan, 2018; Yunitsyna & Shtepani, 2023). These approaches assess network segregation by mapping the potential for social encounters based on spatial configuration. Expanding on this, Carpio-Pinedo (2021) introduced the concept of multi-accessibility, which captures how multimodal transport infrastructures enhance access and opportunities for social mixing. However, while these methods reveal structural potential, they do not account for actual travel behaviour, which may be constrained by socioeconomic factors, highlighting the need for empirical mobility data.

Recent mobility studies have adopted a dynamic approach to socio-spatial disparities through the concept of activity space, which captures individuals' actual travel behaviours and daily destinations (Barbosa et al., 2021; Gao et al., 2022). This perspective enables a more accurate analysis of segregation by focusing on actual patterns of urban engagement beyond the home and workplace. The increasing availability of large-scale mobility datasets, often linked with demographic attributes, enables researchers to assess how activity spaces differ across social groups. Compared to static network analyses, these data-driven methods offer more nuanced and empirical insights into how mobility behaviours shape access, inclusion, and exclusion in cities.

Several established methods exist to quantify activity space patterns, each capturing different dimensions of mobility behaviour (Barbosa et al., 2021; Yan et al., 2011). These include the gyration radius, which measures how far an individual typically moves from their centre of activity and reflects the spatial spread of movement (González et al., 2008; Yan et al., 2011); the mean activity space distance, which assesses the average travel distance or time, indicating how constrained or expansive one's daily mobility is (Barbosa et al., 2021); and destination diversity, which captures the variety of unique locations visited, often measured through entropy. Higher entropy values reflect broader engagement with the urban environment. Together, these indicators provide a comprehensive view of the magnitude and richness of mobility, enabling the identification of spatial inequalities across demographic and socioeconomic groups. While gyration radius and travel frequency require individual-level trajectory data, activity space distance and destination diversity can be derived from aggregated mobility datasets, making them especially valuable for large-scale spatial equity analysis, such as in this study.

Although age, gender, and income are widely recognised as key determinants of mobility (Panahi et al., 2023), much of the existing research tends to generalise their effects. Many studies focus on demand-side factors, such as transport infrastructure and network connectivity (Seyedrezaei et al., 2023), with limited attention to the actual mobility behaviours of vulnerable groups. Metrics such as activity space size, destination diversity, and temporal variation are essential for diagnosing spatial disparities, yet remain underutilized, particularly in studies relying on small-scale surveys. While large-scale datasets such as GPS and mobile phone records offer more objective and granular insights, their potential for revealing urban mobility inequalities has not been fully realised.

Despite growing theoretical discussions on gendered urban spaces in Korea (Ahn, 2011), empirical research on gendered mobility patterns in Seoul remains limited. This gap is particularly significant given the city's dense, transit-oriented urban form and the critical role that gender plays in shaping access to urban opportunities. At the same time, Korea's rapidly ageing population presents distinct mobility challenges, as older adults often exhibit different travel behaviours due to physical, cognitive, or social constraints (Giménez-Nadal et al., 2024; Arentze et al., 2008). Mobility disparities linked to income also persist, with lower-income individuals facing obstacles such as limited transport options and reduced access to diverse destinations (Yabe et al., 2023). Understanding how gender, age, and income intersect to shape urban mobility is crucial for designing equitable cities. This is particularly urgent in metropolitan areas like Seoul, where, contrary to expectations, residents often experience lower exposure to socioeconomically diverse populations, suggesting that spatial segregation may be more pronounced in cosmopolitan settings than assumed (Nilforoshan et al., 2023).

Socioeconomic factors play a pivotal role in shaping how individuals navigate and utilise urban spaces (Gauvin et al., 2020; Giménez-Nadal et al., 2024; Jo et al., 2020). Variables such as income, education level, and occupation influence where people live, work, and participate in leisure activities (Macedo et al., 2022; Salon & Gulyani, 2010). These characteristics are closely linked to mobility patterns, which reflect a city's broader social and economic structure (Chong et al., 2020). For example, lower-income individuals may lack access to private transportation and rely more heavily on public transit, which limits their spatial reach and activity spaces. Analysing these socioeconomic dimensions helps identify the root causes of spatial inequity and informs the development of targeted policy interventions.

Socioeconomic disparities in mobility have critical implications for inclusive urban planning. Mobility data can guide policies that ensure all residents, regardless of income, age, or gender, have equitable access to services, jobs, and leisure opportunities. By addressing spatial inequalities and anticipating the needs of ageing populations and gender-specific mobility patterns, cities can become more resilient, adaptive, and socially cohesive. In Korean cities especially, demographic trends point to a growing challenge: without proactive planning, elderly residents and women may face increasing constraints in accessing activity spaces (Kim & Kim, 2020). To address these issues, this study employs data-driven methods to investigate spatial and temporal disparities in non-commuting mobility across Seoul.
By focusing on the diverse array of activities beyond the traditional commute, our study contributes to a more nuanced understanding of urban mobility. This perspective is essential for developing more liveable, inclusive, and efficient urban environments, enabling urban planners and policymakers to better address the needs of various demographic groups and foster a more equitable and vibrant city.

3. Methodology

3.1. Data and study area

This study focuses on the city of Seoul, South Korea, which is home to over 9 million residents and characterised by a high-density urban environment. Seoul presents a compelling case for mobility research due to its marked socioeconomic diversity, rapidly ageing population, and spatial disparities in neighbourhood income. We utilise two datasets in this study.

To analyse non-commuting mobility patterns, we employed anonymised large-scale smartphone mobility data from KT (Korea Telecom), made available through the Seoul Open Data Plaza (data.seoul.go.kr). The dataset captures origin–destination (O–D) flows between administrative neighbourhoods (dong level), disaggregated by age, gender, and purpose of travel. Mobility records are timestamped and categorised by trip type, allowing us to isolate non-commuting activities, such as leisure, caregiving, and errands (Table 1). The dataset was also crucial for analysing socioeconomic indicators and their relationship with urban mobility.

Table 1. Structure and visualization of O–D mobility data

Classification	Structure	O-D Visualization
Departure time	yyyy/mm/dd hh:mm (20-min span)	Arrival time	yyyy/mm/dd hh:mm (20-min span)	
Departure area	Neighbourhood unit	
Arrival area	Neighbourhood unit	
Age groups	5-year-old span	
Mobility type	H – residence, W-Work and school, E- Other	
Travel time	Average travel time (minutes)	
Number of people moving	Sum of people moving	

To examine the impact of socioeconomic factors on urban mobility patterns, we used indicators related to age, gender, and income. Age and gender data were sourced from the KT Human Movement dataset, which provides mobility information segmented by 5-year age groups. In addition, we incorporate neighbourhood-level income data from the Smart Policing Big Data Platform, which aggregates mean income estimates to the same spatial units used in the mobility data. This integration allows us to examine how income intersects with age and gender in shaping daily non-commuting mobility across the city.

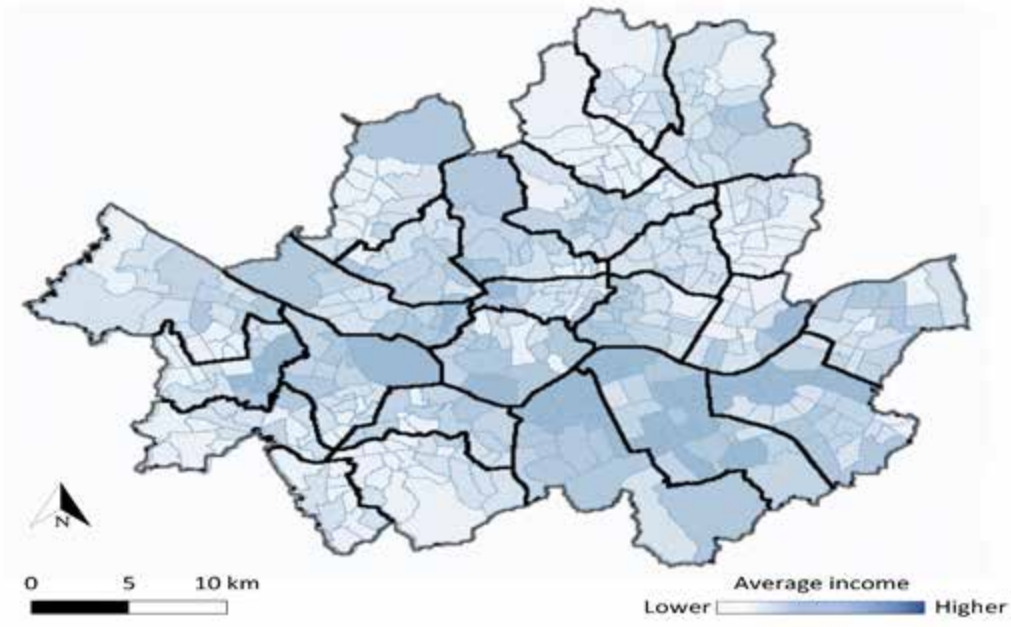

Figure 1. Average income of neighbourhoods in Seoul

3.2. Pattern extraction and processing

We began by preprocessing the origin–destination (O–D) mobility data to remove invalid records (Figure 2). Trips were limited to those within Seoul, with filters applied to exclude identical origin-destination pairs, travel times exceeding 100 minutes to remove implausible trips and outliers, and individuals under the age of 10.

Trip types were classified using purpose codes, and commuting trips (e.g. HW, WH, EH, EW) were excluded. Only non-commuting trips, including EE (other–other), HE (home–other), and WE (work–other), were retained, representing discretionary activities such as leisure, social visits, shopping, and personal errands. Records were grouped into four time periods (morning, daytime, evening, and nighttime) to enable temporal analysis.

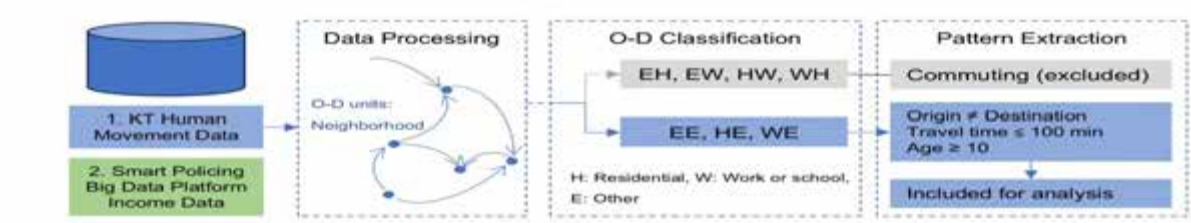

Figure 2. Data Processing and Pattern Extraction Workflow for Non-Commuting Mobility Analysis

The cleaned mobility data were then merged with neighbourhood-level income data using administrative codes. This integration produced a structured dataset disaggregated by gender, age, time of day, and income, which formed the basis for our analysis of activity space distance and destination diversity.

3.3. Mobility and inequality metrics

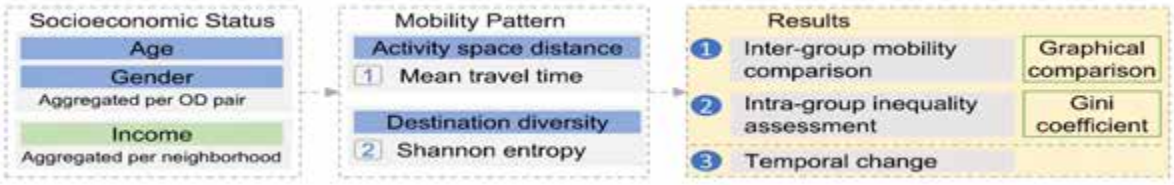

Figure 3. Framework for measuring and comparing socioeconomic disparities in non-commuting mobility

The empirical analysis in this study aims to explore urban mobility patterns within Seoul's neighbourhoods, with a focus on variations across different socioeconomic groups, particularly age, gender, and income. To quantify non-commuting mobility, we employed two key indicators: activity space distance and destination diversity (Figure 3). Activity space distance refers to the average travel time (minutes) from a given origin neighbourhood, weighted by the number of individuals from each socioeconomic group taking each trip. It serves as a proxy for the spatial reach of daily movement. Higher values reflect a broader reach of urban activities, implying that individuals are willing or able to travel longer durations to access diverse areas of the city, while lower values may indicate spatial constraints or reliance on nearby amenities.

To calculate activity space distance, we used the following formula to determine the average travel time for an individual's or group's trips:

$$Activity\ space\ distance = \frac{1}{N}\sum_{i=1}^{N} t_i$$

N is the total number of trips made by within a group during the specified time period,
t_i represents the travel time (in minutes) for each trip from the origin to the destination.

To calculate destination diversity, we used Shannon entropy based following formula:

$$Destination\ diversity = -\sum_{i} p_i \log_2(p_i)$$

where;
p_i is the proportion of visits to destination i relative to the total number of visits across all destinations for a person or group.

Next, destination diversity is measured using Shannon entropy (log scale), which captures the variety and evenness of destination choices. Entropy values increase with the number and distribution of unique destinations, providing insight into how dynamic or concentrated a socioeconomic group's urban engagement is. A higher entropy value indicates that a person visits a wider range of destinations, suggesting a more varied and dynamic urban experience. In this study, entropy was calculated for each gender–age group and income level, across four daily time periods. Using graphical visualizations, first, we showed intergroup mobility comparison between different socio-economic groups.

Secondly, to assess intra-group inequality in mobility access within the same socioeconomic groups, we computed the Gini coefficient for both indicators across neighbourhoods. This metric reveals how equally activity space distance or destination diversity is distributed within demographic groups. A higher Gini suggests greater internal disparity, some individuals in the group are more mobile or spatially privileged than others. This approach allows us to capture not just average behaviour, but also equity of mobility access within each group. The formula for Gini coefficient is as follows:

$$G = \frac{\sum_{i=1}^{n}\sum_{j=1}^{n}|x_i - x_j|}{2n^2\bar{x}}$$

Where x_i and x_j represent values of the mobility indicator for each neighbourhood, n is the number of observations, and $\bar{x}$ is the mean value of the indicator.

Thirdly, we examined temporal variation in mobility by dividing the day into four distinct periods: morning (06:00–08:59), daytime (09:00–15:59), evening (16:00–18:59), and nighttime (19:00–23:59). This segmentation captures fluctuations in mobility behaviour across the daily cycle, allowing us to observe how different demographic groups engage with the city at various times. For example, working-age adults may be more active during rush hours, while older adults may concentrate their trips in midday periods. This temporal lens was applied not only in the graphical inter-group analysis, but also in the intra-group inequality assessment, enabling us to investigate whether mobility disparities persist or vary by time of day.

Together, these metrics support a multidimensional understanding of urban mobility: activity space distance reflects the scale of movement, entropy captures spatial diversity, and the Gini coefficient uncovers hidden inequalities in access. This framework enables us to examine how age, gender, and income shape not only who moves, but also how equitably urban opportunities are distributed among similar individuals

4. Results

This section presents the main findings on non-commuting mobility. Results are organised into two parts: inter-group differences across age, gender, and income groups, and intra-group disparities within the same socio-economic groups at the neighbourhood level. We first report patterns in activity space distance and destination diversity, followed by an assessment of inequality using the Gini coefficient.

4.1. Inter-group differences in mobility

In this investigation, we focused on urban mobility, examining activity space distance and destination diversity, to understand demographic differences in urban movement patterns across Seoul.

4.1.1 Activity space distance

Figure 4 and Figure 5 illustrate gender and age differences in activity space distance across four daily time periods. These periods, morning, daytime, evening, and nighttime, were defined to reflect typical daily rhythms in urban life, capturing commuting hours, discretionary travel, and evening activities. This temporal segmentation enables a more nuanced understanding of how mobility patterns shift across the day. While some trends remain consistent, such as the reduced mobility of older adults and children under 15, other patterns, particularly gender gaps among younger groups, vary considerably depending on the time of day.

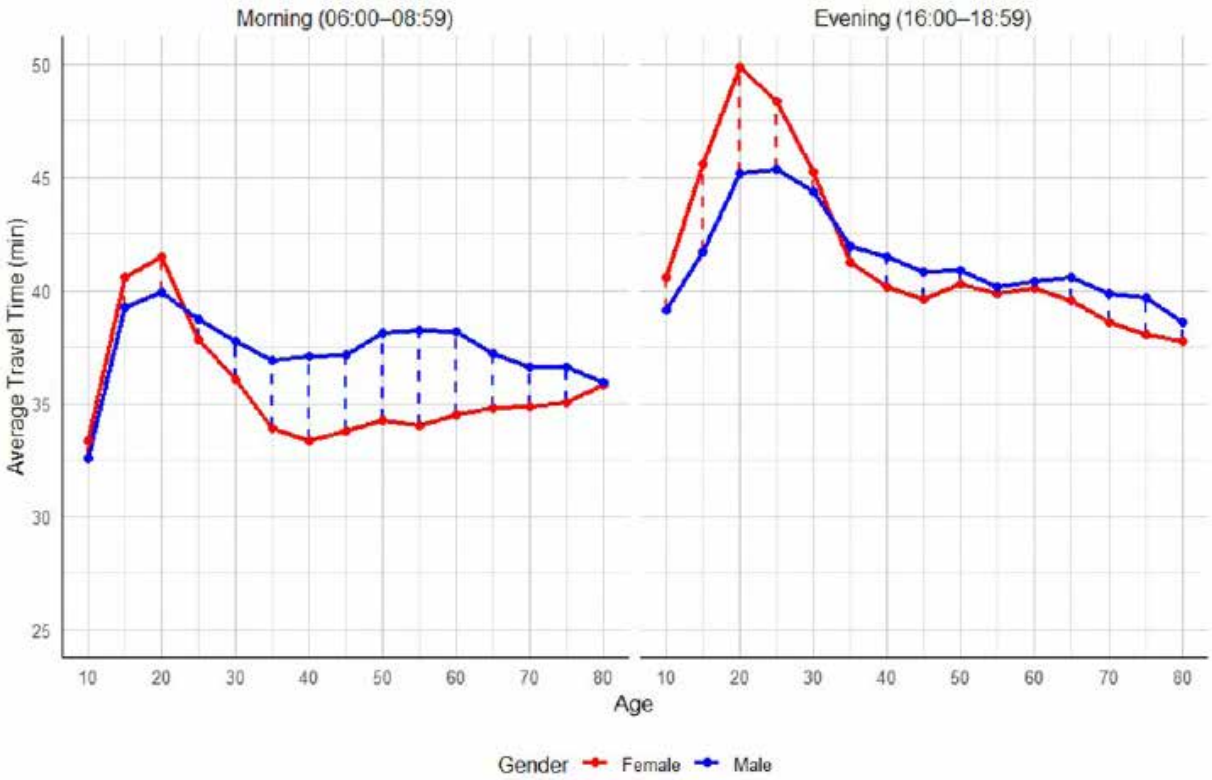

Figure 4. Gender and age differences in average travel time across morning and evening.

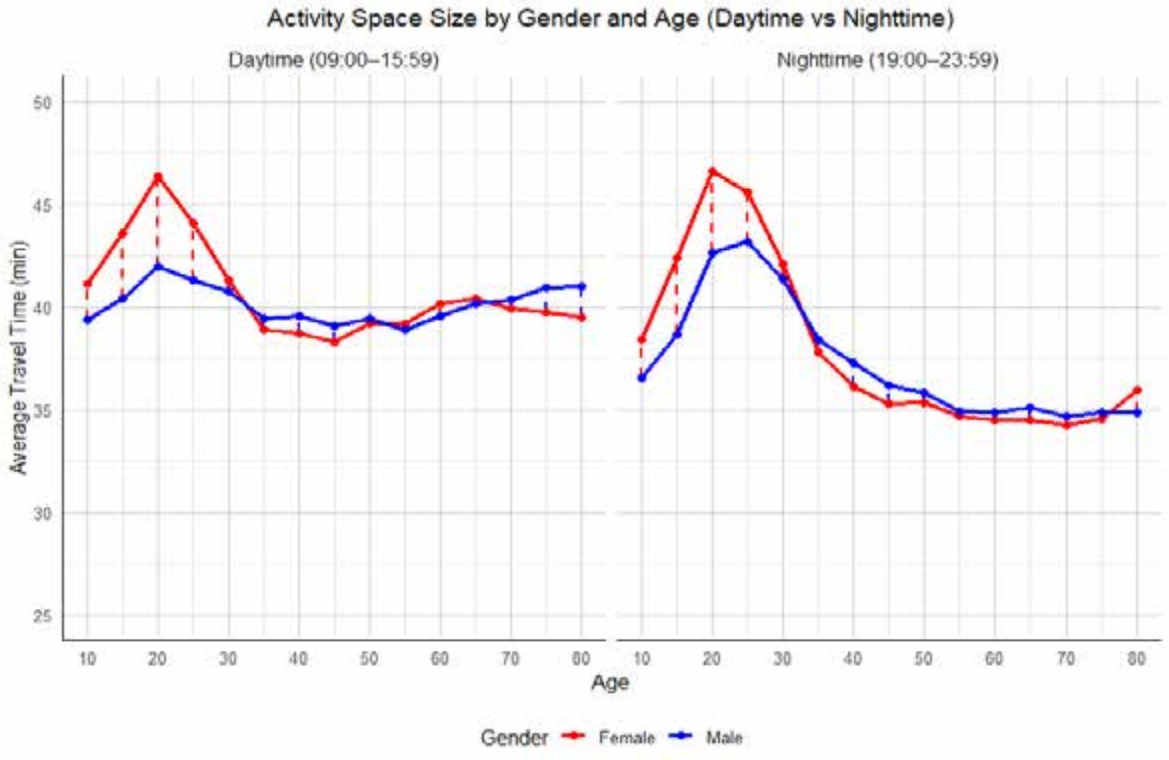

Figure 5. Gender and age differences in average travel time across daytime and nighttime

During the morning period, activity space distance is relatively short compared to the other three periods, suggesting more spatially constrained leisure or caregiving activities in the early hours. As the day progresses, travel distances increase, peaking during the daytime and remaining relatively high into the evening, before declining slightly at night. When disaggregated by gender and age, individuals in their 20s and 30s consistently exhibit the greatest spatial reach, while children under 15 and older adults maintain shorter travel ranges across all periods. The generational mobility gap is most pronounced during the evening and nighttime.

Gender differences are most notable in the morning, where men over the age of 25 tend to travel farther than women in the same age group. In other time periods, this gender gap among adults narrows. However, across the daytime, evening, and nighttime, young women under the age of 25 consistently travel farther than young men, likely reflecting their engagement in discretionary activities such as shopping or social visits. This trend stabilises after age 30, where gender differences become minimal.

Next, we examined how neighbourhood income influences travel distance across daily periods (Figure 6 & Figure 7). The results reveal a clear negative association between income and activity space distance during the morning (06:00–08:59), where residents of lower-income neighbourhoods tend to travel farther than those from higher-income areas. This trend is supported by a moderate R^2 value of 0.31, indicating a meaningful level of explanatory power. The pattern may reflect unequal distribution of leisure or essential amenities, forcing residents in less affluent areas to travel farther during early hours to reach services located in wealthier parts of the city.
During the daytime, however, the relationship between income and travel distance almost disappears (R^2 = 0.008), suggesting a more level playing field for mid-day mobility regardless of income. In the evening and nighttime, the association reverses slightly, particularly in the evening (R^2 = 0.119), with higher-income residents exhibiting longer average travel distances. This shift could be attributed to lifestyle-related discretionary activities, such as dining or cultural outings, which are more accessible to wealthier populations. These findings demonstrate how mobility inequality fluctuates throughout the day, with structural limitations more pronounced in the morning and lifestyle-based divergence emerging later in the day.

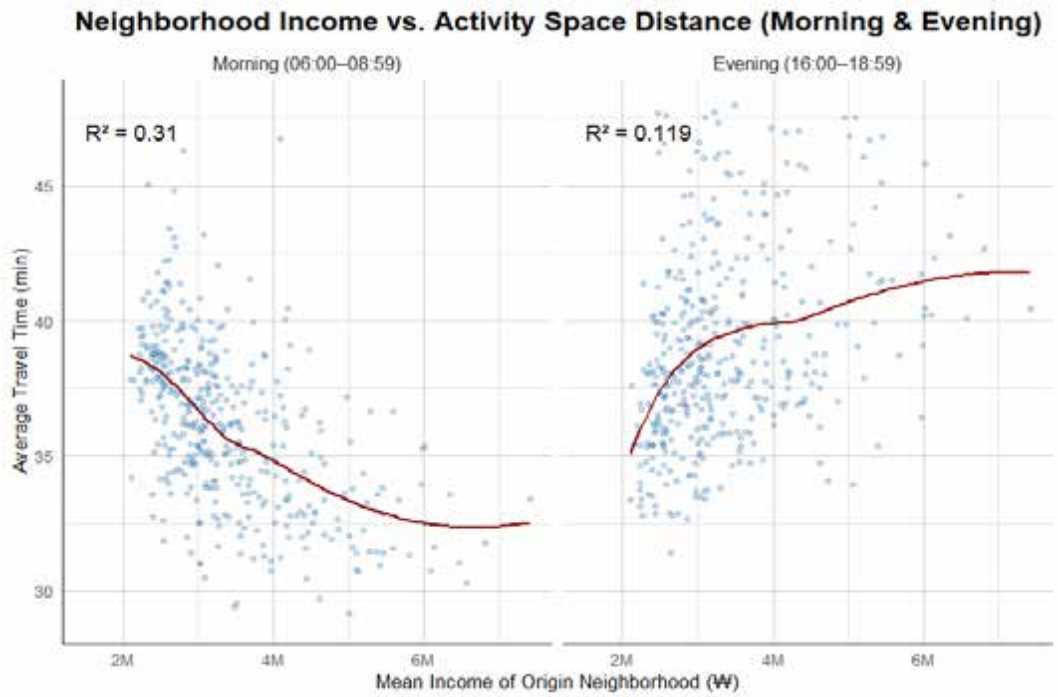

Figure 6. Neighbourhood income levels and average travel time across morning and evening

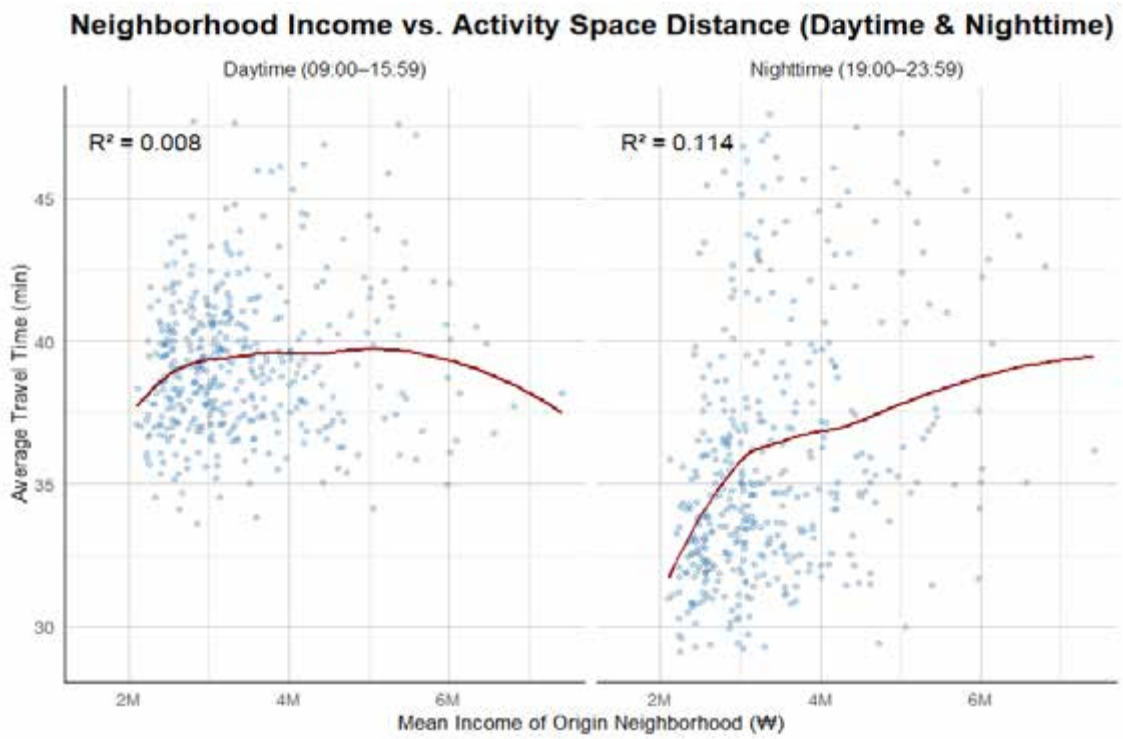

Figure 7. Neighbourhood income levels and average travel time across daytime and nighttime

While the income-travel time correlation is relatively weak, these observations provide valuable insights for transportation planning, as income-level disparities impact accessibility and the spatial distribution of activity spaces across the city.

4.1.2 Destination diversity

Our second investigation of inter-group mobility differences, destination diversity, is measured using Shannon entropy. It captures the extent to which individuals or groups visit a wide range of neighbourhoods during non-commuting trips. Unlike activity space distance, which measures the scale of travel, entropy captures the variety and distribution of destinations, reflecting the breadth of urban engagement. Higher values indicate more diverse mobility patterns and potentially greater access to urban opportunities, while lower values suggest spatial confinement or routine-based travel. Entropy is particularly useful for identifying subtle mobility inequalities, where long distances may mask limited exposure to different areas.

Figure 8 and Figure 9 Illustrate gender and age differences in destination diversity across four daily time periods. Patterns of destination diversity show distinct trajectories for men and women. Notably, children under 15 and elderly individuals over 60 exhibit generally lower destination diversity across both genders, suggesting that these groups tend to frequent a smaller, more consistent set of locations in their daily non-commuting activities. However, the gap between the two genders is small in both the early and later stages of life.

For women, entropy peaks in the 20–25 age group across all time periods and declines steadily with age, suggesting that younger women are more likely to engage with a broader set of destinations, possibly linked to lifestyle, education, or social activities. After age 25, their spatial diversity gradually narrows, reflecting more routine-based mobility or caregiving responsibilities. In contrast, men exhibit a more sustained level of high entropy between the ages of 25 and 60, particularly during the morning and daytime, with a peak around age 45 in the morning period. This implies that adult males maintain a broader range of destination choices throughout middle adulthood. However, during nighttime, men's entropy declines more rapidly after age 30, mirroring the trend observed in women. These gendered patterns highlight how mobility diversity is shaped not only by age but also by differing social roles and temporal rhythms across the day.

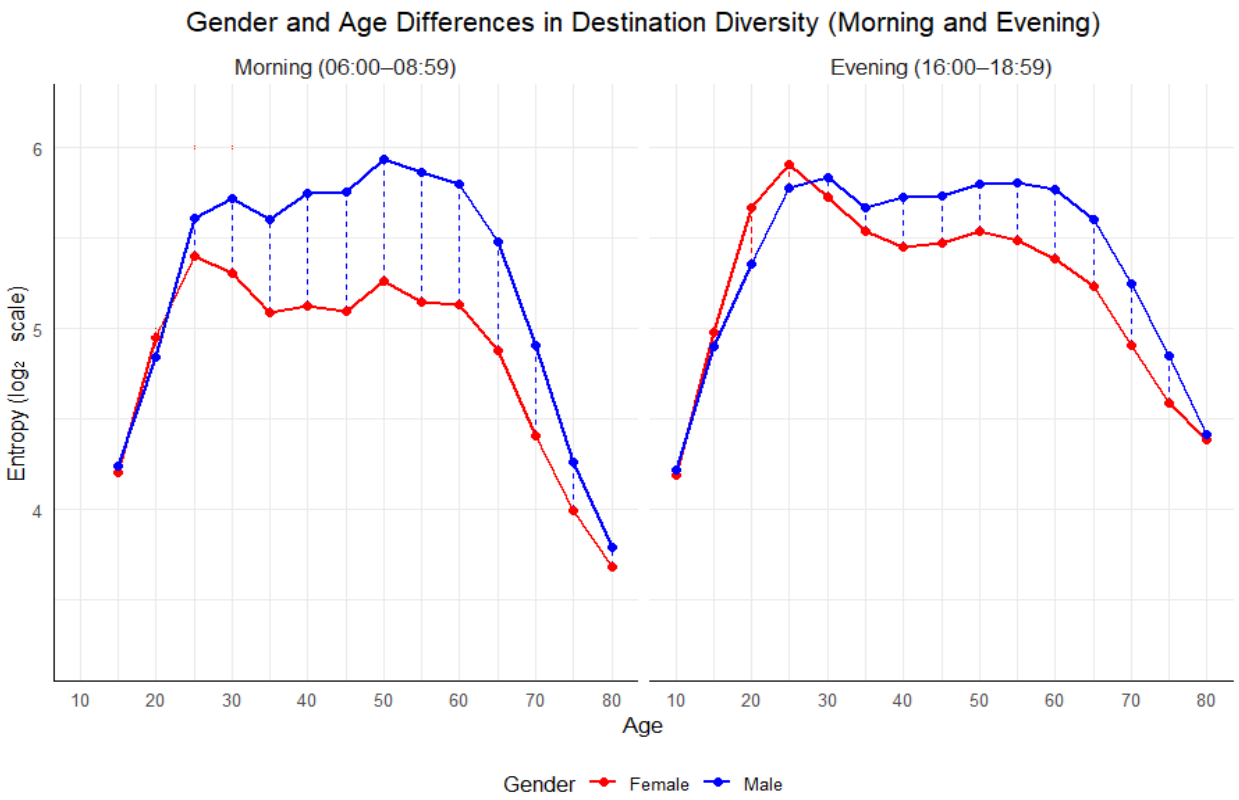

Figure 8. Gender and age differences in destination diversity across morning and evening.

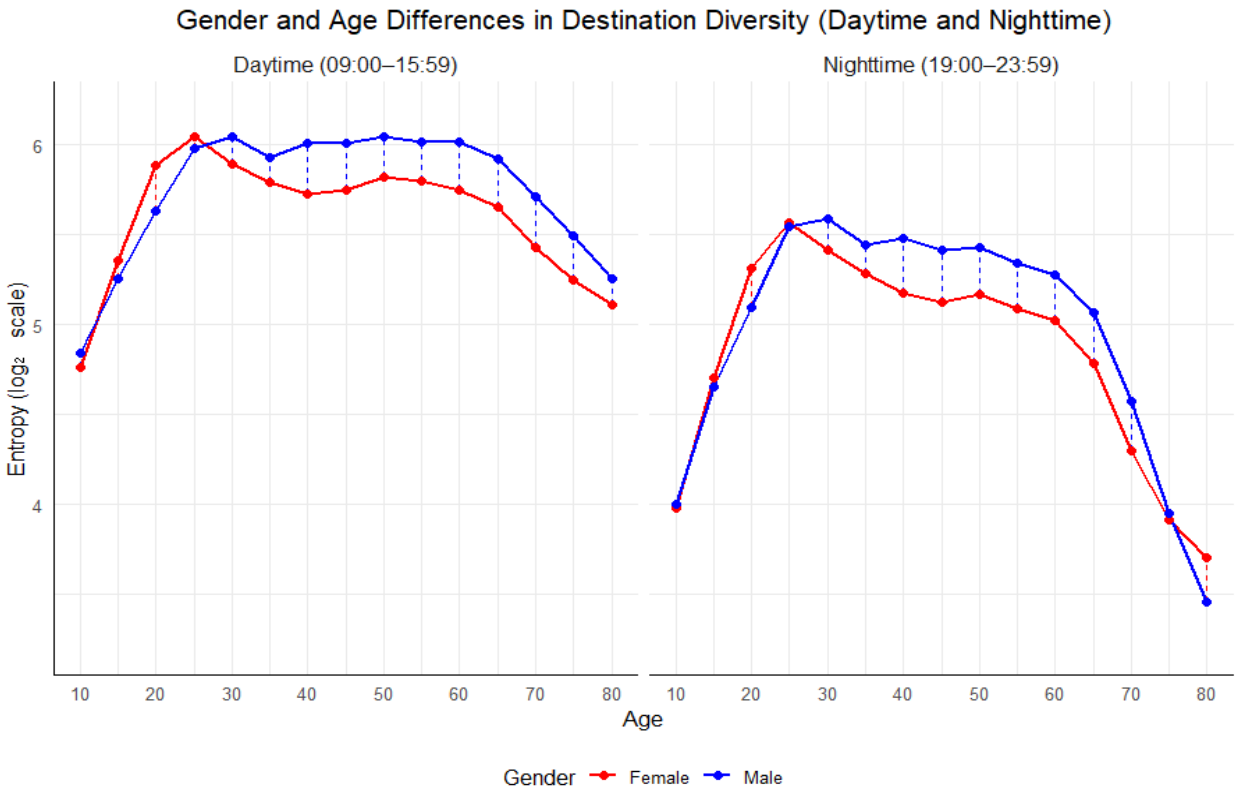

Figure 9. Gender and age differences in destination diversity across daytime and nighttime

Next, we examined how neighbourhood income levels influence destination diversity across four daily time periods (Figure 10 & Figure 11). The analysis reveals a distinctive temporal pattern. In the morning period (06:00–08:59), individuals from higher-income neighbourhoods display lower entropy, indicating more routine-based or spatially confined travel. Higher-income residents might be more likely to engage in early morning activities that are routine and closer to home, such as visiting local parks or cafes, which are less diverse in nature compared to activities later in the day. This contrasts with the rest of the day, when entropy increases with income, suggesting that wealthier individuals engage with a broader variety of urban destinations. This shift reflects the greater flexibility and resources that higher-income groups have to access a diverse range of activities across the city. These results highlight how spatial inequality unfolds throughout the day. While high-income residents initially show lower diversity in the morning, their access to varied destinations expands in later periods. In contrast, lower-income groups consistently exhibit more limited spatial diversity, suggesting constraints in reaching a broad range of urban amenities. This persistent disparity may reduce opportunities for social interaction and urban participation, highlighting the need for policy efforts that enhance access to diverse destinations in underserved areas. The observed differences in destination diversity highlight the need for targeted urban planning interventions to address the specific mobility needs and constraints of different demographic groups, promoting more equitable access to urban resources and opportunities. This intervention not only promotes social equity but also enhances the overall vibrancy and sustainability of urban communities.

Figure 10. Income factor in destination diversity across morning and evening

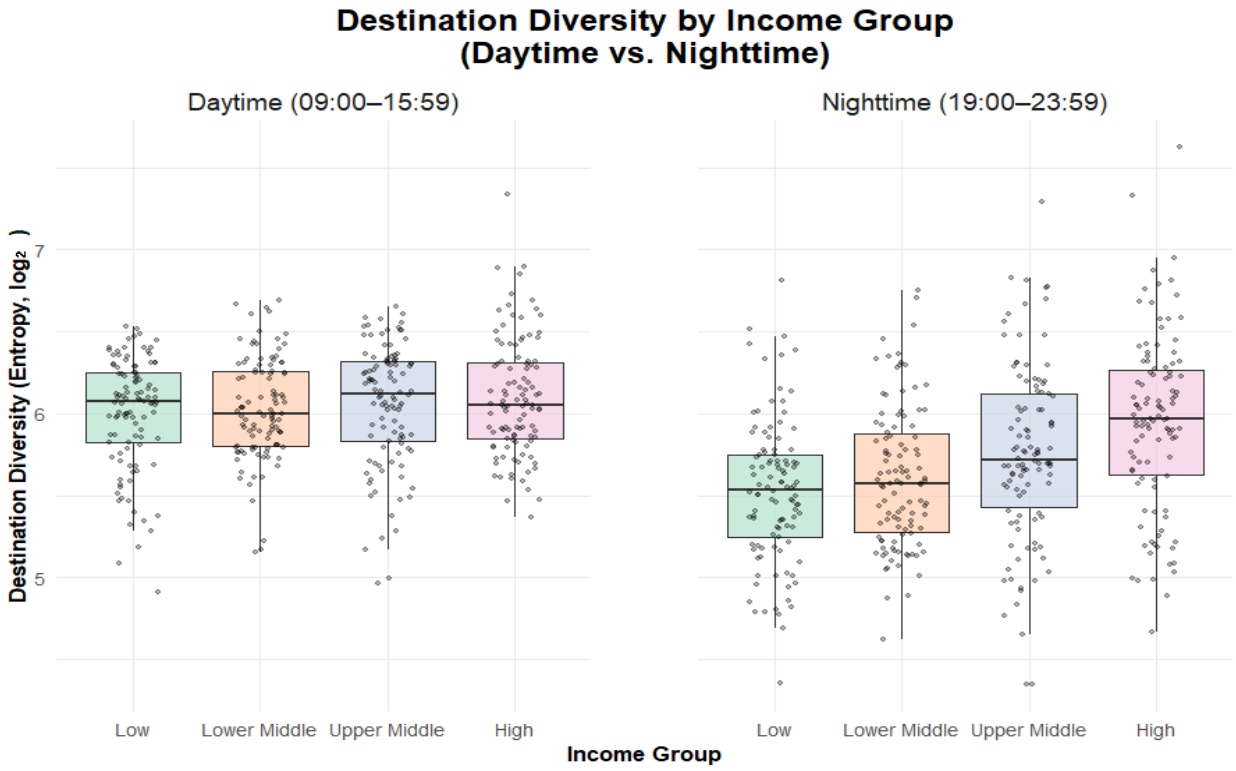

Figure 11. Income factor in destination diversity across daytime and nighttime

4.2. Intra-group mobility inequality

To complement inter-group comparisons, we calculated Gini coefficients for both activity space distance and destination diversity across Seoul's neighbourhoods, segmented by age group, gender, income group, and time of day (Table 2 & Table 3). These inequality metrics provide a more profound insight into intra-group spatial disparity, revealing the varied mobility experiences within the same demographic or income bracket. While average values describe general mobility levels, the Gini coefficient highlights how unevenly mobility is distributed within groups. A higher Gini value indicates greater internal disparity, suggesting that some individuals enjoy broader spatial access while others remain more constrained. This approach allows us to uncover hidden inequalities in access to urban opportunities, even among individuals who share similar socioeconomic characteristics.

The Gini coefficients for activity space distance reveal notable intra-group disparities across both demographic and income groups (Table 2). Among age groups, younger individuals under 25 exhibit the highest inequality, particularly in the morning (Gini = 0.109 for males; 0.110 for females), suggesting that travel opportunities within this group vary widely depending on neighbourhood context. In contrast, middle-aged adults (35–60) consistently exhibit low Gini values across all time periods, indicating more uniform spatial behaviour within this group. Gender differences are minimal overall, though young women display slightly higher inequality than their male counterparts during the evening and nighttime periods.

Table 2. Intra-group inequality in activity space distance (Neighbourhood-level Gini coefficients)

Socioeconomic Factors			Gini coefficient of Activity Space Distance (unit = neighbourhood)			
			morning	evening	daytime	nighttime
Age / Gender	Under 25	M	0.109	0.077	0.051	0.081
		F	0.110	0.081	0.055	0.087
	25-34	M	0.074	0.065	0.047	0.081
		F	0.073	0.071	0.054	0.092
	35-60	M	0.073	0.059	0.042	0.066
		F	0.067	0.061	0.044	0.068
	60+	M	0.075	0.057	0.040	0.080
		F	0.079	0.063	0.041	0.079
Income	Low		0.083	0.060	0.046	0.072
	Lower-Middle		0.082	0.060	0.046	0.073
	Upper-Middle		0.081	0.071	0.050	0.088
	High		0.081	0.069	0.054	0.084

When examining income groups, the distance between activity spaces becomes more unequal among higher-income groups, especially during evening and nighttime hours. This may reflect greater individual variation in lifestyle flexibility and mobility choices among wealthier residents. Additionally, the spatial heterogeneity of affluent neighbourhoods may contribute to this disparity, as some high-income areas are centrally located with dense access to amenities. In contrast, others are situated in more suburban or secluded zones. This geographic variation could lead to differing levels of dependency on travel, thus widening intra-group inequality. Conversely, lower-income groups exhibit slightly more constrained but uniform mobility patterns, likely reflecting shared limitations in transportation access and discretionary travel options. Temporal differences are also evident: inequality is generally lowest during daytime, suggesting that mobility is more evenly distributed across groups in midday hours compared to mornings or evenings. The Gini coefficients for destination diversity highlight additional layers of inequality within socioeconomic groups (Table 3). Unlike activity space distance, which reflects the extent of spatial reach, entropy-based Gini values capture variation in the diversity of urban experiences. The analysis reveals that younger age groups, particularly those under 25, consistently exhibit the highest intra-group inequality across all time periods, especially during the morning and evening hours. This suggests that while some young individuals engage with a wide range of destinations, others in the same group remain limited to a narrow set of familiar locations. In contrast, older adults (60+) display more consistent and lower levels of entropy inequality, reflecting relatively uniform, though limited, mobility behaviour across this group.

Table 3. Intra-group inequality in destination diversity (Neighbourhood-level Gini coefficients)

Socioeconomic Factors			Gini coefficient of Destination Diversity (unit= neighbourhood)			
			morning	evening	daytime	nighttime
Age / Gender	Under 25	M	0.141	0.083	0.062	0.090
		F	0.154	0.092	0.070	0.099
	25-34	M	0.053	0.040	0.037	0.054
		F	0.055	0.043	0.039	0.060
	35-60	M	0.046	0.048	0.035	0.059
		F	0.051	0.053	0.037	0.066
	60+	M	0.105	0.083	0.050	0.121
		F	0.095	0.082	0.052	0.106
Income	Low		0.119	0.078	0.057	0.095
	Lower-Middle		0.112	0.077	0.053	0.094
	Upper-Middle		0.109	0.077	0.055	0.102
	High		0.099	0.075	0.051	0.096

Gender patterns are also notable: while overall differences between males and females are small, women consistently exhibit higher inequality in destination diversity compared to their male counterparts. This may reflect a divergence in lifestyle and access, where some women participate in diverse activities across the city. In contrast, others remain more spatially restricted due to social or safety concerns. As with activity space distance, the middle-aged group (35–60 years old) shows the most uniform diversity patterns across neighbourhoods.

Across income groups, the highest Gini values are observed in high-income neighbourhoods, particularly during daytime and nighttime hours. This mirrors the pattern observed in activity space distance and likely stems from the same spatial heterogeneity of affluent areas, some offering rich, central amenities and others being more peripheral. In contrast, lower-income groups exhibit more uniform but limited diversity, highlighting again the shared constraints in their activity space. These results highlight that even within high-mobility groups, inequality in access to urban variety persists, with some individuals enjoying rich urban experiences while others remain excluded.

Across income groups, differences in Gini values for destination diversity are relatively modest, but a few patterns emerge. In the morning, lower-income neighbourhoods show slightly higher inequality, suggesting that access to diverse destinations may be more uneven at the start of the day. And, in general, inequality is lower in daytime and evening for all income groups.

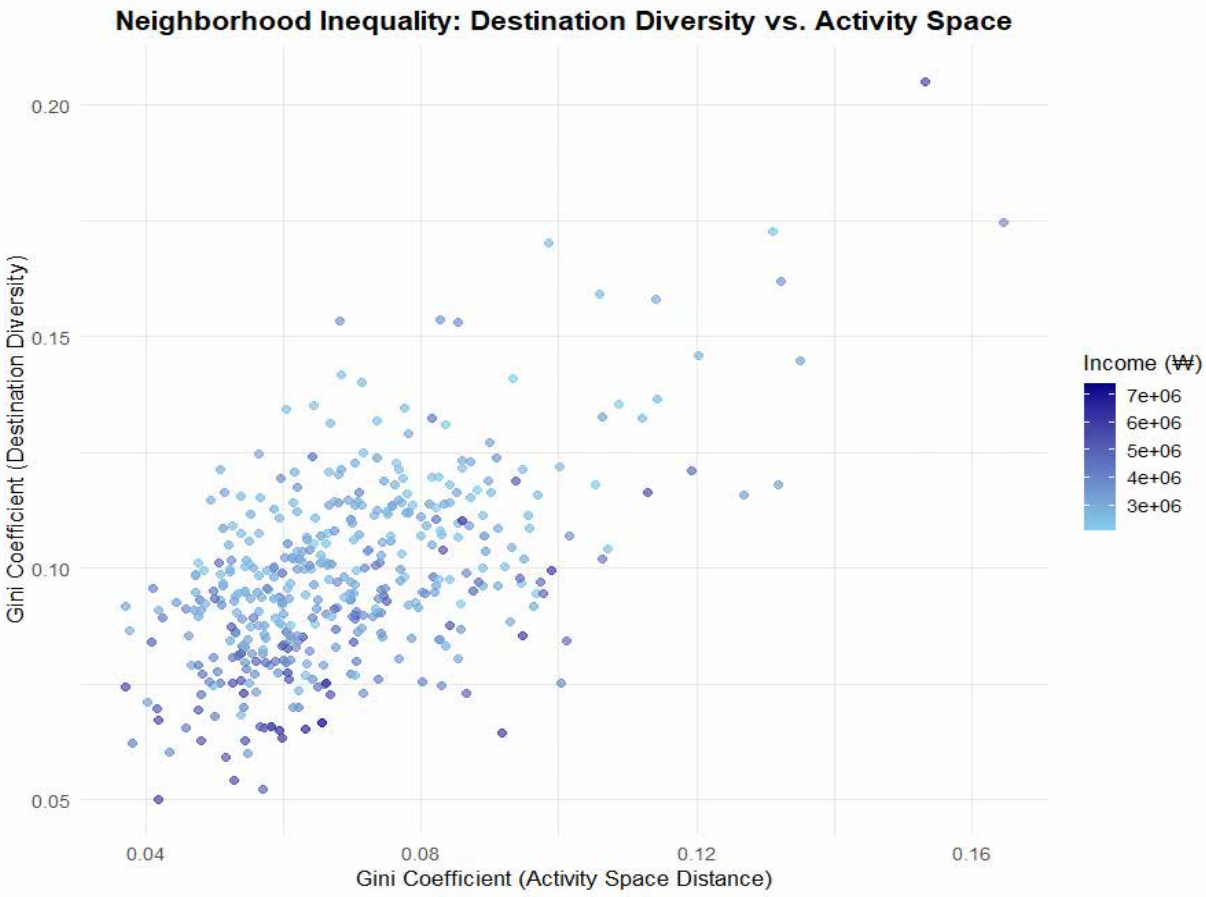

Figure 12. Relationship between intra-neighbourhood inequality in activity space distance and destination diversity. Each dot represents a Seoul neighbourhood; colour intensity reflects average neighbourhood income.

Figure 12 presents a bivariate relationship between neighbourhood-level inequality in activity space distance and destination diversity, with each dot representing a Seoul neighbourhood and coloured by average income level. The weak positive trend suggests that these two dimensions of spatial inequality are related but not strongly correlated, indicating that they capture different aspects of mobility disparity. While some neighbourhoods show low inequality in both metrics, others experience high disparity in either scale or diversity of movement. Notably, higher-income areas (darker dots) appear across a wide range of Gini values, reinforcing earlier findings that wealth does not necessarily imply internal equity. This figure underscores the importance of analysing both activity space and destination diversity to fully understand the multi-faceted nature of urban mobility inequality.

5. Discussions and Conclusions

5.1. Discussions

This study examined non-commuting mobility patterns in Seoul using large-scale smartphone data, focusing on the spatial scale and diversity of daily movement across different socioeconomic groups. We found clear inter-group disparities: higher-income individuals and those in their 20s and 30s travelled farther and engaged with a broader range of destinations. At the same time, older adults and children exhibited more spatially confined routines. Gender differences were more complex; middle-aged women tended to show reduced spatial reach, likely due to caregiving roles or safety concerns, whereas younger women displayed broader destination diversity, especially during daytime and evening hours.

In addition to group-level differences, we revealed substantial intra-group inequalities by calculating Gini coefficients for both activity space distance and destination diversity. These disparities were especially pronounced in young individuals and high-income neighbourhoods. Temporal segmentation further revealed how mobility inequalities shift throughout the day; morning periods exhibited more uniform travel patterns, while

evening and nighttime hours amplified these disparities. Together, these findings highlight that urban mobility is stratified not only across but also within demographic and income groups, necessitating multidimensional and time-sensitive approaches to equity analysis.

This study provides new theoretical insights into how socioeconomic status affects both the scale and diversity of urban mobility. By employing two complementary indicators —activity space distance and destination diversity —we demonstrate that these dimensions, together, provide a nuanced understanding of spatial inclusion. Higher mobility is not just about travelling farther, but also about engaging with a broader array of destinations, each essential for capturing different facets of urban opportunity and interaction.

Our findings reinforce the value of temporal segmentation in mobility analysis. By examining morning, daytime, evening, and nighttime periods separately, we uncover dynamic patterns that would be masked in daily aggregates. Gender disparities, for instance, are not static: younger women display high diversity during the daytime and evening, while the gap narrows or reverses at other times. Similarly, older adults consistently exhibit reduced mobility diversity, suggesting age-related constraints that persist regardless of time. These findings extend earlier work (Gauvin et al., 2020; Zhou et al., 2022) by demonstrating how gender- and age-related disparities in mobility persist across different groups and vary over time. For instance, the gap between genders for both activity space distance and destination diversity of adults (30-60) is highest in the morning. This reinforces the importance of temporally sensitive planning strategies.

Our findings reveal notable variations in mobility patterns across women's life stages. Women under 30 display higher mobility diversity and longer travel distances, likely reflecting more flexible lifestyles and fewer caregiving responsibilities. However, this trend reverses after the age of 30, when mobility becomes more localised, suggesting increasing spatial constraints linked to societal expectations around work and family. On the other hand, for both genders, mobility inequality is highest among younger individuals under 25. This may reflect differing levels of family dependence or opportunity; some youth experience greater autonomy and flexibility in their daily routines. In contrast, others remain more constrained by family obligations or limited resources. These findings extend urban mobility theory by demonstrating how gendered and generational life-course transitions influence spatial behaviour, and they underscore the importance of policies that address mobility equity across different life stages.

Importantly, we argue that activity space distance and destination diversity function as proxies for access to urban social and economic life. Broader activity spaces and richer destination portfolios increase opportunities for interaction, participation, and inclusion. These mobility patterns should therefore be seen not only as behavioural outcomes but also as indicators of underlying urban equity, or lack thereof. As Jacobs (1961) argued, diverse, interconnected urban experiences are key to vibrant city life; our findings show how mobility constraints limit these opportunities for certain groups.

While our study interprets broader activity spaces and greater destination diversity as indicators of opportunity and inclusion, it is important to acknowledge that these patterns do not universally reflect enhanced access or well-being. In some cases, longer travel distances may result from a lack of proximate amenities—indicating spatial exclusion rather than mobility freedom. Conversely, shorter travel distances can signal either convenience and sustainability, or constraints imposed by social, economic, or physical barriers. This duality underscores the complexity of interpreting activity space distance. For instance, the principles of the n-minute city (Moreno et al., 2021) emphasise the benefits of proximity-based living, where diverse urban functions are accessible within a short distance, supporting convenience, equity, and environmental sustainability. From this lens, high mobility may sometimes reflect urban inefficiencies rather than voluntary engagement. While destination diversity is often a clearer indicator of social interaction and urban integration, it too must be contextualised. Future research should distinguish between proximity by choice and proximity by constraint, ideally by integrating mobility data with spatial, social, and qualitative indicators to better understand the lived experience behind observed patterns.

The findings of this study carry important implications for designing more equitable and inclusive urban policies. First, the consistent disparities observed across age, gender, and income groups suggest the need for targeted interventions to support the mobility of underrepresented populations, particularly elderly residents,

lower-income individuals, and middle-aged women. Enhancing access to diverse and proximate amenities in underserved neighbourhoods can reduce spatial exclusion and promote urban sustainability. Furthermore, by promoting broader spatial engagement, as highlighted by Wang et al. (2024), infrequent, non-commuting activities can have a significant impact on economic outcomes. Second, the temporal segmentation of mobility patterns highlights that inequality fluctuates across the day, signalling an opportunity for time-sensitive policies, such as improving nighttime transit services or ensuring daytime safety for women and elderly populations. Third, planners should adopt a multidimensional framework that integrates both activity space distance and destination diversity into accessibility metrics. For instance, Zhou et al. (2022) demonstrated that elderly individuals rely heavily on public transport to access essential services. This should also be considered in relation to daily time periods. Rather than focusing solely on commute distances, future urban planning should account for the richness of everyday spatial engagement as a measure of urban inclusion. By doing so, cities can move closer to the ideals of the 15-minute city, where all residents, regardless of socioeconomic background, can access opportunities within reach, by choice rather than by constraint.

While this study provides valuable insights into non-commuting mobility patterns using large-scale smartphone data, several limitations must be acknowledged. First, the analysis is based on aggregated origin–destination flows at the neighbourhood level, which restricts our ability to fully capture individual-level variability or motivations behind trips. Second, although we isolate non-commuting trips, the categorisation of trip purposes may still contain ambiguities, especially in overlapping activities such as shopping combined with caregiving. Third, the study is limited to Seoul, a highly transit-oriented and socioeconomically stratified city; thus, findings may not be directly generalisable to cities with different spatial forms or transit systems. Fourth, mobility patterns were examined without direct integration of spatial built environment variables, such as walkability, land use mix, or centrality, which may influence both activity space distance and diversity. Finally, while entropy and travel distance serve as useful proxies for mobility inequality, they do not capture subjective dimensions such as perceived safety, comfort, or purpose-driven constraints, factors that could enrich the interpretation of disparities across groups. These limitations underscore the need for future studies combining spatial metrics with qualitative and survey-based insights to fully understand the drivers of mobility inequality.

Additionally, while this study emphasizes income as a key factor shaping mobility, neighbourhoods with similar income levels may exhibit distinct spatial characteristics, some of which are centrally located with high accessibility. In contrast, others are more peripheral and residential. These locational differences can influence both the scale and diversity of activity spaces. Future research should therefore incorporate centrality or spatial accessibility metrics to understand better how socioeconomic and geographic factors interact to shape mobility patterns.

5.2. Conclusions

This study highlights that spatial equity in non-commuting mobility is not only a question of access, but a critical dimension of urban sustainability and social justice. By analysing activity space distance and destination diversity through entropy and Gini coefficients across different times of day, we reveal how socioeconomic factors, particularly age, gender, and income, shape both the extent and equity of mobility in Seoul. The combination of these indicators with temporal segmentation offers a novel, multidimensional perspective on urban mobility patterns, providing actionable insight into where and when mobility inequalities are most pronounced.

Looking forward, future research could build on this work by employing longitudinal data to observe how mobility patterns evolve over time in response to urban development or policy interventions. Comparative studies across cities with varying spatial forms and transport systems could also deepen understanding of contextual influences. Furthermore, integrating mobility metrics with built environment features, such as land use diversity, connectivity, or centrality, and incorporating qualitative perspectives from residents could help uncover the lived experience behind the numbers. Such approaches will be essential for designing urban environments that are not only efficient but also inclusive, responsive, and just.

Future research could also explore the underlying social, cultural, and institutional factors that shape the observed disparities in activity space distance and destination diversity, helping to unpack not just where and when disparities occur, but why they persist. For example, the widening gender gap in both mobility scale and diversity after the age of 30 warrants further examination, particularly in relation to caregiving roles, workplace

expectations, or safety perceptions. Comparative studies across different cultural or urban contexts would also help to validate and expand these findings. In addition, evaluating the effectiveness of time-sensitive interventions, such as enhancing nighttime accessibility for older adults or increasing the diversity of amenities in underserved areas, could offer practical guidance for inclusive mobility planning.

Abstract
The development of railway station areas hinges on their transition from "transfer hubs" to "destinations," where the scale and structure of passenger flows determine how built environments respond to traveler needs. Traditional node-place models often characterize station node attributes using volatile metrics like passenger volume or train frequency. This study selects 49 railway stations in China's most economically developed region, constructing a multilayer L-space rail complex network model from timetable data to investigate how nodal attributes across distinct rail networks influence Passenger Staying Rate and Passenger Structure. Key findings reveal that the Economically-Weighted PageRank (integrating city GDP) in the Integrated Rail Network exhibits significant correlations with all passenger-related metrics. Ultimately, a "Node-Passenger" analytical framework is established, offering new perspectives for railway station area development.

Keywords: Station areas; multi-scale accessibility; multi-centrality analysis; node-place model

1. Introduction

The emergence of high-speed rail (HSR) technology heralds the advent of the "Second Railway Era," further compressing spatiotemporal distances between cities. This acceleration has intensified intercity rail passenger flows, significantly boosting urban economic growth and regional integration. Within this context, as noted by Professor Edwards of the University of Sheffield School of Architecture in The Modern Station: New Approaches to Railway Architecture, "Railway stations stand as integral elements of urban life and culture. Their unique significance stems from serving as interfaces between 'two worlds'—the convergence points of railway systems and urban ecosystems."(Edwards, 2013). The railway system, a network of constant flow, has railway passenger stations as its nodes. In contrast, the urban system is where people live and conduct various activities, functioning as a place. Nodes represent movement and transfer, while places imply stays and activities. As a key public space in cities, the development of railway station areas hinges on transforming stations from mere transfer points to destinations for diverse social interactions. This shift not only saves time for time-sensitive passenger groups like business and commuter travelers but also reduces overall transportation costs and alleviates environmental pollution from urban congestion and car dependency (Carlton, 2009).

Since the launch of its high-speed rail system in 2008, China has witnessed the rapid development of its high-speed rail network. However, there remain significant differences between China's railway passenger structure and that of Europe and Japan. In China, long-distance travelers constitute a larger proportion, whereas the number of commuters and business travelers is relatively smaller. Variations in passenger volumes and the composition of passenger types at different stations place diverse demands on the built environment of station areas. As conduits for transporting various passenger flows, is there a relationship between the configuration of different railway networks and the types of passenger groups they serve? Can this relationship be observed at the meso-scale level of station areas?

To answer these questions, Section 2 provides a review of relevant literature, Section 3 outlines the methodological approach, data sources, and study scope, and Section 4 presents and analyzes the research findings. Finally, Section 5 concludes the study.

2. Literature Review

The classic Node-Place model proposed by Bertolini(1999), has been widely used in station typology research and in analyzing development strategies for station areas—that is, assessing whether a station area should further develop its "place" functions or enhance its "node" functions. This model has been extensively applied around

the world, including in the Netherlands, Japan, and Australia(Chorus and Bertolini, 2011; Kamruzzaman et al., 2014; Peek et al., 2006; Zemp et al., 2011) Internationally, transit oriented development (TOD. It is not only used to analyze railway station areas but also stations along urban rail transit and bus rapid transit (BRT) corridors(Amini Pishro et al., 2022; Pezeshknejad et al., 2020)Transit-Oriented Development (TOD.

The model often evaluates the strength of a node based on quantitative indicators, such as the number of train services or passenger volumes. This approach works well in regions where differences in passenger types are minimal. However, in China, long-distance travelers still dominate the railway system overall. Yet, in economically developed regions, the proportion of business and commuting passengers has been increasing, thanks to the rapid expansion of high-speed and intercity rail in recent years. These two groups exhibit distinct behavioral patterns, travel choices, functional needs, and sensitivity to time. Therefore, whether passenger volume alone can accurately reflect the “node value” of a station remains questionable in the Chinese context.

On the other hand, passenger volume and train frequency are values that are easily influenced by the built environment and are subject to fluctuations over time. Changes in the built environment inherently imply potential shifts in passenger flow. For newly constructed stations or those undergoing major redevelopment, it is difficult to accurately predict future passenger volumes or train frequencies, which, to some extent, limits the applicability of the Node-Place model.

However, as the conduit for passenger flows, the structure and characteristics of a transport network influence the ease of movement within it. A station’s node attributes within different types of networks may offer a more stable proxy for the “node value.” Yet, most existing studies on railway complex networks typically treat cities rather than individual railway stations as nodes, making them of limited value when addressing development issues at the meso-scale of station areas.

At the “place” level, traditional Node-Place models often use indicators such as the number and diversity of employees across industries (Zemp et al., 2011)which focuses on transport related issues, blending performance with preconditions at a given site. We argue that a classication system for strategic planning should focus on the demands and conditions of the site within which the railway station must function, i.e. system context. Here, we present such a classication system: a cluster analysis of the 1700 Swiss railway stations relying solely on context factors. The resulting classes vary primarily in density (of land use and transport services, rental prices of various types of buildings, or the number of public facilities (Amini Pishro et al., 2022). However, these indicators are not direct measures of the extent to which a station area serves as a true “destination” for travelers. In recent years, with the advancement of big data technologies, Location-Based Services (LBS) data have made it possible to directly determine whether travelers remain in the station area after alighting, and what activities they engage in, allowing for the inference of passenger types. Such indicators can serve as direct performance metrics for evaluating the degree to which a station area functions as a destination.Therefore, this study employs complex network analysis techniques to quantify the centrality of stations within different network structures and explores the relationship between network centrality and both passenger volume and passenger composition using LBS data. Finally, the study attempts to construct a Node-Place model based on these two dimensions, offering a new perspective for analyzing and understanding station area development.

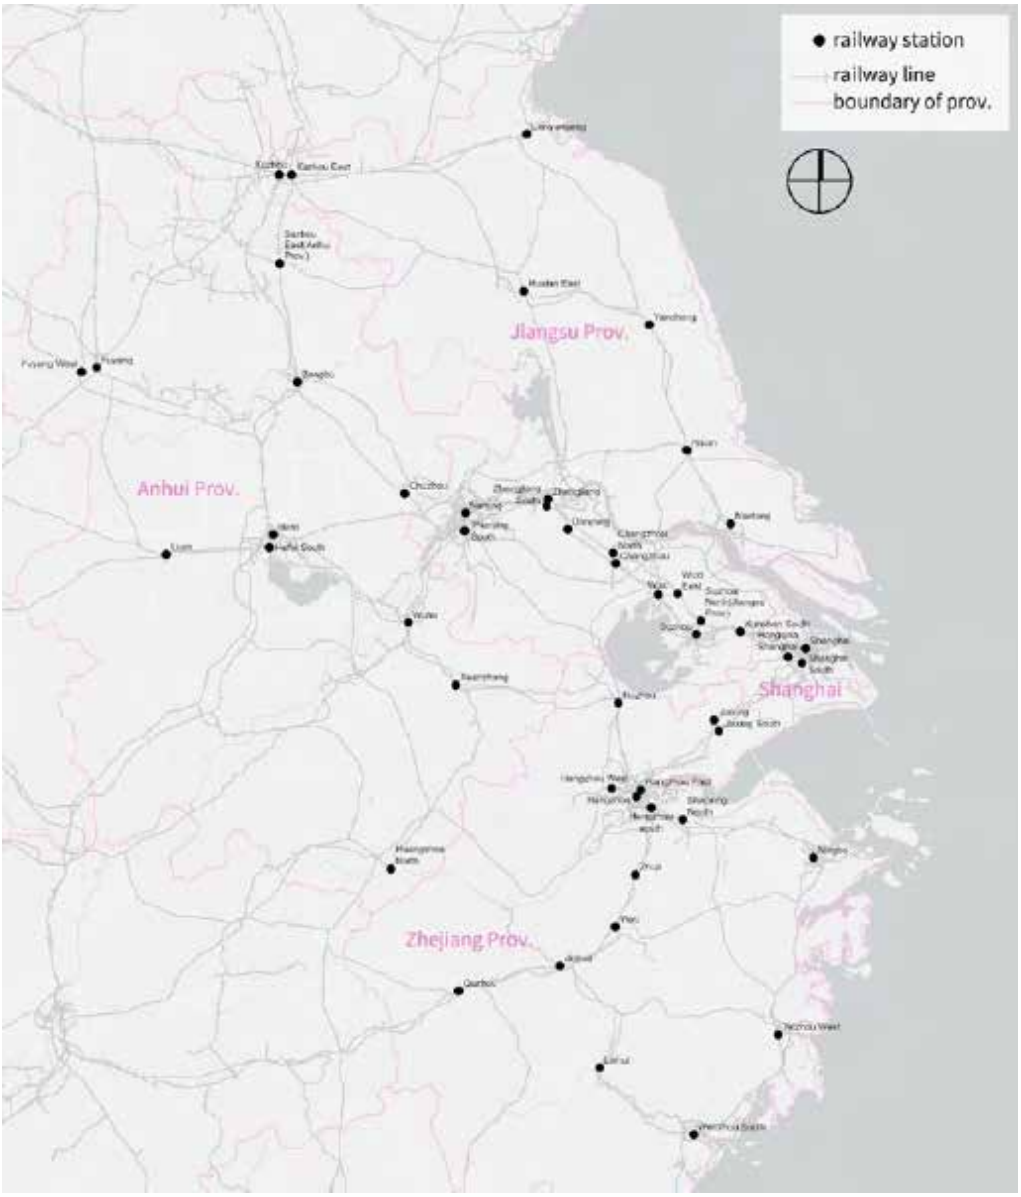

Figure 1. The research cases

3.Methodology

3.1 Samples and the Data Source

This study selects 49 railway stations within the Yangtze River Delta—one of the most economically developed regions in China—as research subjects. These stations are all served by at least two railway lines, with at least one being a high-speed or intercity rail line (Fig. 1). Passenger group data associated with these stations are derived from Sun Juan et al. (2024), who used LBS trajectory data covering 72 million person-trips in the Yangtze River Delta railway station areas in 2021. Individuals who traveled by train and conducted activities within a 5 km radius of a station (excluding the station itself) were defined as "arrival-activity travelers." Among them, travelers who stayed in office buildings for more than one hour and for longer durations than in leisure venues were defined as "business travelers." Travelers who spent more than one hour in scenic areas, shopping zones, or entertainment venues—and whose time in these areas exceeded time spent in business districts—were defined as "leisure travelers."Travelers whose residence and workplace (for more than three months) were located in different cities and who regularly commuted by train were categorized as "commuters." All remaining travelers were classified as "other travelers," with travel purposes including cross-city medical visits, family or friend visits, and transport transfers.

The railway network data were obtained from the Chinese Railway Passenger Train Timetable, which includes train numbers, station information, and departure and arrival times. The dataset contains a total of 10,737 passenger trains and 3,212 railway stations. The initial letter of each train number indicates its type, with a total of eight categories

(Wang et al., 2020) (see Table 1). Due to differences in speed and ticket pricing among these train types, their correspondence with different passenger groups also varies.

Business travelers and commuters, who are generally more time-sensitive, mainly correspond to the G, D, C, and S train types. These are grouped in this study as "High-speed/Short-haul trains," and the corresponding railway network is referred to as the HSR (High-Speed Railway) Network. The remaining train types—Z, T, K, numeric-only trains, and Y—are classified as "Conventional/Long-haul trains," forming the CLR (Conventional Long-distance Railway) Network, which mainly serves passengers with lower time sensitivity.The combination of both networks is referred to as the Integrated Railway Network, abbreviated as IR.

Table 1. Chinese Passenger Train Classification Framework

Type		Discreption
Z	Non-Stop Express Passenger Train	- Max speed: 160km/h - Limited intermediate stops - Point-to-point service
T	Limited-Stop Express Train	- Max speed: 140km/h - Major city stops only - Medium-long distance focus
K	Fast Passenger Train	- Max speed: 120km/h - Multi-stop configuration - Cost-effective service
-	Conventional Local Train	- Speed: ≤120km/h - Green-body coaches - Frequent stops, low fares
Y	Scenic Tour Train	- Max speed: 120km/h - Routes: Tourist attractions - Themed service
G	High-Speed EMU Train (G-Series)	- Design speed: 250-400km/h - Business/Top-class seats - Long-distance premium service
D	High-Speed EMU Train (D-Series)	- Operating speed: 200-250km/h - Regional corridor service - Medium-distance comfort
C	Intercity EMU Shuttle	- Speed: 200-350km/h - High-frequency operation - Metropolitan area connectivity
S	Metropolitan Commuter Rail	- Speed: 100-160km/h - Urban-suburban transit - Mass transit configuration

3.2 Modeling the Railway Networks

There are various methods for constructing railway complex networks. In this study, the L-space approach is adopted, where stations are represented as nodes, and any two adjacent stations traversed by the same train are considered connected(Lin and Ban, 2013). The train number and travel time between each pair of adjacent stations are recorded, and the average travel time of all trains passing through that segment is used as the time cost of the corresponding edge. This process is conducted separately for the HSR, CLR, and IR networks.

The constructed HSR network contains 1,629 nodes and 9,771 edges nationwide, with an average edge travel time of 30.05 minutes. The CLR network consists of 2,071 nodes and 7,049 edges, with an average edge travel time of 77.48 minutes. The average travel time between CLR stations is 257.58% of that between HSR stations. The combined IR network contains 3,212 nodes and 15,810 edges (Fig. 2).

3.3 Measuring Node Attributes of Stations in the Rail Network

This section proposes a multidimensional node evaluation framework that systematically assesses the structural functions and strategic positions of stations within the railway network. The framework integrates the topological characteristics of different networks with both the time cost between stations and the economic attributes of the cities where the stations are located. The measurement system includes two core indicators: Temporal Closeness Centrality and Economically-Weighted PageRank.

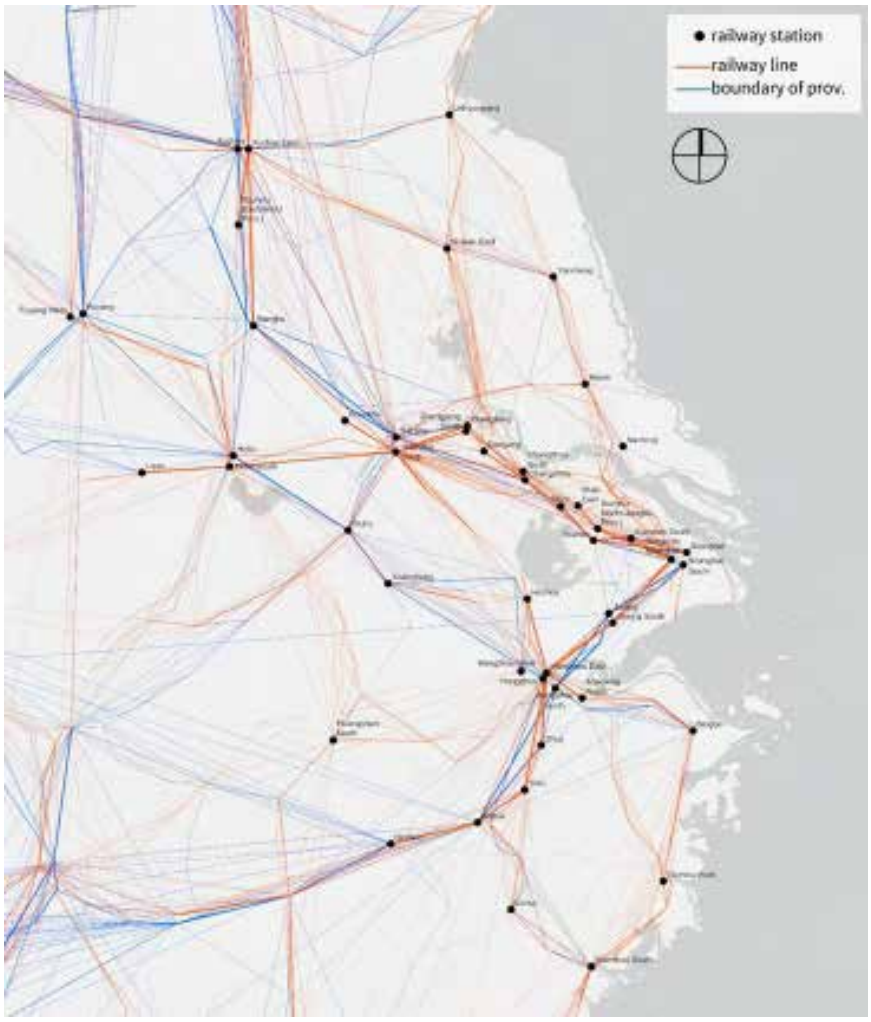

Figure 2. Multi-tiered Rail Complex Network in L-Space Constructed from Train Services (Link width corresponds to service frequency between stations)

Given prior research confirming the symmetric nature of China's railway network (Wang et al., 2020), all indicator calculations in this study are based on an undirected network. By weighting the traditional closeness centrality with time cost between stations, the Temporal Closeness Centrality is defined as follows:

$$Closeness_v = \frac{n-1}{\sum_{u \neq v} T_{uv}} \quad (1)$$

Where $Closeness_v$ represents the Temporal Closeness Centrality of station v; T_{uv} denotes the shortest travel time between stations u and v (assuming u and v are within the same connected component), calculated as the sum of average travel times across all edges in the time-optimal path between them; and n is the number of nodes within the connected component that includes station v. Temporal Closeness Centrality measures the average ease (or difficulty) of reaching all other stations from station v, using travel time as the cost metric across different types of railway networks.By incorporating both the economic context of each city and the connectivity between stations, we define the following:

$$PageRank_v = \alpha \sum_{u \in M(v)} PR_0(u)/L_u + (1-\alpha)/N \quad (2)$$

$$PR_0(u) = GDP/m \quad (3)$$

Where a is the damping factor, set to the default value of 0.85; N is the total number of stations within the connected component; $M(v)$ denotes all neighboring stations of station v; L_u is the number of neighboring nodes of station u; and $PR_0(u)$ is the initial importance of station u, calculated as the GDP of the city where station u is located divided by the number of railway stations (m) in that city. After several iterations, the final importance values for each station can be obtained.

This study calculates both Temporal Closeness Centrality and Economically-Weighted PageRank for each station in the HSR, CLR, and IR networks, and analyzes their correlations with different types of passenger group indicators at each station (Table 2).

Table 2. The Metrics and Specifications

Dimension	Metric	Specification
Node Metrics	Closeness	Temporal Closeness Centrality
	PageRank	Economically-Weighted PageRank
Passenger Metrics	N_Y	number of yearly passengers depart only
	P_S	Proportion of passengers staying in the station area
	P_B	Proportion of business passengers among passengers staying in the station area
	P_C	Proportion of commuters among passengers staying in the station area
	P_L	Proportion of passengers for leisure among passengers staying in station area
	P_O	Proportion of other passengers among passengers staying in station area

4. Results

4.1 Correlation Analysis

Among the 49 station samples, 23 stations only have high - speed rail lines. Thus, samples with only high - speed rail lines will be excluded when calculating CLR - related indicators. After normality testing, C_IR, C_HSR, PR_CR, P_B, P_L, and P_O follow a normal distribution. The Pearson correlation coefficient will be used to calculate the correlation between them. For the rest, the Spearman correlation coefficient will be applied (Table 3).

Table 3. The Correlation Analysis Results

Rail Networks	Metric	N_Y	P_S	P_B	P_C	P_L	P_O
IR	Closeness	0.066	0.028	*-0.092*	-0.111	*-.366***	*0.229*
	PageRank	**.726****	**.639****	**.577****	.456**	.331*	**-.597****
HSR	Closeness	0.087	0.006	*-0.144*	-0.108	*-.301**	*0.253*
	PageRank	**.632****	.490**	**.525****	.477**	0.245	**-.514****
CLR	Closeness	0.091	0.079	-0.015	-0.278	-0.247	0.088
	PageRank	0.350	.406*	*0.198*	-0.058	*0.172*	*-0.207*

Italicized values in the table represent Pearson correlation coefficients;
**. Significant at the 0.01 level (2-tailed);
*. Significant at the 0.05 level (2-tailed).

The correlation calculation results reveal the following characteristics:
(1)PageRank Correlations: Station PageRank on IR and HSR networks correlates with passenger metrics, with stronger overall correlations on IR (except for Proportion of commuters, where HSR PageRank shows a stronger correlation).

(2)CLR Network Irrelevance: Station node properties on the CLR network generally show no significant correlation with passenger metrics, except for the Proportion of passengers staying in the station area, which has a significant positive correlation with CLR PageRank (correlation coefficient: 0.406).

(3)Temporal Closeness Centrality: On IR and HSR networks, Temporal Closeness Centrality only shows a significant negative correlation with the Proportion of passengers for leisure and no correlation with other metrics.
(4)Strongest Correlation: Proportion of passengers staying at the station area has the strongest positive correlation with IR PageRank, followed by HSR PageRank.

(5)Significant Negative Correlation: Proportion of other passengers shows a strong significant negative correlation with PageRank on both IR and HSR networks.

These characteristics indicate that the High-speed and Short-haul Rail Network is positively correlated with the proportion of business and commuter travelers but negatively correlated with other traveler types. As stations become more important in the HSR network, the increase in business and commuter travelers outpaces that of leisure and other travelers. Node importance considering urban GDP better explains station attractiveness than high temporal accessibility, and the Integrated Rail Network, combining HSR and CLR, shows stronger explanatory power.

Despite the Yangtze River Delta being one of China's most HSR-developed regions, incorporating the conventional rail network into railway complex network modeling for station analysis remains valuable.

The PageRank of stations in the conventional long-distance rail network positively impacts passenger station-area staying rates. This might be because the conventional rail system, with a longer development history, has more mature and comprehensive urban construction around high-importance stations, making them more attractive for passenger stays.

4.2 Node-Passenger modal

Drawing on the Node-place model for 'Node-Passenger' analysis: Min-max normalize the PageRank values of stations in the IR network and the Proportion of passengers staying at station areas. Plot the normalized PageRank values on the x-axis and the normalized proportion of passengers on the y-axis, then perform curve fitting(Fig. 3).

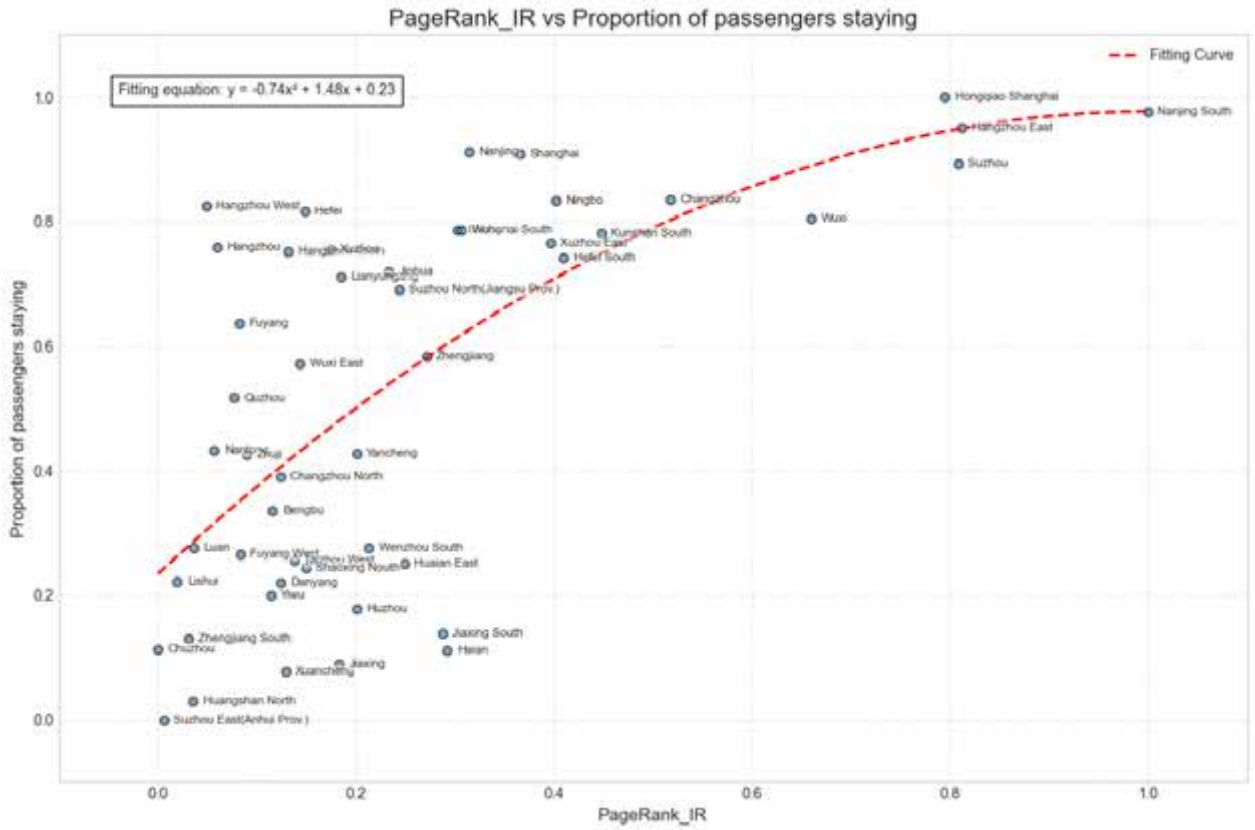

Figure 3 Node-Passenger Modal

The fitted trend line, a parabola, shows that in the Yangtze River Delta, the proportion of passengers staying at station areas increases with the PageRank value of stations in the IR network, but at a declining rate. When PageRank reaches around 63%, growth in passenger proportion halts.

Five stations hitting this threshold are Nanjing South, Hongqiao Shanghai, Hangzhou East, Suzhou, and Shanghai Station, all major stations in the region's most economically advanced cities.

Using the classic Node-Place Theory to explain the Node-Passenger model shows no "unbalanced nodes" in the Yangtze River Delta, but many "unbalanced places" cluster in the upper-left quadrant. These are mostly old stations (e.g., Hangzhou, Hefei, and Xuzhou Stations) with low railway network importance but high urban development around them, making them attractive for passenger stays. Numerous Dependency stations are in the lower-left quadrant. They have low IR network importance, struggle to attract business and commuter travelers, and thus have low passenger retention rates and destination-formation levels.

5. Conclusions

This paper focuses on railway stations' node properties in rail networks. It uses stable and accessible network structure indicators instead of the volatile and hard - to - get passenger flow and train frequency indicators to represent station node properties. It checks their correlation with the Proportion of passengers staying, which directly shows the "destination-formation degree" of stations. Results show that PageRank (considering city GDP) of stations in the combined HSR and CLR networks strongly correlates with passenger activity rates (correlation coefficient: 0.726) and with proportions of business, commuter, and leisure travelers. This proves that stations' importance in HSR networks significantly attracts time-sensitive passenger groups. It also finds an upper limit

(63%) for passenger retention rates in the Yangtze River Delta.

For future research, it's suggested to include more built-environment indicators in the analysis system. This will help form a comprehensive "Node - Passenger - Place" analysis system.

An Exploration of Route Synergy between Attractions in Xi'an's Main Urban Area Based on the Node-Place Model

Wendi Dong
Xi'an University of Architecture and Technology
990306dd@xauat.edu.cn

Abstract
Currently, China is in the period of high - quality and intensive urban development. Handling the relationship between the traffic value and the tourism value of the routes between scenic spots is crucial for the efficient utilization of tourism resources. This paper takes 120 public transportation connection routes among 15 scenic spots above 4A level in the main urban area of Xi'an as the research object. It establishes an index system for the traffic value and tourism value of the routes, and uses the ArcGIS platform to conduct a minimum resistance analysis of each index. Based on the node - place model, it evaluates the current development status of each route. The research results show that there is a phenomenon of non - coordinated development among the routes: the scenic spots can be divided into four states: balanced, subordinate, pressured, and imbalanced. Corresponding development strategies are proposed for each state. For example, in the balanced state, the values should be increased or decreased simultaneously; in the subordinate state, the traffic and tourism facilities need to be improved; in the pressured state, the traffic pressure should be relieved; in the imbalanced state, the value structure should be optimized. This research provides a basis for improving the public transportation facilities in scenic spots, optimizing traffic organization, and enhancing the level of intelligent transportation services.

Keywords: Node-place model; Minimum resistance model; Public transportation routes; Tourist needs; Main urban area of Xi'an

Introduction

With the acceleration of the global urbanization process, the efficient utilization of urban space and sustainable development have become the focus of attention for governments and academia around the world. Against this backdrop, the optimization of the urban transportation system and the rational allocation of tourism resources are of particular importance. As the link connecting various functional areas within the city and external regions, the public transportation system is not only the "lifeblood" of urban operation but also an important driving force for urban tourism development. However, how to balance traffic efficiency with the harmonious co - existence of tourism experience and the urban environment has become a major challenge in current urban planning and transportation management.

Luca Bertolini proposed the node - place model, which profoundly reveals the dual characteristics of station areas. That is, the dialectical relationship between its attribute as a key node in the transportation network and its attribute as a place for diverse urban life spaces. This theoretical framework points out that station areas need to efficiently integrate multiple transportation modes to ensure the smooth transfer of people and goods, meeting the rapid - flow needs of modern society. At the same time, it shoulders the heavy responsibility of urban function expansion, integrating multiple activities such as business, leisure, and entertainment, attracting and promoting people to stay and interact in specific areas. The core of the node attribute lies in promoting the efficient distribution of people, while the place attribute focuses on creating a pleasant environment to encourage people's in - depth participation and experience.

The tension and synergy between the two constitute the internal dynamic mechanism for the development of station areas. On the one hand, the improvement of node efficiency (such as the optimization of transportation facilities) can attract more people, laying the foundation for the realization of place value. On the other hand, the enrichment and quality improvement of place functions further stimulate transportation demand, forming a positive cycle. This process reflects the trend of the harmonious co - existence of node value and place value in dynamic adjustment, which is a model for urban space optimization and transportation system integration.

In terms of results, the node - place model describes three synergy states: The subordinate state means that the node value and the place value are in synergy but at a low level, indicating low - level development in the area; The balanced state is the ideal state, where the node value and the place value are in synergy and at a moderate level, representing sustainable development in the area; The pressured state means that the node value and the place value are in synergy but at a high level, indicating over - development in the area; An imbalanced node means that the node value is much higher than the place value; An imbalanced place means that the place value is much higher than the node value. The practical significance of the node - place model lies in summarizing the

complex problems of station areas into the synergistic interaction relationship between the node value and the place value, and using quantitative means to evaluate the development status of station areas, guiding the key points of future construction in station areas and proposing targeted development ideas.

Based on this understanding, Luca Bertolini proposed the node - place model in 1999. This model quantifies two performance indicators of station areas - node value and place value - by establishing an index system. Scholars highly recognize Luca Bertolini's ideas and have conducted some fruitful research. There are also quite a number of studies in the context of Chinese cities. For example, Zheng Degao and others pointed out that transportation hubs should be combined with urban planning, with a focus on the value of transportation nodes and the value of urban places; Chen Lan and others summarized station areas as "multi - modal transportation nodes" and "functionally complex urban places"; Wang Chengfang and others proposed a planning and design idea for station areas based on the dual characteristics of nodes and places in combination with the conceptual design scheme of the new public transportation system in Nanhai District, Guangzhou.

In summary, scholars generally believe that the mutual coordination and promotion of node value and place value are the keys to the sustainable development of station areas. Based on this, this paper uses the traffic value of routes as the node value and the tourism value as the place value, extending it to the traffic - tourism value of public transportation routes between scenic spots, and studies the development synergy of public transportation routes between scenic spots in the central urban area of Xi'an. Studying the integration between scenic spots and the existing urban transportation also provides a basis for improving the public transportation facilities in scenic areas, optimizing traffic organization, and enhancing the level of intelligent transportation services in a targeted manner.

1 Research Design

1.1 Overview of the Research Area

The research area of this paper is the main urban area of Xi'an, which includes Yanta District, Beilin District, Lianhu District, Weiyang District, Baqiao District, and Xincheng District, with a total area of approximately 832 square kilometers. Xi'an is one of the first batch of famous historical and cultural cities. As the core development area of Xi'an, the main urban area has 15 scenic spots above 4A level, such as the Big Wild Goose Pagoda, Shaanxi History Museum, and Daming Palace National Heritage Park, attracting a large number of domestic and foreign tourists. Therefore, the number and distribution of scenic spots in the research area are appropriate, providing sufficient data samples. Meanwhile, with the acceleration of the old - city renovation and urban renewal process, how to coordinate the intensive development of urban scenic - area resources has become a major challenge for cities. In summary, selecting the main urban area of Xi'an as the research area has important demonstration value (Figure1).

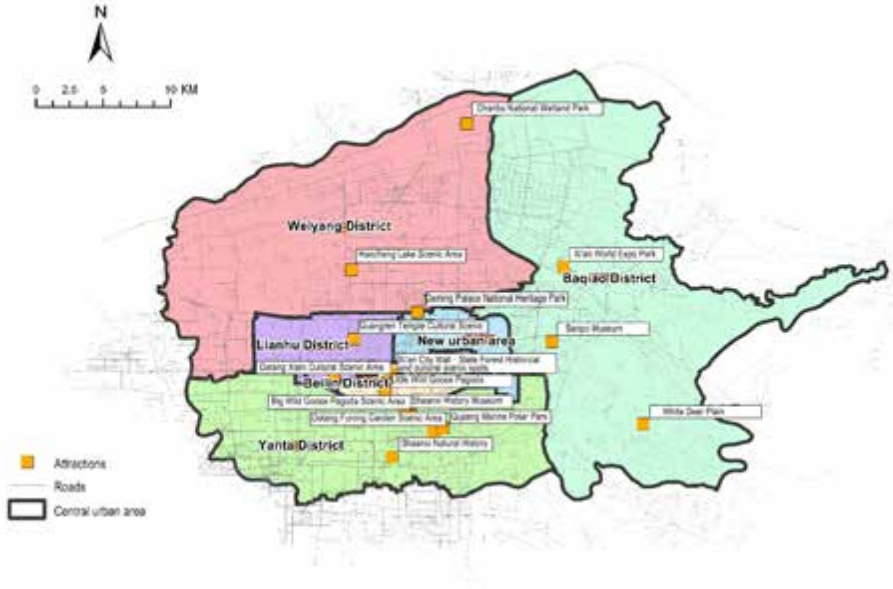

Figure 1. Scope map of main urban area of Xi'an

1.2 Research Steps

First, the optimal routes for 15 scenic spots in the main urban area of Xi'an were selected through the recommendation of Gaode Map and recorded using the ArcGIS platform (Table 1). Then, by reviewing relevant literature and considering the characteristics of tourist needs, a factor system for the traffic and tourism values of scenic - area routes in the main urban area of Xi'an was determined. The traffic value includes the density of public - transportation stations and road - network density, while the tourism value includes the density of characteristic shops and scenic - spot density. The method of constructing resistance surfaces was used to generate individual - factor resistance surfaces and classify and overlay them to obtain the traffic and tourism resistance values of each tourism route (Table 2).

The Minimum Resistance Model is an academic theoretical framework used to describe and analyze that when systems, individuals, or groups face multiple possible paths or choices, they tend to choose the paths with the least resistance, lowest cost, or highest efficiency.

Finally, the node - place model analysis was conducted using the two types of resistance values obtained for each route to get the synergy results of the development of five types of tourism routes.

To eliminate the differences in dimensions and orders of magnitude among indicators, this paper first performed max - min standardization on the data. The specific formula is as follows: In the transformation function, x is the original data value, x' is the standardized value, max is the maximum value in the original data, and min is the minimum value in the original data.

$$\chi' = \frac{\chi - min}{max - min}$$

1.3 Data Sources

In terms of scenic - spot selection, this paper referred to the data published by the Xi'an Culture and Tourism Bureau and screened 15 scenic spots at or above 4A level within the main urban area of Xi'an. The road - network data were sourced from the 2023 Chinese road data published on the Open Street Map website. The text data of bus and subway stations and lines were obtained from the official website of Xi'an Metro and the urban rail development plan of Xi'an. The route directions were selected from the optimal public - transportation routes recommended by Gaode Map, including transfer data and travel - time information. The POI data of shops were obtained from the Baidu Map API interface.

2. Research Process

Table 1. List of scenic spots in the main urban area of Xi'an

Number	Level	Name of scenic spot
1	5A	Big Wild Goose Pagoda Scenic Area
2	5A	Datang Furong Garden Scenic Area

Table 2. Resistance factor table

First order factor	Secondary factor	Grading method	Resistance coefficient	Weight
Tourist experienceSite properties	Scenic spot density	According to nuclear density or linear density analysis, it is divided into five categories by natural breakpoint method	1-9	0.35
	Characteristic store density			0.25
Road connectivityNode properties	Road network densityRoad network density			0.15
	Density of bus and subway stations			0.25

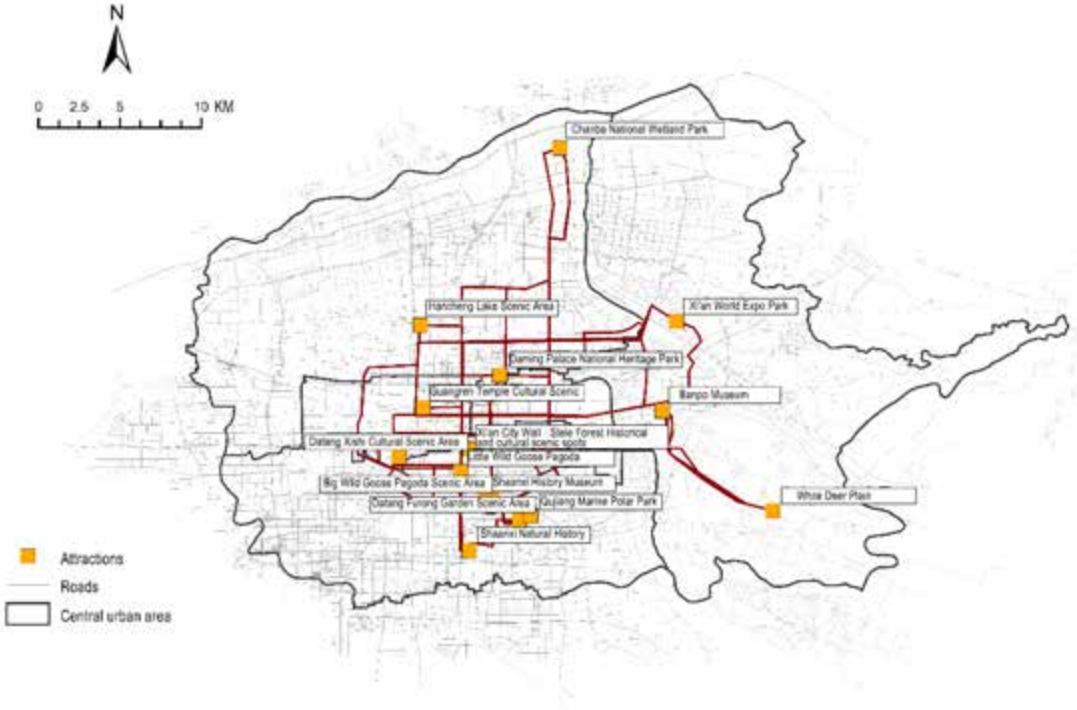

Figure 2. Traffic routes between scenic spots

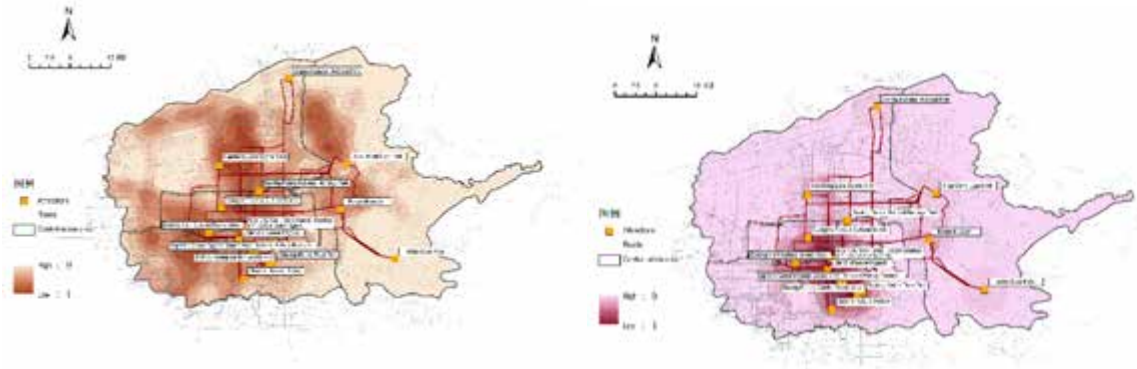

Figure 3. Traffic value (left) and tourism value (right) resistance results

This research takes public transportation as the research perspective and uses Gaode Map as the platform. The selected travel modes include a combination of subway, bus, and walking (more than 1 km) for public transportation. The ArcGIS platform is used to record the starting points, transfer times, and overall travel time data of each route. A total of 120 routes between 15 scenic spots are screened (Figure 2).

2.2 Node (Traffic) Value Measurement

2.2.1 Public Transportation Station Density

The density of public transportation stations (bus stops and subway stations) can represent their distribution and, to some extent, reflect the closeness of the connection between scenic spots and the city. This paper uses the Kernel Density tool for cluster analysis. The results show that the station distribution density around Han City Lake Scenic Area, Datang West Market, Expo Park, Banpo Museum, and the Ming City Wall area is relatively large, and the public transportation accessibility in these areas is better.

2.2.2 Road Network Density

The road network density represents the convenience of tourists' transfers to some extent. In areas with a high density, there are more transportation options and better accessibility. The analysis using the Kernel Density tool shows that the road network density around Datang West Market, the Big Wild Goose Pagoda, and the Ming City Wall area is relatively high. Scenic spots like Bailuyuan are far from the urban area, so the road network density is low.

2.2.3 Quantitative Superposition Results

By referring to relevant literature, weights are assigned to the two factors of public transportation station density and road network density, and reclassification is carried out. Then, the Weighted Sum tool is run to obtain the comprehensive resistance surface of traffic value (Figure 3).

2.3 Place (Tourism) Value Measurement

2.3.1 Characteristic Shop Density

In this paper, the POI data of characteristic shops are obtained from the Baidu Map interface. Shops such as homestays, specialty stores, and characteristic food stores that meet the six major needs of tourists, namely "eating, accommodation, transportation, sightseeing, shopping, and entertainment", are screened. Therefore, areas with a high density of characteristic shops represent, to some extent, the more developed tourism areas in the main urban area of Xi'an. The analysis using the Kernel Density tool shows that the density of characteristic shops near the Bell and Drum Towers and the Datang Ever - Bright City is relatively high, with relatively high tourism value and more attractive to tourists. The tourism industry construction near the Expo Park and the Bailuyuan Scenic Area is relatively poor.

2.3.2 Scenic Spot Density

The scenic spot density can represent the concentration of tourism resources to some extent. The analysis using the Kernel Density tool shows that the area composed of the Shaanxi History Museum, the Big Wild Goose Pagoda, the Datang Furong Garden, and the Qujiang Ocean Polar Park has a relatively high scenic spot density and is more attractive to tourists.

2.3.3 Quantitative Superposition Results

By referring to relevant literature, weights are assigned to the two factors of characteristic shop density and scenic spot density, and reclassification is carried out. Then, the Weighted Sum tool is run to obtain the comprehensive resistance surface of tourism value .

2.4 Node - Place Model Construction

Analysis of 20m buffer area for routes between scenic spots. Using the 14 routes of each scenic spot as a mask, the raster data of traffic value and tourism value are extracted, and the average value of each scenic spot's route is recorded. The obtained data are processed by max-min standardization to get two values for each scenic spot (Table 3). Taking the traffic value as the y - axis and the tourism value as the x - axis, a node (traffic) - place (tourism) model is established. Through model evaluation, it can be found that half of the scenic spots are in a balanced state, and some are in a subordinate state, a pressured state, or an imbalanced state.

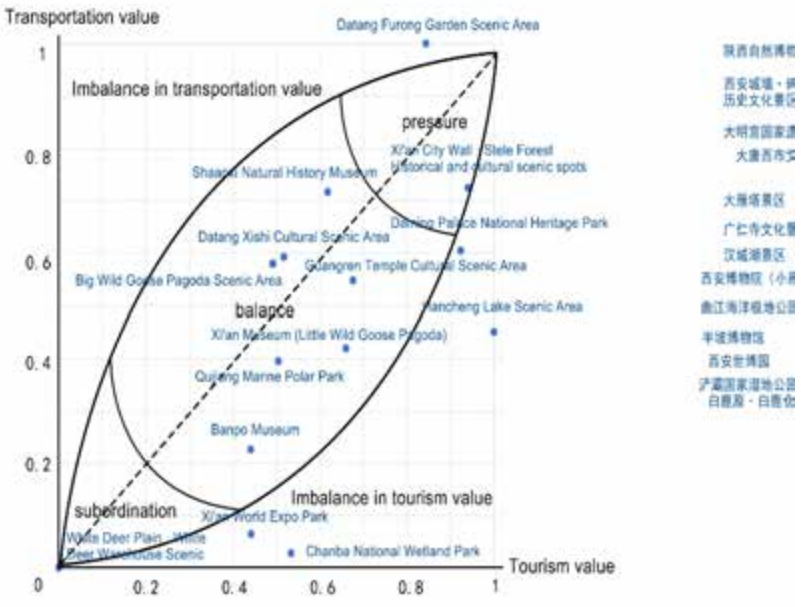
3. Development Judgment and Development Strategies

3.1 Balanced State

Table 3. Table of transportation tourism value of each scenic spot

Name of scenic spot	Traffic value	Tourism value
Big Wild Goose Pagoda Scenic Area	0.51	0.42
Datang Furong Garden Scenic Area	0.16	0.00
Xi'an City Wall · Stele Forest Historical and cultural scenic spots	0.06	0.28
Xi'an City Wall · Stele Forest Historical and cultural scenic spots	0.08	0.40
Shaanxi History Museum	0.51	0.42
Qujiang Marine Polar Park	0.50	0.61
Datang Xishi Cultural Scenic Area	0.48	0.41
Banpo Museum	0.56	0.77
Xi'an Museum (Little Wild Goose Pagoda)	0.34	0.58
Xi'an World Expo Park	0.56	0.94
Hancheng Lake Scenic Area	0.00	0.55
Chanba National Wetland Park	0.47	0.97
Shaanxi Natural Museum	0.38	0.28
White Deer Plain · White Deer Warehouse Scenic Area	1.00	1.00
Guangren Temple Cultural Scenic Area	0.32	0.45

Figure 4. Traffic tourism value model of scenic spots in the main urban area of Xi'an



According to the result analysis, the Shaanxi Natural History Museum, the Qujiang Ocean Polar Park, the Xi'an Banpo Museum, the Xi'an Museum (Xiaoyanta), the Guangren Temple Cultural Scenic Area, the Xi'an Datang West Market Cultural Scenic Area, the Xi'an Big Wild Goose Pagoda Scenic Area, and the Shaanxi History Museum are all in a balanced state, but their synergy levels vary. Specifically, the Big Wild Goose Pagoda Scenic Area and the Datang West Market Scenic Area are close to the 45° line, showing a better synergy state. Therefore, in their subsequent development planning, emphasis should be placed on ensuring that the traffic value and tourism value increase or decrease simultaneously to maintain and promote the continuous evolution of the synergy state. In contrast, although the Banpo Museum and the Xi'an Museum maintain a balanced state, they deviate significantly from the 45° line. Therefore, in the subsequent strategic deployment, attention should be focused on optimizing the value structure: strengthening the relatively low - level elements of their traffic value to avoid potential imbalance risks and ensure the robustness of overall balance and coordinated development.

3.2 Subordinate State

According to the result analysis, the Bailuyuan·Bailucang Scenic Area is in a subordinate state, with the traffic and tourism values being in synergy but at a low level, and the two values are equal and both low. In the later stage, targeted optimization strategies can be proposed, such as creating tourism special lines, adding bus stops, and increasing the implantation of characteristic shops.

3.3 Pressured State

According to the result analysis, the traffic value and tourism value of the Xi'an City Wall·Beilin Historical and Cultural Scenic Area are both at a high level, belonging to the pressured state. The advantages of popular scenic spots are fully reflected, and the node value and place value are relatively high, which is also consistent with people's general perception. The future development of this scenic area should focus on relieving traffic and urban development pressure and avoiding over - tourism development and traffic congestion as much as possible.

3.4 Imbalanced State

According to the result analysis, the Xi'an Datang Furong Garden Scenic Area, the Xi'an Chanba National Wetland Park, the Xi'an Expo Park, the Daming Palace National Heritage Park, and the Xi'an Han City Lake Scenic Area are all in an imbalanced state. Among them, the Datang Furong Garden Scenic Area is in a traffic - value imbalanced state, and the others are in a tourism - value imbalanced state. Therefore, in the subsequent tourism development, the Datang Furong Garden Scenic Area should pay attention to relieving traffic pressure and appropriately balancing tourism resources; the other scenic spots have good traffic accessibility but insufficient tourism development. In the future, attention should be paid to the implantation of the tourism industry to improve the tourist experience.

4. Conclusion

In summary, based on Luca Bertolini's node - place model, this research takes 15 scenic spots at or above 4A level in the main urban area of Xi'an as the research object and deeply explores the synergy between the traffic value and tourism value of public transportation routes between scenic spots. By constructing a comprehensive resistance surface, key factors such as public transportation station density, road network density, characteristic shop density, and scenic spot density are quantitatively analyzed, and then the development states of each scenic spot in the node - place model are revealed. The research results show that the development states between scenic spots are diverse, including the balanced state, the subordinate state, the pressured state, and the imbalanced state. According to the characteristics of each state, corresponding optimization strategies are proposed: for scenic spots in the balanced state, the traffic and tourism values should be increased or decreased simultaneously to promote coordinated development; for those in the subordinate state, the overall value should be improved by adding transportation facilities and enriching the tourism industry; for scenic spots in the pressured state, attention should be paid to traffic diversion and the balance of tourism carrying capacity to avoid over - development; for those in the imbalanced state, according to the specific situation, the transportation facilities should be optimized or the tourism industry should be implanted to achieve value balance and improvement. This research not only provides a scientific basis for the optimization of public transportation routes between scenic spots in the central urban area of Xi'an but also offers valuable references for the integrated development of transportation and tourism in other cities.

Evaluation and Optimization of Public Service Facility Accessibility in Planning Future Community Living Circles: A Case Study of Yangpu District, Shanghai, China

Wang Su, Wang Yuchen, Zhang Shangwu, Huang Jianzhong
College of Architecture and Urban Planing,Tongji University
Email:3235987330@foxmail.com

Abstract
Addressing imbalanced public cultural and sports facility (PCSF) allocation amidst China's urban quality enhancement and "15-minute community life circle" initiatives, this study investigates Siping Road Sub-district, Shanghai, to reveal PCSF supply-demand contradictions and propose optimization strategies. It innovatively employs an "availability-accessibility-adaptability" framework, integrating objective supply-demand metrics with subjective satisfaction surveys. Availability is assessed via current statistics; accessibility via the 2SFCA method and resident usage (time, preferences); and adaptability via questionnaires and regression models analyzing satisfaction and its influencing factors. Finally, the Importance-Performance Analysis (IPA) model identifies core contradictions, with "place-based" and "people-based" optimization suggestions providing empirical references for precise PCSF allocation and "15-minute community life circle" construction.

Keywords: Life Circle; Public Cultural and Sports Facilities; Supply-Demand Relationship; Accessibility; Satisfaction

1. Introduction

1.1 Research Background

The "14th Five-Year Plan" mandates accelerating urban development transformation, promoting urban spatial structure optimization and quality improvement. Consequently, the "Shanghai '15-Minute Community Life Circle' Planning Guidelines (Trial)" emerged, offering a new policy framework for improving residential public service facility allocation(Wu and Sun 2024).However, despite China's promotion of national fitness and modern public cultural services, public cultural and sports facility supply-demand contradictions persist(Peng et al. 2023).These include insufficient venues, uneven high-quality resource distribution, service-need disconnects, and varied facility management levels, causing significant allocation imbalances and inadequacies (Song, Kong and Cheng 2024).Shanghai's "15-minute community life circle" initiative, which prioritizes rectifying cultural and sports facility shortcomings and enhancing service efficiency to improve community life quality and resident well-being, necessitates this research.

1.2 Research Purpose and Significance

This study selects Siping Road Sub-district, Yangpu District, Shanghai, to: comprehensively evaluate its public cultural and sports facility allocation and resident perception; deeply analyze facility supply and resident demand matching (supply-demand ratio, usage behavior, satisfaction); accurately identify current allocation's main contradictions; and propose targeted, operable optimization strategies from the "15-minute community life circle" perspective, integrating "place-based" and "people-based" ideas.

The research's significance is: theoretically, constructing a multi-dimensional "Availability-Accessibility-Adaptability" evaluation framework for cultural and sports facility planning, deepening understanding of community residents' behavioral geography; practically, providing decision support for Siping Road Sub-district and similar areas' cultural/sports facility planning and "15-minute community life circle" construction, aiming to enhance living environments and resident well-being.

1.3 Relevant Theoretical Basis

This research uses Public Service Facility Accessibility theory. Accessibility, a core measure of residents' ease of accessing public services, includes physical access (distance, transport) and non-spatial dimensions (service acquisition fairness, subjective service quality perception). Classic methods include shortest distance and 2SFCA. (Xie et al. 2023)

This study adapts Wiszbinski and Thomas et al.'s 5A service accessibility model (Availability, Accessibility, Affordability, Acceptability, Adaptability). (Peng et al. 2023)Considering cultural/sports facilities' public welfare nature and research focus, a localized, simplified three-dimensional framework was built:

1)Availability: Objective supply level of public cultural/sports facilities (type, quantity, scale, coverage)—the basis for evaluating supply-demand.

2)Accessibility: Convenience of resident access/utilization and facility service capacity manifestation—how supply-demand plays out in service. Measured by supply-demand ratio and resident usage behavior (time, preference).

3)Adaptability: Degree facilities meet diverse, personalized resident needs and residents' subjective service evaluation—demand feedback. Measured by resident satisfaction and influencing factors.

This framework aims for a comprehensive evaluation from "objective facility existence" to "actual resident use" to "residents' subjective feelings," reflecting true service effectiveness.

2.Research Area Overview and Facility Status

2.1 Overview of Siping Road Sub-district

Siping Road Sub-district, in central-western Yangpu District, Shanghai (approx. 2.64 km²), is core to the "Tongji Knowledge Economy Circle." Dominated by education/research and residential functions, it hosts many design/creative industries. Residential buildings, mainly 1950s-1980s workers' new villages (low-rise, high-density), face renewal pressure. High population density shows an "elderly, young, and highly educated" structure: many over 60s and college-educated individuals, plus adolescents, creating diverse demands for public cultural/sports facilities.

2.2 Current Status of Public Cultural and Sports Facilities in Siping Road Sub-district

Field surveys, data collection, and POI analysis show:

Sports Facilities: Mainly outdoor small fitness points and simple park venues; lacks large, comprehensive indoor stadiums. Quality resources (standard fields, pools) are concentrated in units like Tongji University, with limited community sharing, creating scarcity. Overall: "many small points, limited types, difficult quality resource sharing, limited service radius," failing to meet growing, diverse fitness needs, especially for young/middle-aged groups.

Cultural Facilities: Mainly elderly activity rooms, neighborhood center chess/card/reading rooms; lacks comprehensive centers, libraries, exhibition halls, small theaters for all ages, especially young/middle-aged. Uneven spatial distribution (mostly southeast) shows: "elderly-focused, singular functions, no comprehensive venues, uneven distribution," failing diverse cultural exchange, learning, leisure needs. Generally, Siping's facilities lack sharing, quantity/quality, functional diversity, and balanced layout, short of "15-minute community life circle" goals.

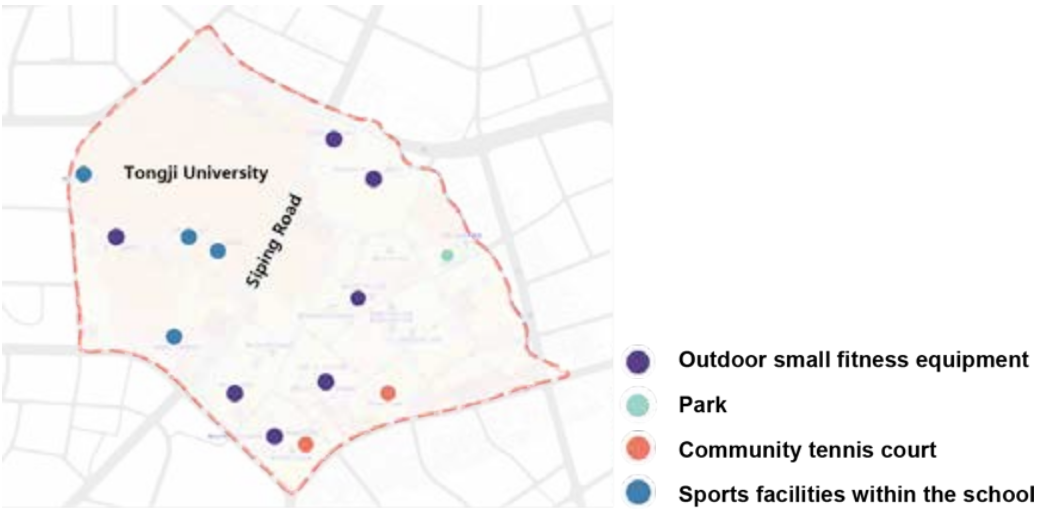

Fig.1. The current distribution of sports facilities

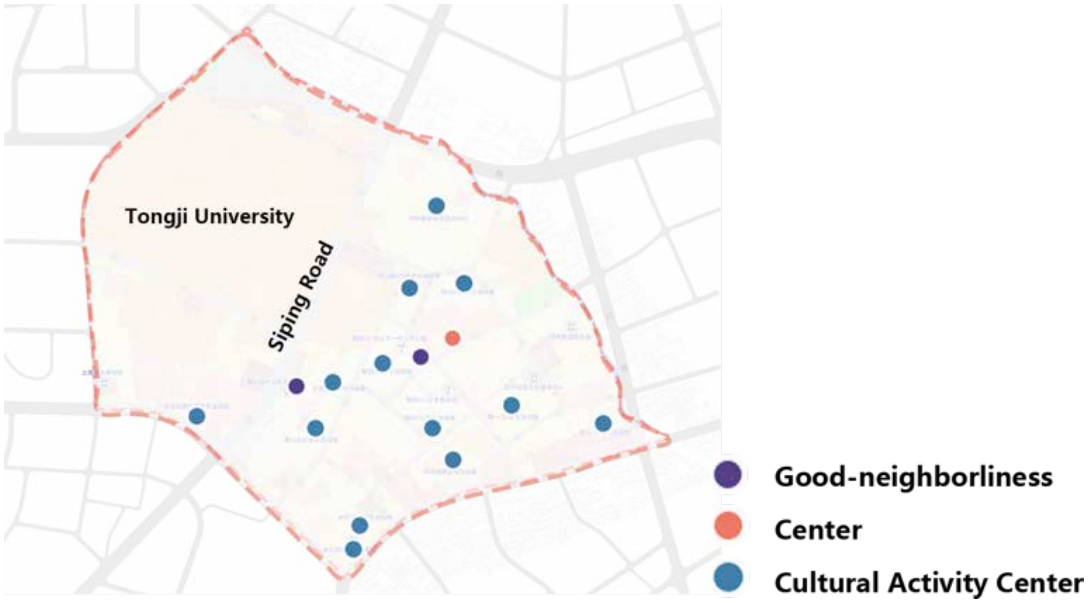

Fig.2. The current distribution of cultural facilities

2.3 Life Circle Division and Resident Cognition
Siping Sub-district has two main life circle types:

1 University Life Circle: Around Tongji University, serving mainly students, faculty, some nearby residents. Facilities are partly campus-internal, with sharing barriers.

2 Residential Life Circle: Covering vast workers' new villages; high population density, high aging, urgent need for embedded, accessible cultural/sports facilities.

A preliminary survey on resident facility perception found: over half feel a lack of facilities (especially cultural), prominent in southeastern older areas. Information is mainly via community/internet promotions. Nearly a quarter perceive no facilities within a 15-minute walk. Most are willing to use facilities, but unsuitable functions, poor accessibility, conflicting hours, and outdatedness are obstacles. A 10-15 minute walk is desired. These findings underpin deeper analysis and highlight the need for a resident-centric view.

3. Research Design and Methods
This study, using the "Availability-Accessibility-Adaptability" framework, employs multi-source data and quantitative methods to evaluate Siping's public cultural/sports facility supply-demand. Availability evaluation integrates field surveys, government data, and Gaode POI data (facility types, quantities, distribution), using GIS for spatial visualization/density analysis. Accessibility evaluation (neighborhood committee as unit) uses 2SFCA to quantify facility service capacity-population demand matching, with spatial autocorrelation for supply-demand ratio clustering. Concurrently, 182 resident questionnaires analyze usage frequency, time preferences, and functional demand differences. Adaptability evaluation (subjective resident perception) uses multiple linear regression to identify impacts of eight factors (e.g., environment, functional richness) on overall satisfaction. IPA, correlating supply-demand ratios with satisfaction, identifies four contradictory area types (e.g., high supply-demand/high satisfaction), guiding differentiated optimization.

Data sources: 1) Facility data: field mapping, government documents, POI cross-validation. 2) Population data: sub-district office's neighborhood committee-level statistics. 3) Resident behavior/satisfaction: stratified sampling (online/offline surveys) covering usage, satisfaction, importance ranking. Methods: GIS spatial analysis (layout balance), 2SFCA (spatial accessibility), statistical regression (satisfaction drivers), IPA (priority improvement areas), achieving objective supply-subjective demand diagnosis.

4.Research Results and Analysis

4.1 Availability Analysis of Public Cultural and Sports Facilities

As per Section 2.2, Siping's facilities are deficient in total quantity, type diversity, spatial distribution balance, and quality resource sharing. Sports facilities are mainly small-scale/outdoor; large comprehensive venues are scarce, campus resources undershared. Cultural facilities favor elderly services, lacking comprehensive, high-quality venues for other groups. This supply-level "inherent deficiency" underlies subsequent supply-demand issues.

4.2 Accessibility Analysis of Public Cultural and Sports Facilities

4.2.1 Supply-Demand Matching Analysis (based on 2SFCA)

2SFCA calculation of Siping's neighborhood committee cultural/sports facility supply-demand ratios shows significant overall "demand exceeding supply." Spatially, matching is heterogeneous: Tongji University and adjacent areas have higher ratios (due to campus resources, despite sharing issues); most dense, older workers' new villages are supply-demand "lowlands" due to severe under-configuration. Spatial autocorrelation (Moran's I) confirmed non-random spatial distribution: significant positive correlation (high-high, low-low clustering). Local LISA maps identified "Low-Low" clusters, mainly in workers' new villages—key deficient areas needing urgent attention.

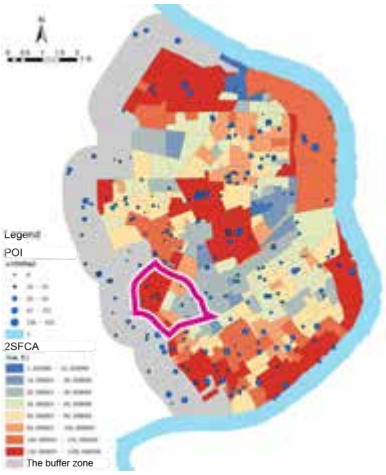

Fig.3. 2SFCA for calculating the supply-demand ratio

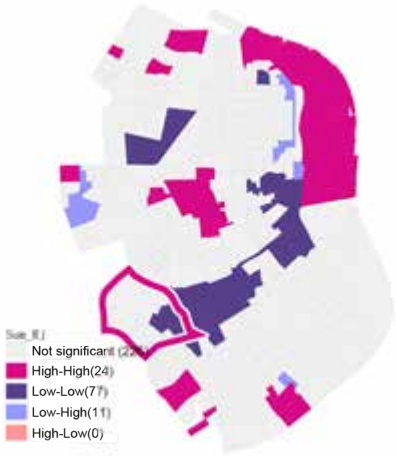

Fig.4. Spatial clustering analysis

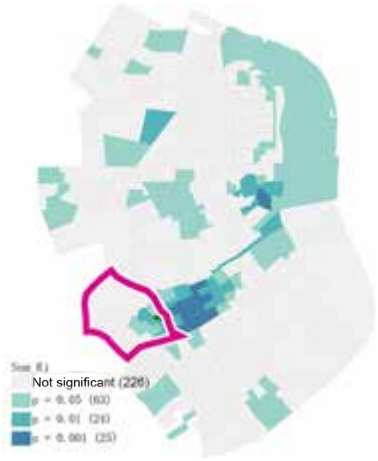

Fig.5. Analysis of spatial agglomeration significance

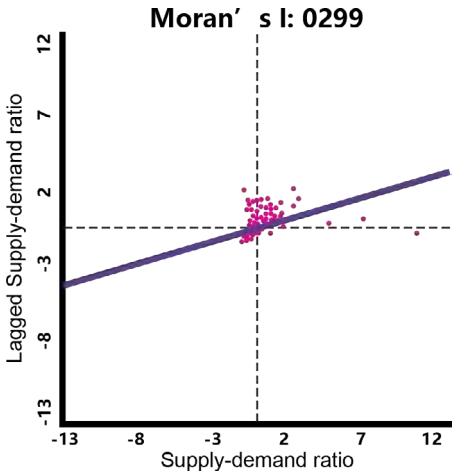

Fig.6. Moran index scatter plot

4.2.2 Analysis of Resident Usage Time Characteristics

Questionnaire data show distinct age-group patterns in facility usage times:

Usage Frequency: Younger (19-28 years) and elderly (over 60 years) groups are more frequent users. Younger individuals for post-study/work leisure/fitness; elderly due to more retirement leisure. Middle-aged (29-45, 46-60 years) use is less frequent/consistent, likely due to work/family pressures.

Overall, sports facility usage frequency is generally higher than cultural facilities, reflecting stronger daily fitness demand.

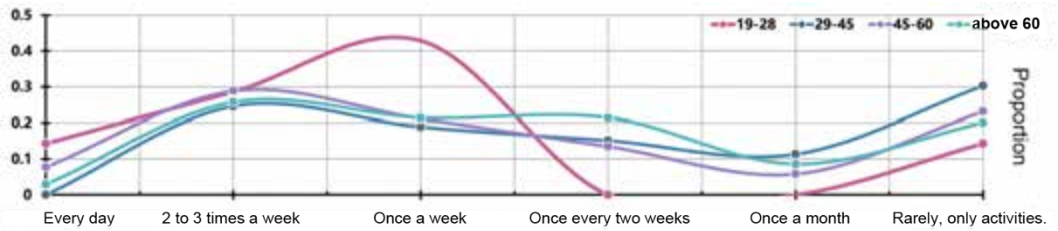

Fig.7. Frequency of use of public cultural facilities

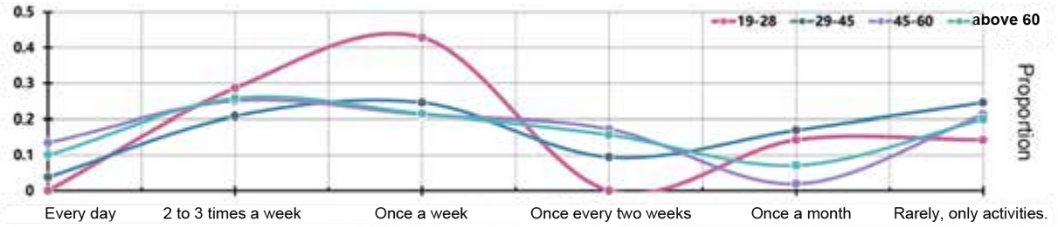

Fig.8. Frequency of use of public sport facilities

Usage Duration:Younger and elderly groups spend longer average times per visit. Middle-aged groups prefer shorter, efficient use (e.g., <30-min fitness). Elderly cultural activity time is increasing.

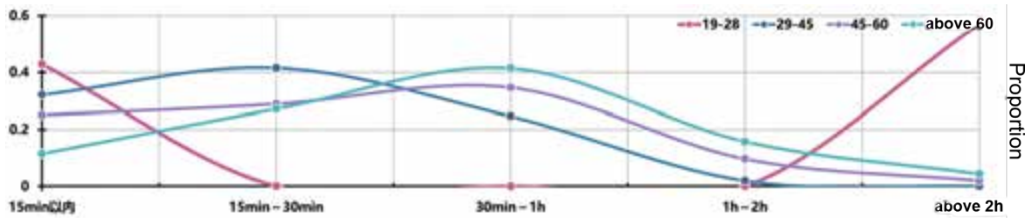

Fig.9. The duration of use of public cultural facilities

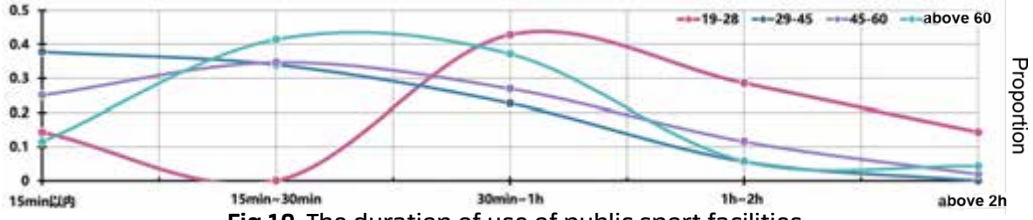

Fig.10. The duration of use of public sport facilities

Usage Time Distribution (Weekdays and Weekends):
Cultural Facilities:
1-Younger groups: Mainly weekend daytime (e.g., 9:00-18:00).
2-Middle-aged groups: More often weekday evenings (e.g., 18:00-21:00) and weekends.
3-Elderly groups: Widely distributed, but early mornings (weekdays/weekends) (e.g., 6:00-9:00) are a peak for cultural activities (morning exercises, reading).

Sports Facilities:Bimodal or multimodal characteristics across age groups.
1-Younger groups: Peaks on weekday evenings and weekends.
2-Middle-aged groups: Primarily weekday evenings for fitness.
3-Elderly groups: Early mornings (weekdays/weekends) (morning exercises) and off-peak daytime are main times.

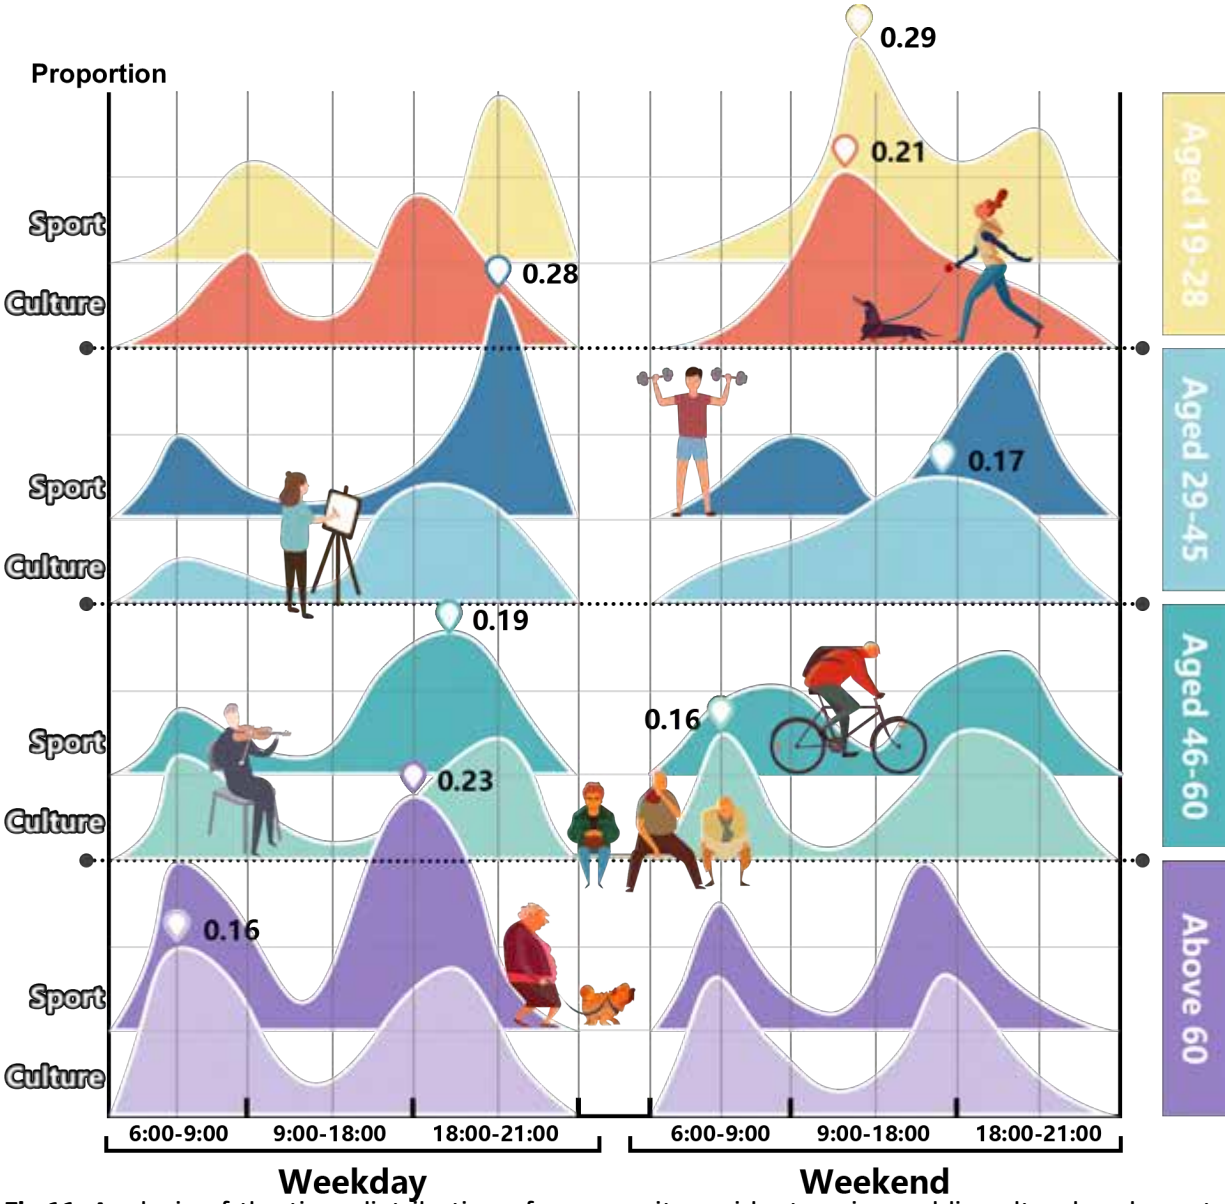

Fig.11. Analysis of the time distribution of community residents using public cultural and sports facilities

These time differences demand specific facility opening hours, off-peak guidance, and enhanced nighttime service.

4.2.3 Analysis of Resident Usage Preferences
Facility type/function preferences show significant age differentiation:

Cultural Facility Preferences:
Facility Type:
1-All ages: Libraries and cinemas (if available/accessible) are popular.
2-Younger: Higher demand for museums, art/exhibition halls.
3-Middle-aged: Besides libraries, community classrooms, art studios (skills/interests).
4-Elderly: Strongest demand for community cultural centers, elderly activity/chess/calligraphy rooms.

Facility Function:
1-Younger: Emphasize exhibitions, reading/research, knowledge acquisition, skills training.
2-Middle-aged/Elderly: Prefer leisure/entertainment, social interaction, cultural activities/festivals.
3-Universal: Leisure/entertainment and reading/research are core expectations.

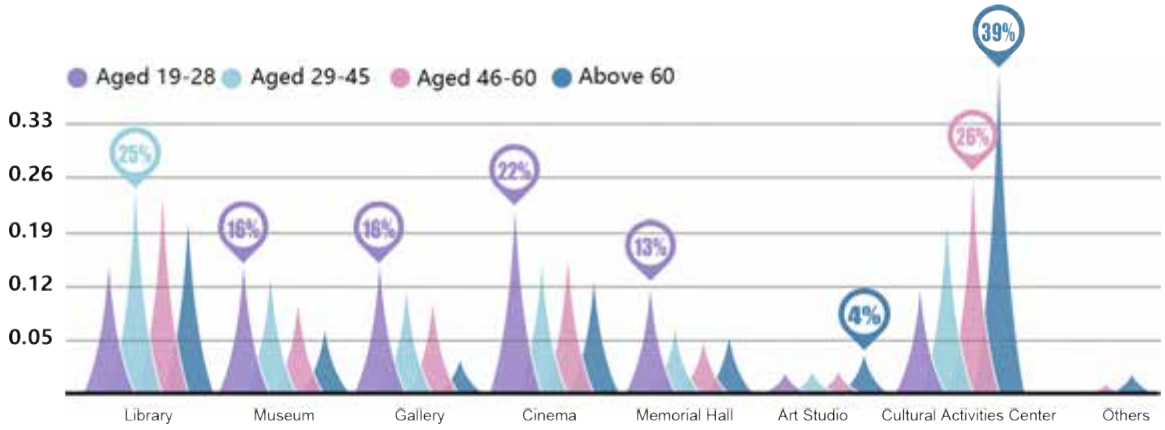

Fig 12. Analysis of Public Cultural Facilities Preference Types

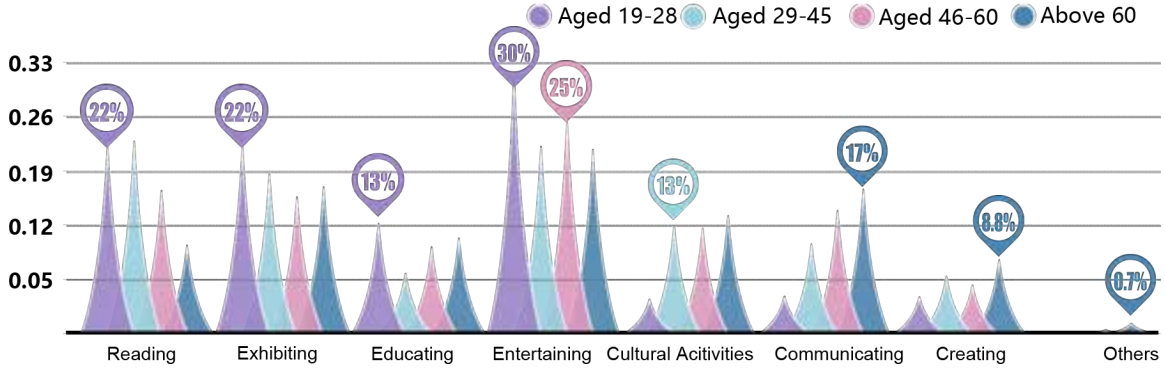

Fig 13. Analysis of Functional Preferences for Public Cultural Facilities

Sports Facility Preferences:
Facility Type:
1-Younger: Prefer comprehensive fitness centers, pools, courts (basketball, badminton, tennis), climbing gyms; strong demand for open school facilities.
2-Middle-aged: Higher demand for gyms, multi-functional sports grounds, fitness trails.
3-Elderly: Most use outdoor venues (parks, squares), outdoor equipment, gateball courts, Tai Chi areas, community fitness trails; indicates lack of suitable indoor elderly facilities.
Community sports centers (if composite) can meet some needs across ages.

Facility Function:
1-All ages: Fitness/exercise is core.
2-Younger: Prefer sports training, competitions, courses.
3-Middle-aged: Also health guidance, relaxation.
4-Elderly: Increasing demand for leisure, social interaction, health preservation.

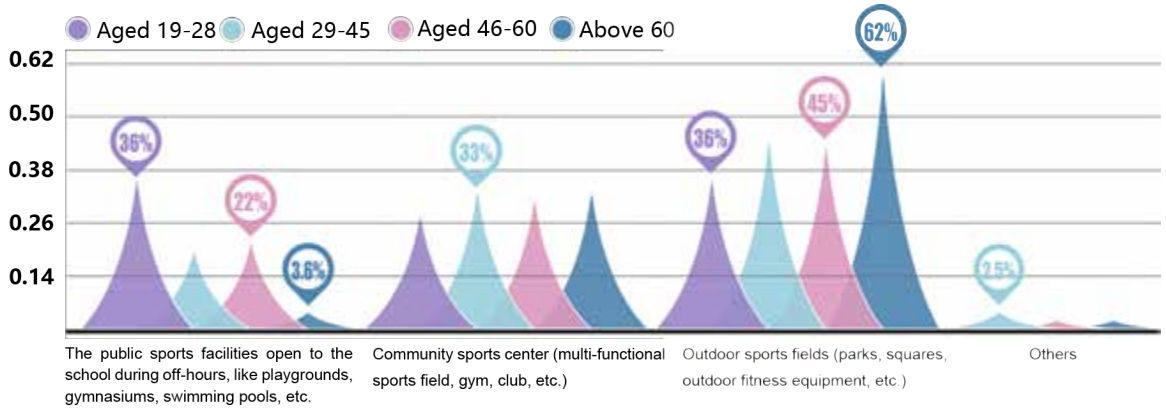

Fig 14. Analysis of Public Sports Facilities Preference Types

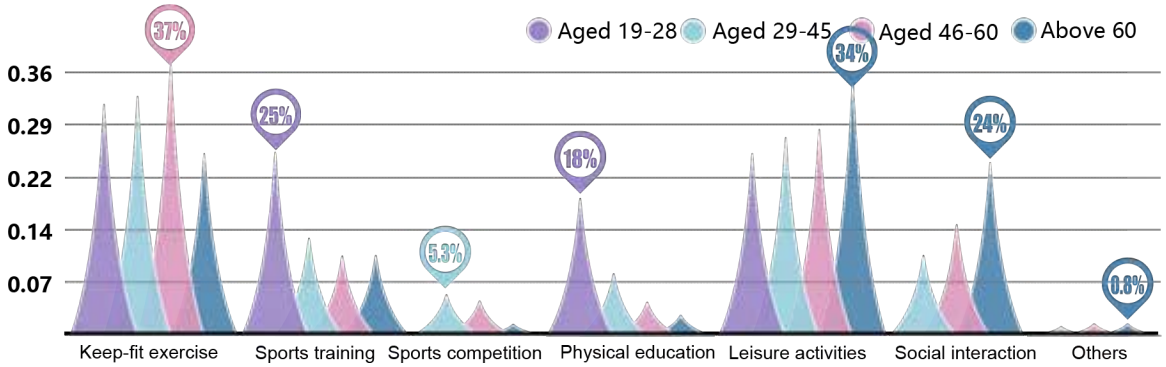

Fig 15. Analysis of Functional Preferences for Public Sports Facilities

Matching Degree: Existing Functions vs. Resident Needs:
1-A significant gap exists; complete matching is very low. Original data: cultural facilities 10.7% complete match, sports 3.6%.
2-Specific mismatches: High demand for cultural leisure/reading, but supply/quality need improvement, especially for middle-aged/elderly. Sports: high demand for fitness/leisure, but existing facilities insufficient, especially for middle-aged. Elderly better, but need age-appropriate, guided indoor options.
3-The middle-aged group (29-45 years) shows severe cultural/sports functional mismatch, needing focus.
These preferences guide facility type, function, design, and service innovation.

4.3 Adaptability Analysis of Public Cultural and Sports Facilities (Satisfaction Evaluation)

4.3.1 Overall Resident Satisfaction

Relatively high overall dissatisfaction: Over 30% "overall dissatisfied" or "somewhat dissatisfied." Sports facilities: 35% dissatisfied; cultural: 33.5%. Widespread problems meeting expectations.

Significant age differences:
1-Elderly (over 60): lowest overall satisfaction. Possibly due to stronger reliance but unmet needs (accessibility, age-friendly design, service).
2-Middle-aged (29-45), especially younger segment: relatively higher satisfaction. Possibly due to lower use frequency or expectations; needs further analysis.

Satisfaction with specific indicators:
1-Sports: 19-45 age group: higher satisfaction with opening hours, environment, functional richness, participation convenience. Elderly (over 60): significantly lower satisfaction with accessibility, opening hours (insufficient morning/early evening closure), environment (outdated equipment, uneven grounds, no shade/rain protection).
2-Cultural: 19-45 age group: higher satisfaction with environment, functional richness, participation convenience, educational value. Over 46, especially elderly (over 60): lower satisfaction, particularly accessibility (distance, no elevators), opening hours (insufficient lunch/weekend opening), environment (small spaces, poor lighting, uncomfortable seating).

Key factors influencing satisfaction (resident perspective, preliminary ranking): Facility accessibility, opening hours, environment, special group friendliness considered most important. Cleanliness, safety, comfort directly impact experience; distance/transport affect use; schedule-matching opening hours crucial; elderly/child-friendly design significantly enhances satisfaction.

4.3.2 Analysis of Satisfaction Influencing Factors (Based on Multiple Linear Regression Model)

To more scientifically reveal the specific contribution of each sub-item to overall satisfaction, this study utilized multiple linear regression analysis.

Table 1. Analysis of Influencing Factors of Satisfaction

	Facility accessibility	Opening hours	Facilities and environment	Functional richness	Convenience of participation	Educational Value	Interactive experience	Friendliness to special groups
Satisfaction with public sports facilities	0.07	0.083	0.357	0.195	0.19	0.02	0.098	0.024
Satisfaction with public cultural facilities	0.203	0.134	0.218	0.087	0.045	0.257	0.032	0.138
Comprehensive satisfaction with public cultural and sports facilities	0.125	0.09	0.256	0.137	0.168	0.151	0.041	0.056

Main drivers of satisfaction with public sports facilities:
1-Facilities and Environment (largest standardized regression coefficient, strongest impact): This includes the cleanliness of the venue, the condition and maintenance of equipment, safety during use, and overall aesthetics and comfort. A good physical environment is fundamental to guaranteeing the sports activity experience.
2-Functional Richness: This refers to whether the types of programs offered by sports facilities are diverse and can meet the needs of different age groups and people with different sports preferences. Facilities with monotonous functions struggle to attract residents in the long term.
3-Convenience of Participation: This includes the simplicity of the reservation process, waiting time for venue use, and ease of information access. Convenient participation channels can effectively increase usage frequency and satisfaction.

Main drivers of satisfaction with public cultural facilities:
1-Educational Value (largest standardized regression coefficient, strongest impact): This refers to whether the content provided by cultural facilities contributes to knowledge dissemination, skill learning, cultural inheritance, and personal literacy improvement. Residents' demand for the spiritual and cultural aspects of cultural facilities is increasing.

2-Facilities and Environment: Similar to sports facilities, the cleanliness, comfort, safety, and cultural atmosphere of cultural facilities are also important factors affecting satisfaction.
3-Facility Accessibility: Convenient geographical location, smooth traffic connections, and reasonable walking distances are prerequisites for residents to choose and use cultural facilities.

Gap analysis between importance and current satisfaction status:
By comparing the "importance" scores (representing expectation levels) and "satisfaction" scores (representing current status evaluations) for each sub-item in the questionnaire, it was found that: for both public sports facilities and public cultural facilities, residents' average expectation level for each indicator was higher than their average evaluation of the current situation.

The items with larger gaps, indicating significant shortcomings, were mainly concentrated in: Facilities and Environment (high expectations, but generally low current evaluations), Functional Richness (desire for diverse facility functions, but current supply is monotonous), and Friendliness to Special Groups (e.g., designs and services suitable for the elderly and children, high expectations, but generally insufficient currently). These gap items are the key areas where future facility optimization and improvement efforts should be focused and invested.

4.4 Analysis of Supply-Demand Contradictions in Public Cultural and Sports Facilities (Based on IPA Model)

To comprehensively present the complex relationship between supply-demand matching (represented by the "supply-demand ratio") and residents' subjective perceptions (represented by "overall satisfaction"), this study drew on the IPA model concept to classify each neighborhood committee into four quadrants, thereby identifying different types of supply-demand contradictions. Fig.16 illustrates the supply-demand ratio values for each neighborhood committee, Fig.17 shows the overall satisfaction with public cultural and sports facilities in each neighborhood committee, and Fig.18 depicts the heterogeneity of the IPA result space.

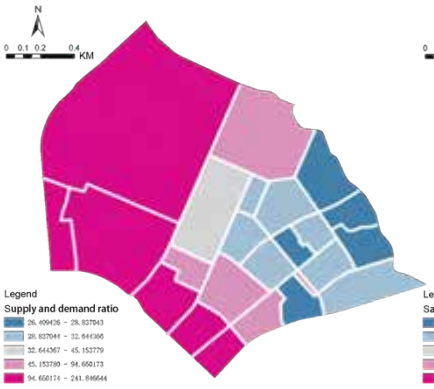

Fig.16. The supply-demand ratio values of each neighborhood committee

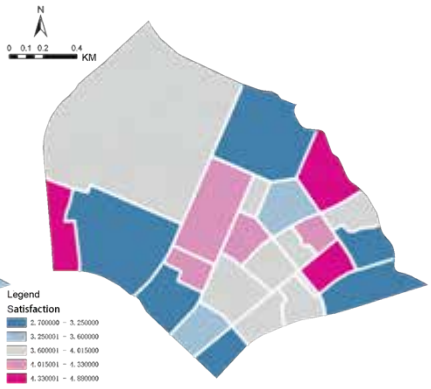

Fig.17. Overall satisfaction with public cultural and sports facilities in each neighborhood committee

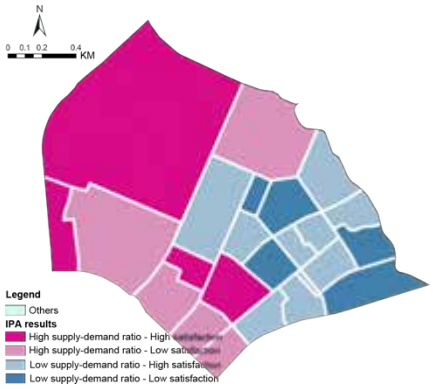

Fig.18. Heterogeneity of the IPA result space

Quadrant A: High Supply-Demand Ratio - High Satisfaction (Advantage Maintenance Zone):
∑ **Characteristics**: These areas (such as Miyun Road Neighborhood Committee, Jin'an Neighborhood Committee, etc., mentioned in the original report) have relatively abundant cultural and sports facility resources, and residents' satisfaction with these facilities is also high.

∑ **Interpretation**: This indicates that in these areas, not only is the quantity of facilities relatively guaranteed, but their quality, operation management, and services also effectively meet residents' needs. Strategically, existing service levels should be maintained and enhanced, and these areas can serve as models for promotion.

Quadrant B: Low Supply-Demand Ratio - High Satisfaction (Potential Mining Zone / Priority Area for Improving Supply):
∑ **Characteristics**: In these areas (such as Anshan Third Village Neighborhood Committee, etc.), although the objective supply of cultural and sports facilities (supply-demand ratio) is not high, residents' satisfaction is relatively high.

∑ **Interpretation**: This may imply that the few facilities in these areas are of high quality and well-operated, or that residents have low expectations for community facilities, or that specialized services accurately meet the needs of specific groups. Strategically, while maintaining the existing service quality and features, the focus should be on increasing the quantity and types of facilities to alleviate the pressure of insufficient supply and further enhance the overall service level.

Quadrant C: High Supply-Demand Ratio - Low Satisfaction (Key Service Improvement Zone / Prominent Human-Oriented Contradiction Zone):
∑ **Characteristics**: These areas (such as Tongji New Village Neighborhood Committee, Anshan Sixth Village Neighborhood Committee, etc.) have a relatively large number of cultural and sports facilities (higher supply-demand ratio), but residents' satisfaction is low.

∑ **Interpretation**: This is a typical phenomenon of "supply-demand mismatch" or "quantity without quality". Possible reasons include: facility types not matching residents' needs, outdated and poorly maintained facilities, chaotic management, poor service quality, unreasonable opening hours, or overcrowding leading to a poor user experience. Strategically, instead of blindly increasing quantity, the focus should be on improving facility quality, optimizing functional combinations, enhancing operational management, and enriching service content to address unmet "human-oriented needs".

Quadrant D: Low Supply-Demand Ratio - Low Satisfaction (Comprehensive Improvement Zone / Coexisting Human-Land Contradiction Zone):
∑ **Characteristics**: In these areas (such as Anshan First Village Third Neighborhood Committee, etc.), the supply of cultural and sports facilities is severely insufficient, and residents' satisfaction is also very low.

∑ **Interpretation**: This is the most problematic area, with significant shortcomings in both the quantity and quality of facilities, representing the most concentrated manifestation of supply-demand contradictions. Strategically, comprehensive and systematic improvements are needed, including increasing facility quantity, optimizing spatial layout, enhancing facility quality, and enriching service content.

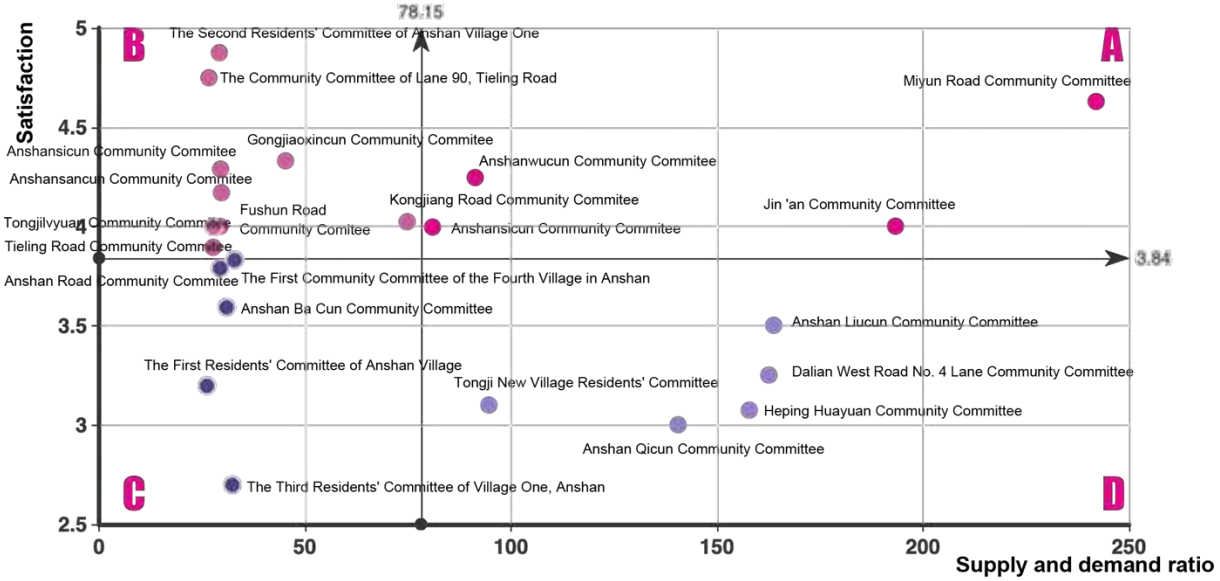

Fig 19. IPA Model Analysis

Based on the above analysis, the core supply-demand contradictions of public cultural and sports facilities in Siping Sub-district can be summarized as follows:

∑ **1-Contradictions at the Availability Level**: Insufficient total quantity and monotonous types of facilities make it difficult to cover and meet the basic cultural and sports needs of diverse populations within the sub-district (especially for the young and middle-aged groups and those with different interest preferences). Barriers to the sharing of high-quality resources (such as facilities within universities) exacerbate the scarcity of available resources.

∑ **2-Contradictions at the Accessibility Level**: Uneven spatial layout leads to some densely populated old residential communities becoming service blind spots or weak areas, resulting in poor convenience for residents to actually reach and use facilities. The functional supply of existing facilities does not fully match the actual usage behavior habits of residents (such as time preferences, functional preferences), leading to inefficient resource utilization.

∑ **3-Contradictions at the Adaptability Level**: The quality, maintenance level, operational management, and service content of existing facilities have failed to effectively respond to the actual needs and expectations of residents, especially special groups such as the elderly, leading to low subjective satisfaction among residents. Facilities have shortcomings in terms of humanized design, professional guidance, interactive experience, and cultural atmosphere creation.

The identification of these contradictions lays a solid foundation for proposing targeted optimization strategies in the next stage.

5. Conclusions and Optimization Suggestions

5.1 Main Conclusions

Based on a systematic analysis of the availability, accessibility, and adaptability of public cultural and sports facilities in Siping Sub-district, this study draws the following main conclusions:

1-Coexistence of Supply-Side Structural Shortages and Spatial Imbalances: The total quantity of public cultural and sports facilities in Siping Sub-district struggles to meet the actual demands of its high-density population, presenting an overall situation where "supply falls short of demand". Concurrently, prominent issues include the homogeneity of facility types (sports facilities are predominantly small-scale outdoor equipment, while cultural facilities are largely oriented towards elderly services) and an uneven spatial distribution (high-quality resources are concentrated within universities or specific areas, with insufficient coverage in older residential communities). There is a particularly severe undersupply of cultural and sports spaces catering to young and middle-aged groups and meeting diverse, high-quality needs.

2-Significant Group and Temporal Differentiation in Resident Usage Behavior: The "young and old" demographic groups (youth and the elderly) are the primary users of public cultural and sports facilities, exhibiting relatively higher usage frequency and longer single-use durations. Clear, differentiated characteristics are observed among different age groups concerning preferences for facility types (e.g., youth prefer professional sports and experiential cultural activities, while the elderly favor outdoor fitness and social-cultural activities), functional demands (e.g., youth prioritize skill enhancement and knowledge acquisition, whereas middle-aged and elderly individuals focus on leisure, entertainment, and health-related social interaction), and usage time slots (e.g., youth during weekends and weekday evenings, the elderly in mornings and daytime).

3-Overall Resident Satisfaction is Not High, with a Gap Between Service Experience and Expectations: Over thirty percent of residents expressed dissatisfaction with existing cultural and sports facilities. Elderly groups, in particular, reported significantly lower satisfaction regarding facility accessibility, reasonableness of opening hours, comfort of the facility environment, and friendliness towards special groups. Regression analysis identified facility environment, functional richness, educational value (for cultural facilities), and convenience of participation as key factors influencing resident satisfaction. Residents' expectation levels for these factors generally surpassed their current evaluations, reflecting a considerable disparity between the service quality and experiential aspects of existing facilities and the actual needs and expectations of the residents.

4-The Phenomenon of Supply-Demand Mismatch Cannot Be Ignored; Precise Alignment is Key to Improvement: The IPA model analysis revealed instances of "high input (high supply-demand ratio) - low satisfaction" or "low input (low supply-demand ratio) - low satisfaction" in certain areas. This indicates that merely increasing the quantity of facilities cannot fully resolve the issues; the crucial aspect lies in achieving a precise alignment between facility provision and actual resident needs across multiple dimensions, including facility type, function, quality, and operational management.

5.2 Optimization and Improvement Strategies

Based on the above conclusions and identified core supply-demand contradictions, this study adheres to the principles of "problem-oriented, demand-led, context-specific adaptation, and classified policy implementation". From both "place-based" (focusing on spatial optimization and facility layout) and "people-based" (focusing on population needs and service improvement) dimensions, an "identification-evaluation-optimization-improvement" action system is constructed, proposing the following specific optimization and improvement strategies:

5.2.1 The "Identification-Evaluation-Optimization-Improvement" Action System Construction Logic

This system emphasizes first identifying specific supply-demand contradictions and their characteristics in different areas and for different facility types through scientific methods (such as 2SFCA, questionnaire surveys, IPA model); then conducting a multi-dimensional evaluation to clarify the severity of the problems and influencing factors; based on this, targeted optimization plans are formulated; finally, through continuous monitoring and feedback, the service capacity is continuously improved.

5.2.2 Specific Optimization and Improvement Strategies (Category-based Policies)

1-**For "High Supply-Demand Ratio - Low Satisfaction" Areas (Prominent Human-Oriented Demand Contradiction, corresponding to Quadrant C of the IPA model):**The core strategy for this area is to improve quality and efficiency and optimize the service experience. Specific measures include: comprehensively inspecting and optimizing the quality and environment of existing facilities, such as updating old equipment, improving site conditions (increasing lighting, seating, enhancing cleanliness, etc.), and creating a safe and comfortable atmosphere; conducting in-depth research on resident needs (especially for low-satisfaction groups) to reshape facility functions or update content, introducing more popular projects and courses; flexibly adjusting opening hours based on residents' usage time characteristics (e.g., extending evening hours, ensuring weekend availability), promoting staggered usage, and introducing professional management or volunteers to enhance guidance and service levels, and establishing convenient reservation and feedback mechanisms.

2-**For "Low Supply-Demand Ratio - Low Satisfaction" Areas (Coexisting Human-Land Demand Contradiction, corresponding to Quadrant D of the IPA model):**The core strategy for this area is to address shortcomings and improve quality simultaneously, carrying out systematic comprehensive improvement. Specific measures include: prioritizing from a "people-based" perspective, based on the demographic structure and needs assessment of the area, supplementing the most lacking facility types that residents urgently need, such as professional sports venues, fitness centers, or youth centers for young people, multi-functional activity rooms and fitness trails for young and middle-aged people, and health and wellness activity places and teaching points for elderly universities for the elderly; simultaneously, considering "place-based" conditions, fully tapping into potential spaces (such as idle factories, community rooms awaiting renovation), conducting scientific site selection and intensive, networked layout according to facility service radius and coverage gaps, avoiding new imbalances; and promoting the "1+N" embedded spatial layout model, i.e., creating a functionally composite "People's Square" style community comprehensive service core, supplemented by flexible, scattered "Six Arts Pavilion" style micro-service contact points, connected by slow-traffic systems to form a conveniently accessible service network.

3-**For "Low Supply-Demand Ratio - High Satisfaction" Areas (Prominent Place-Based Demand Contradiction, corresponding to Quadrant B of the IPA model):**The core strategy for this area is to focus on increasing supply while maintaining service quality. Specific measures include: learning from the successful operational experience of existing facilities, maintaining their service characteristics and quality; accurately identifying spatial coverage gaps, prioritizing the addition of similar or related types of high-quality facilities in service blind spots or underserved adjacent areas;

rationally determining the type and scale of new facilities based on available site conditions and coordinating with the surrounding environment; while increasing quantity, continuously monitoring and enhancing facility quality and capacity to prevent service quality decline due to scale expansion.

4-**Universal Optimization Strategies (Applicable to all areas):**The open sharing of cultural and sports facilities in campuses and enterprises/institutions with the community should be vigorously promoted, with sound incentive and management mechanisms established to open up high-quality resources in phases, at different times, and under certain conditions to alleviate insufficient supply. At the same time, flexible and small-scale embedded cultural and sports spaces, such as the "Six Arts Pavilion" model (e.g., community shared living rooms, neighborhood libraries, pocket park fitness corners), should be actively introduced and cultivated to meet residents' immediate and fragmented needs. In all new construction, renovation, and operation of facilities, high attention must be paid to comprehensively improving friendliness towards special groups such as the elderly, children, and persons with disabilities, implementing barrier-free designs and age-appropriate/child-friendly services. Furthermore, intelligent empowerment and information-based management need to be strengthened, establishing a unified information release, inquiry, and reservation platform, promoting online services, and optimizing facility operations through big data analysis. Finally, social forces should be encouraged to participate in facility construction and operation through policy guidance, service procurement, and cooperative operation, forming a positive situation of multi-subject co-construction and co-governance.

6. Research Deficiencies and Prospects

Although this study has conducted a relatively systematic analysis of the supply-demand relationship concerning public cultural and sports facilities in Siping Sub-district and proposed specific optimization strategies, certain limitations still exist:

1-Sample Representativeness and Generalizability: Despite efforts to ensure the coverage of the questionnaire survey sample, the sample size (182 respondents) is relatively limited due to constraints in research time and resources. Caution should be exercised when generalizing these conclusions to a broader context. Future research could further expand the sample size and employ more refined stratified sampling techniques to enhance the statistical validity and generalizability of the findings.

2-Tracking of Dynamic Demand Changes: This study primarily reflects the demand situation of residents at a specific point in time. However, resident needs are dynamic and influenced by various factors such as social development, lifestyle changes, and unforeseen events (e.g., pandemics). Future research could consider incorporating longitudinal tracking surveys to better capture the evolutionary trends of demand.

3-Depth of "Qualitative" Assessment: The assessment of facility "quality" in this study relies mainly on residents' subjective satisfaction evaluations and some objective indicators (e.g., facility environment, functionality). For aspects such as the professionalism of services, the depth of cultural content, and the quality of activity organization, future research could employ more in-depth qualitative methods, including expert evaluations, in-depth interviews, and participatory observation.

4-Feasibility Assessment of Strategy Implementation: The optimization strategies proposed in this report are currently at a conceptual and directional level. Their concrete implementation requires more detailed feasibility assessments and scheme refinements, considering the sub-district's fiscal capacity, land resource constraints, multi-departmental coordination mechanisms, and residents' willingness to participate.

Looking ahead, the planning and development of urban public cultural and sports facilities will increasingly emphasize a people-oriented approach, precise supply, intelligent operations, and resilient adaptation.

Subsequent research can be extended in the following directions:

1-Refined Demand Profiling and Dynamic Monitoring Based on Big Data: Utilizing big data resources such as mobile signaling, social media, and smart wearable devices to more accurately delineate the spatio-temporal behavior patterns and cultural/sports activity preferences of different population groups, thereby achieving dynamic monitoring and prediction of demand.

2-Research on Revitalization and Innovative Design of Existing Stock Spaces: Against the backdrop of increasingly scarce land resources, in-depth research is needed on how to activate existing urban spatial resources through micro-renewal, adaptive reuse, and composite function implantation to create more attractive and vibrant community cultural and sports venues.

3-Exploration of Multi-Actor Collaborative Governance and Sustainable Operation Models: Investigating the establishment of effective collaborative governance mechanisms among government, market actors, social organizations, and community residents, and exploring sustainable development models featuring diversified investment, professionalized operation, and community participation.

4-Planning Responses for Cultural and Sports Facilities from the Perspectives of Healthy Cities and Active Aging: In conjunction with the "Healthy China" strategy and the national strategy for actively responding to population aging, future research should focus on how the optimized allocation of cultural and sports facilities can promote the formation of healthy lifestyles among residents and enhance the quality of life and sense of community integration for the elderly.

Through continuous in-depth research and practical exploration, it is anticipated that greater wisdom will be contributed to the improvement of planning, construction, operational, and managerial standards for urban community public cultural and sports facilities in China, ultimately aiding in the construction of a more equitable, efficient, inclusive, and vibrant city for the people.

A Study on the Travel Characteristics of Rail Transit Passengers in Township Areas of Wuxi City

Wang Yuchen, Chen Ge, Huang Jianzhong
College of Architecture and Urban Planing,Tongji University
Email:wyc04042022@163.com

Abstract
With China's new urbanization driving integrated urban-rural transport, this study examines the Wuxi–Jiangyin S1 township rail line serving over 30,000 daily riders. Using high-precision LBS data from October 2024, we identified township passengers via spatio-temporal filters, inferred trip purposes through a white-box model combining spatial and temporal rules, and classified last-mile modes with fuzzy membership functions. Ridership is dominated by middle-aged, multi-generational households; leisure trips comprise over 50%; medium-distance (8–29 km) travel prevails; and bicycles/motorcycles lead access/egress. More than 60% of travelers make no station-area stops, indicating weak station-city integration. Findings offer guidance for service optimization, TOD planning, and policies to enhance sustainable township rail development.

Keywords: Rail Transit; Township Areas; Wuxi City; Travel Characteristics

1 Introduction

National strategies for new urbanization and integrated urban-rural development are driving the evolution of intercity railways, which are reshaping urban-rural spatial links. The "Yangtze River Delta Regional Integration Development Plan Outline" aims to establish a "one-hour commuter circle," fostering composite transportation systems that merge urban rail transit (metro) with intercity railway functions. Township rail transit, through technical standard compatibility (e.g., platform spacing, vehicle types) and innovative operational modes (e.g., bus-like scheduling, through-line operations), creates high-frequency, efficient connections between core metropolitan cities and outlying townships (Li Fengjun et al., 2020; Yang Shaohui et al., 2022; Zhang Pei et al., 2017). By 2023, the Yangtze River Delta's intercity railway network surpassed 1500 km, projected to exceed 3000 km by 2025, deeply serving low-urbanization areas (2000-5000 people/km²), signifying a new "rail transit extending to townships" phase.

The Wuxi-Jiangyin S1 Line in Wuxi exemplifies such systems, pioneering through-operation between an intercity railway and an urban metro in China. It connects Jiangyin's urban area, township nodes like Zhouzhuang and Qingyang, and Wuxi's main urban area via a "one-train direct access" model, serving over 30,000 daily bidirectional urban-rural commuters. Its data reveal unique spatio-temporal distribution, travel purposes, and behavioral preferences of township rail passengers. While current research focuses on urban rail transit, a gap exists regarding township rail passengers with both intercity and metro characteristics. Analyzing these patterns is vital for optimizing transportation in urban-rural integration and addressing dilemmas like the "urban siphon effect" versus "township transportation deserts". This study analyzes the S1 Line's township passenger travel characteristics to inform operational optimization, station-area land use planning, and broader urban-rural transport policies.

2 Literature Review

Rail transit, as a pivotal component of urban public transportation systems, demands systematic investigation of passenger travel characteristics to optimize operational strategies, enhance service quality, and inform future infrastructure planning. With accelerating urbanization and shifting socio-economic structures, usage patterns among distinct passenger cohorts have become markedly heterogeneous. Accordingly, segmenting passengers by individual attributes—such as age, gender, and occupation—or by behavioral characteristics—such as trip purpose and frequency—is a critical step in understanding and addressing diverse needs. Through such segmentation, the unique travel patterns of specific groups can be identified, furnishing a basis for designing personalized services that elevate overall passenger satisfaction and system efficiency. Furthermore, targeted research on special populations (e.g., the elderly, children, and persons with disabilities) facilitates the development of more inclusive policies, ensuring that all members of society enjoy equitable access to effective rail transit services.

Travel characteristics differ significantly across passenger groups. Research categorizes groups by individual attributes, travel features, or combined factors. Some studies focus on age and gender impacts. Xiong Meicheng et al. (2022) found that older elderly (≥70) in Kunming have reduced mobility but increased public transport reliance compared to younger elderly (60-69). Yang Hong et al. (2023) noted Wuhan's elderly avoid peak hours and prefer shorter distances. Xiaohan Liu et al. (2024) found travel distance, time, and space variations among different gender and age groups.

Other studies examine travel purposes and frequencies to identify patterns and drivers. Cheng Xiaoyun et al. (2020) proposed a classification framework based on travel days, daily trips, concentration, time consumption, and line utilization entropy. Comprehensive approaches consider multiple simultaneous factors. Rezwana Rafiq et al. (2021) used Latent Class Analysis (LCA) for user classification, identifying five activity-travel patterns, such as employed white males on simple transit-based work trips and employed white females on complex work trips. Some research classifies passengers by activity within hub station areas, finding differences in activity range and travel time distribution (Cheng L et al., 2024).

Travel characteristics are often described by time, space, and intensity (Zou Qingru et al., 2024). Spatial attributes include origin (LE M K et al., 2015), path, stations (MA X et al., 2013), and commuting distance (JI Y J et al., 2019; and Kang Hehe et al., 2018). Temporal attributes include average travel time (Long Ying et al., 2015), departure time (LE M K et al., 2015), journey time (MA X et al., 2013), and first departure time (JI Y J et al., 2019). Rail usage intensity is measured by trip counts over periods (El MAHRSI M K et al., 2017) or average trips and travel days (Liu Ying et al., 2019).

Effective classification algorithms are critical(Cheng Xiaoyun et al., 2020). Studies have used DBSCAN, GMM, OPTICS (VENUGOPAL S et al., 2016), LCA, k-means++ (Xu Xiaowei et al., 2017), and hierarchical clustering with k-means (ZHAO J J et al., 2014; Pang L et al., 2023) for urban rail user segmentation, providing rich methods for understanding travel diversity.

Existing research offers robust perspectives and methods for urban rail optimization. However, township rail stations and passengers remain understudied. Townships differ from urban centers in population density, land use, economic activities, and lifestyles, leading to unique passenger flow and demands at their rail stations. Lines like the Wuxi-Jiangyin S1, connecting cities with townships and integrating with urban metros, may serve complex demands (commuting, services, leisure) and exhibit distinct travel behaviors (purpose, duration, access/egress modes) compared to traditional urban or suburban rail users. This disparity is this study's focus, as specialized research on such hybrid-feature township rail transit is scarce.

This research aims to fill this gap by studying Wuxi-Jiangyin S1 Line's township passengers, detailing their attributes and behaviors for a comprehensive understanding of their composition and needs. This supports S1 Line's operational optimization and service improvement, offering empirical references and theoretical insights for non-urban rail service models and station-area integrated development.

3 Research Content and Methods

3.1 Research Scope and Data

This study focuses on the Wuxi-Jiangyin S1 Line, stretching 30.4 km (10.5 km underground, 0.2 km transitional, 19.7 km elevated) with 10 stations (5 underground, 5 elevated) and a design speed of 120 km/h, operating through-service with Wuxi Metro Line 1. The Jiangyin urban section is underground; the Xuxiake Avenue section is elevated. Qingyang, Xuxiake, and Science City stations are elevated. The selected suburban section includes Nanzha, Qiaoqi, Qingyang, Xiake Bay Science City, and Mazhen Stations (Figure 1).

The study uses LBS data from Wuxi City (October 14-20, 2024), providing high-precision user spatio-temporal trajectories, enabling capture of travel chains, stay point identification, and travel purpose inference.

3.2 Research Methods

3.2.1Identification of Rail Transit Passengers in Township Areas

LBS data provide certain spatial identification of metro stations, allowing high-precision matching via hard thresholds. The study first anchors metro travel to maintain base passenger group purity, adopting a phased identification: first, identify township rail passengers, then use fuzzy theory for access/egress modes, balancing data traits and research goals.

A framework for identifying township rail passengers uses multi-source data fusion and spatio-temporal analysis. High-precision LBS data (error ≤ 50m) and geofencing match user stay points with metro station coordinates, filtering records within a 100m station buffer with stay duration ≥3 minutes. Travel chain continuity rules extract records of continuous visits to different metro stations consistent with prior knowledge, identifying metro users. To target township rail passengers, travel chains through township stations (Mazhen, Qingyang, Science City, Qiaoqi defined as township functional stations) are extracted, identifying those with at least one township station stop.

3.2.2 Stay Point Identification Based on Density

Trajectory stay point identification is key for mining travel activity semantics and characterizing crowd demands. Existing methods include cluster-based, probability-based, and discrimination-based strategies (Lu Jianfeng et al., 2020). Cluster-based density algorithms are common but spatially limited. Probability-based methods (Bayesian, Gaussian mixture models) infer frequent locations but ignore trajectory temporal sequences. Discrimination-based methods focus on stay/representative points, missing spatio-temporal aggregation (Zhang Xun, 2022). To address these, Li Yuru et al. (2018) proposed SPID (Stay Point Identification based on Density), which considers temporal continuity, directionality, and spatio-temporal aggregation.

This study uses SPID for Wuxi's LBS data. Steps: Identify trajectory points; calculate distances to other points chronologically (forward/backward); add points within distance thresholds to a set; stop when distances exceed thresholds. Stay points are determined by point set density (He Guofeng, 2022). Following literature (Jin Tanhua, 2019), spatial threshold is 100m, time threshold is 15min.

3.2.3 Travel Purpose Inference

To ensure effective semantic identification of passenger activities and precise crowd feature characterization, this study builds on identifying daily township rail users and stay points. It uses LBS travel chain data and stay point spatio-temporal attributes (period, duration) for activity chain semantic recognition for each passenger's daily stay points. Rail station spatio-temporal matching rules extract metro travel segments for precise analysis of purposes and patterns.

Traditional activity chain data from surveys are costly and not timely (Hartgen et al., 2009; Collia et al., 2003; McDonald et al., 2008). Mobile phone data are now used. Methods include: 1) Regression models, like Diao et al. (2016) using multinomial logit for semantic labels from activity time, weather, etc.; 2) Hidden Markov Network (HMN) sequence models, e.g., Widhalm et al. (2015) on Boston/Vienna data, and Yin et al. (2018) with HMN optimized by activity transfer patterns; 3) Machine learning (e.g., random forests), like Zhao Pengjun et al. (2020) using RF for metro trip purpose classification. However, these methods have limitations: 1) "Black-box" models lack interpretability (HMNs, ML). 2) Data dependency versus universality: require proprietary survey data for transition probabilities or fine-grained land use/large training sets, creating researcher barriers. 3) Massive data processing challenges (Cao, J. et al., 2019; Deville, P. et al., 2014).

This study, referencing Yin L et al. (2021), uses a transparent, rule-based inference algorithm considering spatial/temporal features for activity purpose, with Monte Carlo for final determination. This ensures interpretability and uses open-source geographic data, offering an operable tool.

• Stay Point Type Classification. This study classifies travel activity purposes into five categories: living, working, schooling, leisure, and other. Since the attributes of activities (start time, end time, location) are long-term choices made by individuals and authorities in the case of fixed activities, while the characteristics of flexible activities vary greatly among different people and on different days for the same person. Therefore, this study, based on the dual dimensions of activity priority and spatio-temporal decision-making freedom, divides activities into

fixed and flexible. According to activity priority from high to low, they are special, fixed, semi-flexible, and flexible activities (Figure not provided).

• Calculating Activity Purpose Probability Based on Spatial Features. People's daily activities are closely related to the spatial features (such as land use type and building type) around their activity locations (Yang et al., 2019). The relationship between daily activities and geographical attributes can be used to support the inference of one attribute given the other (Yin L et al., 2021). To infer activity patterns from geographical attributes, the research by Widhalm et al. (2015) and this study both use the basic assumption: the activity a person engages in is closely related to the corresponding spatial features. Therefore, a link must be established between spatial features and activity purposes. Spatial features are usually described as enumerated types. Combined with POI service capacity (Li S et al., 2021; Liu J et al., 2023), different weights are assigned to each POI type to assess the probability that a specific activity category is dominant at each location.

• Calculating Activity Purpose Probability Based on Temporal Features. Residents' daily activity arrangements are often constrained by prevailing social norms and life rhythms, thus forming daily behavioral patterns with a certain cadence. The transition patterns between different types of activity purposes (e.g., departing from "home" for "work" in the morning, returning from "work" to "home" in the evening, or engaging in "leisure" activities on weekends) can effectively characterize this regularity. These transition patterns can be extracted from auxiliary data, such as historical resident travel surveys, social network check-in data, or through statistical analysis of large-scale LBS data (Yin L et al., 2021). This study will set corresponding temporal transition probability matrices based on different demographic attributes (e.g., age groups) and date types (weekdays/weekends) to reflect the likelihood of different activities occurring at specific times.

• Inferring Activity Purpose Based on the Combination of Spatial and Temporal Features. To integrate spatial and temporal features and clearly demonstrate their impact on activity purpose inference, this study adopts a concise model that linearly combines these two features. Specifically, a weighting parameter[0,1] is used to flexibly combine the activity purpose results inferred from spatial and temporal features. We denote by the combined probability that an individual performs an activity of type k during a certain stay. A straightforward intuitive method, defined by the formula, is used to combine the probabilities derived from the two types of features.

A Monte Carlo simulation method is employed to determine the specific activity purpose for each stop based on the activity purpose probability distribution .

• Model Validation

Due to the unavailability of ground truth for activity chains derived from mobile phone location data, this study employs methods such as manual comparison with attribute information inherent in LBS data and small-sample questionnaire survey data to validate the reasonableness and effectiveness of the model inference results.

3.3 Research Content

This study's core content involves: 1) Focusing on the Wuxi-Jiangyin S1 Line, a typical township-serving rail line. 2) Using LBS travel chain data and multi-stage screening to identify core township rail passengers. 3) Applying SPID to LBS trajectories for stay point identification, extracting spatio-temporal stay point data. 4) Using a transparent, rule-based "white-box" model integrating spatio-temporal features to infer activity types (travel purposes) of stay points. 5) Extracting complete metro travel segments (origin/destination stations, related stay points). 6) Using fuzzy theory (prior knowledge, membership functions) to infer last-mile access/egress modes.

After data processing, a structured township rail travel dataset with rich attributes will be analyzed for passengers' ontological (socio-demographics, residence) and behavioral (purpose, spatio-temporal patterns, access/egress choices) characteristics. Findings aim to provide evidence for optimizing township rail operations, guiding station-area development (TOD models), and enhancing urban-rural transport integration.

4 Analysis of Travel Characteristics

4.1 Indicator Construction

To comprehensively and systematically characterize the features of township rail transit passenger groups, this study has constructed an indicator system comprising two main categories: ontological attributes and behavioral attributes. The selection of these indicators aims to capture key factors influencing travel behavior and the multidimensional manifestations of travel behavior itself.

Ontological attributes primarily reflect the relatively stable demographic, socio-economic, and spatial locational characteristics of the passenger group (Table 2). These indicators are chosen because an individual's natural attributes (e.g., age, gender), social attributes (e.g., education level, income, family structure), and the geographical location of their residence profoundly influence their travel demand, travel capability, choice of travel mode, and expectations for transportation services. For example, "age" is closely related to travel activity levels and the composition of travel purposes; "household size" in township areas may be more associated with joint travel as a family unit; "income level" directly affects sensitivity to travel costs and demand for travel comfort; and "residential location" directly reflects the service coverage and attractiveness of rail transit to different areas (Jiangyin townships, Jiangyin sub-districts, Wuxi townships, Wuxi sub-districts, and other areas).

Table 2. Ontological Attributes

Ontological attributes	Attribute category	Quantitative indicators	Label extraction
Natural attribute	Gender	Male	Male
		Female	Female
	Age group	20-29 years old	Youth
		30-49 years old	Middle-aged
		Above 50 years old	Elderly
	Education level	Junior high school and below	Low education
		High school or junior college	Medium education
		Bachelor's degree or above	High education
	Household size	1 person	Single
		2 people	Small family
		3 people and above	Big family
Social attribute	Income level	Monthly income of 4.5K and below	Low income
		Monthly income: 4.5K-10K	Medium income
		Monthly income of more than 10K	High income
Regional attribute	Residential location	Whether it belongs to a township area of Jiangyin City	Jiangyin Township
		Whether it belongs to a sub-district of Jiangyin City	Jiangyin Sub-district
		Whether it belongs to a township area other than Jiangyin in Wuxi City	Wuxi Township
		Whether it belongs to a street in Wuxi City other than Jiangyin	Wuxi Sub-district
		It doesn't belong to the heart of Wuxi City	Other places

Behavioral attributes focus on the dynamic manifestations of the passenger group while using rail transit (Table 3). These indicators are selected because they can directly reflect the passenger group's travel purposes, spatio-temporal preferences, travel efficiency, degree of reliance on rail transit, and solutions for the "last mile." "Travel semantics" reveals what kinds of needs rail transit meets; "temporal characteristics" describe the timing, duration, and frequency of travel, where labels like "happy commuting" for "travel duration" provide a preliminary assessment of the travel experience; "spatial characteristics" focus on the spatial span of travel and the utilization of station areas, with "number of activities at station" being an important indirect indicator of station-city integration; "subway connection method" within "travel diversity" is particularly crucial for township areas with inconvenient transportation.

Table 3. Behavioral Attributes

Behavioral attributes	Attribute category	Quantitative indicators	Label extraction
Temporal characteristics	Day of travel	10.14.-18.	Weekday
		10.19.-20.	Weekend
	Working/non-working travel time	6:00-10:00	Morning rush hour
		10:00-15:00	Noon
		15:00-19:00	Evening rush hour
		19:00-6:00	Night
	Travel duration	None	None
		Within 45min	Happy commuting
		Within 45-60min	Normal commuting
		Above 60min	Extremely long commuting
	Frequency	Once a day	Low frequency
		Twice a day	Intermediate frequency
		3 times a day	High frequency
		4 times a day or more	Ultra-high frequency
Spatial characteristics	Subway travel distance	Within 8km	Short-distance travel
		8-29km	Medium-distance travel
		Above 29km	Long-distance travel
	Number of arrival activities	0 times	No arrival activities
		1 time	Arrival activities included
		2 times or more	Rely on rail transit to connect activities

4.2 Analysis of Ontological Dimensions

Based on a multi-dimensional analysis of natural, social, and regional attributes, the township rail transit passenger group exhibits significant structural characteristics (Table 4). In terms of natural attributes, the core of the passenger group is middle-aged individuals (30-49 years old, 80.61%), with family structures predominantly being large, multi-generational households (71.51%). Education levels are concentrated at medium (high school or junior college, 52.89%), reflecting the typical characteristic of the middle-aged labor force in township areas shouldering dual family and economic responsibilities. The travel demands of this group often revolve around fixed activities such as work commutes and children's education, and are significantly influenced by family cooperation patterns. In terms of social attributes, income distribution shows a "spindle-shaped" structure, with the medium-income group (monthly income 4.5K-10K, 51.29%) accounting for the highest proportion. High-income (17.09%) and low-income (31.62%) groups form two poles, suggesting that rail transit services need to balance fare affordability with comfort upgrades to meet differentiated needs. Regional attribute analysis further reveals the spatial distribution characteristics of the passenger group: a clear trend of localization and agglomeration is evident, with local residents from Jiangyin and Wuxi collectively accounting for 84.3% (Jiangyin Township 28.62%, Wuxi Sub-district 21.41%, etc.), while users from other areas only account for 15.7%. This indicates that rail transit primarily serves the medium and short-distance travel of permanent residents. Significant differences exist in urban-rural distribution: township users (Jiangyin Township 28.62%, Wuxi Township 7.29%) rely on rail transit to address issues of inadequate access and egress facilities, while urban users (e.g., Wuxi Sub-district 21.41%) are more inclined towards multimodal travel combinations.

Overall, the passenger group's behavior patterns are driven by both demographic structure and socio-economic attributes: the middle-aged and family-oriented characteristics reinforce the priority of fixed activities such as commuting and medical care; the predominance of the medium-income bracket requires a balance between efficiency and cost in service design; and differences in urban-rural distribution necessitate targeted optimization of access/egress networks (e.g., adding dedicated bus lines in townships, improving transfer efficiency in urban areas). The portrait system constructed in this study provides data support for the precise matching of "demand-service" for township rail transit. In the future, dynamic spatio-temporal behavior data can be incorporated to further deepen the analysis of causal mechanisms.

Table 4. Profile of Township Rail Transit Passengers

Variable	Percentage/%
Natural attribute	
Gender	
Male	52.62
Female	47.38
Age group	
Youth	9.70
Middle-aged	80.61
Elderly	9.68
Household size	
Single	24.65
Small family	3.85
Big family	71.51
Education level	
Low education	32.69
Medium education	52.89
High education	17.22
Social attribute	
Income level	
Low income	31.62
Medium income	51.29
High income	17.09
Regional attribute

Jiangyin Township	28.62
Jiangyin Sub-district	26.98
Wuxi Township	7.29
Wuxi Sub-district	21.41
Other places	15.70

4.3 Analysis of Behavioral Dimensions

(1) Temporal Characteristics

Travel time characteristics are a crucial dimension for understanding passenger travel patterns and evaluating the efficiency of transportation services. This section will analyze the distribution of travel on weekdays/weekends, the temporal distribution of different travel purposes throughout the day, travel duration, and the frequency of metro usage.

According to data analysis (Table 6), work-related travel during the morning rush hour (6:00-10:00) accounts for 13.60%, which is the main period for work travel, consistent with basic commuting patterns. It is noteworthy that work-related travel during the midday period (10:00-15:00) also reached 14.10%, while the evening rush hour (15:00-19:00) accounted for 11.00%, and the night period (19:00-6:00) was lower at 4.39%. The higher proportion of work travel during midday may reflect that some township residents are engaged in non-standard work hours (such as in the service industry or freelance work), or that there are instances of round trips between work and home (or other activity points) during midday. The 56.91% of "None" for work travel time corresponds to the previously mentioned proportion of passengers whose trips do not include work.

Non-work-related travel, however, exhibits different temporal distribution characteristics. The midday period (10:00-15:00) and the evening rush hour period (15:00-19:00) are the two peaks for non-work travel, accounting for 27.26% and 28.08% respectively. This aligns closely with the occurrence times of activities such as leisure and shopping. Non-work travel during the morning rush hour (6:00-10:00) accounts for 17.13%, and non-work travel during the night period (19:00-6:00) also constitutes a certain proportion (14.35%), indicating the broad timing of leisure activities for township residents. The 13.18% of "None" for non-work travel time corresponds to passengers with no non-work activities or only work activities in their travel purposes.

Table 6. Proportion of temporal characteristics

Variable	Percentage/%
Temporal characteristics	
Working travel time	
Morning rush hour (6:00-10:00)	13.60
Noon (10:00-15:00)	14.10
Evening rush hour (15:00-19:00)	11.00
Night (19:00-6:00)	4.39
None	56.91
Non-working travel time	
Morning rush hour (6:00-10:00)	17.13
Noon (10:00-15:00)	27.26
Evening rush hour (15:00-19:00)	28.08
Night (19:00-6:00)	14.35
None	13.18
Day of travel	
Weekday	67.28
Weekend	32.72
Travel duration	
Within 45min	42.93
Within 45-60min	10.16
Above 60min	46.90
Frequency	
Once a day	45.67
Twice a day	32.83
3 times a day	13.20
4 times a day or more	8.31

Weekday travel (Oct 14-18, 2024) is 67.28%; weekend (Oct 19-20) is 32.72%. Higher weekday volume links to commuting regularity and some weekday leisure (e.g., post-work).

Travel duration: 42.93% are "happy commutes" (≤45 min); 10.16% "normal" (45-60 min); 46.90% "extremely long" (>60 min). The S1 line, connecting Jiangyin townships to Wuxi, serves long distances, causing many long trips, likely cross-regional work/leisure commutes.
Daily metro frequency: 45.67% once (one-way/one leg of round trip); 32.83% twice (typical round trip); 13.20% thrice; 8.31% ≥4 times (ultra-high). Most use it 1-2 times daily (low/medium frequency).

In sum, township rail users travel mainly on weekdays; non-work travel peaks midday/evening. High "extremely long commuting" is notable. If for high-value leisure (to Wuxi centers), tolerance for long travel may be high, suggesting S1 expands activity space and life choices, justifying longer travel for higher needs.

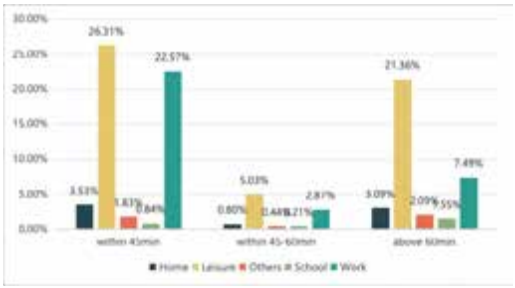

Fig 2. The distribution of travel duration for various types of trips

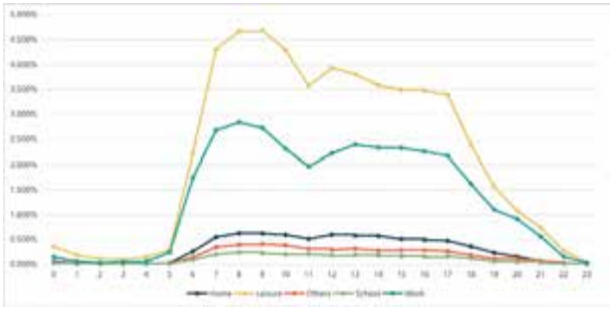

Fig 3. The distribution of travel start times for various types of trips

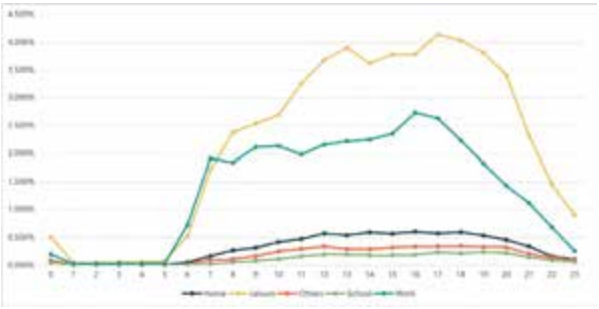

Fig 4. The distribution of travel end times for various types of trips

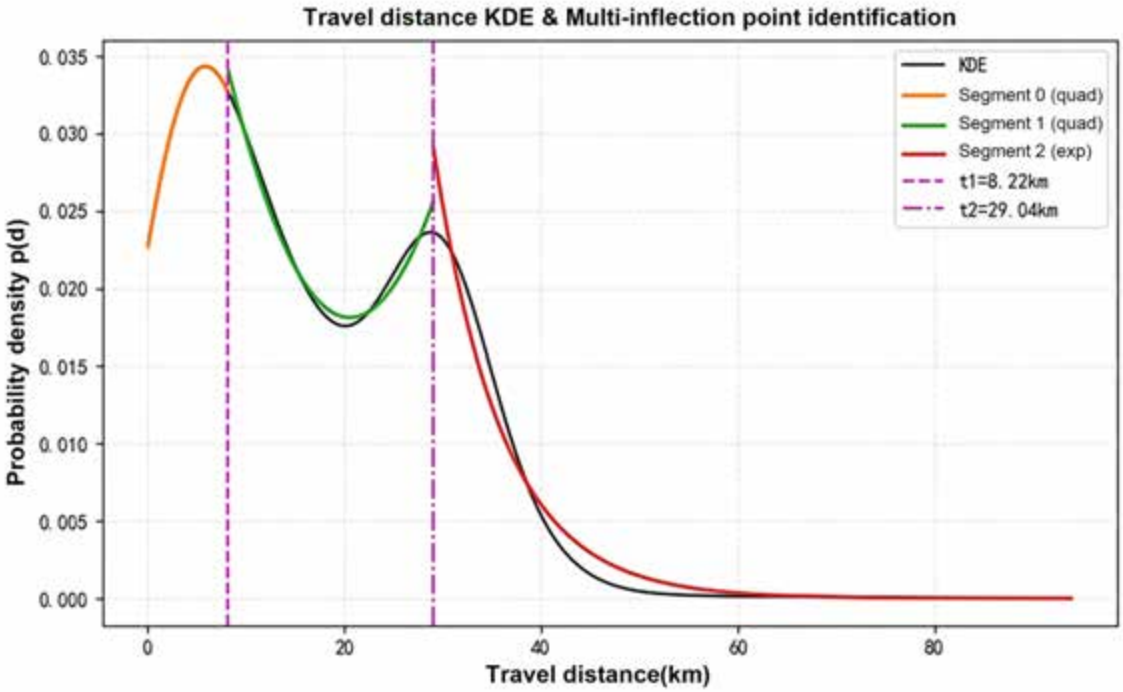
(2) Spatial Characteristics
This study mainly refers to the research of Qiao et al. (2019), Raja et al. (2015), and Shi Ruizheng et al. (2022). It employs the Euclidean distance between the origin and destination of passengers' metro trips, i.e., the shortest straight-line distance between the two points, as the travel distance for each metro trip. Using travel distance as the fitting object, a probability distribution function for travel distance is fitted, with different distributions at its two ends. By comparing the coefficient of determination R^2 for different distances, the corresponding travel distance cutoff thresholds are determined (Qiao Mengling et al., 2019). The specific method uses Kernel Density Estimation (KDE) to divide travel distances by thresholds, with the optimal fit shown in the figure.



Remark: The first segment is fitted with a quadratic function, model , ; the second segment is fitted with a quadratic function, model , ; the third segment is fitted with an exponential function, model ,

Fig 5. The optimal fitting situation of the probability distribution graph of travel distance

The travel distance for passengers using township area rail transit follows a quadratic function when less than 8.22km (Model 1, yellow line); it follows a quadratic function distribution when the distance is between 8.22-29.04km (Model 2, green line); and it follows an exponential function when the distance is greater than 29.04km (Model 3, red line). For statistical convenience, thresholds are rounded to integers, determining cutoff values of 8km and 29km.

Based on this, a statistical analysis of travel distance was conducted (Table 7). It can be seen that medium-distance travel (64.77%) is mainstream for township rail transit passengers, followed by short-distance travel (22.91%), with long-distance travel being the least common (12.32%). Looking at different travel purposes, medium-distance leisure travel has the highest proportion (23.94%), indicating that cross-city leisure trips from Jiangyin residents to Wuxi commercial districts, scenic spots, etc., are numerous. Although short-distance work travel accounts for over 40%, considering the "2024 China Major Cities Commute Monitoring Report" released by the China Academy of Urban Planning and Design, the average one-way commute distance in Wuxi is 7.4km, with 55% of commutes being "happy commutes" within 5km. Work travel on the Wuxi-Jiangyin S1 Line is still dominated by medium to long-distance commutes. As a cross-city rail line, its passengers' travel characteristics are significantly different from those of Wuxi's main urban metro. Residential and school-related travel are mainly medium-distance, reflecting that some families may choose a "dual-city life" model of living in Jiangyin and schooling in Wuxi. For other (medical) travel, short-distance travel has the highest proportion, but at the same time, the proportion of long-distance travel is the highest among the five categories, indicating a prominent rigid demand for long-distance medical treatment.

Further analysis of the coverage of township rail transit stations (Table 7) reveals that over 60% of passengers have no additional activities after arriving at the station, indicating a lack of commercial and service facilities around the stations, with passengers merely using rail transit as a "point-to-point" commuting tool. Cross-analysis (Figure 6 and Figure 7) shows that leisure travel accounts for the highest proportion within the station coverage area, indicating that the rail coverage area primarily serves leisure demand, but activity frequency is still low, mainly single instances. Work-related travel covered by stations is relatively small, only half of that for non-station-

based work activities. According to the "2024 China Major Cities Commute Monitoring Report," the proportion of commutes covered by rail transit in Wuxi is only 9%, meaning the proportion of the commuting population whose residences and workplaces are both within 800 meters of a rail station is far below the national average of 20%. This indicates that Wuxi's rail transit provides weak support for residential and employment spaces, and the Wuxi-Jiangyin S1 Line shares this problem. In addition, school-related travel within station coverage areas is much lower than non-station-based travel, possibly because schools are often located in areas not covered by rail, exacerbating the pressure of "cross-district schooling." The low frequency of activities at S1 Line stations and Wuxi's weak rail coverage for commuting jointly point to the core contradiction of "rail construction being disconnected from urban functions." It is necessary to promote the new urbanization process in township areas through "comprehensive station development + equalization of public services," rationally allocate public service facilities, and upgrade rail transit from a "commuting corridor" to a "vitality link."

Table 7. Spatial Characteristics of Township Rail Transit Passengers

Variable	Percentage/%
Spatial Characteristics	
Subway travel distance	
Short-distance travel	22.91
Medium-distance travel	64.77
Long-distance travel	12.32
Number of arrival activities	
0 times	61.60
1 time	26.39
2 times or more	12.01

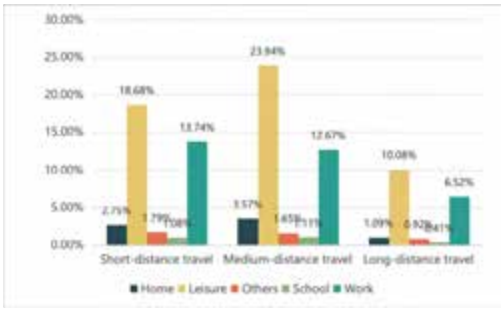


Fig 6. The distribution of travel distances for various types of trips

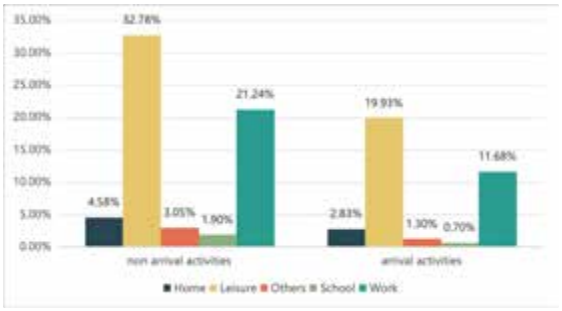

Fig 7. The distribution of arrival activities for various types of travel

5 Conclusion

This study of Wuxi-Jiangyin S1 Line using LBS data analyzed township rail passenger attributes and behaviors, revealing unique traits and offering insights for service optimization and regional development.

- Distinct Passenger Profile: Core users are middle-aged (30-49), from larger local families, with medium/low education and income, differing from urban metro users; their needs may be more complex/pragmatic.
- Leisure Travel Dominance: Over 50% of trips are for leisure, far exceeding work travel, unlike traditional commute-focused rail. S1 is a "lifeline" expanding lifestyle options and activating cross-regional leisure consumption.
- Medium-Long Cross-District Travel: Medium (8-29km) and longer trips are common for leisure, work, and medical needs, reflecting S1's role as an intercity urban-rural connector. Some "extremely long commutes" (>60min) exist.
- Severe Lack of "Station-City Integration": >60% of passengers have no activities around township stations. Stations are mere transfer points, poorly integrated with urban functions; "rail-city disconnect" is prominent, failing TOD potential.

Optimize services for passenger traits. Address family needs (middle-aged, large families) with off-peak/weekend family tickets, better in-carriage facilities (storage), and improved station accessibility (barrier-free, maternal-child facilities). Empower leisure/lifestyle travel by linking S1 with attractions/commercial centers, enhancing station-city integration for vitality. Implement locally adapted TOD: treat station areas as township renewal nodes, introducing mixed uses (retail, community services, entertainment, offices) matching resident needs and local resources to create vibrant micro-centers, requiring planning/transport/land development synergy.

LBS data may have representation bias (e.g., underrepresenting elderly, non-smartphone users). Stay point/purpose inference accuracy is limited by data granularity and algorithm universality. The study is mainly quantitative, lacking qualitative depth on motivations/perceptions. It's a cross-sectional study, not capturing dynamic evolution; characteristics may change with township development and S1 operation time.

Abstract
High-quality surroundings and the comfort of journeys encourage the use of sustainable modes of transportation to attend daily-life resources. Spatial ergonomics studies the capacity of a territory to fulfil the needs of its inhabitants at least costs. Its subdomain access ergonomics which provides an approach through mobility, offer a relevant analytical framework to assess if a territory enables its residents to access essential daily-life resources, efficiently and comfortably. Ergonomics should be analysed both qualitatively and quantitatively, and simulation provides many insights relevant to this evaluation. This paper focuses on a state of the art of ergonomics in urban planning then proposes a framework to improve precision in access ergonomics assessment using multi-agent modelling to simulate mobility behaviours based on socio-spatial profiles.

Keywords
access ergonomics; sustainable mobility; multi-agent models; proximity; accessibility

Introduction

Since the 1980s, many European cities have implemented several policies to reduce transportation and mobility related negative externalities, especially those caused by individual cars. Among them, the Eurométropole de Strasbourg, a mid-size city located in the extreme east of France, along the German border. Strong measures have been introduced to limit car use while promoting sustainable transport (Stambouli, 2005, Héran, 2020). This includes developing public transportation, enhancing shared and active modes (walking, cycling) usage, and urban planning focused on a "proximity metropolis" model (Eurométropole de Strasbourg, 2024) to support sustainable mobility. Furthermore, the Eurométropole de Strasbourg has restricted motorized mobility, particularly internal combustion engine vehicles, by creating one of the first Low Emission Zone in France covering its 33 municipalities. The city also supports energy transition, encouraging the adoption of electric vehicles including electric bikes through purchase subsidies. Strasbourg is also a precursor in France for its actions to encourage cycling. It has had a significantly higher cycling modal share than other French cities from 1980 to 2000 (Guidez, 2007) and the Eurométropole de Strasbourg is the French metropolis with the highest modal share for cycling in the 2021 census. Like many other cities, previous studies have shown that amenities and transportation infrastructures are not uniformly distributed throughout the city (Hached, 2019) and that some areas are underserved for active modes users (Saint-Gérand et al., 2021). The main question is how well the Eurométropole de Strasbourg enables its residents to access essential daily-life resources, efficiently, comfortably, and at which cost (financial cost, effort, risk, emissions, energy, and time) while using sustainable transport modes. The obtained indicators (both a synthetic score and subscores on a 200 by 200 metre grid) can then be employed to assess equity and highlight social disparities.

This paper focuses on three aspects: first a review of the uses of ergonomics applied in urban settings, in particular to urban mobility, with a focus on access ergonomics, its similarities and differences with related concepts. After a review of modelling methods to find the most suitable one to assess access ergonomics. Then, we propose an integrated method for the appraisal of ergonomics of access through multi-agent modelling. The proposed approach deploys multi-agent activity-based modelling to place trips in activity chains. In further studies, more parameters will be considered to assess access ergonomics on a larger scale.

1. Review of urban ergonomics

Ergonomics is "the scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data, and methods to design in order to optimize human well-being and overall system performance" (IEA, 2000). On an etymological standpoint, it is the science of work, also referred to as human factors engineering, especially in American English and workplaces are historically the first places where ergonomics was developed and applied. In this paper, we will consider its applications and transpositions to urban settings. In the Scopus Database, as of May 20th, 2025, 632 documents[1] contain both the words urban and ergonomics (Figure 1). Of those, 151 are applied to vehicles (including 80 regarding cars and motorcycles[2]) and 110 are applied to the urban scale, with 15 of them considering the ergonomics of urban mobility and 11 of them considering pedestrian behaviours in cities.

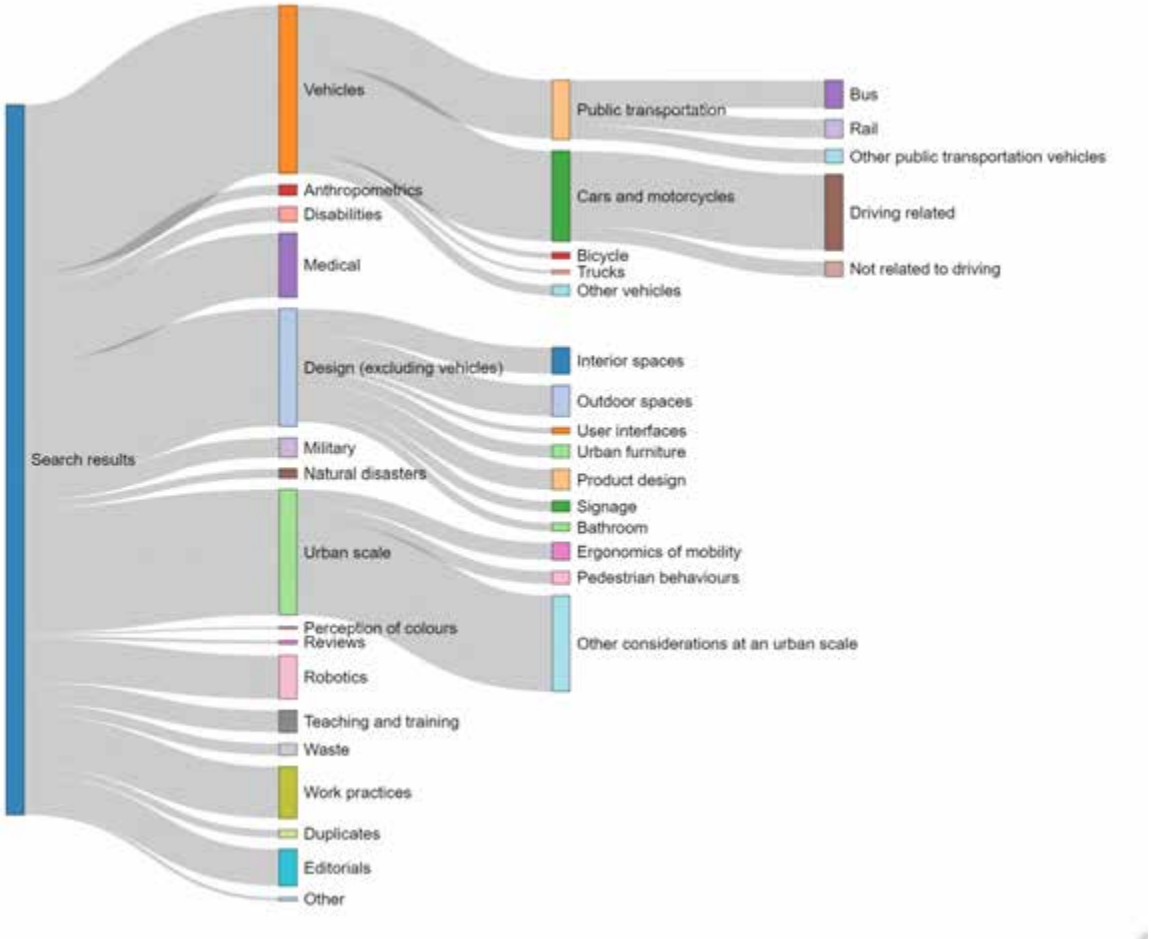

Figure 1: Topics covered in Scopus (Hacquard, 2025)

Macroergonomics (Hendrick, 1985), developed from the end of the 1970s considers organisational aspects in ergonomics, opposed to the human-machine interactions (microergonomics) that were solely considered before and relies on group dynamics. Its scope not only includes work but "any form of human effort or activity, including recreation and leisure pursuits" (Hendrick, 2002). As such, macroergonomics have been leveraged as community ergonomics to improve inner cities (Smith et al., 1994) and for the analysis of mobility in the Brazilian city of Belo Horizonte (Botelho et al., 2018). Several authors have used the concept of ergonomics in geography and urban planning. In their paper Human Factors in Urban Transportation, Hoag and Adams (1975), note the overwhelming proportion of data from military settings considered in ergonomics and their low relevance for urban transportation. They analyse the travel conditions, not only on an anthropometric standpoint, but also on

1 Seven duplicates are found in the results and are not processed further.
2 A paper (Nathanael et al., 2019) concerns pedestrian-vehicle interactions and is classified both in pedestrians and vehicles.

a psychological one, and envisioning user evaluation. De Carvalho (2012) proposes ERGOPOLIS: an ergonomics approach applied to a city, mobilising the macroergonomics and listing nine projects that might be considered for an ergonomic approach to the city, including accessibility and improvement of urban mobility. The same term ergopolis is also used in unrelated manners by Gangadhar, Nagendra and Chikkarangaswamy (2012) about sustainable rural development and at a French roundtable with both researchers and practitioners (POPSU, 2016) where ergopolis (also called ergonomic metropolis in the roundtable's report) is defined as a "territory that takes better into account the question of work" (J.M. Offner in the said roundtable), also underlining that "a metropolis should deliver to its users, not only to its inhabitants", as a reference to the origin of ergonomics as the science of work.

Other authors have considered ergonomics of walking: Stevens and Salmon (2015) apply cognitive work analysis to footpaths and public places to make them more inclusive, further research was then performed on other spaces (Stevens et al., 2021). Appolloni et al. (2020) developed an approach to evaluate walkability with ergonomic criteria, three main needs for the "Human-Environment Interface" are identified: well-being, safety and usability, the weight for the different factors has been elaborated with "a multidisciplinary panel of 10 experts", the methodology has been applied to various areas in Rieti, Italy.

Antoni (2014) has reviewed various approaches of spatial ergonomics in the French-language literature. Sperandio (1976) proposed the concept of "ergonomics of the built environment" as he remarked that "ergonomists [were] starting to take interest in the design of built environment" with scales ranging from the interior to neighbourhoods. His research on this topic were not pursued, mostly due to ergonomists taking interest on human-machine interfaces in computer science (Sperandio, 2011). Hached and Propeck-Zimmermann (2021) have proposed a methodology to assess ergonomics of access of daily life resources. Their approach includes most of the criteria considered by other authors for walkability and cyclability but can also be applied to other modes. We retain the ergonomics of access (also called access ergonomics in other sources), as this framework is suitable not only for a specific mode but can be applied to different modes, including intermodal trips.

2. Access ergonomics: spatial ergonomics applied to access to daily life resources

The ergonomic approaches in urban settings can then be classified in two groups: either the city is a human-machine system to which the methods from ergonomics of workplaces can be directly applied (Sperandio, 1976) or a conceptual transfer is needed from classical ergonomics such as in spatial ergonomics (Saint-Gérand, 2002).

Spatial ergonomics is a conceptual transfer from ergonomics as it is applied in industrial settings to geography (Saint-Gérand, 2002, Propeck-Zimmermann et al., 2018). The geographical space is assimilated (Figure 2) to the industrial settings considered in classical ergonomics, while socio-economic resources are assimilated to the industrial settings' products and resources (Propeck-Zimmermann et al., 2018). Spatial ergonomics is then defined as the "endogenous and exogenous capacity of a space to provide a population/society with the entire set of social and economic resources they require at the least cost" (Saint-Gérand, 2002).

Ergonomics		Spatial ergonomics
working action		daily life actions
worker	⟷	population (individual, categories, spatial community)
workshop / workplace	semantical translation and / or change of conceptual space	space (daily life area)
materials		resources
tools		amenities (infrastructures)
costs	⟷	costs
process		social and spatial behaviour (stability/mobility)
efficacity / productivity		adequation / performance

Figure 2: Spatial Ergonomics Concepts translated from Saint-Gérand (2002)

Access ergonomics (Hached, 2019) is a subdomain of spatial ergonomics as an approach through mobility. It provides a framework for the analysis of the disposal of daily life resources and "assesses the more or less capacity to minimize the costs (in the broad sense) of appropriating the resources that the population needs in daily life" (Hachette, Propeck-Zimmermann and L'Hostis, 2024). This approach assesses accessibility while focusing on its conditions not only regarding travel duration but also considering daily-life resources availability, infrastructure, as well as mobility conditions and quality (facilities, safety, comfort, environment) adapted to each transport mode. Access ergonomics relies on the hypothesis is that a high-quality environment helps to promote sustainable transport, especially for active modes. Mobility behaviours are known to be influenced by safety, comfort, and environmental factors (Piombini, 2013). Access ergonomics integrates these factors into a synthetic access ergonomics score composed of several sub-indicators to identify and analyse socio-spatial inequalities in accessing daily resources. The sub-indicators consider the urban environment, network and infrastructure, alternative resources availability, number of proximity resources, diversity of proximity resources, availability of resources, and safety. Access ergonomics consider interactions between three constituents of the territory: the resource potential, population and stakeholders needs and practices, and the structure of the territory (Figure 3).

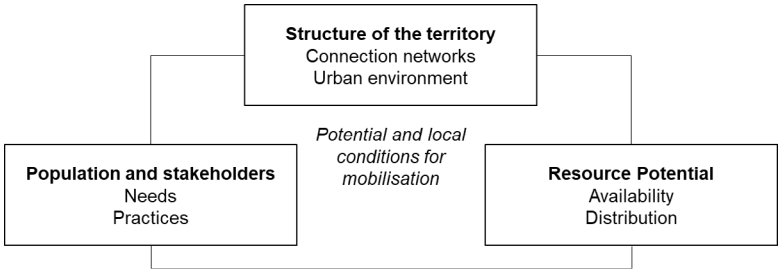

Figure 3: General model of access ergonomics (Hachette, Propeck-Zimmermann and L'Hostis, 2024)

Two previous approaches for access ergonomics have been developed:

- A large-scale isochrone-based approach, used to assess ergonomics of access to resources of the whole Eurométropole de Strasbourg (Propeck-Zimmermann et al., 2018).
- A more detailed route-based approach (Figure 4) has been used to assess ergonomics of access for 13 locations in the Eurométropole de Strasbourg (Hachette, Propeck-Zimmermann and L'Hostis, 2024).

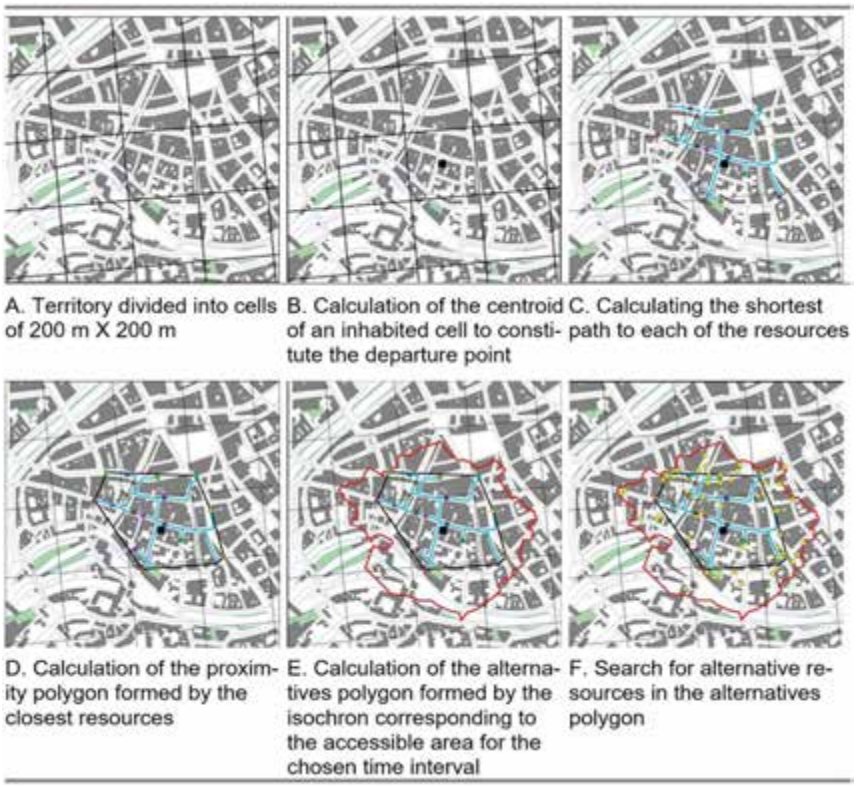

Figure 4: Computation of Access Ergonomics (Hachette, Propeck-Zimmermann and L'Hostis, 2024)

Both methods use a 200 × 200 m grid corresponding to the highest resolution (in France) for income and census data and use the shortest path from the centre of each tile. Both approaches consider not only the closest amenity but also its suitable alternatives. The detailed method generates a synthetic score from 0 to 100 but its subscores can also be analysed individually to distinguish between situations with the same synthetic score while having different characteristics. In both approaches, travel times were not issued from modelling, but from the distance travelled. Hached (2019) showed significant variability in access ergonomics across the Eurométropole de Strasbourg through a synthetic indicator built using GIS for active modes, showing a gradient from the centre and comparing it between walking, cycling and driving. The highest ergonomics of access for bicycles and pedestrians was in the city centre whereas it was highest in the outer ring by car, due to traffic calming actions in the city centre. The amenities considered are classified from a statistical classification (nomenclature d'activités française) to classes containing similar amenities (Table 1) that are considered together in the assessment of ergonomics of access.

Table 1: Amenities considered in Hached, 2019

Category	Class	Resource type in the *nomenclature d'activités française*
Shops	A	Bakery
		Pastry shop
		General food store
		Grocery
		Butcher shop
	B	Small-size supermarket
		Medium-size supermarket
	C	Large supermarket
	D	Tobacco shop
		Newsstand and stationery shop
	E	Pharmacy
	F	Market
Schools	G	Preschool
		Primary school
	H	General secondary school
Healthcare	I	Hospital
		Surgical activities (clinics)
	J	General practitioner
		Nurse or midwife
	K	Radiodiagnosis or radiotherapy
		Dental practice
		Medical laboratory
Public services	L	City hall
		Police station
		Medical and social centre
		Employment agency
Leisure	M	Cinema
		Museum
		Performance venue
	N	Public library
	O	Sports clubs
		Sport facility

Evaluations of access ergonomics were performed considering a temporal threshold. Three values (5, 10 and 20 minutes) were considered. This corresponds to a proximity criterion, in line with the renewed interest in proximity, in particular with the rise of the 15-minute city concept. Electric vehicles and micromobility were not considered, nor was public transportation. The rise of micromobility and intermodality requires adaptation of these analyses. Hachette, Propeck-Zimmermann and L'Hostis (2024) also note that access to employment should ideally be considered. Access ergonomics, as its name suggests, attach importance not only to ergonomics but also to accessibility. As such, its assessment can only be performed it the condition of accessibility is ensured.

3. Notions close to access ergonomics: accessibility, proximity, and mobility

Access ergonomics is linked to several other notions: ensuring accessibility is possible is a prerequisite to the appraisal of access ergonomics. Accessibility can be attained through two means: proximity and mobility whereas walkability and cyclability are applications of accessibility to a particular means of transportation. The differences in scales, modes, and goals of these close notions are summarised in Table 2.

Accessibility is considered "an important dimension of quality of life" and though it has varying meanings among authors, it can be defined as "the ease of reaching desired activities" (Silva et al., 2024). It is a major field of interest in geography, Silva et al. (2024) note that "scientific papers concerned with accessibility have grown tenfold in one decade, surpassing the average of 200 papers per year in 2014" though mobility is still more represented in scientific literature. Dumolard (1999) distinguishes distance, an "abstract and theoretical notion", and accessibility which is a "more contextual and concrete metric of remoteness". Geurs and Van Wee (2004) categorize four components of accessibility: "transport component", "land-use component", "temporal component" and an "individual component"; these components can be analysed through four types of measures: "infrastructure-based", "location-based", "person-based" and "utility-based". They note that interpretability and communicability need to be improved and that "spatial–temporal constraints" of an individual should be included in accessibility studies.

Silva and Larsson (2019) describe accessibility as a goal whereas proximity and mobility are means towards accessibility. Hachette, Propeck-Zimmermann and L'Hostis (2024) differentiate spatial ergonomics and accessibility on their objectives: "access ergonomics seeks to understand the overall functioning of the territory and its capacity to meet needs through different elements, in particular the arrangement of its resource potential and its ability to respond to disturbances, whereas accessibility focuses on a very specific aspect of the functioning of the territory, that of travel and transport".

The 15-minute city concept (Moreno et al., 2021), which relies on proximity of amenities by walking or cycling to improve accessibility while reducing the need for motorised transportation between activities is gaining traction; 98 cities were identified by Teixeira et al. (2024) as implementing or planning to implement the concept or practices close to it. However, Papadopoulos, Sdoukopoulos and Politis (2023) identified multiple shortcomings in the current approaches to measure compliance with the 15-minute city concept, noted a focus on walking but a lack of consideration of the different walking speeds among the population and recommend the use of disaggregated origins to represent the travellers. They also note a low scalability in most of the considered studies.

Table 2: Comparison between access ergonomics and close notions (Hacquard, 2025)

Term	Scale	Mode	Goal
15-minute city	Citywide	Walking, cycling or other active modes	Proximity of resources so inhabitants can fulfil their needs within a 15 min radius
Access ergonomics	Living area	Ideally multimodal	"*Understanding of the overall functioning of the territory*"
Accessibility	Varying (from the building to global)	Varying between studies (can be mode-focused or multimodal)	Ease of reach
Cyclability	Varying (from the neighbourhood to city-wide)	Cycling	Ease of reach by cycle
Mobility	Varying (from the neighbourhood to global)	Varying between studies (can be mode-focused or multimodal)	Ease of reach through efficient transportation
Proximity	Neighbourhood to living area	Usually either walking or cycling	Ease of reach through low distances
Walkability	Varying (from the neighbourhood to city-wide)	Walking	Ease of reach by walking (Cervero and Kockelmann's 3D: density, diversity, design)

4. Transportation modelling approaches

Most of the forementioned notions include spatial and temporal (either travel time or variation during the day) aspects. Modelling allows to analyse both spatial and temporal travellers' behaviours, which can refine the assessment of access ergonomics. In this part, we review different modelling approaches to find the most suitable one to analyse access ergonomics.

Multi-agent systems are made of agents, which are "computing entities able to act and interact to perform a fragmentary task in a system where the consideration of complexity is left to the interactions" (Dumolard, 1999). These systems can be used for modelling purposes. Agent-based models in transportation provide a "microscopic representation of travel individuals as they move from place to place" (Kagho et al., 2020) whereas activity-based models are transportation models describing activities of the population of interest with transportation as a derived need between activities. Agent-based models have multiple advantages, especially the possibility to have individuals as agents as well as a representation of interactions between individuals, making them particularly relevant for activity-based models (Ortúzar and Willumsen, 2016).

Activity-based models are used for evaluating accessibility through a trip completion rate by measuring the proportion of the trips below a certain threshold (Somanath et al., 2025). This approach however does not consider key parts of access ergonomics (safety and convenience of trips). Staves et al. (2025) use an agent-based model to estimate travel times and take street-level environment into account to model active travel accessibility in Greater Manchester. Their approach includes gradient, surface, ambience and stress though a mix of open and proprietary data with parameters that "were chosen through an iterative process and validated in consultation with regional experts" from heuristics and literature. Cycling accessibility is assessed through personas who can cycle on links with varying levels of cyclable infrastructure.

Activity-based models require a population with multiple socio-economical characteristics for each individual and an initial demand with initial activity plans. As these data are not directly available, either from census or from surveyed individuals, for privacy concerns among others, a synthetic population is necessary to run most activity-based models. Hörl and Balac (2021a) have developed eqasim, an open-source and reproducible pipeline to recreate a synthetic population and its travel demand for the Île-de-France region using only open access data. The use of the pipeline for other locations in France such as Nantes (Le Bescond et al., 2023), Lyon (Manout and Diallo, 2023) has been successfully done and for locations in other countries including Switzerland (Grübel et al., 2023) and China (Hu et al., 2022). The required input data for the pipeline is laid out in a data paper (Hörl and Balac, 2021b) and consists of national census (which in France contains commute flows between municipalities), income distribution data (Fichier Localisé Social et Fiscal, FILOSOFI), an household travel survey (either a local one or the national household travel survey), the address database (Base Adresse Nationale, BAN), enterprise census (Système national d'identification et du répertoire des entreprises et de leurs établissements, SIRENE) and a service and facility database (Base permanente des équipements), OpenStreetMap and GTFS data are additionally used to create the MATSim network. The travel demand and activities of the synthetic population are built around "primary activities" (home, work and education) while "secondary activities" are fitted in the schedule around the constrained primary activities.

5. Assessing access ergonomics through multi-agent modelling

To answer the question stated in the introduction, we retain access ergonomics as the approach considers not only travel time but also travel conditions and alternatives. It can be extended to include more modes and to consider access to other amenities. To overcome limitations from previous approaches, in particular the fact that trips related to work are not considered, nor is public transportation; a new methodology is being developed to improve realism and precision in evaluating access ergonomics (Figure 5). Multi-agent modelling is used to simulate mobility behaviours based on detailed socio-spatial profiles, considering diverse socio-economic and demographic data at a fine scale (200 × 200 m). These profiles are fed to a geographic information system to assess access conditions using various transport modes (car, public transportation, cycling and walking). Trips are analysed within activity chains, where each activity (work, leisure, services) can be interconnected. The model also considers resource availability and transport service schedules, identifying potential inconsistencies that impact access ergonomics.

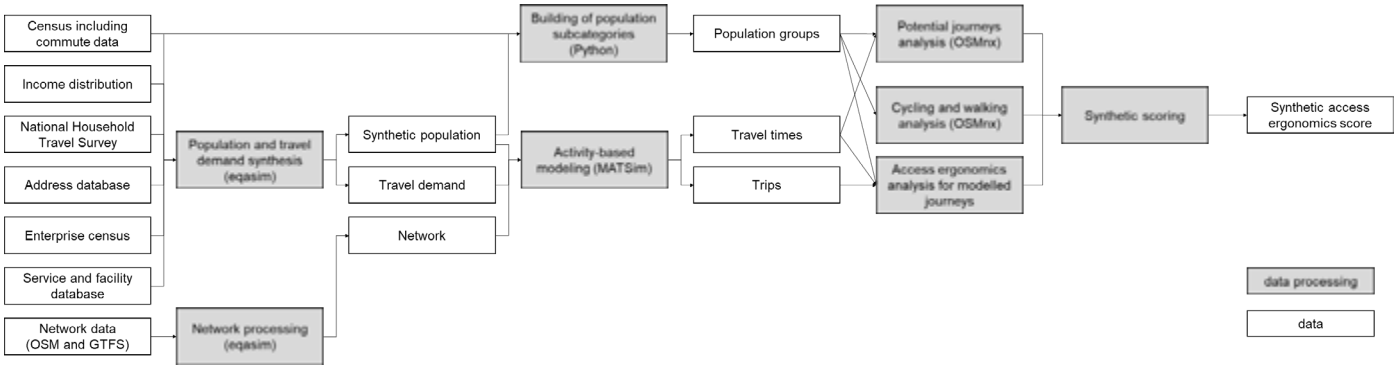

Figure 5: Data processing steps (Hacquard, 2025)

The study relies on open geographic and statistical data covering the Eurométropole de Strasbourg. The synthetic population is generated using eqasim (Hörl and Balac, 2021a) with the input data following its accompanying data paper (Hörl and Balac, 2021b). The main difference with the Île-de-France Region considered in the data paper is that public transport networks are in different GTFS files as multiple competent local authorities cover the sector. As the latest local household travel survey (Enquête Mobilité 2019) is not in open access and a newer household travel survey is being performed in 2024-2025, the national household travel survey (Enquête Nationale Transports et Déplacements 2008) has been used instead. The multi-agent model is larger than the Eurométropole de Strasbourg and includes the whole département of Bas-Rhin (1,152,662 inhabitants in the 2021 census) where the Eurométropole is located to include interactions with the surroundings.

Simulations are performed using MATSim (Horni et al., 2016) and are run using a sampling rate of 10%. Car assignment is performed with QSIM (Dobler, 2010) while public transport routing is performed using SwissRailRaptor (based on Round-Based Public Transit Routing, Delling et al., 2015), this method considers journeys using different public transport modes and walking. In accordance with the eqasim pipeline, bicycle and pedestrian routing is not performed and replaced with beeline distance factors to estimate travel time.

The national household travel survey does not contain data about micromobility such as electric scooters. Results from local household travel surveys in France between 2021 and 2023 show that micromobility represents 0.4 % of the trips of the surveyed individuals aged between 15 and 44 (Cerema, 2024). Due to its low share, as a first approach, micromobility is not modelled and is only considered in the score computing phase.

Two types of journeys need to be considered to assess ergonomics of access: the ones that actually took place (or the one modelled in this case) and the one that would have happened, should the users have decided to travel to a resource. Both must be separated in the modelling phase as potential journeys should not cause congestion.

Public transportation and car journeys representing the journeys that would have happened in the modelled day are directly available from the multi-agent model whereas the links travelled cycling or walking are rebuilt using OSMnx (Boeing, 2025). Potential travels are modelled using OSMnx and NetworkX (Hagberg, Schult and Swart, 2008) on a network with the travel times from the simulation at peak periods for car journeys and without taking congestion into account for other modes.
Population groups are built to recreate the variation of walking speed between age classes, to reflect the varying use of cycling according to age and to reflect the needs of various groups (i.e., households with young children need access to childcare).

6. Study case

The Eurométropole de Strasbourg regroups 33 municipalities with population ranging from 802 to 291,313 in the 2021 Census and a total population of 514,651. The Eurométropole is located on the left bank of Rhine River which is the border between France and Germany in this area. The highest population densities are in the central part of Strasbourg and in neighbouring municipalities (Figure 6).

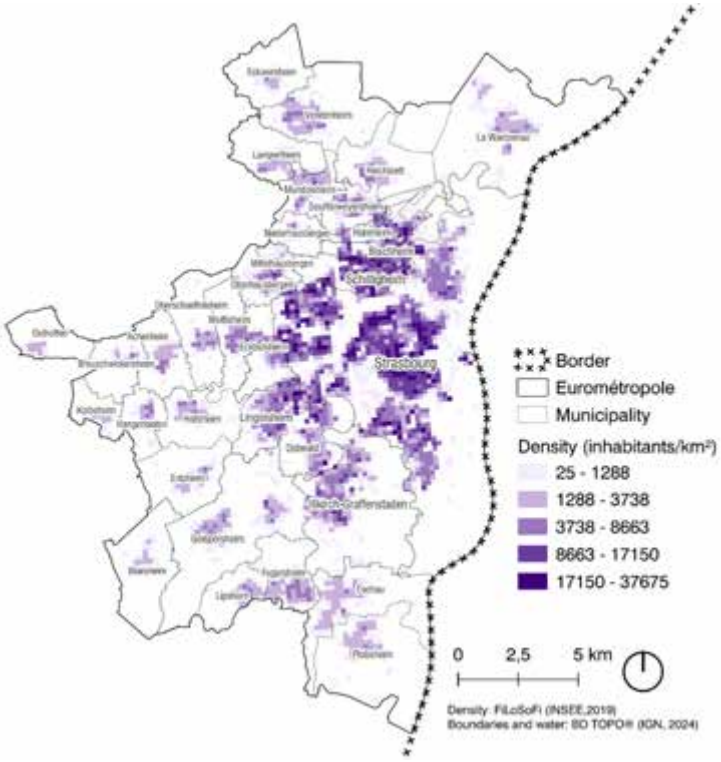

Figure 6: Population density in the Eurométropole de Strasbourg

Mobility in the Eurométropole de Strasbourg is characterised by a higher modal share of cycling compared to other cities in France; with a 14.3 % share for commuting trips in the 2021 Census, cycling in the Eurométropole de Strasbourg has the highest modal share of all 22 French metropolises.

The meshed tram network (Le Tourneur, 2016) serves Strasbourg as well as 6 other municipalities in the Eurométropole (Bischheim, Hœnheim, Illkirch-Graffenstaden, Lingolsheim, Ostwald and Schiltigheim) and Kehl in Germany with 6 lines, some of them partially overlapping. The tram network is completed by two bus rapid transit lines that serve municipalities also served by the tram network.

7. First Results

The literature review for ergonomics in urban settings indicates that published documents are split between three major topics: vehicle-related topics, urban-scale matters and design. Cars and motorcycles constitute the main part of the literature on vehicle-related topics and most of the documents consider the ergonomics of driving. On urban-scale matters, various authors have written on methodologies to assess urban ergonomics, especially regarding mobility; most of them focus on a particular mode and walking is particularly represented. Most of the approaches rely on existing data on travel conditions.

The proposed methodology uses open data, is sensitive to changes in travel conditions and aims to be replicable. The post-processing mitigates some artifacts that may happen with population synthesis: the use of personas alleviates some issues linked to structural zeroes. This method is however more computer intensive than methods solely relying on isochrones made from existing travel times or purely distance based.

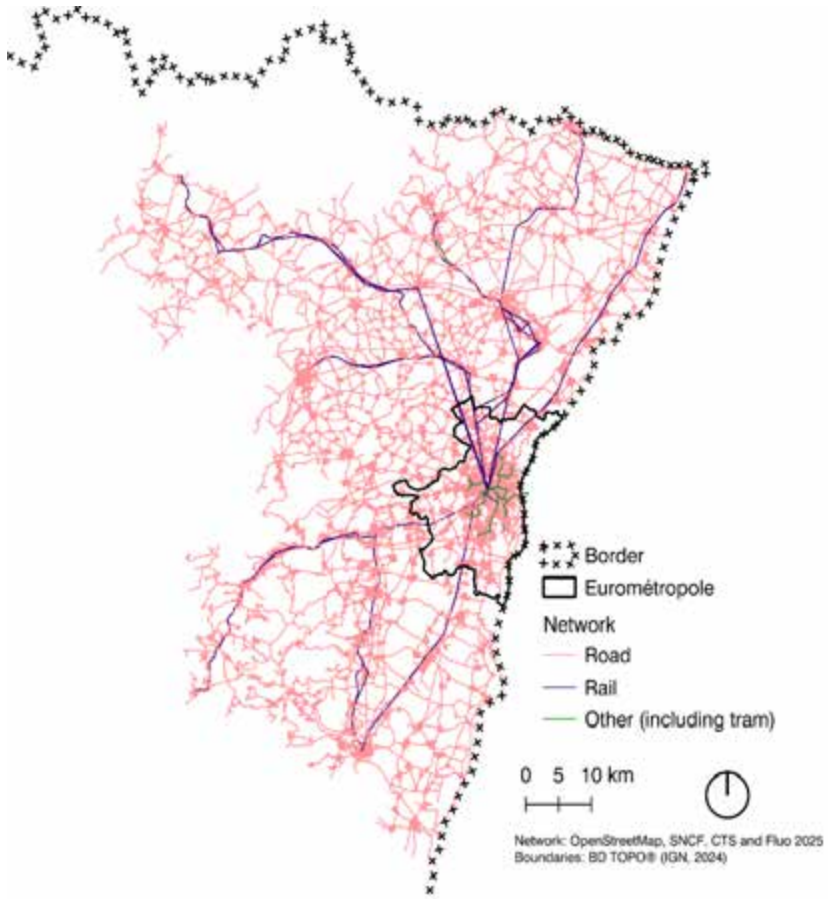

Figure 7: Modelled network

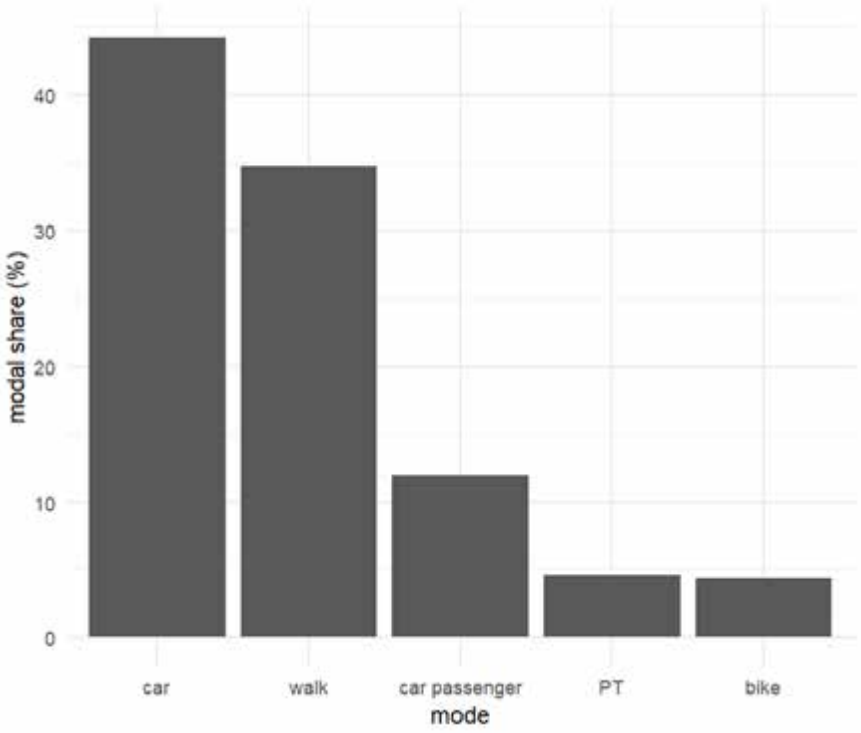

Figure 8: Modal shares

The modelled network (Figure 6) covers a wider area than the Eurométropole and includes 161,269 links. The German side of the border is not modelled due to the difference between data sources. The modal share (Figure 7) differs from the ones for Bas-Rhin in the 2021 census, this is due both to a lack of calibration and to differences in the way data is accounted for as modal share in the census only includes home to work travels.

8. Discussion

Many approaches in urban ergonomics are defined and trialled in an initial paper but are not applied further in other places. The transferability of many methods seems to be a significant issue as most of them rely on data that either requires manual input or depends on local authorities and is not standardised among data sources, qualitative approaches are more sensitive to this issue. The challenge is however that most datasets that cover more places are less defined. A challenge is then to find an equilibrium between data definition and availability, the identification of correlation between lower-scale elements and higher-scale indicators may be a way to reduce the number of needed data sources in further studies while considering the quality of surroundings during journeys.

Regarding modelling and post-processing, a further goal is also to streamline the process and develop a tool which will generate an access ergonomics score for each inhabited grid square, providing a detailed and comprehensive view of socio-spatial inequalities. The synthetic score broken down into sub-indicators (travel time, safety, comfort, etc.) and transport modes will enable comparison across the territory. These results will help to identify actions for improving access ergonomics and for reducing inequalities. In further studies, the developed tool will be improved by considering the aspect of energy transition, especially to take its consequences into account on the access ergonomics. The electric scooter availability is considered uniform in the study area in the present study. As the newer household travel survey will include data about micromobility vehicle availability, further studies may represent variations in the availability rate, the same way car ownership is modelled. The current model is uncalibrated as the latest local household travel survey results are to be released and uses the national household travel survey from 2008. Pedestrian and bicycle routing might also be an enhancement of the model, though these modes are less prone to congestion. Disposal of resources in Germany is not considered in this current paper though some communities in France near the border include amenities in Germany for their daily life, mostly for shopping purposes according to the report of the 2019 Household Travel Survey. A synthetic population of Bavaria has been built (Hörl et al., 2025) using an adapted version of the eqasim pipeline. Data availability in Baden-Württemberg (the German state neighbouring the Eurométropole de Strasbourg) and data heterogeneity between the two countries represent however a significant challenge.

Conclusion

Ergonomics in the city includes both the ergonomics of objects or spaces in the city as well as the ergonomics of the city as a system. Though the original definitions of ergonomics initially considered the human-machine interactions at the workplace, several authors have written about non-work activities and have created a wider frame for ergonomics: macroergonomics considers not only human-machine interactions, but the interaction between humans and organisations, on activities that are not limited to work. Macroergonomics have been applied to transportation systems since the 1970s with approaches such as the one Hoag and Adams applied to public transportation networks.

More recently, the return of consideration of proximity is linked to a renewed interest in the environment during travels as the users of active modes being more sensitive to their environments and literature regarding walkability includes elements of ergonomics. Most of the approaches however are either focused on a particular means of transportation or lack quantitative elements. The ergonomics of access has mostly been trialled with walking and cycling, but its outline can be adapted to other transportation modes, especially public transportation.

The proposed framework links the assessment of access ergonomics to a multimodal activity-based multi-agent model. The multi-agent paradigm allows the analysis of interactions between users and the analysis of individual properties of each agent. As access ergonomics not only describe travels done by users but also the potential ease of access to amenities including their alternatives, post-processing of the transportation simulation is necessary.

The objective to the approach is to provide a toolkit for a more holistic analysis of access to resources that is sensitive to changes in mobility conditions, whether from the network or from the demand. The multi-agent paradigm also allows further developments such as considering competition between the users for resources.

Impact of Multi-Station Aggregate Hub Redevelopment on Surrounding Urban Areas: A Case Study of London's King's Cross

Yufei Qu, Yuying Zhu, Xiaoxi Zhang, Chuan Wang*
Affiliation: School of Architecture, Southeast University
*Correponding Author Email: chuanwang@seu.edu.cn

Abstract
Multi-station aggregation hubs – interconnected transport nodes in high-intensity urban areas – significantly influence metropolitan growth, yet systematic research on their regional development impacts remains limited. This study examines London's King's Cross–St Pancras hub redevelopment using spatiotemporal data (1996–2023). Three analytical zones (Core zone, Central Impact Zone and Wider Impact Zone) were established to assess transport networks, functional vitality, and development intensity via GIS and qualitative methods. Findings indicate a 25:11:8 ratio of renewed building areas across zones, with development intensity strongly correlated to hub proximity. The core zone saw significant growth in consumer/service-oriented POIs, evolving into a mixed-use creative hub. Insights are provided for redeveloping similar hubs in high-density cities, particularly China.

Keywords
Multi-Station Aggregation; Transportation Hubs; Urban Area; King's Cross; Spatiotemporal Evolution

1 Introduction

Rail transit is reshaping existing urban spatial configurations and travel patterns (Chu and Wei, 2017; Li et al., 2015), even accelerating the redefinition of architectural boundaries, pathways, and frequencies, thereby creating new spatial forms oriented toward speed (Chu and Su, 2024). Since the 21st century, the rapid development of urban rail transit systems, exemplified by metro networks in Chinese metropolises, has profoundly transformed spatiotemporal perceptions of urban spatial development. In Asia, large cities are planning and implementing massive investments in public transport networks, where the promotion of transit-oriented development (TOD) policies has become pivotal to building public transport-centric cities (Kidokoro, 2020). For instance, Tokyo's rail system enhanced transport capacity and efficiency through measures such as double-track expansions, metro development, new route creation, express services, and station upgrades, supporting the city's transition toward compact and low-carbon spatial structures (Cao, 2022). Rail transit development influences urban layout and intensity, offering sustainable frameworks for creating compact, mixed-use communities around transport hubs in city centers.

Existing studies on the integration of rail transit stations and surrounding land development primarily focus on single-station-centered approaches, categorizing research based on station functions or locational characteristics. However, as cities evolve, urban transport hubs increasingly interconnect with neighboring stations, while metro lines constructed in different periods form complex spatial structures (Li et al., 2024). In recent years, metropolises central areas have witnessed intensified rail station clustering and increasingly intricate network configurations (Yang, 2021). Due to factors such as the alignment of new lines, construction challenges, and infrastructure constraints, later-built stations may not align with existing ones but could emerge within walkable distances. These stations, through infrastructure upgrades, coalesce into multi-station aggregation hubs (Zhu and Wang, 2022). Such hubs, often located in urban cores or critical transport nodes, present significant opportunities for shaping surrounding areas (Li et al., 2024; Desjardins, Maulat and Sykes, 2014). Over the past three decades, these hubs have proliferated in global urban development, with their optimized layouts structurally enhancing spatial quality in central districts (Yang, 2021). Nevertheless, systematic research on multi-station hubs and their interconnected urban functional districts remains insufficient, and their spatiotemporal evolution mechanisms require further study.

The King's Cross area in London, a vital transport hub and urban core in the city's northeast, hosts two major rail stations (King's Cross and St Pancras) and six underground lines. Its closely linked stations exhibit rich spatial hierarchies and order, making it a representative multi-station aggregation hub. This study traces the redevelopment of King's Cross over the past two decades, employing multi-source archival surveys, GIS-based quantitative analyses of transport networks, functional shifts, and development intensity, and typological examinations of renewal modes. By combining quantitative and qualitative methods, it analyzes the impact of

multi-station hub redevelopment on regional development, aiming to uncover patterns of influence exerted by such transport complexes on urban growth. The findings are expected to provide insights for the planning and redevelopment of multi-station aggregation hubs in other emerging metropolises.

2 Research Methods

2.1 Case: King's Cross, London

The King's Cross area is located in the northeast of central London, at the junction of the Camden and Islington boroughs, serving as a critical transport hub where King's Cross Station and St Pancras Station converge. After World War II, containerized rail freight replaced traditional freight methods, leading to large areas of land and buildings within the region being repurposed for cargo storage. Due to poor management, the station environment became increasingly dirty and dim, while unemployment severely impacted local communities. By the 1980s, the area had become a region in urgent need of urban revitalization. However, redevelopment efforts in the 1980s and 1990s repeatedly failed due to challenges in coordinating land ownership, incomplete public facilities, and unclear industrial targets.

The real reconstruction of the area began in 2000 with the Channel Tunnel Rail Link project. A development consortium named King's Cross Central Development Partnership (KCCLP), composed of companies such as Argent, LCR, and Exel, was established as the sole landowner to lead the redevelopment of the King's Cross core zone. Building on comprehensive upgrades to King's Cross and St Pancras stations, the project capitalized on high transport connectivity to integrate multiple underground lines, transforming former industrial sites into a mixed-use urban district combining commerce, culture, creativity, and research. This revitalization became a new engine for urban development, driving growth in surrounding areas. The urban transformation also brought significant opportunities: between 2010 and 2022, the number of companies in the core zone nearly doubled to 800, office rents surged from 48% below to 19% above central London averages, and employment increased from 8,000 to 27,000 jobs (Regeneris Consulting, 2017). The King's Cross redevelopment project stands as one of the UK's largest and most notable urban regeneration initiatives of the past three decades.

As a representative multi-station aggregation hub with nearly two decades of redevelopment history and a stabilized built environment in recent years, King's Cross was selected as the focus of this study. Based on reports published by the King's Cross development authority (Regeneris Consulting, 2017) and the King's Cross Master Plan (Allies and Morrison Architects, 2007), the research scope was divided into three zones (hereafter referred to as the "Three Zones," Figure 1): Core zone, Central Impact Zone and Wider Impact Zone.

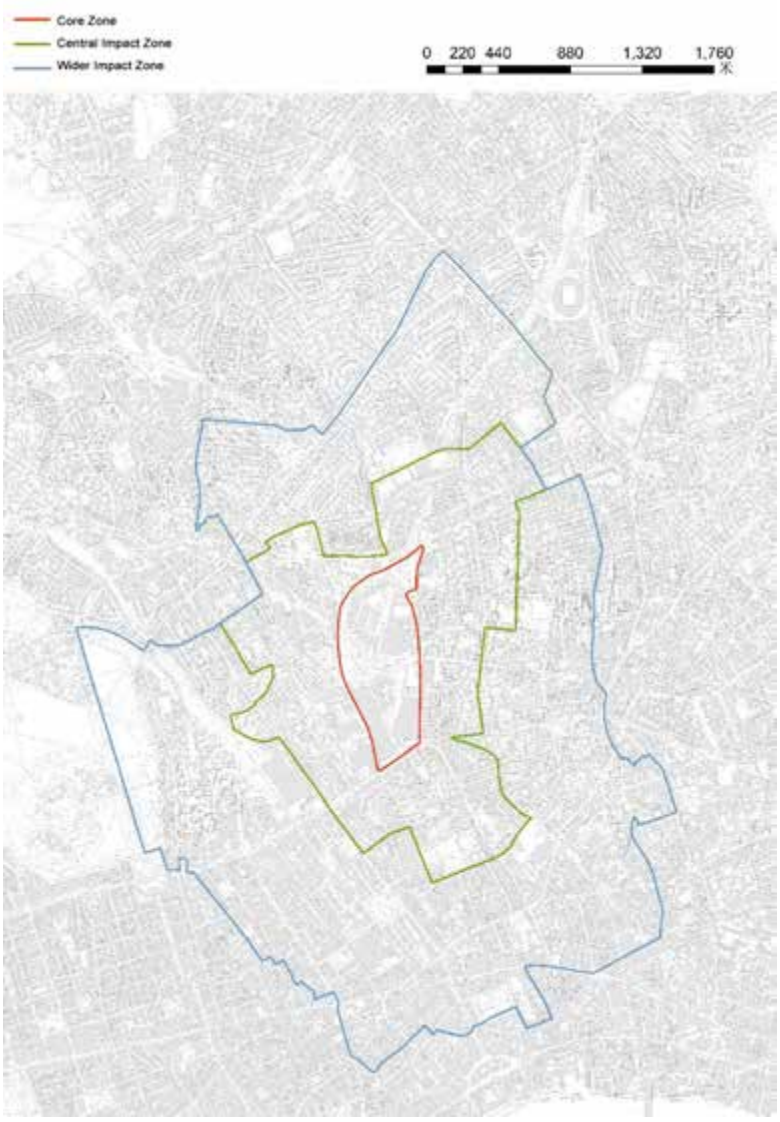

Figure 1: Three Analytical Zones of King's Cross

2.2 Data Sources: Documents and Spatial Data

This study collected and analyzed documents and spatial data related to the redevelopment of King's Cross from multiple sources. For documentary data, this included historical records of the area, planning and design proposals from developers and urban designers, relevant planning documents published on the official websites of the Camden and Islington local authorities, progress reports on the King's Cross core zone (2008–2024) published by KCCLP on its official website, and a 2017 construction evaluation report for the core and impact zones by Regeneris Consulting (Regeneris Consulting, 2017). For spatial and statistical data, the study acquired: Ordnance Survey datasets (2007–2023): Built-environment typology maps, building height data, and Points of Interest (POIs); Transport for London (https://tfl.gov.uk): Ridership statistics for stations (2007–2017); UK Office for National Statistics (www.ons.gov.uk): Census data (2001, 2011, 2021) at the Output Area (OA) level, with each OA typically covering 40–250 households.

2.3 Analytical Methods: Integration of Qualitative and Quantitative Approaches

The research first clarified the historical development trajectory of King's Cross through document analysis, with a particular focus on the evolution of the core zone's built environment and the historical integration of rail and underground lines. Historical changes were mapped visually. At the macro level, ridership variations across stations were visualized, while transport networks, functional vitality, and development intensity within the three zones were analyzed and visualized using ArcGIS to quantify the impact of multi-station transport

development on surrounding areas. Building on this spatial analysis, the study classified and examined spatial renewal patterns across the three zones. Typical buildings were categorized by renovation scale, from largest to smallest:1) Brownfield redevelopment, 2) Demolition and reconstruction, 3) Functional adaptation and renovation, 4) Vertical or horizontal expansion. The development of King's Cross was systematically analyzed through both renovation typologies and spatial layouts.

3 Multi-Station Aggregation Hub and Regional Impact in King's Cross

3.1 Aggregation Development of Transport Hubs

In the 1990s, the King's Cross–St Pancras underground station comprised three distinct stations: the Metropolitan/Circle Line (constructed 1864–1870), the Piccadilly/Northern Line (1906–1907), and the Victoria Line (1968). These stations were connected by narrow, temporary passageways, which became severely congested by the late 1990s due to escalating passenger volumes (Bessant, 2004). Following the 1987 King's Cross fire, the 1989 Fennell Report (Fennell, 1989) by the UK House of Commons recommended that London Underground investigate "riderships and overcrowding at stations and implement remedial measures." The London Underground (King's Cross Station) Act 1993 authorized infrastructure upgrades to alleviate congestion. The underground connectivity project, designed in 1999 and constructed from 2000, was implemented in two phases: Phase I (2006): Expanded the original ticket hall and constructed a new western ticket hall adjacent to St Pancras Station, directly linking to the Metropolitan/Circle Line platforms; Phase II (2009): Added a northern ticket hall with tunnel access to the Piccadilly Line and improved accessibility features (Figure 2).

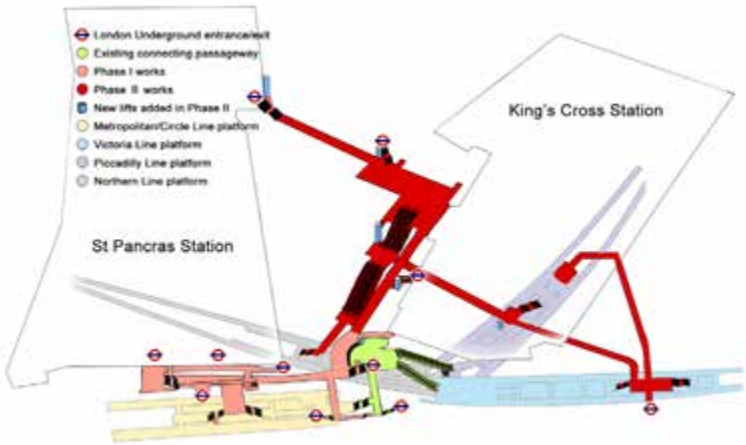

Figure 2: Schematic Diagram of the Multi-Station Aggregation Project at King's Cross

The redevelopment added six new access points in Phase I and two in Phase II, resulting in 11 underground entrances across three ticket halls. These upgrades integrated six underground lines and two national rail stations, resolving congestion and providing capacity for the 2012 London Olympics. The consolidation of previously fragmented stations into a multi-station aggregation hub significantly improved accessibility, enabling the hub to accommodate Eurostar's high-speed rail services and catalyzing large-scale urban renewal in the surrounding core zone (Allies and Morrison Architects, 2007).

Following the November 2007 opening of St Pancras International Station and further optimization of underground and above-ground facilities, rail and underground riderships exhibited steady growth. From 2008 to 2017, annual ridership at King's Cross–St Pancras underground station increased by 46%, King's Cross rail station by 40%, and St Pancras International nearly doubled. The growth rate at King's Cross–St Pancras far exceeded the London Underground average and ranked highest among surrounding stations (Figure 3), driving substantial ridership growth in the King's Cross area, particularly in the core zone.

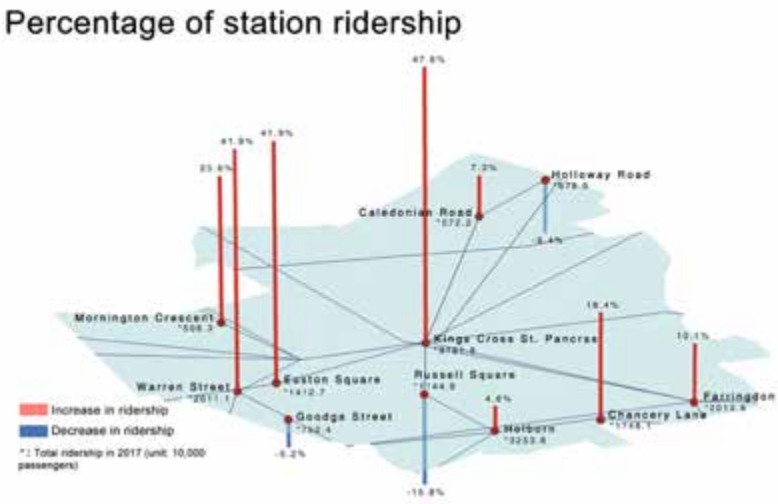

Figure 3: Annual Ridership Changes at King's Cross Stations (2007–2017)

3.2 Evolution of the Transport Network

The redevelopment of the King's Cross area has had an impact on the transport network mainly in terms of the reconfiguration of roads in the core zone, where the northern part of the site, which was previously divided by transport routes and freight depots, has been reconfigured in a phased manner, and the links with the surrounding area, in particular the aggregated sites, have been enhanced in the following ways (Figure 4): Early redevelopment focused on opening east-west freight routes and extending Camley Street and Pancras Road into the core zone. These newly connected arteries, alongside the existing York Way, redefined the primary transport network of King' s Cross. In the middle of the redevelopment, two narrow historic canal bridges were replaced with 18-meter-wide pedestrian bridges—dual-function structures designed for daily foot traffic and emergency access (e.g., firefighting). This phase also rationalized key north-south connections, establishing a cohesive axis from York Way through the canal to the station area and onward to A501 Road. In the concluding stage, vacant plots were systematically redeveloped to form a comprehensive pedestrian network. Newly constructed building clusters integrated well-defined public spaces and streetscapes, further enhancing the core zone's vibrancy. Post-redevelopment, the entire zone achieved a balanced yet diverse street layout, markedly improving traffic fluidity and urban functionality.

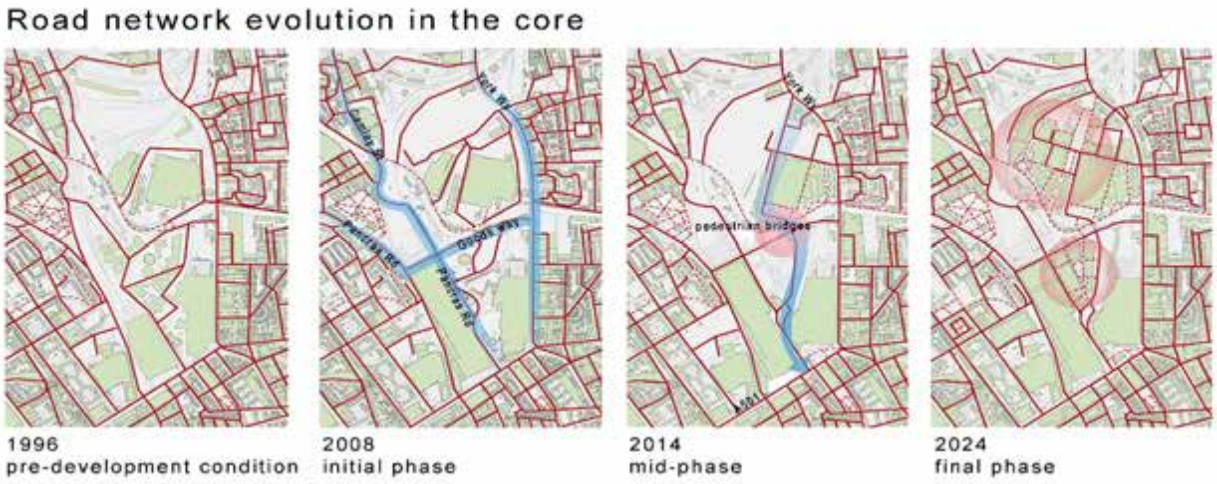

Figure 4: Road network evolution in the core zone (1996–2024)

3.3 Functional Vitality Transformation

The redevelopment of King's Cross spurred significant socio-economic agglomeration, with increased activity levels across surrounding areas. Points of Interest (POI) data, reflecting the diversity and density of urban functions, provide critical insights into the spatial evolution of economic and social activities driven by the hub's growth (Desjardins, 2014). Between 2014 and 2023, the total number of POIs across the entire King's Cross area remained relatively stable, with minor fluctuations. Notably, manufacturing-related POIs experienced a sharp decline of 19.5%, signaling the outward relocation of industrial activities and the reallocation of space for commercial and social uses (Regeneris Cunsulting, 2017).

A comparative analysis of the three zones reveals divergent trends. While the central and wider impact zones saw slight decreases in total POIs, the core zone experienced a 102.7% surge over the decade. Specifically, consumption and entertainment POIs in the core zone grew by 127.4%, and commercial services POIs surged by 200%, contrasting with marginal declines in the other two zones (Figure 5). This transformation underscores the core zone's emergence as a dynamic urban functional district. Its enhanced functional diversity and economic agglomeration capacity have revitalized the once transit-dominated hub into a vibrant, attractive destination.

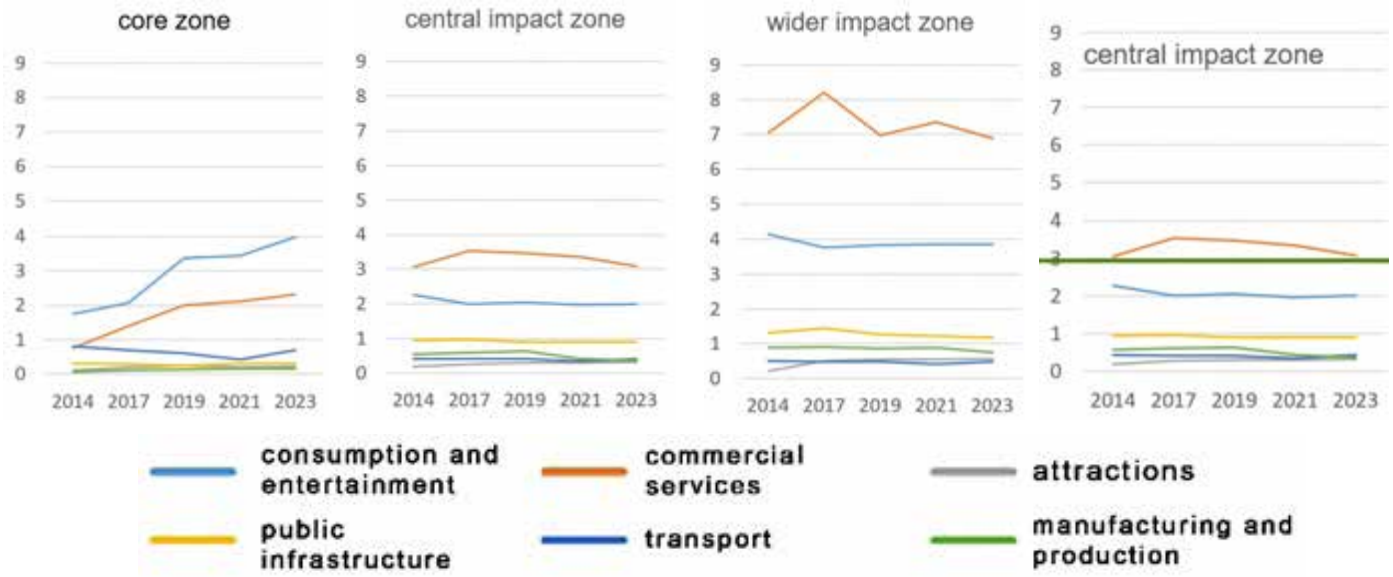

Figure 5: Changes in POI density per hectare across zones (2014–2023)

3.4 Intensity of Spatial Development

Analysis of building volume records since 1996 reveals stark disparities in development intensity across the three zones. core zone, central impact zone and wider impact zone exhibited a 25:11:8 ratio in newly added floor area per hectare. Driven by extensive brownfield regeneration opportunities, the core zone—despite occupying less than 5% of the total study area—accounted for over quarter of the total development volume, far outpacing the other zones. The central impact zone saw slower growth, with approximately 1% of buildings undergoing annual additions or major expansions, a renewal rate higher than that of the potential impact zone, which represents typical central London development patterns (Table 1).

This pattern underscores the catalytic role of the King's Cross–St Pancras multi-station hub in amplifying spatial development momentum. Overall, the development rate exhibits a strong positive correlation with proximity to the hub: areas closer to the aggregated transport nodes demonstrate higher spatial value and greater redevelopment incentives.

Table 1: Spatial Development Metrics Across Zones (1996–2023)

Metric	core zone	central impact zone	wider impact zone
Newly added floor area (10,000 m²)	93.3	73.6	196.8
Total floor area (10,000 m²)	126.5	275.0	977.4
Land area (hectares)	48.0	266.6	709.6
New floor area per hectare (100 m²)	193.7	27.6	27.7
Proportion of building volume renewal	73.7%	26.8%	20.1%
*Floor area is estimated based on building morphology and height data, assuming an average floor height of 3.5m.			

The three zones exhibited distinct spatiotemporal development trajectories. Notably, the core zone did not immediately witness large-scale construction at the outset; in fact, no buildings were completed in the four years following the integration of St Pancras International Station, primarily due to delays in the development cycle. Significant construction commenced in 2007, spurred by the influx of passengers from Eurostar services and the aggregation of multi-station connectivity. This catalyzed the area's transformation into a hub for cultural, research, and corporate institutions, attracting multinational corporations, startups, and Central Saint Martins (University of the Arts London) to occupy office complexes built on regenerated brownfield sites. From 2011 onward, a wave of high-intensity development swept the core zone, with buildings progressively erected from south to north. By 2020, however, most core-area projects had been completed, leading to a decline in development rates. In contrast, the primary and potential impact zones experienced far lower construction volumes, characterized by fluctuating, modest growth. Yet, at every stage, the primary impact zone consistently outpaced the potential impact zone in development volume, reflecting the substantial momentum generated by the King's Cross hub aggregation. Spatially, most developments in the primary impact zone clustered around the core zone (Figure 6). Planned developments in adjacent areas further amplified this effect. For instance, Islington Council proposed high-density developments along York Way (adjacent to the core zone), including office, retail, leisure, and residential spaces. The plan identified four sites for high-rise buildings (30+ meters) and prioritized commercial floor space categories such as Grade-A offices, mixed-use spaces, and co-working facilities. (Islington Concil, 2023)

	1996-1998	1999-2001	2002-2004	2005-2007	2008-2010	2011-2013	2014-2016	2017-2019	2020-2022
wider impact	152.8	294.9	323.8	311.2	463.0	226.4	278.7	469.9	252.0
central impact	189.8	128.3	387.0	260.4	362.0	70.3	755.4	351.6	257.9
core	0.0	0.0	137.5	1247.6	756.9	2123.3	5868.1	4423.6	4808.6

Figure 6: Spatial distribution and comparative metrics of redeveloped buildings (1996–2022)

4 Spatial Renewal Methods in King's Cross Area

The King's Cross Opportunity Area, driven by the demand for foot traffic from transportation aggregation nodes, has spatially sought a variety of development patterns to promote economic agglomeration and diversification in and around the core zone. By tracing the spatial changes within the three King's Cross districts from 2007 to 2023, this study summarizes the development patterns into four types of patterns based on the underlying conditions

and spatial changes: overall demolition and redevelopment patterns, functional renewal and alteration, and expansion upwards and to the periphery (Figure 7). These types provide a large number of possibilities for spatial change and growth in multi-site agglomeration lots in already built-up urban high-density areas, progressively optimizing the relationship between transportation-space-function.

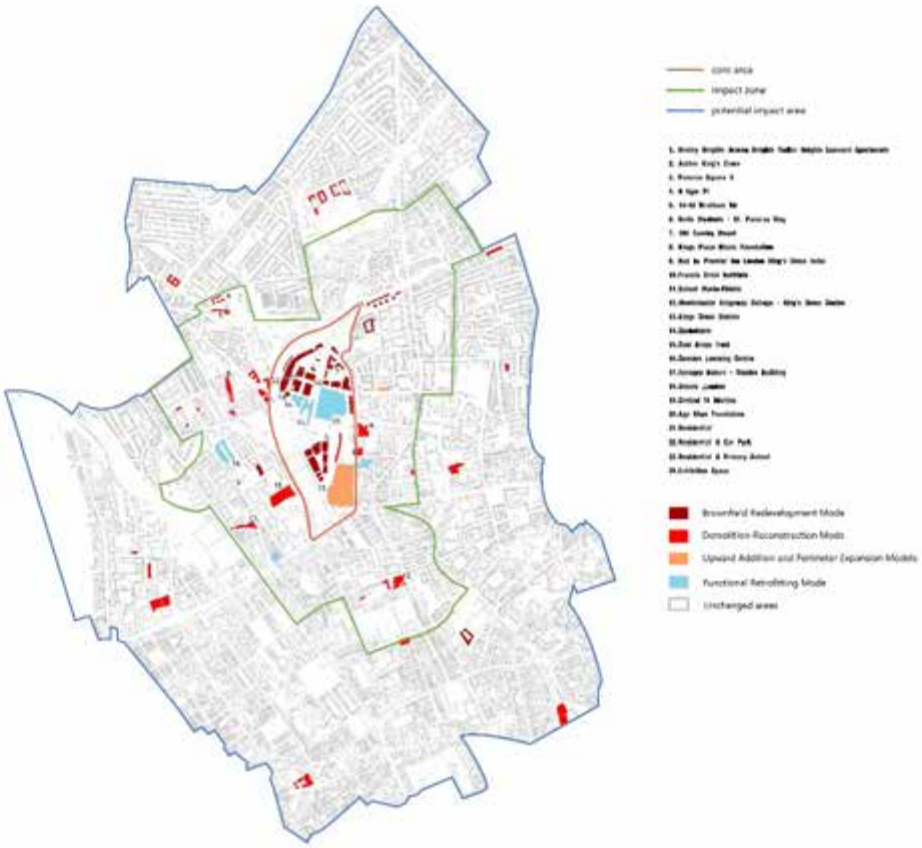

Figure 7: Distribution of the four development patterns in the King's Cross area

4.1 Brownfield Redevelopment Mode

The King's Cross and St Pancras stations, with their long histories, historically required extensive land for freight yards and rail operations. With advancements in transportation and logistics, many low-efficiency lands previously used for storage and rail operations were repurposed for redevelopment. This mode involves completely transforming the original land use to meet new spatial demands, significantly enhancing land value and utilization. Due to the abundance of brownfield sites in the northern part of the core zone, this became the most prevalent renewal mode in King's Cross (indicated by wine-red buildings in Figure 7).

A representative example is Pancras Square in the core zone. Located in the triangular area between King's Cross Station and St Pancras International Station, this prime urban site was previously occupied by rail yards and gas holders. After relocating the gas holders, redevelopment began in 2008, resulting in seven medium-height, high-density office blocks arranged in a street-like layout (Figure 9). Completed between 2013 and 2023, these buildings include Pancras Square 1 (designed by David Chipperfield Architects) and Pancras Square 4 (designed by Eric Parry Architects), which harmonize new structures with preserved historical buildings. The lower floors feature publicly accessible amenities such as retail, dining, a library, and leisure spaces, while the upper floors provide premium office space. The area's superior transport connectivity and livable environment have attracted global corporations like Universal Music, Google, and Meta.

Figure 8: Aerial view of Pancras Square (Source: Apple 3D Maps)

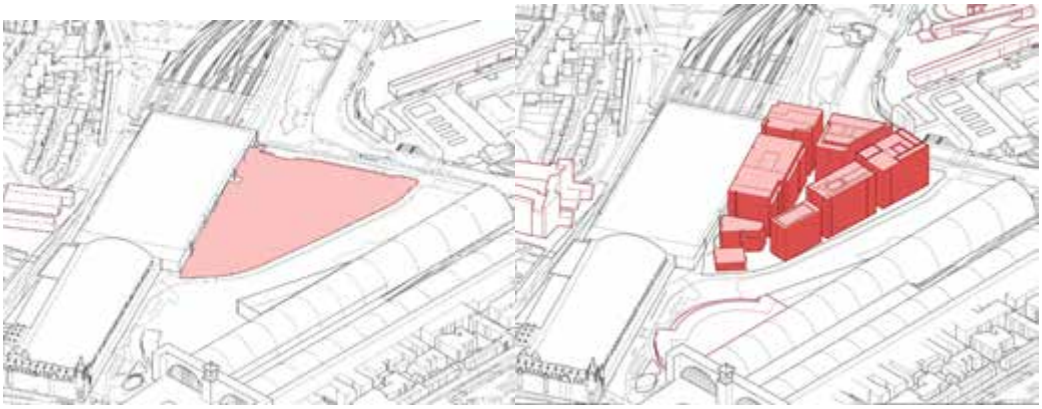

Figure 9: Before-and-after comparison of Pancras Square 1–7.

4.2 Demolition-Reconstruction Mode

Driven by the development momentum generated by multi-station aggregation, non-historic buildings with poor quality or low intensity near the hub were demolished and replaced with higher-density structures. This mode primarily occurred in the primary impact zone, where original buildings held limited historical value (marked by red buildings in Figure 7).

The Francis Crick Institute, a major biomedical research center west of St Pancras Station, exemplifies this approach (Figure 10). Construction began in 2007 with the demolition of fragmented, low-value buildings on the site. Completed in 2016, the 12-story, 100,000 m² complex integrates one-third of its structure below street level to minimize visual impact and creates public gardens. The institute now employs over 1,000 scientists, further energizing the area.

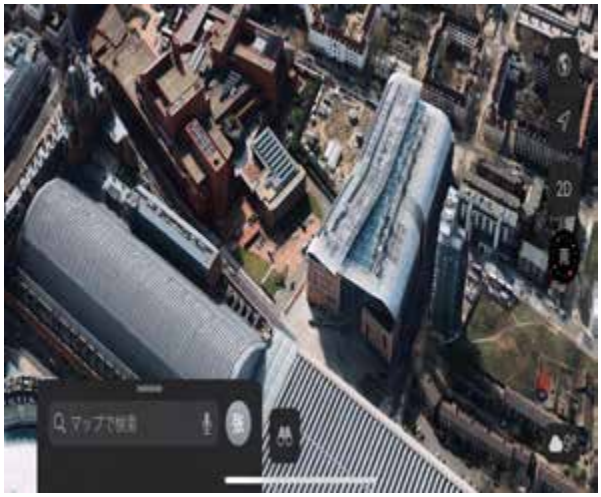

Figure 10: Aerial view of the Francis Crick Institute (Source: Apple 3D Maps).

Figure 11: Francis Crick Institute Before and After

4.3 Functional Retrofitting Mode

This mode involves partial renovations or expansions of existing buildings to adapt to new functions. It is categorized into three types:

1. Partial Retrofitting: Modifying specific sections of a building to enhance functionality or aesthetics while complying with regulations.
2. Functional Conversion: Repurposing structures while retaining their core framework (e.g., converting factories to residences or shops to offices).
3. Complete renovation with structural retention: Preserving the original structure but fully refurbishing it for new uses.

Heatherwick Studio undertook the restoration and adaptive reuse of two Victorian-era warehouses in the King's Cross core zone. These elongated brick warehouses, constructed in 1850 alongside railway viaducts, were interconnected via elevated walkways to create cohesive public spaces (Figures 12 and 14). The design introduced sloping glass extensions that extend upward from the original gabled roofs, forming interconnected upper-level spaces that serve as focal points for events and retail activities. The lower levels feature double-height volumes for hosting concerts, while the preserved cobblestone courtyards and historical façades maintain the site's industrial heritage. While creating new elements, the project's careful restoration of the surviving Victorian buildings and cobblestone courtyards to retain their historic character has created an unusual mix of retail spaces through the adaptation of internal spaces.

Figure 12: Coal Drop Plaza Elevation and Existing Conditions

The adaptive reuse of three historic gas holders exemplifies functional conversion combined with structural preservation. The original cast-iron gasometers—iconic symbols of the area's industrial past—were relocated and repurposed into residential complexes housing over 140 apartments (Figures 13 and 14). The design preserved the gasometers' industrial aesthetic and physical integrity while introducing a fourth "virtual drum" at their intersection to form shared courtyards for residents. The apartments range from studio to three-bedroom layouts, with the interstitial spaces between the gasometers transformed into landscaped gardens.

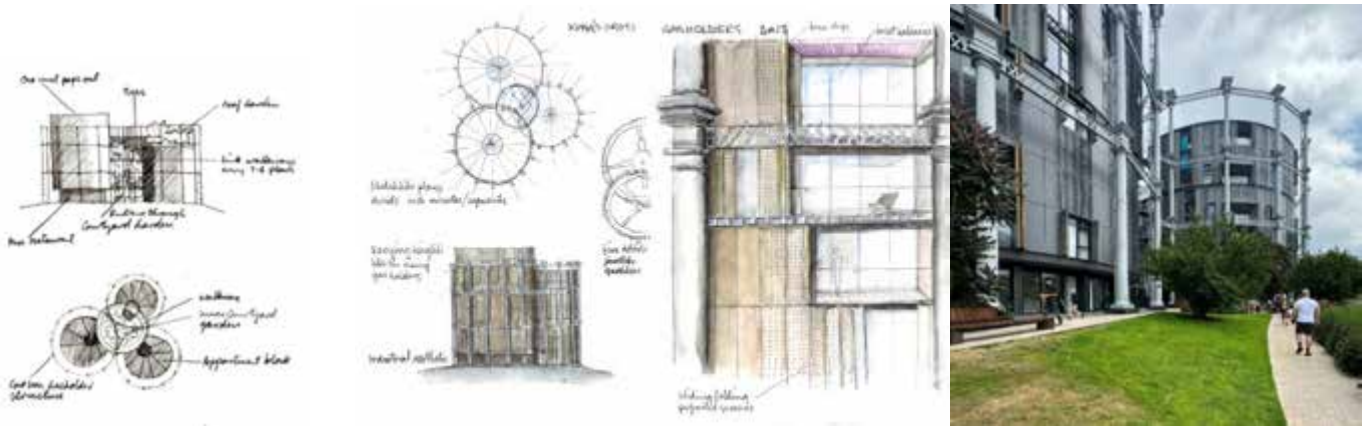

Figure 13: Triplex Gas Storage Tank Design Analysis Diagram and Current Status

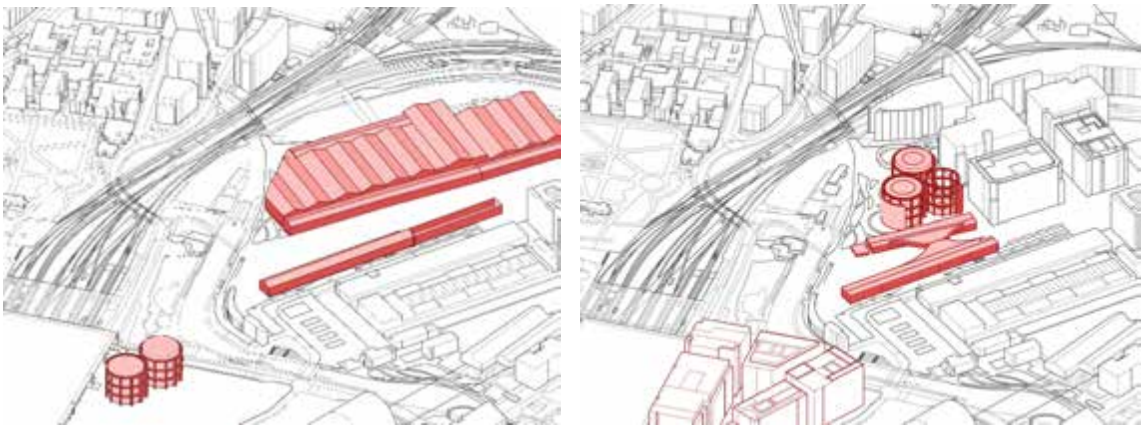

Figure 14: Comparison of Triplex Gas Storage Tank and Coal Drop Plaza before and after construction

4.4 Upward Addition and Perimeter Expansion Models

This mode expands buildings vertically (adding floors) or horizontally (extending laterally) to meet spatial demands.

The original height of buildings on some plots is lower than the upper limit of statutory requirements or urban design guidelines, or there are available plots in the vicinity, and reasonable expansion is carried out through optimization of design to meet the present new space requirements, which can be classified into two modes according to the two dimensions of expansion: 1) Horizontal Expansion - adding a Horizontal expansion - adding a new structure or building next to or around the original building to expand its scale or function and integrate with the original building; 2) Vertical expansion - adding a new floor or structure on top of the existing building to increase the available space.

The new west side ticket hall between King's Cross and St. Pancras International stations is a typical example of a horizontal expansion (Figures 15-16). The new West Side Ticket Hall extension designed by John McAslan + Partners (JMP) is an important extension to achieve multi-station interconnectivity as King's Cross and St. Pancras stations become increasingly important as transport hubs and St. Pancras becomes the starting point for access to the continent, and in anticipation of the London 2012 Olympic Games. The new West Side Ticket Hall Extension, designed by John McAslan + Partners (JMP), is an important extension that will enable the interconnection of multiple stations. Echoing the adjacent Great Northern Hotel, the hall is 20m high and dominated by a 150m span semi-circular arch that spans the west elevation of the existing Grade I listed King's Cross station, creating a new entrance to the station that leads from the southernmost point of the structure to the northernmost point of the station's west concourse. Considering the protection of the original station façade, the structural survey report concluded that only the central part of the original station façade could have a structural support base. Therefore, the project was cleverly designed as a semi-circular dome structure to fully utilize this structural support foundation. The dome was independently supported by 16 dendritic steel columns and was the largest single-span structure in Europe at the time. The transformation of the ticket hall was both visually striking and able to accommodate 50 million passengers a year, acting as a catalyst for the transformation of King's Cross into London's new transportation hub.

Figure 15: Aerial view of the new Western Ticket Hall and human eye viewpoints

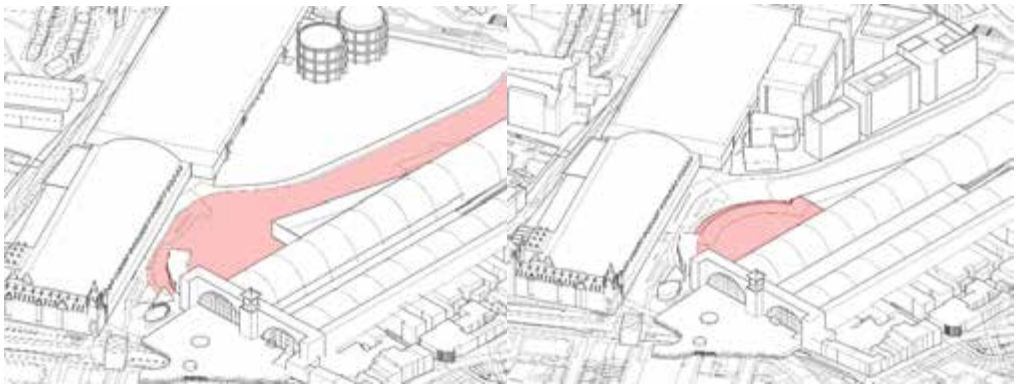

Figure 16: Comparison of the New Western Ticket Hall before and after its completion

5 Discussion and Conclusions

The redevelopment of King's Cross demonstrates that the aggregation of transport hubs—through the expansion of rail networks and integration of existing stations—creates efficient connectivity, driving increased passenger flows and stimulating demand for complementary functions and spatial provisions. The introduction of Eurostar services in 2007 and the completion of two multi-station ticket halls between 2006 and 2009 streamlined passenger transfers, amplifying the hub's aggregation effect. From 2008 to 2017, annual passenger growth at King's Cross rail station, St Pancras International, and the King's Cross–St Pancras Underground stations exceeded 40%, surpassing London-wide average growth. This passenger flow has generated a greater demand for more intensive spatial usage, as evidenced by the significant growth of consumption/entertainment and commercial services POIs in the core zone. Over the 1996–2023 period, the emergence of new economic and employment models transformed the transport-aggregated area into a creative industry cluster, fostering a live-work balance that established King's Cross as a desirable mixed-use district.

In recent years, reduced demand for freight storage and rail infrastructure—driven by containerization and rail-overbuild technologies—has freed up land for multi-station hub redevelopment (Chen and Zhuang, 2022; Chen, 2018). At King's Cross, the shift from a historic freight-passenger hub to a passenger-dominant transport node unlocked underutilized rail yards and storage sites. Post-2007, the core zone prioritized redeveloping the strategic corridor between St Pancras and King's Cross, creating Pancras Square—a high-density office and retail cluster. Subsequent phases regenerated northern brownfield sites, integrating cultural, educational, residential, and commercial functions into a cohesive urban district.

Proximity to the multi-station hub strongly correlates with development intensity. From 1996 to 2023, 25: 11: 8 of new floor area per hectare was added in the core, central impact, and wider impact zones, respectively. Spatiotemporal analysis reveals that most developments occurred post-2009, following the completion of St Pancras International's integration and underground connectivity upgrades. Market-driven dynamics prioritized sites closest to the hub, where spatial value and redevelopment incentives peaked. For instance, Islington Council's high-density plans along York Road—adjacent to the core—emphasized Grade-A offices and mixed-use spaces, reinforcing the hub's catalytic role.

Against the backdrop of global urbanization shifting from expansion-driven growth to stock optimization, how to strategically reshape urban structures and functions through spatial regeneration has become a shared challenge for cities worldwide. King's Cross exemplifies how rail-concentrated areas can lead urban renewal. Aggregating proximate existing and planned stations enhances foot traffic, driving spatial-functional optimization and broader regional revitalization. It is foreseeable that with continuous advancements in transportation technology, the reduced demand for ancillary transport infrastructure and increased functional integration will enable sophisticated mixed-use design to unlock greater development potential in urban multi-hub aggregation zones. Under the synergistic effects of various urban models, such approaches will significantly enhance district functionality and elevate spatial quality. This transportation-hub-driven regeneration model may well become an indispensable pathway for emerging cities to achieve low-carbon, efficient, and human-centered urban transformation.

Urban freight mobility modes recognition classification and inclusive freight policy exploration based on truck trajectory data: A case study of Shanghai, China

JIA WEI, SHANGWU ZHANG, QUAN YUAN
Affiliation: Urban Mobility Institute, Tongji University, Shanghai, China
Email: weijiatongji@163.com

Abstract
In high-density cities like Shanghai, freight trucks are essential but face significant constraints and high costs. This study addresses the shortfalls of current "one-size-fits-all" freight policies. Using extensive GPS data from heavy trucks and a two-step clustering method, the research identifies typical activity patterns from a micro-perspective. It classifies truck activities into two main categories and five sub-categories, revealing significant differences in travel distance, hub stops, and journey types (intra-city vs. inter-city). Based on these findings, the study proposes targeted management suggestions, such as more detailed requirements for short-distance trucks and flexible traffic restrictions informed by big data, paving the way for innovative, localized urban freight systems.

Keywords: Freight mobility modes, Inclusive policies, Sustainable mobility systems, Truck trajectory data, Shanghai

1. Introduction

1.1. Background and Significance

The intricate web of freight transportation is indispensable to the daily lives of households and the seamless operations of businesses, profoundly influencing urban development and prosperity. Within the dense fabric of high-density urban areas, freight trucks serve as the undisputed backbone of goods movement. However, their critical role is often juxtaposed with significant operational constraints and substantial costs (Li, 2020). Understanding the nuanced behaviour of freight trucks is not merely an academic exercise; it is foundational for enhancing the efficiency of freight transport, optimising supply and demand forecasting, and refining urban governance strategies.

Historically, the analysis of freight activity has often relied on aggregated data or macroscopic models, which can obscure the underlying complexities of individual truck movements. This 'one-size-fits-all' approach to freight policy, while administratively convenient, frequently overlooks the diverse operational requirements and characteristics of various freight activities. This oversight can lead to inefficiencies, increased costs for logistics operators, and exacerbated urban challenges such as traffic congestion, air pollution, and noise (Liu and Zhang, 2023).

The necessity of delving deeper into urban freight truck activity is multifaceted. Firstly, from an economic perspective, gaining a profound understanding of these behaviours can significantly contribute to cost reduction and efficiency gains within the freight transport sector, thereby fostering economic growth. Secondly, from an urban planning and management viewpoint, a detailed analysis of truck activity patterns is an imperative for the precise refinement of urban traffic governance and the substantial improvement of road network operational efficiency. Traditional approaches to urban freight management often lack the granularity required to implement effective, tailored policies that acknowledge the varied functions and impacts of different truck operations.

The feasibility of conducting such micro-level research has dramatically improved in recent years. The proliferation of high-frequency truck trajectory data, primarily derived from Global Positioning System (GPS) devices, has opened unprecedented avenues for detailed observation and analysis. This wealth of data makes it possible to investigate the microscopic patterns of truck activity, uncover underlying behavioural regularities, and construct more sophisticated models of freight movement (Ma et al., 2016; You and Ritchie, 2018). This study leverages these advancements to provide a comprehensive analysis of urban freight mobility in Shanghai, China.

1.2. Research Content

This study aims to address the aforementioned gaps by undertaking a detailed examination of freight truck activity patterns, supported by extensive high-frequency trajectory data. The research encompasses several key areas:

- **Characterisation of Truck Travel Characteristics:** Utilising high-frequency truck trajectory data, the study first focuses on identifying stop points and performing path map matching. This process extracts fundamental travel information, which is then used to characterise various aspects of truck travel, including trip duration and frequency, spatial distance and range, and the utilisation of infrastructure.
- **Inference of Truck Activity Purpose:** By integrating diverse data sources such as land use, enterprise registration information, and Points of Interest (POI) data, the research moves beyond a mere empirical understanding of individual truck trajectories. It explores methodologies to infer the specific purposes behind observed truck activities, providing crucial insights into the 'why' of their movements.
- **Categorisation of Truck Activity Modes:** Drawing upon the insights gleaned from the characterisation of truck travel characteristics and the inference of activity purposes, the study aims to summarise typical truck activity modes. This involves exploring classification methods to identify distinct patterns of freight movement.
- **Management Recommendations for Different Truck Activity Types:** Based on the identified and categorised truck activity types, the research proposes management recommendations. These suggestions are developed in consideration of existing urban freight management policies and are designed to be more congruent with industry needs and the inherent patterns of truck activity. The ultimate goal is to formulate more inclusive and effective freight policies that cater to the diverse operational demands of urban logistics.

2. Literature Review

Understanding freight truck movement patterns is a multidisciplinary challenge that draws insights from urban planning, logistics, transportation engineering, and data science. This section reviews existing literature, highlighting key methodologies and findings pertinent to this study.

2.1. Stop Point Identification

The identification of "stop points" or "stay points" from raw GPS trajectory data is a crucial preliminary step for understanding vehicle behaviour. A stop point signifies a period when a vehicle remains stationary or moves within a very limited area, often indicating an activity such as loading, unloading, parking, or waiting. Various methods have been proposed for stop point identification, typically involving thresholds for speed, time, and spatial proximity.

Early approaches often relied on simple speed thresholds, deeming any point below a certain speed as part of a stop (e.g., Wang et al., 2012). However, this can be problematic in congested urban environments where slow movement does not necessarily equate to a stop. More sophisticated methods incorporate time thresholds, defining a stop as a period where the vehicle remains within a predefined spatial radius for a minimum duration (e.g., Li, 2020). For instance, Li (2020) utilised a method that clusters GPS points within a certain radius and time window to identify stop points, a common practice in freight research.

Recent advancements in stop point detection involve more complex algorithms, including density-based spatial clustering of applications with noise (DBSCAN) or grid-based methods, which are more robust to GPS signal fluctuations and varying speeds. Ji et al. (2019) proposed a parallel algorithm that combines stay point features and moving features to detect traffic patterns, showcasing the evolution towards more integrated approaches. The accuracy of stop point identification directly impacts the subsequent analysis of activity chains and trip purposes.

2.2. Freight Trip Chaining Analysis

Freight trip chaining, or the sequence of stops and movements that constitute a complete vehicle tour, offers a holistic view of freight operations. Unlike passenger trips, freight tours often involve multiple stops for pick-ups and deliveries, making the concept of "trip chaining" particularly relevant. Analysing these chains helps in understanding the operational logic, efficiency, and spatial distribution of freight activities.

Ma et al. (2016) explored freight trip-chaining behaviour using a spatial data-mining approach with GPS data, revealing common patterns and influencing factors. Their work underscored the importance of geographical context in understanding trip structures. Similarly, You and Ritchie (2018) developed a GPS data processing framework specifically for the analysis of drayage truck tours, highlighting the unique characteristics of port-related freight movements.

The duration and sequence of stops within a trip chain are critical indicators of efficiency and potential bottlenecks. Duan et al. (2020) further advanced this area by comprehending and analysing multiday trip-chaining patterns of freight vehicles using a multiscale method with prolonged trajectory data, demonstrating the complexity and continuity of freight operations over longer periods. Their research emphasized that freight vehicles often exhibit complex multi-day activity patterns, not just simple round trips. Liu and Zhang (2023) focused on identifying urban freight stay behaviour based on truck GPS data, providing a model that can pinpoint where and for how long trucks pause, which is crucial for infrastructure planning.

2.3. Freight Activity Purpose Inference

Inferring the purpose of freight activities is perhaps the most challenging aspect, as GPS data alone provides location and movement, not intent. This typically requires integrating external data sources, such as land use, Points of Interest (POI), and business registration data.

For instance, a truck stopping at a logistics park or warehouse is likely involved in loading/unloading, while a stop at a retail area might indicate delivery to a store. Chen et al. (2022) analysed the spatiotemporal differences and influencing factors of heavy freight vehicle travel, implicitly touching upon the varied purposes behind these movements. The integration of land use data allows researchers to contextualise stops, inferring purposes based on the type of activity typically conducted at that location. For example, stops in industrial zones often relate to manufacturing or warehousing, while stops in commercial areas are usually for retail delivery.

Some studies have employed machine learning techniques to classify activity purposes based on a combination of GPS features (e.g., duration of stay, frequency of visits, average speed) and external data. However, the accuracy of such inference heavily relies on the quality and granularity of the supplementary data. The challenge lies in developing robust methodologies that can accurately distinguish between, for example, a delivery stop, a maintenance stop, or a driver rest stop.

2.4. Freight Activity Mode Classification

Building upon trip chaining and purpose inference, the next logical step is to classify recurring freight activity patterns into distinct "modes" or "typologies." This classification helps in understanding the heterogeneity of freight operations and developing targeted policies.
Common classification criteria include:

- **Journey Type:** Intra-city vs. inter-city, reflecting different operational scales and regulatory environments.
- **Vehicle Type:** Heavy-duty vs. light-duty trucks, each with different capacities, speeds, and road access restrictions.
- **Cargo Type:** While difficult to infer directly from GPS, this is a key differentiator in freight logistics.
- **Operational Pattern:** E.g., hub-and-spoke operations, direct deliveries, multi-stop routes, return trips, or maintenance trips.

Research often uses clustering algorithms (e.g., K-means, hierarchical clustering, or two-step clustering) to group similar trip chains or activity sequences. The effectiveness of these classifications depends on the features used for clustering, which can include trip distance, duration, number of stops, stop duration distribution, and inferred activity purposes. The aim is to identify distinct operational profiles that can be used for policy differentiation.

2.5. Inclusive Freight Policy Development

Traditional urban freight policies often adopt a blanket approach, applying the same restrictions or incentives to all freight vehicles regardless of their specific operational needs. This can lead to inefficiencies, increased costs for businesses, and unintended negative consequences. The reviewed literature strongly suggests a move towards more "inclusive" or "differentiated" freight policies that acknowledge the diversity of freight activities.

Such policies could include:

- **Time-window restrictions:** Differentiated by vehicle type or purpose.
- **Access restrictions:** Based on emission standards, vehicle size, or specific routes.
- **Loading/Unloading Zones:** Strategically located and managed to minimise disruption.
- **Pricing mechanisms:** Such as congestion charges or differentiated tolls.

The core idea is to tailor regulations to the specific characteristics of different freight activity modes. For instance, short-distance, intra-city deliveries might require different policy interventions than long-haul inter-city movements. This requires a granular understanding of freight behaviour, which is precisely what the preceding research areas aim to provide.

This study aims to bridge the gap between microscopic behavioural analysis and macroscopic policy formulation, offering data-driven insights for more effective and inclusive urban freight management in Shanghai.

3. Data and Methodology

This section details the data sources utilised and the methodologies employed for stop point identification, truck trip generation, and activity mode clustering.

3.1. Data Sources

The primary data source for this study is high-frequency GPS trajectory data from a large fleet of heavy freight trucks operating in Shanghai. This dataset provides a rich, granular record of truck movements over an extended period. Each GPS record typically includes:

- **Vehicle ID:** Unique identifier for each truck.
- **Timestamp:** Date and time of the GPS recording.
- **Latitude and Longitude:** Geographical coordinates of the truck's location.
- **Speed:** Instantaneous speed of the truck.
- **Direction:** Bearing of the truck's movement.

The data covers a significant number of heavy trucks, ensuring a representative sample of freight activity within and around Shanghai. The high frequency of data points (e.g., every few seconds or minutes) allows for precise identification of movement patterns and stationary periods.

In addition to GPS data, the study incorporates supplementary data for activity purpose inference:

- **Land Use Data:** Provides information on the predominant activities in different urban zones (e.g., industrial, commercial, residential). This helps contextualise truck stops.
- **Points of Interest (POI) Data:** Offers specific information about businesses, facilities, and infrastructure (e.g., logistics parks, warehouses, retail centres, wholesale markets). POI data is crucial for inferring the specific nature of activities at stop points.
- **Enterprise Registration Data (where available):** Can provide insights into the type of business operating at a specific location, further aiding in purpose inference.

3.2. Stop Point Identification

Accurate identification of stop points is fundamental for segmenting continuous GPS trajectories into discrete trips and activities. The methodology for stop point identification in this study combines spatial and temporal thresholds to distinguish genuine stops from brief pauses or slow movements due to traffic.

The process involves:

a) **Initial Filtering:** Raw GPS data is first cleaned to remove outliers or erroneous readings (e.g., sudden jumps in location or unrealistic speeds).

b) **Candidate Stop Point Detection:** For each truck, consecutive GPS points are examined. If a sequence of points exhibits a speed below a predefined threshold (e.g., 5 km/h) for a continuous duration exceeding a minimum time threshold (e.g., 5 minutes), these points are flagged as a potential stop.

c) **Spatial Clustering:** Candidate stop points are then clustered spatially. If multiple GPS points from the

same truck within a short time window fall within a small geographical radius (e.g., 50 meters), they are grouped into a single stop point. The centroid of these clustered points is designated as the stop location.

d) Stop Duration Calculation: The duration of a stop is calculated from the timestamp of the first point to the last point within the identified stop cluster.

e) Trip Segmentation: Once stop points are identified, the continuous trajectory is segmented into individual "trips" (movements between two stop points) and "stops." A typical trip chain would look like: Stop A – Trip 1 – Stop B – Trip 2 – Stop C, and so on.

The selection of appropriate speed, time, and spatial thresholds is critical and often determined through empirical analysis of the data and domain knowledge to best represent actual truck activities.

3.3. Truck Trip Generation

Following stop point identification, individual truck trips are generated. A "trip" is defined as the movement segment between two consecutive stop points. For each generated trip, key attributes are extracted:

- **Origin Stop ID and Destination Stop ID:** Linking trips to their respective start and end locations.
- **Trip Start Time and End Time:** Derived from the timestamps of the origin and destination stop points.
- **Trip Duration:** Calculated as the difference between end and start times.
- **Trip Distance:** Calculated by summing the distances between consecutive GPS points along the trajectory, or using map-matched distances.
- **Average Speed:** Total distance divided by total duration.
- **Number of GPS Points:** Indicating the data density for the trip.

3.4. Path Map Matching

To enhance the accuracy of trip distances and ensure that trajectories align with the actual road network, a path map-matching algorithm is applied. This process maps the raw GPS points onto the most probable roads on a digital map. Map matching helps:

- **Correct GPS Errors:** Reducing the impact of signal drift or inaccuracies.
- **Obtain Realistic Distances:** Calculating distances along the actual road network, which is more accurate than straight-line distances or distances derived from raw GPS points in complex urban environments.
- **Identify Road Segments Used:** Providing insights into routing patterns and network utilisation.

The map-matching process typically involves algorithms that consider the proximity of GPS points to road segments, the topological connectivity of the road network, and the sequence of GPS points.

3.5. Inference of Truck Activity Purpose

Inferring the purpose of a truck's activity at a stop point is a complex task. This study employs a rule-based approach, combining geographical context from land use data and specific facility information from POI data. The methodology involves:

a) Geocoding Stop Points: Each identified stop point is geocoded to obtain its precise location.

b) Overlay with Land Use Data: The stop point location is overlaid with urban land use maps. This provides a general categorisation of the area (e.g., industrial zone, commercial area, residential area, logistics park).

c) Proximity Analysis with POI Data: A buffer zone (e.g., 100-200 meters) is created around each stop point. All POIs within this buffer are identified.

d) Rule-Based Inference: A set of heuristic rules is applied to infer the activity purpose. Examples of rules include:

- o If a stop is in an industrial zone and near a warehouse or factory POI, the purpose is likely "Loading/ Unloading - Industrial."
- o If a stop is in a commercial area and near a retail store or supermarket POI, the purpose is likely "Delivery - Commercial."
- o If a stop is near a logistics park or distribution centre POI, it's likely "Transshipment/Distribution."
- o If a stop is prolonged and near a residential area, it might be "Driver Rest" or "Home Base."
- o Specific POI categories such as petrol stations, repair shops, or truck stops can indicate "Refuelling/ Maintenance" or "Rest."

o Stops with no clear POI or land use match, or very short durations, might be categorised as "Traffic Wait" or "Unidentified."

This rule-based approach, while requiring careful definition of rules and thresholds, provides a robust framework for associating observed stops with likely freight activities.

3.6. Truck Activity Mode Clustering

To identify typical truck activity patterns, a two-step clustering method is applied to the processed truck tour data. This method is particularly suitable for large datasets with mixed data types (numerical and categorical). The clustering process involves:

a) Feature Selection: Key features representing the characteristics of each truck's activity tour are selected for clustering. These features include:

- **Total Daily Travel Distance:** A measure of the scale of operation.
- **Total Daily Travel Duration:** Reflecting time spent on the road.
- **Number of Stops per Day:** Indicating the complexity of the tour.
- **Average Stop Duration:** Revealing the nature of activities at stops (quick deliveries vs. lengthy loading/unloading).
- **Proportion of Intra-city vs. Inter-city Trips:** Distinguishing between local and regional operations. This is determined by analysing if origin and destination points of trips fall within or outside Shanghai's administrative boundaries.
- **Number of Unique Hub Stops:** Defined as frequently visited locations (e.g., logistics parks, distribution centres) that serve as primary operational bases.
- **Distribution of Inferred Activity Purposes:** Proportions of different activity types (e.g., proportion of loading/unloading stops, delivery stops, rest stops).

b) Two-Step Clustering Algorithm:

- **Pre-clustering (Distance-Based):** In the first step, a distance-based clustering algorithm (e.g., agglomerative hierarchical clustering or a custom grid-based approach) is used to group similar observations into pre-clusters. This step is efficient for handling large datasets by reducing the number of individual instances.
- **Clustering (Model-Based/Hierarchical):** In the second step, a more sophisticated clustering algorithm (e.g., hierarchical clustering or K-means on the pre-clusters) is applied. This step aims to identify the optimal number of clusters and define the distinct activity modes. The optimal number of clusters is often determined using statistical criteria such as the Bayesian Information Criterion (BIC) or silhouette scores.

The output of the clustering process is a set of distinct truck activity modes, each characterised by a unique profile based on the selected features. These modes represent different operational strategies and roles of freight trucks in the urban logistics system. The results of this clustering will form the basis for differentiated policy recommendations.

4. Results and Discussion

This section presents the findings from the data analysis, including the characterisation of truck travel, the identified activity purposes, and the derived truck activity modes.

4.1. Characterisation of Truck Travel in Shanghai

The analysis of high-frequency GPS data from heavy freight trucks in Shanghai reveals several key characteristics of their travel patterns:

- **Trip Length Distribution:** The majority of truck trips within Shanghai are relatively short, reflecting the high density of urban activities and the prevalence of last-mile and intra-city distribution. A significant proportion of trips fall within the 10-50 km range, indicating intensive urban logistics operations. However, a noticeable tail exists for longer trips (over 100 km), representing inter-city or regional freight movements that connect Shanghai with its surrounding provinces (As shown in **Figure 4.1.1.**).

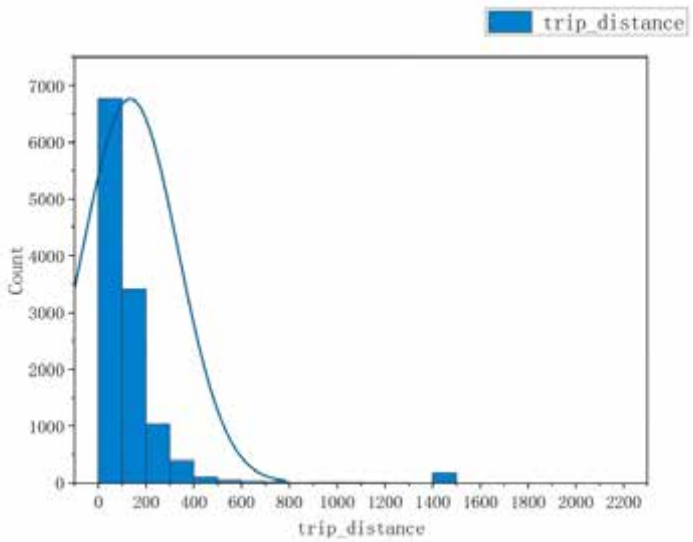

Figure 4.1.1. Distribution Map of Travel Distances (Image source: Self-drawn)

- **Trip Duration:** While trip lengths might be moderate, trip durations are often extended due to urban congestion, traffic restrictions, and the time spent at stop points for loading/unloading. The average speed of trucks within the city proper is generally low, especially during peak hours (As shown in **Figure 4.1.2.**).

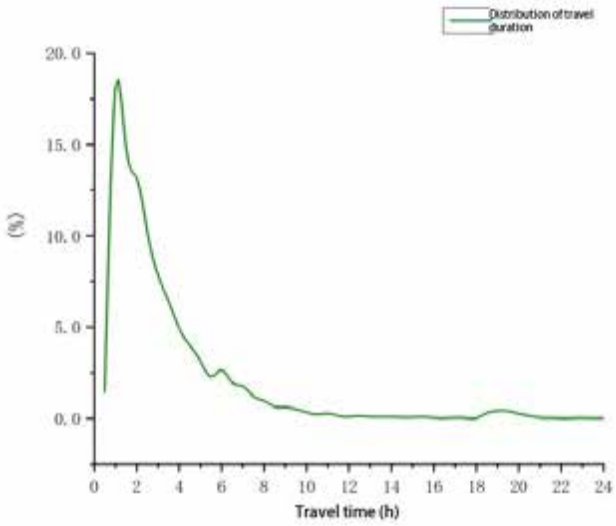

Figure 4.1.2. Travel duration distribution map (Image source: Self-drawn)

- **Stop Frequency and Duration:** Trucks exhibit a high frequency of stops, particularly those engaged in urban distribution. The duration of these stops varies significantly. Short stops (e.g., 15-30 minutes) are typical for quick deliveries or drop-offs, while longer stops (e.g., 1-3 hours or more) are associated with major loading/unloading operations at warehouses, logistics parks, or industrial facilities.
- **Spatial Distribution of Activities:** Truck activities are heavily concentrated in specific areas:

    - **Logistics Hubs:** Areas with a high density of warehouses, distribution centres, and freight yards show intense activity, serving as major origins and destinations.
    - **Industrial Zones:** These areas are key for raw material input and finished goods output.
    - **Commercial Districts and Wholesale Markets:** Represent significant destinations for deliveries, often involving multiple stops.
    - **Port Areas:** For Shanghai, port-related drayage is a distinct and high-volume activity, involving movements between ports and inland logistics facilities.

- **Time-of-Day Patterns:** Heavy truck movements often exhibit distinct diurnal patterns influenced by urban traffic regulations. A significant portion of inter-city movements occurs during off-peak hours or at night to avoid daytime traffic restrictions. Intra-city deliveries, while also affected by restrictions, might have more dispersed patterns depending on the type of goods and recipient requirements. There is usually a surge in activity during early mornings and late evenings (As shown in **Figure 4.1.3.**).

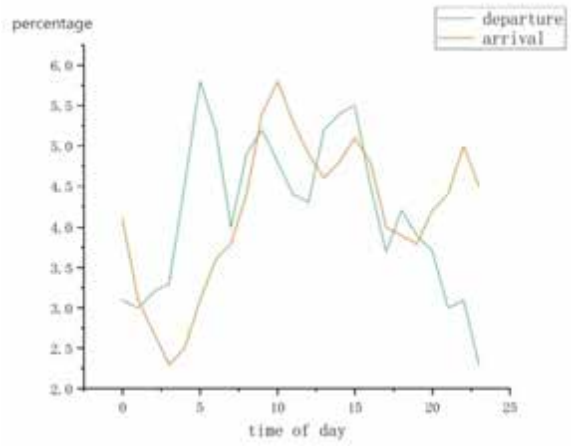

Figure 4.1.3. Travel time distribution map (Image source: Self-drawn)

These characteristics highlight the dynamic and constrained operational environment for freight trucks in a high-density urban context like Shanghai.

4.2. Inferred Truck Activity Purposes

Based on the integration of GPS data with land use and POI information, the primary purposes of truck activities at identified stop points were inferred and broadly categorised. The findings indicate a diverse range of activities beyond simple pick-up and delivery:

- **Loading/Unloading at Industrial/Warehousing Facilities (approx. 40%):** This category represents the most frequent activity, occurring at factories, large warehouses, and logistics parks. These stops are typically longer, indicating significant cargo handling.
- **Delivery to Commercial/Retail Outlets (approx. 25%):** These stops are often shorter and more numerous, characteristic of last-mile delivery to shops, restaurants, or smaller businesses within commercial zones.
- **Transshipment/Cross-docking (approx. 15%):** Occurring primarily at distribution centres or logistics hubs, these stops involve the transfer of goods between different trucks or modes of transport. This highlights the multi-stage nature of many freight operations.
- **Driver Rest/Personal Activity (approx. 10%):** These stops, often at designated rest areas, service stations, or even residential areas, reflect non-freight specific activities essential for driver well-being and regulatory compliance.
- **Vehicle Maintenance/Refuelling (approx. 5%):** Stops at petrol stations, repair shops, or maintenance depots.
- **Waiting/Congestion-related Stops (approx. 5%):** These stops are often involuntary, due to traffic queues, entry/exit delays at facilities, or waiting for appointments. While not a "purpose" in the productive sense, they represent significant operational time.
- **Other/Unidentified:** A small percentage of stops where a clear purpose could not be definitively inferred from the available data.

The distribution of these inferred purposes underscores the complexity of urban freight, involving not only the movement of goods but also associated logistical, regulatory, and human-factor considerations.

4.3. Classification of Truck Activity Modes

The two-step clustering algorithm, applied to the selected features of truck activity tours, successfully identified distinct activity modes. The analysis revealed two main categories of truck activities, further subdivided into a total of five sub-categories (The proportion of each subcategory is shown in **Figure 4.3.1.**), each with unique characteristics, as shown in **Tables 4.3.1. -4.3.3.**:

	5	2986	265	4	2036	1219
	Total	9684	2282	48	7188	4826

Main Category 1: Localised Urban Freight Operations This category predominantly involves trucks operating within the metropolitan area, characterised by shorter travel distances, higher stop frequencies, and intense interaction with the urban fabric.

- **Sub-category 1.1: Multi-Stop Urban Distribution (e.g., "City Courier")**
  - **Characteristics:** Short daily travel distances (e.g., 50-150 km), high number of stops (e.g., 10-20+ per day), short average stop duration (e.g., 15-45 minutes), almost exclusively intra-city trips. Few, if any, hub stops, typically starting from a single depot. The specific example is shown in **Figure 4.3.2.**.
  - **Inferred Purpose Dominance:** Delivery to Commercial/Retail Outlets, Collection from businesses.
  - **Operational Profile:** These trucks are typically engaged in last-mile delivery of varied goods (e.g., parcels, perishables, retail supplies) to multiple addresses within a specific urban zone. Their efficiency is highly dependent on route optimisation and quick turnaround times at delivery points.

Figure 4.3.2. Pattern 1.1 Representative trip Trajectory Analysis Diagram (Image source: Self-drawn)

- **Sub-category 1.2: Dedicated Industrial/Commercial Haulage (e.g., "Industrial Shuttle")**
  - **Characteristics:** Moderate daily travel distances (e.g., 100-300 km), moderate number of stops (e.g., 2-8 per day), longer average stop duration (e.g., 1-3 hours), primarily intra-city but potentially short inter-district trips. Often involves repeated trips between a limited set of industrial or large commercial hubs. The specific example is shown in **Figure 4.3.3.**.

o **Inferred Purpose Dominance:** Loading/Unloading at Industrial/Warehousing Facilities, Transshipment.
o **Operational Profile:** These trucks specialise in transporting goods between specific industrial sites, large warehouses, or major commercial distribution centres. Examples include moving raw materials to factories, finished goods from factories to distribution centres, or large-volume deliveries to hypermarkets. Their routes are often fixed or semi-fixed.

Figure 4.3.3. Pattern 1.2 Representative trip Trajectory Analysis Diagram
(Image source: Self-drawn)

- **Sub-category 1.3: Differentiated Intra-city Logistics (e.g., "Service Provider")**
  o **Characteristics:** Highly variable daily travel distances (e.g., 30-200 km), low to moderate number of stops (e.g., 1-5 per day), stop durations can vary significantly (e.g., 30 minutes to several hours), entirely intra-city. May include stops for specific services or irregular deliveries. The specific example is shown in **Figure 4.3.4.**.
  o **Inferred Purpose Dominance:** Could be a mix of specialised deliveries, waste collection, construction material transport, or service-related stops (e.g., maintenance, utilities).
  o **Operational Profile:** This heterogeneous group includes trucks performing specialised tasks not directly tied to general merchandise distribution. Examples include construction material delivery, waste management, or technicians' vehicles carrying heavy equipment. Their routes are less predictable and more demand-driven.

Figure 4.3.4. Pattern 1.3 Representative trip Trajectory Analysis Diagram
(Image source: Self-drawn)

Main Category 2: Regional/Inter-city Freight Operations This category comprises trucks primarily engaged in long-distance movements connecting Shanghai with other cities or regions, often involving fewer stops within the city itself, but longer hauls.

- **Sub-category 2.1: Long-Haul Inter-city (e.g., "Regional Connector")**
  - **Characteristics:** Long daily travel distances (e.g., 300-800+ km), very few stops (e.g., 1-2 per day), typically long stop durations at origin/destination hubs (e.g., 3-8 hours), high proportion of inter-city travel. Origin and destination are often outside Shanghai, with a single stop within Shanghai for loading/unloading at a major logistics hub. The specific example is shown in **Figure 4.3.5.**.
  - **Inferred Purpose Dominance:** Loading/Unloading at Logistics Hubs, Transshipment.
  - **Operational Profile:** These trucks are the backbone of regional and national supply chains, transporting goods between major cities. Their time is primarily spent on the road, with concentrated activities at large-scale distribution centres or intermodal terminals. They are heavily impacted by highway regulations and cross-provincial logistics networks.

Figure 4.3.5. Pattern 2.1 Representative trip Trajectory Analysis Diagram
(Image source: Self-drawn)

- **Sub-category 2.2: Hub-and-Spoke Regional (e.g., "Regional Distributor")**
  - **Characteristics:** Moderate to long daily travel distances (e.g., 200-500 km), moderate number of stops (e.g., 2-5 per day), variable stop durations, a mix of inter-city (to/from a central hub) and intra-city (distribution from the hub) trips. Characterised by a primary hub stop within Shanghai and subsequent distribution to peripheral urban or suburban areas. The specific example is shown in **Figure 4.3.6.**.
  - **Inferred Purpose Dominance:** Transshipment/Distribution from Hub, followed by Delivery to Commercial/Retail Outlets or Industrial Facilities.
  - **Operational Profile:** These trucks operate within a hub-and-spoke model, where a major logistics centre in Shanghai serves as a consolidation or break-bulk point. Goods arrive from other cities, are processed at the hub, and then distributed to destinations within Shanghai or its immediate hinterland, or vice versa.

Figure 4.3.6. Pattern 2.2 Representative trip Trajectory Analysis Diagram
(Image source: Self-drawn)

Key Differences and Insights:
The classification highlights significant differences across the identified modes:

- **Travel Distance:** Ranges from short (Sub-category 1.1) to very long (Sub-category 2.1), indicating different operational scales.
- **Number of Stops:** Differentiates between point-to-point transfers and multi-point distribution.
- **Hub Dependence:** Some modes (Sub-category 2.2) are highly dependent on major logistics hubs, while others (Sub-category 1.1) operate more autonomously from a single base.
- **Intra-city vs. Inter-city Focus:** This is a fundamental discriminator, with distinct policy implications for local versus regional traffic management.

These distinct profiles underscore the limitations of "one-size-fits-all" urban freight policies. Recognising these activity modes provides a robust foundation for developing targeted and effective policy interventions.

5. Management Recommendations and Policy Implications
The detailed understanding of truck activity modes derived from this study offers a unique opportunity to refine urban freight management policies in Shanghai, moving towards a more nuanced and inclusive approach. Current policies often impose uniform restrictions that disproportionately affect certain freight operations while failing to adequately address the specific challenges posed by others. Based on the identified two main categories and five sub-categories of truck activities, the following targeted management suggestions are proposed:

5.1. Tailored Regulations for Localised Urban Freight Operations
The "Localised Urban Freight Operations" category (Sub-categories 1.1, 1.2, 1.3) represents the majority of heavy truck movements within the immediate urban area, directly impacting daily urban life.

- **For Multi-Stop Urban Distribution (Sub-category 1.1 – "City Courier"):**
  - **Challenge:** High stop frequency, short distances, often operating in congested commercial/residential areas. Existing blanket time-window restrictions can severely limit their operational efficiency.
  - **Recommendation:** Implement more flexible and granular time-window restrictions. Instead of broad bans, consider designated delivery windows for specific zones (e.g., pedestrian streets) or allow access during certain off-peak hours for smaller, cleaner trucks. Promote the use of dedicated urban loading/unloading zones that are clearly marked and enforced, potentially equipped with smart sensors to manage usage. Explore micro-consolidation centres at the edge of high-density areas to reduce the number of large trucks making individual stops.
  - **Policy Focus:** Optimising last-mile delivery efficiency and minimising urban disruption.

- **For Dedicated Industrial/Commercial Haulage (Sub-category 1.2 – "Industrial Shuttle"):**
  - **Challenge:** Regular, heavy-volume movements between fixed points, often requiring access to industrial parks and large commercial complexes. These routes might intersect with general traffic, contributing to congestion.
  - **Recommendation:** Develop dedicated freight corridors or preferential routes for these regular high-volume movements, especially connecting industrial zones with major logistics hubs or arterial roads. Implement intelligent traffic signal priority systems for heavy trucks on these designated routes where feasible. Consider differentiated access permits based on destination and frequency, rather than blanket restrictions.
  - **Policy Focus:** Ensuring efficient supply chain connectivity for industries and large businesses, and mitigating their impact on general traffic flow.
- **For Differentiated Intra-city Logistics (Sub-category 1.3 – "Service Provider"):**
  - **Challenge:** Diverse operations, often unpredictable routes, and varied cargo types (e.g., construction waste, specialised equipment). Their impact on traffic can be sporadic but significant.
  - **Recommendation:** Categorise and regulate based on cargo type and vehicle purpose where appropriate. For instance, specific routes or disposal sites for construction waste trucks. For service vehicles, consider issuing special permits for access during restricted hours if their work is critical and time-sensitive (e.g., utility repairs). Promote technology adoption (e.g., dynamic routing, real-time communication) to optimise their movements.
  - **Policy Focus:** Facilitating essential urban services while managing their varied impacts.

5.2. Strategic Management for Regional/Inter-city Freight Operations

The "Regional/Inter-city Freight Operations" category (Sub-categories 2.1, 2.2) plays a crucial role in connecting Shanghai to the broader national and international supply chains, but their long hauls and large sizes pose different challenges, particularly at urban entry points.

- **For Long-Haul Inter-city (Sub-category 2.1 – "Regional Connector"):**
  - **Challenge:** Primarily concerned with efficient movement between major urban centres, often operating on highways, but needing smooth access to and from large logistics hubs within Shanghai. Time-window restrictions at urban entry points can lead to bottlenecks.
  - **Recommendation:** Implement "big data informed, flexible traffic restrictions." Instead of fixed time-window bans, use real-time traffic data, weather conditions, and predicted demand to dynamically adjust access times to major logistics parks or expressways leading out of the city. Promote the use of off-peak hours and night-time for these movements. Invest in intelligent truck parking facilities at the urban periphery to manage waiting times before entry.
  - **Policy Focus:** Enhancing regional connectivity and reducing congestion at urban gateways.
- **For Hub-and-Spoke Regional (Sub-category 2.2 – "Regional Distributor"):**
  - **Challenge:** A combination of long-haul movements to a central hub and subsequent intra-city distribution. This requires efficient transshipment and effective last-mile delivery from the hub.
  - **Recommendation:** Prioritise investment in and optimisation of urban logistics hubs (e.g., multi-storey warehouses, automated sorting facilities) that serve as critical interfaces for these operations. Policies should encourage the use of smaller, cleaner vehicles for the intra-city distribution leg from these hubs. Facilitate intermodal transfers at these hubs where possible (e.g., rail or water links). Provide clear, efficient routes from highways to these hubs.
  - **Policy Focus:** Streamlining the interface between long-haul freight and urban distribution, promoting sustainable last-mile solutions.

5.3. Cross-Cutting Policy Considerations

Beyond mode-specific recommendations, several overarching policy directions emerge:

- **Leveraging Big Data and AI:** The success of these differentiated policies relies heavily on continuous data collection and analysis. Shanghai should invest further in smart city infrastructure to gather real-time freight data, use AI for predictive analytics (e.g., congestion hotspots, optimal delivery times), and support dynamic policy adjustments.
- **Green Freight Initiatives:** Differentiated policies can also be used to incentivise greener freight vehicles. For example, preferential access or reduced charges for electric or low-emission trucks, particularly for urban distribution (Sub-category 1.1).

- **Collaboration with Industry:** Effective policy implementation requires strong collaboration with logistics companies, industry associations, and drivers. Pilot projects and feedback mechanisms can help refine policies to ensure they are practical and beneficial for all stakeholders.
- **Infrastructure Investment:** Targeted investment in critical freight infrastructure, such as multi-functional urban logistics hubs, dedicated truck parking, and improved last-mile delivery infrastructure, is essential to support the proposed policy changes.
- **Driver Welfare:** Any policy reforms should also consider the impact on truck drivers, including access to rest facilities, clear communication of regulations, and support for their working conditions.

By moving away from simplistic, uniform rules, Shanghai can develop an urban freight management system that is more responsive to the diverse needs of freight operators, more efficient in its use of urban space, and ultimately, more conducive to a sustainable and prosperous urban environment. This study provides the empirical foundation for such a transformative shift.

6. Conclusion

This study embarked on a comprehensive investigation into urban freight mobility in Shanghai, leveraging extensive high-frequency GPS trajectory data from heavy trucks. The research successfully moved beyond aggregate observations to infer the underlying activity patterns and purposes of individual truck movements, providing a micro-perspective crucial for effective urban freight management.

Through rigorous data processing, including precise stop point identification and path map matching, the fundamental characteristics of truck travel in a high-density urban environment were thoroughly detailed. The integration of land use and Points of Interest data allowed for a robust inference of activity purposes at various stop locations, revealing the complex interplay of industrial, commercial, and logistical functions.

The application of a two-step clustering method was pivotal in identifying distinct truck activity modes. The study successfully classified freight truck operations into two main categories: "Localized Urban Freight Operations" and "Regional/Inter-city Freight Operations," which were further subdivided into five specific sub-categories. These categories exhibit significant differences in key operational attributes, such as daily travel distance, the number and nature of stops, and the predominant travel scope (intra-city versus inter-city). This differentiation underscores the inherent heterogeneity of urban freight and highlights the inadequacy of traditional "one-size-fits-all" policy approaches.

Based on these findings, the study proposes a suite of targeted management recommendations. These suggestions advocate for a paradigm shift towards more inclusive and differentiated urban freight policies. For instance, specific requirements are suggested for short-distance, multi-stop urban distribution trucks, acknowledging their unique challenges in congested areas. Simultaneously, the study proposes the implementation of flexible traffic restrictions for long-haul and regional trucks, dynamically informed by real-time big data, rather than rigid, static time windows.

The insights generated by this research pave the way for the development of innovative, localised urban freight systems in Shanghai and potentially other high-density cities. By understanding and addressing the specific needs and operational patterns of different freight activity modes, urban planners and policymakers can foster a freight ecosystem that is not only more efficient and cost-effective for businesses but also more harmonious with urban life, contributing to reduced congestion, lower emissions, and improved quality of life for residents. Future research could explore the integration of real-time traffic conditions into activity mode prediction and the socio-economic impacts of implementing these differentiated policies.

Abstract
The recent rise of generative artificial intelligence (GenAI) tools promises to disrupt how cities are planned and designed. Some of these tools aim to empower diverse stakeholders to "reinvent their streets" by visualising how adopting a cycling lifestyle or adding outdoor seating could transform an urban environment. Implemented as part of educational exercises, text-to-image generative AI offers opportunities to help future planners envision different urban scenarios in a studio learning environment. However, biases, injustice and glitches remain a pressing concern, underscoring the need for future planners to critically engage with these technologies. In this paper, we draw on our experience designing and teaching a course focused on fostering critical skills for engaging with GenAI in urban design studio learning. Using a novel framework, we discuss how these tools can be integrated into planning education.

Keywords: Generative AI; Street experiments; Urban design pedagogy; Critical framework; Studio-based learning; AI bias

1 Introduction

Future generations of urban planners and designers will confront intertwined challenges of climate change, social justice and rapid digital transformation. To navigate such complexity and uncertainty, students must master transformative tools and skills (Bertolini, 2020; McCune et al., 2023). A core competence is the ability to catalyse societal transitions. Tassone et al. (2018) highlight three essential abilities for future planners: a) engagement with real-world problems; b) responsiveness in formulating actions; and c) critical thinking that questions preconceived assumptions. Further, pedagogical approaches grounded in regenerative education—learning that remains within the planet's socio-ecological boundaries—can strengthen students' sense of agency (Mang, n.d.). Planning curricula are therefore beginning to embed futuring exercises: active, critical and reflective explorations of alternative futures (Bertolini et al., 2024; Hoffman et al., 2021). These activities respond to the urgency of environmental crises while challenging expert-determined modes of thought. Urban design, urban experimentation and tactical-urbanism modules offer a practical entry point, with several programmes now introducing courses on street re-allocation and street experiments, defined as temporary interventions that subvert car-oriented streetscapes, re-allocate space to prioritise active mobility and public life, to help communities to envisage radically different mobility systems (Bertolini, 2020).

A growing body of educational material is being developed on street experiments. Open-access MOOCs such as Street Experiments for Sustainable and Resilient Cities (Technical University of Munich / EIT Urban Mobility, Coursera) and Reclaiming the Street for Liveable Urban Spaces (University of Amsterdam, Coursera) guide learners through planning, implementing and evaluating street experiments, while Planetizen's Learning Tactical Urbanism video series provides practitioner-led tutorials. At the university level, semester-long studios—for example, California College of the Arts' Active Urbanism: Tactical Interventions and the University of New Mexico's Urban Design Methods elective—immerse students in tactical-urbanism projects. Together, these courses illustrate the range of teaching formats that can be adapted when embedding futuring exercises in planning curricula. However, teaching such interventions demands that students collect, and compile detailed local spatial data, design alternative streetscapes and create visualisations—even though the intent of these projects is limited in duration and spatial extent.

Digital transformation in urban planning and design education is prompting debates on technology's role in education (Mishra et al., 2025). Generative artificial intelligence (GenAI) tools, as text-to-image generators are poised to reshape urban design studio teaching and learning. New platforms enable stakeholders—including students—to "reinvent their streets" and imagine allegedly 'healthier environments' (NL, 2025). They can illustrate, for example, how a cycling lifestyle or outdoor seating might transform a specific street. While GenAI opens fertile ground for experimentation, questions of how students and educators will consider mobility justice and equity

and biases remain pressing and demand critical engagement. To date, we know little about the pedagogical opportunities and challenges of GenAI in urban design studio learning and how to improve AI literacy in teaching and learning and critically engage students and educators with the visual material produced in urban planning and design studios.

This paper addresses that gap by evaluating a pilot studio format introduced at the University College Dublin that integrated text-to-image Generative AI into a placemaking and urban design module centred on street experiments. In what follows we retrace media studies scholarship on critical content analysis of AI-generated images and present an analytical framework for interrogating AI-generated streetscapes and their cultural, social and political assumptions. After, we outline the urban design studio structure, tools adopted and implementation and report preliminary learning outcomes and student reflections. We conclude by identifying opportunities and challenges for future studio practice, proposing directions for further research, including longitudinal studies of GenAI-enhanced planning education and the development of open-source teaching resources.

2 Artificial intelligence in urban planning and design education

Recent research focuses on the emergence of generative AI in education and its impact on creativity and learning. A transformative application of generative AI in planning education offers opportunities for empowerment and creativity within the learning environment. An AI-enabled approach to higher education can enhance students' agency: it "embraces the idea that learners should pursue paths that align with their individual interests and potential, leading to diverse rather than uniform outcomes" (Mishra et al., 2025: 252). Previous studies indicate that generative AI can serve as a tool to support this agency—whether through storytelling, visualising abstract concepts or historical settings (Choi and Chang, 2025).

Yet, within planning we still know little about AI's potential to help envision alternative futures; meanwhile, mobility injustice remains a pressing concern, underscoring the need for planners to engage critically with these technologies. Planning education continues to struggle to integrate transformative skills into curricula. We aim to address this challenge by introducing and evaluating an educational approach that draws on one interdisciplinary module developed at University College Dublin.

2.1 Characteristics of Text-to-Image Generators for Studio-based Learning

Recently, Generative Artificial Intelligence (GenAI) has introduced new methodologies that can facilitate visualisation alternatives to urban design scenarios. This is particularly in relation to the domain of street experiments and mobility transformations. One of the advancements of this tool is the text-to-image generators. These generators can allow urban planners and designers to quickly conceptualise design alternatives for streetscapes. This is usually done by converting language descriptions into vivid visualisations (Virtual City Systems, 2024; Valença et al., 2025; Cabrera-Nyst, 2024). GenAI tools generally streamline urban design's conceptual and creative process. In addition, they ease the participatory planning process by making complex design ideas accessible to a broader range of stakeholders (Virtual City Systems, 2024; Valença et al., 2025).

2.2 Existing theories of text-to-image AI critical use

Established scholarship in media studies reflects on how images and other visual material are a "collective representation" (Barthes 1977), such that they reproduce social, cultural, ideological and historical meanings. Typically, meanings are encoded into images by their creators (e.g. photographer, designer) and decoded by the viewers. While in the past humans were the creators of images and were encoding meanings into them, now novel AI tools produce images that are a representation of data, and infographics for their underlying dataset (Salvaggio, 2023). Diffusion-based models are trained on collections of image-text pairing datasets, which are in turn assembled by humans (Salvaggio, 2023). The training images-and-text pairing datasets are created within specific social, economic and political contexts, thus exemplifying unstated assumptions, inscribed into datasets. Machine learning models by identifying patterns, reveal underlying assumptions of the human-gathered datasets. 'Just as archives are the stories of those who curate them' AI generates images are representations of information in the training datasets (Salvaggio, 2023). Details that are absent or poorly indexed in the dataset are omitted, indicating that ai-generated images can be analysed. Recent research in media studies suggests that as datasets are encoded into AI-generated images, we can understand and analyse layers of socio-cultural encoding within the data used to produce them (idem).

3 Critical framework for the analysis of GenAi street experiments in studio learning

Our overarching aim was to set up studio-learning sessions based on a framework that would allow students and educators to critically analyse how well AI-generated images reflect the realities and aspirations of street experiments or open streets, uncover biases in the underlying datasets, and use the images as discussion points for urban planning learning. The framework aims to critically analyse AI-generated images that depict various street experiments, such as car-free streets, pedestrian zones, or public open spaces. Using prompts and AI tools (e.g., Bing Image generator), in a studio learning environment, students will generate images and examine them through a detailed framework, identifying both strong and weak design elements, biases, and urban planning relevance. Based on the media studies scholarships on encoding/decoding meaning in images (Salvaggio, 2023) and urban design pedagogy, we developed a five-phase framework that guided the students throughout their systematic street experiments' AI-generated images critique (Table 1, Figure 1). The development of the framework was also guided by the following questions:

- How much does AI know about street experiments?
- What are the biases and glitches in ai-generated street experiment images?
- Are there clear references to one city/context?
- What about the use of colours/materials/transport means/people?
- Are there aspects in the Ai-image that openly undermine the aim of street experiments?
- How does the AI-generated street vary from the street experiments you analysed as groups?

This method allows students to critically analyse how well AI-generated images reflect the realities and aspirations of street experiments or open streets, uncover biases in the underlying datasets, and use the images as discussion points for urban planning.

Table 1 Critical Analysis Framework for AI-Generated Images of Street Experiments

Phase	Aim	Guiding Question	Analytical Focus
1. **Create a Sample Set**	Identify patterns	What do we see?	First-pass visual scan of dominant elements, activities and omissions.
2. **Content Analysis**	Identify strengths & weaknesses	What works and what glitches?	Systematic listing of well-rendered versus distorted or missing features. **Strengths:** Identify which elements are consistently well-rendered and accurate, e.g. clean streets, open spaces, or vibrant community activity. These might reflect frequent representations in the underlying datasets. **Weaknesses:** Look for distortions, missing features, or underdeveloped aspects, such as widespread car presence, poorly defined interactions between pedestrians and cyclists, unrealistic street furniture, or inaccessible design for differently abled people. This can indicate biases in the dataset, such as overrepresentation of certain types of cities or demographics.
3. **Link patterns to Dataset**	Interrogate values embedded in the data	- Whose streets, whose narratives? - What types of urban environments are overrepresented or underrepresented (e.g., car-centric cities vs. pedestrian-friendly ones)? - What cultural, social, or political biases might have influenced the data?	Tracing cultural, social and political assumptions that surface from the underlying training data. Considering if these datasets reflect specific societal priorities like sustainability, safety, or inclusivity in urban planning.
4. **Connotative Analysis**	Examine social implications	Who benefits, and who is marginalised?	Reflection on potential equity impacts when applying each AI output to real contexts. Reassessment the original image and develop hypotheses about what might be missing or emphasized due to biases.
5. **Start Over**	Test hypotheses & model boundaries	Can we prompt alternative, fairer futures?	Iterative re-prompting to probe the latent space and validate (or reject) initial assumptions. Experimentation with prompts that push the AI to generate alternative or diverse visions of street experiments, Evaluation of how well the AI adapts to more niche or socially conscious prompts.

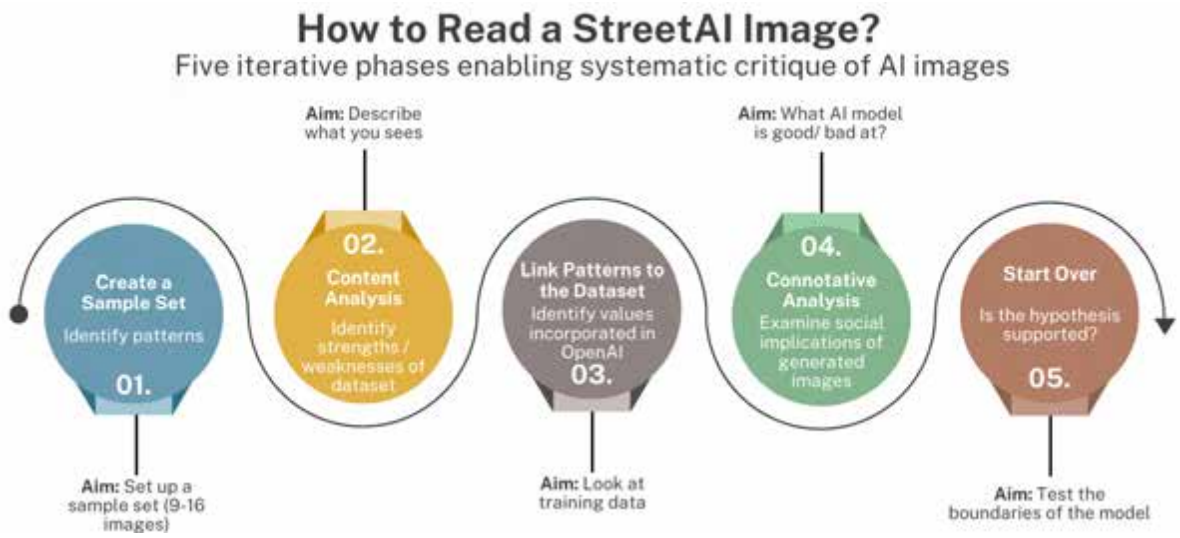

Figure 1 Five Phases for Systematic Critique of AI Images

4 Methods and Case Study

For this paper, we used the Placemaking Urban and Rural Design module (Plan4005W) run at the Chang'an–Dublin International College of Transportation (CDIC), University College Dublin as a case study. It focuses on the fundamentals of urban design, tactical urbanism and analysis of street experiments across cities around the world. Within this module, the students were introduced to the concept of generative AI and its integration into urban design. Students practice using this new tool in a studio-based exercise as part of one assessment of the module. Within this exercise, the students were asked to examine and critique the images produced by AI text-to-image generators.

Three experimental lab sessions aimed to explore with students: (1) the use of AI-image generation services to create images of street experiments, (2) to build on and develop terminology on and about street experiments and use it as AI-image generation prompts, and (3) to critically examine the images created by AI, based on bias/glitch/strength/weakness.

For each phase, a corresponding tutorial and hands-on studio task were delivered during Autumn 2024. In the assignment, the students (n = 116) were required to analyse selected case studies of pedestrian streets, street experiments, play streets or open streets. Students worked in groups of 4–5 and generated 9–16 images per prompt using the platforms listed below (section 5.1). The students also documented their reflections in an individual report.

This exercise aims to enhance the student's ability to critically evaluate how AI-generated visuals can support or misrepresent urban design principles discussed during the theoretical lectures of the module. Consequently, by the end of this exercise, the students should be able to a) understand how AI-generated images can visualize urban street experiments, b) develop critical thinking skills to analyse visual representations in urban design, c) identify biases in AI-generated content and reflect on their implications for urban planning, and d) synthesize their findings into an actionable urban design reflection.

By engaging with readings and texts assigned during theoretical lectures, students demonstrated their knowledge of relevant urban design literature in their assignments. In the assignment students critically analysed AI-generated images based on prompts that they developed that depict various street experiments, such as car-free streets, pedestrian zones, or public open spaces. Using prompts and AI tools (e.g., Bing Image generator), they generate images and examine them through the critical framework (section 3), identifying both strong and weak design elements, biases, and urban planning relevance of the AI-generated images.

Four generative AI platforms (Playground AI, Lumenor, GETIMG, and Bing Image Creator) were introduced to provide students with a broad overview of available technologies. However, students were instructed to select and work with only three tools for their assignments. This decision was based on several pedagogical and practical considerations:

1- The assignment sought to allow the students to deeply engage with the AI tools and the generated images. Thus, engaging with three platforms was more practical in allowing the students to perform an in-depth critical analysis of each tool's outputs.
2- Time and workload constraints were also contributing factors. The studio module took place within a limited number of sessions. Therefore, there was a risk of overwhelming the timeframe allocated for hands-on experimentation, prompting refinement and reflective writing, if we had asked the students to engage meaningfully with all four tools.
3- Some platforms had occasional access issues for students based on their geographic location or region. This could have introduced inconsistencies across students' submissions and hindered steady progress and completion of the assignments.
4- Lastly, giving the students the freedom to choose their preferred AI platforms encouraged comparative learning.

Data sources included teachers' feedback (based on the assessment rubric) and diary entries from in-class observations, students' individual reflective reports, and formal course evaluations. Images generated through text-to-image generative AI are referenced following the UCD Library Artificial Intelligence Library Guide (University College Dublin Library, 2025)

5 Findings

In this study, a selection of text-to-image generation tools has been tested in an urban design studio-based class to assist the students in the conceptualisation and communication of innovative streetscape design ideas. The incorporation of these AI-driven tools into pedagogical practices has been proven to be valuable for rapid design ideas generation and conceptualisation. However, adopting GenAI also has some drawbacks and challenges. For instance, during the studio classes, it was quite challenging for students to generate images with relevance and realism. Besides, Seneviratne et al. (2022) claim that addressing potential biases in data training and managing the technical learning curve is critical, particularly for new users of these tools.
This section outlines the different characteristics, strengths and limitations of each GenAI tool that has been utilised in the urban design studio-based classes. The aim is to emphasise the applicability of these tools in urban design pedagogical practices.

5.1 Overview of Generative Tools

We utilised four image-generation software: Playground AI, Lumenor, GETIMG, and Bing Image Creator (powered by DALL·E 3). They were selected based on their accessibility, diversity in model architectures, ease of use, and relevance to participatory and educational applications in urban design and planning. Most of these tools interpret natural language prompts to generate images, however, their performance and applicability differ (Table 2).
Recent studies indicate that the potential of utilising GenAI in generating urban design ideas is growing. GenAI tools enable users to generate novel forms of spatial expressions using language-based prompts (Paananen et al., 2024; Seneviratne et al., 2022). Nevertheless, these tools usually reflect a degree of inherited biases in data training and architecture models. This limits the applicability of tools in diverse or non-western contexts (Wang et al., 2025).

5.1.1 Tools Descriptions

- **GETIMG**

This AI-powered image generation tool is a comprehensive tool that can be used by designers and creators. It can allow users to select the AI model they prefer (e.g., GPT Image and FLUX.1). This tool has greater flexibility in its use; it can facilitate the following:

- Text-to-image generation by using text prompts.
- Image-to-image transformation through existing image modifications.
- AI Canvas (outpainting) through the expansion of images beyond their original borders.
- DreamBooth custom AI Models that enable users to train their own model (good for experimentation and idea modifications). (Getmig.ai, n.d.)

• Playground AI
This AI platform features a highly flexible web-based interface that supports multiple AI models, including Stable Diffusion and DALL-E (Liu et al., 2024). It has the flexibility of using language-based prompts and reference image upload. Also, it allows users to train their own models. It offers stylistic control and model switching, which makes it ideal for experimentation and learning environments (Liu et al., 2024). Nonetheless, the outputs of this platform are mostly aesthetic rather than analytical. In addition, they lack the spatial logic needed for rigorous urban planning applications (Paananen et al., 2024). Despite these drawbacks, this tool is still considered useful for composition and exploring visual ideas.

• Lumenor AI
This platform is an advanced AI-powered image generation platform. It is mainly designed to aid in digital art creation. It uses advanced AI algorithms that facilitate image generation based on various inputs such as text descriptions and image references (Access Newswire, 2023; Newswire, 2023). This tool is similar to Playground AI in its ease of use and flexibility. Thus, making it applicable for learning purposes. Yet, it also has cultural and contextual biases.

• Bing Image Creator
This platform is powered by DALLE.E 3. It offers a user-friendly interface that uses text-based prompts to render or generate images. Bing Image Creator has the potential to recognise and understand urban elements such as streets, sidewalks, signage, bike lanes, street furniture, etc. However, the architectural or spatial quality and scale of its outputs can be inconsistent since it is still under training (Seneviratne et al., 2022). Moreover, the outputs of this interface usually lack cultural specificity. Nevertheless, altering the prompts to give more description of the geographical location can enhance the cultural representation of the generated image.

Table 2 Summary of the different AI platforms during the studio-based learning

Tool	Model Type	Strengths	Weaknesses	Input Types	Best Use Case
Playground Ai	Stable Diffusion, DALL·E	Flexible model selection; strong prompt control	Stylised outputs may require prompt tuning	Text prompts and reference image	Iterative design, prompt testing
Lumenor AI	Proprietary ML/DL models	High-quality digital art generation, adaptive learning; seamless integration with design software	Limited documentation on backend architecture; potential lack of urban planning specificity	Text prompts and reference image	Iterative design, prompt testing
GETIMG	Custom generative model	Equity-oriented; designed for mobility visualisations	Comprehensive toolset; user-friendly interface; supports custom model training	May require a learning curve for advanced features; potential limitations in architectural specificity	Iterative design, prompt testing
Bing	Transformer + Diffusion	Clear visual-semantic match, text rendering, and user-friendly interface	Can misrepresent urban scale; less stylistic nuance	Text Prompts	Planning demonstrations, quick visuals

5.2 Illustrative Student Assignment
This assignment, authored by one of the students (Code - **S1**), presents a critical analysis of AI-generated images from three platforms (Lumenor, GETIMG and Microsoft Bing). The student in this assignment evaluated how well these outputs support the transformation of urban spaces through street experiments. The student critiqued

the AI-generated images using the analytical framework that examines functionality, social impact, aesthetics, and sustainability (see section 3). Following the assignment brief, the student used 5 variations of prompts on every one of the three platforms and compared their outputs. The three prompts are as follows:

• **Prompt 1:** "A street experiment (an intentional, temporary change of the street use, regulation and/or form, aimed at exploring systemic change in urban mobility, away from "streets for traffic", and towards streets for people)" (see Figures 2, 3 and 4).

Figure 2 Image generated using Lumenor. The image was generated in response to the prompt 1

Figure 3 Image generated using GETIMG. The image was generated in response to Prompt 1.

Figure 4 Image generated using Microsoft Bing. The image was generated in response to Prompt 1.

Prompt 2: "A parklet is a small, intentional, temporary conversion of a parking space or street segment into a public space designed for people rather than vehicles. This intervention typically includes seating, greenery, and amenities that encourage social interaction, relaxation, and community engagement. Parklets serve to reclaim underutilized road space, fostering a shift in urban mobility paradigms towards more pedestrian-friendly environments and enhancing the overall quality of urban life" (see Figures 5, 6 and 7).

Figure 5 Image generated using Lumenor. The image was generated in response to Prompt 2.

Figure 6 Image generated using GETIMG. The image was generated in response to Prompt 2.

Figure 7 Image generated using Microsoft Bing. The image was generated in response to Prompt 2.

Prompt 3: "Play streets are designated areas where vehicular access is restricted to create a safe and inviting environment for children and families to engage in play and recreation. This intentional, temporary street transformation promotes community interaction and active lifestyles by repurposing the street as a dynamic space for games, activities, and social gatherings. Play streets challenge traditional street use, advocating for a vision of urban mobility that prioritizes children's needs and fosters a sense of community" (see Figures 8, 9 and 10).

Figure 8 Image generated using Lumenor. The image was generated in response to Prompt 3.

Figure 9 Image generated using GETIMG. The image was generated in response to Prompt 3.

Figure 10 Image generated using Microsoft Bing. The image was generated in response to Prompt 3.

Prompt 4: "Open streets are temporary closures of public roads to motor vehicle traffic, transforming them into vibrant spaces for pedestrians, cyclists, and community activities. This street experiment aims to explore the potential of urban thoroughfares as public plazas, promoting active transportation and social cohesion. By facilitating outdoor activities, such as markets, performances, and recreational events, open streets encourage a fundamental rethinking of street design and usage, prioritizing people over cars in urban environments" (see Figures 11, 12 and 13).

Figure 11 Image generated using Lumenor. The image was generated in response to Prompt 4.

Figure 12 Image generated using GETIMG. The image was generated in response to Prompt 4.

Figure 13 Image generated using Microsoft Bing. The image was generated in response to Prompt 4.

Prompt 5: "The reuse of public space refers to the intentional, temporary adaptation of existing public areas to serve new functions, such as community gatherings, art installations, or pop-up markets. This approach seeks to maximize the utility of underused urban spaces by fostering social interaction and cultural expression. By experimenting with diverse uses of public space, cities can better understand the needs and desires of their communities, leading to more responsive urban planning and a shift towards spaces that prioritize people and community engagement over traditional vehicular traffic" (see Figures 14, 15 and 16).

Figure 14 Image generated using Lumenor. The image was generated in response to Prompt 5

Figure 15 Image generated using GETIMG. The image was generated in response to Prompt 5

Figure 16 Image generated using Microsoft Bing. The image was generated in response to Prompt 5

For the critical analysis of the AI-generated images, the student followed the structure of the five-phase critical framework introduced in the course. This student's work demonstrates how this framework can be operationalised in student work.

In Phase 1 (Create a Sample Set - Identify patterns**):** The student conducted the first visual scan of recurring elements in the images. For instance, the frequent presence of greenery, benches and pedestrian zones (see Figures 5, 6 & 3). S1 was also able to note the absence of some elements such as seasonal variations and representation of elderly and disabled users. This indicates the student's awareness of the inclusion and omission of AI-generated visuals.

In Phase 2 (Content Analysis – Identify strengths and weaknesses): S1 highlighted some strengths within the outputs, such as green infrastructure, seatings, social interactions and pedestrian-friendly layouts. Besides, the student was also able to indicate some homogeneous design features and unrealistic or utopian representations (see Figures 4, 10 & 14).

In Phase 3 (Link patterns to Dataset – interrogate values embedded in data): S1 critically examined the underlying assumptions in the data training of GenAI platforms. For example, S1 identified some cultural and socio-economic biases that were represented in the Western design aesthetics of the urban contexts in the images (see Figures 2, 12 & 15). This indicates that GenAI tools tend to neglect the needs of diverse users or non-Western environments in their urban design visuals.

In Phase 4 (Connotative Analysis – examine social implications): The student linked the embedded biases to real-world planning consequences. S1 highlighted that privileging one aesthetic or demographic group can create a state of inequality. In the analysis, the student also indicated that these misrepresentations can unintentionally marginalise certain groups that are not visualised by GenAI tools.

In Phase 5 (Start Over – Test hypotheses and model boundaries): Even though S1 did not provide wide variations of prompting examples, the student was able to reflect on the value of each prompt iteration to refine the outcomes and challenge the initial assumptions. S1 discussed how rephrasing the prompting language or words could produce more inclusive and context-sensitive outputs and visuals

.

Beyond applying the analytical framework, S1 compared the generated outputs of the different tools used in the assignment. S1 indicated that each tool provided visually engaging streetscapes, however, the quality and the degree of realism differed greatly between each tool. For instance, Bing Image Creator was identified as having the capability to produce coherent urban compositions and plausible human figures. Nevertheless, Lumenor AI and GETIMG were noted for generating images with distorted or surreal elements, which questions their design capabilities.

In the student's report, some discrepancies in the way each tool interprets prompts were identified. This aligns with Salvaggio's (2023) and Seneviratne et al. (2022) findings that these tools still have limited platform-specific training data and algorithmic parameters. This comparative analysis shows the importance of tool selection and critical cross-platform evaluation when employing GenAI in urban design pedagogy.

5.3 Key Strengths and Challenges in Using GenAI in Studio Classes

As part of the studio-based module undertaken by students, a portion of their assessment involved evaluating their critical reflection and engagement with the GenAI tools used in their urban design tasks. By going through the students' work and writing their feedback, key distil trends were noticed. Table 3 summarises the main strengths and challenges observed.

Table 3 Summary of Key Strengths and Challenges in Student Engagement with GenAI Tools

Category	Observed Strengths	Observed Challenges
Critical Reflection	Most of the students carefully questioned the results of AI-generated images and were able to highlight ethical issues.	Some students lacked depth in analysing AI biases or broader implications.
Understanding of Bias	The students had some degree of awareness of cultural and geographical limitations in image outputs.	For some students, it was hard to explain how biases show up in visuals or impact fairness in cities.
Urban Design Theoretical Framework Application	Most of the students successfully integrated theoretical frameworks to guide their critiques.	There were some inconsistent applications of theoretical frameworks; some students relied more on aesthetics than critical analysis.
Prompt Engineering	Most of the students used creative and well-structured prompts that generated contextually rich outputs.	Several students struggled with specificity and realism in their prompt design.
Use of Visuals	The students presented clear visual representations, which supported their arguments effectively.	It was noticed that most of the students were over-reliant on visuals with insufficient accompanying critique.
Engagement with Tools	The students demonstrated a strong ability to navigate and use multiple GenAI platforms.	There was limited comparison between the different platforms; some focused only on tool functionality rather than outcomes.
Equity and Mobility Lens	The students showed a strong understanding of how AI tools can reveal or obscure mobility injustices.	There was a tendency to generalise equity concerns without linking them to concrete design implications.

These findings indicate that the students successfully engaged, reflected on, and critically analysed the integration of GenAI image generation tools in their module. They were also able to highlight the biases attached to these tools. However, more support is needed, particularly regarding integrating analytical frameworks in the prompt creation and output image analysis.

6 Discussion and conclusion

This paper explored the applicability of integrating GenAI tools into urban design education through a structured studio exercise. The objective was to investigate ways to develop students' transformative skills through an integrated learning approach designed to equip university students to navigate complex challenges and support societal transitions. This application also seeks to elevate the students' competencies in critical analysis, reflexivity and spatial justice awareness. These competencies align with the broader pedagogical aims of planning education, which includes developing future literacy, responsiveness, and the capacity for ethical reasoning as claimed by Tassone et al. (2018) and McCune (2023).

This paper presented a five-phase critical framework as part of an urban design studio-based module. This framework offers a clear structure for deconstructing GenAI outputs. The exercise undertaken by the students built on media studies theories of visual encoding and decoding (Salvaggio, 2023; Barthes, 1977), which encouraged them to look beyond general urban design aesthetics and look deeper to critique assumptions encoded in generated image datasets. This analytical approach adheres to the call for considering AI ethics and digital humanities when utilising algorithmic outputs (Crawford, 2021).

Throughout the studio classes and assessment of the students' individual reports, it was evident that the students were able to generate and analyse images and interrogate embedded socio-cultural and political assumptions. The student's assignment example presented here in this paper demonstrated how utilising the critical framework can support layered analysis. This layered analysis included not just identifying patterns, but also questioning whose narrative are being visualised. In addition, the student's comparison across the different used platforms in the exercise highlighted the major interpretive differences in GenAI tools. This supports the existing concerns in the literature about the opacity and variability of large text-to-image models (Seneviratne et al., 2022; Valença et al., 2025).

Furthermore, several pedagogical challenges were observed. Some students struggled with prompt engineering, which confirms the findings by Paananen et al. (2024) that prompt specificity is a skill and at the same time a barrier in GenAI-based design. Other students were struggling with articulating the spatial or equity-related implications of AI imagery. This indicates that the students need more scaffolding to connect urban theory to AI visual critique.

Generally, the findings of the paper indicate that GenAI can enhance urban design pedagogy when incorporated into urban design studio classes, particularly when using a structured/critical framework. GenAI can also foster the development of ideas, support visual thinking and enhance digital literacy. Nevertheless, there is a risk of reproducing dominant design imaginaries and marginalising alternative urban futures when implemented without explicit critical guidance, as claimed by (Townsend, 2020; Wang et al., 2025).

In conclusion, AI platforms provide opportunities and challenges as futuring exercises. Open dialogue between educators and students should foster debates on the development of culturally responsive prompts and integrate comparative analysis within the curriculum to expose the students to a wide range of tools. Moreover, the future direction of GenAI in urban design should include extensions to non-Western urban contexts, include the needs of marginalised groups, and develop collaborative pedagogy with open-access repositories of tested prompts and images. This pilot studio reinforces the imperative of embedding AI literacy in urban planning curricula as a technical and ethical practice.

Exploring Pedestrian Comfort and Urban Mobility: A Multi-Modal Assessment of Walking Experiences at Popular Restaurant Destinations in Shanghai

Yutong Ma, Mengyue Mei, Tongyu Sun
Affiliation: Tongji University
Email: _yutong@tongji.edu.cn

Abstract
This study examined pedestrian comfort and urban mobility in Shanghai's inner-core restaurant destinations by identifying three distinct access patterns: Public transportation + non-motorized/ long distance walk (PNLW), Public transportation + short distance walk (PSW), and Motorized vehicle + short distance walk (MSW). Using spatial audits, navigation data, and social media text analysis, it evaluates comfort through pedestrian characteristics and traffic conditions. Findings reveal that MSW destinations—despite being less sustainable—offer the highest pedestrian comfort due to better-designed access zones and reduced pedestrian-electric scooter conflict. PSW areas suffer from congestion and inadequate micro-scale planning, while PNLW zones are most impacted by infrastructural shortcomings. The study concludes that pedestrian comfort depends on the continuity and convenience of the space where different modes of transportation changed.

Keywords: pedestrian comfort; travel; destination;

1. Introduction

The travel behavior of citizens is closely related to urban space and urban transportation systems. In megacities such as Shanghai, the evolution of mixed-use developments, commercial hubs, and transit-oriented infrastructure has heightened the need for pedestrian-friendly environments. More comfortable walking can enhance travelers' willingness to travel actively (Knowles, et al, 2020) and is a core part of the sustainable travel transformation (Loo, 2021). Walking comfort is a measure of the quality and attributes provided by the walking environment through space and walking facilities, which makes the walking experience easier (Ma, et al, 2021). It includes material, physical and psychological comfort (Sarkar, 2003). However, walking during travel is not an isolated process: As a higher-level walking demand (Alfonzo, 2005), the comfort of walking is also dynamically influenced by factors such as the relationship between the person and the vehicle and travel characteristics.

Among various urban functions, dining play a unique role in shaping urban pedestrian flow. Popular restaurant destinations, often located in high-footfall commercial districts, naturally attract large volumes of pedestrian movement and serve as key nodes in urban pedestrian networks. While existing research primarily examines broad walkability metrics such as land use and infrastructure, fewer studies focus on how walkway conditions, traffic flow, and transportation infrastructure impact pedestrian experiences during the travel.

This study adopts the destination-oriented approach, aiming to fill this gap by evaluating the pedestrian comfort in Shanghai's inner-ring commercial areas, focusing on locations with high restaurant-driven foot traffic. By integrating navigation data, spatial audits, and text analysis from social media platforms, this research provides a comprehensive understanding of pedestrian experiences and offers multi-modal data-driven recommendations for urban planning and design. Specifically, it focuses on understanding how pedestrian comfort varies across different arrival modes and urban fabric at popular restaurants destinations.

The study has three primary objectives:
1) To analyze the access pattern of popular restaurant destinations in Shanghai's inner core area and the relationship with their urban fabric and transportation infrastructure.
2) Evaluate the pedestrian comfort in these areas based on walkway quality, pedestrian characteristics, and traffic conditions, and add other special criteria such as dedicated parking areas, station facilities, and attractiveness according to different arrival patterns. The relevant high-frequency words that appear on social media are also important supplementary evidence for the evaluation.
3) Seek the correlation between access patterns and pedestrian comfort.

2. Literature Review

Studies on pedestrian comfort in urban design focus on the influence of built environments on pedestrian behavior and perception, encompassing both objective and perceived characteristics of the built environment, as well as walking behavior and related factors. This research further examines pedestrian comfort during travel, investigating how travel characteristics—such as trip purpose, mode of transportation, and travel time—affect comfort levels.

Walking serves as a critical link between various travel segments and transportation modes, spanning multiple stages from origin to transfer points and final destinations. Pedestrian comfort directly influences individuals' willingness to adopt other modes of transportation. High-quality walking environments, convenient pedestrian facilities, and appropriate walking distances can significantly enhance residents' travel satisfaction (Van Lierop et al, 2018).

From a travel perspective, research on walking comfort treats walking as a distinct mode of transportation, views pedestrians as individual units within traffic flow, and integrates pedestrian systems as an essential component of urban transportation networks. This approach emphasizes the systemic role of walking in shaping overall mobility experiences and urban accessibility.

2.1 The influence of travel links on pedestrian comfort

Academic research has established that pedestrian comfort in transit station areas - encompassing bus stops, metro stations, and railway terminals - significantly influences travelers' modal choices and willingness to walk to transit nodes. Empirical studies utilizing citizen satisfaction evaluations demonstrate that perceived walkability (Gan et al, 2021) and sidewalk conditions, pedestrian facilities, and intersection design (Gupta et al, 2022) in station access zones, positively correlate with metro ridership. For Bus Rapid Transit (BRT) systems, research indicates that pedestrian comfort perceptions depend fundamentally on sidewalk quality and cleanliness, with tree-shaded routes particularly enhancing walking propensity (Jiang et al, 2012). Emerging scholarship employs quantitative measures like street tree density and bench availability to assess how Light Rail Transit (LRT) station-area built environments (within 5-minute walk radii) support active transportation adoption (Oluyomi et al, 2019).

Transfer stations present unique comfort considerations, where platform accessibility, vertical circulation systems, and crossing infrastructure substantially impact commuter experience, as evidenced by studies in Indian contexts (Sil et al, 2022). Alexander's seminal work establishes 180-200m (approximately 3-minute walk) as the maximum acceptable transfer distance for maintaining passenger comfort (Alexander, 2018).

The first-mile/last-mile (FMLM) challenge remains a critical barrier to transit adoption (Fehr & Peers et al, 2015). High-quality FMLM environments simultaneously enhance both utilitarian functionality and experiential quality of transit journeys (Tilahun et al, 2016). Ergonomics research reveals that travelers' overall comfort evaluations are disproportionately weighted toward terminal trip segments (Richards, 1978), with destination-area microclimate comfort particularly influencing satisfaction assessments (McKercher, 2015). Improved walkability in FMLM zones demonstrates pro-social impacts, enabling greater transit use among low-income commuters - with origin-area walkability proving more influential than destination conditions (Ha et al, 2023). For bus riders, FMLM comfort and transfer duration exert greater satisfaction impacts than in-vehicle conditions (Park et al, 2021).

Regarding metro access, "last-mile" qualitative aspects like sense of place outweigh basic facility availability in promoting walking mode share (Chidambara, 2019).

2.2 Pedestrian characteristics and pedestrian comfort

The fundamental significance of pedestrian comfort lies in optimizing travel experience, making micro-scale behavioral metrics essential for operationalizing comfort assessment. Under optimal conditions, empirical studies document an average walking speed of 1.24 m/s (Chen and Dong, 2005), with personal space requirements of 1.4-2.3 m^2/person (Fruin, 1971) and flow rates below 23 persons/m·minute maintaining perceived environmental freedom. The personal space construct, encompassing both pacing zones (physical movement requirements) and sensory zones (psychological buffer areas), has emerged as a robust proxy for design quality and level-of-service evaluation.

Contemporary research methodologies employ diverse approaches: sidewalk width-to-volume ratios for crowd density analysis, computer vision processing of transit vehicle dashcam footage for crossing behavior studies (Fan and Loo, 2021), and IoT-enabled environmental sensors (e.g., air quality monitors) capturing spatiotemporal usage patterns (Loo and Tang, 2019). Wi-Fi signal clustering techniques also effectively detect group movement patterns. Participatory sensing through opt-in smartphone applications further enriches data granularity by correlating mobility patterns with individual attributes.

While demographic (age/gender), socioeconomic, and cultural factors preclude universal comfort standards, consensus emerges around three core requirements: unimpeded walking pace, adequate personal space allocation, and controlled pedestrian densities. Comfort manifests behaviorally through unconstrained movement patterns-characterized by purposive gait unaffected by negative psychological states, minimal flow conflicts (<15° angular deviation in trajectory intersections), and limited friction with other modal users (vehicular/bicycle). These observable parameters collectively establish an evidence-based framework for comfort evaluation across varied urban contexts.

2.3 Auditing Frameworks and Criteria of pedestrian comfort measurement

Comfort has been explicitly incorporated into various walkability audit tools and guidelines, which can be categorized by scale and methodology. At the macro urban scale, quantitative tools provide comprehensive assessments of city-wide factors, while micro street-scale evaluations qualitatively characterize outdoor spaces through user perception. Current measurement instruments are inherently context-specific, can be classified into five methodological approaches:

1) Perceptual Tools
Neighborhood Environment Walkability Scale (NEWS) (Cerin et al, 2002)

2) Perceptual-Observational Hybrid Tools
Pedestrian Environment Data Scan (PEDS) (Clifton et al, 2007)
Systematic Pedestrian and Cycling Environment Scan (SPACES) (Pikora et al, 2002)
Systematic Social Observation of Public Spaces (SSO) (Sampson and Raudenbush, 1999)

3) Observational Tools
Chinese Urban Built Environment Scan Tool (CUBEST) (Su et al, 2014)
Analytic Audit Tool (AAT) (Brownson et al, 2004)
Active Neighborhood Checklist (ANC) (Hoehner et al, 2007)
Neighborhood Active Living Potential (NALP) (Gauvin et al, 2005)

4) Observational-Archival Hybrid Tools
Walkability Framework for Health (WFH) (Zuniga-Teran et al, 2016)
Pedestrian Level of Service - Quality (Q-PLOS) (Talavera-Garcia and Soria-Lara, 2015)

5)Archival Tools
Walkability Index (WAI) (Frank et al, 2010)
Walk Score (WS) (Arellana et al, 2020)
The Physical Activity and Redesigned Community Spaces (PARCS) study (Huang et al, 2016)

3. Methodology

3.1 Study Area and Site Selection

This study focuses on popular restaurant destinations within Shanghai's inner-ring commercial areas, selected based on Gaode Map navigation data. The inner ring represents the city's core zone, characterized by the highest density of transportation and pedestrian activity. To ensure that walking segments occur exclusively in outdoor built environments and urban streets, restaurants located within TOD (Transit-Oriented Development) buildings were excluded from the analysis.

The selection of restaurants was determined by Gaode Travel Score, a data-driven metric derived from real user navigation behavior, including travel popularity and experience quality. This score reflects a restaurant's relative

standing compared to others in the same category and urban context. The data is updated daily based on a 30-day dynamic rolling window, ensuring objectivity without manual intervention or manipulation.

To capture representative dining destinations, the study identified the top three most-visited restaurants in each administrative district within the inner ring, ensuring spatial diversity and high pedestrian accessibility (Fig.1). In addition, Yangpu District and Pudong District have no restaurants that meet the requirements. This approach allows for a systematic evaluation of walkability and pedestrian comfort in high-traffic urban dining areas.

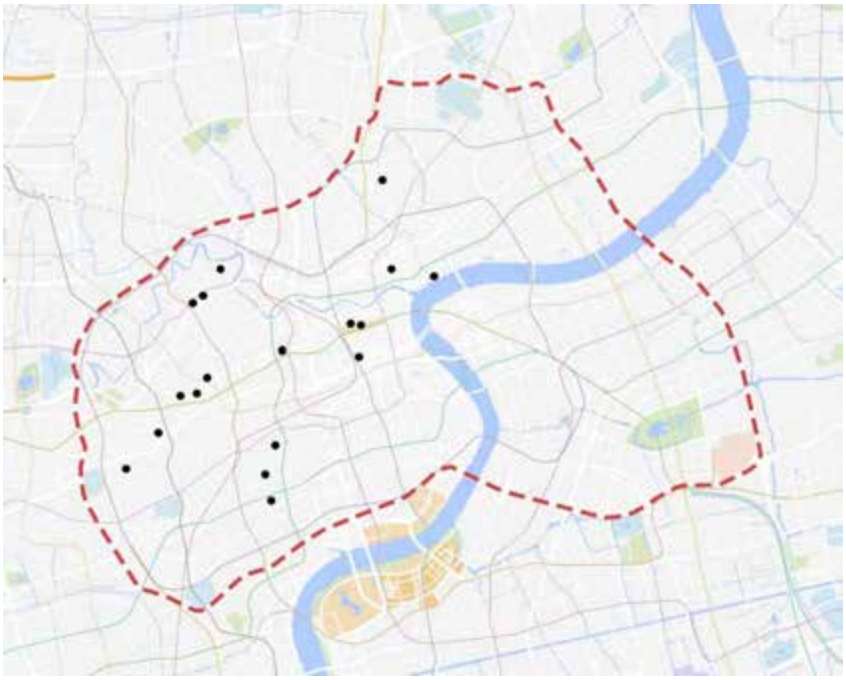

Figure 1 Selected restaurants

Source: Author's own illustration based on raw data from Gaode Map.

3.2 **Online Data Sources and Collection Methods**

This study employed a comprehensive multi-source data collection framework to systematically evaluate the pedestrian environment surrounding selected restaurants. The spatial analysis was conducted within an 800-meter radius buffer zone centered on each restaurant location, encompassing key pedestrian transportation infrastructure elements including sidewalks, parking facilities, and public transportation nodes including bus stops (within 300 meters) and subway stations (within 500 meters). These geospatial datasets were acquired through application programming interfaces (APIs) from Gaode, ensuring data accuracy and temporal relevance.

For dynamic pedestrian flow analysis, the study utilized Baidu Map's heatmap functionality, which provides real-time visualization of human mobility patterns through anonymized location data from mobile devices. Data collection was strategically scheduled during peak activity periods - specifically weekday evenings (17:30) and weekend noontime (11:30) - to capture maximum pedestrian volumes. These temporal samples enabled identification of high-traffic corridors for subsequent field observations while providing quantitative evidence of congestion patterns (Fig.2).

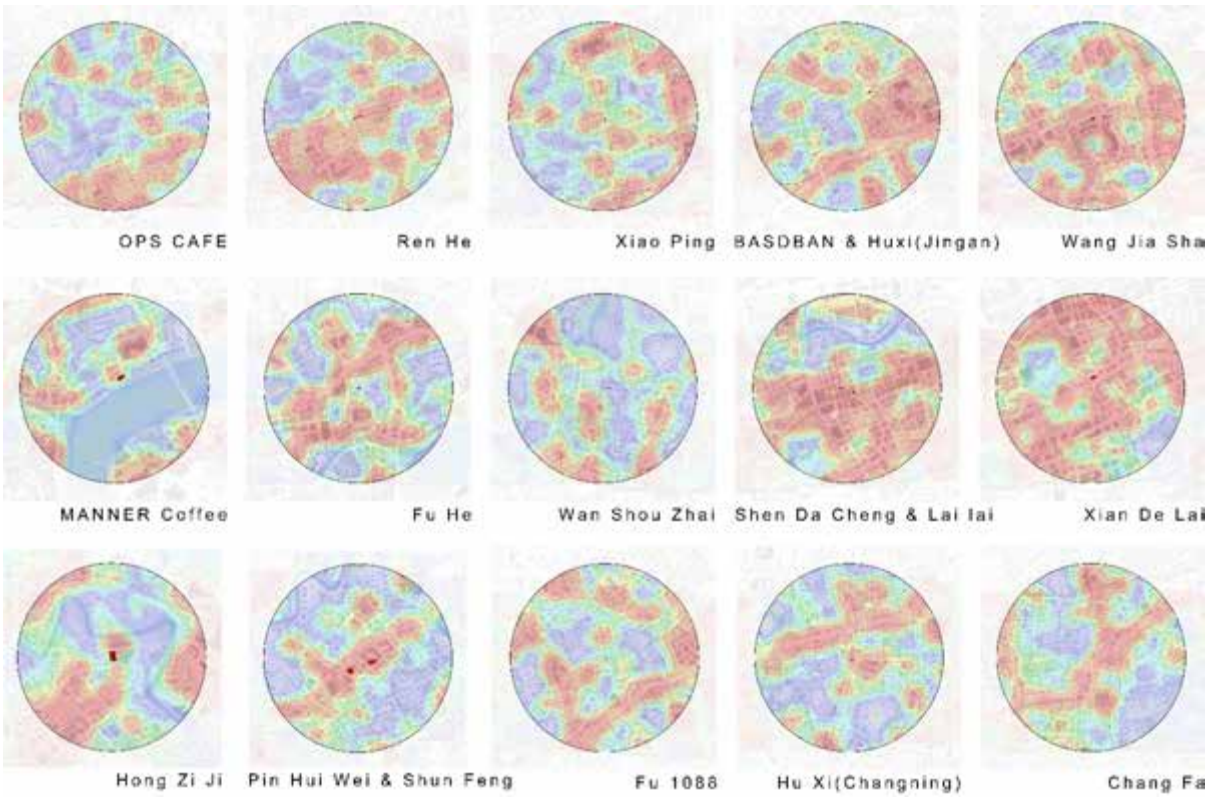

Figure 2 Heat map of the restaurants

Source: Author's own illustration based on raw data from Baidu Map.

Complementing the pedestrian flow data, shared bicycle availability data were extracted from the Meituan platform's real-time feed. This dataset, collected synchronously with the heatmap recordings, provided insights into micro-mobility patterns and last-mile connectivity around each study site. Spatial analysis of bicycle distribution patterns helped identify parking hotspots and potential conflicts with pedestrian flows.

To complement spatial and mobility data, social media text data was extracted from Xiaohongshu (Little Red Book), a platform where users share image-text posts. A structured keyword search protocol was implemented using terms such as "walking experience", "accessibility", and "pedestrian comfort" in combination with each restaurant's name.

This multi-method approach, combining spatial analysis, movement pattern visualization, and text analysis, provided a robust foundation for evaluating pedestrian comfort from both objective and subjective perspectives.

3.3 Quantitative pedestrian comfort evaluation method

Building on previous mobility-focused studies of pedestrian comfort, this research categorizes evaluation metrics into 4 common criteria (universally applicable criteria for all access pattern) and 9 specialized criteria (context-sensitive measures tailored to specific access patterns). To enable precise quantification, each restaurant is systematically scored across all relevant indicators using a standardized 0-2 point scale (where 0 = poor, 1 = moderate, 2 = optimal), with summation generating a composite Pedestrian Comfort Score (PCS) for individual restaurant (Tab. 1).

Table. 1 pedestrian comfort evaluation

Evaluation criteria			Pedestrian comfort score			Access pattern		
Category	criteria	Description	0	1	2	PNLW	PSW	MSW
Common criteria	Sidewalk Quality	Width	2m	2-3m	>3m	√	√	√
		maintenance	uneven and dirty surface	slightly uneven with minor stains	flat and clean surface			
	Pedestrian Characteristics	Pedestrian Flow Rate	>30 or <10 persons/min	20-30 persons/min	10-20 persons/min	√	√	√
		Queue Encroachment	queue obstructs sidewalk	minor queue	no queue			
	Traffic Conditions	traffic congestion	severe congestion (vehicles cannot move)	moderate congestion (vehicles slow down)	no congestion	√	√	√
		Pedestrian-Electric Scooter Mixing	frequent mixing (pedestrians avoid vehicles)	occasional mixing	no mixing			
Special criteria	Dedicated Parking Areas	Pavement Material Differentiation	no differentiation	marked differentiation	material differentiation	√	×	√
		Direct Access	no direct access	access via underground/ overground passage	direct entrance access			
		Dedicated Waiting Area	no dedicated waiting area	dedicated waiting area	no dedicated waiting area	×		
		Independent Parking Lot	no parking lot	available but insufficient	sufficient independent parking			
	Station Facilities	Escalators at Exits	no escalators	escalators available	escalators and accessible elevators	×	√	×
		Exit Time	underground passage and multi-level vertical transit	underground passage or multi-level vertical transit	no underground passage or multi-level transit			
		Bus Stops	<10	10-20	>20			
		Walking Distance to Nearest Metro	>800m	500-800m	<500m	√		
	Attractiveness	-	ordinary street	historic/ commercial district	central business district	√	√	×

3.4 Pedestrian Comfort Audit

According to the evaluation framework (Tab. 1), the study employed a rigorous, multi-dimensional approach to assess pedestrian comfort through systematic field audits. Quantitative measurements followed standardized protocols: 1) sidewalk width was recorded using laser distance meters at 5-meter intervals along restaurant frontages, with three measurements taken at each point to ensure reliability (recording minimum, maximum and average widths). 2) Pedestrian flow rates were measured in units of 5 minutes through manual counting at 15-minute intervals during both weekday evening (17:30-19:30) and weekend midday (11:00-13:00) peak periods. 3) Queue encroachment was documented through scaled photographs and actual measurements of occupied sidewalk area, with particular attention to instances where more than 50% of walkway width was obstructed.

Qualitative assessments employed structured observation protocols. 1) Pathway maintenance was evaluated by features such as surface evenness, cleanliness, visual coherence, and drainage conditions. 2) Traffic conditions were analyzed through photograph recording during audit periods, with conflict points mapped. 3)Parking infrastructure was inventoried through field surveys documenting, including dedicated bicycle parking capacity, electro mobile parking encroachment, and vehicle parking lot capacity serving the restaurant. 4) Metro station accessibility was assessed through timed walk tests from nearest exits, documenting vertical circulation options and wayfinding signage to make sure how to smoothly reach the concourse level from the platform level and find the exit.

The audit incorporated specialized vertical mobility assessments, including inventory of skyway and step counts for underground passages. These vertical elements were found to disproportionately affect pedestrian comfort due to additional physical exertion required and the increased difficulty of finding the way.

All audit data was collected by trained teams using standardized digital forms with geotagged photographs and timestamped observations. The comprehensive methodology enabled both cross-site comparisons and context-specific analysis of pedestrian comfort determinants across Shanghai's varied urban environments. Particular attention was given to transitional spaces between different transport modes, where comfort compromises were most frequently observed. The audit framework successfully captured both measurable physical parameters and subjective user experience factors affecting pedestrian comfort.

3.5 Identifying Pedestrian Access Patterns Through Field Survey

To determine how pedestrians arrive at restaurants, the study employs a multi-method field audit protocol that combines behavioral observation, infrastructure mapping analysis and text analysis from Xiaohongshu.
Pedestrian access patterns during peak hours (weekday evenings (17:30-19:30) and weekend midday (11:00-13:00) by observing:1) Whether pedestrians used means of transportation such as vehicles, bicycles or electric bikes or wore helmets when they arrived. 2) Randomly track an array of pedestrians at the nearest subway exit, and calculate the proportion of these pedestrians who reach the destination restaurant among the total number of people who arrive at the restaurant during this period.

An analysis of the transportation infrastructure around the restaurant can also obtain supplementary evidence: 1) A distance of less than 500 meters from the restaurant to the nearest subway station is more likely to be dominated by public transportation. 2) The dense bicycle parking area near the restaurant will encourage pedestrians to ride bicycles at "the last mile". 3) Restaurants that are over 800 meters away from subway stations, have their own parking lots and are not popular check-in spots are more likely to be reached by private cars or ride-hailing services. 4) When the destination restaurant is highly attractive, such as having a good urban view or being located in a historical district, pedestrians are more likely to tend to reach it on foot.

In addition, by searching for Xiaohongshu posts with keywords such as "restaurant name", "travel", "subway", and "walking", and conducting word frequency analysis on the transportation methods within them, it can also help study and determine the arrival methods of most travelers.

Finally, the research will determine the access patterns of a certain restaurant based on the most dominant arrival means. This identifying method effectively reduces subjective bias through cross-validation of multi-dimensional data.

4. Results and Findings

4.1 Classification of Arrival Patterns

This study categorizes pedestrian access patterns into three typologies based on infrastructure constraints and behavioral preferences: PNLW (Public transportation combined with Non-motorized or Long-distance Walk), PSW (Public transportation combined with Short-distance Walk), and MSW (Motorized vehicle combined with Short-distance Walk). It should be noted that the usage frequency of buses has significantly decreased in both the field research and in text analysis of Xiaohongshu. The public transportation referred to in the research is more about the subway.

Each pattern reflects distinct urban fabric conditions—historic-district morphologies for PNLW, transit-oriented development for PSW, and motor-centric adaptations for MSW—collectively shaping pedestrian comfort and route choices. The classification underscores how spatial design and transport resource allocation either facilitate or hinder more comfortable last-mile connectivity.

4.1.1 Public transportation + Non-motorized/ long distance walk (PNLW)

The formation of the PNLW (Public Transportation + Non-motorized/Long-Distance Walk) access pattern is primarily attributed to restaurants being located beyond 500 meters or even 800 meters from metro stations,

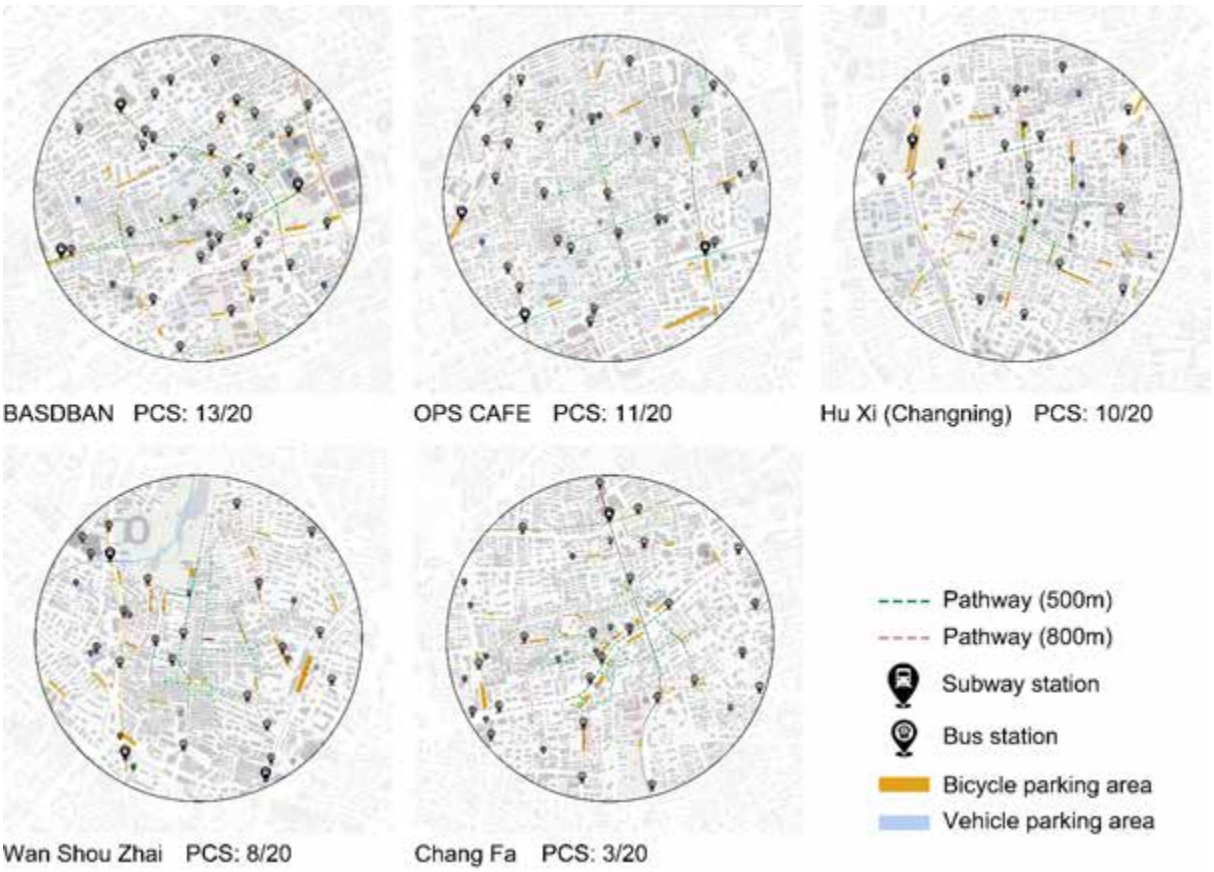

Figure 3 PNLW restaurant mapping
Source: Author's own illustration based on raw data from Gaode Map.

"Check-in" restaurants in historical district—such as BASDBAN, OPS CAFÉ, and Wan Shou Zhai—represent the first category of PNLW destinations due to: 1) Narrow roadways lacking dedicated bicycle lanes, forcing cyclists to share roads with motor vehicles, 2) Artificially enforced bicycle-restricted zones that create pedestrian-only segments along access routes.

Despite these constraints, such destination restaurants often benefit from being clustered with adjacent attractions, creating hybrid bicycle-and-walking routes that maintain strong pedestrian appeal.

The second category of PNLW destinations includes establishments like Hu Xi (Changning) and Chang Fa located near elevated roads. These sites present unique accessibility challenges: 1) Pedestrian flows are fragmented by overpass structures; 2)Certain road sections remain impassable for bicycles.

This spatial configuration effectively forces longer walking distances while limiting alternative micro-mobility options, reinforcing the PNLW pattern's dominance in these locations. The combination of physical barriers and policy restrictions creates a distinct pedestrian experience that differs markedly from transit-oriented or motor-centric access patterns.

4.1.2 Public transportation + short distance walk (PSW)

The PSW pattern emerges when restaurants are within 500 meters of the nearest subway exit (Fig. 4). These destinations—typically "check-in" spots—attract predominantly tourist visitors. Top-rated Huangpu District

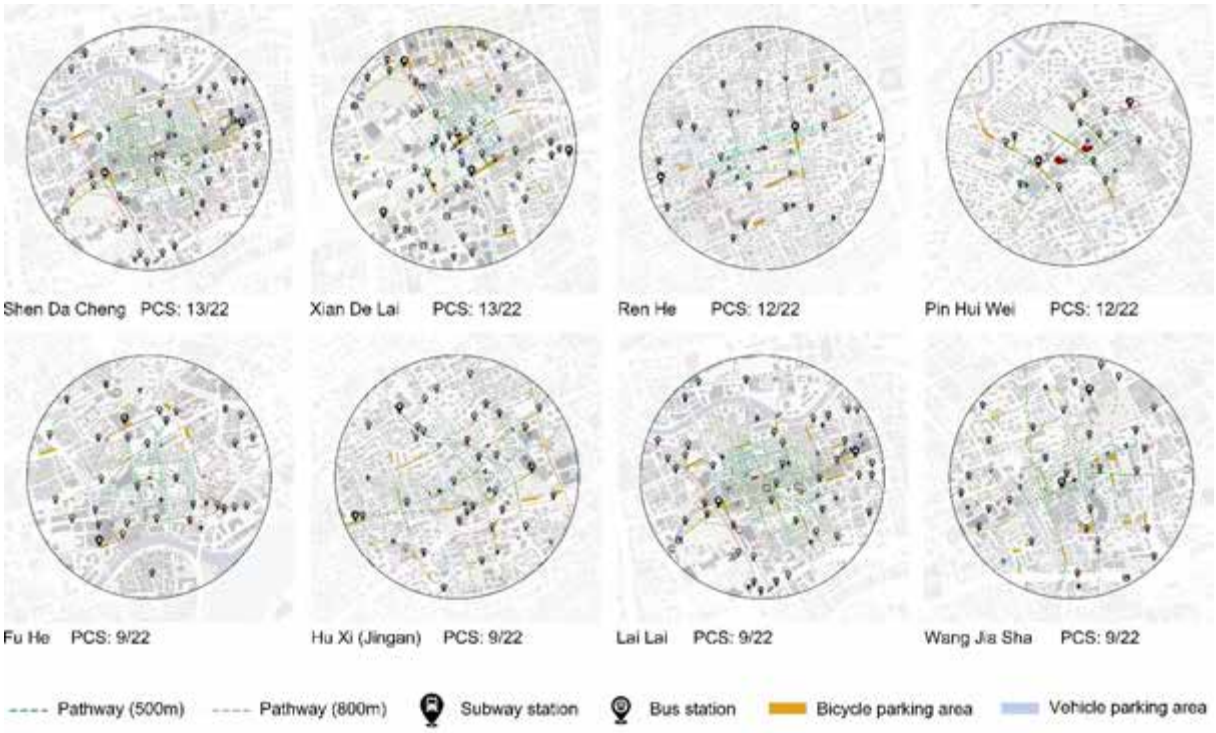

Figure 4 PSW restaurant mapping
Source: Author's own illustration based on raw data from Gaode Map.

Critical transit nodes that facilitate this pattern include major interchange stations, including Nanjing East Road (Lines 2/10), Jing An Temple (Lines 2/7/14), Nanjing West Road (Lines 2/12/13), Chang Shou Road (Lines 7/13), and Jia Shan Road (Lines 9/12). These hubs create concentrated restaurant clusters by capitalizing on two key advantages: their role as transportation interchanges and their embeddedness within vibrant commercial or historic districts. The resulting pedestrian networks enable dense, multimodal access to dining establishments. Moreover, PSW restaurants are supported by high bus-stop density (more than 10 stops within 300 meters, sometimes exceeding 20), reinforcing transit convenience.

This comprehensive transit ecosystem ensures consistent pedestrian flows while minimizing access friction, creating an environment particularly conducive to casual dining and tourism-oriented food establishments. The spatial efficiency of these areas demonstrates successful transit-oriented development principles in practice, where transportation infrastructure and commercial land uses achieve symbiotic integration.

4.1.3 Motorized vehicle + short distance walk (MSW)

The MSW pattern represents a distinct category where travelers predominantly utilize private vehicles or ride-hailing services to access restaurants, followed by brief pedestrian segments. This access mode emerges under two primary circumstances: 1) when restaurants are situated beyond convenient walking distance from metro stations (>800 meters) but provide dedicated parking lots; and 2) when the dining occasion involves group gatherings where motorized transport is preferred for social or logistical reasons (Fig. 5).

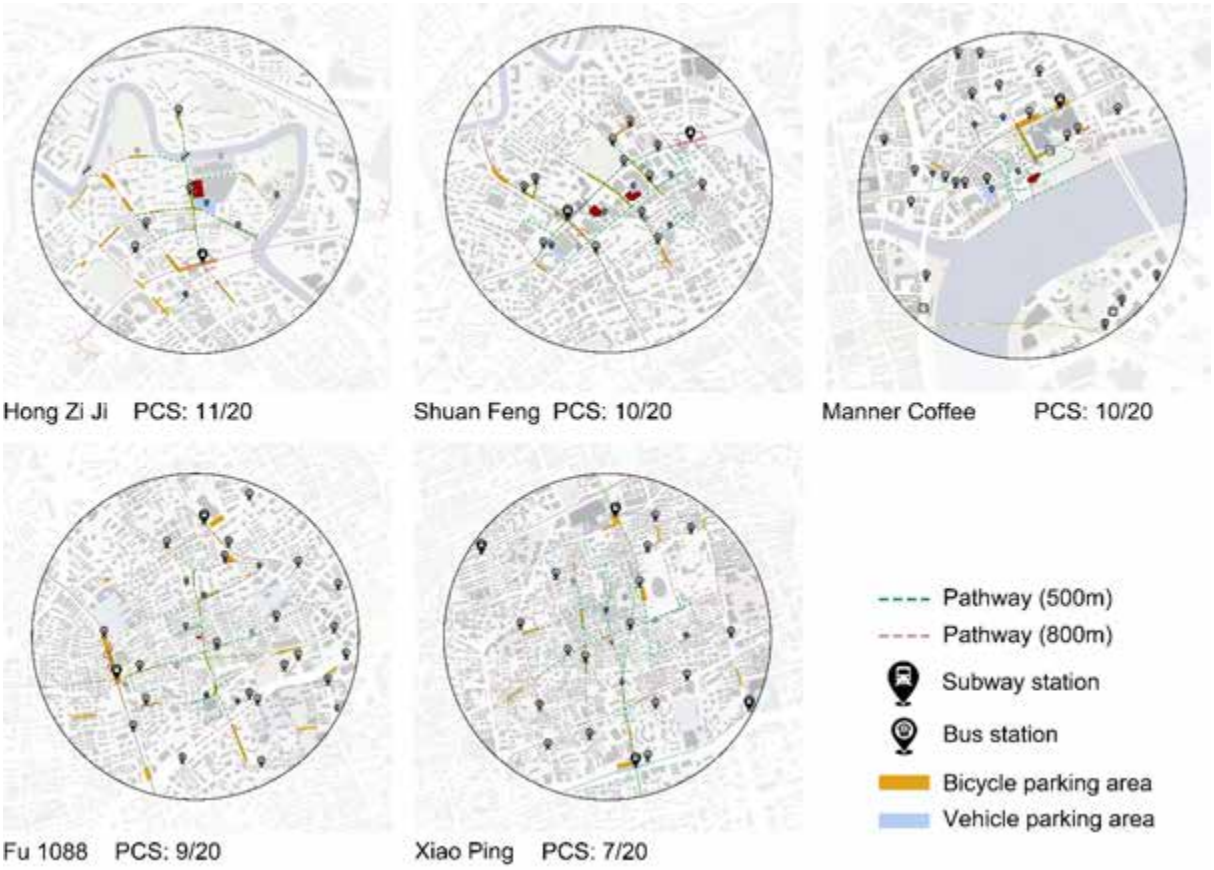

Figure 5 MSW restaurant mapping
Source: Author's own illustration based on raw data from Gaode Map.

Notably, restaurants located in historical districts - such as Fu 1088 - present unique challenges for MSW accessibility. These establishments are typically surrounded by low-rise commercial buildings with limited parking capacity, as most available spaces are allocated to private lots serving adjacent properties. This parking scarcity inadvertently increases reliance on short-distance walking, as patrons are often compelled to park at more distant locations and complete their journey on foot.

The spatial analysis reveals that MSW pattern restaurants cluster in two distinct urban contexts: 1) commercial centers with sufficient surface parking lots (e.g., Hong Zi Ji, Shun Feng), and 2) where public transport coverage is sparse but road infrastructure supports convenient vehicle access such as urban waterfront spaces (e.g., Manner Coffee and Hong Zi Ji) and lower-grade urban roads (e.g., Fu 1088, Xiao Ping). In both settings, the walking segments, though short, often present disproportionate comfort challenges due to inadequate sidewalk provisioning and lack of weather protection along parking-to-restaurant routes.

4.2 Pedestrian Comfort Assessment

The pedestrian comfort scores (PCS) varied notably across the three access patterns. On average, restaurants accessed via the MSW pattern achieved the highest comfort score (11.6/20), followed by PSW pattern with 10.5/22, and PNLW pattern with the lowest score of 9.0/20. These differences primarily stem from distinct infrastructure

challenges: MSW's transitional zone deficiencies, PSW's crowd management issues during peak hours, and PNLW's inherent distance penalties compounded by narrow sidewalks. The superior performance of MSW destinations can be attributed to clearer spatial organization, dedicated parking access, and better-maintained pedestrian zones. In contrast, PSW areas, while benefiting from proximity to transit infrastructure, often suffered from high pedestrian density and queue encroachment near exits. PNLW destinations showed the greatest variability, with comfort scores largely dependent on sidewalk quality and traffic mixing conditions.

These results highlight how pedestrian comfort is shaped by both macro-level accessibility and micro-scale design solutions specific to each access pattern. Sidewalk infrastructure, traffic separation, and spatial crowd management are critical determinants of perceived pedestrian comfort, often outweighing the presumed advantages of public transit-oriented accessibility.

4.2.1 PNLW: Structural and Psychological Barriers in Long-distance Walk

The PNLW access pattern exhibits several challenges that significantly compromise pedestrian comfort (Tab.2). Primary issues include inadequate sidewalk infrastructure, with most restaurants scoring only 1 or 2 for width (2-3m) and several scoring 0 (<2m), particularly Chang Fa and Wan Shou Zhai. This spatial constraint is exacerbated by frequent queue encroachment (scoring 0-1 across all cases) and poor maintenance conditions (0-2 scores). Traffic conditions present another major barrier, with most locations experiencing moderate to severe congestion (scores 0-1) and problematic pedestrian-vehicle mixing (scores 0-1). Queuing for road occupation, pedestrian flow and road width have basically the same impact on pedestrian comfort. Although both OPS Café and BASDBAN have queuing situations, walkways of different widths accommodate a different number of pedestrians, so the actual difference in appearance is not significant (Fig.6).

Figure 6 PNLW restaurants of different PCS
Source: Photographed by author.

The pattern's defining characteristic - long walking distances which more than 500 meters from subway station - combines with these infrastructure deficiencies to create range pedestrian discomfort. Furthermore, the lack of direct access (scores 0-1) and inconsistent pavement material differentiation (scores 0-2) contribute to navigation difficulties. These cumulative factors resulted in half of the restaurants having a pedestrian comfort score of less than 10/20, with the highest score being only 13/20. Chang Fa (Fig. 6) representing the most severe case of compromised walkability due to its combination of narrow sidewalks (1), poor maintenance (0), and frequent pedestrian-electric scooter mixing (0). The data suggests that PNLW destinations require comprehensive improvements in both physical infrastructure and operational management to enhance pedestrian experiences.

4.2.2 PSW: Infrastructure and Operational Challenges

The PSW access pattern, while generally demonstrating better pedestrian comfort than long-distance walking scenarios, still presents several persistent challenges that hinder optimal walkability (Tab.3).

The most critical issues stem from inconsistent sidewalk maintenance, with scores ranging from 0 (poor) to 2 (excellent) across different locations, creating uneven pedestrian experiences even within the same access pattern. Queue management emerges as another significant problem, particularly at popular destinations like Shen Da Cheng and Wang Jia Sha, where pedestrian flow scores of 0 indicate severe congestion during peak hours (Fig. 7).

The pedestrian- electric scooter mixing remains problematic at multiple sites, with mixing scores of 0-1 reflecting ongoing conflicts between walkers and micro-mobility users.

Figure 7 PSW restaurants of different PCS
Source: Photographed by author.

While metro proximity is generally excellent (with most locations scoring 0-1 for distances <500m), the supporting vertical circulation infrastructure shows variability and the exit method is usually rather complicated, as evidenced by escalator availability scores ranging from 0 to 1.

These operational shortcomings are compounded by the pattern's inherent vulnerability to peak-period stress, where even minor infrastructure deficiencies become magnified under heavy pedestrian volumes. The data reveals that while the PSW pattern's fundamental premise of short transit-to-destination distances provides a solid foundation for walkability, its full potential remains unrealized without addressing these persistent issues in infrastructure quality and crowd management.

4.2.3 MSW: Last-50-Meter Discontinuities in Motorized Access

The evaluation of Motorized Vehicle + Short-distance Walk (MSW) pattern restaurants revealed a moderate level of pedestrian comfort, with Pedestrian Comfort Scores (PCS) ranging from 9/20 to 13/20 (mean=11.6±1.6). As shown in Table 3, the top-performing establishments (Hong Zi Ji and Shun Feng, both 13/20) demonstrated balanced performance across all indicators, while Xiao Ping (9/20) represented the most compromised case (Fig. 8). Three key performance characteristics emerged from the analysis:

Figure 8 MSW restaurants of different PCS
Source: Photographed by author.

First, sidewalk infrastructure showed significant variation, with width scores ranging 1-2 (mean=1.4) and maintenance scores 0-2 (mean=0.8). Notably, all restaurants scoring 0 in maintenance (Hong Zi Ji, Xiao Ping) underperformed their width-adjusted PCS potential by 1.5-2 points, suggesting maintenance quality disproportionately impacts comfort in motorized-access environments.

Second, transition zone elements proved critical determinants. Restaurants with superior parking-to-walkway transitions (Hong Zi Ji: parking=2, direct access=2) achieved 1.3× higher PCS than those with poor transitions (Xiao Ping: parking=0, direct access=2). The dedicated waiting area variable showed particularly strong discrimination, with establishments scoring 2 (Shun Feng, Manner Coffee) averaging 12.5/20 versus 10.3/20 for others.

Third, electric scooter conflicts emerged as a newly significant factor. While traffic congestion scores averaged 1.0±0.8, pedestrian-scooter mixing scores averaged just 0.4±0.5, indicating this emerging mobility form creates disproportionate discomfort. Manner Coffee's exemplary scooter management (score=0) contributed significantly to its 12/20 PCS despite parking deficiencies.

The data suggests MSW comfort depends less on individual element excellence than on avoiding critical weaknesses - no restaurant overcame multiple 0 scores in core categories. This "weakest link" phenomenon differentiates MSW from other access patterns and underscores the need for holistic design approaches in motorized-access environments.

Table. 2 Pedestrian comfort score of PNLW pattern restaurants

Restaurant	Sidewalk quality		Pedestrian characteristics		Traffic conditions		Special criteria				PCS
	width	maintenance	pedestrian flow rate	queue encroachment	traffic congestion	pedestrian-electric scooter mixing	pavement material differentiation	direct access	distance to nearest metro	attractiveness	
OPS CAFÉ	1	2	2	0	1	2	0	1	0	2	11/20
BASDBAN	2	2	1	1	2	1	1	1	0	2	13/20
Hu xi (Changning)	1	1	2	1	1	2	1	1	0	0	10/20
Chang fa	1	0	2	0	0	0	0	0	0	0	3/20
Wan shou zhai	0	0	2	1	1	1	0	2	1	1	8/20

Table. 3 Pedestrian comfort score of PSW pattern restaurants

Restaurant	Sidewalk quality		Pedestrian characteristics		Traffic conditions		Special criteria					PCS
	width	maintenance	pedestrian flow rate	queue encroachment	traffic congestion	pedestrian-electric scooter mixing	escalators at exits	exit time	bus stops	distance to nearest metro	attractiveness	
Pin Hui Wei	2	0	0	1	1	1	1	1	0	2	1	10/22
Shen Da Cheng	2	2	0	1	0	2	1	0	1	2	2	13/22
Lai Lai	0	0	2	0	0	1	1	0	1	2	2	9/22
Xian De Lai	1	0	2	2	1	2	0	1	2	2	1	13/22
Ren He	2	1	1	1	1	2	0	2	0	2	0	12/22
Hu Xi (Jingan)	2	1	1	1	0	1	1	0	1	1	0	9/22
Wang Jia Sha	2	2	0	0	0	0	1	0	0	2	2	9/22
Fu He	0	0	1	1	1	1	1	2	1	1	0	9/22

Table. 4 Pedestrian comfort score of MSW pattern restaurants

Restaurant	Sidewalk quality		Pedestrian characteristics		Traffic conditions		Special criteria				PCS
	width	maintenance	pedestrian flow rate	queue encroachment	traffic congestion	pedestrian- electric scooter mixing	dedicated waiting area	pavement material differentiation	direct access	independent parking lot	
Hong Zi Ji	1	0	2	2	2	1	1	0	2	2	13/20
Shun Feng	2	1	0	2	1	1	2	1	1	1	13/20
Xiao Ping	1	0	2	1	0	0	0	1	2	0	9/20
Fu 1088	1	1	0	2	2	0	1	1	2	1	11/20
Manner Coffee	2	2	2	2	0	0	2	1	1	0	12/20

The text analysis of Xiaohongshu posts shows that: 1) Citizens are generally very sensitive about the distance from the destination restaurant to the subway station, which is a key factor determining the travel mode of most people. 2) The different purposes of dining at restaurants do indeed determine the mode of travel chosen by travelers. For instance, "checking in" and "dining together" are to some extent directly related to public transportation-oriented travel and motor vehicle-oriented travel respectively. 3) Travelers are quite concerned about the "uncomfortable" factors in the last mile, such as the inconvenience of parking. In addition, shading, cleanliness and clear signs are also key comfort factors that are often mentioned. Crowded intersections and overpasses are usually regarded as problematic places.

Overall, the quality of the sidewalk are the most fundamental factors affecting the pedestrian comfort, while different arrival patterns have corresponding key factors decided by urban fabric and transportation facilities.

5. Discussion and Recommendations

This study assessed pedestrian comfort around popular restaurant destinations in Shanghai by classifying access modes into three patterns: pedestrian + non-motorized / long distance walking (PNLW), public transportation + short distance walking (PSW), and motorized vehicle +short distance walking (MSW). The results indicate clear differences in comfort scores across these patterns, highlighting the influence of infrastructural, environmental, and traffic factors.

5.1 Comparing Comfort Across Modal Patterns

This study examined pedestrian comfort around popular restaurant destinations in Shanghai across three access modes: MSW, PSW, and PNLW. The findings reveal that MSW destinations achieved the highest average pedestrian comfort score (11.6/20), followed by PSW (10.5/22), and PNLW (9.0/20) as the lowest.

The MSW pattern's superior performance reflects the impact of dedicated design for vehicular arrivals, which often includes better-maintained sidewalks, clearly defined access routes, and lower congestion levels near destinations. Although the parking facility conditions of Manner Coffee and Hong Zi Ji are quite different, both offer smooth transitions from the parking areas to the entrance and minimal pedestrian conflict zone. Therefore, their PCS do not show significant differences either. This challenges conventional assumptions about parking's role in pedestrian comfort.

In contrast, PSW destinations, despite benefitting from public infrastructure, frequently suffer from overcrowding, bottlenecks near transit exits, and unmanaged queuing, which compromise comfort. While locations like Shen Da Cheng and Ren He performed reasonably well due to integrated exits and escalators, many PSW restaurants scored poorly on pedestrian flow and queue encroachment.

The PNLW group scored the lowest overall, showing the greatest variance. These areas tend to lack formal pedestrian facilities, rely on mixed-use streets shared with bicycles and scooters, and are less supported by municipal planning. Locations like Chang Fa and Wan Shou Zhai showed severe deficits in sidewalk condition, traffic mixing, and overall accessibility.

This pattern suggests that, in practice, pedestrian comfort does not automatically correlate with proximity to transit or active mobility infrastructure. Instead, purpose-built vehicle access or well maintained side walk—when paired with clear pedestrian design—can offer unexpectedly high comfort. The MSW data particularly highlights crumbling sidewalks' psychological impact on drivers-turned-pedestrians.

5.2 Key Indicators Influencing Comfort

Across all access patterns, sidewalk quality remained the single most influential determinant of pedestrian comfort. Restaurants with wide, well-maintained walkways—such as BASDBAN (PNLW), Shen Da Cheng (PSW), and Manner Coffee (MSW)—consistently scored higher in total PCS. This underscores the foundational role of physical walking space in perceived comfort, supporting earlier studies that emphasize the need for uninterrupted and navigable pathways.

In MSW environments, traffic separation and controlled pedestrian access helped reduce conflict. Many locations featured independent parking lots, clearly demarcated walking routes, and dedicated waiting areas, improving safety and spatial clarity. While traditionally seen as car-oriented and hostile to pedestrians, when benchmarked against PSW (11.5/22) and PNLW (9.0/20) patterns from prior studies, this positions MSW as neither superior nor inferior, but distinctly different in its comfort determinants. The MSW zones can achieve high comfort when pedestrian access is intentionally designed and carefully integrated with transportation systems

Conversely, in PSW pattern restaurant, pedestrian-electric scooter mixing and queue encroachment were common problems. Restaurants near busy metro stations often struggled with overlapping pedestrian streams, particularly where escalators were absent or exit times were long. Although these areas benefit from public infrastructure, poor micro-scale spatial planning appears to negate the walkability advantages typically associated with transit zones.

PNLW destinations, while more organically integrated with surrounding neighborhoods, lacked investment in street quality, often displaying broken pavements, encroaching electric scooters, and weak signage. The unmanaged interface between pedestrian and non-motorized traffic contributes significantly to discomfort in these locations.

5.3 Environmental & Behavioral Factors

Beyond physical infrastructure, the study also reveals the importance of spatial programming and aesthetic quality in pedestrian comfort. MSW destinations benefited from clear access flow and often had lower pedestrian density, reducing psychological and spatial stress. Manner Coffee, despite being in a vehicle-oriented area, achieved one of the highest comfort scores due to clean, clearly defined paths and attractive surroundings.

PSW destinations experienced congestion-induced discomfort, particularly in areas without escalators or wayfinding tools. While Xian De Lai and Ren He maintained decent scores through efficient layouts, restaurants like Lai Lai and Wang Jia Sha struggled due to high pedestrian overlap and limited waiting zones.

In all patterns, attractiveness—referring to visual interest, urban greenery, or engaging storefronts—played a supportive but not decisive role. Locations with higher attractiveness scores (e.g., OPS CAFÉ, Hong Zi Ji) tended to be more favorably rated overall, suggesting a synergistic effect between visual quality and functional infrastructure.

Behavioral patterns such as queuing spillover, temporary obstructions, and sidewalk vending also impacted comfort. These issues were particularly prevalent in PNLW and PSW zones, where space is more contested. This underscores the need for micro-level pedestrian management, including buffer zones, signage, and crowd channeling.

This study reveals a surprising reversal of conventional assumptions: motorized access patterns (MSW) currently provide the highest level of pedestrian comfort in Shanghai's popular restaurant areas, primarily due to intentional spatial design, clear vehicular-pedestrian separation, and lower density conflict zones. In contrast, public transit-linked (PSW) and non-motorized (PNLW) access patterns, often promoted for their sustainability, suffer from crowding, poor micro-scale design, and limited infrastructural support.

Ultimately, while promoting sustainable mobility remains essential, this study suggests that true pedestrian comfort requires attention to spatial design details across all modes—not just mode choice itself.

6. Conclusion

This study provides a comprehensive assessment of pedestrian comfort and urban mobility in Shanghai's commercial restaurant hubs. By combining navigation data and other online GIS data, spatial audits, and text analysis, it offers a multi-modal perspective on pedestrian comfort in high-footfall areas.

By categorizing pedestrian access patterns into three modes—Public transportation + short distance walk (PSW), Public transportation + short distance walk (PSW), and Motorized vehicle + short distance walk (MSW)—the research offered a comparative analysis of pedestrian comfort using a detailed spatial audit framework. Incorporating both physical observation and quantified evaluation, the study contributes to a more nuanced understanding of how infrastructural, behavioral, and environmental factors shape pedestrian comfort in dense commercial zones.

Contrary to conventional assumptions that prioritize public transit and active mobility as inherently walkable, the findings reveal that MSW destinations achieved the highest average comfort score (11.6/20), outperforming both PSW (10.5/22) and PNLW (9.0/20) patterns. This unexpected outcome highlights the importance of pedestrian-oriented spatial design, even in car-accessible areas. In particular, MSW locations benefitted from wider sidewalks, reduced traffic mixing, and clearer pedestrian channeling from parking areas to restaurant entrances.

In contrast, PSW areas—despite being linked to sustainable transportation—often suffered from congestion, poor queue management, and inadequate vertical circulation infrastructure near transit hubs. While transit integration offered some advantages, these were frequently offset by high density and poorly managed transitions. PNLW zones exhibited the greatest variability in comfort, largely influenced by local sidewalk quality, vehicle encroachment, and inconsistent traffic control. These findings suggest that mode of access alone does not guarantee a comfortable pedestrian experience; rather, comfort is the result of deliberate design, clear separation of movement modes, and effective micro-level planning.

Several key factors emerged as strong predictors of pedestrian comfort: sidewalk width and maintenance, level of pedestrian-vehicle interaction, and the presence of guiding infrastructure, such as signage, shading, and waiting areas. While attractiveness and environmental aesthetics played a complementary role, they were less influential than core infrastructural elements in determining overall PCS.

This study also demonstrates the methodological value of combining spatial audits with mode-specific criteria, allowing for context-sensitive assessments of pedestrian environments. The hybrid framework developed here—drawing from observational data and structured scoring—can be replicated in other urban contexts to evaluate the effectiveness of pedestrian planning strategies. The relevant high-frequency words that appear in the posts and comments on Xiaohongshu also provide qualitative evidence for the assessment of pedestrian comfort through text analysis.

From a policy perspective, the findings advocate for a shift in focus from mode-centric planning to experience-centric design. Urban designers and transportation planners should prioritize interventions that enhance micro-scale pedestrian experiences, particularly in areas surrounding popular destinations with mixed arrival patterns. By addressing sidewalk continuity, traffic separation, and flow organization, cities can create walkable environments that are not only sustainable in function but also inclusive and comfortable in form.
While this study yields significant findings, several methodological limitations must be acknowledged. Primarily, the geographic scope is confined to Shanghai's inner-ring area, potentially limiting the generalizability of results. Additionally, the analysis does not incorporate comparative assessments during off-peak periods, and may be subject to cultural specificity in pedestrian comfort perceptions.

Future research could extend this study by incorporating real-time pedestrian behavior data, expanding the sample size, or comparing multiple cities to further validate the framework. As cities evolve toward more complex and multi-modal urban forms, understanding the qualitative dimensions of walking will be critical in shaping equitable and livable public spaces.

Abstract
This study presents a methodology for evaluating pedestrian accessibility within the 15-minute city framework, focusing on Istanbul's Küçükçekmece district. By integrating spatial clustering, slope-adjusted walking speeds, and categorized point-of-interest (POI) data, the study assesses accessibility across 15-, 20-, and 25-minute intervals. The Mean Shift algorithm identified 42 urban clusters based on building density. The findings show that while 71.5% of the district is accessible within 15 minutes, significant spatial inequalities remain, especially in cultural facility access in peripheral neighborhoods. High-density areas with irregular urban forms exhibit limited internal connectivity, which reduces walkability. The study highlights the need for inclusive planning in underserved areas and provides a framework for promoting equitable, resilient, and pedestrian-friendly urban development.

Keywords: 15-Minute Cities; Accessibility; GIS; Machine Learning; Performance Metrics

1. Introduction

Modern cities have faced a multitude of complex challenges, ranging from growing social inequalities and economic instability to pressing environmental concerns such as climate change and resource depletion. To address social, economic, and environmental challenges, various planning principles have been adopted, including livable, inclusive, sustainable, and walkable designs that prioritize accessibility and active mobility (Akrami, Sliwa, and Rynning, 2024). In recent times, the world has faced two significant challanges: the COVID-19 pandemic and the growing climate crisis. These events have significantly reshaped urban priorities, prompting cities to reevaluate how space, mobility, and public health are intertwined. As a result, urban areas are increasingly committed to fostering healthy, resilient, and equitable environments (Liu, Kwan, and Wang, 2023). Amid this backdrop, Professor Carlos Moreno introduced the concept of the "15-minute city" in 2016. This innovative concept seeks to establish self-sufficient areas that encompass essential functions for humans, including living, working, commerce, healthcare, education, and entertainment (Khavarian-Garmsir, Sharifi and Sadeghi, 2022).

This approach is designed to create mixed-use, densely populated, and pedestrian-friendly neighborhoods, allowing residents to access all essential amenities within a 15-minute walk. Additionally, the concept of the 15-minute city is grounded in chrono-urbanism, which posits that the quality of urban life diminishes as the time spent on transportation increases (Moreno et al., 2021). The novel concept aims to enhance transportation efficiency, reduce automobile-related pollution, and transform urban environments so that residents can access essential services and facilities within a designated time frame (Olivari et al., 2023). Additionally, the concept of the 15-minute city is built on four pillars that address various issues, resulting in improvements to both human well-being and urban resilience: proximity, density, diversity, and digitalization (Moreno et al., 2021).

The 15-minute city concept seeks to create urban environments that are mixed-use, livable, sustainable, and pedestrian-friendly (Allam et al., 2024). Since its introduction in 2016, this innovative urban model has sparked ongoing studies and debates, resulting in a continually evolving definition and scope. The effective implementation of the 15-minute city largely depends on the spatial characteristics, as well as the social, environmental, and economic dimensions of each specific urban area. As a result, various adaptations have emerged, leading to the development of cities centered around different time thresholds, collectively referred to as the "x-minute city" concept (Logan et al., 2022). For instance, there have been numerous implementations and studies related to time-based urban models across different cities: the 1-minute city in Stockholm (Schwimmer and Schaufler, 2023), the 5-minute city in Copenhagen (State of Green, 2016), the 10-minute city in Stavanger (Kesarovski and Hernández-Palacio, 2022), the 15-minute city in Milan (Abdelfattah, Deponte, and Fossa, 2022a), the 20-minute city in Tempe, Arizona (Da Silva, King, and Lemar, 2019), and the 30-minute city in Montreal (Birkenfeld et al., 2023).

The literature presents a range of approaches to evaluating accessibility in time-based urban areas. For instance, Staricco (2022) conducted a study in Turin that measured pedestrian accessibility within 5-, 10-, and 15-minute intervals. However, this study focused solely on the number of accessible facilities and did not implement a categorical classification of services. In contrast, another study introduced a categorical framework, grouping facilities into six categories: groceries, healthcare, education, recreation, services, and public transport. This systematic approach aimed to assess accessibility and identify spatial inequalities. Furthermore, this research proposed an innovative index to evaluate the 15-minute city concept, emphasizing the importance of considering a broader spectrum of urban opportunities and addressing the varied needs of populations with different social identities (Guzman, Oviedo, and Cantillo-Garcia, 2024). Additionally, Pour and Partanen (2024) conducted a two-level spatial analysis to examine Tallinn's alignment with the principles of a 15-minute city. The first level focused on population distribution, transport infrastructure, and access to essential services, while the second level identified suitable areas for urban expansion using land use/land cover data, a digital elevation model (DEM), and proximity analysis. Similarly, Ferrer-Ortiz et al. (2022) carried out a network-based accessibility analysis using cadastral parcels, classifying urban social functions into five main categories: care, education, provisioning, entertainment, and public/non-motorized transportation.

Numerous studies have examined accessibility analysis within the context of the 15-minute city concept. Nevertheless, there remains a notable gap in comprehensive and realistic assessments of pedestrian accessibility that account for topographical conditions. Furthermore, defining the spatial structure and layout of the 15-minute city poses a significant challenge for its practical implementation in varying urban contexts. This research aims to address two fundamental questions: a) how to develop appropriate 15-minute zones within already constructed areas, and b) how accessibility varies under different topographical conditions across various time intervals. To accomplish this, the study will evaluate the performance of 15-minute city zones through the application of spatial and machine learning techniques. In the first stage, points of interest (POI) data for various facilities were gathered using the Google Maps Platform Places API and categorized into ten groups to address daily needs. The second stage assessed accessibility based on topographical conditions by utilizing a Digital Elevation Model (DEM) and road network data from OpenStreetMap (OSM) through zonal analysis. The third stage involved obtaining building footprint data from the Humanitarian OpenStreetMap Team (HOT) and applying the Mean Shift clustering algorithm to identify potential 15-minute accessibility zones, with hyperparameter tuning to ensure accuracy. Finally, the fourth stage conducted accessibility analyses over three-time intervals—15, 20, and 25 minutes—and compared the results.

2. Data and Methodology

This study consisted of four steps: a) pre-processing input data, b) clustering of buildings, c) accessibility analysis for three different time intervals, and d) evaluation of accessibility results.

2.1. Study Area

This study examines the Küçükçekmece district of Istanbul to assess the 15-minute city concept, taking into account the district's active participation in related projects. Küçükçekmece is situated in the southwestern part of Istanbul, on the European side, and is approximately 15 km from the city's historical center. The district spans an area of 37.75 km² and is home to a population of 792,030, resulting in a population density of about 17,600 people per square kilometer (Endeksa, 2025). This high density is evident from land cover analysis. Based on land cover data from Esri (ESRI, 2025) for 2023, the land use in Küçükçekmece is diverse, but predominantly urban. Residential areas account for 93% of the district's total land use, highlighting its highly urbanized and densely populated character. Agricultural land comprises 3%, while forested areas make up only 2%, indicating a significant reduction in rural and natural spaces. Furthermore, green spaces constitute just 1% of the total land area, underscoring the limited amount of public open space and the relatively low share of greenery per capita. Bare ground is virtually nonexistent at 0%, with other land uses representing the remaining 1%. This suggests that nearly all available land has been developed, primarily for residential and urban purposes.

2.2. System Architecture

The system architecture is shown in Figure 1 and consists of four essential steps: pre-processing, clustering, accessibility analysis, and evaluating results. Each step is briefly explained below.

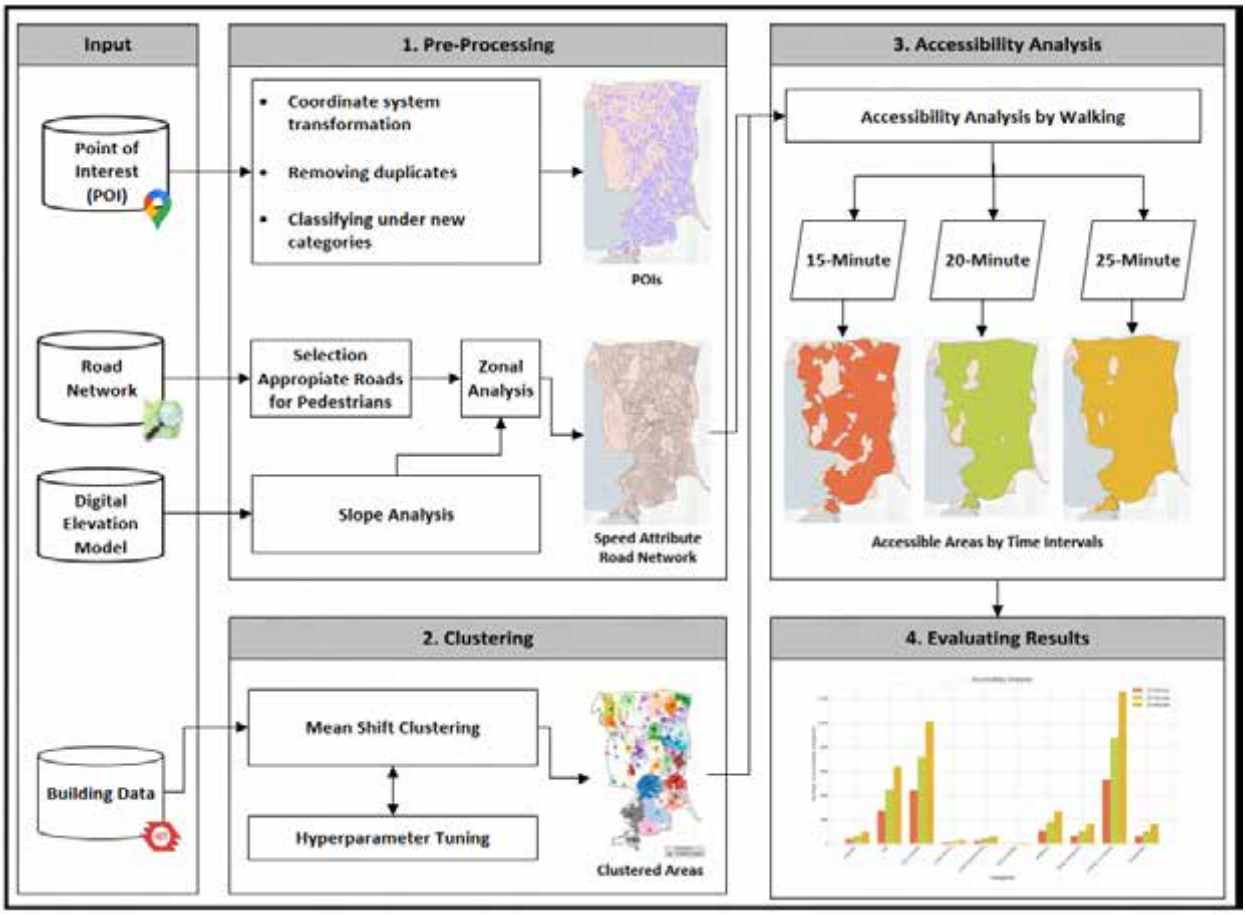

Figure 1. The proposed framework for evaluating 15-minute city concept.

To initiate the analysis, data is gathered from a diverse range of sources, including both open-source repositories and commercial mapping service. Initially, POI data, which covers various types of facilities, is sourced from the Google Maps Platform Places API, a commercial repository. This API offers detailed location information, and for this study, it is utilized within the constraints of its free data request allowance (Google Maps Platform, 2025). For the accessibility analysis, the road network constitutes another crucial dataset. In this research, road data is obtained from the well-regarded open-data platform, OSM (Geofabrik, 2025). To assess variations in walking speed in sloped areas, a Digital Elevation Model (DEM) is employed. The specific model utilized is the Shuttle Radar Topography Mission (SRTM) 1 Arc-Second Global data from the United States Geological Survey (USGS, 2025). Lastly, to develop clustered areas within the district for evaluating the 15-minute city concept, building data is incorporated. This data is sourced from the HOT, which updates building footprints on a monthly basis (Humanitarian Data Exchange, 2025).

2.2.1. Pre-Processing

The essential initial phase in interpreting spatial data is pre-processing. This stage involves several key steps: transforming the coordinate system, removing duplicate POIs, and classifying the retrieved data based on predefined categories. In the proposed framework, the coordinate system of the POI dataset was converted to a projected coordinate reference system, which supports metric-based calculations and is essential for accurate accessibility analysis. Due to limitations associated with the Google Maps Platform Places API, duplicate POIs may appear within the dataset. To prevent misleading results, these duplicates must be identified and

removed prior to analysis. Also, there are various approaches to assess accessibility based on categories. One of these was developed by Prof. Dr. Carlos Moreno in 2021, encompassing six categories: living, working, commerce, healthcare, education, and entertainment (Moreno et al., 2021). In another study, nine categories were determined namely food/grocery stores, commercial stores, cultural venues, educational facilities, parks and green spaces, restaurants, health facilities, sports facilities and other (Abdelfattah, Deponte and Fossa, 2022b). Moreover, according to Regulation on the Preparation of Spatial Plans of Türkiye (Official Gazette, No. 29030), some spatial areas are defined such as small industrial areas, cultural areas, social infrastructure areas, and social facility areas. Hence, within this study, in order to cover all relevant aspects of daily urban life and align with both international and national frameworks, a customized categorization scheme was developed. This classification integrates widely accepted categories from the literature with those defined in national planning regulations.

Moreover, slope is an important factor on pedestrian accessibility. Sloping walkways tend to diminish pedestrian flow performance compared to level surfaces (Wei et al., 2023). Considering DEM in accessibility analysis is essential. However, there is a notable gap in the literature regarding the use of DEM for assessing accessibility within the 15-minute city concept. To address this shortcoming, the present study incorporates slope information derived from a DEM to adjust walking speeds throughout the road network. This adjustment enables the analysis to account for the effects of terrain variations on walking accessibility, resulting in a more accurate representation of areas that can be reached within designated time thresholds. This approach not only enhances the methodological rigor of evaluations related to the 15-minute city but also introduces topographic realism into pedestrian accessibility modelling.

2.2.2. Clustering

The study employs the Mean Shift clustering algorithm, a popular machine learning technique that is also used in spatial clustering applications (Chen et al., 2018; Peng et al., 2024). This clustering algorithm is introduced by Fukunaga and Hostetler in 1975 (Fukunaga and Hostetler, 1975). Mean Shift clustering is an unsupervised learning algorithm that organizes data according to its natural distribution. One of its most notable characteristics is that it does not require any prior knowledge of the number or positions of the cluster centers. Furthermore, Mean Shift imposes no assumptions about the shape of the clusters and places no restrictions on their size (Tehreem et al., 2017). The study clusters building data using the Mean Shift algorithm and applies hyperparameter tuning to optimally identify clustered areas based on building density.

2.2.3. Accessibility Analysis

The concept of the 15-minute city encompasses several time-based proximity approaches. Initially proposed by Prof. Dr. Carlos Moreno in 2016, this framework seeks to enhance walkability and develop pedestrian-friendly neighborhoods. Since its introduction, various time-oriented strategies such as 15, 20, and 30 minutes have been implemented across different regions to further this objective (Giuffrida et al., 2024). Overall, the policy directions related to this concept are inconsistent across thematic areas and geographic regions (Lu and Diab, 2022).

The built-up surface per capita is 13 m^2/capita in Küçükçekmece resulting high density and compact city (OECD Local Data Portal, 2020). This study analyzes pedestrian accessibility by examining three walking time intervals for clustered areas with varying building densities: 15, 20, and 25 minutes. These intervals are utilized to define the spatial reach of services and amenities from the centers of clusters identified through the Mean Shift algorithm. The cluster centers represent the most densely developed areas within the study region and serve as potential focal points for urban activity. By creating service areas around these centers for each time threshold, the study seeks to quantify how far individuals can walk within the specified time frames and to assess the distribution and coverage of accessible urban functions in relation to population density.

2.2.4. Evaluation of Results

In this step, pedestrian accessibility results for various time intervals, 15, 20, and 25 minutes, are assessed and compared to provide insights into how accessibility levels shift with walking time. The analysis aims to highlight differences in the spatial extent of reachable areas from each cluster center and examines how these variations correspond to the distribution of urban amenities. In addition to this comparative evaluation, special emphasis is placed on outlier areas—locations that significantly fall outside the primary clustered accessibility zones.

These outliers are analyzed to identify spatial mismatches, underserved regions, or peripheral zones with limited access to urban functions. The recognition of such areas is essential for uncovering potential gaps in service provision and informing equitable urban planning strategies.

3. Results and Discussion

3.1. Pre-Processing

In this step, walking accessibility is evaluated by pre-processing the collected spatial data from various perspectives. Initially, the coordinate system of POI dataset is transformed to a projected coordinate reference system (EPSG:5254) to ensure necessary metric-based spatial accuracy for accessibility analyses. Subsequently, duplicate POIs are removed to eliminate any potential skewing or misleading outcomes in the accessibility results. The POI dataset, which originally contained a range of labels such as "bank," "police," "food," and "supermarket," is reclassified according to a system developed for assessing 15-minute cities. A refined classification system comprising ten thematic categories is utilized, reflecting essential components of daily urban life: education, food, daily essentials, public services, small industrial areas, cultural facilities, healthcare services, social infrastructure, commerce & economy, and transportation. Each category is considered crucial for fostering a well-rounded and accessible urban environment. In the Table 1, POI labels for defined categories are given.

Table 1. Defined categories and belonging POI labels.

Categories	POI Labels
Education	primary_school, school, secondary_school, university
Food	supermarket, bakery, convenience_store, food, grocery_or_supermarket, liquor_store
Daily essentials	shoe_store, restaurant, parking, meal_takeaway, meal_delivery, laundry, hair_care, atm, beauty_salon, clothing_store, gas_station
Public services	post_office, police, local_government_office, city_hall, courthouse, fire_station, lawyer
Small industrial areas	*These category is evaluated manually from POI data.*
Cultural facilities	library, movie_theater, museum
Healthcare services	veterinary_care, physiotherapist, dentist, doctor, drugstore, health, hospital, pharmacy
Social infrastructure	stadium, spa, premise, place_of_worship, park, night_club, mosque, amusement_park, aquarium, gym, lodging
Commerce & Economy	store, shopping_mall, roofing_contractor, real_estate_agency, plumber, pet_store, painter, locksmith, jewelry_store, insurance_agency, home_goods, hardware, general_contractor, furniture_store, finance, electronics_store, electrician, department_store, accounting, bank, bar, bicycle_store, book_store, cafe
Transportation	taxi_stand, train_station, transit_station

In the second step, a DEM was used to improve the accuracy of accessibility measurements by incorporating topographic features. Firstly, the appropriate roads for pedestrians were selected from road dataset. Specifically, slope values for the Küçükçekmece district were extracted from the DEM. These slope values were then integrated with the road network through zonal analysis, creating a slope-attributed road dataset where each segment reflects its corresponding gradient. According to Giannoulaki and Christoforou (2024), the average walking speeds for males and females in Türkiye are 1.34 m/s and 1.27 m/s, respectively. For this study, an average walking speed of 1.31 m/s was utilized to represent the general population.

By combining this standardized walking speed with the slope information for each road segment, adjusted walking speeds were calculated, allowing for a more accurate modelling of pedestrian accessibility across varying terrain conditions.

3.2. Clustering

In the proposed assessment system for a 15-minute city, the Mean Shift clustering algorithm is used to categorize buildings based on their densities and analyse potential areas for the 15-minute city. To do that, building footprint dataset is utilized in Mean Shift clustering algorithm. In the Mean Shift clustering algorithm, the bandwidth parameter is essential for determining the results of clustering. It defines the kernel radius used to estimate data density, which influences the number, size, and shape of the clusters formed. A larger bandwidth results in fewer, broader clusters, while a smaller bandwidth creates more, smaller clusters that capture local variations in the data. To determine the appropriate bandwidth value for the Mean Shift algorithm, hyperparameter tuning was conducted by evaluating both quantitative metrics and visual interpretations of the resulting clusters. Although slightly higher Silhouette scores were observed with alternative bandwidth settings, a bandwidth defined by a quantile value of 0.02 and 300 samples was ultimately selected, yielding a Silhouette score of 0.38. This configuration was preferred because it provided a good balance between cluster compactness and spatial interpretability, ensuring that the identified clusters aligned well with the underlying built environment and urban density patterns. As a result of this hyperparameter selection, a total of 42 clusters were generated. In the Figure 2, the clustered buildings and cluster centers are presented.

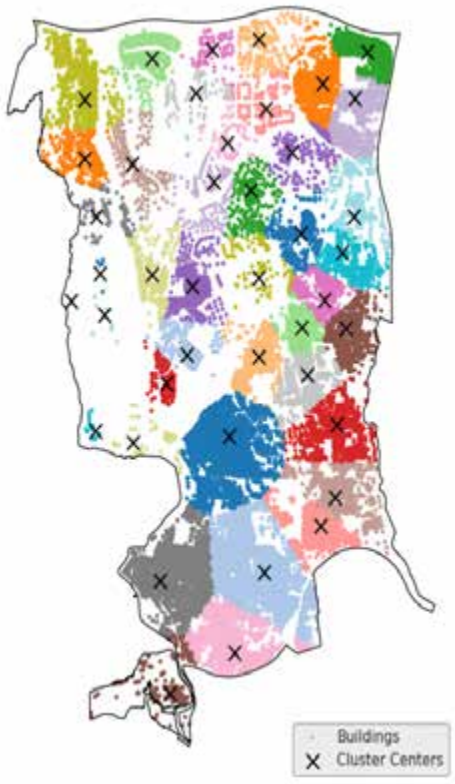

Figure 2. Clustered buildings and cluster centers.

It has been noted that the southern part of the study area has developed through unplanned and irregular urbanization. In this region, residential density has increased in a fragmented and uncontrolled manner, resulting in a significant decline in the continuity and accessibility of green spaces. Conversely, the north-western part of the study area displays a more organized urban layout, where the balance between green spaces and built-up areas has been preserved through careful planning. This spatial contrast is clearly reflected in the Mean Shift clustering results. As illustrated in Figure 2, clusters in the planned areas are smaller and more compact, while those in regions affected by irregular urbanization are larger and more dispersed. This observation underscores a strong correlation between unplanned urban sprawl and building density, a relationship further confirmed

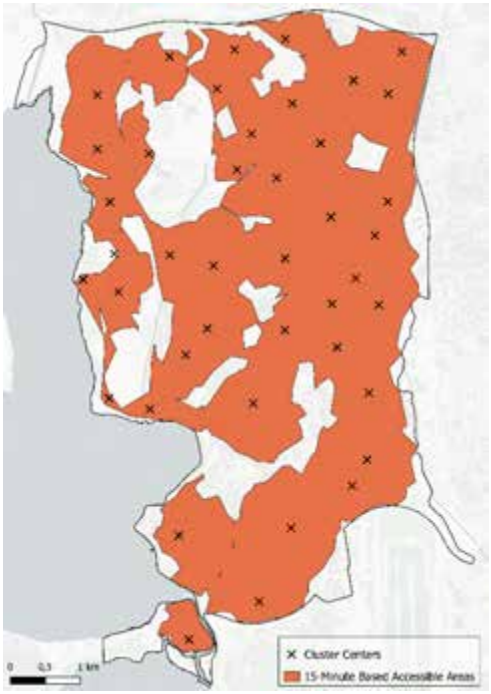
by the Mean Shift clustering analysis. Figure 3 presents a comparative example of high- and low-density urban zones within the study area. Moreover, it has been observed that the data sourced from the HOT does not entirely capture ground realities. When compared to actual field conditions, certain areas lack complete building footprints or contain outdated information.

a) Southern side of the study area. **b)** North-western side of the study area.

Figure 3. Clustering results from urban layout: (a) urban area with high building density, (b) urban area with low building density (yellow crosses indicates cluster centers).

3.3. Accessibility Analysis

This study examines accessibility in the Küçükçekmece district by analyzing designated cluster centers and utilizing a modified road network that reflects variations in walking speed due to slope data. The objective of the analysis is to determine the spatial reach of areas accessible on foot within specific timeframes. The findings reveal that approximately 71.5% of the district can be accessed within a 15-minute walking distance, 85.5% within 20 minutes, and 91.6% within 25 minutes. These results indicate that a significant portion of Küçükçekmece lies within walking distance of the identified urban clusters, reinforcing the viability of the 15-minute city concept in certain areas of the district. These results are shown in Figure 4.



a) 15-minute based accessible areas.

b) 20-minute based accessible areas.

c) 25-minute based accessible areas.

Figure 4. 15-,20- and 25-minute based accessible areas.

When examining accessibility from a comprehensive perspective, it becomes clear that the north-western portion of the study area—comprised of planned residential neighborhoods with a balanced distribution of green spaces and buildings—remains partially inaccessible, despite its proximity to major arterial roads. This inaccessibility can be attributed to the design of these areas as enclosed systems surrounded by major thoroughfares, which results in a lack of pedestrian-friendly internal connectivity. In the southern parts of the district, characterized by significantly higher building density, the algorithm encounters difficulties in identifying an adequate number of cluster centers. As a result, despite the high residential density and substantial pedestrian potential, these areas cannot be reached within a 15-minute walking threshold. The 20-minute analysis reveals an expansion in overall accessibility, owing to the extended walking time. However, certain regions—particularly newly developed neighborhoods and high-density residential zones—remain unreachable because of their distance from the identified cluster centers and the limited pedestrian infrastructure available. The 25-minute analysis demonstrates that a considerable portion of the district becomes accessible. Nevertheless, areas without any development, especially in the north-eastern part, continue to lack pedestrian access and remain unreachable in all time-based scenarios. Moreover, across all analyses, it is observed that accessibility improves in regions with steep terrain as the time threshold increases. However, during the 15-minute interval, these high-slope areas remain notably less accessible. Overall, the findings underscore that construction sites and enclosed residential complexes in the north-western part of the study area face significant challenges regarding pedestrian accessibility, highlighting their unfavorable position within the urban landscape.

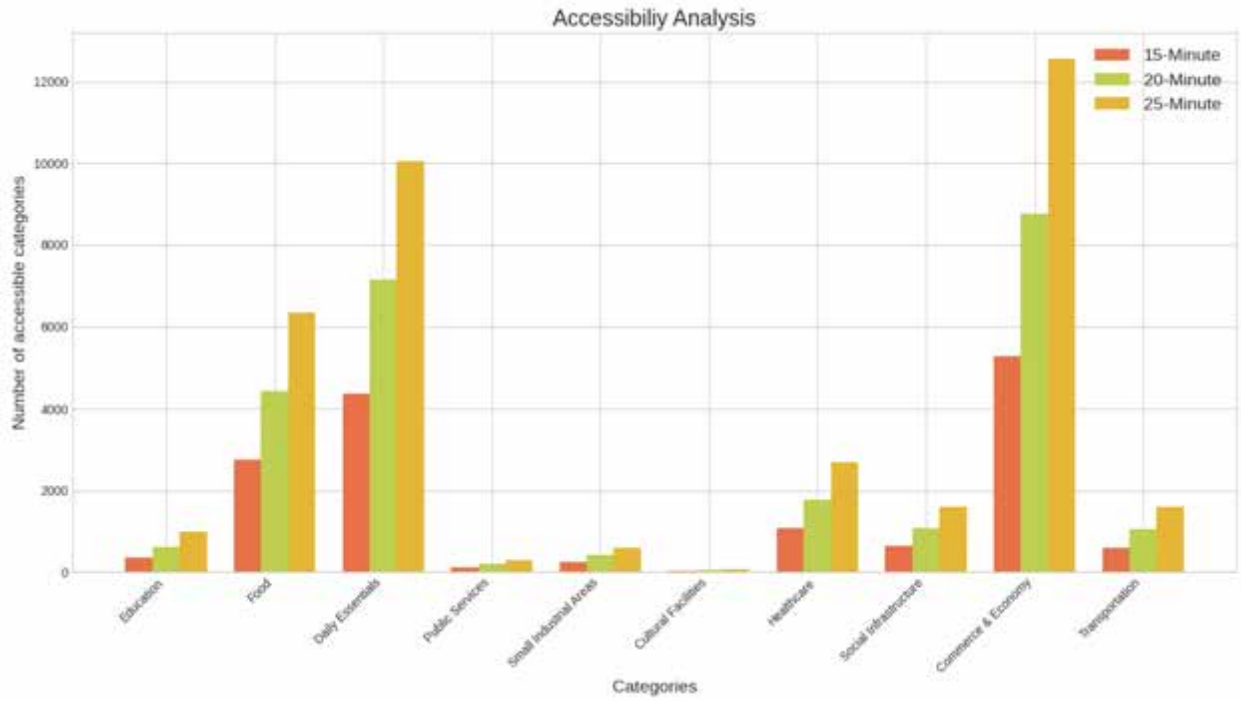


Figure 5. Number of accessible categories regarding to different time-based intervals.

As depicted in Figure 5, the number of accessible facilities increases considerably as walking time expands. This trend is particularly evident in categories such as daily essentials, food, and commerce and economy. For instance, there are 4,368 facilities reachable within 15 minutes, which escalates to 10,047 within 25 minutes, indicating a relatively well-distributed supply of these services across the district. In contrast, categories like public services and, more notably, cultural facilities demonstrate low levels of accessibility. Cultural facilities consistently rank the lowest in accessibility across all time intervals, with only 27 facilities reachable within 15 minutes and just 80 within 25 minutes. This observation highlights not only the scarcity of such facilities but also their concentration in specific areas of the district. Moderate and relatively balanced accessibility patterns are found in education, healthcare, social infrastructure, and transportation. This suggests a more deliberate spatial distribution for these services. However, some deficiencies are still apparent, particularly in newly developed neighborhoods and peripheral zones of the district. Additionally, the findings reveal that accessibility levels are closely tied to

both functional distribution and urban form and morphology. While the planned and orderly developments in the north-western part of the district exhibit high pedestrian accessibility, the irregularly developed areas in the south show more limited and uneven access. This is particularly noticeable in gated communities or unplanned residential areas, which, despite having a high building density, suffer from poor internal connectivity, significantly impeding walkability within a 15-minute range.

4. Conclusion

This study offers a comprehensive methodology for assessing pedestrian accessibility within the framework of the 15-minute city concept, using the Küçükçekmece district of Istanbul as a case study. By integrating spatial clustering, elevation-based speed adjustments, and categorized POI data, the analysis effectively captures both the physical and functional aspects of accessibility in a densely populated urban environment. The findings indicate that while over 70% of the district is reachable within a 15-minute walking distance, notable spatial disparities persist across various areas and functional categories. Though services related to daily needs, food, and economic activities are fairly well-distributed, essential public services and cultural facilities remain limited in both quantity and spatial coverage. This imbalance highlights the necessity for more inclusive spatial planning to ensure equitable access to all urban functions, especially those linked to cultural participation and civic engagement. Furthermore, the study emphasizes the influence of urban form on accessibility outcomes. Well-planned and integrated areas in the north-western part of the district generally facilitate walkability, whereas fragmented and irregular developments—particularly in the southern and peripheral areas—encounter structural barriers to pedestrian movement, such as disconnected street networks and gated communities. Incorporating slope data into the accessibility model further refines the analysis by illustrating how terrain variation can significantly impact walkability, especially within shorter time thresholds. In conclusion, this research demonstrates that the 15-minute city framework is partially attainable in a high-density context like Küçükçekmece. However, to fully capitalize on its potential, Geomatics Engineers, Urban Planners and decision-makers must advocate for a more equitable distribution of public and cultural services and prioritize pedestrian-oriented urban design, particularly in high-density and newly developed areas. The methodology presented in this study can also be adapted for use in other urban settings seeking to enhance proximity-based accessibility and cultivate more resilient, inclusive, and livable cities.

The Appropriate Intensity of Rail Transit Station Area near Historic Districts: A Case Study of Shanghai, Nanjing, Kyoto and Tokyo

Xinrui Guo, Yuan Zhu
Affiliation: Southeast University
Email: 1341514159@qq.com, 104671868@qq.com

Abstract
Recent urban trends focus on integrated development around metro stations, promoting intensive, three-dimensional land use. This necessitates re-evaluating the redevelopment potential of rail transit stations area of historic districts. However, strict building height controls for urban fabric and heritage preservation challenge increasing development intensity there. Existing research lacks fine-grained quantitative studies on development intensity in such areas. This study first establishes a multi-dimensional intensity index system (building height, density, above/below-ground floor area ratio). Selecting 18 stations in historic areas of Shanghai, Nanjing, Tokyo, and Kyoto, it quantitatively analyses development intensity through multi-path comparisons. This considers precise station accessibility isochrones and spatial relationships to the historic district, aiming to identify suitable development intensity under multi-dimensional balance.

Keywords: Transit Oriented Development,Urban Rail Transport, Historical Blocks, Development Intensity.

1. Development Trends of Suitable Intensity in Historic Districts Around Transit Stations

In recent years, with the rapid development of the global economy and the acceleration of urbanization, the comprehensive development and utilization centreed around urban rail transit—particularly the integration of transit stations and their surrounding areas—has become a significant trend in urban development. This trend is driving transit station areas toward more intensive, three-dimensional, and integrated development. Concurrently, re-evaluating the redevelopment potential of rail transit stations area of historic districts is imperative. However, due to the requirements for preserving the urban fabric and historical landscape, construction and development in these historic districts face strict controls on building heights, posing challenges to enhancing the development intensity around rail transit stations.

Existing studies on the renewal and protection of historic districts around transit stations predominantly focus on directional strategies prioritizing preservation, with limited quantitative analysis. Research on the development intensity of station area spaces has primarily addressed specific planning measures and implementation steps, while the conceptualization of development intensity itself has seen scholars globally explore multi-indicator frameworks to comprehensively assess it. These frameworks often categorize and regulate development based on station hierarchy, types, and spatial layers (e.g., concentric zones). Such approaches provide a reference for this study's subsequent investigation into influencing factors and relationships among indicators of development intensity. In the field of historic district construction and utilization, Western countries began exploring floor area ratio (FAR) transfer or incentive mechanisms as early as the 20th century, while many Chinese cities initiated similar explorations after 2000. However, quantitative studies from the perspective of "suitable intensity" remain scarce, particularly lacking a refined synthesis of the impacts of rail transit stations and historic districts.

This paper addresses the inherent tension between development and preservation in historic districts around rail transit stations. Drawing on case studies of high-density Asian cities such as Shanghai, Nanjing, Kyoto, and Tokyo, the study constructs a multi-dimensional indicator system to measure development intensity, incorporating metrics such as building height, building density, above-ground and underground floor area ratios. By integrating statistical methods with GIS spatial analysis, the research conducts multidimensional comparative analyses of the compiled data to quantitatively identify patterns and regularities in the distribution of development intensity across intra-urban contexts, inter-city comparisons, and different developmental timelines within historic districts adjacent to rail transit stations.

2.. From Unidimensional Indicators to Indicator Clusters

2.1 Concept of Suitable Intensity

In historic districts, the development intensity of rail transit stations is primarily influenced by two factors: first, the constraints imposed by heritage protection planning, which mandates strict adherence to regulatory requirements. Development intensity must be controlled through regulations on building height, volume, and spatial form to maintain the integrity of the heritage character. Second, the surrounding areas of transit stations, due to the agglomeration effect of rail transit, possess higher development potential. Thus, this study defines the "suitable intensity" of station area spaces in historic districts adjacent to rail transit stations as a concept that integrates the impacts of both the historic district and the transit station's influence zone. The term "suitability" here refers to a framework centreed on rail transit stations, ensuring the protection of historical heritage integrity while simultaneously balancing the development potential of land parcels and the reasonable utilization of economic efficiency. The core connotation lies in establishing refined, parcel-specific construction intensity control standards tailored to the functional positioning and spatial characteristics of different zones, thereby achieving synergistic optimization between heritage conservation and urban development value.

Based on existing studies, the urban space within a 5-minute walking time (approximately 200 meters) from a transit station has been identified as the area most directly influencing pedestrian behaviour. The 10-minute walking radius (approximately 400–500 meters) is recognized as the reasonable walking range and is defined as the direct influence zone, where the station exerts the most immediate impact on land development intensity. Therefore, this study delineates the 5-minute walking isochrone as the core zone and the 10-minute walking isochrone as the influence zone. The research focuses specifically on metro stations where historic districts overlap with the 10-minute walking isochrone, with the study scope encompassing all land parcels within this 10-minute isochrone boundary.

2..2. Construction of Indicator Clusters

Previous studies have predominantly used floor area ratio (FAR) as the primary metric to assess land development intensity. However, in historic districts, development must balance the preservation of unified urban heritage character with compliance to local planning regulations, where underground space development has emerged as a critical direction. Simultaneously, building density and building height are key determinants of architectural spatial form, collectively influencing FAR. Therefore, this study constructs a comprehensive indicator cluster by integrating maximum building height, building density, above-ground FAR, and underground FAR to holistically measure land development intensity.

Land parcels within historic districts must adhere to stringent heritage control requirements. Based on the protective planning frameworks of respective cities, this study categorizes parcels into three hierarchical zones: core conservation areas, construction control zones, and general zones. A differential scoring system (Table 1 [H]) is applied to these zones to enable fine-grained evaluation of heritage impact. This tiered mechanism allows for flexible land development potential across broader spatial scales while maintaining heritage integrity.

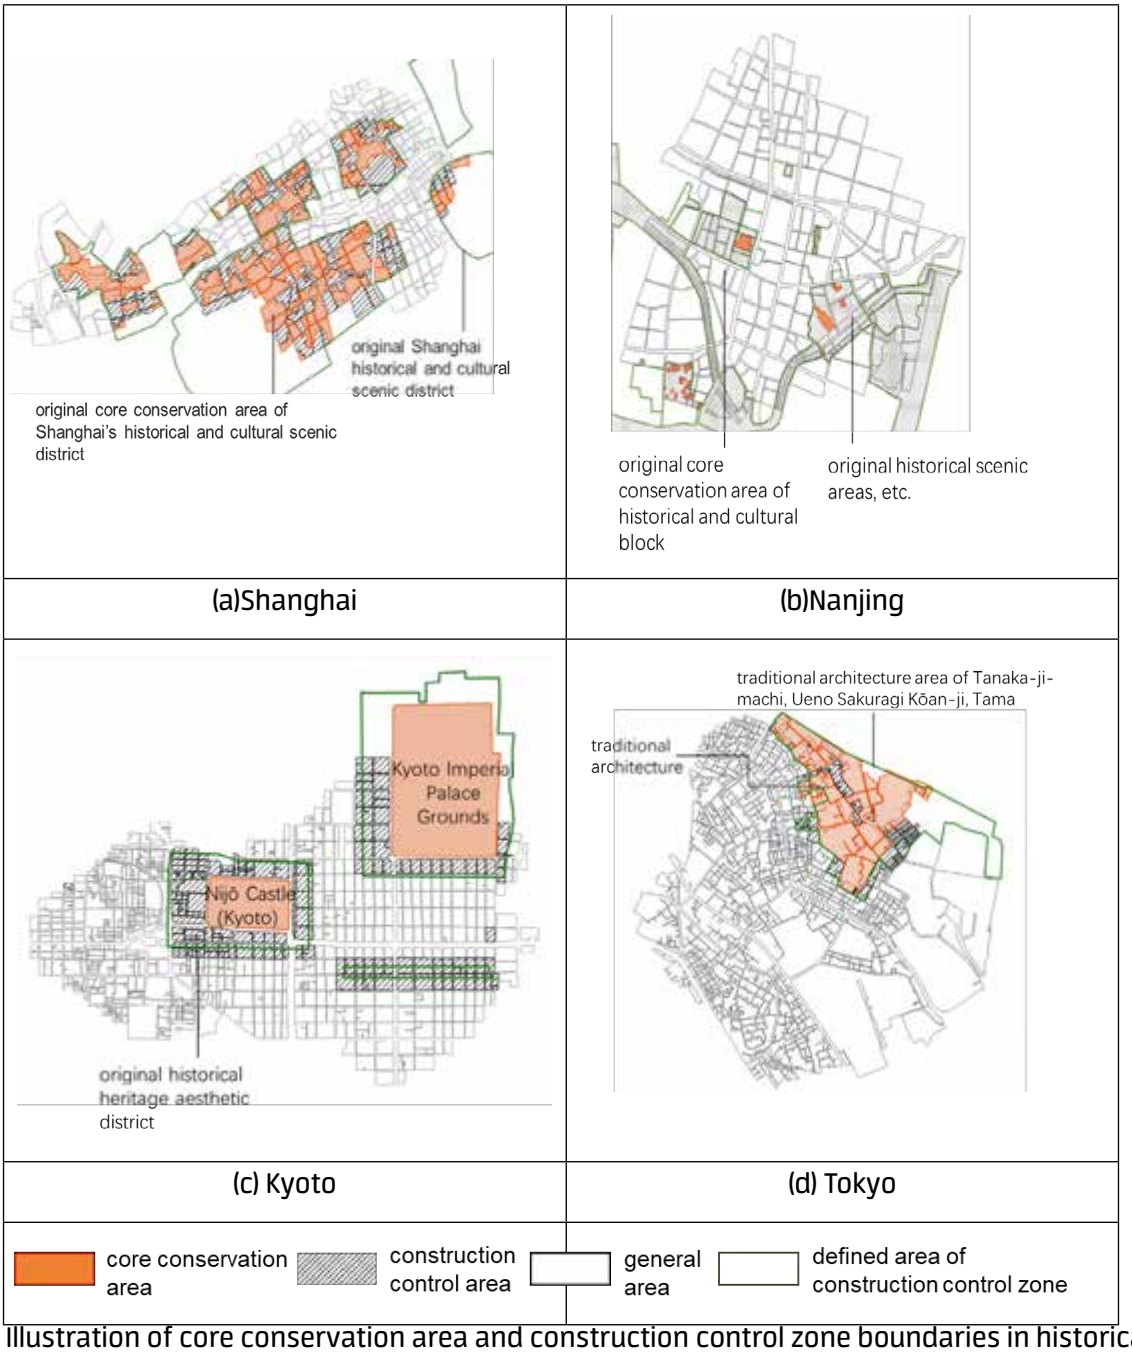

Figure 1. Illustration of core conservation area and construction control zone boundaries in historical cities.

Land parcel development intensity is closely related to both proximity to transit stations and location within heritage zones. In terms of station proximity, rail transit stations significantly influence the functional layout, transportation organisation, and land value of surrounding areas, with the magnitude of each impact correlated to distance from the station. High-intensity, mixed-use development in the core area of rail transit stations has become a societal consensus, as the station's influence intensity and spatial boundary are tightly linked to pedestrian accessibility. Based on existing research, it is generally recognized that the closer a parcel is to a station, the higher its commercial development value and development intensity tend to be. To facilitate cluster analysis in subsequent studies, the authors assigned values to 17 possible scenarios based on the isochrone layers in which the land parcels are located (Table 1 [L]).

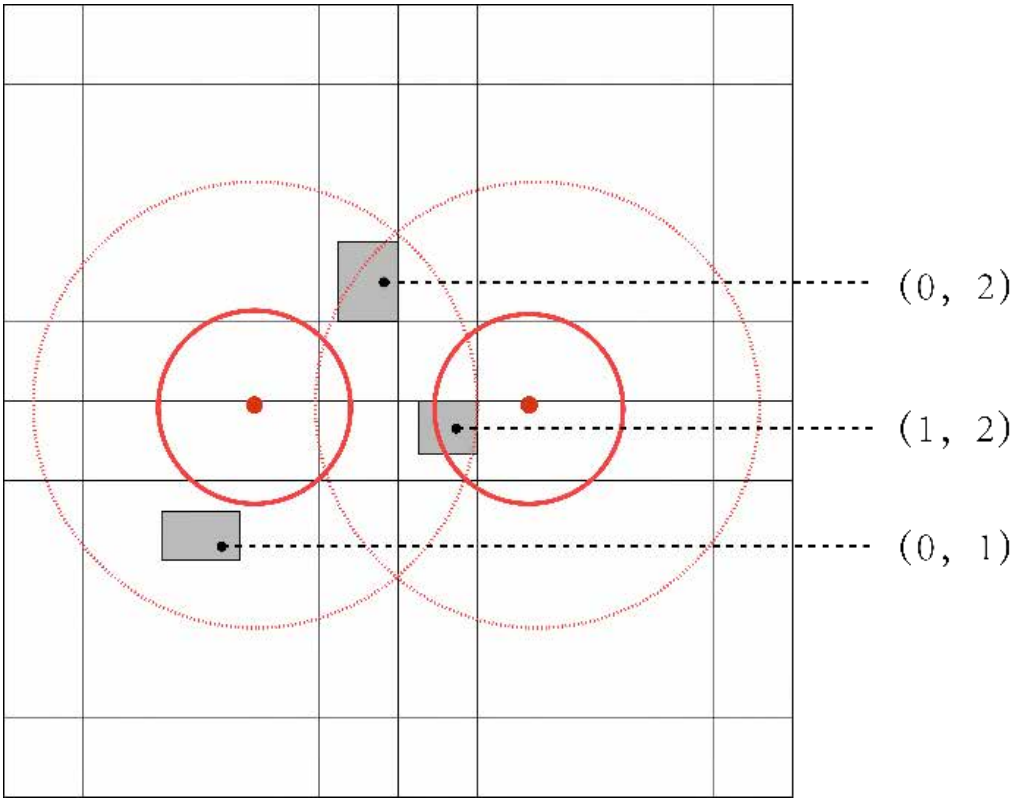

Figure 2. Labeled schematic diagram of spatial relationships between land parcels and station isochrones.

Table 1. A multidimensional indicator system for development intensity in station areas of historical districts.

Category	Specific Feature Value		Unit/Representation	Description	Data Source

3. Study Object and Methodological Framework

3.1 Study Object

This study selects Shanghai, Nanjing, Tokyo, and Kyoto as case cities due to their shared characteristics of a high-density urban context, mature rail transit systems, and representative historical district conservation practices. The station study scope focuses on central urban areas, encompassing diverse locational relationships with historical districts and varying spatial scales to enhance the specificity of case analysis.

Table 2. Selected rail transit case study sites.

City	Historic District Name	Station	Location within Historic District			Number of Transfer Lines
			Inside	Periphery	Outside	
Shanghai	People's Square Historic Cultural Area	People's Square	√			3
		Dashijie			√	2
	Nanjing West Road Historic Cultural Area	Nanjing West Road	√			3
	Hengshan Road–Fuxing Road Historic Cultural Area	Jing'an Temple		√		3
		Shaanxi South Road	√			2

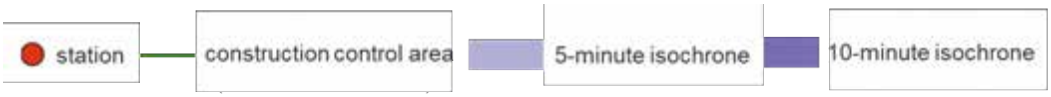

Figure 3. Study area of case study sites in various cities

3.2 Data Sources

The foundational urban data for Japanese cities in this study are sourced from the PLATEAU open data portal (https://www.mlit.go.jp/plateau/open-data/) of Japan's Ministry of Land, Infrastructure, Transport and Tourism (MLIT). For Chinese cities, building data were obtained from Baidu Maps, while plot data were derived by importing open-source road network data from OpenStreetMap into ArcGIS for segmentation. Subsequently, metrics such as floor area ratio (FAR) and building density were calculated using ArcGIS.

To account for the temporal influence of construction sequences on the suitability of land development intensity, this study utilized high-resolution satellite/aerial imagery from different historical periods to compare the architectural texture of plots. Specifically, plots exhibiting significant changes in architectural characteristics—such as building height, density, and FAR—were annotated. This enabled the classification and comparative analysis of all plots based on their periods of redevelopment. The historical aerial imagery was sourced from the Geospatial Information Authority of Japan (GSI) (https://service.gsi.go.jp/map-photos/app/), Google Maps, and the USGS Lockheed Martin (Keyhole) satellite imagery archive.

3.3 Methodological Framework

This study conducts a comparative analysis of how multi-station isochrone overlays influence development intensity distribution around historic district transit stations, primarily through the following two pathways:

Pathway 1: Inter-City Comparison

By constructing a multi-city comparative framework, this pathway examines the similarities and differences in development intensity distribution among cities, considering their distinct urban development models and policy orientations. The analysis operates at a macro level to identify patterns influenced by regional contexts.

Pathway 2: Temporal Sequencing Comparison

This pathway employs a dual-time axis analytical framework to integrate the temporal sequence of construction with the cycles of conservation and planning policies. It emphasizes the spatiotemporal evolution of land development intensity, revealing the interactive relationship between urban construction activities and institutional planning mechanisms. This approach provides empirical evidence to elucidate the historical pathways shaping the intensity of land use.

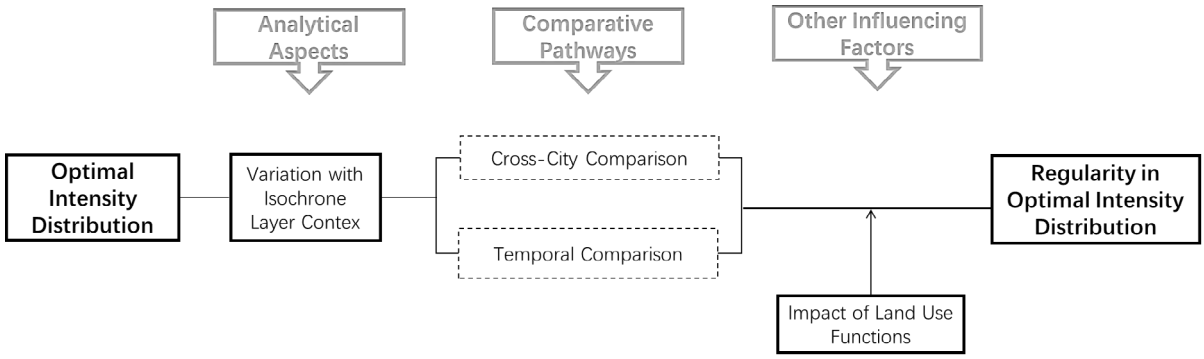

Figure 4. A comparative multi-path analysis framework.

4. Inter-City Comparison: Policy-Oriented Correlation of Development Intensity Distribution

Through comparative analysis of floor area ratio (FAR), maximum plot height, and building density in the vicinity of historical stations in Shanghai, Nanjing, Tokyo, and Kyoto, this study reveals significant spatial differentiation patterns and policy-oriented disparities in development intensity and urban form characteristics across the four cities.

4.1 Floor Area Ratio (FAR) Comparison

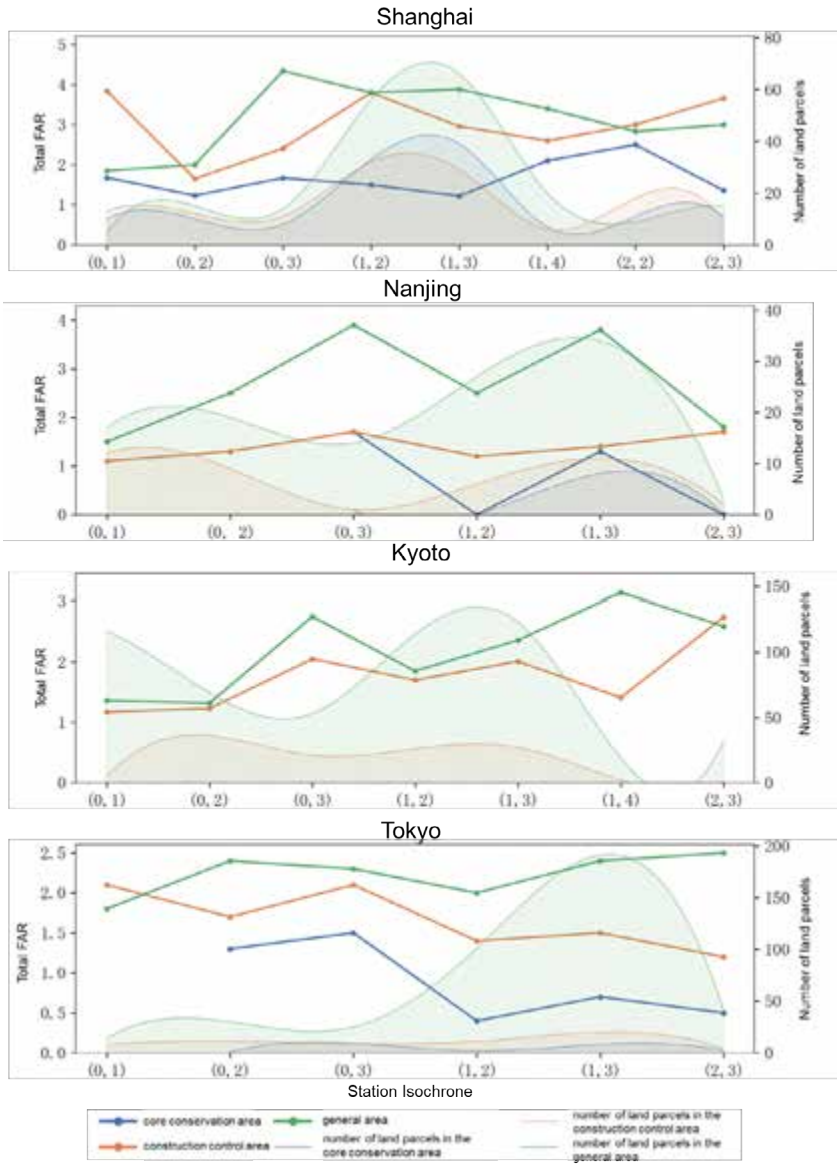

Figure 5. Comparison of floor area ratios (FAR) in four cities.

In terms of absolute FAR values (Figure 5), Shanghai exhibits the highest development intensity, with general areas and construction control zones predominantly ranging between 2–4. Nanjing follows a similar pattern, with general areas also ranging between 2–4, while Kyoto's general areas and construction control zones show lower values (1.5–3), and Tokyo demonstrates the lowest intensity overall (1.5–2.5). These differences reflect Shanghai's rapid urbanization and high-intensity development trajectory.

Spatial distribution patterns in relation to station proximity further highlight policy-driven distinctions. Across all four cities, a gradient variation in FAR is observed within core protection zones, construction control zones, and general areas. In Shanghai, Nanjing, and Tokyo, the disparity between general areas and construction control zones is particularly pronounced. Conversely, Kyoto exhibits a more nuanced gradient, with significant differences only in select regions. This underscores Kyoto's stringent protection strategies for its historical urban core, where cautious regulatory measures effectively mitigate the intensity gap between construction control zones and general areas, ensuring the continuity of the city's historical character.

Additionally, all four cities demonstrate notable FAR peaks in multi-isochrone overlapping areas—specifically, within (0, 3) and (1, 3) time-based concentric zones around stations (Figure 5). These peaks illustrate the cumulative effect of layered development intensity driven by overlapping station influences, highlighting the spatial superposition phenomenon in multi-station contexts.

4.2 Comparison of Maximum Building Heights by Plot

Building height, to some extent, reflects the urban form presented by plots within a city. The magnitude of height differences between areas indirectly indicates the variation in morphological characteristics. In terms of the absolute values of maximum plot heights (Figure 6), plots in Shanghai's General Areas and Development Control Zones, as well as Nanjing's General Areas, are significantly higher than those in Tokyo and Kyoto, predominantly falling within the 60-90 meter range. Furthermore, the height difference between Shanghai's Core Conservation Areas and its Development Control Zones/General Areas ranges between 20 and 60 meters, representing a significantly wider difference. In contrast, the height variation between different zones in Tokyo is within 5 meters, and in Kyoto, it is even less than 3 meters. This analysis reveals/has revealed that within the study areas of the two Japanese cities, morphological differences between different zones are minimal, resulting in a stronger overall visual coherence in the urban landscape. This finding aligns with the actual characteristics of the cities' urban form.

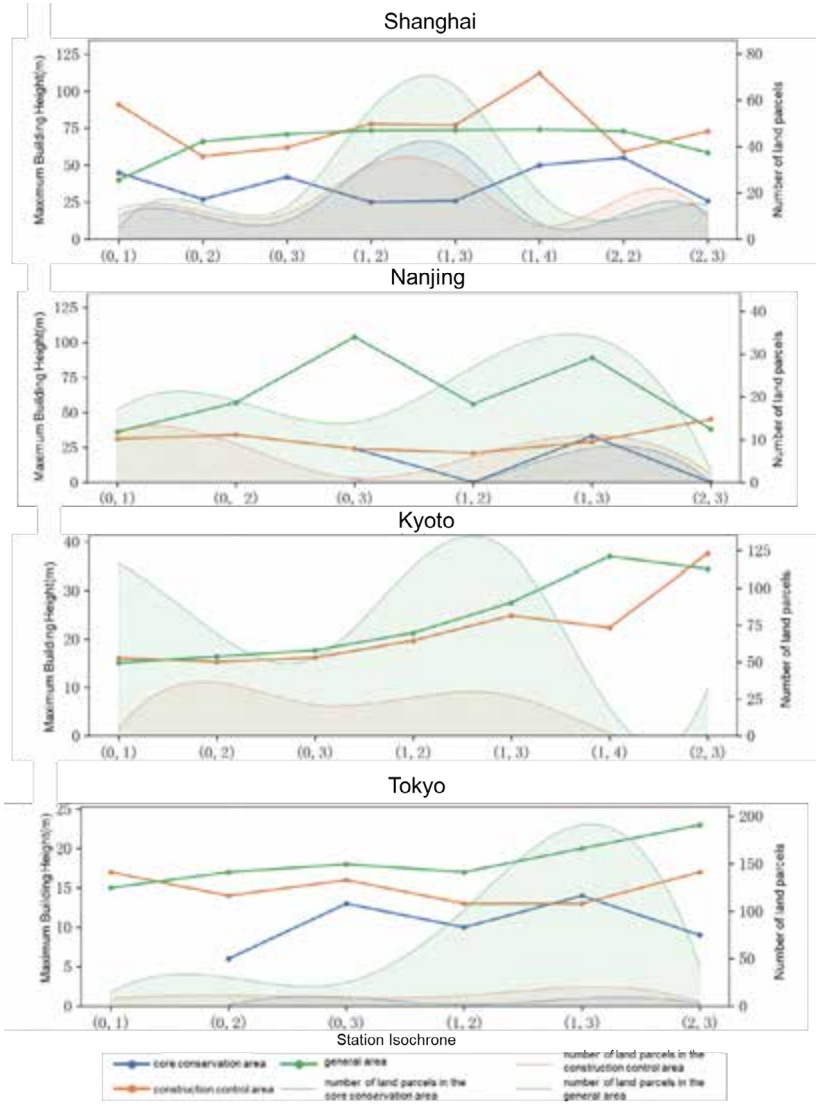

Figure 6. Comparison of maximum building height in four cities.

Regarding trends in building height changes, Shanghai exhibits pronounced fluctuations. Building heights demonstrate a high-low-high-low oscillation pattern as the isochrones expand. This pattern reflects the alternating occurrence of high-density, low-rise buildings and low-density, high-rise buildings during Shanghai's urban development process. Differing markedly from this, Tokyo displays a relatively stable trend in building heights, maintaining levels between 12 and 20 meters with minimal variation. This stability stems from restrictions imposed by historical and cultural preservation policies on both the density and height of land development in Tokyo, resulting in/leading to a limited potential for significant increases in building height. Kyoto's building heights exhibit a gradual upward trend, reaching a maximum of 37.6 meters. Notably, significant height increases occur in areas farther from the core, particularly in zones (1,4) and (1,3). This indicates that as isochrones expand, areas in Kyoto increasingly distant from the core, influenced by multiple stations, are gradually subject to/ experiencing greater development pressure.

4.3 Comparison of Building Density

Building density serves as a critical indicator of urban spatial form and textural characteristics. The Tongji University team led by Zhuang Yu (Zhuang et al., [reference number]) previously conducted empirical research, categorizing sample blocks in Shanghai's central urban area into typical morphological types such as low-rise high-density (historical heritage protection zones), mid-rise medium-density, high-rise low-density, and high-rise medium-density. This classification validated the correlation between building density variations and regional landscape characteristics.

In terms of absolute values (Figure 7), Tokyo and Kyoto exhibit significantly higher building densities compared to Shanghai and Nanjing, consistently maintaining levels between 60–70%. This reflects the spatial strategies of these two Japanese metropolitan areas, which prioritize high-density development to achieve efficient land resource utilization. Notably, the construction of subways has not disrupted the established urban fabric, demonstrating the coexistence of intensive development and preserved historical character.

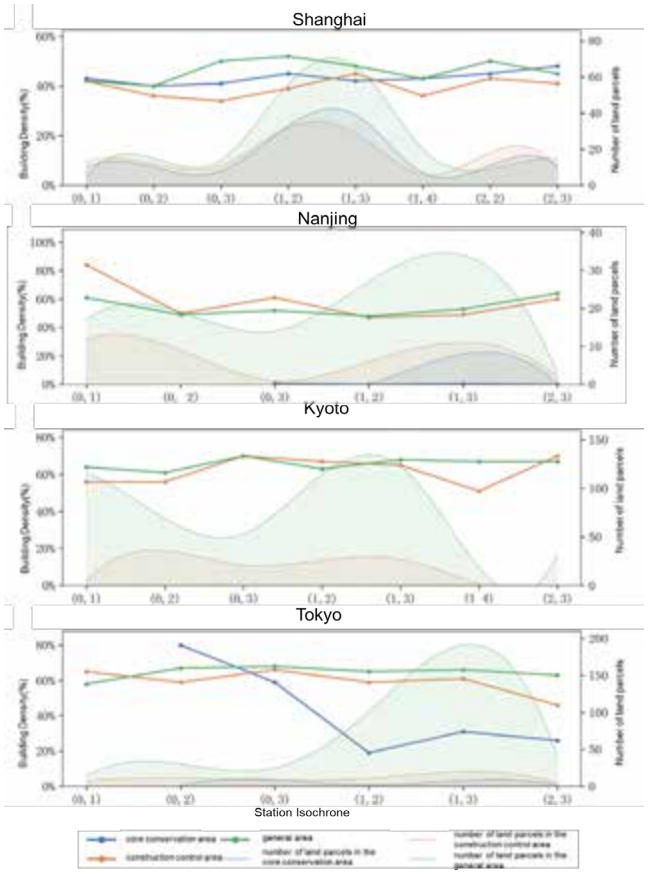

Figure 7. Comparison of building density in four cities.

In terms of density variation trends, Shanghai exhibits marked fluctuations, with significant disparities in building density between core protection zones, construction control zones, and general areas. This spatial differentiation is closely linked to the temporal sequence of urban land development and the dynamic updates of historical preservation policies—divergent development priorities across different periods have resulted in substantial spatiotemporal disparities in building density.

In contrast, Tokyo and Kyoto demonstrate a progressive growth trend in building density. Tokyo reaches a stabilized density of 70% in areas within the (1, 3) isochrone range, reflecting effective control over density thresholds during development. Kyoto's density distribution curve mirrors Tokyo's pattern but achieves stronger overall coherence in preserving the historical street fabric through a gradual, incremental increase in density gradients (Figure 7).

5. Temporal Comparison: Assessment Principles Based on Construction Chronology

The comparative analysis reveals that the chronological relationship between the implementation of conservation planning and rail transit construction timelines in different cities significantly influences the distribution of development intensity in urban blocks surrounding historical station areas.

Table3. A Temporal comparison of development and conservation sequences in case study cities.

	Shanghai	Nanjing	Kyoto	Tokyo
Timeline of Conservation Planning Implementation	1991: Designation of historical character protection zones; 2003: Revised core protection and construction control boundaries under the Shanghai Historical and Cultural Landscapes and Excellent Historic Buildings Protection Regulations.	1984: First Nanjing Historic City Conservation Plan designating Qinhuai River scenic zones as priority protection areas; 2010: Expanded to three historic urban cores, nine historic districts, 22 historic landscapes, and 10 general heritage sites with strict height controls.	1972: Designation of Aesthetic Zones under the Kyoto Urban Landscape Regulation Ordinance; 1973: Designation of Height-Control Zones.	1984: Grassroots preservation initiatives; 2000: Sugamo-Ueno-Sakuragaoka Urban Development Charter established .
Timeline of Station Construction	1993: Line opening; 1996: Station completion.	2005: Opening of Metro Line 1.	1981: Kyoto Subway Uzumasa Line operational; 1997: Opening of the East-West Line.	1969: Kanda and Rootsu Stations operational; 1996: Todai-mae Station operational [Todai-mae Station, 2025-05-04].
Type	RetroactivOe Conservation Model	Proactive Conservation Model	Proactive Conservation Model	Dual-Track Model
Characteristics	Metro construction preceded conservation planning, leading to significant fluctuations in development intensity. Some areas failed to meet both heritage preservation and station development requirements.	Metro construction followed conservation planning. Post-planning, pre-construction redevelopment led to relatively homogeneous intensity distribution but limited synergistic interaction with stations.	Metro construction followed conservation actions. Restrictive redevelopment in construction control zones ensured landscape coherence, while general areas adapted to station development, reflecting zonal regulation strategies.	Metro construction preceded conservation planning. However, spatial constraints and community engagement mechanisms limited intensity increases in construction control zones, while general areas adapted to station development.

Table 4. Comparative analysis of land parcel intensity distribution across cities and time periods.

City & Model Type	Phases of FAR Distribution Changes	
Shanghai (Retroactive Planning)	 (a) Rail transit construction commencement – Pre-refinement of conservation planning	 (b) Post-refinement of conservation planning
Nanjing (Proactive Planning)	 (a) Conservation planning – Rail transit construction commencement	 (b) Post-rail transit construction commencement
Kyoto (Proactive Planning)	 (a) Conservation planning – Rail transit construction commencement	 (b) Post-rail transit construction commencement
Tokyo (Parallel Development & Conservation)	 (a) Rail transit construction commencement – Pre-initiation of conservation efforts	 (b) Post-initiation of conservation efforts: Concurrent development and conservation

5.1 Retroactive Planning Model

Although Shanghai's historical heritage protection system is relatively comprehensive and detailed by domestic standards, the temporal disarray between conservation and development has led to a "cross-waved" phenomenon in Table 4, where "historical districts" are juxtaposed with "high-rise buildings." Professor Zheng Shiling noted that "over the past two decades, high-rise buildings have been inserted into marginal areas of historical sites in Shanghai, often resulting in urban forms driven by profit rather than heritage, creating a fragmented spatial pattern where new and old structures intersect." Similarly, Professor Zhang Song of Tongji University observed that "Shanghai's old city renewal has never ceased, yet historical preservation has remained intermittent and localized." This inconsistency partly explains why Shanghai had to expand its protection scope and re-designate historical cultural landscapes in later planning stages to mitigate heritage loss.

5.2 Proactive Planning Model

In contrast, Kyoto, a model of Japanese historical cities, employed height zoning to regulate urban form prior to rail transit development (Table 4). This proactive approach ensured that post-development intensity remained within controlled thresholds, gradually adapting to station areas. The result was a harmonious coexistence of modernity and heritage, offering insights for optimizing development intensity in historical station zones:

(1) Proactive Planning Promotes Suitable Intensity Distribution

Kyoto's differentiated regulatory mechanisms—such as height zoning and development strategy zoning—established clear intensity gradients and controllable vertical differences. This framework balanced rail transit development with heritage preservation, enabling functional renewal while maintaining the coherence of historical districts.

(2) Moderate Intensity Gradients Between Zones

Rail transit influenced different zones unevenly: general areas and construction control zones exhibited distinct intensity variations.

However, Nanjing, another proactive model, demonstrated a more homogeneous intensity distribution in redevelopment areas before metro construction. Post-metro opening, development intensity did not align with the expected increase in isochrone overlap around stations. This discrepancy stemmed from Nanjing's rapid expansion during the late 20th to early 21st century, where infrastructure and building projects were concentrated without foresight for rail transit integration. Consequently, existing facilities and subsequent metro systems lacked functional compatibility, leading to missed opportunities for high-potential sites to leverage transit-driven intensity. This temporal misalignment is particularly evident in Nanjing's southern historical districts.

During periods of rapid rail network expansion, strict heritage policies constrained new construction heights, limiting floor area ratio (FAR) growth and weakening synergies between development and stations.

5.3 Dual-Track Model

Tokyo's Sugamo-Ueno-Sakuragaoka area (Yanaka, Ueno, Sakuragaoka) experienced slow redevelopment over 56 years since the Kanda and Rootsu stations opened in 1969. Unlike other regions, its renewal dynamics involved complex interplay of factors. A 1984 community-based preservation initiative marked a turning point, dividing the timeline into two phases:

Pre-Preservation Phase: Road networks primarily guided land use along corridors.
Post-Preservation Phase: Development shifted to the western general areas and the eastern side of the JR railway line, while historical zones (construction control and core protection areas) focused on "reproductive" updates—adaptive reuse of existing structures.

This duality created two intensity-balancing mechanisms: incremental updates and large-scale development. Consequently, regional intensity harmonized across broader zones, and post-mid-development synergies with stations emerged (Table 4).

6 Conclusion and Discussion

6.1 Station Cluster Effect

The findings demonstrate that in urban districts, a certain coupling relationship exists between station isochrone overlap (m, n) and development intensity (FAR, building density, building height).

(1) Positive Correlation Between Development Intensity and Isochrone Overlap
Across all cities studied, development intensity generally increases with the degree of isochrone overlap. For example, as isochrone overlap shifts from (0, 2) to (1, 4), development intensity intensifies accordingly. This trend aligns with Transit-Oriented Development (TOD) principles, emphasizing compact, high-density urban growth driven by dense subway station networks.

(2) Non-Linear Relationships Under Station Cluster Influence
Development intensity data across multiple cities exhibit fluctuating growth patterns and localized peak phenomena. For instance, FAR peaks at (0, 3) and building height peaks at (1, 4). These peaks indicate that development intensity does not follow a simple linear relationship with isochrone layers: an area overlapping a 5-minute isochrone may not necessarily exhibit significantly higher intensity than one overlapping a 10-minute isochrone.

From a spatial geographic perspective, station clusters—comprising multiple stations—generate stronger influence than single stations. Regions such as (1, 3) and (1, 4), where multiple 10-minute isochrones overlap, show substantial intensity fluctuations. This suggests that areas affected by overlapping station clusters possess higher development value and potential. Planners should prioritize these zones when formulating strategies to optimize urban intensity distribution.

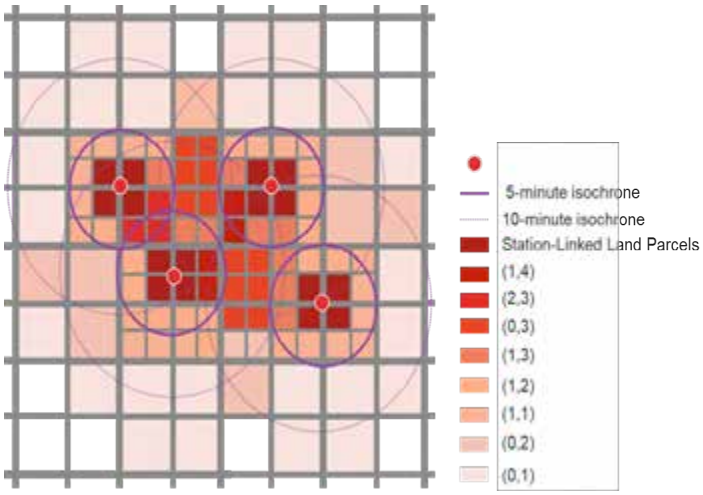

Figure 8. Schematic diagram of intensity distribution in general areas of kyoto.

6.2 Formation of Appropriate Development Intensity

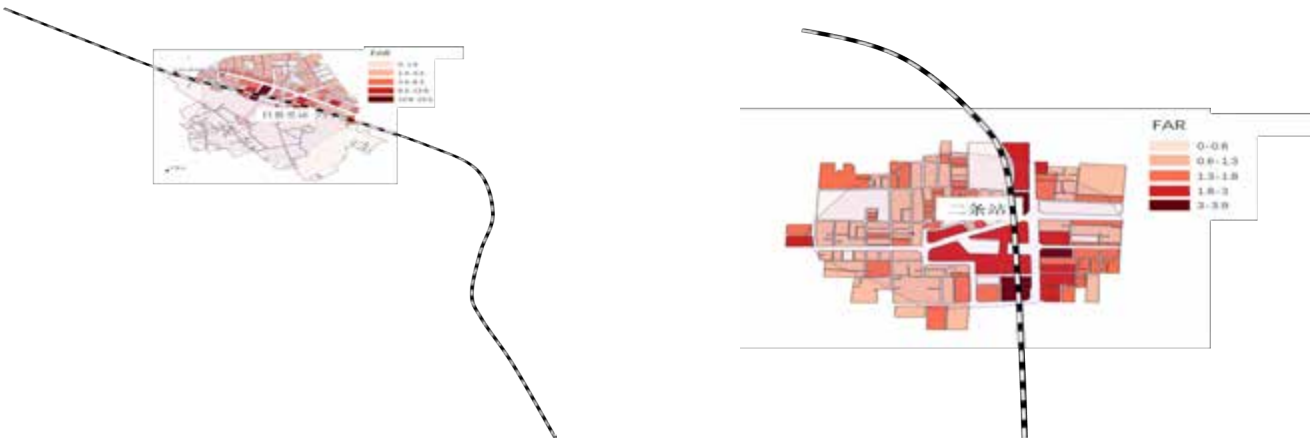
Core protection zones in historical districts prioritize heritage preservation, requiring development intensity to balance landscape conservation, functional vitality, and urban transit adaptability. Unlike ecologically protected regions, their regulatory logic emphasizes a dynamic equilibrium between historical context preservation and moderate renewal. Therefore, integrating and coordinating intensity across core protection zones, construction control zones, and general areas is critical. The comparative analysis across multiple cities and regions reveals the following key conclusions:

(1) Differentiated Intensity Gradients Across Protection Hierarchy
The analysis demonstrates a prevalent intensity gradient of "core protection zones < construction control zones < general areas" among historical districts. This pattern is particularly pronounced in Kyoto and Tokyo, where heritage preservation is well-maintained. As isochrone overlap levels escalate from (0, 1) to (1, 4), the disparity in development intensity between control zones becomes more pronounced. For example, in Kyoto, the FAR difference between general areas and construction control zones widens progressively with increased isochrone overlap. This phenomenon highlights that general areas benefit more from station-driven radiating effects, while construction control zones face constraints due to heritage regulations. Additionally, intensity gradients may be influenced by land-use characteristics and policy implementation timelines in specific contexts.

(2) Inter-Zonal Coordination and Overall Balance
The observed intensity gradients between zones enhance flexibility in development distribution around historical stations, enabling an overall balance across core protection zones, construction control zones, and general areas. This balance effectively reconciles conservation and development objectives.

Core Protection Zones: Strict intensity controls are essential to safeguard heritage integrity.
General Areas: Higher FAR or building density can optimize land use efficiency.
Construction Control Zones: A balanced approach is required—limiting intensity to preserve landscape coherence while allowing sufficient development space to avoid over-restriction and promote sustainable urban form.

The balanced relationship also exists within station areas. In individual stations in Kyoto and Tokyo (e.g., Hizuminokita Station in Tokyo, Nijo Station in Kyoto), it was observed that due to the integration of JR lines and subway lines at transfer stations, the presence of elevated tracks leads to significant spatial disparities in development intensity between the two sides. This results in one side exhibiting high-intensity development while the other remains low-intensity, creating a notable floor area ratio (FAR) transfer phenomenon within the station area.



(a) Nippori Station in Tokyo (b) Nijo Station in Kyoto

Figure 9. The plot ratios on both sides of the special station demonstrate balance within the station area.

(3) Multi-dimensional Index Coordination and Appearance
The analysis above reveals significant regional differentiation in the impact of building density and height on floor area ratio (FAR): in core conservation zones, strict height restrictions constrain development intensity, which is primarily driven by building density. In contrast, in general areas with relaxed height controls, "low-rise podium + high-rise" mixed-use commercial complexes achieve high FAR through vertical expansion.

Diverse morphological mechanisms exist for high-intensity districts across cities. Kyoto attains high FAR via low-rise, high-density layouts, while Shanghai relies on high-rise, low-density configurations to achieve similar intensity levels. This indicates that under different regulatory contexts, multiple balancing pathways and spatial

forms for development intensity coexist. Specifically, in general areas within the (0, 3) range, high-intensity development is often realized through "verticalization" strategies—increasing building floors while reducing density. Conversely, in construction control zones constrained by appearance coordination requirements, "horizontal expansion" models (prioritizing building density and limiting height) still achieve intensity balance. These differentiated index combinations signal a shift from single FAR constraints to multi-dimensional index coordination in development regulation.

6.3 Impact of Construction Sequencing on Intensity Distribution

(1) Conservation Planning and Rail Transit Construction Sequencing Determine Regulatory Effectiveness

Comparative analysis of development intensity distribution in updated plots across Shanghai, Nanjing, Kyoto, and Tokyo reveals that plot intensity varies temporally due to differing dominant factors. When conservation planning precedes rail transit construction (as in Kyoto's model), a "pre-defined control framework followed by adaptive development" mechanism emerges. This enables rigid control in conservation zones, moderate construction in buffer zones, and flexible, TOD-oriented development in general areas, forming a gradient model. This proactive coordination between construction and regulation is characteristic of such cities.

Conversely, when conservation planning lags behind rail transit construction (e.g., in Shanghai's study area), some plots in buffer zones already exhibit high-intensity development before designation, while others remain underdeveloped due to earlier construction. This results in stark intensity disparities between buffer zones and general areas, exemplified by adjacent high- and low-rise structures. Such spatial misalignment reflects planning delays and coordination failures. These findings underscore the need for conservation planning to prioritize foresight, comprehensiveness, and integration to avoid reactive regulation. Kyoto's "planning-first, development-adaptive" approach offers a replicable temporal coordination model for cities balancing historic preservation and rail transit expansion.

(2) Plot Differentiation Evaluation Under Temporal Relationships

Plot development intensity arises from long-term interactions of multiple factors, with construction and conservation sequencing as critical variables. Establishing plot classification evaluation principles based on these temporal relationships enables more precise identification of intensity imbalances, facilitating targeted optimization strategies.

(3) Identification of Appropriate Intensity Distribution Patterns

By comparing intensity distribution characteristics across cities with divergent planning and construction sequences and integrating urban appearance analyses, this study preliminarily reveals that "planning-precedence" models better support appropriate intensity distribution. For example, Kyoto's model demonstrates a reasonable intensity gradient between core conservation zones, buffer zones, and general development areas, with buffer and general zones synergizing with rail transit station development.

6.4 Conclusion

As most global cities transition from incremental construction to stock-based renewal, historic districts near rail transit stations face deepening tensions between preservation and development. This study, starting with plot-level zonal assessments and constructing an indicator system through comparative case analysis, identifies four key distribution patterns of development intensity in high-density historic station areas across cities. It elucidates interactive mechanisms among factors such as station size, layered land use, historical appearance protection, and construction sequencing, providing a reference for non-early-stage cities seeking appropriate intensity evaluations.

However, limitations persist: the broad geographic and temporal scope, coupled with restricted access to historical data, necessitate manual data collection. Further refinement is required for underground FAR estimation and the completeness of historical renewal records.

Abstract
With the intensification of low birth rates and population aging in China, the proportion of elderly individuals is steadily increasing. Currently, research on the travel behavior of the elderly largely focuses on urban areas, with relatively limited attention paid to rural elderly populations. However, towns—which serve as a vital link between urban and rural areas—present more complex geographic, social, and transportation conditions that significantly impact elderly travel. This study employs network analysis methods, combining mobile signaling data with transportation survey data to deeply investigate the travel characteristics of township residents aged 65 and above in their daily lives. It also analyzes and summarizes the key influencing factors and proposes corresponding planning strategies.

Keywords: Elderly travel; Town; Urban-rural population mobility; Shanghai Metropolitan Area

1. Introduction

China's population development has entered a "new normal" phase, characterized by negative population growth, declining birth rates, an aging population, shrinking household sizes, and increasingly differentiated spatial distribution across regions (Liu, 2021; Qi, 2019). The country is transitioning from focusing on child-rearing to elder care, as the working-age population continues to decline and both demographic size and structure become more polarized. With these trends intensifying, the proportion of elderly individuals is steadily increasing, prompting the government to place greater emphasis on meeting the social needs of older adults.

In the Shanghai metropolitan area, Shanghai itself is not only the earliest city in China to enter an aging society, but also the one with the most severe aging level. Other cities in the region, such as Nantong, have also entered a stage of deep population aging. The growing travel demand of elderly populations makes building an age-friendly and inclusive society a key focus of urban and regional planning.

To date, most research on elderly travel behavior has concentrated on urban areas, with relatively little attention paid to elderly individuals in rural settings. Townships, which serve as critical links between urban and rural areas, face more complex geographic, social, and transportation conditions. Due to the frequent outmigration of younger labor forces, a significant number of elderly people are left behind in these townships. Compared to resource-rich urban areas, township-dwelling elderly populations deserve greater attention, which is an essential component of constructing an inclusive society. With the advancement of mobile signaling data, it is now possible to analyze the travel characteristics of rural elderly populations, offering a foundation for governments to allocate urban-rural resources more effectively and build an age-friendly society.

This study focuses on all townships within the Shanghai metropolitan area. Using network analysis methods and integrating mobile signaling data with transportation survey data, it constructs urban-rural and rural-rural population mobility networks. The study deeply explores the travel characteristics of township residents aged 65 and above in their daily lives and examines the relationship between these characteristics and the socioeconomic development of the townships. It identifies the main influencing factors and attempts to provide a clearer understanding of the spatial mobility and cross-regional interactions of elderly people from the perspective of population mobility networks. The findings reveal the specific needs and behavioral patterns of the elderly in townships, offering insights for differentiated planning tailored to the unique characteristics of elderly populations across different regions. This will support government efforts to improve transportation infrastructure, enhance social support services, and optimize medical resource allocation—contributing to the development of an inclusive society and addressing the challenges of population aging.

2. literature review

In the context of an increasingly aging population, the daily activity patterns and travel convenience of the elderly have drawn significant attention from scholars both domestically and internationally. Unlike younger age groups who often occupy a more "mainstream" position in society, elderly individuals tend to have lower incomes and diminished physical capacities. As a result, they rely more heavily on public service systems, healthcare systems, and social welfare programs. This dependence contributes to a range of "social isolation" issues faced by the aging population.

Unlike other countries, elderly travel behavior in China is influenced by its unique social environment, leading to distinct patterns. In recent years, there has been a growing body of research focused on the travel behavior of older adults in China. For example, Zhang et al.(2007) used travel survey data from Beijing residents to compare the travel characteristics (including travel rate, time, distance, mode, and purpose) of elderly individuals aged 61–65 with those of people aged 19–60. They also examined how travel modes and purposes change with age and analyzed differences in travel behavior between elderly residents of central and non-central urban areas at a spatial level.

Similarly, Hu et al.(2013) conducted surveys and analyses of elderly travel behavior in Changchun, exploring aspects such as travel frequency, travel purpose, and mode choice. They compared travel behavior in developing and developed countries, identifying the causes of differences, and proposed urban transportation policies to improve the travel frequency and comfort of the elderly. These policy recommendations included the integration of transportation and land use planning, improvements to pedestrian infrastructure, and enhanced accessibility of public transportation services. Zhang et al.(2019) argued that issues such as traffic congestion, complex traffic environments, and poor travel comfort for the elderly have long been neglected. To address this, they applied a Nested Logit model to study the travel patterns of the elderly in Beijing, finding that public buses play a crucial role in elderly mobility.

When it comes to analyzing the factors that influence elderly travel behavior, the literature points to a combination of socioeconomic conditions, external environmental factors, and policy-related influences. Socioeconomically, studies have shown that age, gender, education level, income, car ownership, and household size significantly affect elderly travel behavior. In terms of the external environment, factors such as population density, diversity, urban design, destination accessibility, and distance to public transit also impact travel decisions. From a policy perspective, welfare initiatives targeting the elderly—such as free or discounted public transportation and improved accessibility through barrier-free infrastructure—can significantly encourage elderly use of public transit and enhance social inclusion, thereby helping to mitigate social isolation (Zhang, 2019).

Overall, existing research on elderly travel characteristics tends to focus primarily on urban populations, with limited attention given to elderly individuals living in townships. There is also a lack of analysis concerning the mobility characteristics of elderly populations moving between urban and rural areas. Moreover, while many studies rely on statistical or travel survey data, fewer incorporate big data approaches, such as mobile signaling data, which could offer deeper insights into travel patterns.

3. Methodology and data

The Shanghai Metropolitan Area, located in eastern China, is a key component of the Yangtze River Delta region. The planning area encompasses the "1+8" administrative units, including Shanghai, Wuxi, Changzhou, Suzhou, Nantong, Ningbo, Huzhou, Jiaxing, and Zhoushan. With a diverse population and a relatively high degree of aging, the region experiences frequent inter-regional transportation connections. Township elderly populations also exhibit notable travel demands, making the study of their travel characteristics crucial for promoting urban-rural integration.

This study takes the Shanghai Metropolitan Area as the research region and divides the nine cities into 913 sub-city administrative units at the subdistrict (township) level. Based on the "Statistical Compilation Rules for Administrative Division Codes and Urban-Rural Division Codes"

(index no. 410A03-1201-201708-0006) from the National Bureau of Statistics of China, each subdistrict or township is classified according to the first digit of its urban-rural division code: 1 for urban and 2 for rural. In total, 404 urban subdistricts and 495 rural townships were identified (Figure 1).

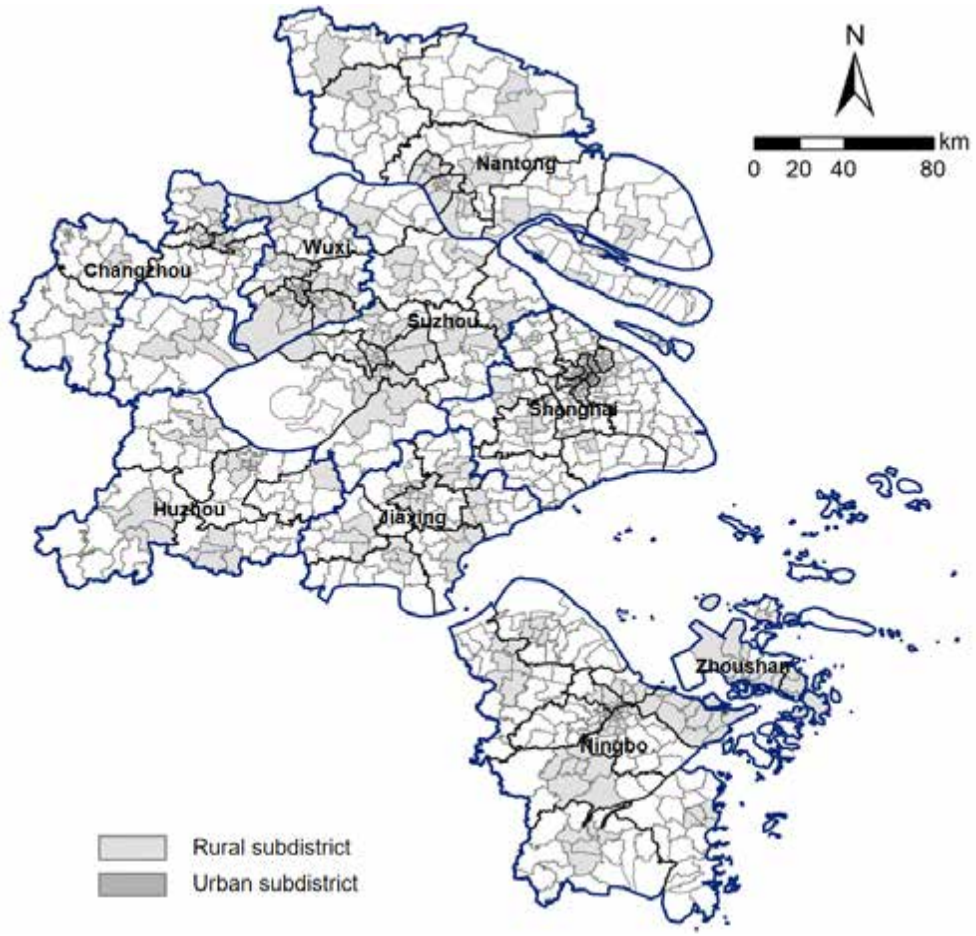

Figure 1. Location and urban-rural classification layouts of Shanghai metropolitan area

The primary data sources for this study include mobile signaling data and POI (Point of Interest) data. The mobile signaling data is derived from travel OD (origin-destination) data from October 2022, using base station grids to locate users' movements. The dataset captures trips for all purposes. By combining POI locations with dwell time, the purposes of trips are inferred to better understand the travel patterns of the elderly population in townships within the Shanghai Metropolitan Area.

Unlike traditional static data analysis, this study adopts a regional spatial network perspective to analyze the travel behaviors of elderly people between urban areas and townships, as well as between different townships. First, a population mobility network within the Shanghai Metropolitan Area is constructed using big data on population movements. The study explores the travel characteristics of elderly individuals through two layers: urban-rural and rural-rural mobility networks, thereby examining interconnections from a broader urban-rural perspective. Second, a statistical analysis is conducted on the travel destinations of elderly individuals for both urban–town and town–town trips. Finally, the study summarizes elderly travel characteristics and preferences by integrating survey data and other contextual information.

4. Results and discussion

4.1 The characteristics of urban-rural travel for the elderly in towns

Using mobile signaling data, this study extracts travel information of the elderly population and constructs urban–rural and rural–rural travel OD (origin–destination) networks. Due to age-related limitations, the number of elderly mobile phone users is relatively small, resulting in a lower overall volume of travel connections. However, observable patterns of elderly travel connectivity still emerge.

In the urban–rural travel network, high-intensity connections are mainly concentrated in Suzhou, showing a multi-centered structure. Although Shanghai exhibits tighter internal linkages between districts, the overall volume of connections is lower. This difference is directly related to the population composition of the two cities—Shanghai has a higher proportion of young people due to its more prominent emerging industries, whereas Suzhou's central districts have a higher proportion of elderly residents, resulting in stronger urban–rural travel connections among the elderly. In other cities within the metropolitan area, elderly urban–rural connections in townships are weaker and more pronounced in peripheral areas. Elderly individuals in townships mainly form direct connections with their regional urban centers, and travel distances are somewhat constrained. Only elderly residents in townships near city centers show relatively frequent travel. In the outer townships of each region, the elderly population generally has little direct interaction with urban districts, which is closely tied to differences in local economic industries and transportation accessibility.

Additionally, there are few cross-jurisdictional travel connections. Only limited intercity linkages are observed between Shanghai and Suzhou, while elderly mobility in other areas remains largely confined within municipal boundaries, typically within district or county-level jurisdictions. Some cross-district or cross-county elderly travel occurs within cities such as Wuxi, Changzhou, and Ningbo.

In the rural–rural travel network, elderly mobility demonstrates a more distinct networked structure. Centered around Suzhou and Shanghai, there is more frequent movement of elderly individuals between townships. Furthermore, elderly cross-border activities between townships are more evident, indicating that inter-township linkages are less constrained by administrative boundaries. In peripheral areas, elderly movement between townships is more frequent than between townships and cities, with elderly individuals tending to travel within nearby townships.**(Figure 2)**

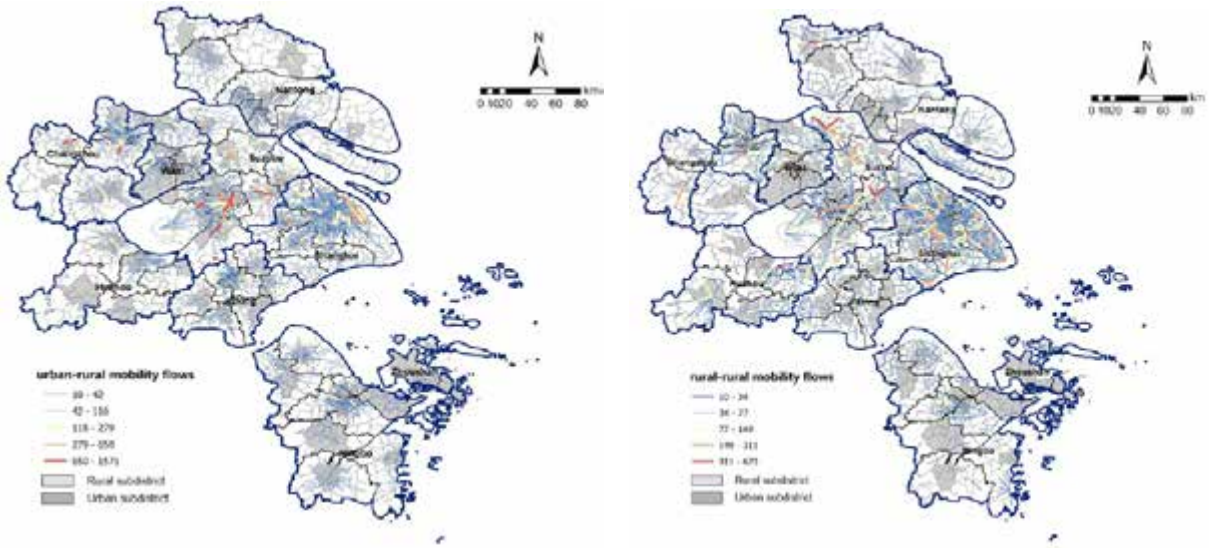

Figure 2. Characteristics of urban - rural elderly population flow network in towns of Shanghai metropolitan area

Overall, both urban–rural and rural–rural elderly travel connections are strongly influenced by distance and administrative boundaries. These constraints are closely related to elderly travel preferences, as most elderly travel in townships occurs within the local area—primarily driven by needs such as family visits, social interactions, and shopping. In contrast, intercity or cross-regional travel is less common, though certain groups—such as those with specific medical needs or those with children living in urban centers—exhibit higher frequencies of long-distance travel.

4.2 The characteristics of urban-rural travel purpose for the elderly in towns

The destinations of elderly travelers were extracted and analyzed separately for urban–rural and rural–rural travel patterns, revealing distinct differences between the two types of mobility.

For elderly individuals traveling between urban and rural areas, a significant portion have specific medical needs or children living in urban districts. Although these elderly residents live in townships, they often travel to urban centers for family visits or medical checkups, indicating that social needs and the availability of public services have a direct impact on their travel behavior. Additionally, shopping and leisure activities account for a relatively high proportion of urban–rural travel. This is largely because urban areas offer a wider range of public services and cultural facilities, attracting elderly township residents to engage in recreational activities. In contrast, travel purposes such as grocery shopping, running errands, child care, and work account for a smaller share of urban–rural travel. These types of travel are more common among elderly residents of townships that are geographically closer to urban centers and are more sensitive to distance and transport accessibility.

For elderly individuals traveling between townships, their travel purposes are closely related to the functions of the respective townships. Firstly, daily shopping accounts for a higher proportion of such travel. These trips typically involve going to central towns to purchase daily necessities such as food and household items, addressing basic everyday needs. Compared to urban–rural travel, the proportions of travel for purposes such as child care and participation in educational or community activities for the elderly are relatively higher, reflecting a preference for frequent, short-distance daily activities. On the other hand, the shares of travel for shopping, leisure, and medical purposes are lower in rural–rural contexts, likely due to smaller differences in service facilities between townships, which leads to reduced demand for such activities.

Moreover, visits to relatives and friends are also less common in rural–rural travel, suggesting that this type of travel is more often driven by the presence of children in urban areas. This pattern is closely related to China's urbanization process, wherein many young and middle-aged township residents have relocated to urban areas for work, prompting elderly family members to travel between rural and urban areas. Finally, since most elderly individuals are already retired, commuting for work is uncommon, with low proportions observed in both urban–rural and rural–rural travel. **(Figure 3)**

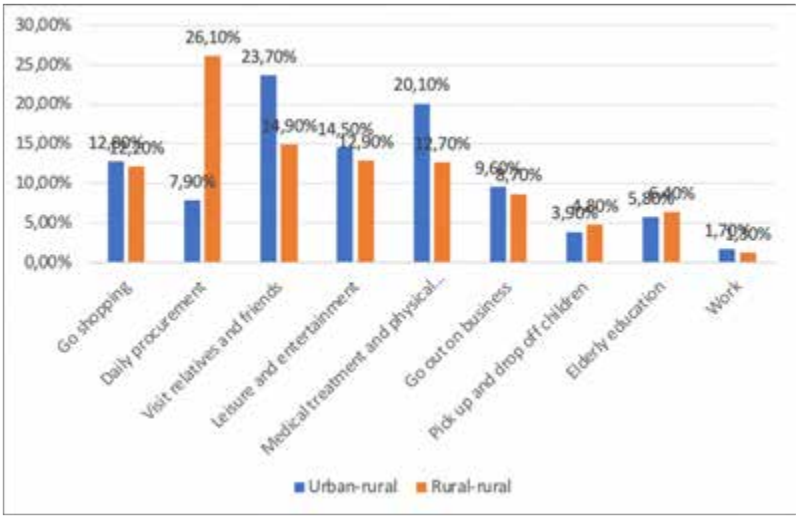

Figure 3. Characteristics of urban-rural travel purposes for the elderly in the Shanghai metropolitan area

4.3 Travel characteristics of the elderly based on traffic surveys

Based on the analysis of mobile signaling big data, this study incorporates survey data on the travel behavior of the elderly population in township areas of Shanghai. It statistically analyzes travel purposes, frequency, and timing across different age groups of elderly individuals. These travel behaviors are significantly influenced by factors such as physical health conditions and exhibit clear patterns and regularities.

4.3.1 Travel purpose

Shopping is the most fundamental travel activity for the elderly, accounting for over 35% of total trips and remaining above 33% across all age groups. The younger elderly group (ages 60–65) has a higher proportion of shopping-related travel. Leisure, entertainment, and cultural activities constitute a relatively stable share of travel across age groups, generally maintaining around 10%.

Due to increased health awareness and rising demand for medical services, doctor visits and health check-ups have become a significant travel purpose for the elderly, accounting for over 10% of trips. As age increases and physical function declines, the proportion of travel for medical reasons rises significantly—from 8% in the 60–64 age group to 35.7% among those aged 80 and above.

In contrast, travel for visiting family and friends, handling personal or household affairs, escorting others, and work-related purposes tends to decrease with age. **(Figure 4)**

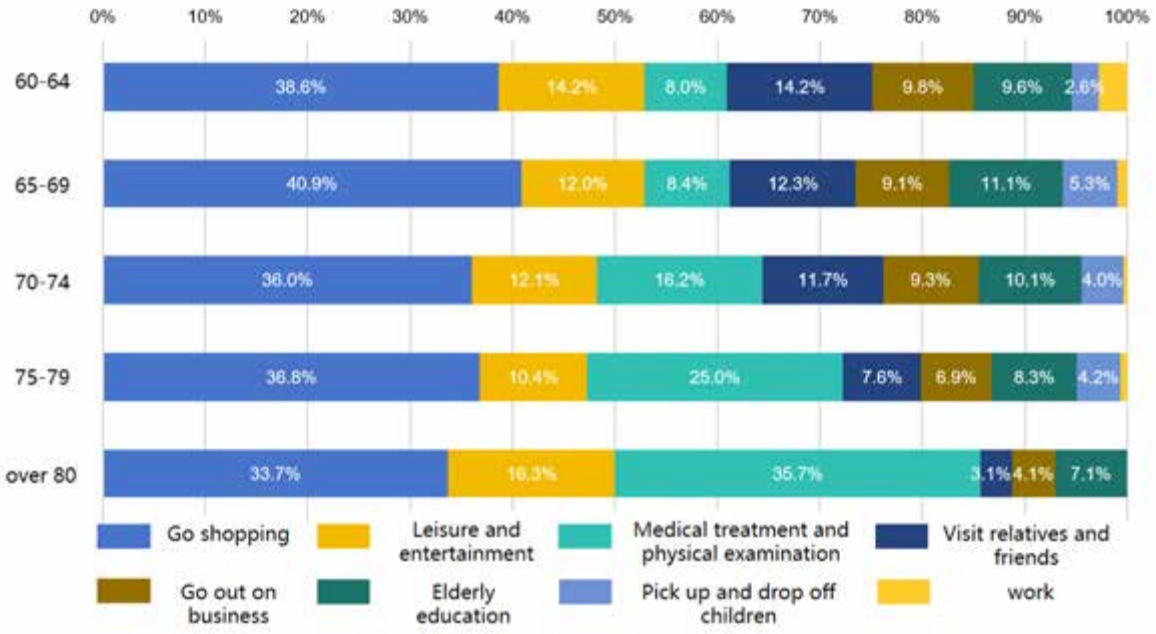

Figure 4. The travel purposes of the elderly of different age groups

4.3.2 Travel frequency

Elderly travel frequency is highly correlated with age. Survey results indicate that travel frequency decreases significantly as age increases: elderly individuals aged 60–62 make an average of 2.27 trips per person per day, while those aged 83 and above make only 0.77 trips per person per day.

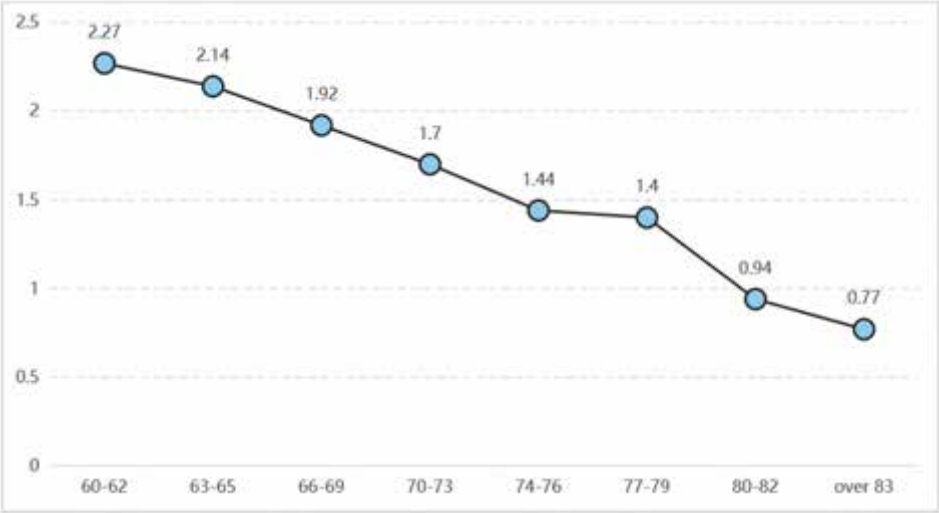

Figure 5. The travel frequency of the elderly of different age groups

From a frequency perspective, the travel level of the 60–65 age group (2.27 trips/day/person) is close to that of residents in central Shanghai (2.37 trips/day/person), suggesting that this age group represents a key transitional phase from working life to retirement. After age 66, travel frequency gradually declines, particularly after age 80, when physical deterioration becomes more pronounced and average travel frequency generally falls below 1.0 trip per person per day.**(Figure 5)**

4.3.3 Travel time

Cross-analysis results show that there is no significant correlation between travel time and age among the elderly. The distribution of travel times across different age groups is generally consistent, displaying two distinct peak periods: 7:00–9:00 a.m. and 1:00–2:00 p.m., with the morning peak showing significantly higher travel volume than the afternoon.

This pattern reflects the elderly's relatively abundant and flexible time management capacity. Their travel activities are more driven by daily habits and personal needs rather than by changes in age. It also indicates that, in post-retirement life, elderly individuals are able to choose more comfortable travel times that avoid congestion, resulting in regular but non-compulsory peak travel behaviors.**(Figure 6)**

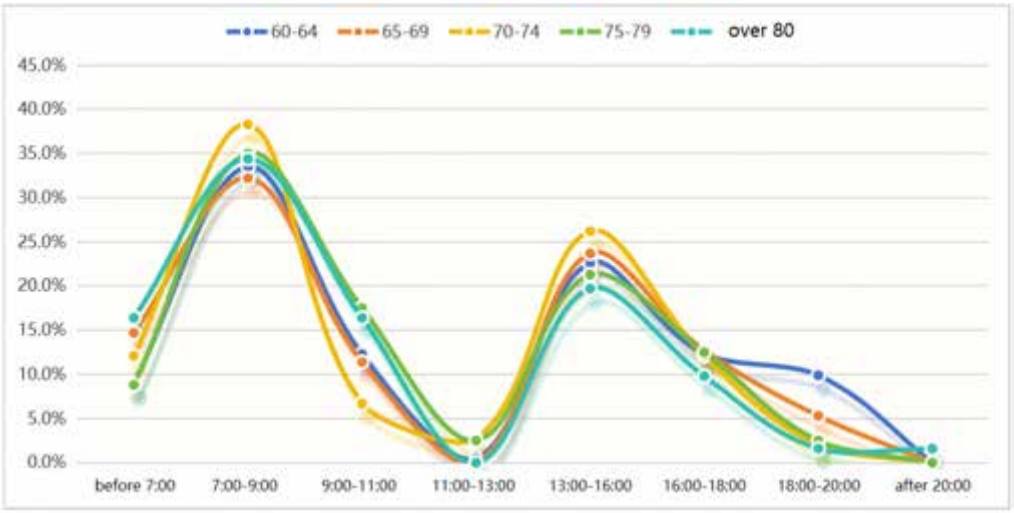

Figure 6. The travel time characteristics of the elderly of different age groups

4.4 Influencing factors of travel for the elderly in towns

Combining the previous data analysis and travel surveys, the travel characteristics of elderly residents in townships are influenced by multiple factors, primarily dominated by physical health and age stage, and constrained by geographic distance, transportation infrastructure, family structure distribution, and administrative boundaries. Among these, health needs, distribution of relatives, and availability of service resources are the core drivers for non-routine cross-regional travel by the elderly, while proximity-based daily life needs still dominate their everyday travel behavior.

First, individual characteristics play a role: physical decline due to aging directly affects travel frequency, travel time, and mode choice. After retirement, elderly people's travel purposes shift from "survival-oriented" to "life-oriented" activities (such as shopping and leisure), with a reduction in travel range, frequency, and duration. Health status and medical needs also have a direct impact, as medical visits and checkups become major travel purposes for the oldest age groups.

Second, spatial and geographic factors are influential. Whether urban-to-rural or rural-to-rural travel, trips tend to be limited to short distances and localized areas. Especially for elderly residents in peripheral townships, connections to urban core areas are weak, and activities tend to revolve around their immediate surroundings. The urban-rural spatial structure difference means urban centers—with their dense resources—attract more township elderly for medical visits, shopping, and family visits; meanwhile, township-to-township travel is more oriented toward daily needs like shopping and caregiving, with smaller service facility disparities leading to weaker incentives for cross-township trips. Both urban-rural and rural-rural elderly population flows are largely confined within municipal and district/county boundaries, with relatively few cross-administrative boundary connections, reflecting the continuing barrier effect of administrative borders on travel behavior.

Third, transportation and service facility distribution matter. The proportion of high-age elderly using public transit declines due to fixed routes, boarding difficulties, and balance issues, limiting their willingness to use buses. Township transportation infrastructure is relatively weak, making walking the primary mode; rigid needs such as medical visits often rely on taxis or private cars. Currently, elderly self-driving rates are low, but with generational shifts and improvements in transportation systems, township elderly driving rates may increase in the future, which could in turn affect travel frequency and range.

Fourth, social relationships and family structure influence travel motivations. The residential distribution of relatives affects travel purposes; urban-rural family visits are closely related to children's places of residence. Family structure and intergenerational residential separation are important drivers of elderly cross-regional travel. Daily caregiving responsibilities, such as picking up grandchildren and managing household chores, increase travel frequency within townships, especially among those aged 60 to 70.

5. Conclusions

The travel behavior of elderly residents in townships is characterized by "short-distance, life-oriented, and high dependency," influenced by multiple factors including age-related physical capacity, service resources, transportation infrastructure, and spatial structure. Elderly travel is not only a transportation issue but also an important reflection of eldercare services, urban-rural integration, and social equity. The travel needs of township elderly should be incorporated into long-term strategies for urban-rural integration and the equalization of public services. Through a combination of "soft and hard" measures, a low-cost, highly accessible, continuously serviced, and user-friendly travel system should be built. This paper proposes the following planning and policy recommendations focusing on transportation facilities, service layout, travel support, and spatial coordination:

1. Improve Elderly-Friendly Transportation Facilities System: Optimize non-motorized transport systems and enhance the age-appropriateness of public transit services. Improve bus route coverage to address shortcomings in inter-urban and rural transit, and increase medium- and short-distance shuttle lines between core towns and townships. Promote "customized bus" services by piloting appointment-based travel services for the elderly, meeting high-frequency demands such as medical visits and shopping.

2. Strengthen Balanced Layout of Public Service Resources Between Urban and Rural Areas and Townships: Address gaps in basic township-level services and enhance medical, shopping, and cultural facilities in central towns to meet elderly residents' daily needs for shopping, entertainment, and medical care, thereby reducing pressure for cross-district travel. Allocate medical resources reasonably and establish grassroots medical outreach for the elderly, especially in remote townships, promoting "village doctors at home" services to reduce travel for medical care among the oldest elderly. Enrich local activity spaces for the elderly by establishing senior centers, cultural halls, and other venues in townships to foster localized social and recreational environments.

3.Promote Diversified Travel Support Policies for the Elderly: Expand age-friendly transportation subsidies, especially for elderly individuals with high cross-district travel frequency between urban and rural areas (such as those regularly seeking medical care), to alleviate economic burdens. Establish a dynamic elderly travel data monitoring system that integrates mobile signaling data, transportation surveys, and community feedback to identify demand hotspots and weak points dynamically, supporting infrastructure optimization. Encourage volunteers or social workers to assist elderly persons during frequent and essential trips (e.g., medical visits, errands), improving travel safety and comfort.

4. Promote Cross-Administrative Regional Coordination and Resource Sharing: Strengthen regional collaborative transportation planning and establish mechanisms for elderly cross-city travel coordination in highly integrated areas. Optimize the allocation of cross-boundary public service resources, especially in regions where elderly residents frequently travel to other cities for medical care (e.g., elderly residents from Suzhou seeking treatment in Shanghai). Facilitate medical insurance recognition across cities, dedicated direct transit lines, and service linkage mechanisms.

Why public transport interventions work or not? A meta-analysis based on the behaviour change wheel model

Jiayu Gu, Luyao Niu & Wenjia Zhang

Abstract

Public transportation promotion policies are vital for reducing carbon emissions, improving public health, and fostering sustainable urban development. However, assessing their effectiveness is challenging due to inconsistent research findings and methodologies stemming from varied classification criteria. Additionally, existing meta-analyses often fail to explain why certain policies are more effective, primarily due to a lack of theoretical frameworks underlying these policies. This uncertainty can lead to the misallocation of financial resources, diminished public trust in policy initiatives, reduced overall policy impact, and the persistence of inefficient urban growth patterns. Therefore, there is an urgent need to develop a clear and unified classification framework for evaluating public transport policies, which would standardize future research and meta-analyses, thereby promoting deeper insights and advancements in this field. To address the research gap, our study pioneers the use of the Behaviour Change Wheel (BCW) to analyze public transport policies. Originally developed for public health and environmental protection, the BCW enhances policy design by systematically integrating factors that drive individual behavior change. This framework breaks down interventions into three layers: policy, intervention strategies, and the Capability-Opportunity-Motivation-Behaviour (COM-B) model. Within the BCW, the intervention strategies layer encompasses targeted actions that directly influence behaviors, while the COM-B layer identifies and addresses the key factors—capability, opportunity, and motivation—that drive or impede these behaviors. Existing research has extensively evaluated the impact of public transportation promotion policies using the Behaviour Change Wheel (BCW) framework, which comprises three dimensions: policy, intervention strategies, and the Capability-Opportunity-Motivation-Behaviour (COM-B) model. The policy layer categorizes these policies into six types: **1) Guidance; 2) Environmental and social planning; 3) Service provision; 4) Fiscal; 5) Communication and marketing; 6) Regulations,** which are further broken down into specific strategies within the intervention layer and analyzed for their effects on individuals' capabilities, opportunities, and motivations in the COM-B layer. By conducting a meta-analysis across all three layers, this study aims to provide a deeper understanding of policy effectiveness, particularly in explaining why certain interventions are more effective than others.To deepen the analysis of policy effectiveness, this study conducted a meta-analysis within the BCW framework, synthesizing data from 24 high-quality studies across 16 countries with over 5.59 million data points. We systematically coded each policy into the BCW's three layers and performed stratified subgroup analyses to investigate the causal effects and mechanisms of six public transportation policy categories in promoting transit adoption. The key findings are as follows:

1. The overall meta analysis effect size of public transport policies is 0.5165. Within the policy layer, only guidance policies surpass this average; in the intervention strategies layer, incentivization, coercion & restrictions, modelling, and enablement demonstrate effect sizes above the average; within the COM-B layer, social opportunity and automatic motivation show effect sizes that exceed the mean.
2. Guidance policies are the most effective in promoting public transit adoption (n=12, d=0.881), including incentivization, education, and coercion & restriction interventions. They work well because they enhance reflective motivation (n=7, d=0.3418), automatic motivation (n=5, d=0.9034), and physical opportunities (n=5, d=0.4102), providing strong support for behavioral change.

3. Environmental and social planning policies are least effective policies (n=17, d=0.2093), including environmental restructuring interventions. These measures mainly improve physical opportunities through environmental changes (n=16, d=0.4102), but their limited impact on motivation makes it harder to sustain long-term behavior change.

4. Service provision policies provide substantial long-term benefits (n=21, long term d= 0.5285), which combine environmental restructuring and enablement interventions. These approaches strengthen automatic and reflective motivation (n=7, long term d= 0.6998; n=11, long term d=0.4148) and physical opportunities (n=17, long term d=0.438), leading to both immediate behavior changes and sustained public transit adoption.

1.Introduction

Public transportation interventions are essential for reducing carbon emissions, improving public health, and promoting sustainable urban development (C40 Cities, 2021; Doru, 2021; Bibri et al., 2020). In recent years, the number of studies on various public transportation interventions has been steadily increasing, signifing the academic community's growing focus on optimizing public transportation system interventions and promoting sustainable travel modes (Bamberg et al., 2021)2015(Pluntk, 2013;Gaerling et al., 2022;Zeiske et al., 2021). However, the effectiveness of these interventions presents significant challenges, as current research often lacks

consistency in findings and methodologies due to the varying criteria used to classify interventions.
Even existing meta-analyses fail to explain why a particular intervention is effective, due to a lack of theoretical basis for the mechanisms through which these interventions operate. Therefore, this underscores the need for a more systematic approach to evaluate these measures.

A significant challenge in current public transportation research is the absence of a clear theoretical framework and standardized classification for intervention measures. Existing studies attempt to categorize interventions into two categories (Bamberg et al., 2011; Graham-Rowe et al., 2011; Steg, 2003): "hard" interventions aim to change transportation behavior by modifying the physical environment (e.g., building bicycle lanes) and through legal or economic policies (e.g., congestion pricing); "soft" interventions aim at influencing people's beliefs, attitudes, values, and norms (Steg, 2003, p. 190) , which rely on persuasion, incentives, information provision, etc (Möser & Bamberg, 2008). However, these classifications often lack consistent theoretical support, leading to blurred boundaries between categories,. For example, policies like introducing car-sharing schemes, which including both infrastructure and promotion, may simultaneously fall into both "hard" and "soft" interventions (Berg et al., 2019). The current binary classification system complicates the systematic understanding and evaluation of intervention effects, hinders the development of a unified framework for assessing their effectiveness, and obstructs the integration and application of research findings in policy design. Consequently, there is an urgent need to establish a clear and unified classification framework for intervention measures. Such a framework would provide standardized guidance for future public transportation research and meta-analyses, fostering deeper insights and advancements in this field.

A significant body of existing studies has focused on classifying and evaluating the effectiveness of different public transportation policies. However, these studies often fall short in explaining why certain policies are more effective than others. While some research has attempted to employ methods such as SEM, ITS, and targeted learning to shed light on policy mechanisms(Niu & Zhang, 2023; Thorhauge et al., 2019; Y. Zhang et al., 2025), these approaches are often empirical and subjective, subject to contextual changes. Our perspective is that to understand the true mechanisms behind policy effectiveness, it is crucial to recognize that a single policy can be implemented through a variety of interventions, each driven by distinct subjective motivations, which can lead to varying outcomes depending on the contextual backdrop. Thus, to offer more applicable policy recommendations, we have to analyze both the objective interventions and the subjective motivations behind policies. Additionally, we find that many existing studies focus solely on the immediate effectiveness of policies, neglecting their long-term impacts, which may evolve or accumulate over time and require a temporal perspective for a more comprehensive analysis.

The Behaviour Change Wheel (BCW) offers a solution by providing a comprehensive framework that dissects interventions into three interconnected layers: policy, intervention strategies, and the Capability-Opportunity-Motivation-Behaviour (COM-B) model. Originally applied in public health and environmental protection, BCW helps in understanding and designing effective policies by systematically integrating the factors driving individual behavior change. By breaking down each intervention policy into specific strategies and examining how these strategies influence individuals' capabilities, opportunities, and motivations, BCW facilitates a deeper analysis of why certain interventions are effective. This framework thus bridges the gap in existing research, providing a more nuanced understanding of the mechanisms through which public transportation policies can achieve their intended outcomes.

In this study, we aim to apply the Behaviour Change Wheel (BCW) framework to clearly demonstrate how public transport interventions achieve their effects and conduct a meta-analysis within this framework. The primary goal of this approach is to address key questions left unanswered by existing research:

1. Do the seven types of policies—Regulation, Service Provision, Communication and Marketing, Environmental and Social Planning, Guidelines, Fiscal Measures, and Legislation—effectively influence individuals' travel behavior and encourage greater use of public transportation?
2. What explains the varying effectiveness of these policies, considering the different intervention strategies and the underlying motivations driving them?
3. How do the effects of these policies differ when implemented in the short term versus the long term, and what mechanisms account for these differences?

The paper is structured as follows. Section 2 presents a literature review, discussing existing studies on the effectiveness of public transport interventions and defining the Behaviour Change Wheel while exploring its application in understanding the mechanisms behind public transport interventions. Section 3 outlines the methodology used for our meta-analysis, along with details of our data cleaning, coding, and analysis processes. In Section 4, we present the results of the meta analysis, providing a detailed explanation of the specific processes involved in various public transport interventions. Finally, Section 5 discusses the implications of our findings for policymakers.

2.Literature Review

2.1 Effectiveness of Public Transport Interventions

Public transportation interventions play a crucial role in promoting sustainable urban development and improving residents' travel behaviors. In existing studies, public transportation interventions are generally categorized into several types:1 built environment improvement, including.....2)... (such as infrastructure upgrades and transportation network optimization), soft interventions (such as public education and behavior guidance), incentive measures (such as economic incentives and subsidies), and planning policies (such as land use policies and traffic control) (Bamberg et al., 2021)2015(Pluntk, 2013;Gaerling et al., 2022;Zeiske et al., 2021). These classification methods vary across studies but share a common goal of increasing public transportation usage and reducing reliance on private vehicles.

The effectiveness of different intervention types varies significantly in evaluation. For example, built environment improvements can substantially enhance the attractiveness of public transportation, but their effectiveness often depends on long-term implementation and substantial financial investment(Kärmeniemi et al., 2018). Soft interventions and incentive measures are more flexible, but their effectiveness may vary depending on the target audience (Semenescu et al., 2020). Additionally, the effectiveness of planning policies is often closely linked to the enforcement strength and consistency of local governments. Therefore, when evaluating the effectiveness of public transportation interventions, it is essential to carefully distinguish and analyze the effects of different types of interventions (Tirachini & Cats, 2020)2020.

In recent years, many studies have employed meta-analysis to synthesize and evaluate the effectiveness of various public transportation interventions on travel behavior. These analytical methods integrate results from multiple studies to provide quantitative support for the overall effectiveness of different interventions. However, while meta-analyses can reveal which interventions are generally more effective, they often fail to explore why these interventions work and struggle to uncover the underlying mechanisms. Particularly due to the diversity of research methods and data sources, meta-analysis results often lack consistency in explaining the effectiveness of interventions (Pluntk, 2013; Gaerling et al., 2022; Zeiske et al., 2021).

2.2 Application of the BCW in Understanding Public Transport Intervention

To better understand the mechanisms through which public transportation interventions achieve their effects, it is necessary to introduce a framework that can systematically analyze these measures. In this context, the Behaviour Change Wheel (BCW), a comprehensive framework for analyzing behavioral interventions, offers a new perspective for understanding and optimizing the effectiveness of public transportation interventions (Bamberg et al., 2021)2015.

The Behaviour Change Wheel (BCW) is a comprehensive behavioral intervention analysis framework proposed by Michie et al. in 2011, aimed at unifying and simplifying interdisciplinary theories of behavior change. The BCW model integrates 19 different behavior analysis frameworks and uses the Capability-Opportunity-Motivation-Behavior (COM-B) model to systematically identify and design effective behavioral interventions. The structure of BCW consists of three layers: the core layer, which is the COM-B model; the intervention strategy layer; and the policy layer (Michie et al., 2011)but it is not clear how well they serve this purpose. This paper evaluates these frameworks, and develops and evaluates a new framework aimed at overcoming their limitations. A systematic search of electronic databases and consultation with behaviour change experts were used to identify frameworks of behaviour change interventions. These were evaluated according to three criteria: comprehensiveness, coherence, and a clear link to an overarching model of behaviour. A new framework was developed to meet these criteria. The reliability with which it could be applied was examined in two domains of behaviour change: tobacco control and obesity. Nineteen frameworks were identified covering nine intervention

functions and seven policy categories that could enable those interventions. None of the frameworks reviewed covered the full range of intervention functions or policies, and only a minority met the criteria of coherence or linkage to a model of behaviour. At the centre of a proposed new framework is a 'behaviour system' involving three essential conditions: capability, opportunity, and motivation (what we term the 'COM-B system'. Currently, the BCW has been widely applied in various fields, including public health (e.g., smoking cessation and obesity prevention), environmental protection (e.g., reducing plastic waste), and healthcare (Belanger-Gravel, 2019; Gould et al., 2017) Coupe et al., 2021). These application cases demonstrate that the BCW has broad applicability and practicality in understanding and designing behavioral interventions.

Although the BCW has been successfully applied in multiple fields, its application in public transportation interventions remains relatively limited. However, with the onset of the COVID-19 pandemic, the potential of the BCW in transportation behavior analysis has gradually emerged. For example, Wells et al. (2022) utilized the BCW model to analyze post-pandemic traveler behavior in selecting distant destinations, finding that improving transportation facilities and providing value-based social information effectively changed travel behavior . Similarly, Krusche et al. (2022) used the BCW to analyze the barriers and facilitators of public transportation use among UK residents to identify more effective communication strategies that could enhance public confidence in using public transportation.

2.3 BCW in Public intervention policy research

The BCW model, with its three-layer structure, provides a systematic analytical tool for understanding the specific pathways through which public transportation interventions exert their effects. First, the COM-B model helps identify how interventions influence individuals' capabilities, opportunities, and motivations, thereby guiding behavior change. Second, the intervention strategy layer offers nine strategies targeting different behavioral influences, which can be used to design more effective public transportation interventions. Finally, the policy layer provides the necessary policy support and environmental conditions for implementing these strategies (Michie et al., 2011)but it is not clear how well they serve this purpose. This paper evaluates these frameworks, and develops and evaluates a new framework aimed at overcoming their limitations. A systematic search of electronic databases and consultation with behaviour change experts were used to identify frameworks of behaviour change interventions. These were evaluated according to three criteria: comprehensiveness, coherence, and a clear link to an overarching model of behaviour. A new framework was developed to meet these criteria. The reliability with which it could be applied was examined in two domains of behaviour change: tobacco control and obesity. Nineteen frameworks were identified covering nine intervention functions and seven policy categories that could enable those interventions. None of the frameworks reviewed covered the full range of intervention functions or policies, and only a minority met the criteria of coherence or linkage to a model of behaviour. At the centre of a proposed new framework is a 'behaviour system' involving three essential conditions: capability, opportunity, and motivation (what we term the 'COM-B system'. By utilizing the BCW model, researchers and policymakers can gain deeper insights into and optimize the effectiveness of public transportation interventions. This enables the design of more targeted and effective strategies that increase public transportation usage and ultimately achieve sustainable urban transportation systems.

3.Method

This study conducted a systematic review and meta-analysis following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (see Fig. 2), to evaluate the effectiveness of interventions designed to promote public transportation use. Strict inclusion, exclusion criteria, and a structured team-based review process ensured the reliability of study selection and the inclusion of high-quality evidence. The research procedure involved developing a search strategy, selecting relevant databases, defining screening criteria, reviewing and selecting studies, extracting and coding eligible data, and performing the meta-analysis.

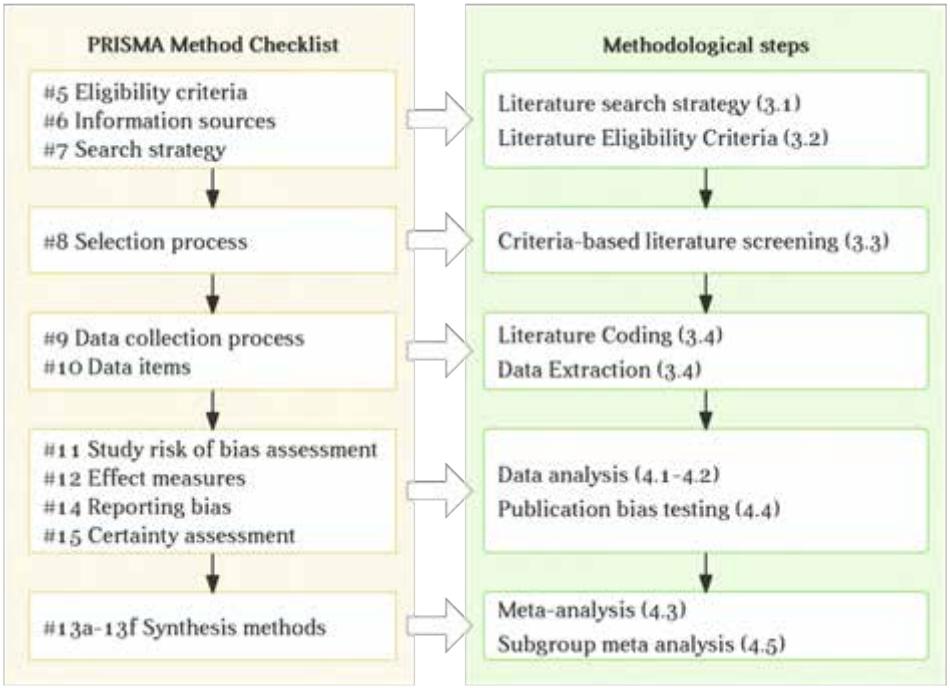

Fig. 2 PRIMA Checklist

3.1 Literature Search Method

The literature search primarily focuses on interventions aimed at promoting public transportation use. The search strategy incorporated key terms (see Supplemental Material Table S1) related to

- public transport modes (e.g., “public transport”, “bus”, “metro”, “rail”, “BRT”).
- intervention behaviors (e.g., “reduce”, “decrease”, “incentive”, “promote”).
- intervention types (e.g., “built environment”, “policy”, “program”).
- study designs (e.g., “natural experiment”, “quasi-experiment”).

The main databases are Scopus, Web of Science, and the Transportation Research Information Service (TRIS). Additionally, reference lists of included studies were manually screened (snowballing) to identify potentially relevant research missed by the database search.

3.2 Eligibility Criteria

Studies retrieved from the search were screened based on the following pre-defined inclusion and exclusion criteria:

(1) Publication Period: Studies published between 2000 and 2023.

(2) Language: Studies published in English.

(3) Publication Type: Peer-reviewed quantitative studies. Reviews, qualitative studies, and preprints were excluded.

(4) Research Field: Studies within behavioral science, transportation, mobility, urban planning, human geography, social sciences, urban studies, or geographic information systems. Studies from unrelated fields (e.g., biology, medicine, chemistry, physics) were excluded.

(5) Study Focus: Studies examining individual public transportation behavior (e.g., bus, BRT, subway, light rail).

(6) Study Design: Studies employing natural or quasi-experimental designs to assess interventions influencing the shift from non-use to regular use of public transport.

(7) Participants: Studies involving general population samples. Studies focusing on specific subgroups (e.g., children, women, students, elderly) were excluded.

(8) Intervention Type: Studies evaluating interventions explicitly designed to promote public transportation use. Studies where public transport use was an indirect outcome (e.g., impact of ride-sharing services like Uber) or where intervention effects were confounded by uncontrolled variables were excluded.

(9) Outcomes: Quantitative studies reporting outcomes related to actual public transport usage (e.g., mode share, frequency, trip duration), based on objective or self-reported data. Studies measuring only behavioral intentions or relying on hypothetical scenarios were excluded.

(10) Data Availability: Studies providing sufficient data to calculate effect sizes, including pre- and post-intervention means and standard deviations (SDs), or values convertible to SDs (e.g., 95% confidence intervals (CIs), standard errors (SEs), p-values, t-values), following Higgins et al. (2019). Studies were excluded if necessary data remained unobtainable after contacting authors for missing data.

3.3 Literature Screening Process

The initial search yielded 11,918 records. After removing 6,824 duplicates using Endnote, 5,094 records remained. Two researchers independently screened titles and abstracts based on criteria 3-5, resulting in 179 potentially relevant studies for full-text review.

These 179 full texts were then independently assessed by the same two researchers against all eligibility criteria (1-10). Disagreements were resolved through discussion with a third researcher. Ultimately, 24 studies (reporting 38 independent effect sizes) met all criteria and were included in the meta-analysis. Key reasons for exclusion at the full-text stage were: non-intervention studies (n=85), inappropriate statistical models (n=37), insufficient data for effect size calculation (n=28), and inaccessible full texts (n=5). The detailed screening process is illustrated in Fig. 3.

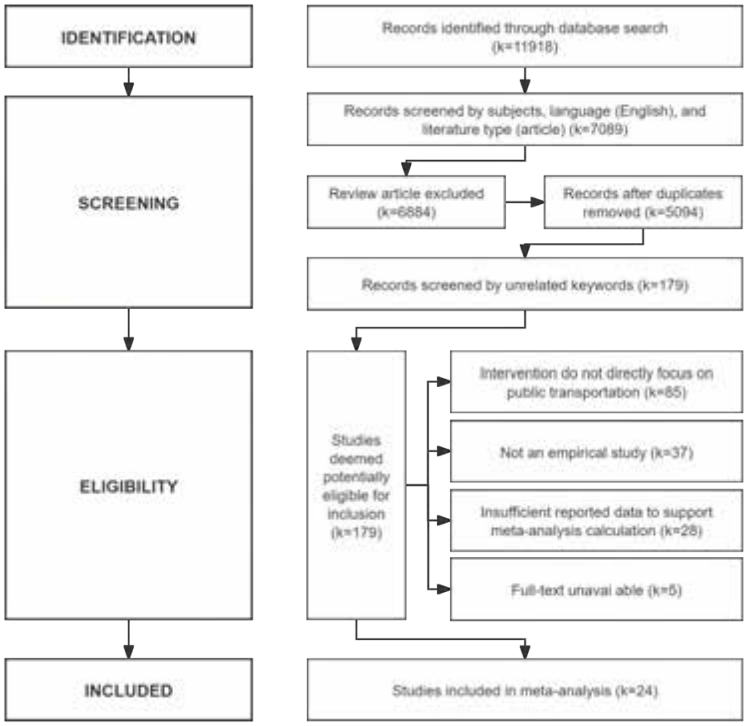

Fig. 3 Literature screening process and details

3.4 Data Extraction and Coding

We developed and employed a standardized form (details in Supplemental Material Table S2) to extract and code data from the 24 included studies (representing 38 effect sizes). Key information extracted included:

(1) Basic Study Information: Authors, publication year, source.

(2) Study Characteristics: Study Design, location (country/city), target transport mode, intervention duration (short-term: ≤180 days; long-term: >180 days), intervention start/end years, sample characteristics (unit of analysis, sample size, presence of self-selection).

(3) Intervention Description: Detailed account of the intervention implemented.

(4) Outcome Measures: Specific public transport behavior outcomes (e.g., ridership, frequency, share), measurement methods (objective/self-reported), data type (e.g., count, survey).

(5) Quantitative Results: Data required for effect size calculation (e.g., sample sizes, means, standard deviations, or convertible statistics like CIs, SEs, p-values, t-values).

(6) BCW Coding: Each intervention was classified according to the Behaviour Change Wheel (BCW) framework, including policy category, intervention function(s), and relevant COM-B components (Capability, Opportunity, Motivation). Detailed coding rules are in Supplemental Material Tables S3-S5.

Two researchers independently performed data extraction and coding. Discrepancies were resolved through discussion to ensure accuracy and consistency. Effect sizes (Cohen's d) and their standard errors (SE) were calculated or converted using the Campbell Collaboration's online tool (Wilson, 2023), following the methods recommended by Higgins (Higgins et al., 2019).

3.5 Meta-Analysis Strategy

This study performed a random-effects meta-analysis, assuming variability in true effect sizes across studies due to the diversity of interventions, contexts, and designs. The analysis strategy included:

(1) Handling Multiple Outcomes: If a study reported multiple related outcomes for one intervention, effect sizes were calculated for each and treated as independent comparisons in the analysis. Sensitivity analyses were conducted where potential dependencies existed.

(2) Handling Multiple Time Points: If a study reported outcomes at multiple post-intervention time points, effect sizes were calculated separately for the earliest (short-term) and latest (long-term) measurements.

(3) Sample Size Allocation: If intervention and control group sample sizes were not reported separately, the total sample size was divided equally between the groups.

(4) Heterogeneity Assessment: Cochran's Q test assessed statistical significance of heterogeneity, while the I^2 statistic quantified its magnitude (interpreting <25% as low, 25%-75% as moderate, and >75% as high heterogeneity)

(5) Moderator Effect Analysis: Subgroup analyses and meta-regression explored the influence of pre-specified moderators (e.g., BCW classifications, intervention duration, sample characteristics, location) on effect size variability.

(6) Publication Bias Assessment: We visually inspected funnel plot symmetry and used Egger's regression test to quantitatively assess potential publication bias.

All meta-analyses were conducted using the 'metafor' package in R software.

4.Results

4.1 Search Result

The literature search initially yielded 11,918 records across the selected databases (Fig. 3). After removing duplicates, 5,094 records remained for title and abstract screening, from which 179 studies were selected for full-text review. Following the application of all eligibility criteria and excluding five articles where the full text could not be accessed, 24 studies were deemed relevant. These 24 studies reported a total of 38 independent effect sizes, which formed the basis for this meta-analysis.

4.2 Study Characteristics

Key characteristics were extracted from the 38 included effect sizes (derived from the 24 studies), as detailed in Supplemental Material Table S6. Publication years ranged from 2002 to 2023, with a majority (60.5%) published between 2020 and 2023. Geographically, studies originated primarily from the United States (n=15 effect sizes) and China (n=5), with others from the Netherlands (n=5), Singapore (n=4), Italy (n=2), and Japan (n=2). Interventions targeted buses (n=18), Bus Rapid Transit (BRT) (n=6), subways (n=5), and light rail (n=9).

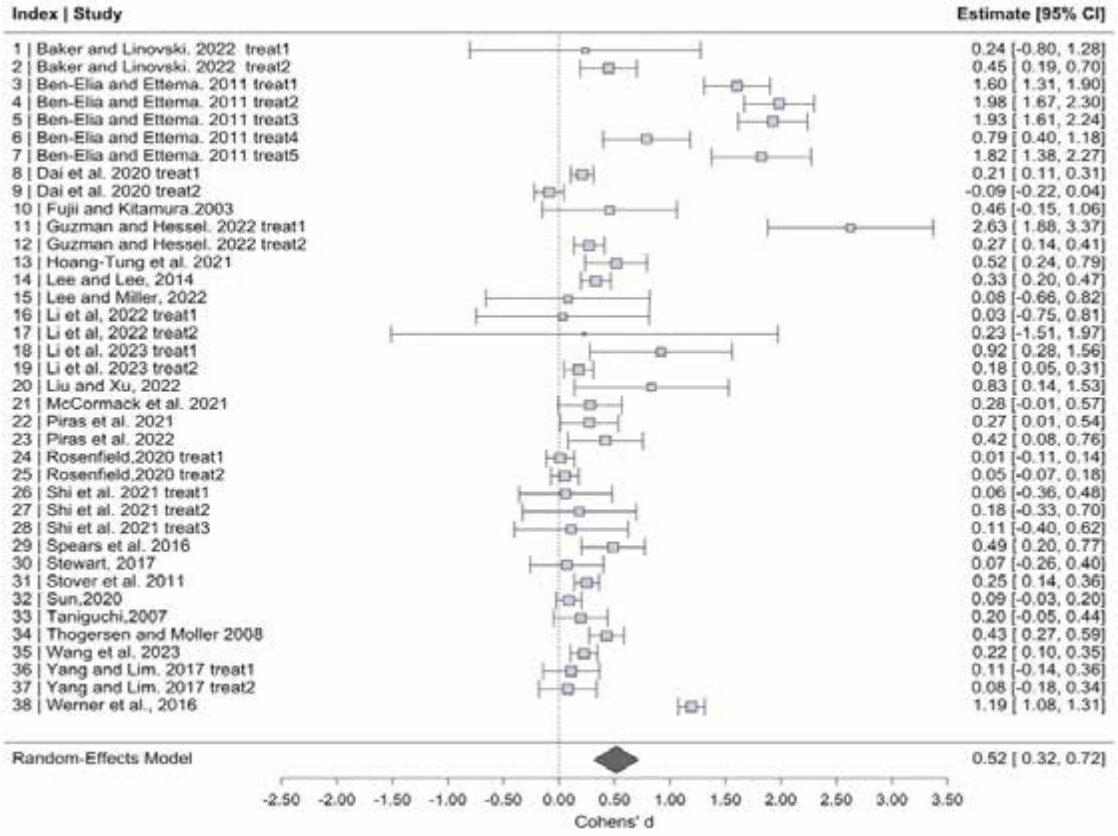
All included studies utilized experimental or quasi-experimental designs. Data sources varied, including travel big data (n=11), surveys (n=20), and statistical yearbooks (n=7).

Most interventions were classified as long-term, lasting over 180 days (57.9%), although intervention durations varied significantly, ranging from a single day to 15 years. The unit of analysis was typically the individual (n=22), but some studies analyzed effects at the level of roads/stations (n=11) or cities (n=5). Sample sizes were predominantly medium (n=20) or large (n=11), with fewer small samples (n=7). Baseline sample sizes ranged from 2 to 270,000, and follow-up samples ranged from 4,000 to 140,000. Most studies (n=27) employed designs that minimized self-selection bias. Control groups consisted of participants not exposed to the specific public transport intervention under investigation, while treatment groups received the intervention. Supplemental Material Table S7 provides a summary of the interventions.

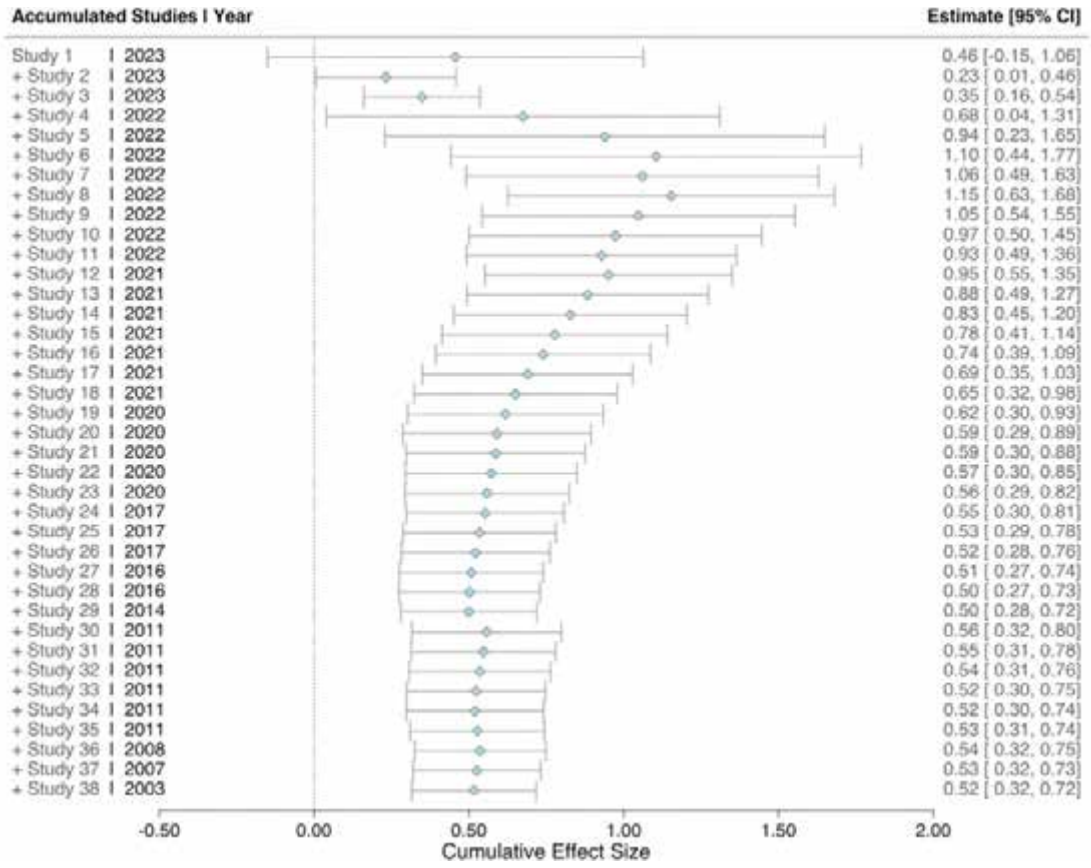
The primary outcome measure across studies was public transport usage frequency or ridership, although some also reported changes in total trips, distance, or mode share (Hoang-Tung et al., 2021; Li et al., 2023a; McCormack et al., 2021). Effect sizes (Cohen's d) and standard errors were calculated for each study outcome. Supplemental Material Table S8 summarizes sample sizes, results, and effect characteristics for each included effect size.
Overall, interventions generally showed a positive effect on public transport usage. However, some studies reported non-significant findings (Marshall Baker & Linovski, 2022), and the magnitude of effects varied considerably across interventions. No studies reported negative (suppressive) effects, likely because all included studies focused on promoting public transport. This variability underscores the importance of investigating potential moderators of intervention effectiveness.

4.3 Meta Analysis and Moderators

We used Cohen's d as the standardized effect size metric to quantify the impact of interventions on public transportation behavior. Positive Cohen's d values indicate that the intervention promoted public transport use. Conventionally, effect sizes are interpreted as small ($d < 0.2$), moderate ($0.2 \leq d < 0.8$), or large ($d \geq 0.8$). Given the substantial expected heterogeneity across the diverse interventions, study designs, contexts, and measurement approaches, we employed a random-effects model for synthesizing the 38 independent effect sizes.



a. Forest Plot of Meta Analysis



b. Cumulative Forest Plot

Fig 4. Results of General Meta-Analysis

The meta-analysis included 38 effect sizes from 24 studies, encompassing a total of 756,328 participants. Using a random-effects model, the overall summary effect size was moderate and statistically significant (Cohen's d = 0.5165, 95% CI [0.3158, 0.7172], z = 5.0437, p < 0.0001). This indicates that, on average, interventions effectively promoted public transportation use.

	Passively Collected Data	11	0.2748	0.2748	[-0.0035,0.5531]	.	90.97%
	Administrative Data	7	0.7132	0.7132	[0.1228,1.3036]	*	98.62%
Country	America	16	0.2868	0.2868	[0.102,0.4715]	**	89.69%
	Europe	8	1.1498	1.1498	[0.6298,1.6698]	***	96.17%
	Asia	12	0.1923	0.1923	[0.0902,0.2945]	***	69.08%
	Rest of World	2	1.42	1.4200	[-0.887,3.7269]		97.30%
Total		38	0.5165	0.1024	[0.3158, 0.7172]	***	97.16%

However, significant heterogeneity was detected across studies ($Q(37) = 706.93$, $p < 0.0001$; $I^2 = 97.16\%$), indicating substantial true variation in intervention effects beyond sampling error (Semenescu et al., 2020). This high heterogeneity necessitated moderator analyses to explore potential sources of variation.

We examined several pre-specified moderators related to study characteristics (Table 1). Significant differences in effect sizes were found based on the unit of analysis: interventions showed larger effects when measured at the individual level (d = 0.636, n = 22) compared to the road/station (d = 0.312, n = 11) or city level (d = 0.275, n = 5). Effect sizes were notably larger in studies with medium sample sizes (d = 0.677, n = 20) compared to those with large (d = 0.310, n = 11) or small samples (d = 0.383, n = 7). Data collection method also moderated effects: studies using statistical yearbook data reported the largest average effect (d = 0.713, n = 7), followed by survey data (d = 0.584, n = 20), while studies using objective measurements (e.g., smart card data) showed smaller effects (d = 0.275, n = 11). Studies avoiding self-selected samples reported larger effects (d = 0.615, n = 27) than those with potentially self-selected participants (d = 0.279, n = 11), suggesting self-selection bias may attenuate observed effects. Regional differences were observed, with interventions appearing generally more effective in Europe, Africa, and South America compared to North America and Asia. Effects also varied by transport mode, with light rail interventions showing the strongest effects compared to bus, subway, or BRT interventions.

High heterogeneity persisted within several moderator subgroups, particularly for studies using individual or city samples, medium sample sizes, statistical data, non-self-selected samples, and long-term interventions. The duration of the intervention emerged as a key factor related to heterogeneity; long-term interventions exhibited higher variability than short-term ones. Furthermore, cumulative meta-analysis suggested a trend of decreasing effect sizes over time (Fig. 4b), potentially indicating that initial intervention impacts may diminish as the duration increases.

4.4 Publication Bias

We assessed potential publication bias using a funnel plot (Fig. 5) and Egger's regression test. The funnel plot visually relates study effect sizes to their precision. A symmetrical plot suggests low risk of bias, while asymmetry can indicate missing studies (often those with non-significant or small effects). Our funnel plot displayed some asymmetry, with studies clustering more densely on the right side (positive effects), particularly in the lower precision (bottom) part of the plot. This could suggest potential publication bias against non-significant or negative findings, or it might reflect the true distribution of effects given that all included interventions aimed to promote public transport use, coupled with the high heterogeneity observed.

Egger's regression test was performed to quantitatively assess funnel plot asymmetry. The result was not statistically significant ($t = 1.8661$, $p > 0.05$ [based on t-value and df=36]; intercept $b = 0.1310$, 95% CI [-0.1297, 0.3916]). Therefore, Egger's test did not provide significant evidence of publication bias. The observed asymmetry in the funnel plot is more likely attributable to the substantial heterogeneity among the included studies rather than systematic publication bias.

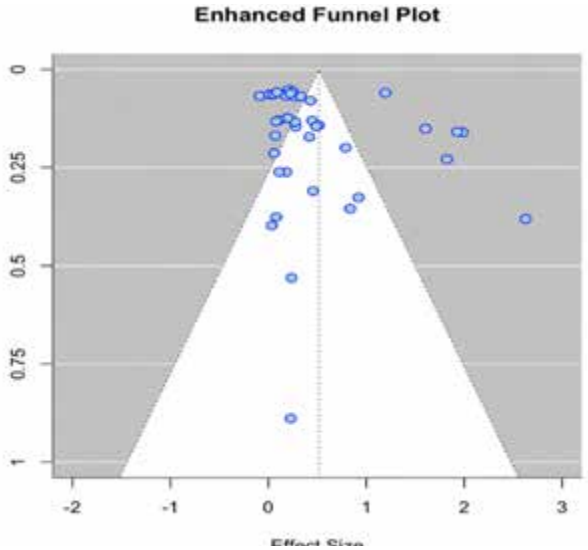

Fig. 6 Funnel plot of publication bias

4.5 Intervention and BCW

We coded the interventions from the 38 included effect sizes according to the three layers of the BCW framework: policy categories, intervention functions, and COM-B components (details in Supplemental Material Table S3-S5). Subgroup analyses were conducted based on these BCW classifications to evaluate differential effects on public transportation behavior (Table 2). Following common meta-analytic practice, subgroup analyses are reported only for categories containing three or more independent effect sizes(Leong et al., 2023).

4.5.1 Policy Categories

At the policy level, representing macro-level strategies, interventions most frequently involved Service Provision (e.g., real-time bus information; n=19), Environmental and Social Planning (e.g., new subway lines; n=16), and Guidance (e.g., bus riding guides; n=12). Subgroup analysis revealed significant differences in effectiveness, with Guidance policies showing the largest positive effect ($d = 0.881$, n=12, $I^2 = 95.3\%$), while Environmental and Social Planning policies showed the smallest effect ($d = 0.209$, n=16, I^2 high). Service Provision ($d = 0.462$, n=19, $I^2 = 97.7\%$) and Fiscal policies (e.g., monthly passes; $d = 0.418$, n=10, I^2 high) also yielded moderate positive effects. Communication/Marketing and Regulation policies were excluded from subgroup analysis due to insufficient

studies (n<3). High heterogeneity was observed within most policy categories. Intervention duration significantly moderated policy effects: Guidance policies were most effective in the short-term (≤ 80 days; d = 1.087, n=8), whereas Communication/Marketing (d = 0.555, n=3) and Service Provision (d = 0.529, n=14) demonstrated substantial positive effects over the long-term (> 180 days). Although Fiscal policies showed positive long-term effects (d=0.656, n=5), this was not statistically significant. Notably, Guidance policies had significantly stronger short-term effects compared to their long-term impact (d=0.380, n=4), while Communication/Marketing effects appeared stronger long-term (short-term d=0.261, n=3). Heterogeneity remained high within policy subgroups across both short- and long-term durations, particularly for Guidance, Service Provision, and Fiscal policies.

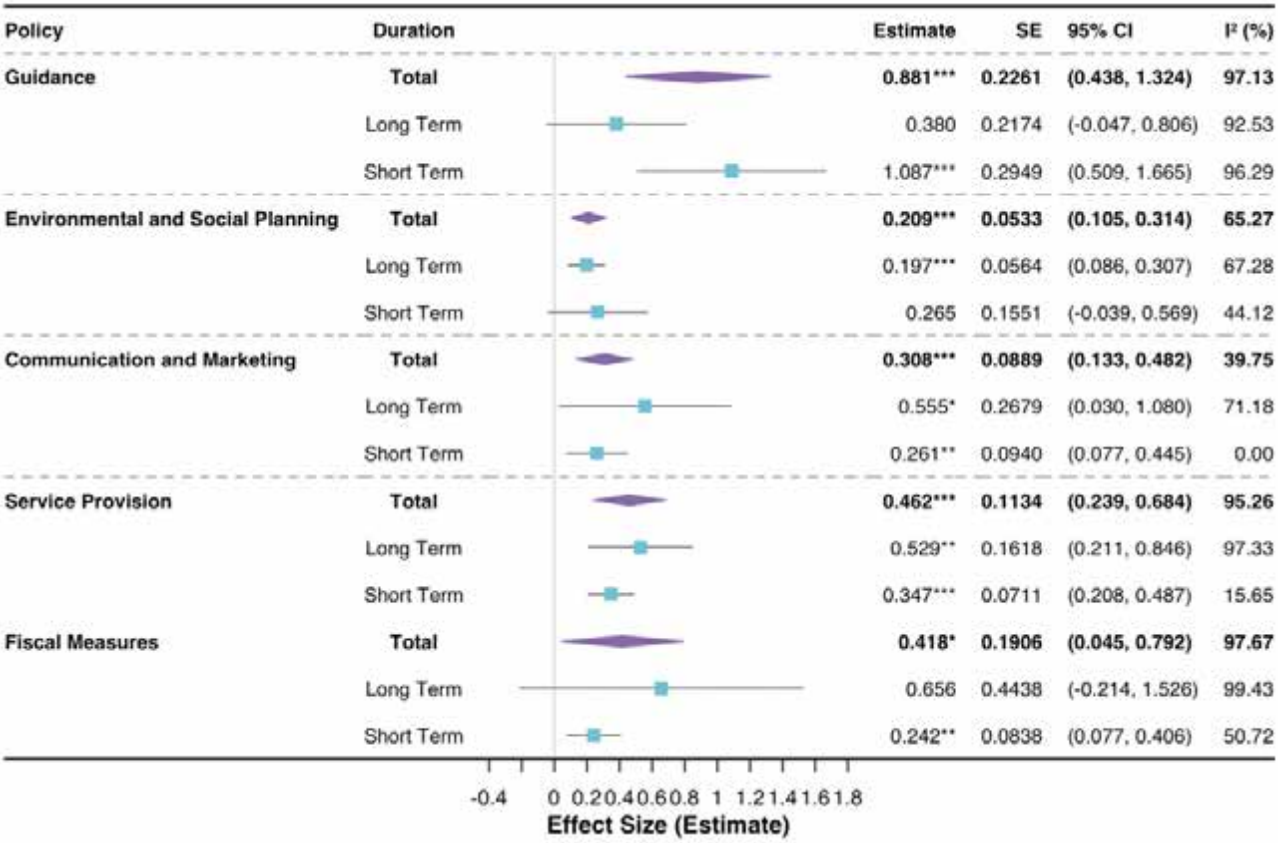

Fig. 7 Sub-group analysis of Policy Layer

4.5.2 Intervention Functions

Examining intervention functions, which describe the specific implementation mechanisms, we found Environmental Restructuring (e.g., building new lines; n=20), Incentivisation (e.g., free rides; n=12), and Enablement (e.g., passenger assistance; n=9) were the most common, while Persuasion (n=3) and Modelling (n=3) were least frequent. Subgroup analysis showed statistically significant positive effects for all functions with sufficient data. Coercion and Restriction yielded the largest effect (d = 1.11, n=8, I^2 = 97.9%), closely followed by Incentivisation (d = 0.93, n=13, I^2 = 98.1%). Conversely, Education (d = 0.084, n≥3, I^2 = 99%) and Persuasion (d = 0.27, n=3, I^2=?) showed the smallest effects. Training interventions were too few for analysis (n<3). High heterogeneity was prevalent within most function categories. In the short-term, Coercion/Restriction (d = 1.40, n=6) and Incentivisation (d = 0.94, n=10) were most effective. For long-term interventions, Modelling produced significant positive effects (d = 0.55, n=3); Incentivisation (d = 0.95, n=3) and Enablement (d = 0.66, n=6) also showed strong positive effects, although these were not statistically significant in the long-term subgroup analysis. Effect sizes for most functions were broadly similar across durations, often slightly larger long-term. Heterogeneity remained high within function subgroups and generally increased for long-term interventions compared to short-term ones.

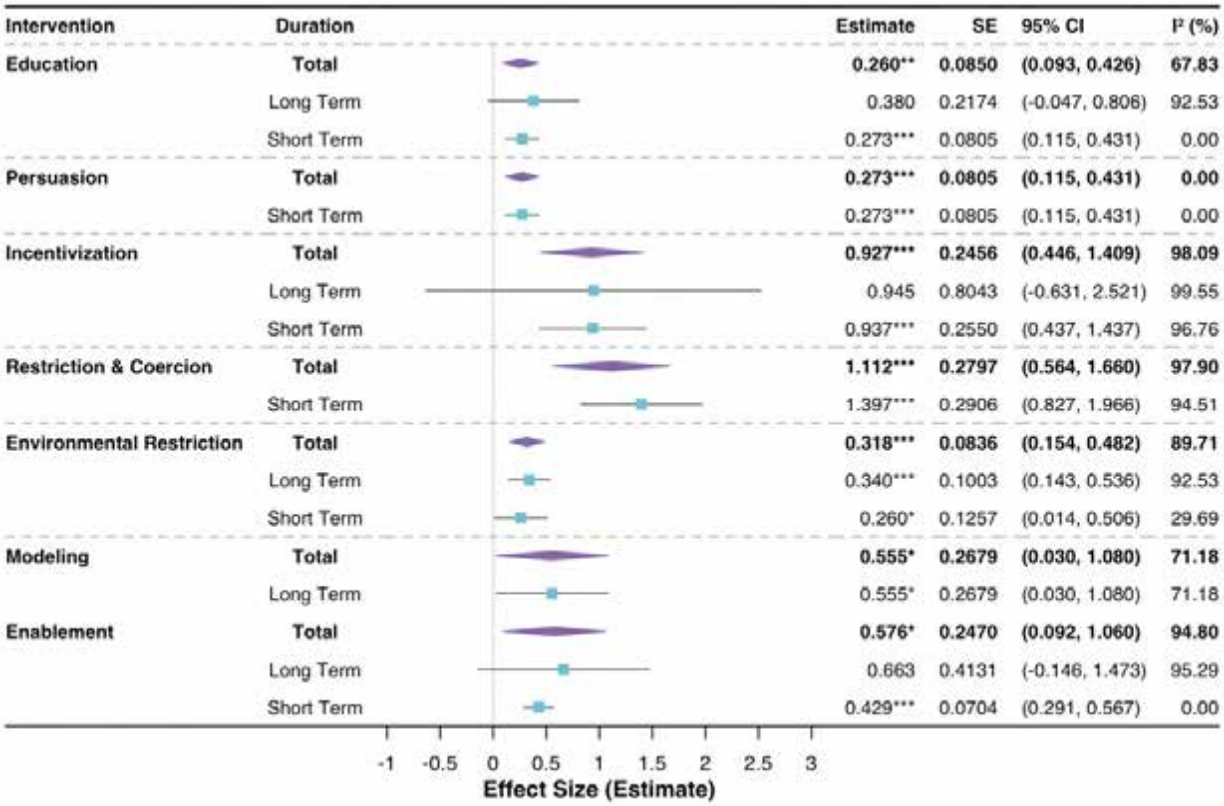

Fig. 8 Sub-group analysis of Intervention Layer

4.5.3 COM-B Components

Finally, analyzing interventions based on the target COM-B components (Capability, Opportunity, Motivation), we found Physical Opportunity (e.g., adding stations; n=23) and Reflective Motivation (e.g., promotional posters; n=17) were most frequently addressed, while Social Opportunity (e.g., school travel projects; n=3) was targeted least often. Subgroup analysis indicated that targeting Automatic Motivation yielded the largest overall effect (d = 0.87, n=15, I^2 = 97.6%), followed by targeting Social Opportunity (d = 0.55, n=3, I^2 = 71.2%). Targeting Psychological Capability (e.g., providing information to reduce perceived complexity) was least effective (d = 0.20, n=9, I^2 = 58.6%). High heterogeneity was observed within the Automatic Motivation subgroup. Considering duration, targeting Automatic Motivation showed the strongest short-term effect (d = 0.96, n=10), while targeting Reflective Motivation had a smaller short-term effect (d = 0.17, n=5). For long-term interventions, targeting Social Opportunity was most effective and showed relatively low heterogeneity (d = 0.55, n=3). Targeting Automatic Motivation also produced a large long-term effect (d = 0.70, n=5), though this was not statistically significant in the long-term subgroup. Interventions targeting Psychological Capability had similarly small effects in both short-term (d=?) and long-term analyses (d = 0.26, n=5). Comparing durations, the effect of targeting Automatic Motivation appeared slightly attenuated long-term, whereas the effect of targeting Reflective Motivation was substantially larger long-term (d = 0.41, n=12) compared to short-term (d = 0.16, n=5). As with other BCW layers, heterogeneity within COM-B subgroups was generally higher for long-term interventions compared to short-term ones.

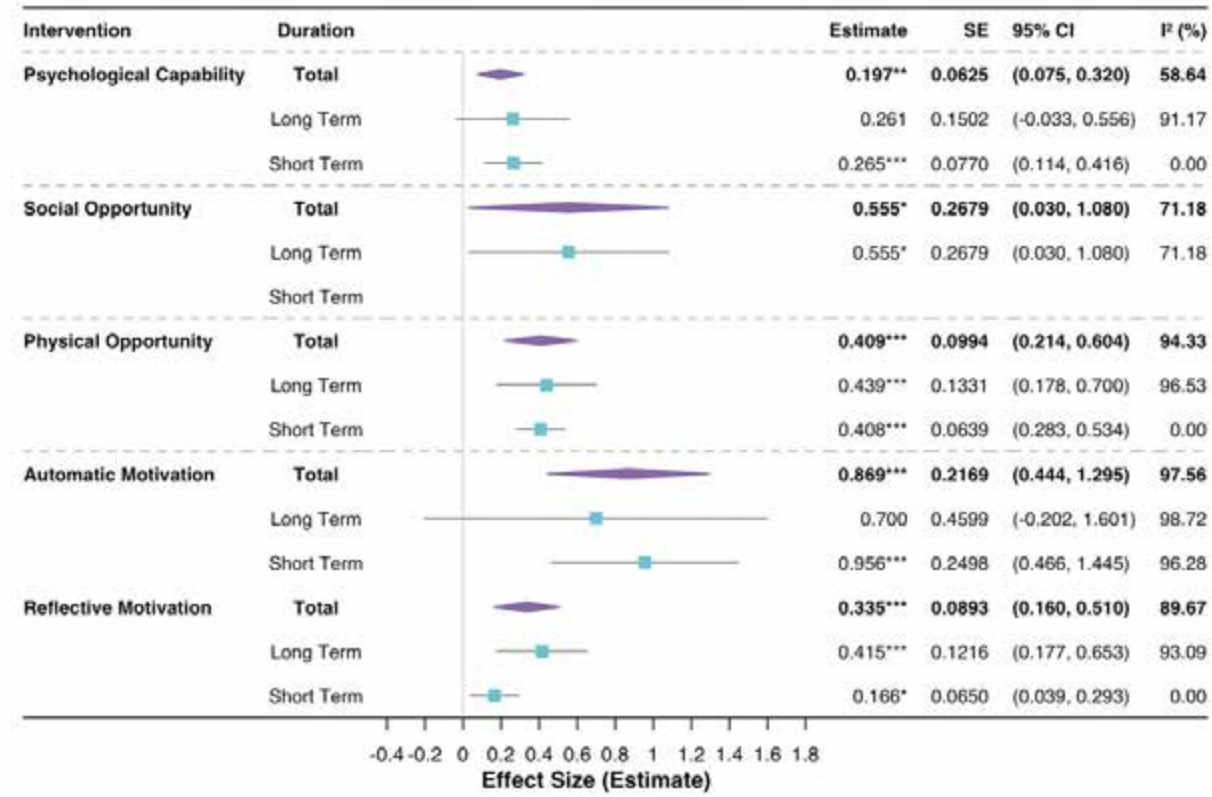

Fig. 9 Sub-group analysis of COM-B Layer

5.Discussion

This study presents a meta-analysis evaluating interventions aimed at promoting public transportation use, employing the Behaviour Change Wheel (BCW) framework to classify these interventions and elucidate the mechanisms underlying their effectiveness. By analyzing how different interventions, categorized by the BCW, influence travel behavior, we sought to understand why certain approaches are more successful than others. Our findings offer a structured understanding of intervention mechanisms, providing theoretical and practical insights for developing more effective future public transport policies.

Synthesizing data from 38 effect sizes across 24 studies and 16 countries, our meta-analysis revealed a statistically significant, moderate positive overall effect of interventions on public transportation usage (Cohen's $d = 0.5165$, $p < 0.0001$). This general finding aligns with previous research indicating that various interventions can successfully promote public transport adoption(Aravind et al., 2024; L. Zhang et al., 2019). However, the analysis also uncovered substantial heterogeneity ($I^2 = 97.16\%$), signifying considerable variability in intervention effectiveness across different contexts, populations, and intervention designs. This variability is exemplified by contrasting findings, such as the large effect reported for ticket discounts by Guzman & Hessel (2022; $d \approx 2.63$) compared to the negligible effect of transport card subsidies found by Rosenfield et al. (2020; $d \approx 0.01$). (Guzman & Hessel, 2022; Rosenfield et al., 2020). Such discrepancies underscore the necessity of delving deeper into the specific conditions and mechanisms—as facilitated by the BCW framework—that determine why and when interventions succeed or fail.

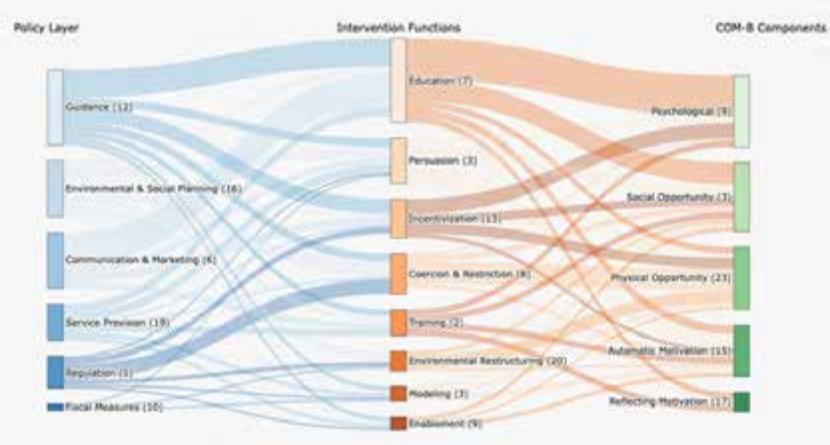

Fig. 10 Distribution of included studies within the BCW framework

To elucidate the mechanisms linking public transportation policies to behavior change, this study employed the Behaviour Change Wheel (BCW) model. We developed a novel three-level analytical framework categorizing interventions by 'policy category', 'intervention function', and 'COM-B component' (Capability, Opportunity, Motivation). This approach reveals how macro-level policy tools translate into impacts on individual travel decisions. Our analysis suggests a hierarchical pathway: policy categories establish strategic direction, implemented via specific intervention functions, which ultimately drive behavior change by influencing individuals' capabilities, opportunities, or motivations (COM-B). The interplay between these levels explains not only the key factors influencing behavior but also the causal pathways and necessary conditions for intervention effectiveness. Thus, policy success hinges on the synergy between the chosen intervention functions and their alignment with relevant COM-B targets.

Applying this BCW framework, we mapped the distribution of intervention types across the included effect sizes (Fig. 7). This revealed distinct patterns: Environmental and Social Planning (n=16 coded instances) and Service Provision (n=19) were the predominant policy categories. These typically relied on Environmental Restructuring (n=20) and Incentivisation (n=13) as core intervention functions, primarily targeting Physical Opportunity (n=23) and Reflective Motivation (n=17). This pattern supports a dual-pathway mechanism for behavior change, emphasizing improvements in infrastructure accessibility (Physical Opportunity) and influencing conscious decision-making through incentives (Reflective Motivation). The strong association observed between Physical Opportunity and Environmental Restructuring interventions (representing 43.5% of all coded connections) highlights the focus on infrastructure optimization within these policy types. In contrast, Guidance policies exhibited more complex pathways, often combining multiple functions (e.g., Education, n=7; Persuasion, n=3) to influence Automatic Motivation (n=15), underscoring the role of cognitive approaches in reshaping habits. The scarcity of interventions classified under Regulation (n=1) or Training (n=2) suggests potential gaps in research and practice regarding institutional constraints and skills development.

Significant variations exist in the effectiveness and pathways of different policy interventions. Our meta-analysis identified Guidance policies as the most effective overall (d = 0.881), significantly exceeding the average effect size (d = 0.5165). This aligns with findings from included studies where strategies like rewarding commuters (Ben-Elia & Ettema, 2011) or establishing pilot low-carbon cities (Li et al., 2023b) substantially increased public transport use, consistent also with related literature (Zarabi et al., 2024). The BCW analysis helps explain this high effectiveness: Guidance policies often integrate multiple intervention functions, such as Incentivization, Education, and Coercion/Restriction. This multi-pronged approach simultaneously targets Reflective Motivation (e.g., changing attitudes via education), Automatic Motivation (e.g., fostering habits via incentives/restrictions), and Physical Opportunities (e.g., providing convenient information), thereby removing barriers while strengthening drivers for behavior change (Bamberg et al., 2007). Their success likely stems from this ability to influence both conscious deliberation and automatic habits, potentially creating feedback loops that reinforce habit formation, perhaps through mechanisms related to reward processing (Schultz, 2015). This aligns with their strong short-term effects (d = 1.087). However, the diminished long-term impact (d = 0.380) may reflect processes like hedonic adaptation or diminishing marginal utility over time (Loewenstein & Ubel, 2008).

Our analysis revealed that Environmental and Social Planning policies, despite their frequent implementation, yielded the weakest overall effect on promoting public transport use (d = 0.209), significantly below the average intervention effect. Illustrative examples include the negligible impacts observed following the opening of Singapore's CCL Circle Line (Dai et al., 2020) or the introduction of Washington State's RapidRide BRT service replacing traditional buses (Cohen's d = 0.0705, SE = 0.1683)(Stewart et al., 2017). The BCW framework clarifies this finding: these policies predominantly utilize Environmental Restructuring functions to enhance Physical Opportunity (e.g., adding infrastructure). While seemingly contradictory to studies highlighting the positive effects of environmental changes (Nagaraja, 2002; Wu et al., 2023) , our BCW-informed analysis suggests these interventions often fail because they neglect the motivational components of the COM-B model. This creates an "infrastructure-motivation gap," where improved physical access does not translate into a willingness to change established travel behaviors (Chen et al., 2022). The insufficient focus on motivation likely also explains why the long-term effects of these policies were weaker (d = 0.197) than their short-term effects (d = 0.265). This aligns with theoretical perspectives suggesting that interventions lacking cognitive engagement may be ineffective (Sunstein, 2017) and highlights that overcoming ingrained preferences often requires more than infrastructure improvements alone, especially considering external factors like the rise of ride-hailing or remote work (Erhardt et al., 2022). Therefore, relying solely on physical infrastructure enhancements typical of Environmental and Social Planning policies appears insufficient to bridge the "infrastructure-motivation gap" and drive substantial shifts towards public transport. Achieving synergistic effects and promoting sustained behavior change likely requires complementing these structural interventions with strategies that actively engage cognitive and motivational factors, such as targeted incentives or behavioral guidance.

Furthermore, this study highlights intervention duration as a critical moderator of policy effectiveness, revealing distinct temporal patterns consistent with dual-process theories distinguishing immediate responses from considered intentions (Kahneman, 2002). Guidance policies, particularly those employing Coercion/Restriction or Incentivization functions, exhibited significantly stronger short-term effects (d = 1.087) compared to their long-term impact (d = 0.380). This suggests such approaches can induce rapid behavioral shifts, but their effects may decay without sustained reinforcement. Conversely, Service Provision policies demonstrated the most substantial and enduring positive effects over the long term (d = 0.529). This resonates with research indicating that consistent improvements in service quality and accessibility foster sustained public transport use (Hynes et al., 2018; Zarabi et al., 2024). Interventions like providing updated bus information pamphlets (Taniguchi & Fujii, 2007), or enhancing station accessibility and payment systems (Lee & Miller, 2022) function akin to "fluency nudges" (Ölander & Thøgersen, 2014), simplifying the user experience and gradually reshaping preferences. These policies typically combine Environmental Restructuring and Enablement functions, addressing not only Physical Opportunity but also enhancing information access (Capability) and convenience (Motivation). By targeting multiple COM-B components, they foster positive experiences that, consistent with the Theory of Planned Behavior (Ajzen, 1991), can solidify attitudes and intentions, leading to more lasting behavior change.

Our analysis consistently highlights the centrality of COM-B components in driving behavior change. Evaluating the pathways from policy through intervention functions to COM-B targets reveals significant differences in effectiveness based on which behavioral determinants are addressed. Using COM-B components as moderators confirms that interventions targeting Motivation (both automatic, $d \approx 0.90$, and reflective, $d \approx 0.34$) yield the largest effects. In contrast, interventions focusing primarily on Physical Opportunity or Psychological Capability demonstrated weaker impacts (pooled effect $d \approx 0.25$). This underscores that while enhancing opportunities (e.g., via infrastructure) is necessary, effectively stimulating motivational drivers is crucial for promoting behavior change. Furthermore, intervention functions that directly influence motivation, such as Incentivization, Modelling, and Enablement, appear particularly effective precisely because they successfully engage these motivational levers.

This study also examined the moderating influence of contextual factors on intervention effectiveness. Findings indicate that effectiveness is significantly shaped by multiple contextual dimensions. The level of analysis emerged as a key factor, with interventions targeting individuals ($d \approx 0.64$) showing larger effects than those at the road/station ($d \approx 0.31$) or city level ($d \approx 0.28$), reflecting potential "proximity effects" where interventions closer to the individual decision-maker are more impactful. However, city-level analyses exhibited greater stability (lower I^2), suggesting policy-level interventions might possess greater cross-context robustness. Measurement method also mattered significantly: effect sizes derived from administrative census data were largest ($d \approx 0.71$) but showed extreme heterogeneity ($I^2 > 98\%$), possibly reflecting variations in data protocols.

Critically, objective travel data yielded significantly smaller effect sizes ($d \approx 0.27$) compared to self-reported data ($d \approx 0.58$; $\Delta d \approx 0.31$, $p < 0.01$). This likely reflects social desirability bias in self-reports (Paulhus & Reid, 1991), suggesting that evaluations relying solely on subjective measures may systematically overestimate intervention impacts. Geographic characteristics showed complex relationships; for instance, mid-sized cities appeared to be effective intervention contexts ($d \approx 0.68$), potentially due to a balance of social norms and resources. Higher effects were observed in Europe compared to Asia ($d \approx 1.15$ vs. 0.19), possibly reflecting cultural or policy environment differences. The intervention duration effect was confirmed, with short-term interventions ($d \approx 0.69$) outperforming long-term ones ($d \approx 0.37$), potentially hinting at behavioral inertia and suggesting the value of intermittent reinforcement strategies. Finally, transport mode mattered: interventions involving rail systems showed larger effects ($d \approx 0.98$) than other modes, possibly due to their structured nature, although the diminished effect for mature metro systems ($d \approx 0.40$) suggests a potential threshold effect where excessive system rigidity might limit further intervention impact. Collectively, these findings emphasize the crucial role of context in shaping intervention outcomes, necessitating customized strategies.

These findings yield important practical implications for public transportation policy. First, policymakers should move beyond single-strategy approaches towards integrated, multi-layered intervention systems. Such systems should strategically combine enhancements to Physical Opportunity (e.g., infrastructure via Environmental/ Social Planning) with efforts to stimulate and sustain Motivation (e.g., via Guidance, Communication/Marketing, Service Provision). For instance, new infrastructure should be paired with informational campaigns, seamless payment systems, and potentially targeted incentives to bridge the "infrastructure-motivation gap." Second, strategies must be temporally aligned with policy goals. For rapid behavioral shifts, approaches like incentives or restrictions (often under Guidance policies) may be prioritized due to their strong short-term effects. However, fostering sustainable habits requires a longer-term focus on enhancing Service Provision and Enablement, continuously improving the travel experience and system efficiency. Third, given the identified synergy between opportunity and motivation, and the risk of solely focusing on infrastructure, initiatives must strategically balance investments in both physical and psychological domains to maximize resource efficiency and policy impact. Finally, intervention design must be context-sensitive, tailoring approaches based on factors like city size, cultural context, existing transport system characteristics, and target population characteristics to optimize effectiveness.

This research offers several novel contributions. Primarily, by systematically applying the BCW framework, it provides an integrated theoretical lens for analyzing diverse public transportation interventions, decomposing them into policy categories, intervention functions, and target COM-B components to clarify their operational logic. Second, moving beyond typical meta-analyses focused on overall effects or broad categories, this study delves into the underlying mechanisms driving intervention success or failure. It quantifies effectiveness differences (e.g., Guidance vs. Environmental Planning policies) and, crucially, offers explanations grounded in behavioral theory for why these differences exist, particularly emphasizing the distinct roles of opportunity and motivation. Third, through rigorous coding and detailed subgroup analyses, the study provides robust empirical evidence supporting these mechanistic explanations. Overall, this comprehensive framework bridges behavioral science theory and empirical policy evaluation, offering a theoretically sound basis for designing more sophisticated and effective public transportation strategies.

Despite these contributions, the study has limitations that warrant caution in interpretation. First, the substantial heterogeneity observed ($I^2 > 97\%$ in some analyses) indicates that intervention effects are influenced by numerous unmeasured factors, including specific study designs, implementation fidelity, local contexts, and concurrent events. While moderator analyses explained some variance, considerable heterogeneity remains, highlighting the need for future research employing more controlled designs or focusing on more homogeneous intervention types. Second, our inclusion criteria (English-language, quantitative studies, 2000-2023) may introduce publication and selection biases, potentially omitting relevant findings. Future syntheses could broaden inclusion criteria. Third, reliance on Cohen's d as the primary effect size metric, while standard, simplifies complex behavioral shifts; future work could benefit from incorporating richer, multi-dimensional outcomes or mixed-methods data. Finally, while the BCW framework is comprehensive for behavioral analysis, it inherently focuses less on broader external factors (e.g., political dynamics, macroeconomic trends) that undoubtedly influence public transport use. Future research employing mixed methods and expanding geographic/temporal scope could further enrich understanding of intervention effectiveness and mechanisms within these wider systems.

6.Conclusion

This study systematically evaluated the impact and underlying mechanisms of public transportation interventions using a novel three-level analytical model based on the Behaviour Change Wheel (BCW) framework. By synthesizing evidence on the short- and long-term effects of different policy categories, we draw the following main conclusions:

First, Guidance policies demonstrate the largest overall positive effect on promoting public transport use. These interventions, often employing education, promotion, and social norm strategies, effectively enhance awareness and positive attitudes, leading to significant short-term increases in ridership. By fostering understanding of environmental and economic benefits and shaping social norms, they contribute to reinforcing positive attitudes and building a foundation for longer-term behavior change. However, our analysis suggests that the impact of Guidance policies may diminish over time if not complemented by other sustained strategies, highlighting the need for integrated approaches rather than relying solely on guidance for long-term sustainability.

Second, Environmental and Social Planning policies, while crucial for improving the physical environment and accessibility of public transport through infrastructure development, exhibit limited effectiveness in driving sustained behavior change independently. This underscores the challenge of the "infrastructure-motivation gap," where structural improvements alone often fail to overcome ingrained travel habits. To achieve lasting impacts and enhance transportation sustainability, these policies must be integrated with interventions that actively engage motivational and capability factors, such as targeted incentives or behavioral guidance strategies.

Third, Service Provision policies demonstrate significant positive effects, particularly notable for their lasting impact over the long term. These policies succeed by not only enhancing Physical Opportunity but also by providing ongoing support, convenience, and technological innovations that address other key behavioral determinants. From a COM-B perspective, effective Service Provision often targets multiple components—including Opportunity, Motivation, and Capability—thereby comprehensively supporting the adoption and maintenance of public transport use.

In conclusion, achieving sustainable public transportation systems requires comprehensive, integrated strategies that leverage the strengths of different policy approaches. Effective interventions should combine the motivational impetus often provided by Guidance policies, the essential infrastructure improvements from Environmental and Social Planning, and the sustained, multi-faceted support offered by well-designed Service Provision. Utilizing frameworks like the BCW to understand these mechanisms allows for the design of more targeted, efficient, and ultimately more effective policies. Such evidence-informed policy design is crucial for promoting public transport use and contributing to the development of greener, healthier, and more livable urban environments. Continued research, expanding methodological approaches and scope, will be vital for further refining our understanding and fostering adaptive, resilient public transportation systems.

Supplemental Material

Table S1 Search strategy

Table S2 Standardized Form of Extracting and Coding data

Table S3 Definitions of policy categories as described by the Behaviour Change Wheel

Policy category	Definition	Public Transport Examples
Guidelines	The development and dissemination of documents that make recommendations for action in response to defined situations	Orientation documents issued in the programme (e.g. some pilot zones)
Environmental and social planning	Architecture, urban and rural planning, object and location design, and planning for housing, social care, employment, equality, benefits, security and education	Construction, improvement of public transportation routes
Communications and marketing	Mass media campaigns, digital marketing campaigns, and correspondence	Leafleting, SMS, large screen publicity, etc.
Service provision	Provision of any kinds of service or material resource and aids, whether they be structured or ad hoc, financed or unpaid	Fare subsidies, new lines, etc.
Regulation	Development and implementation of rules regarding behaviour that instruct the behaviour and possibly provide rewards and punishments for conforming	temporary incentives in MRT(a full rebate of subway fare)
Fiscal measures	Use of taxation and tax relief	public transit tax credit

Table S4 Definitions of intervention types as described by the Behavior Change Wheel

Interventi-on type	Definition	Pub-lic Transport Examples
Environmen-tal restructu-ring	Changing the physical or social context	construct new met-ro line
Education	Increasing knowledge or understanding	Promote information on health/public transpor-tation/environment;
Persuasion	Using communication to induce positive or negative feelings or sti-mulate action	Providing public transit information through communication and lectures
Incentiviza-tion	Creating an expectation of reward	Free tickets, subsidies, differential pricing po-licies
Coercion and Restriction	Creating an expectation of punishment or cost or use of rules to reduce opportunities to engage in target behaviors	Increase in gasoline prices∆Restrictions on automobile travel
Training	Imparting skills	Emerging transit software use through training
Modelling	Providing an example for people to aspire to or imitate	Workplace mobility ma-nagement program
Enablement	Increasing means/ reducing barriers to increase capability (be-yond education and training) or opportunity (beyond environmen-tal restructuring)	Simplifying ticket pur-chasing by smart-card system

Table S5 Components of the COM-B model

	COM-B model compo-nent	Definition	Public Transport Examples
C	Physical capa-bility	Physical skill, strength, or stamina	?
	Psychologi-cal capability	Knowledge or psychological skills, strength, or stamina to enga-ge in the necessary mental processes	Real-time Information System; Mobi-le apps and GPS trackers to provide motiva-tions and advice
O	Physical oppor-tunity	Opportunity afforded by the environment involving time, resour-ces, locations, cues, and physical 'affordance'	BCT, Integrated Mass Transit Sys-tem, new railway, new metro line, entran-ce of Uber
	Social oppor-tunity	Opportunity afforded by interpersonal influences, social cues and cul-tural norms that influence the way that we think about thin-gs, e.g. the words and concepts that make up our language	Workplace pt programme
M	Reflective moti-vation	Reflective processes involving plans (self-conscious intenti-ons) and evaluations (beliefs about what is good and bad)	Use of mobile apps and GPS trac-kers to provide motivation and advice
	Automatic mo-tivation	Automatic processes involving emotional reactions, desi-res (wants and needs), impulses, inhibitions, drive states and ref-lex responses	Temporary incentives in MRT (a full reba-te of subway fare)

Abstract
Planetary climate and resource crises reshape urban spatial logic and transport networks. With diverse mobility modes emerging, sustainable and adaptive planning is key to managing uncertainty. Traditional approaches fail to capture dynamic demand and complex variables, causing supply adjustments to lag. This study explicates adaptive planning theory, revisits the pivotal support role of buses and structural causes of imbalances, and proposes an adaptive evaluation framework integrating spatial and social indicators. It embeds mobility-mode interactions and uncertainty-response methods to extend conventional bus-planning paradigms. Analysing representative cities' bus supply–demand matching in China and Europe, we propose possible pathways for adaptive response, including multi-level governance, data-driven systems, resource allocation, and emergency mechanisms, which provide resilient, science-based decision support for transport planning in crises.

Keywords: Adaptive Transformations; Mobility Crisis; Public Transport; Evaluation System; Sustainable Development

1. Introduction

1.1 Background and Problem Statement

Composite shocks from climate change, energy scarcity and public health crises are systematically reshaping the sustainable development agenda of urban transport (Meyer and Weigel, 2011; Gaskin, Zare and Delarmente, 2021; Payakkamas, de Kraker and Dijk, 2023; Macdonald et al., 2024). Against a backdrop of frequent extreme weather events, heightened dependency risks on fossil fuels and routine epidemic control, public transit—as a critical urban system embodying social equity (Palm et al., 2021; Gadson and Park, 2024) and environmental benefits (Jiang, Zhou and Liu, 2019; Zhao et al., 2024)—have transcended mere mobility services to become core carrier for urban resilience construction (Goncalves and Ribeiro, 2020; Mirzaee and Wang, 2020).

However, the traditional transport planning paradigm, long constrained by efficiency-driven static optimisation logic (Horiuchi et al., 2024; Li et al., 2024), exhibits clear limits when addressing dynamic supply–demand imbalances, service Resilience deficits and shock events (Cats and Jenelius, 2015). Classical tools such as the four-stage model, due to excessive reliance on historical extrapolation and steady-state equilibrium assumptions (Li et al., 2021), fail to adapt to non-linear evolutions like sudden demographic change (Kasu and Chi, 2018), heterogeneous travel behaviour (Wang et al., 2024) or urban–rural transport dynamics (Xiao and Xu, 2022).

For instance, the pandemic-induced collapse in bus ridership revealed a stark mismatch between rigid service supply and elastic travel demand (Petrov and Petrova, 2020), exposing structural flaws in vulnerability assessment and adaptive regulation within modern bus systems (Man, Andor and Birsanuc, 2022). This underscores the urgent need to shift from a predict–control paradigm to a monitor–respond approach, reconstructing an adaptive methodology for planning and transport under uncertainty by integrating Adaptive Planning theory with socio-technical transition frameworks (Xiang et al., 2023; Deng et al., 2025).

1.2 Research Questions and Objectives

This study addresses three questions: **First**, how can we deconstruct the theoretical core of adaptive planning under planetary crisis, and delineate its transformational features—in value orientation, methodology and implementation—relative to traditional paradigms? **Second**, how can we develop a dynamic, feedbackcapable evaluation framework for bus systems that accurately identifies supply–demand imbalance transmission

mechanisms? **Third**, how can innovative governance models translate planning concepts into operational practice?

To answer these, we integrate complex adaptive systems theory with Transformation Planning thought to build an Adaptive Planning framework for buses, propose sociotechnical transition analysis tools, and construct a dynamic evaluation model. Descriptive analyses of representative Chinese and Central European cities then distil governance pathways for transport Adaptive Planning under varied institutional contexts.

1.3 Significance and Innovation

By uniting the theoretical lineages of Adaptive Planning and Transformation Planning, this study transcends the cognitive limits of traditional static analysis paradigms. Employing a multicriteria dynamic evaluation system, it introduces a quantitative method to assess vulnerability transmission pathways in bus systems. This method exemplifies the interdisciplinary nexus of urban planning, public policy, equity, environmental sustainability and system Resilience, offering effective policy interfaces for innovating bus service provision in the postpandemic era. The paper unfolds along the logic of theory review–dilemma analysis–method development–case validation–policy translation.

2. Theoretical Foundations: Adaptive Planning and Its Transformative Logic

2.1 Overview of Adaptive Planning Theory

Adaptive Planning, emerging as a novel paradigm for navigating uncertainty and complexity under the planetary crisis (Pelling, O'Brien and Matyas, 2015), centres on continuous adjustment and feedback to ensure co-evolution between planning systems and external environments (Smith, 2016; Thomas Machiels et al., 2023). Rooted in late-20th-century concepts of Dynamic Planning and Adaptive Management (Margoluis and Salafsky, 1998; Schreiber et al., 2004), it later integrated with theories of urban resilience and complex adaptive systems (Dovey, 2012; Meerow, Newell and Stults, 2016), culminating in a process-oriented, systems-thinking framework (Ahern, 2011; Davoudi, 2021).

The theoretical evolution of Adaptive Planning spans ecological resource management and urban resilience enhancement, eventually advancing into multidimensional, collaborative governance tailored to climate crises and digital transformation (Varzeshi, Fien and Irajifar, 2024). Three core principles underpin this approach:

Dynamic Responsiveness: Enhancing systemic responsiveness to external disruptions—such as extreme climate or public health emergencies—through real-time monitoring and flexible adjustment mechanisms.

Multidimensional Collaboration: Building cross-sectoral (transport, energy, environment), cross-scalar (urban–regional–national), and multi-actor (government, residents, enterprises, planners) governance networks that transcend administrative boundaries and conventional models.

Social Inclusiveness: Embedding equity in planning decisions, prioritising the needs of vulnerable groups, particularly in relation to mobility and welfare.

Essentially, Adaptive Planning operationalises the Sustainable Development Goals (SDGs) and the principle of equity. Through phased policy adaptation and flexible interventions (Haasnoot et al., 2024), it aims to mitigate spatial exclusion (Ghasemi et al., 2025).

2.2 Transformative Logic of Adaptive Planning

Transformative Planning entails a paradigmatic shift from linear growth thinking to circular, low-carbon, and resilience-oriented transformation (Huq, 2020; Novalia and Malekpour, 2020). Its intellectual foundations lie in Socio-Technical Transitions (Kern, 2012) and Just Transition frameworks (Forde, 2024). Within the planetary crisis context, urban planning transformation engages three interlinked dimensions:

Cognitive Reconstruction: A shift from static, blueprint-oriented visions to dynamic goals of safety, resilience, and liveability;

from fixed long-term planning cycles to a hybrid of short-term action and long-term targets; and from linear planning–implementation–completion trajectories to iterative cycles of identification–action–evaluation–adjustment–re-identification.

Institutional Innovation: A transition from top-down decision-making to bottom-up, citizen-driven governance. This involves multi-level institutional architectures integrating central policy guidance, urban pilot innovations, and community co-governance.

Technological Transformation: Leveraging tools such as digital twins and AI-based forecasting to enhance systemic resilience, enable adaptive planning implementation, and ensure rapid response.

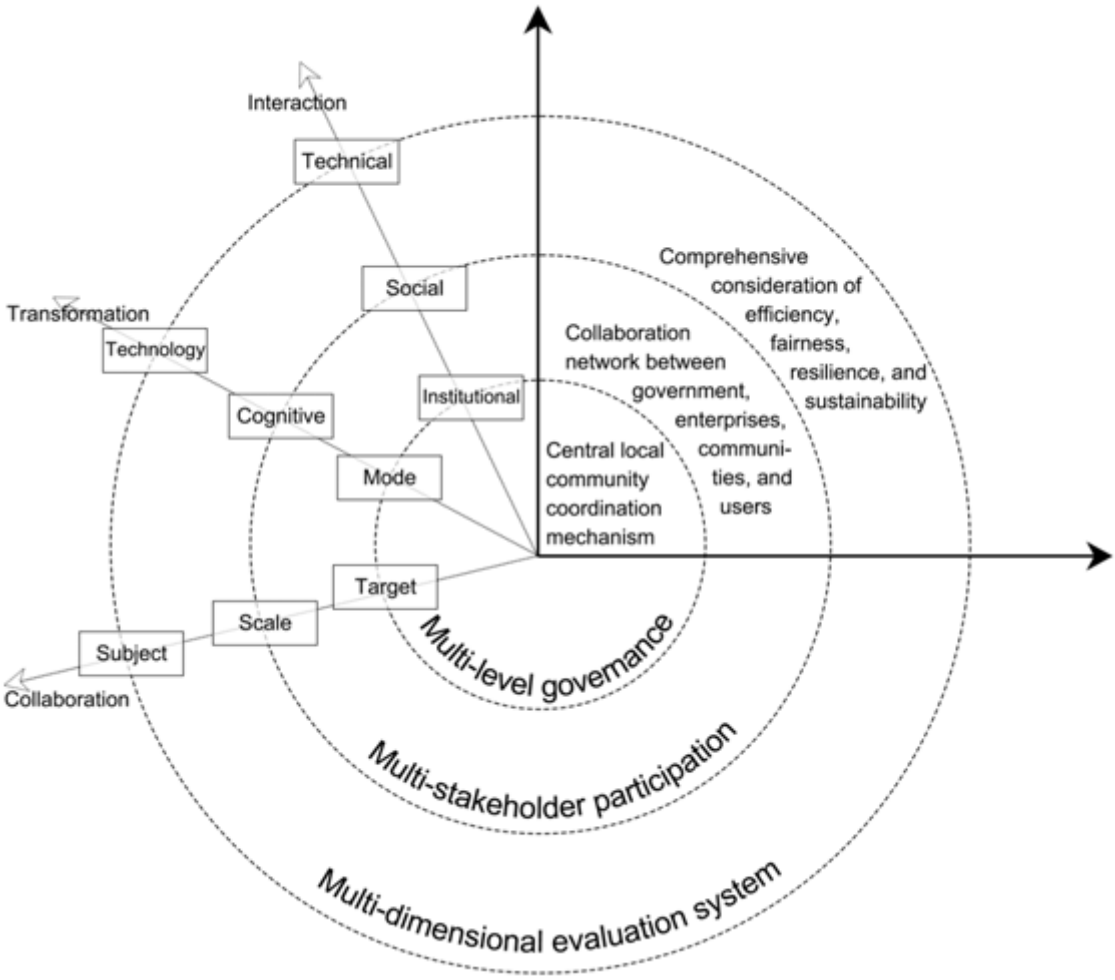

Fig.1 Theoretical Framework for Adaptive Planning Transformation

Overall, the transformation of planning should follow a co-evolutionary pathway across technological, social, and institutional domains (Figure 1). On the governance front, it entails forging risk-sharing and benefit-sharing coalitions among governments, businesses, and the public. On the evaluation front, it necessitates establishing composite indicator systems that integrate efficiency, equity, resilience, and sustainability (Fu and Li, 2022).

3. Role Reconfiguration: Supply–Demand Imbalance and Coopetition in the Context of the Mobility Crisis

3.1 Global Mobility Crisis and Transport Challenges

The dominant paradigm of public transport planning—rooted in car-centric and efficiency-focused logics—is increasingly being challenged. In the face of unpredictable disruptions triggered by climate, economic, or health-

related events, the limitations of conventional planning models become evident. Their reliance on static equilibrium assumptions and technocratic optimisation tools renders them ill-equipped to address dynamic and uncertain conditions. This often results in structural rigidity within transit networks and inadequate responsiveness in resource allocation (Schmidt and Meyer, 2009; Efthymiou et al., 2018).

Globally, the transport sector faces dual pressures from planetary crisis-induced events and shifting mobility demand. Climate imperatives compel a low-carbon transition in bus systems, necessitating breakthroughs in energy structure and emission intensity (Yang, Ma and Sun, 2018). Simultaneously, recurring public health and extreme weather events expose vulnerabilities in operational resilience. Moreover, the proliferation of remote work and diversified travel behaviours have profoundly altered demand structures, rendering fixed-service models increasingly mismatched with spatially and temporally dispersed patterns (Van Nieuwerburgh, 2023).

In China's rapidly urbanising context, these mobility crises are even more acute. While urban expansion fuels travel demand, a car-centric mobility structure exacerbates congestion and pollution. Persistent underfunding, spatial mismatches between networks and jobs-housing patterns, and uneven service quality underscore deeper structural tensions. Temporal and spatial imbalances in supply and demand of public transport remain evident (Wan, Wang and Sperling, 2013).

Resolving these contradictions requires a multidimensional analytical framework encompassing spatial fragmentation (e.g., jobs–housing separation), social stratification (e.g., limited accessibility for vulnerable groups), and technological lag (e.g., inadequate real-time demand sensing). Adaptive planning offers a mechanism for institutional transformation, bridging the disjuncture between static planning paradigms and dynamic urban change. It provides a pathway for bus systems to integrate environmental resilience and social equity as core values (Wall et al., 2015).

3.2 Coopetition between Diverse Transport Modes and Bus Systems

Amid mobility transformation, bus systems are undergoing a critical redefinition of roles (Knowles, Ferbrache and Nikitas, 2020). The interplay among diverse transport modes exhibits dynamic and complex characteristics. Real-time data-sharing platforms dismantle information silos, enabling responsive demand sensing—setting the stage for adaptive transformation in the transport domain.

On the side of coordination, the innovation of "bus+" models has facilitated deep multimodal integration. A composite network combining trunk-line buses and microcirculation feeders can achieve seamless modal linkages. For example, shared bicycle systems extend the effective service radius of buses, while multimodal hubs promote regional integration. This requires planners to reassess the foundational role of buses as both structural backbones and connective supports.

On the side of competition, emerging mobility modes are reshaping urban transport hierarchies. Rising private car ownership and the immediacy of ride-hailing services place buses at a disadvantage in terms of time efficiency and comfort. Micromobility options—such as shared bikes and e-scooters—have significantly diverted demand for short-distance trips (3–5 km). Surveys in cities like Beijing indicate that up to 15% of bus demand has already been displaced by such modes.

In the future, disruptive technologies such as autonomous driving and vehicle–infrastructure integration may trigger fundamental shifts in mobility structures. Market mechanisms also deepen inequality: high-income groups shift towards customised services, while marginalised populations bear the brunt of declining service quality. This necessitates public service safeguards within competitive transport ecosystems.

In sum, the evolution of future transport systems will increasingly hinge on the diversified roles of multiple modes.

The digital revolution is accelerating adaptive transformation: real-time demand sensing and optimisation algorithms enable dynamic system adjustments (Legaspi et al., 2020). Consequently, buses can be deeply integrated within service-oriented platforms such as Mobility-as-a-Service (MaaS), shifting from physical connectivity to service fusion.

With digital technologies as enablers, governance mechanisms should also undergo adaptive transformation to balance market dynamism with public value. Crucially, beyond redesigning institutional arrangements such as bus priority or carbon quota trading, policy frameworks should also recognise the public nature of buses—reinforcing their role in mobility systems through precise targeting, quality enhancement, and service innovation. Ultimately, this would enable a strategic leap for bus systems—from mere transport vehicles to resilient urban infrastructure. A rational understanding and evaluation of the bus system constitutes a critical step in this policy pathway, serving as a fundamental reference for quality service innovation.

4. Rethinking Approach: Evaluation Framework and Indicator System for Adaptive Bus Planning

4.1 Design Principles and Structural Logic of the Evaluation Framework

In response to the transformative demands of bus systems under the planetary crisis, this study develops a dual-layered evaluation framework (Figure 2). Grounded in the paradigm shift towards the reconfiguration of planning values—efficiency (accessibility), equity resilience, and sustainability—it aims to enhance crisis responsiveness, service sustainability, and social inclusiveness through multidimensional coordination mechanisms.

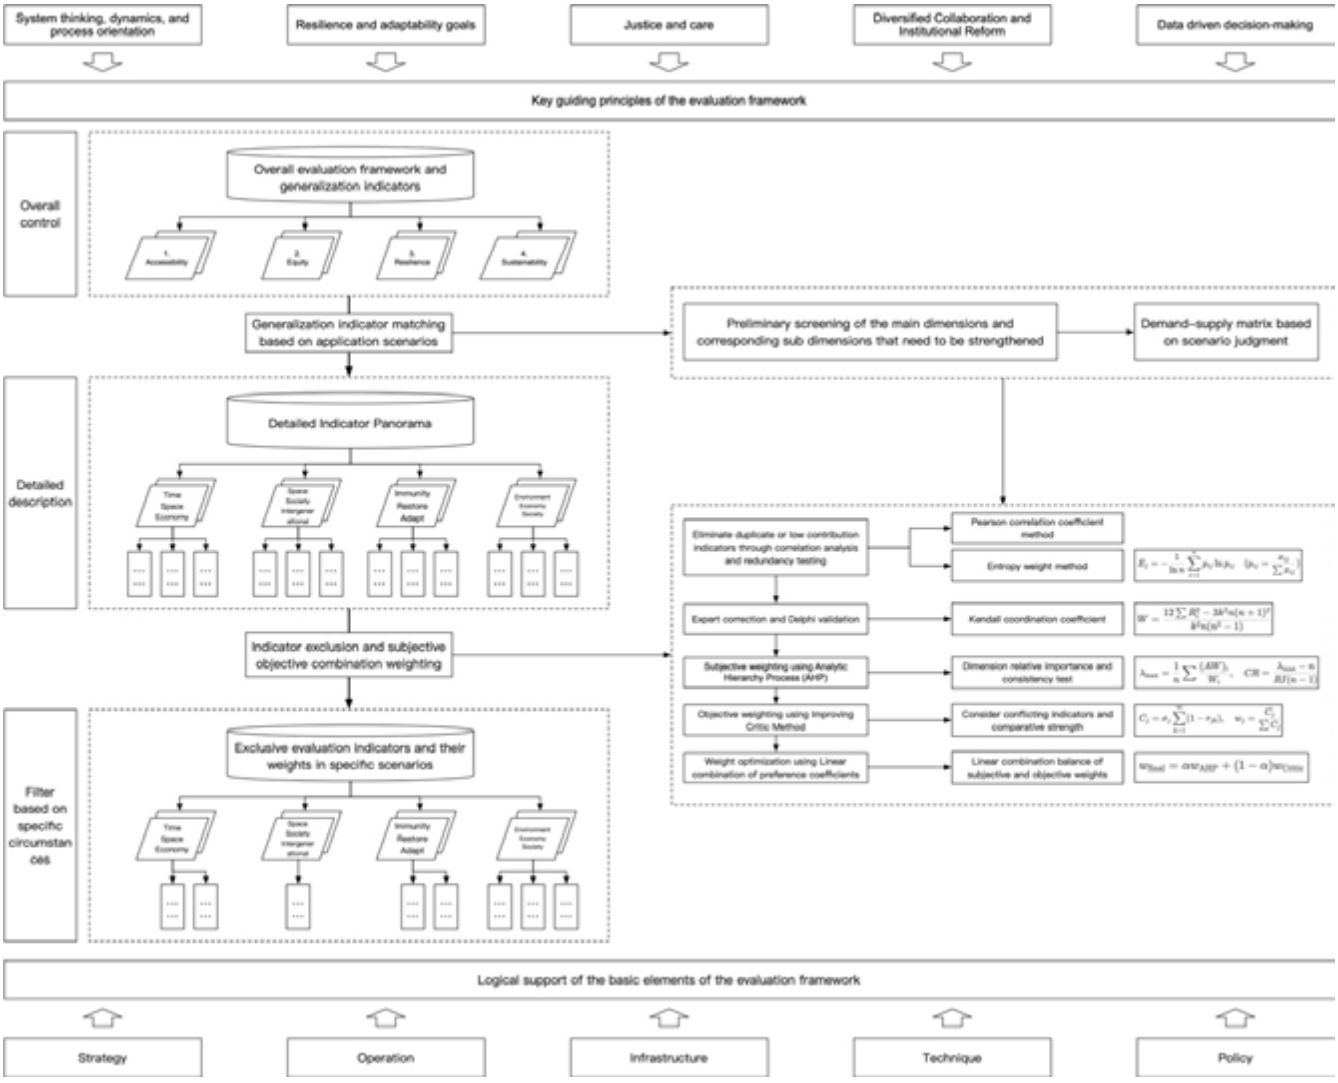

Fig.2 Evaluation Framework for Adaptive Bus Planning

The framework follows a three-tiered progressive structure.

First, at the value level, it moves beyond the efficiency-dominant paradigm, drawing on degrowth theory and care mobility to propose a holistic evaluation matrix centred on accessibility, equity, resilience, and sustainability.

Generalised indicators are accordingly introduced to capture the coupling of system resilience, environmental sustainability, and spatial justice.

Second, a scenario-oriented indicator mapping process constructs a panoramic indicator library, offering dimensional depth as the foundation of the framework.

Third, through systematic indicator screening and a combined subjective-objective weighting mechanism, context-specific indicators and weighting schemes are developed to support tailored evaluations. This process involves correlation analysis, redundancy detection, expert-based elimination, hybrid weighting, and linear combination optimisation.

The framework is supported by a multi-level logic structure. Strategically, it incorporates long-term visions and multi-scenario planning to guide adaptive mechanisms. Operationally, it introduces flexible network and frequency scheduling. Infrastructurally, it addresses the integration of stations, energy, and other physical resources. Technically, it considers real-time data monitoring. Also, at the policy level, it emphasises crisis preparedness and low-carbon mobility incentives.

These are reinforced by key guiding principles such as dynamic systems thinking, resilience-oriented mechanism design, and pluralistic participatory models grounded in social equity. Collectively, these elements enable iterative feedback loops and continuous system evolution under conditions of uncertainty.

4.2 Multi-Criteria Indicator System for Adaptive Evaluation: Accessibility, Equity, Resilience and Sustainability

Under the integrated framework, a comprehensive multi-criteria indicator system is established (Table 1), spanning both supply and demand dimensions. Centred on four core principles—accessibility, equity, resilience, and sustainability—the system bridges internal operational efficiency and external societal effects, providing a dynamic tool for adaptive planning.

Supply-side indicators address resource allocation, service provision, and operational control, while demand-side indicators reflect user satisfaction, perceived equity, and environmental interaction. Their interaction captures the multidimensional essence of bus system transformation.

Tab.1 Multi-Criteria Evaluation Indicators

		Supply Side	Demand Side
1. Accessibility	Space Time Economic	Service coverage, Service frequency, Site coverage……	Walking distance, Ticket affordability, Travel time cost ……
2. Equity	Spatial Social Intergenerational	Regional allocation of public transportation resources, Coverage of barrier free facilities… …	Satisfaction rate of vulnerable groups' needs, Subjective evaluation of fairness……
3. Resilience	Immunity Recover Adaptability	Emergency response time, Redundancy of backup facilities……	Evaluation of passenger diversion efficiency, Reliability of emergency services……
4. Suitability	Environmental Economic Social	Carbon emission intensity, Operational efficiency, On-time performance……	User satisfaction, Public participation……

The framework further disaggregates each dimension, yielding a panoramic set of 68 supply-side and 60 demand-side indicators, serving as a reference for context-specific indicator selection in diverse scenarios.

4.2.1 Accessibility Evaluation: Coupling Spatial-Temporal Opportunity and Cost Constraints

As the core functional expression of bus services, accessibility should be analysed through spatial, temporal, and economic lenses (Table 2).

Spatial accessibility is assessed via supply indicators such as S1 and S3, reflecting network layout efficiency, while demand indicators like D1 and D4 measure users' practical ease of network access. Temporal accessibility

relies on supply-side operational parameters (e.g., S8, S11) and demand-side metrics (e.g., D6, D9) that quantify user experience in space-time cost. Economic accessibility combines supply indicators (e.g., S15, S16) capturing affordability policies with demand indicators (e.g., D10, D14) that reveal service penetration across socio-economic gradients. This dimension also introduces GIS-based spatial analytics, incorporating non-transport variables to evaluate the system's latent support for urban functions.

Tab.2 Accessibility Evaluation

1. Accessibility	Space	S1	Stop density	D1	Average distance of walking to the nearest stop
		S2	Line network density	D2	Walking accessibility time distribution
		S3	Service coverage rate within xx meters	D3	The straight-line distance from residential areas to stations
		S4	Coverage rate within a 500 - meter service radius	D4	Differences in accessibility among different landuse types
		S5	Number and distribution of transfer nodes		/
		S6	Network connectivity index		/
		S7	Average distance between stops		/
	Time	S8	Departure frequency	D5	Average travel time
		S9	Length of operating hours	D6	Total door-to-door travel time
		S10	Average operating speed	D7	Delayed time during peak hours
		S11	On-time performance rate	D8	Time costs between different Origin-Destination (OD) pairs
		S12	Stability of headway	D9	User perception of time reliability
		S13	Transfer waiting time		/
	Economic	S14	Fare level setting	D10	The ratio of fares to household income
		S15	Fare structure (sectional/zonal)	D11	Travel cost per unit distance
		S16	Transfer discount policy	D12	Comparison of costs with other modes of transportation
		S17	Fare discounts for special groups	D13	Price sensitivity among different income groups
		S18	Allocation of operating costs	D14	Travel cost burden index

4.2.2 Equity Evaluation: Aligning Spatial Balance and Group Justice

Equity evaluation transcends traditional homogenised approaches by integrating spatial, social, and intergenerational dimensions (Table 3).

Spatial equity is reflected in indicators such as S19 and S21, which reveal spatial disparities in resource allocation, while D18 captures travel exclusion experienced by residents in marginalised areas. Social equity includes institutional inclusiveness (e.g., S24, S28) and demand-side perceptions of justice (e.g., D20, D23). Intergenerational equity introduces long-term low-carbon transitions into present planning via indicators like S29 and D25. This dimension highlights path dependence rooted in historical injustices and interrogates structural contradictions embedded in bus service distribution.

Tab.3 Equity Evaluation

		Supply Side		Demand Side	
2. Equity	Spatial	S19	Standard deviation of service levels in different regions	D15	Evaluation of travel convenience for residents in different regions
		S20	Service ratio between the central urban area and the peripheral regions	D16	Inter - regional accessibility difference coefficient
		S21	Gini coefficient of bus network coverage	D17	Travel time cost for residents in peripheral areas
		S22	Spatial distribution equilibrium of transport capacity input	D18	Spatial Deprivation Index
		S23	Regional differences in facility configuration standards	D19	Differences in services atisfaction across different regions
	Social	S24	Coverage rate of barrier-free facilities	D20	Travel satisfaction levels among different age groups
		S25	Proportion of low-floor vehicles	D21	Evaluation of Travel Convenience for People with Disabilities
		S26	Multilingual information service coverage	D22	Bus dependence of low-income groups
		S27	Configuration of special facilities for the elderly and children	D23	Gender differences in perceived travel safety
		S28	Service policies for special groups	D24	The degree of travel exclusion for vulnerable groups
	Intergenerational	S29	The proportion of renewable energy use	D25	Intergenerational sharing of environmental costs
		S30	Level of investment in green technology	D26	Satisfaction of future travel demand prediction
		S31	Environmental protection facilities configuration standards	D27	Preferences for sustainable travel mode selection
		S32	Proportion of sustainable development investment	D28	Assessment of intergenerational environmental burden
		S33	Technology upgrade cycle	D29	Long-term development benefit distribution

4.2.3 Resilience Evaluation: Reconstructing Systemic Resilience and Adaptive Capacity

The resilience of bus systems is assessed through a tripartite framework encompassing resistance, recovery, and adaptation (Table 4).

Structural robustness, as an expression of resistance, is captured by supply-side indicators such as S34 and S39, while D30 and D31 reflect the social cost of disruption propagation on the demand side. Recovery is evaluated

through technical metrics including S40 and S44, alongside behavioural adjustment processes tracked by D36. Adaptation focuses on the system's capacity for dynamic realignment under climate variability and demand fluctuations. The coupled analyses using S47 and D40 reveal the system's evolutionary potential. This dimension emphasises stress testing and scenario simulation, validating resilience indicators through compound scenarios involving extreme climate and energy crises.

Tab.4 Resilience Evaluation

		Supply Side		Demand Side	
3. Resilience	Immunity	S34	Network redundancy coefficient	D30	Impacts cope of single-point failures
		S35	Identification and protection of critical nodes	D31	Passenger detention time during service interruptions
		S36	Number of backup facilities/paths	D32	Availability of alternative routes
		S37	System fault-tolerant design level	D33	Performance of system stress testing
		S38	Completeness of emergency response plans	D34	Service stability perceived by users
		S39	Dispersion of critical facilities		/
	Recover	S40	Emergency response time	D35	User acceptance time after service restoration
		S41	Average duration of fault repair	D36	Travel mode conversion during the recovery period
		S42	Emergency vehicle and personnel deployment	D37	Users' satisfaction with the recovery effect
		S43	Response speed of information release	D38	Increased travel costs during the recovery process
		S44	Initiation time of alternative services	D39	Time to reach normal service level
		S45	Standardized process for resuming operations		/
	Adaptability	S46	System upgrading and transformation capabilities	D40	Adaptability of response to demand changes
		S47	The application level of technological innovation	D41	New technology acceptance and utilization rate
		S48	Flexibility in adjusting the operation mode	D42	Adaptation time for service mode changes
		S49	Adaptability of long-term planning	D43	Long-term evolution trends of travel modes
		S50	Diversified services supply capacity	D44	The dynamism of meeting user needs

4.2.4 Sustainability Evaluation: Dynamic Equilibrium of the Triple Bottom Line

Sustainability is assessed through a lifecycle-based framework aligned with the environmental-economic-social triple bottom line (Table 5).

Environmental sustainability is quantified via S51 and S52, indicating progress towards low-carbon Transformation, while D45 captures ecological behavioural responses. Economic sustainability is reflected in balanced cost inputs (S57) and the long-term market viability of service provision (D50, D52). Social sustainability transcends conventional satisfaction metrics, with indicators such as S64 and S67 illuminating the social capital underpinning system operation, while longitudinal data like D60 trace the cumulative effect of institutional credibility.

Tab.5 Sustainability Evaluation

		Supply Side		Demand Side	
4. Suitability	Environmental	S51	Carbon emissions per unit of transport volume	D45	The proportion of bus trips replacing private car trips
		S52	Proportion of new energy vehicles	D46	Residents' preference for environmentally friendly travel choices
		S53	Energy consumption efficiency	D47	Users' awareness of environmental benefits
		S54	Noise control level	D48	Degree of change in green travel behavior
		S55	Air pollutant emission standards	D49	Acceptance of internalizing environmental externalities
		S56	Green infrastructure configuration		/
	Economic	S57	Operation cost control level	D50	Stability of fare affordability
		S58	Degree of diversification of income structure	D51	Matching degree between demand growth and input
		S59	Degree of dependence on government subsidies	D52	Changes in users' willingness to pay
		S60	Asset utilization efficiency	D53	Service quality-price satisfaction
		S61	Payback period	D54	Long-term awareness of financial sustainability
		S62	Operation efficiency indicators		/
	Social	S63	Maintenance of service quality standards	D55	User satisfaction and its trends
		S64	Stability of practitioners	D56	Perceived stability of service quality
		S65	Level of investment in technical training	D57	Social recognition and support
		S66	User complaint handling mechanism	D58	Perceived continuous improvement of travel experience
		S67	Degree of community participation in decision - making	D59	Perception of equity in public services
		S68	Level of information transparency	D60	Long-term service trustworthiness

Taken together, the integrated panorama of supply–demand indicators across the four dimensions offers a robust foundation for selecting context-specific metrics in diverse application scenarios. The framework's value lies not only in its comprehensiveness but in its dynamic calibration mechanism. Through regionalised adjustment of weighting parameters (as detailed in Figure 2), tailored submodules may be derived for mountainous cities,

high-density metropolises, and suburban development zones, thereby providing methodological support for differentiated Transformation of bus systems under planetary crisis.
Preliminary findings suggest that while enhanced accessibility may exacerbate spatial inequity, improved resilience often entails economic trade-offs. In practical planning scenarios, the equity threshold and resilience baseline may be constrained in accordance with specific planning goals, enabling differentiated strategies. The following case studies and planning propositions will offer more targeted insights.

5. Case Outlook: Descriptive Comparison and Evaluation Application of Chinese and European Cities

5.1 Research Design and Methods

This study selects Shanghai, Shenzhen, and Paris as core cases to preliminarily explore adaptive strategies of urban bus systems under differing institutional and cultural contexts in response to the planetary crisis, using descriptive comparative analysis. The study also aims to demonstrate the potential application of a multidimensional evaluation framework.

Shanghai and Shenzhen, as megacities in China, respectively represent characteristics of high-density built-up areas and rapidly expanding urban forms. Paris exemplifies a mature European metropolitan region, with its "15-minute city" vision and low-carbon policies offering global reference value. While Chinese cities are primarily driven by top-down planning, European cities emphasise participatory processes and multimodal integration. These divergences between the two make their comparison more representative.

Drawing on publicly accessible policy documents and interview materials, this section identifies both commonalities and divergences among the three cities. It distils their planning logics and governance attributes while reflecting on existing shortcomings. This provides insight into the mutual responsiveness between evaluation frameworks and planning practices. Additionally, the study assesses the framework's feasibility in each case, incorporating both the effectiveness of routine planning and dynamic scenarios involving extreme events.

5.2 Case Comparison and Evaluation Application

5.2.1 Shanghai: Exploring Bus System Resilience in a High-Density City

Shanghai's high-density built-up areas feature a complex bus network, yet significant passenger loss persists due to modal competition. In recent years, improvements in service efficiency have been achieved through bus electrification and intelligent dispatching platforms such as Shencheng Mobility. However, deficiencies remain in suburban coverage and peak-time capacity. During the pandemic, partial suspension of bus services exposed severe supply–demand mismatches under extreme conditions.

This suggests that even under normal conditions, Shanghai's bus services face persistent imbalances and operational inefficiencies. During crises, buses have yet to serve as effective mechanisms for dynamic response and baseline mobility provision. It is therefore essential to establish an evaluation system that accounts for both regular and emergency scenarios, and to develop corresponding mechanisms for dynamic coordination in infrastructure and operations.

5.2.2 Shenzhen: Supply–Demand Mismatch in Rapid Urbanisation

Shenzhen's bus system supports the city's polycentric expansion through an extensive road network. The Transit Metropolis policy has successfully integrated buses with metro systems and shared bikes. In response to extreme coastal weather, real-time route adjustments and reserve dispatching have proven effective. Nonetheless, accelerated urbanisation has resulted in lagging bus services in peripheral areas, with equity indicators significantly lower than in the city centre.

Although the technologically driven planning model has enhanced operational efficiency in new districts, the key issue lies in its limited community engagement, resulting in insufficient responsiveness to vulnerable groups. An evaluation framework guided by mobility equity goals should therefore be introduced to identify deficiencies and enhance public participation and interdepartmental coordination.

5.2.3 Paris: Dual Pathways of Decarbonisation and Resilient Governance

Beyond its bus network, Paris operates a multi-tiered public transport system including metro and RER services.

Recent efforts have centred on decarbonisation through the "15-minute city" initiative and policies focused on low-emission zones (Zone à faibles émissions, ZFE), aimed at reducing car dependency. Measures include bus fleet decarbonisation, cycling infrastructure expansion, and carpooling promotion to reduce transport-related emissions.

However, Paris's green transition has prompted concerns over policy efficiency and fiscal sustainability. Thus, evaluation frameworks for Paris and similar cities should adopt an environment- and sustainability-oriented scenario, with indicators explicitly addressing effective mobility and economic viability. This would help avoid compromises in service quality due to fiscal constraints and efficiency challenges.

5.3 Preliminary Insights from Comparative Analysis

Descriptive comparison reveals divergent patterns in urban bus planning between Chinese and European cities. Chinese cases exhibit technology-driven, centralised responses prioritising hardware upgrading and large-scale interventions. In contrast, Paris emphasises societal engagement and green transformation, focusing on policy flexibility and equitable distribution.

Preliminary findings suggest: Shanghai's central areas enjoy good bus accessibility but suffer from peak-hour pressure. Shenzhen shows strong resilience in crisis scenarios but should enhance equity in service provision. Paris ensures equitable bus coverage but still faces questions regarding operational efficiency and fiscal viability.

The proposed Evaluation Framework for Adaptive Bus Planning demonstrates cross-cultural applicability by enabling tailored indicator systems for varying scenarios. Given data limitations, the study uses 2013 data from Shenzhen to illustrate urban bus supply–demand conditions (Figure 3, 4). Future research should employ updated datasets to better characterise dynamic patterns, integrate supply–demand modelling, and contribute to globally relevant strategies for planning transformation under planetary crisis.

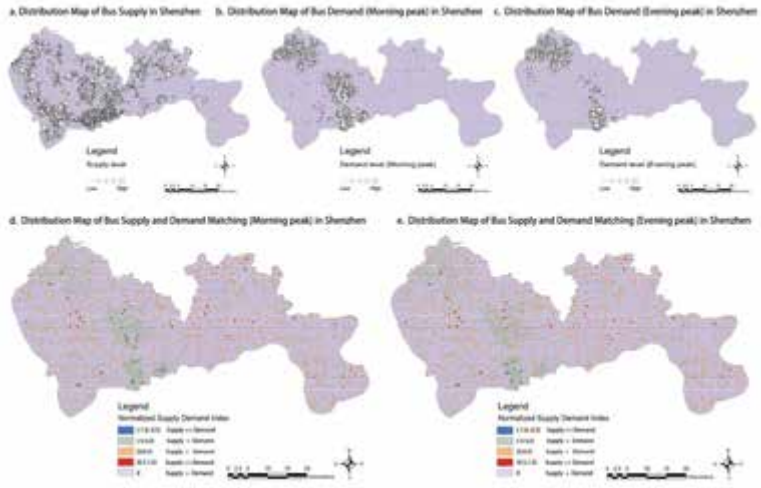

Fig.4 Bus Supply–Demand Conditions and Matching in Shenzhen in 2013

6. Discussion: Planning and Policy Implications

6.1 Theoretical Linkages and Transformative Innovation of the Framework

The adaptive transformation and evaluation framework for bus systems developed in this study integrates resilience-oriented design and community engagement mechanisms, achieving theoretical convergence with urban resilience theory, the Sustainable Development Goals, and system transformation theory.

By incorporating both the shock resistance of physical infrastructure and the self-organising recovery capacity of socio-ecological systems, the framework underscores the structural advantage of public transport in achieving dynamic balance during the adaptation–transformation process. This advantage lies in turning short-term crisis responses into long-term drivers of low-carbon technology adoption, inclusive service provision, and intelligent governance upgrades, thereby shifting planning paradigms from passive adjustment to proactive guidance.

Conceptually, adaptive planning for buses reflects three major shifts. **First**, it reorients from efficiency-driven to equity-led values, restructuring spatial justice through optimised accessibility. **Second**, it moves from static blueprints to dynamic adaptation, establishing real-time data-driven planning responses. **Third**, it transforms governance from siloed departments to cross-sectoral, multi-system coordination.

To ensure the framework's policy feasibility, institutional safeguards are needed—such as planning standards, emergency protocols, and public participation procedures—alongside fiscal instruments including green bonds and reinvestment of carbon trading revenues. These institutional designs, together with the multidimensional evaluation model proposed in this study, form a dynamic monitoring synergy that underpins governance for adaptive transformation in transport systems.

6.2 Planning Strategies for Coping with Crisis and Uncertainty

6.2.1 Establishing a Data-Driven and Scenario-Based Dynamic Response System

Addressing complex and evolving internal and external shocks requires a dynamic mechanism that integrates real-time sensing, intelligent analytics, and agile responses.

First, a real-time monitoring network should be deployed to continuously and accurately track passenger flows, traffic conditions, and service quality, thereby providing timely data support for decision-making.

Second, intelligent dispatching capabilities should be enhanced through big data analytics and demand forecasting, enabling flexible capacity allocation and dynamic optimisation of bus operations to improve resource efficiency.

Third, a feedback and iteration mechanism should be established to ensure closed-loop management based on performance evaluation, driving continual improvement in service processes and standards.

Lastly, scenario simulation and risk assessment should be deepened by constructing multiple future scenarios—such as climate events, technological shifts, and demographic changes—to identify latent vulnerabilities in the bus network and to pre-develop targeted strategies for risk mitigation and adaptive planning.

6.2.2 Advancing Innovation in Emerging Technologies

Technological empowerment is a critical driver of bus system transformation. In the era of planetary crisis, the development of intelligent technologies offers new possibilities for adaptive bus planning.

Advanced tools—such as big data, artificial intelligence, and synthetic population modelling—should be leveraged to enhance the scientific rigour and operational efficiency of bus systems. This includes real-time route optimisation, intelligent dispatching, and improved transparency of information services.

Forward-looking exploration is also needed, including the integration of autonomous driving and vehicle–infrastructure cooperation technologies, which may offer complementary functions to conventional bus services, such as automated feeder systems.

6.2.3 Enhancing Operational Resilience and Flexibility through Institutional Empowerment
On the one hand, innovative models of operation and governance should be promoted, including the adoption of flexible routes and service modes. Responsive service models—such as network optimisation based on real-time demand and on-demand buses—should be developed to enable finely tuned operational adjustments.

On the other hand, redundancy mechanisms should be established through the strategic reserve of routes, vehicles, and critical infrastructure to ensure rapid recovery and the maintenance of minimum service levels during major disruptions. This calls for the deep integration of all transport subsystems in emergency planning, resource sharing, and coordinated dispatching, supported by a more flexible and responsive dynamic planning decision-making framework.

6.2.4 Strengthening Equity-Oriented Resource Allocation and Multi-Actor Collaboration
Ensuring the inclusiveness and accessibility of bus services is vital for maintaining basic societal functioning during crises. This demands planning based on fine-grained travel demand analyses, especially focusing on the mobility patterns of vulnerable groups, to optimise route networks and ensure balanced and effective service coverage. It also requires targeted support policies, such as fare subsidies for low-income populations and the widespread implementation of accessible infrastructure, to guarantee mobility rights for disadvantaged users.

Moreover, spatial equity under multi-modal coordination should be prioritised by enhancing the physical integration and operational synergy between buses, walking, micro-mobility, and rail systems to reduce service disparities through shared resources.

Deepening participatory governance and collaboration is also key to advancing social equity in transport. This includes building multi-actor platforms led by government, operated by service providers, engaged by communities, and supported by academic institutions, to foster public participation in planning, evaluation, and oversight, and to explore effective models of public–private partnerships and community co-governance.

7. Conclusion
In response to the urgent need for planning transformation under the planetary crisis, this study first systematically reviews adaptive planning theory and interrogates the mobility crisis alongside the developmental dilemmas of buses. Building on this foundation, it proposes a resilience-oriented adaptive planning framework for public buses, accompanied by a multi-criteria evaluation system. By integrating transport efficiency, social equity, system resilience, and environmental sustainability into a unified decision-making perspective, the study extends the theoretical boundaries of adaptive planning within the transport domain.

Case-based analysis reveals interurban disparities in bus adaptability. Cities with high resilience typically exhibit institutional flexibility, technological inclusiveness, and deep civic engagement, confirming the framework's practical efficacy in enhancing system robustness. The resulting policy implications underscore a shift from passive defence to proactive adaptation, requiring legislative safeguards, fiscal incentives, and smart technological empowerment.

Nonetheless, this study has limitations. Case selection is constrained by data availability, particularly the lack of long-term operational data from cities in the Global South. Specific dynamic crisis scenarios—such as cascading disaster chains or multi-modal low-carbon transitions—remain underexplored, and their associated weighting mechanisms call for further empirical validation.

Future research should leverage big data and updated datasets for quantitative refinement of the evaluation framework, conduct comparative analysis across more cities, investigate the impacts of other crisis types on bus planning, and explore theoretical and practical extensions across disciplines and transport network models.

In the era of planetary crisis, the planning paradigm should shift from growth-oriented to resilience-centred. As the backbone of urban life, the adaptive transformation of public transport is not merely a technical endeavour but a governance revolution—redefining human-environment relations and advancing spatial justice.

Critical research frontiers remain open, including context-specific localisation and transnational cooperation aimed at dismantling epistemic silos and co-developing crisis-responsive knowledge systems. What is certain, however, is that embedding adaptive logic into the core of planning institutions offers a guiding compass for navigating urban uncertainty.

Adapting the 15-Minute City Model for Suburban Areas: Key Performance Indicators (KPIs) and Multimodal Mobility Strategies

Jennifer Jiang, Dayanna de Mello Sousa, Ágota Barabás, Jörg Rainer Noennig, Domokos Esztergár-Kiss
Affiliation: HafenCity University Hamburg, HUN-REN Institute For Computer Science And Control (SZTAKI)
Email: jennifer.jiang@hcu-hamburg.de

Abstract
The 15-minute city (15minC) model has emerged as a guiding framework for just and sustainable urban development, prioritising proximity, connectivity, and diversity to enhance residents' quality of life. While widely applied in dense urban centres, its implementation in suburban areas faces particular challenges. In this paper, we define a set of Key Performance Indicators (KPIs) to explore the potential of digitalisation and integrated multimodal mobility strategies as enablers of the 15minC principles in suburban contexts. Six diverse case studies are examined across six countries in Europe: Spain, Portugal, Hungary, Italy, Germany, and Turkey.

Keywords: 15-Minute City – Key Performance Indicators – Multimodal Mobility – Suburban Development

1. Introduction

The 15-minute city (15minC) model has emerged as a guiding framework for just and sustainable urban development, prioritising proximity, connectivity, and diversity to enhance residents' quality of life (Moreno et al., 2023). While widely applied in dense urban centres, its implementation in suburban areas faces challenges due to lower density and limited land-use diversity, which often characterise these areas. From a 15minC model perspective, this results in insufficient connectivity due to poorly integrated and inaccessible transportation networks, such as limited public transport options. This, in turn, leads to car dependency, negatively impacting residents' quality of life in terms of health, time, and financial costs.

To reduce suburban distances, promote accessibility, and achieve the 15minC vision in peripheral areas, this research contributes to the rethinking of distance as a function of time, and defines Key Performance Indicators (KPIs) aligned with the principles of chrono-urbanism—emphasising faster and more cost-effective solutions (Moreno et al., 2023), such as the integration of mobility hubs and the promotion of public transport and active mobility modes. The 15minC model presents itself as a contemporary urban vision (Moreno et al., 2023), as its guiding principles tend to remain aspirational, rather than process-oriented, without clear spatial planning methodologies nor operational frameworks. This paper addresses the aspirational aspect of 15minC mobility strategies and renders them measurable through relevant KPIs.

Accordingly, this study aims to bridge existing research gaps in data-driven methodologies and analytical frameworks, by defining a set of KPIs to assess how digitalisation and integrated multimodal mobility strategies can support the principles of the 15minC in suburban contexts. To achieve this, six diverse case studies are examined across six European countries: Spain, Portugal, Hungary, Italy, Germany, and Turkey.

As part of the FORTHCOMING project (FC)1, the development of the KPIs follows a methodological approach that includes: identifying successful 15minC strategies within selected case studies, assessing available data sources, and integrating insights gathered through focus group workshops with local experts from the respective case study areas.

Ultimately, the study will share preliminary findings on the relevance and applicability of the proposed KPIs in establishing a measurable framework for the 15minC concept, while also reflecting on and examining the challenges and opportunities related to further contextualisation—particularly through the definition and implementation of urban living labs within the case study cities in upcoming project phases.

1 FORTHCOMING: Fostering the City of Proximity through MaaS Integration" is an applied research project under the Driving Urban Transitions (DUT) Partnership. It will develop and test data-driven, user-centric 15-minute city models for suburban contexts, drawing on best practices from central urban areas. https://www.forthcoming.info/

2. Context

2.1. 15minC Dimensions

The dimensions that make up the 15minC framework applied in the FC project are adapted from the concept's core characteristics (Moreno et al., 2023), resulting in the four following dimensions: density, proximity, inclusivity, and digitalisation.

- Density is viewed in terms of mixed land use in a built environment (e.g., retail, residential, offices, leisure & green spaces, etc.), where the number of people in a given area can comfortably sustain the urban service delivery, opportunities, and resources.
- Proximity refers to the spatial and temporal accessibility to opportunities related to transportation, employment, healthcare, education, entertainment, access to green spaces, and retail for every resident through active or sustainable transportation modes.
- Inclusivity refers to addressing everyone's needs and experiences in relation to the opportunities offered by the 15mC, regardless of economic means, age, gender, disability, diversity, race, or ethnicity. Mobility justice, accessibility, social cohesion, and participatory decision-making are at the heart of inclusiveness as well as assessing cautiously the risks of exclusion and gentrification.
- Digitalisation refers to the enabling of the proximity, inclusivity, and density's dimensions using digital technology, such as Mobility-as-a-service (MaaS), smart city management tools, digital twins, and end-user applications.

The dimensions are evaluated in relation to the city's essential services. According to Moreno et al. (2023), essential services are defined through the High Quality of Societal Life (HQSL) index, which identifies six key urban functions that contribute to residents' daily well-being: living, working, getting supplies, enjoying, learning, and caring/being healthy. These social functions serve as the primary domains through which the four dimensions of the 15minC are assessed in practice.

2.2 Key Performance Indicators (KPIs)

KPIs originated in business management as means to measure the success of specific activities against strategic objectives. In urban planning, KPIs similarly serve as means to monitor the performance of key initiatives, aligning with broader goals such as sustainability, liveability, and inclusivity. They offer both quantitative and qualitative methods to assess the effectiveness of urban development strategies—particularly relevant in the context of planning concepts such as the 15minC concept examined in this study. This urban model emphasises proximity to essential services, aiming to create more accessible and sustainable neighbourhoods. In this context, KPIs ensure that goals such as improved resource allocation, enhanced accessibility, and a better quality of life are met through data-driven planning (Pozoukidou and Chatziyiannaki, 2021).

The 15minC model represents a shift toward more localised urban planning, where essential services are reachable within a short radius—such as a 15-minute walk, bike ride or public transport trip. KPIs are crucial in addressing the vision of 15minC, as they help measure factors such as proximity, walkability, and the effectiveness of public transport—elements vital to achieving strategic urban objectives like reducing carbon footprints (Moreno et al., 2023) and enhancing social equity (Pozoukidou and Angelidou, 2022).

Within the framework of the FC project, which encompasses case studies across six countries, KPIs will guide the transfer of 15-minute city mobility strategies to suburban areas. The overarching objective of the project is to adapt and transfer successful city centre strategies to suburban contexts, with a focus on multimodal mobility, user-centric models, and digitalisation—all within the broader aim of promoting public transportation as the backbone of FC's approach to rethinking distance as a function of time.

Overall, the selected KPIs will serve as key criteria for assessing 15minC strategies, determining their effectiveness in the suburban context, and providing measurable insights

3. Research Methodology

The selection process of KPIs was structured into three main phases: (1) consolidation and assessment of successful 15minC strategies across all six case studies; (2) clustering and drafting a list of potential KPIs; and (3) refinement and validation through local focus groups workshops.

Each case study consists of an urban central area (i.e., higher-density regions) and a corresponding suburban area (i.e., lower-density regions), described below:

- Spain: Madrid (urban) and Las Rozas (suburban)
- Portugal: Lisbon (urban) and Vila Franca de Xira (suburban)
- Hungary: Debrecen (urban) and Kertváros (suburban)
- Italy: Turin (urban) and Settimo Torinese (suburban)
- Turkey: Istanbul (urban) and Küçükçekmece (suburban)
- Germany: Hamburg (urban) and Hamburg-Altona (suburban)

In the following sections, the case studies will be referred to by their respective country names for ease of reference; however, this should be understood as referring specifically to the urban core and its corresponding suburban area, as described above.

3.1. Successful 15-minute City Strategies in Six Case Studies

In the first phase of data collection, a comprehensive questionnaire was designed and distributed across the case studies project partners and their local network. This process facilitated the examination of how local planning strategies align with initiatives adopted by planning bodies and transport authorities—such as Sustainable Urban Mobility Plans (SUMPs) (European Commission, 2023) and other relevant official documents—particularly in relation to the 15minC concept. The questionnaire covered several key areas: integration of the 15minC concept with local planning and strategies; practical application of the 15minC approach; perception and public engagement; progress and evaluation; and future directions and additional comments.

Once the responses were collected, each case study's objectives, guiding principles, and strategies were compiled. These strategies were then organised within a comparative framework to identify overlaps and gaps. This facilitated both the rapid identification and later in-depth review of best practices that strongly align with 15minC-based urban mobility strategies.

Across the six case studies, the derived strategies converge around several core themes. A common priority was the improvement of public transport through increased service frequency, expanded network coverage, upgraded rolling stock, and the introduction of new modes. For example, Portugal and Turkey focus on infrastructure, with Istanbul advancing public transport optimisation via station upgrades and hub renovations. Hungary emphasises speed and comfort enhancements in public transport. Germany and Italy aim to increase service frequency and modernise rolling stock, with Turin also expanding intercity rail services. Spain introduces peak-hour express buses, zero-emission routes, fleet renewal, and on-demand services.

Shared mobility solutions are implemented through micro-mobility services and free shuttle systems. Germany enhances its local mobility app, while Italy offers free internal shuttles for students and the elderly. Spain, for instance, develops integrated hubs featuring secure bike parking, EV charging stations, and car-sharing facilities. Turin incorporates a pay-as-you-go system to promote affordability and Mobility-as-a-Service (MaaS) integration.

Active mobility strategies are also prominently featured. All six case studies highlight the expansion of cycling infrastructure, with emphasis on safety improvements and reducing car dependency. Turkey and Spain additionally focus on improving bicycle parking and, in Spain's case, promoting e-bike sharing. Walkability is a shared objective, with initiatives to enhance sidewalks, create pedestrian zones, and develop attractive public spaces that encourage walking. Turkey introduces "shared streets" and prestige corridors accommodating multiple transport modes, while Hamburg promotes flexible public space usage.

People-centered urban design and tactical urbanism are central to several case studies. These include strategies to redevelop public spaces, enhance safety, and support community engagement through participatory processes. Madrid reduces speed limits on school streets; Germany develops multifunctional street furniture; and Lisbon promotes interventions in public squares. Community engagement strategies include workshops, surveys, and public consultations, with Turkey and Spain also utilising digital tools like Decide Madrid [2] to enable digital participation.

2 https://decide.madrid.es/

Additional actions address environmental sustainability, such as expanding green spaces, promoting clean transport, and creating nature-integrated cycling paths or traffic-calmed zones like Italy's "Zone 30."[3] Digital tools are increasingly adopted across the case studies but remain underdeveloped in Portugal, indicating potential for future enhancement. Strategies such as digital twins and MaaS applications are being used to advance planning and digital innovation.

Urban logistics strategies also integrate digital solutions. These focus on improving loading zones and real-time data applications. Turkey implements smart logistics measures, including construction material consolidation centres and the use of ICT/IoT technologies.

3.2. Cluster Formation of Key Performance Indicators for 15minC Strategies

Following the consolidation and assessment of successful 15minC strategies and best practices across the case studies, a collaborative strategy mapping exercise was conducted. This aimed to establish a structured approach for developing KPIs aligned with the identified strategies. During the exercise, a pre-defined set of strategies and policies was reviewed, refined, and validated by project partners from each city to ensure completeness and accuracy in light of their specific contexts. Project partners also contributed to identifying and developing relevant KPIs within their focus areas, organised by both strategy and scope.

Building on the outcomes of this collaborative process, an initial list of KPIs was drafted. This list was then expanded through literature review, which served to establish working definitions and gather additional potential KPIs alongside successful measures identified in previous project phases. Throughout this phase, representatives from the six case studies provided continuous input and feedback to ensure the KPIs reflected locally grounded realities.

This resulted in a list of over 90 draft KPIs—relevant to a range of dimensions in the assessment of 15minC—, capturing in greater detail all relevant gathered inputs, expanding on key elements while avoiding premature definitions of specific metrics and data sources. The intention was to provide a flexible but structured foundation for subsequent filtering and detailed definition. These KPIs were grouped into eight thematic clusters:

- Proximity
- Inclusivity
- Digitalisation
- Density
- Sustainability and Climate Action
- Governance
- Modal Share
- Economic Impact

The clusters of Proximity, Inclusivity, Digitalisation and MaaS, and Density and Land Use reflect adaptations of Moreno's (2023) core dimensions (see Section 2.1). Governance and Modal Share emerged from the specific thematic priorities of the FC project, emphasising the role of policy frameworks and mobility patterns:

- Governance refers to transparent, accountable, and participatory urban management, ensuring that public policies align with local planning strategies and that citizens and stakeholders are actively involved in the decision-making process (Chinellato, M. and Morfoulaki, M., 2019).
- Modal Share refers to the distribution of various transportation modes (such as walking, cycling, public transit, and driving) used by residents within a short, easily accessible radius (Poorthuis and Zook 2023).

Meanwhile, Sustainability and Climate Action and Economic Impact correspond to two of the three pillars of sustainable development—Environmental Sustainability and Economic Sustainability:

- Sustainability and Climate Action aims to reduce environmental impact by cutting carbon emissions, enhancing energy efficiency, promoting green spaces, and climate-conscious policies to mitigate climate change (Sahertian and Sari, 2024).

3 https://www.nuoverigenerazioni.eu/tutte-le-news/1298-citta30subito

- Economic Impact refers to the financial impact on local businesses, property values, and employment resulting from urban planning strategies that prioritise accessibility to essential services within a 15-minute walk or bike ride (Bartzokas-Tsiompras, 2022).

The interim list of KPIs addressed diverse analytical scopes relevant to each cluster and was organised accordingly. The following provides an overview of the clusters and the scopes addressed in that interim list:

- Proximity: Public Transport Access; Essential Services Access; and Green and Blue Space Access.

- Inclusivity: Social Inclusion; Affordable Housing; Socio-ecological Equity.

- Digitalisation: Smart Traffic Management; Smart Technologies Integration; Data Governance; Multimodal Integration and MaaS.

- Density: Diversity of Land Use; Urban Density, Public Space Utilisation; Building Utilisation; Traffic Calming.

- Sustainability and Climate Action: Emission Reduction; Air Quality and Green Coverage; Resilience and Climate Adaptation; Energy Efficiency.

- Governance: Citizen and Stakeholder Engagement; Policy Integration and Governance; Economic Sustainability; Sustainable Mobility Policies.

- Modal Share: Public Transport Modal Share; Active Mobility; Shared Multimodal Mobility; Modal Shift; Car Dependence Reduction.

- Economic Impact: Local Business Growth; Real Estate and Property Value; Circular Economy; Freight and Logistics Efficiency; Return on Investment (ROI).

3.3. Focus groups workshops to define the list of KPIs

Following the consolidation of the interim draft list of KPIs, focus group workshops (FGs) were conducted in each case study city. These workshops involved a broad range of local experts and stakeholders—including representatives from academia and research, planners and transport professionals, municipal staff from urban and suburban transport and planning departments, as well as local transport associations. These stakeholders will later participate in the establishment of urban living labs in their respective case studies (see Section 5).

The primary objective of these workshops was to gather insights and expert opinions to advance the implementation of 15minC strategies and to validate and refine the initial KPI list according to contextual relevance and feasibility. The focus group process included two main parts:

1. A SWOT analysis was conducted to identify local opportunities, challenges, and priorities in urban planning, mobility, and sustainability across the four core dimensions of the 15minC concept (see Section 2.1).
2. A ranking process followed, in which participants evaluated the eight thematic clusters and their corresponding interim list of KPIs (see Section 3.2).

3.3.1. SWOT Analysis Results

The discussions during the FGs revealed contrasting strengths and challenges across the case studies, shaped by varying levels of urban density and infrastructure. Experts from Germany and Portugal highlighted that higher-density areas naturally support walkability, mixed-use development, and efficient public transport. In contrast, participants from Spain and Hungary, where urban density is lower, highlighted the struggle with car dependency and service accessibility.

Reports from the local FGs also showed significant variation in public transport effectiveness. Germany and Portugal reported benefits from well-integrated networks, whereas experts from Turkey noted that heavy congestion reduces efficiency. Areas with ongoing revitalisation efforts, such as Hungary and Italy, focus on improving infrastructure and redistributing populations to enhance connectivity.

Urban diversity and socioeconomic factors also influence mobility patterns. Inequalities in transport access were highlighted in Turkey and Spain, particularly for vulnerable populations. Meanwhile, Germany and Portugal emphasised inclusive housing policies and mixed-use developments, although gentrification was noted as a shared concern.

Digitalisation presents both opportunities and barriers. Case studies with more advanced digital integration can improve accessibility and mobility services but also risk widening social inequalities, as noted in Portugal and Germany. Meanwhile, Spain and Turkey stated that the struggle with real-time data availability and digital infrastructure gaps could limit their ability to implement smart mobility solutions effectively.

Overall, the discussions showed varying degrees of adaptability toward the 15minC concept. While both groups of experts from Italy and Portugal agreed on the relevance of exploring strategies for proximity-based urban living, practitioners from Spain and Hungary separately concluded that there are substantial structural limitations. The reuse of public spaces emerges as a common opportunity, yet governance, funding, and administrative silos remain persistent challenges across multiple cities.

The discussions ultimately suggest that sustainable urban mobility is contingent upon the establishment of a balance between infrastructure investment, accessibility, and density. Addressing congestion and gentrification risks is imperative for high-density cities, while innovative solutions are required for low-density areas to reduce car dependency and improve the viability of public transportation. Digitalisation offers a pathway for cities to optimise mobility, but its success relies on equitable implementation and governance.

3.3.2. 15minC-derived thematic KPIs Cluster Ranking

The eight aforementioned KPI clusters and their corresponding potential KPIs were ranked using a simple dotmocracy method - a participatory approach to prioritisation, where attendees of a focus group rank ideas, statements, or proposals to determine collective preferences (Hidalgo, 2018). The results of the ranking are summarised in the following table, with 1 representing the highest priority and 9 the lowest across the case studies:

Table 1: Table Overall table of KPI clusters ranking results by case studies

KPI Cluster	Spain	Germany	Hungary	Italy	Portugal	Turkey	All
Modal Share	1	2	1	3	2	1	1
Proximity	2	1	1	5	1	3	2
Density	3	3	4	6	5	2	3
Sustainability & Climate Action	4	7	3	2	4	5	4
Inclusivity	6	3	8	1	7	4	5
Governance	7	6	6	4	6	6	6
Digitalisation	5	5	5	7	8	6	7
Economic Impact	8	8	7	8	3	8	8

The Modal Share cluster ranks highest in importance across all case studies, reflecting a strong focus on transportation mode distribution. Proximity and Density follow in ranks 2 and 3, emphasising the role of accessibility and urban planning in mobility strategies.

Sustainability and Climate Action holds a mid-level joint ranking of 4, highlighting varied national priorities in environmental policy. Inclusivity, Governance and Digitalisation are ranked 5, 6 and 7 respectively, indicating that

while they are considered important, they are not the primary focus. Economic Impact has the lowest ranking at 8, suggesting that economic considerations may be less immediate than social, environmental, and infrastructural aspects.

The results indicate that Modal Share and Governance exhibit the lowest variation, showing strong consistency across case studies. Digitalisation, along with Density, also demonstrate stable importance. Proximity and Sustainability and Climate Action show moderate variation, while Economic Impact and Inclusivity have the highest deviations, indicating significant fluctuations in their rankings among different case studies. This suggests a general consensus on the importance of Modal Share and Governance, while Inclusivity and Economic Impact are more context-dependent.

4. Definition of the Key Performance Indicators (KPIs)

Based on the previously mentioned research and analysis conducted across the six case studies, we identified a selection of KPIs. These are categorised as follows: 1) Common KPIs – applicable across all six case studies and 2) Specific KPIs – relevant to one or more of the case studies

The KPIs outlined in the following sections represent a concise yet comprehensive baseline, developed within the resource and capacity boundaries of the FC project. We acknowledge that these indicators are not definitive, as further refinement and updates are expected in subsequent project phases, particularly during the data collection stage and the further development of the Urban Living Labs (ULLs) (see Section 5) in suburban regions.

We defined both quantitative and qualitative KPIs. Notably, studies focusing on end-user KPIs remain relatively scarce in the urban field (Soriano-Gonzalez et al., 2023). As such, we prioritised indicators accessible from a "City Manager" perspective—more often quantitative—drawing on open-source and readily available datasets. This approach aligns with the practical limitations of the project, which does not include extensive surveying or in-depth user data collection. Nonetheless, qualitative indicators are also represented where they can be drawn from in situ observations, interviews, and exchanges with local stakeholders—documenting, for example, the presence or absence of specific spatial or service-oriented characteristics relevant to 15minC mobility strategies.

4.1. Common KPIs

The following table (Figure 3) provides an overview of nine Common KPIs, thematically clustered and ordered based on their relevance as determined through the focus group workshops. It is important to note the following:

- The KPIs vary in complexity, as reflected in their associated key metric(s). These differences will be further explored in later phases of the project.
- All KPIs will be gathered during the upcoming project phase. Consequently, the data release year will reflect the most recent available datasets and may vary slightly across case studies and individual KPIs due to differences in data availability.
- We acknowledge that KPIs should ideally be calculated over different time intervals to fully evaluate their performance. However, due to the limited duration of the project, the KPIs will be calculated specifically for low-density areas and subsequently cross-analysed both within and across the individual case studies.

Cluster	KPIs	Key Metrics Description	Units
Modal Share	Active Mobility Infrastructure[4]	Percentage of the active road length with sidewalks, cycle paths, and pedestrian zones, relative to the total road length of the selected area	%
Proximity	Proximity to Green, Blue and Public Spaces[5]	Percentage-based estimate of the selected area that lies within a 15-minute walking or biking distance to green, blue, and public spaces such as parks, recreational areas, city waterfronts, ponds, lakes, and more. <u>Breakdown as follows:</u> • Walking access – Area within a 15-minute walk. • Biking access – Area within a 15-minute bike ride	%
	Proximity to Essential Services[6]	Percentage-based estimate of the selected area that lies within a 15-minute walking or biking distance of each of the six essential service categories (i.e., points of interest POIs). <u>Breakdown as follows:</u> • Walking access – Area within a 15-minute walk for each category • Biking access – Area within a 15-minute bike ride for each category	%
	Proximity to Public Transport and Demand-Responsive Transport Services[7]	Percentage-based estimate of the selected area that lies within a 15-minute walking distance of fixed-route public transport and, if applicable, demand-responsive transport (DRT) services. <u>Breakdown as follows:</u> • Public transport access – Area within a 15-minute walk of a fixed-route public transport stop • (If applicable) DRT access – Area within a 15-minute walk of DRT service stops or operating zones	%
		<u>Service Frequency:</u> Average number of public transport vehicles (buses, trams, trains, etc.) arriving per hour at stops within the selected area. Include a breakdown by transport mode (e.g., inter-urban vs. intra-urban lines), peak vs. non-peak hours, and weekdays vs. weekends.	rides per hour
Density	Built-up Surface (Urban Density)[8]	<u>Built-up Surface:</u> Amount of built-up land area available per person in a selected area	m2/ppp
		<u>Total Built-Up Area Ratio.</u> Ratio of the total built-up area (including residential, commercial, industrial, etc.) to the total land area.	%
	Diversity of Land Use[9]	<u>Types of Mixed-Use Developments:</u> Identification and count of the different combinations of mixed-use developments[10] within the selected area.	count
		<u>Ratio of Key Land Uses to Total Area:</u> Ratio of key land uses (e.g., educational, residential, commercial, recreational, green spaces, etc.) to the total urbanised area.	%

8 Sources: Abbiasov et al., 2022; Dutta et al. 2020
9 Source: Carpio-Pinedo et al., 2021; Pozoukidou and Chatziyiannaki, 2021
10 Developments refer to urban built and construction (e.g. existing and new buildings) and land-use changes (e.g. infrastructures such as roads, parks, public spaces)

Inclusivity	Inclusivity in Accessing Mobility Infrastructure[11]	Availability of Discounted Public Transport Ticket Types: Types of discounted fare options available for different user groups (e.g. students, seniors, low-income individuals, people with disabilities, families, and more).	count
		Quality of Barrier-Free Walking Infrastructure: Existence and quality of inclusive and accessible pedestrian infrastructure based on pre-defined criteria (e.g. tactile paving, audible pedestrian signals, curb ramps at intersections, etc.)	count and rating
Governance	Citizen Participation in Urban Planning[12]	Number of Public Consultations and Forums: Number of public consultations, forums, and public engagement events held. Include a breakdown by top-down and bottom-up process (if applicable).	count
		Citizen Feedback on Public Consultations: Quality of public consultations from the citizen perspective, based on available feedback (e.g. from municipality records or online platforms).	N/A
Digitalisation	Availability of Multi-modal Mobility Services[13]	Availability of Mobility Services Types: Availability of mobility services in the selected area, including public transport, shared mobility, and micro-mobility services.	count
		Level of Integration Across Mobility Services Degree of integration among various mobility services, focusing on shared travel planning, booking, and payment functions. (e.g. real-time route planning, ticketing integration, in-app payment, etc.)	level

Table 2: Common KPIs List

4.2 Specific KPIs

Consistent with the common KPIs, the following table provides an overview of six specific KPIs, thematically clustered and ordered according to their relevance as determined through focus group workshops. It is important to note that not all case studies include the same number of specific KPIs; for example, in the case of Lisbon, no additional specific KPIs were required to capture local urban strategies and characteristics unique to that context.

Cluster	KPIs	Key Metrics Description	Units	Case Studies
Density	Traffic Calming Zones[14]	Roads with Lower Speed Limits: Percentage of total street kilometers in the selected area with speed limits of 20–30 km/h or lower.	%	Italy; Spain
		Car-free, pedestrian zones streets: Percentage of total street kilometers in the specified area designated as pedestrian-only or car-free zones through traffic-calming measures.	%	
	Public Space Utilisation[15]	Percentage of public spaces (e.g., parks, plazas) actively used by residents, based on measured foot traffic. Breakdown by factors such as time of day and user demographics to be clarified.	%	Hungary
	Land Use Density Around Transit Corridors[16]	Land Use Density Percentage-based estimate of the total built-up area (residential, commercial, industrial, etc.) within a specific radius (e.g., typically 400-800 m) from public transit stations or stops	%	
		Average total floor area (FRA) of all (residential) buildings located within that specific radius	ratio	Turkey; Germany

15 Source: Khoshkhah et al. 2022
16 Sources: Carpio-Pinedo et al., 2021; Pozoukidou and Chatziyiannaki, 2021

Digitalisation	Investment in Smart City Technolo-gies[17]	Total amount of (public) funds allocated for the development and implementation of Smart City technologies, including Digital Twins, within a specific year.	euro per year	Turkey
	Parking Control Man-age-ment[18]	Average Parking Occupancy: Percentage of parking spaces occupied or available during daily use. Breakdown by day of the week and time of the day.	% per day per time	Spain
		Parking Turnover Rate Number of different vehicles that occupy a single parking space over a specified period of time (typically per day)	count per space per day	
Economic Impact	Pilots and Innovation Implemen-tation[19]	Number of innovative mobility projects—such as carpooling systems, shared e-bike networks, or similar sustainable mobility initiatives—launched within a specific year.	count	Hungary

Table 3: Specific KPIs List

5. Next steps and Urban Living Labs (ULLs)

The list of Common and Specific KPIs, developed from general insights across the case studies, will be further refined during the next project phase through the establishment of ULLs (Nesti, 2018; Molinari and Concilio, 2015) in the lower-density suburban areas. These living labs will be set up in collaboration with the local stakeholders identified in the focus groups workshops (see Section 3.3). Their role will be to contextualise the KPIs and to collect data necessary for calculating them, considering each area's specific local characteristics—such as land-use structure, transport options and mobility patterns, as well as existing planning and mobility regulations (Noennig et al. 2025).

ULLs are widely recognised as experimental spaces, testbeds, in cities where diverse stakeholders collaborate to develop, test, and refine innovative solutions for urban sustainability challenges (Nesti, 2018; Molinari and Concilio, 2015). Key characteristics of ULLs include geographical embeddedness, participatory experimentation, active user involvement, leadership, and continuous evaluation (Voytenko et al., 2015).

Notably, while traditional ULLs are predisposed to situations that call for real-world implementation and/or scaling of a sustainable innovation (von Wirth et al., 2018), the FC project adopts a modified approach to ULLs, to emphasise knowledge exchange and vision-sharing. Unlike traditional ULLs that often engage in pilot testing a physical intervention (e.g., smart technologies or urban mobility interventions), FC ULLs serve as a platform for analytical and co-creation in selected neighbourhoods across six partner cities.

In the FC ULLs, researchers and local stakeholder (e.g., public administration, citizens, private actors) engage in more focus group discussions to a) build a common understanding of the 15mC concept; b) identify potential KPIs for measuring 15mC adaptation to suburban areas and c) discuss possible future outcomes & governance impact of operationalisation.

FC ULLs emphasises stakeholder alignment and shared visioning, which is critical for long-term policy integration (Nesti, 2018). The proposed ULL format addresses a gap in the concept's literature regarding conceptual adaptation (e.g., applying 15mC to suburbs) rather than just technological experimentation. However, the lack of implementation focus raises questions about long-term efficacy, suggesting a need for hybrid models that combine visioning with prototyping. Future research could explore how such "soft ULLs" intersect with traditional governance and participatory planning.

19 Source: Aba and Estergár-Kiss 2024

6. Conclusion

On the background of the growing traction of the 15minC concept as a paradigm shift towards a more proximate and diverse lifestyle in dense urban areas, we sought to identify and define KPIs that assess the transferability of 15minC mobility strategies from higher-density to lower-density areas. This assessment draws on six diverse case studies across Spain, Portugal, Hungary, Italy, Germany, and Turkey, highlighting variability in local priorities and the maturity of (planned) 15minC-based mobility strategies.

Through a series of stakeholder exchanges and data collection activities in each case study, it became clear that all locations emphasised the importance of achieving the 15minC through favouring active and sustainable transportation modes. This emphasis underscores the importance of proximity to essential services for local residents. At the strategic level, this is reflected in efforts to improve active and public transport services in all locations—such as increasing service frequency, enhancing network coverage, and expanding cycling infrastructure—with the goal of reducing car dependency. These efforts predominantly address the proximity and digitalisation dimensions of the 15minC.

However, less consensus emerged regarding the other 15minC priorities such as inclusivity, sustainability, and density. For instance, case studies in Italy and Germany ranked these aspects as high priorities, in contrast to Hungary and Portugal, which assigned them lower priority.

Taking this variability into account, we introduced a list of Common KPIs—applicable across all case studies—and Specific KPIs—tailored to individual contexts. Combined, they aim to capture and establish a baseline understanding of the 15minC concept within the mobility domain, while considering the project's time, resource, and capacity constraints.

These KPIs include both quantitative and qualitative measures. Quantitative indicators involve data-intensive methods (e.g, GIS-based analyses) to assess KPIs such as proximity to essential services, proximity to green/blue public spaces, and public transport availability. In contrast, qualitative indicators rely on more observation-based approaches (e.g., in-situ observations or data from open-access sources) to evaluate land-use diversity, availability of shared mobility services, and levels of citizen engagement.

The definition of these KPIs was derived—and in some cases challenged—by the diversity of the case studies: a process that was imperative to capture their broad spectrum, while acknowledging the potential risk of generalisation. Moving forward, iterative data collection and validation processes will be carried out in collaboration with case study stakeholders, primarily relying on publicly accessible sources. Therefore, the precision and applicability of the KPIs will be contingent upon—and informed by—the quality, availability and quantity of data provided by municipalities and local stakeholders.

Acknowledgement

This research was conducted as part of the work of the research project "FORTHCOMING: Fostering the City of Proximity through MaaS Integration," been funded by the Agencia Estatal de Investigación (AEI); by Innoviris Brussels; by DLR Project Management (BMBF); by the National Research, Development and Innovation Office (NKFIH); by the Ministero Dell'Universitá e Della Ricerca; by the Fundação para a Ciência e a Tecnologia (FCT) and by The Scientific and Technological Research Council of Türkiye (TÜBİTAK) under the Driving Urban Transitions Partnership, which has been co-funded by the European Commission. This body of work represents the idea of the researchers alone and does not necessarily reflect the opinion of the funding agency or the project partners.

Abstract:
This study investigates the role of multi-level rail transit systems in optimising spatial structures during China's post-urbanisation phase under the "high-quality development" framework. By comparing international urbanisation trajectories, it identifies China's unique tension: a need to support continued urban development amid population decline and fiscal constraints. The study proposes a multi-scalar optimisation strategy—regional corridors, metropolitan integration, and urban-scale structural reinforcement—highlighting selective, structure-oriented approaches over extensive construction. Using Shanghai's metropolitan region as a case, the paper demonstrates the feasibility and strategic value of this approach in supporting spatial balance, efficient mobility, and sustainable urban transformation.

Keywords: Cities beyond growth; High-quality development; Rail transit network; Regional integration; Spatial structure

1. Introduction

In recent years, terms such as "stock-oriented development" (, development based on existing assets) and "high-quality development" (, development emphasising sustainability, equity, and efficiency) have become increasingly prevalent in government documents and academic publications on urban planning in China (Xi, 2022). After four decades of rapid and large-scale urbanisation, major cities and developed regions in China have begun to exhibit characteristics of a post-urbanisation stage in terms of population growth, economic structure, and spatial expansion. These regions now face associated challenges (Wu and Phelps, 2011). Globally, many cities have experienced slowing or even negative population growth, stabilising or contracting spatial expansion, and a growing need to discuss "de-growth". Against this backdrop, "beyond growth" has emerged in Western contexts, emphasising the optimisation of spatial structures, equitable allocation of public resources, and environmental sustainability rather than continued expansion. However, in China, although some cities display typical features of post-urbanisation, unbalanced regional development, ongoing urban migration, and continuous industrial restructuring mean that China cannot simply replicate the development trajectory of Western countries. Instead, it must adopt a distinct approach through "high-quality development" to respond to the "beyond growth" concept.

Under this framework, rail transit has become more than a mere mode of transport; it now plays a strategic role in optimising spatial structure, fostering regional coordination, and enhancing urban quality (Wu et al., 2020; Cao, 2023). Nevertheless, the development and operation of rail transit in major Chinese cities currently face a series of pressing challenges, including limited corridor capacity, insufficient reusable infrastructure, rising construction costs, and fragmented operational governance. These constraints highlight the urgent need to shift from a traditional expansionist approach to a more layered, structural, and coordinated rail transit system.

This study, therefore, adopts a regional integration perspective contextualised within China's unique urbanisation process to investigate the critical role of rail transit in optimising spatial structure. Focusing on the Yangtze River Delta and the Shanghai Metropolitan Area1 As cases, the study draws on literature review, policy analysis, and case studies to construct a multi-level, collaborative rail optimisation framework tailored to the Chinese context. The main contribution lies in clarifying cross-jurisdictional and multi-scalar spatial coordination strategies under

1 In the Chinese planning context, the term "Metropolitan Area" (Da Dushi Quan, , literally "Metropolitan Circle") often refers to a broad spatial unit centred on a megacity, encompassing multiple adjacent cities with strong functional and economic linkages. For example, the "Shanghai Metropolitan Area ()" covers over 56,000 square kilometres and includes more than ten major urban centres (Shanghai Municipality People's Government et al., 2022). This scale and structure go well beyond the conventional international definition of a "Metropolitan Area," which typically refers to a single large city and its contiguous suburban or satellite areas. To avoid confusion, this paper refers to the Chinese concept of "Da Dushi Quan" as an "Extended Metropolitan Region (EMR)," emphasising its cross-jurisdictional, polycentric, and functionally integrated nature.

China's specific developmental background, thereby enriching theoretical and practical links between high-quality development and rail transit planning.

The paper is structured as follows: first, it outlines the research background and theoretical foundations; second, it examines China's urbanisation stage and its comparison with international processes; third, it analyses the current challenges in rail transit development and proposes multi-scalar optimisation strategies for the regional, metropolitan, and suburban levels; and finally, it evaluates the applicability and feasibility of these strategies through a case study of Shanghai and its surrounding areas.

2. Theoretical Framework and Literature Review

2.1 Definition and Characteristics of Post-urbanisation

Around the 1970s, population stagnation and even decline in some large Western cities attracted attention in the fields of planning and geography. This prompted research on whether urban dispersal signified a new stage of development (Korcelli, 1980). Berry (1980) introduced the concept of "counter-urbanisation" to describe the shift of population from metropolitan areas to smaller towns and rural areas. Subsequent studies have explored various features of "post-urban society", including ageing populations, urban shrinkage, and the governance of urban regeneration (Mitchell, 2004; Tateishi et al., 2025).

Existing literature often evaluates whether a region has entered a "post-urbanisation" stage based on population dynamics, spatial patterns, and industrial transformation (Martinez-Fernandez et al., 2012). The most typical indicator is demographic: a marked slowdown in urban population growth, stabilisation of urbanisation rates at a high plateau, and signs of zero or negative growth in urban population. Under continued population decline, urban shrinkage becomes tangible (Tateishi et al., 2025). Spatially, cities experience slower expansion, decoupling economic growth from land development and trends such as polycentricity, suburbanisation, and counter-urbanisation. Central areas may see declining density and functional reconfiguration (Bontje, 2004; Wan et al., 2023). Industrially, a shift from industrial to service-oriented economies—i.e., post-industrialisation—is observed. Urban development transitions from incremental expansion to productivity enhancement and innovation-driven growth, relying less on population and land increases (Cai et al., 2020).

2.2 Post-urbanisation in the Chinese Context: New Urbanisation and High-Quality Development

"Post-urbanisation" is rarely used in Chinese official and academic discourse. Instead, phrases such as the "later stage of urbanisation" or "second half of urbanisation" are more common and often discussed in relation to concepts like "counter-urbanisation" and "urban shrinkage". Data indicate that China's population began to decline in 2021. However, due to regional disparities, the urbanisation rate of the resident population continues to rise—reaching approximately 67% by the end of 2024—marking an entry into the late stage of urbanisation.

Scholars remain divided on whether China is entering an era of urban shrinkage. Some argue that due to large rural populations and uneven development, China still has untapped potential for rural-to-urban migration, and the demographic dividend of urbanisation has not yet been exhausted (Xie and Lin, 2023). Others note that China's working-age population has already peaked, with one-third of cities exhibiting signs of shrinkage (Li et al., 2025) and that the momentum of urbanisation is weakening. Some scholars contend that, given China's vast territory and internal heterogeneity, post-urbanisation phenomena first appear in megacities and developed regions, while less developed areas remain in earlier stages. There is also no consensus on the urbanisation rate at which China will stabilise: some estimates suggest it will not exceed 80% (Qiao et al., 2018), while others anticipate it will surpass that threshold (Chen and Luo, 2006). Nonetheless, there is broad agreement that China's developed regions and megacities already exhibit post-urbanisation traits. Most researchers advocate for proactive planning responses to the profound impacts of demographic and spatial changes (Wu et al., 2020).

From a policy perspective, the Chinese government has shifted its urban development focus from rapid expansion to stabilisation, calling for a transition from incremental to stock-based optimisation. As such, Chinese discourse centres more on "new urbanisation" or "high-quality development", emphasising rural-urban integration, regional coordination, and qualitative urban enhancement, rather than adopting the "post-urbanisation" label.

In this sense, China's interpretation of "post-urbanisation" implies a phase of quality improvement and structural optimisation, rather than an outright decline following complete urbanisation.

2.3 Optimising Spatial Structures and the Role of Rail Transit under High-Quality Development

The effective interplay between spatial structure optimisation and transport systems is essential for achieving regional high-quality development. In China, megacities showing post-urbanisation features must simultaneously restructure their economies and support regional growth, necessitating refined spatial strategies. Theoretical foundations for spatial structure optimisation—such as central place theory, growth pole theory, polycentricity, and corridor–node theory—have evolved and combined in planning practice to provide robust conceptual tools. It is now widely acknowledged that transport systems—particularly rail transit—play a pivotal role in shaping and improving urban–regional spatial configurations (Urena et al., 2009; Gu and Kou, 2017; Hu et al., 2023). Transport influences spatial form, evolution, and restructuring by enhancing accessibility, guiding land use, and shaping corridors and nodes. International experiences in metropolitan regions reveal the profound effects of rail systems on spatial transformation, underscoring the need for coordinated transport–land use planning as a foundation for structural optimisation (Cao, 2023; Sun, 2024; Chen et al., 2010).

3. "Beyond Growth" in China: Indicators and Contradictions in the Post-urbanisation Stage

3.1 Assessing China's Urbanisation Stage: Domestic and International Comparisons

(1) China's Urbanisation Stage

In recent years, China has entered a transitional period characterised by population decline and a continued rise in the urbanisation rate. This is particularly evident in megacities such as Beijing and Shanghai, where post-urbanisation features have emerged. Although the national urbanisation rate has not yet stabilised, government policy has clearly shifted towards "stock optimisation" and "decremental development", emphasising spatial quality and efficiency more.

From a macro perspective, China raised its urbanisation rate from 20% to 67% within four decades, adding 670 million urban residents. This rapid increase has begun to slow. Meanwhile, by 2024, the national population had fallen to 1.408 billion, with a natural growth rate of –0.99‰—the third consecutive year of negative growth. The proportion of the population aged 65 and above rose to 15.6% and continues to climb (NBS, 2023; NBS, 2024; NBS, 2025). In 2024, the natural growth rates of Beijing and Shanghai were 0.01‰ and –1.53‰, respectively (Beijing Municipal Bureau of Statistics and NBS Survey Office in Beijing, 2025; Shanghai Municipal Bureau of Statistics and NBS Survey Office in Shanghai, 2025). Both cities have adopted "zero growth" targets for built-up areas, and the tertiary sector accounts for over 75% of their GDP, illustrating clear signs of post-urbanisation. However, beyond these megacities, many large cities remain in an expansion phase.

(2) Origins of the "Beyond Growth" Framework: An International Comparison of Urbanisation

Regional disparities in China have resulted in population migration toward cities continuing even as the total population declines. This means that urbanisation is still unfolding even as the negative growth sets in. Despite resource constraints and social tensions, megacities must continue growing to support surrounding underdeveloped areas. During the high-speed urbanisation era, motorisation accompanied urban expansion, leading to spatial growth driven mainly by land development and road construction, while rail transit development lagged. As a result, applying the "beyond growth" framework in China requires addressing both the limitations of growth-dependent planning and the historical challenges of rapid urbanisation.

International comparisons reveal that China's urbanisation exhibits distinct temporal and structural differences. First, China's urbanisation process has been speedy and involves a massive population. While its speed is comparable to that of Japan and South Korea, the scale is much larger. When Japan and South Korea surpassed 60% urbanisation, they had urban populations of approximately 103 million and 41 million, respectively. In contrast, China's population reached 1.4 billion in 2019 when the urbanisation rate hit 60.6%, placing greater pressure on infrastructure and public services. Second, the sequencing of urbanisation and population decline differs significantly. In most developed countries, population decline followed stabilisation at urbanisation rates of over 70%. In China, however, population decline began when the urbanisation rate was around 65%, and rural-to-urban migration had not yet concluded. Urbanisation is still advancing. Consequently, China must simultaneously address ageing, absorb migrating populations, and continue urban development—creating unprecedented fiscal and planning pressures. Third, rail transit development lagged behind motorisation, exacerbating structural urban challenges. Road-based expansion dominated during China's rapid growth phase, but rising congestion now hinders efficiency. Moreover, China entered the post-demographic-dividend phase before fully transitioning to a service economy. As a result, cities face dual pressures: job provision and revenue generation.

In summary, China cannot directly adopt the "stop expanding" model of developed countries. Even in a post-urbanisation context, structural optimisation and functional transformation are necessary to promote spatial efficiency and regional balance—goals for which rail transit is a key driver.

3.2 The Demand and Dilemmas of Rail Transit under High-Quality Development

China's unique urbanisation background explains the necessity of rail transit development and the conditions it must address. As a guiding principle, high-quality development imposes new structural demands on spatial planning and infrastructure systems. Functionally, rail transit is no longer simply a commuter tool but a critical mechanism for urban structural adjustment and transformation of the urban settlement system (Chen et al., 2017; Chen et al., 2022).

However, in practice, Chinese metropolitan rail transit systems still face multiple challenges. First, corridor capacity is limited and construction space in central areas is nearly saturated. Second, reuse rates of existing railways remain low, especially for mid-level suburban rail networks, which are severely underdeveloped (Li, 2022). Third, marginal returns are diminishing, with high construction costs, low returns, and rising fiscal pressure. Fourth, operational fragmentation persists, with inadequate cross-jurisdictional collaboration and a lack of integrated systems.

In response to these issues, China's rail transit must move beyond linear, expansion-based logic and adopt a more efficient, structural, and coordinated development model. On one hand, the system should support regional rebalancing and the reorganisation of urban–rural structures, ensuring strong connections to new towns and key regional nodes. On the other hand, it must also evolve internally—from quantity-driven supply to quality-oriented structure—achieving a clear division of labour and coupling within a multi-level rail system.

Based on these goals, this paper proposes a rail transit optimisation framework across three spatial scales: the regional level, the metropolitan level, and the suburban level. This framework aligns with the values of high-quality development—equity, efficiency, and sustainability—and aims to provide systematic support for spatial restructuring and industrial transformation in China's megacities during this critical "window period".

4. A Framework for Coordinated Optimisation Between Rail Transit Networks and Regional Spatial Structures: Strategy and Case Study

4.1 Key Elements and Framework for Coordination Between Rail Transit Networks and Spatial Development

(1) The Nature of Coordinated Development

The coordinated development between rail transit networks and urban spatial structures is fundamentally a dynamic, bidirectional interaction. Each influences and reinforces the other, forming a feedback mechanism. Urban spatial development goals support and guide the optimisation of rail networks, while rail networks themselves serve as a critical system for directing resource allocation and the evolution of spatial structure.

Optimising rail network layout requires a sound understanding of current spatial conditions and development objectives. A clear strategic vision for spatial development forms the foundation for identifying rail priorities and improving network efficiency. Rail systems, built upon corridors and nodes, directly affect population mobility, land use, and industrial distribution. By improving accessibility and strengthening regional linkages, rail transit shapes spatial structure and influences resource allocation efficiency.

(2) Core Elements and Multi-level Framework

When urban and regional development demands are reflected in rail networks, they manifest as spatial connections and expectations regarding travel time and service intensity. A multi-level framework can represent these dynamics from a spatiotemporal perspective.

This framework should include at least three spatial levels, each with distinct functions and elements. The three core components for coordinated optimisation are rail lines (enabling the flow of resources across different scales), nodes or hubs (connecting systems and spaces), and policy mechanisms (ensuring implementation and governance) (Figure 1). Specifically:

At the regional level, intercity and high-speed rail connect major urban nodes, support the formation of strategic corridors, and serve business travel needs. The target is to reach metropolitan hubs within one hour.
At the metropolitan level, rail systems—comprising suburban rail, intercity lines, and metro—link central cities, new towns, and peripheral urban areas, supporting medium- to long-distance commuting.

At the central level, metro systems form dense intra-city networks primarily used for short-distance daily travel. Service coverage should also reach within an hour.

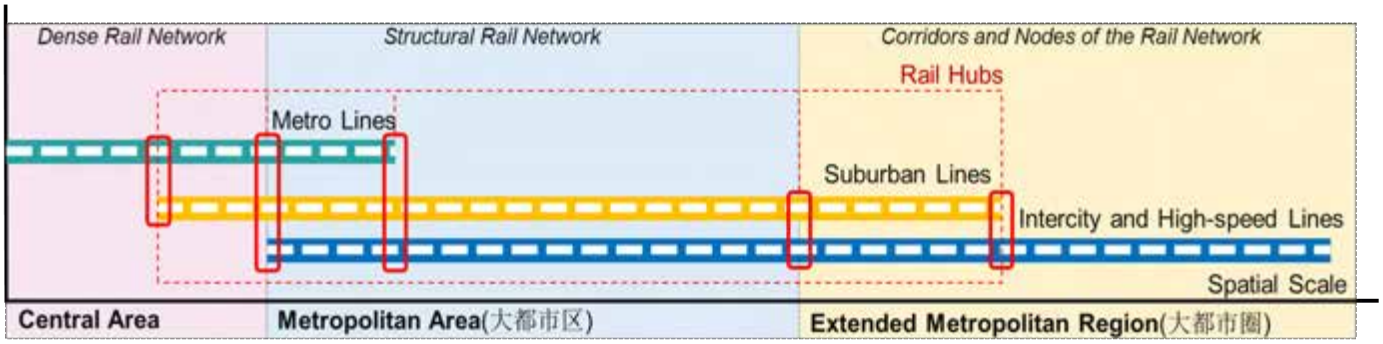

Figure 1. Multi-level Rail Transit Network Framework

4.2 Specific Strategies and Case Studies for Coordinated Optimisation of Rail Transit and Spatial Structure

4.2.1 Objectives and Strategies of Rail Transit Optimisation

The objectives of rail transit network optimisation should be determined by regional challenges and strategic development goals. In the current Chinese context, rail transit optimisation aims to establish a multi-level rail transit system operating across three spatial levels: the regional level, the metropolitan level, and the central level. This system facilitates development goals through strategic node connections and varying operational frequencies.

Specific strategies include: Firstly, at the regional level, enhancing functional corridors centred around major cities to guide the urban settlement system. Secondly, at the Extended Metropolitan Region (EMR) level, promoting efficient resource mobility through multi-layered, multifunctional rail hubs and mitigating spatial fragmentation caused by administrative boundaries. Thirdly, at the metropolitan level, establishing suburban rail as the structural backbone network to overcome the limitations of existing dense metro networks and efficiently connect central urban areas with peripheral new towns (Figure 2).

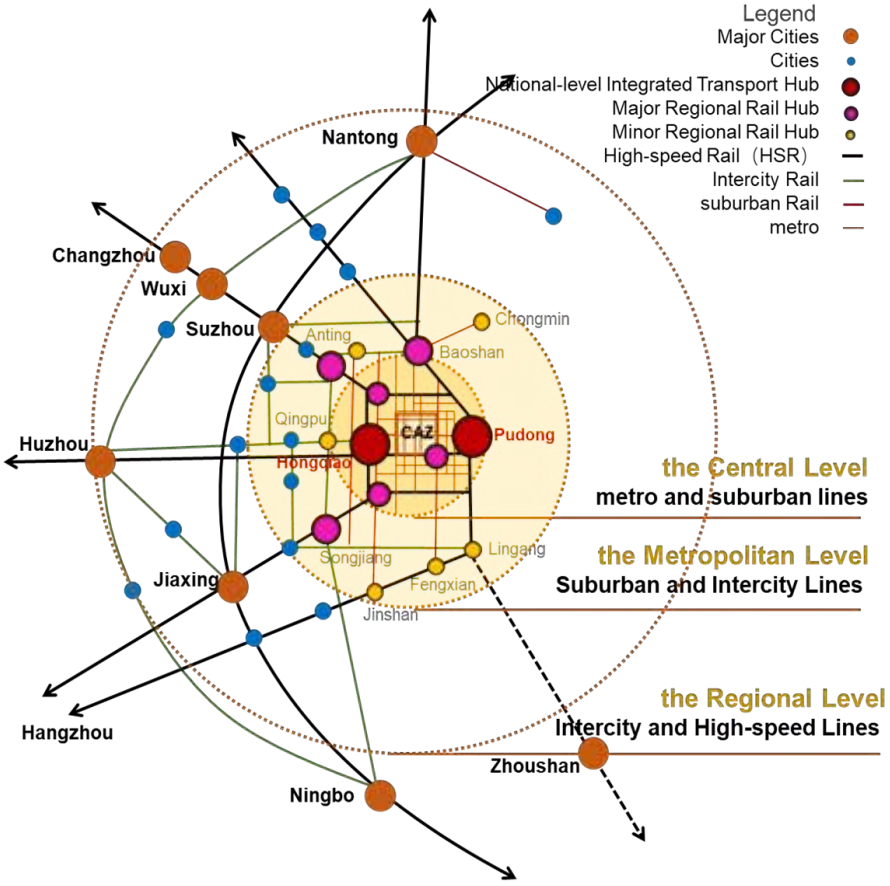

Figure 2. Multi-level Spatial Structure of Rail Transit

The following sections use the Yangtze River Delta and Shanghai Metropolitan Area to further illustrate these strategies.

4.2.2 Urban Agglomerations and Extended Metropolitan Regions: Corridors and Nodes

(1) Regional Corridors and Urban Strategies

At the regional level, rail transit serves not only connectivity functions but also as a strategic instrument for urban development, guiding the implementation of regional goals related to population mobility, economic development, ecological protection, and cultural exchange.

Taking the Shanghai Metropolitan Area as a case, optimisation strategies are developed around these regional strategic goals. Six strategic corridors have been identified: Shanghai–Nanjing, Shanghai–Hangzhou, Yangtze River Corridor, Coastal Corridor, Hangzhou Bay Corridor, and Shanghai–Huzhou Corridor. The Shanghai–Nanjing and Shanghai–Hangzhou corridors should enhance service frequency to maximise existing capacity. The Yangtze River and Coastal Corridors are reserved corridors prioritised based on industrial development demands, while the Shanghai–Huzhou Corridor is prioritised for immediate development, serving tourism and cultural needs (Figure 3). The analysis evaluates corridor performance through both industrial and cultural lenses, ensuring that key natural and cultural nodes—such as World Heritage Sites—are connected to external hubs via rail transit. (Figure 4).

Figure 3. Strategic Rail Corridors in the Shanghai Metropolitan Area

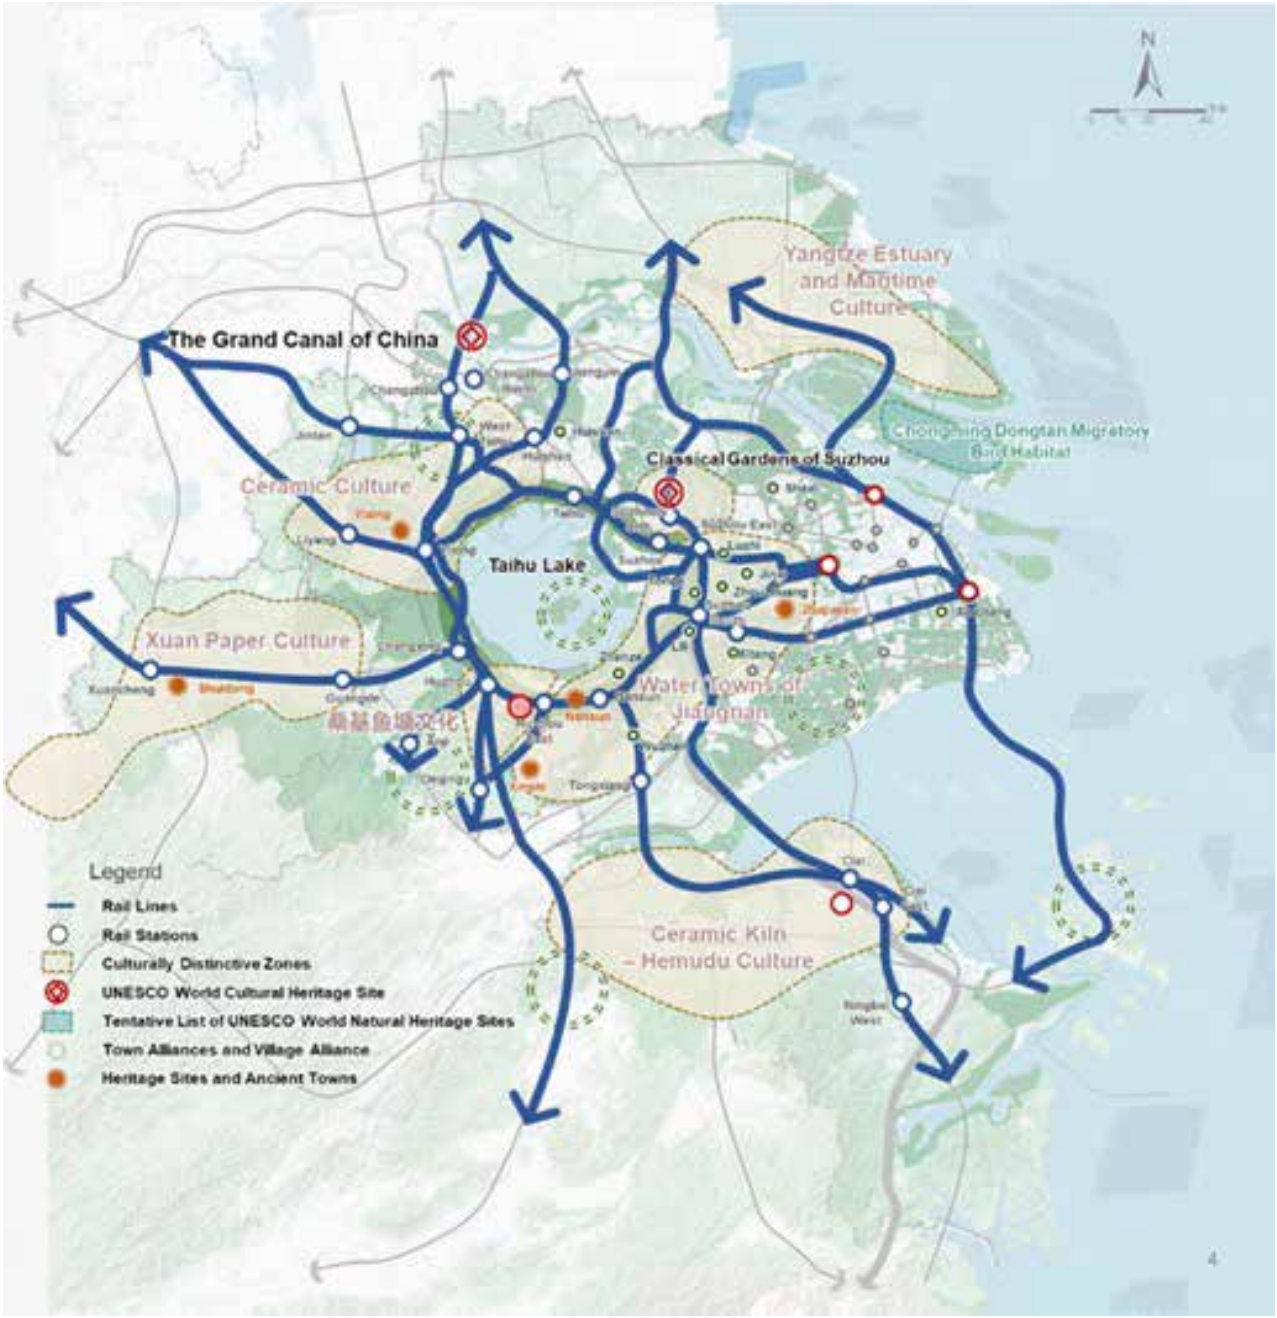

Figure 4. Rail Transit System Supporting Natural and Cultural Heritage in the Shanghai Metropolitan Area

(2) Multi-level Networks and Urban-town Systems
Establishing multi-level rail transit systems supports the optimisation of regional spatial structures and urban settlement systems in the framework of high-quality urbanisation. Rail transit networks should address three connection types: intercity connections at the regional level, daily commuting within Extended Metropolitan Regions, and internal city connections.

Using the Shanghai Metropolitan Area as an example, the study analyses urban development roles and inter-city connectivity, proposing layered and composite optimisation strategies. It emphasises compound utilisation of corridor resources, detailed layered scheduling, and differentiated stop schemes to enhance overall network efficiency and spatial structural optimisation (Figure 5).

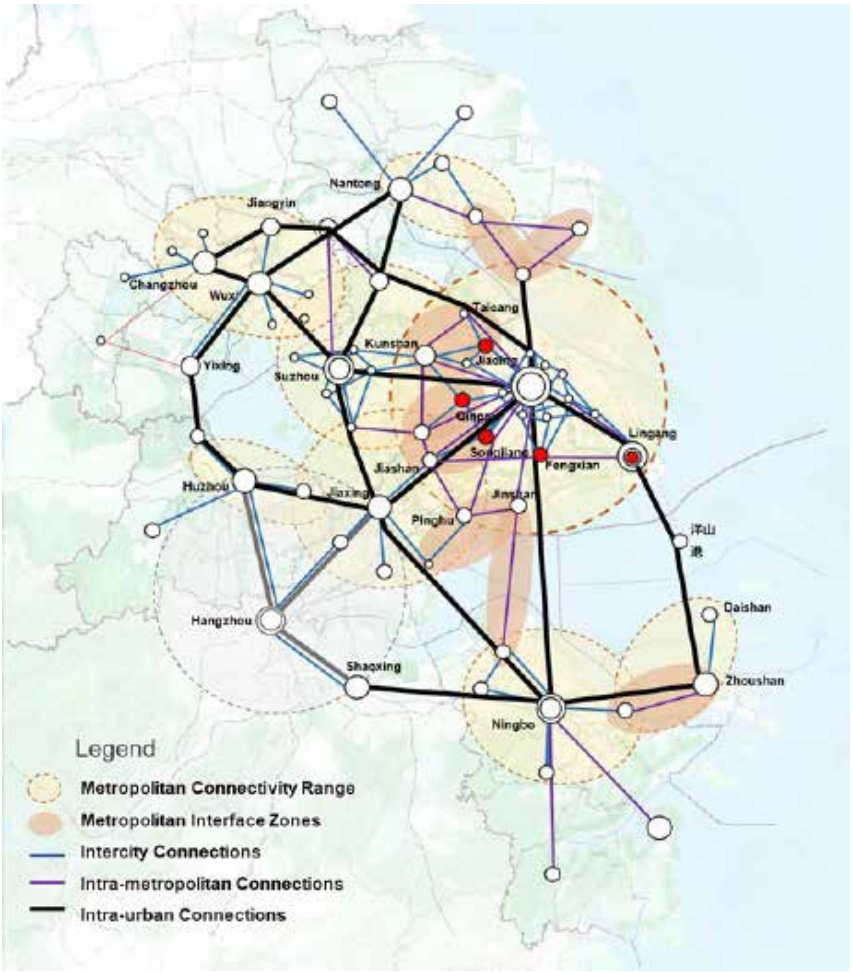

Figure 5. Inter-city Connectivity in the Shanghai Metropolitan Area

4.2.3 Metropolitan Area: Structural Network

(1) Hub Systems and Resource Allocation

Rail stations serve as critical interfaces linking transit systems with urban spaces. Rather than relying on a single mega-hub, tiered and functionally differentiated hub systems can more effectively facilitate the allocation of urban resources. This study proposes a classification of five hub types, divided into two categories. Type I includes national and regional hubs: national-level integrated transport hubs (such as the Hongqiao Integrated Transport Hub), major regional rail hubs, and minor regional rail hubs (Figure 6).. Type II includes suburban network hubs, which consist of new town hubs (designed to link newly developed urban areas with the broader regional network) and central hubs (which integrate suburban rail with metro systems to enable seamless transfers) (Figure 7).

In the case of Shanghai, the city's excessive dependence on the Hongqiao Integrated Transport Hub—currently handling 60% of all rail passengers and operating at nearly 90% of its designed capacity—necessitates a more balanced hub network. To address this, the study recommends strengthening the role of the Eastern Hub, centred around Pudong International Airport, to ease pressure on the western corridor. It also advocates for the enhancement of Baoshan and Longyang Road stations to complement the functions of Shanghai, South, and West stations as part of the regional hub system. Additionally, the study proposes establishing general-purpose suburban hubs along the urban periphery, designating new town hubs in each of the five new towns, and developing new central hubs at the edge of the central area to improve integration between suburban rail and metro services.

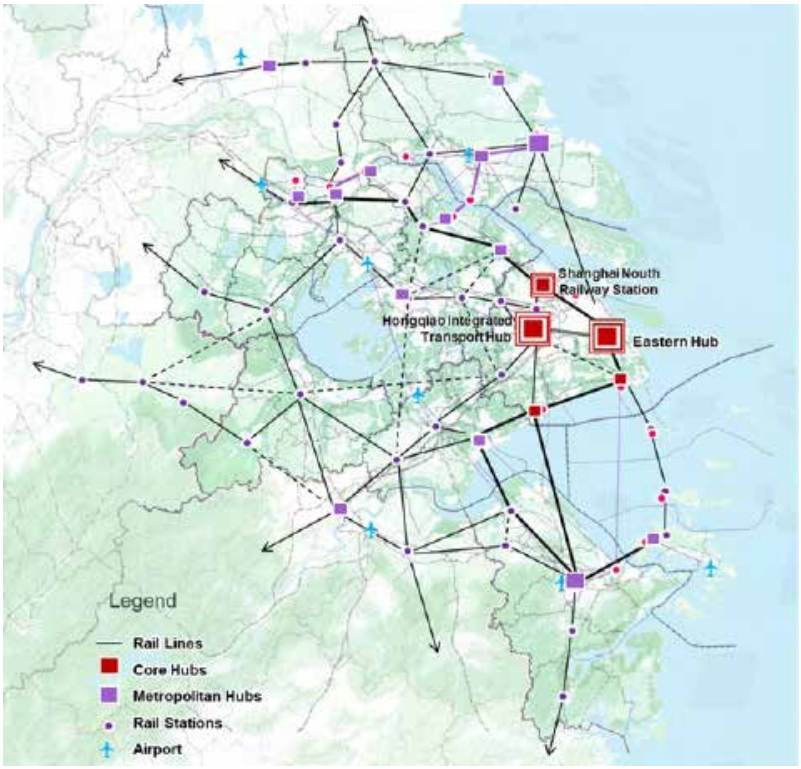

Figure 6. Rail Hub System of the Shanghai Metropolitan Area

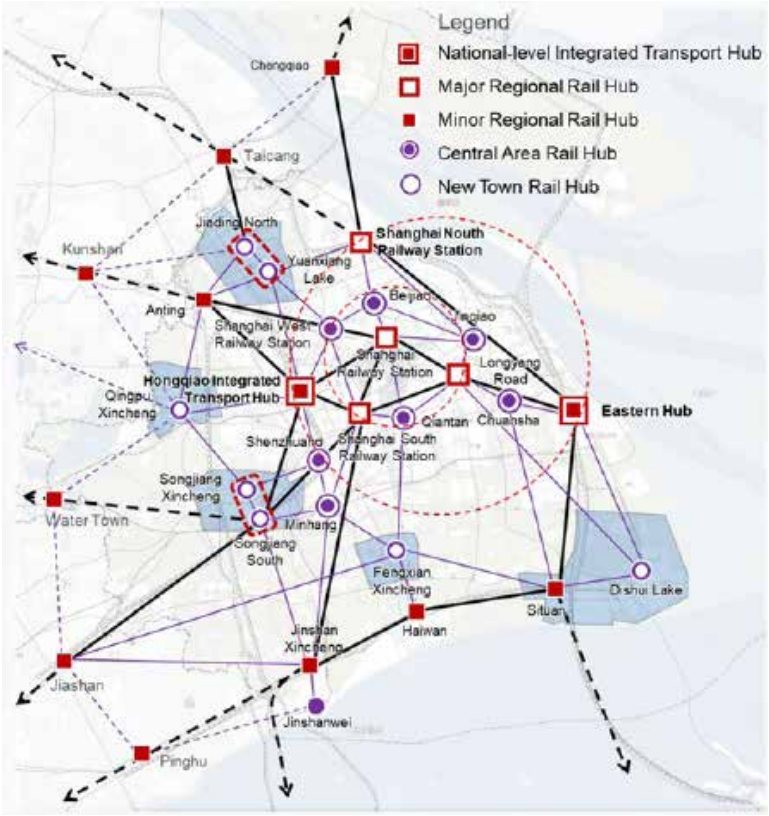

Figure 7. Rail Hub System of Shanghai and Its Adjacent Areas

(2) Suburban Rail and Inter-jurisdictional Cooperation
With increasing cross-boundary commuting within metropolitan areas, administrative boundaries currently limit the effectiveness of rail systems, hindering new town development. The study suggests integrating suburban and intercity rail at boundary regions to enhance connectivity.

In the Shanghai Metropolitan Area, insufficient suburban and intercity rail infrastructure currently restricts cross-city commuting, risking increased traffic congestion. Drawing lessons from Paris and Tokyo, this study advocates detailed reclassification of rail lines within boundary areas, aiming to strengthen regional cooperation and transform peripheral new towns into multifunctional urban nodes, thus preventing their evolution into mere residential towns (Figure 8).

Figure 8. Cross-boundary Rail Coordination

4.2.4 Metropolitan Areas: Structural Dense Networks
Central urban rail networks are increasingly complete in most major cities, but peripheral areas remain inadequately supported. As a structural backbone, suburban rail efficiently links central and peripheral areas. The study recommends a phased, demand-driven approach rather than extensive new construction.

In Shanghai, peripheral central areas experience high commuting pressures, significant industrial and population renewal, and severe congestion. Structural reinforcement through constructing a central loop line and radial suburban lines is proposed to strengthen connectivity between central areas and new towns, optimising regional spatial structures (Figure 10).

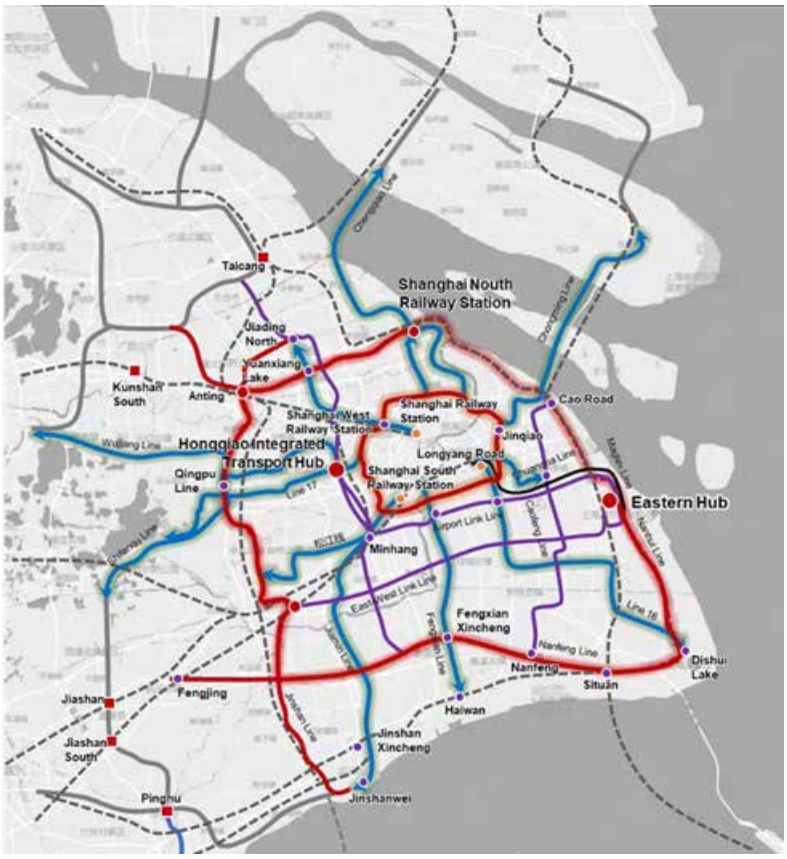

Figure 10. Suburban Rail Structure in Shanghai

4.2.5 Development, Construction and Operation Modes

Clear delineation of rail transit development, construction, and operation responsibilities is critical for sustainability. The study highlights the importance of clarifying roles between central and local governments and establishing inter-jurisdictional coordination mechanisms.

It recommends that Shanghai leads coordination efforts, establishing a comprehensive planning, construction, and operation platform involving neighbouring cities. The coordination should define technical schemes, operational responsibilities, and service standards for network integration. Diversified financing models and Transit-Oriented Development (TOD) approaches should be adopted to ensure sustainable rail transit development.

5. Conclusion

This study, situated in the context of China's transition to the mid-to-late stage of urbanisation, explores the key role and practical challenges of rail transit in promoting spatial optimisation and facilitating the flow of urban elements under the high-quality development paradigm.

Comparative analysis reveals that China's urbanisation path differs significantly from Western models: population decline has begun before urbanisation is complete; inefficient spatial expansion resulted from delayed rail development; and industrial restructuring is under pressure due to an underdeveloped service sector. These contradictions make it clear that China cannot follow a "de-growth" model but must pursue a focused, structure-oriented, high-quality development strategy within the "beyond growth" framework.

To this end, the study proposes a multi-level rail transit optimisation framework across regional, metropolitan, and suburban scales. Unlike traditional large-scale expansion, the proposed approach emphasises structural reinforcement, integrated corridor use, and hub function reconfiguration:

At the regional level, high-speed and intercity rail should support corridors and key nodes.

At the metropolitan level, cross-jurisdictional coordination and balanced functionality are key.

At the suburban level, suburban rail should form the backbone, supported by the metro system, to enhance commuting efficiency and reduce central city pressure.

The case study of the Shanghai Metropolitan Area confirms the framework's applicability and feasibility. Practices such as structural optimisation, corridor integration, and operational coordination align with today's resource constraints and governance complexities more than blind expansion.

This research expands the theoretical discourse on rail transit and offers a context-specific strategy for China's development model. It may also be a reference for other countries facing similar post-urbanisation challenges. Nonetheless, limitations remain—for instance, further research is needed to assess economic impacts and operational mechanisms in greater detail. Future studies should explore the design of inter-jurisdictional governance systems and assess the long-term spatial and socio-economic effects of rail transit strategies.

Beyond Access: A Grid-Based Framework for Measuring Service Levels and Inequity in Multimodal Public Transit

Baekchan Jeon [1] **Myounggu Kang**

Email: sarakael0602@uos.ac.kr, mk@uos.ac.kr

Abstract
Conventional transport studies, focused on accessibility, often fail to capture the actual service levels and spatial inequity of public transport. This study develops a novel grid-based multimodal multiplex network framework for South Korea to overcome these limitations. Using nationwide GTFS data, we model each transport mode as a distinct layer on a 1km² grid, incorporating service frequency as a weight to measure service levels. The analysis reveals extreme spatial polarization: service levels are overwhelmingly concentrated in metropolitan cores while vast non-urban areas experience severe service deprivation. This framework provides a robust tool for diagnosing transport inequity with high precision, offering data-driven evidence for policies aimed at building a more inclusive and sustainable transport system.

Keywords: Multimodal Public Transport, Multiplex Network, Spatial Accessibility, Spatial inequality, Nationwide spatial analysis

1. Intrduction

Transportation services are fundamental to urban functionality, acting as the circulatory system that facilitates the flow of goods and people and enables complex social interactions. Public transport, in particular, is critically important as it provides a broader range of citizens with equitable access to urban opportunities and the freedom of mobility (ITF-OECD, 2023).

Modern cities rely on Public Transport Networks (PTNs) to achieve efficient and sustainable mobility (Kujala et al., 2018). These networks have become critical infrastructure in cities worldwide, offering access to essential services such as employment, education, and healthcare, thereby facilitating diverse activities and social interactions (ITF-OECD, 2023).

In response to rapid urbanization and growing transportation demand, public transport plays a vital role in supporting urban growth and sustainable development (Ding et al., 2019). By enabling large-scale commuter flows, it serves as the foundational infrastructure essential for sustaining core urban functions and enhancing the sustainability of metropolitan areas.

However, despite their importance, PTNs, as complex networks, are inherently characterized by an uneven distribution of service (Mouronte-López, 2021). This structural imbalance, wherein a few hub nodes account for a disproportionate share of network connectivity, not only leads directly to issues of network vulnerability and robustness but also extends to create disparities in service levels and accessibility.

Transport networks fulfill the critical roles of connecting key locations and providing the urban-wide framework for interaction. However, access times from residential areas to essential services and transport facilities vary significantly by region type (Bae et al., 2016).

Specifically, urban areas, with their close proximity to public transport stops and stations, tend to have lower car dependency. In contrast, most low-density regions, such as rural townships (eup and myeon areas), exhibit higher car dependency due to poor public transport accessibility. This reflects a stark disparity in the spatial coverage and service density of PTNs between urban and non-urban areas.

This uneven distribution of transport services risks exacerbating the vulnerability of specific demographic groups. The high demand for subsidized transport options, such as welfare taxis and Demand-Responsive Transit (DRT), in low-income and low-service-density areas serves as empirical evidence of this service imbalance (Kim G. et al., 2019).

1 ORCID : https://orcid.org/0009-0006-5681-3416

As the demand for mobility is derived from the need to access opportunities (ITF-OECD, 2023), a lack of transport services can exclude people from participating in educational, employment, and various social and leisure activities. This issue transcends a mere physical deficit of transport services, leading to severe socio-economic imbalances such as heightened inequality, restricted access to essential services, and hindered regional development.

In rapidly urbanizing areas where economic gaps are widening, the uneven spatial distribution of social resources can intensify feelings of deprivation among vulnerable populations. This, in turn, may trigger psychological changes and social discontent, potentially affecting social stability (Han, C. et al., 2019). Crucially, the gap in transport accessibility between urban and non-urban areas—which diminishes quality of life and constrains opportunities for social participation—poses a direct threat to the realization of transport rights and social equity (Han, C. et al., 2019; Kujala et al., 2018; Mo C. et al., 2013).

On the other hand, as car-centric urban environments create persistent problems such as traffic congestion and pollution, the importance of public transport is ever-increasing. However, existing methodologies for evaluating Public Transport Networks (PTNs) have significant limitations in capturing the complexity of real-world urban transport systems.

Approaches centered on Origin-Destination (OD) data focus primarily on pairwise connectivity between locations, failing to reflect the overall structural properties of the network or actual service operations data (Koo et al., 2024). Consequently, analyzing a transport network based solely on physical links overlooks the service connectivity actually experienced by users. This leads to a loss of critical information, which not only diminishes analytical accuracy but also hinders the formulation of effective policies (Hong D. et al., 2014).

Furthermore, a substantial body of research in transport network analysis has concentrated on evaluating the performance or structural characteristics of single-mode networks. While this approach can be useful for analyzing the efficiency of a specific transport mode, it overlooks the reality that urban travel occurs within a multimodal environment (Hong J. et al., 2019). Specifically, these models have a fundamental limitation in their inability to adequately incorporate user choices and inter-modal connectivity that arise during the transfer process.

Another fundamental reason why existing network analyses fail to capture real-world complexity lies in their methodological choices: namely, the selection of spatial units for analysis and an overemphasis on the dimension of accessibility. Many previous studies, driven by convenience or data availability, have utilized administrative districts such as eup, myeon, and dong as nodes or units of spatial aggregation (Hwang M. et al., 2023; Byeon P. et al., 2016; Park G. et al., 2023; Jang D. et al., 2015). This approach is inevitably subject to the Modifiable Areal Unit Problem (MAUP). This means that analytical results can vary significantly depending on the scale and shape by which a region is partitioned and aggregated, which in turn poses a serious threat to the reliability and generalizability of the findings.

Administrative boundaries rarely align with actual travel behaviors or the spatial distribution of urban functions (Kim J. et al., 2019; Hwang M. et al., 2023), and their areas vary widely even within the same hierarchical level. Consequently, constructing and analyzing networks based on these arbitrary boundaries inherently limits the ability to capture micro-spatial patterns and carries a significant risk of distorting analytical results.

Furthermore, accessibility in public transport is typically defined by the mere presence of physical infrastructure and the potential reach it provides. While the goal of enhancing spatial accessibility through infrastructure improvements is commendable, it overlooks a critical dimension of service quality. For instance, even if a transport service allows for a 15-minute trip to another area, it is of little practical value if the actual service volume is insufficient. The essence of public transport lies not merely in providing the possibility of movement, but in guaranteeing the freedom and quality of mobility. Therefore, examining the quantitative dimension of available services, in addition to their qualitative aspects, becomes a critical subject for investigation.

To address these limitations, this study first redefines user-centric service in terms of the **"Through-Route"**: the set of all pairs of stops that can be reached on a single, transfer-free journey. This concept will serve as the

fundamental unit of connection (the link) in our network analysis. Furthermore, to reflect the complex interactions and transfers between various transport options, this study will construct a multi-modal network by leveraging a **multiplex network** structure—a powerful analytical framework from complex network theory. In this model, each mode of transport (e.g., bus, subway, rail) constitutes a distinct layer, while inter-layer connections representing transfers are established through shared grid-based nodes.

To further enhance analytical reliability and spatial resolution, this study diverges from the common practice of using arbitrary administrative boundaries. Instead, we employ a uniform 1km² grid across the entire nation as the fundamental spatial unit. Each grid cell functions not only as a proxy for a "public transport living zone" but also as a node in the multimodal network model. This large-scale network will be constructed using a comprehensive, nationwide public transport database based on the General Transit Feed Specification (GTFS), thereby relying on big data rather than on samples or estimations.

Moreover, for the links connecting these nodes, our model incorporates service frequency as an additional weight, moving beyond traditional metrics like distance or time. This approach allows us to examine not only the mere possibility of movement but also to investigate the freedom and quality of mobility available to citizens.
This framework will provide a robust foundation for effectively embedding the high-resolution mobility patterns and activity information afforded by big data into our unit of analysis. On this methodological basis, this study seeks to address the following research questions:

1. How can a multimodal public transport network model be constructed to holistically integrate various transport modes and the dynamics of their transfers?

2. When analyzed using the proposed high-resolution, grid-based model, what is the spatial distribution of public transport service quality, and what novel perspectives does this offer compared to conventional analyses based on administrative units?

3. What are the policy implications of incorporating the quantitative dimension of service level into traditional, accessibility-focused public transport analyses?

In conclusion, this study proposes a novel analytical framework—a grid-based, multimodal public transport network analysis—designed to overcome the methodological limitations of prior research. Through this framework, we aim to achieve a comprehensive understanding of the complex structural properties of the nationwide multimodal public transport network, the spatial distribution of its service levels, and the quantitative aspects of service that extend beyond conventional accessibility analysis.

This endeavor, by integrating insights from complex systems science, spatial analysis, and transport planning, seeks to deepen our understanding of urban transport systems. It aims to inform effective policy directions for promoting sustainable urban development and transport inclusion. The findings are expected to contribute by precisely identifying transport-disadvantaged areas, providing data-driven evidence for the efficient allocation of limited resources, and ultimately, suggesting concrete improvements to route planning and transfer systems to mitigate regional service disparities.

2. Literature Review

2.1 Introduction

This chapter builds the theoretical foundation for this study by critically reviewing the literature on public transport performance and equity. It delves into three core research streams to establish the necessity and originality of the proposed framework.

First, it traces the conceptual shift in transport planning from mobility to accessibility and, more recently, to equity and justice, arguing that conventional accessibility metrics are insufficient and a Level of Service (LoS) perspective is required.

Second, it interrogates the limitations of prevailing network models, demonstrating why multi-layer network theory offers a more robust alternative to single-mode or aggregated representations.

Third, it examines the Modifiable Areal Unit Problem (MAUP) as a persistent challenge in spatial analysis and validates the methodological superiority of a grid-based framework.

Through this review, the chapter identifies a critical gap at the intersection of these domains and culminates by presenting the academic and policy significance of this study's integrated approach.

2.2 From Accessibility to Equity and Level of Service

2.2.1 The Normative Shift in Transport Planning

The core paradigm of transport planning has undergone a decisive shift from a "mobility-centric" approach, which prioritizes vehicular flow, to an "accessibility-centric" one that emphasizes connectivity between people and places (Cervero, 2005). This reframed transport systems as social institutions that directly impact quality of life and opportunity, prompting calls in contexts like South Korea to reorient infrastructure policy from efficiency toward equity (Jang et al., 2015).

More recently, this evolution has progressed further, establishing transport equity and spatial justice as central academic and policy agendas (Ruiz-Pérez et al., 2023). This discourse moves beyond simple resource allocation to scrutinize how transport systems may cause or exacerbate the social exclusion of vulnerable populations (Pereira et al., 2021; Smith et al., 2018).

This concern is prominent in South Korean policy, where concepts like the "Transport Inclusion Index" and "inclusive mobility" have been developed to address accessibility gaps and counteract new forms of inequality (Bae et al., 2016; KOTI, 2022). Consequently, ensuring equitable access to essential opportunities for all citizens stands as a core normative goal of modern transport policy.

2.2.2 The Limits of Conventional Accessibility Metrics

While traditional accessibility measures, such as cumulative opportunity and gravity models, have been instrumental in visualizing the uneven distribution of opportunities (Rodrigue et al., 2013), they suffer from several pronounced limitations.

First, they focus on potential reachability while overlooking the actual level of service. The mere existence of a network connection does not guarantee high-quality service (ITF-OECD, 2023). This limitation is starkly illustrated by the problem of "ghost buses"—routes with such low frequency as to be practically unusable. This disconnect suggests that conventional efficiency-driven logic, such as cost-benefit analysis, can create structural problems by failing to adequately consider regional equity, sometimes leading to unintended consequences like the "straw effect" where investment in core areas drains vitality from the periphery (Kim et al., 2020).

Second, and relatedly, they fail to integrate the quantitative dimension of service, particularly operational frequency. As frequency directly impacts user waiting times and travel flexibility, its omission leads to analyses largely disconnected from the actual user experience (Han et al., 2019). Recognizing this, transport authorities have begun to advocate for "minimum service standards" that include frequency as a key component (Kim et al., 2020).

2.2.3 A New Perspective: Integrating Level of Service (LoS)

To overcome these limitations, this study argues that integrating a Level of Service (LoS) perspective is essential. LoS is a multidimensional concept representing the quality and quantity of transport service, with operational frequency as a core, measurable indicator. The increasing availability of standardized public transport big data like the General Transit Feed Specification (GTFS) makes such LoS-based analysis practically feasible (Kujala et al., 2018). GTFS timetable data allows for the extraction of service frequencies, enabling weighted network analysis that reflects the actual supply of service (Háznagy et al., 2018; Ha & Lee, 2017). This integration is the crucial step to realizing the philosophy of "Beyond Access," shifting the focus from supplier-side infrastructure to the quantity and quality of service that users actually experience.

2.3 Representing Multimodal Complexity

2.3.1 Network Science as an Analytical Toolkit

Network science provides a powerful toolkit for quantitatively analyzing the underlying topological properties of transport systems, which can be abstracted as a set of nodes and links (Newman, 2018). Centrality analysis, in particular, is widely used to identify critical hubs and transfer points (Ding et al., 2019), and has been applied extensively in the South Korean context (Koo et al., 2024; Hong et al., 2019). Furthermore, these tools are used to assess network robustness and vulnerability by simulating the impact of node or link failures (Mouronte-López, 2021; Meng, 2024).

2.3.2 The Challenge of Multimodal Representation

Despite the utility of these tools, their application has been hampered by two conventional limitations in representing real-world multimodal systems. First is the oversimplification of the network through aggregation. Aggregating distinct transport modes into a single layer has been empirically shown to severely distort structural properties and produce critical analytical errors, as it erases the unique operational characteristics of each mode (Aleta et al., 2017). Second is the bias toward single-mode analysis, which overlooks the complementary relationships between different modes and fails to model the complex dynamics of transfers. These modeling failures contribute directly to the disconnect between measured accessibility and the actual LoS experienced by users.

2.3.3 The Alternative: A Multi-layer Network Framework

The most promising alternative is the multi-layer network framework, which models different transport modes as distinct but interconnected layers (Alessandretti et al., 2022). This approach is methodologically superior as it: (1) preserves the unique characteristics of each transport mode (Aleta et al., 2017); (2) enables a sophisticated modeling of transfer dynamics through inter-layer links, which is crucial for assessing system-wide properties like resilience (Xu & Chopra, 2023; Ma et al., 2019); and (3) facilitates a more realistic measurement of service level by simulating journeys across multiple modes (Baggag et al., 2018; Alessandretti et al., 2016). Therefore, this study adopts the multi-layer framework as a necessary choice to represent the complexity of the multimodal system with greater precision.

2.4 The Dilemma of Spatial Analysis

2.4.1 The Modifiable Areal Unit Problem (MAUP)

The selection of a spatial unit for analysis is a critical decision that decisively influences research findings. The conventional use of administrative districts is subject to the Modifiable Areal Unit Problem (MAUP), a persistent challenge in spatial science where analytical results change depending on the scale and zonation of the units used for aggregation (Rey & Franklin, 2022). This practice is problematic because administrative boundaries rarely align with actual travel behavior, vary drastically in size and density, and mask micro-level patterns, thereby posing a serious threat to analytical reliability (Bae Y. et al., 2016; Hwang M. et al., 2023).

2.4.2 The Alternative: A Grid-Based Framework

To overcome MAUP, this study adopts a uniform grid-cell as the unit of analysis. This approach is superior for three reasons. First, it ensures objectivity and comparability by mitigating scale and zonation biases. Second, it holds theoretical validity by employing a systematic and neutral "spatial container" to analyze human mobility, which is known to be constrained by geographic context rather than being scale-free (Alessandretti et al., 2020). Third, it aligns with cutting-edge research trends, both internationally and domestically, where grid-based analysis is becoming a standard for leveraging high-resolution data (Hwang M. et al., 2023; Ha & Lee, 2017). The combination of this grid-based framework with the multi-layer network model constitutes the core methodological innovation of this study.

2.5 Synthesis and Originality of the Study

This critical review reveals that while the fields of transport equity, network science, and spatial analysis have advanced, they have largely proceeded in disconnected silos. A critical research gap emerges at their intersection: there is an absence of an integrated framework that can simultaneously (1) measure the quantitative level of service, (2) capture multimodal complexity, and (3) overcome the MAUP with a precise spatial unit.

Therefore, this study aims to fill this gap by proposing and applying a Grid-Based Multimodal Multiplex Network Framework. This novel approach simultaneously addresses the three core challenges by incorporating service frequency into a multi-layer network built upon a uniform grid. This integrated framework will enable the identification of service-vulnerable areas with unprecedented precision, broadening the methodological horizons of transport planning and contributing significantly to policies aimed at promoting national balanced development and transport inclusion.

3. Methodology

This chapter details the methodology designed to diagnose the spatial performance and equity of the nationwide multimodal public transport network in South Korea. The methodology comprises three main parts. First, it describes the process of constructing a nationwide, multi-layer public transport network database by integrating various data sources into a standardized format. Second, it establishes the analytical framework by defining a comprehensive set of indicators to measure the network's efficiency, connectivity, and accessibility. Finally, it outlines the process for identifying transport-vulnerable areas by synthesizing these multifaceted indicators.

3.1 Research Framework and Process

This study adopts a systematic research process, as illustrated in Figure 3.1, to overcome the limitations of prior research and to address the proposed research questions. The process consists of four main stages: (1) data collection and preprocessing; (2) construction of the multiplex network model; (3) calculation and analysis of network indicators; and (4) interpretation of the results and formulation of policy recommendations. Each stage is sequentially and logically linked to the results of the preceding stage, ensuring the reproducibility of the research and the reliability of the analytical results.

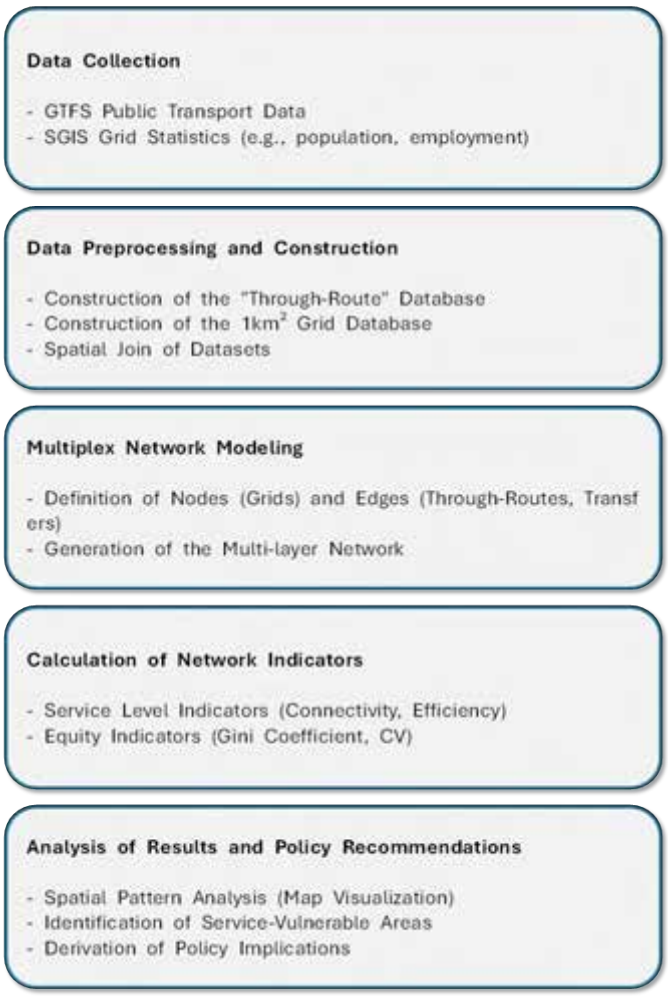

Figure 3.1 Research Process Flowchart

3.2 Data Construction and Preprocessing

A reliable, detailed, and standardized database is a prerequisite for a nationwide analysis of a multimodal public transport network. To this end, this study integrates "Through-Route" information for each mode of transport—derived from TMAP's public transport data which adheres to the General Transit Feed Specification (GTFS) format—with grid-based socioeconomic data from various public and private sources. This process aims to establish a clear and robust foundation for the network analysis.

3.2.1 The GTFS-Based Nationwide Public Transport Database

The foundational data for this research is a 2024 nationwide GTFS dataset provided by TMAP. As a global standard for publishing public transport schedules and associated geographic information, the relational structure of GTFS, comprising files such as stops.txt, routes.txt, trips.txt, and stop_times.txt, allows for a detailed reconstruction of the transport network's spatial and temporal dimensions. The dataset covers the entirety of South Korea and is highly multimodal, including not only intra-city modes like local buses and subways but also inter-city modes such as express/intercity buses, rail, maritime services, and aviation.

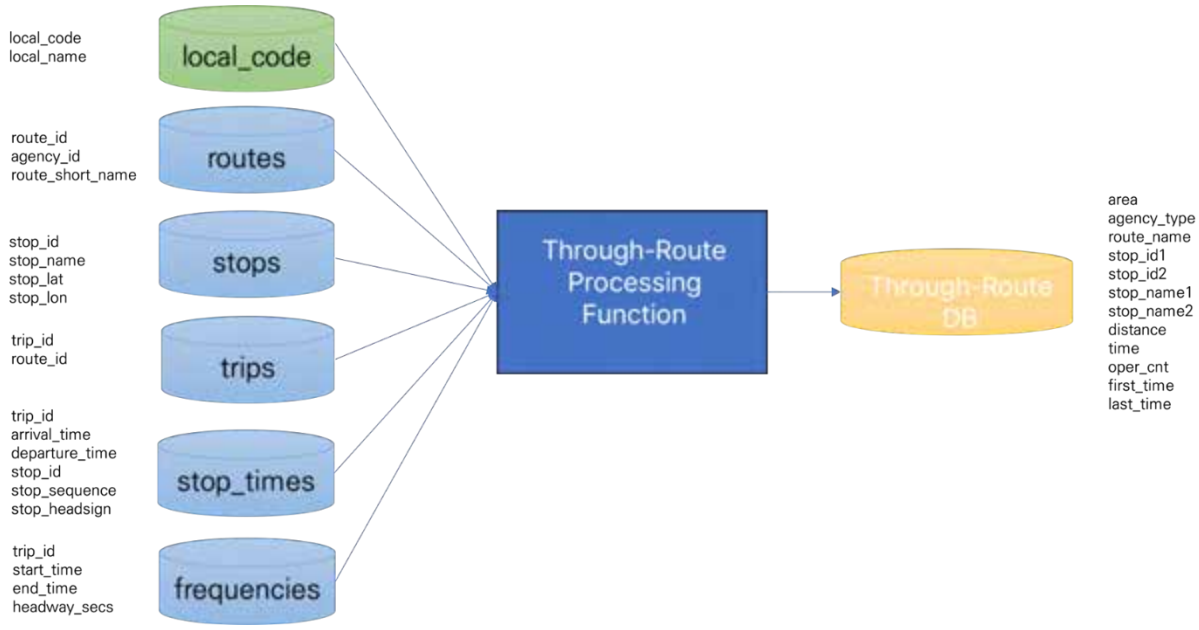

Figure 3.2 GTFS based Public Transport Through-Route DB Processing Process

Table 3.1 Summary of the number of routes and stops in the analysis dataset

Mode	Number of Routes	Number of Stops
Metro	57	1,082
Bus	24,973	192,411
Express Bus	11,851	1,426
Train	13,918	235
Flight	103	13
Marine	2,375	340

3.2.2 Construction of the "Through-Route" Database

To analyze the network from a user-centric perspective, this study first constructed a "Through-Route" database. A "Through-Route" is operationally defined as the set of all pairs of stops that can be reached on a single, transfer-free journey on a given route. This concept serves as the fundamental unit of direct service connectivity. The construction process was as follows:

1. Extraction of Stop Combinations: Utilizing the routes, trips, and stop_times files, all possible sequential origin-destination stop pairs were extracted for each individual trip.
2. Calculation of Travel Attributes: Based on the stop_times data, the travel time for each through-route was calculated. The travel distance was computed using the coordinates from stops.txt. Furthermore, the total number of daily services for a standard weekday was calculated for each route using data from the frequencies. txt or trips files.
3. Calculation of Transport Capacity: The transport capacity for each through-route was calculated by establishing a standard vehicle capacity for each transport mode and multiplying it by the total number of daily services.

3.2.3 The Grid-Based Socioeconomic Database

As discussed in Chapter 2, to overcome the Modifiable Areal Unit Problem (MAUP) inherent in analyses using administrative boundaries, this study adopts a 1km×1km grid system that covers the entire nation. The data were sourced from the Korean Statistical Geographic Information Service (SGIS) for the year 2022, with key variables including total population, age demographics, number of households, and the number of businesses and employees. Each public transport stop was mapped to its corresponding 1km² grid cell. A spatial join was then performed to link the transport network data with the socioeconomic attributes of each grid, creating a rich, multi-layered dataset for analysis.

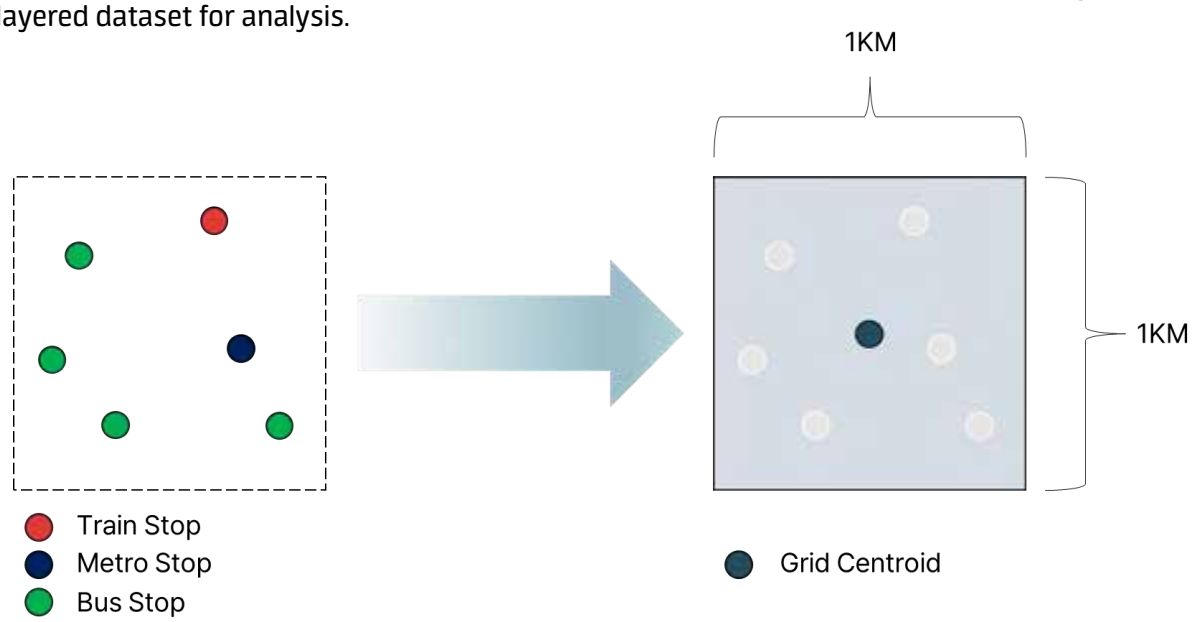

Figure 3.3 Conversion of origin and destination points of public transportation (stop unit – grid unit)

3.3 Construction of the Multiplex Network Model

3.3.1 Definition of Nodes

The nodes of this network model are defined as the 1km² grid cells containing at least one public transport stop. Each node is attributed with the socioeconomic data constructed in Section 3.2.3, including its grid ID, population, number of employees, and Functional Urban Area (FUA) type.

3.3.2 Definition of Edges: A Multi-layer Connectivity Structure

This model possesses a multi-layer structure that treats each distinct mode of transport as a separate layer.

- Intra-layer Edges: These represent connections within each transport mode layer and are generated based on the "Through-Route" data constructed in Section 3.2.2. If a through-route exists from a stop in grid A

to a stop in grid B, a directed and weighted edge is created from node A to node B. The attributes of this edge include weights for travel time, service frequency, and transport capacity.

- Inter-layer Connections and Transfers: Conventionally, transfers in network models are often represented by artificially generating pedestrian links between stops of different modes located within a certain proximity. While this method allows for the explicit addition of transfer penalties, it also introduces artificial links to the original data, which can distort analyses of network connectivity.

Therefore, to avoid this issue, this study does not add artificial transfer links. Instead, it leverages the inherent structure of the multiplex network itself to account for transfers. By fixing the spatial grid cell as the node, transfers are implicitly modeled as movements between different layers at the same node. All stops located within a single 1km² grid cell—a walkable catchment area—are considered mutually accessible, thus enabling transfers between all transport modes present within that grid.

3.3.3 Final Model Specification and Implementation

The constructed network can be represented as a directed, weighted graph G = (V, E), where V is the set of transport hub grid cells, and E is the set of multi-layer edges representing through-routes. For the analysis, this study primarily utilizes the Graph-Tool and GeoPandas libraries in Python, which are optimized for the analysis of large-scale networks.

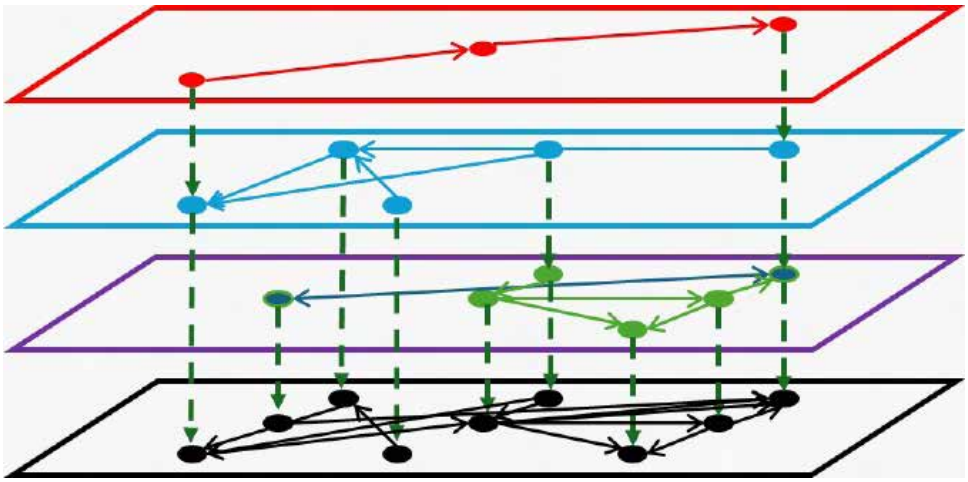

Figure 3.4 Multimodal-Multiplex Network Model

3.4 Selection of Analytical Indicators

To diagnose transport network vulnerability, this study analyzes the network from three dimensions—service level, equity, and structure—using the following selected indicators.

3.4.1 Service Level Indicators

- Weighted Degree Centrality: To move beyond a simple count of connections, this study employs weighted degree centrality, often referred to as node strength, to measure the total volume of service associated with each node. This metric is calculated by summing the weights of all links connected to a node

$$s_i = \sum_j w_{ij}$$

where s_i is the strength of node i, and w_{ij} is the weight of the link between node i and node j. In this study, the weight w_{ij} represents the service frequency or total transport capacity of a given through-route. Therefore, a high node strength indicates that a grid cell is not just connected to many other locations, but that it is served by a high volume of public transport services, marking it as a key hub in terms of service supply.

- Harmonic Closeness Centrality: This measures the overall efficiency of the network and the temporal accessibility of a specific node by using travel time as a weight.

$$H(\Omega) = \sum_{\omega \neq \Omega} \frac{p(\omega, \Omega)}{I}$$

- Cumulative Opportunity Accessibility: This indicator suite measures the practical outcome of the transport service by calculating both the raw number of accessible opportunities and the per capita accessibility within predefined time thresholds.

First, the raw accessibility score calculates the total number of jobs accessible from a given location, providing a measure of the place's potential. The formula is:

$$A_i^T = \sum_j O_j \cdot f(C_{ij}) \quad \text{where} \quad f(C_{ij}) = \begin{cases} 1 & \text{if } C_{ij} \leq T \\ 0 & \text{if } C_{ij} > T \end{cases} \quad \cdots (\text{Eq. 3.8})$$

where A_i^T is the raw accessibility score for node i, O_j is the number of jobs at node j, C_{ij} is the shortest travel time, and T is the time threshold (15, 30, 45, 60 minutes).

Second, to advance a person-centric equity analysis, we calculate the Per Capita Cumulative Accessibility. This metric normalizes the raw accessibility score by the population of the origin node, reflecting the level of competition for opportunities and providing a more nuanced measure of individual-level access. It is calculated as:

$$PA_i^T = \frac{A_i^T}{P_i} = \frac{\sum_j O_j \cdot f(C_{ij})}{P_i} \quad \cdots (\text{Eq. 3.9})$$

where PA_i^T is the per capita accessibility for node i, and P_i is the population of node i.

3.4.2 Equity Indicators

- Gini Coefficient and Lorenz Curve: These are used to quantify the degree of inequality across the entire network by analyzing the distribution of service level indicators (e.g., weighted degree centrality) among the grid cells.

$$G = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} |x_i - x_j|}{2n^2 \bar{x}}$$

- Coefficient of Variation (CV): This measures the relative disparity in service levels between different regions.

$$CV = \frac{\sigma}{\mu}$$

3.4.3 Structural Indicators

- Clustering Coefficient, Largest Connected Component (LCC) Ratio, etc.: These fundamental metrics are utilized to understand the overall topological characteristics of the network.

$$C = \frac{3 \times \text{number of triangles}}{\text{number of connected triplets}}$$

- Largest Connected Component (LCC) Ratio: This measures the proportion of nodes that belong to the largest single connected component of the network, indicating the overall integration of the system.

$$\text{LCC Ratio} = \frac{N_{LCC}}{N}$$

where N_LCC is the number of nodes in the largest connected component and N is the total number of nodes in the network.

4. Results

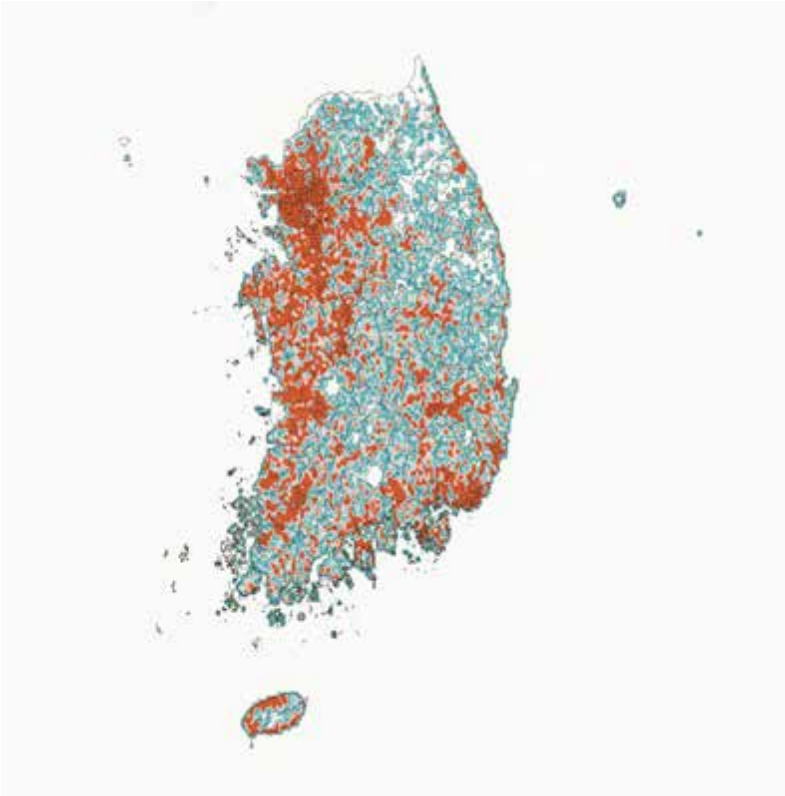

Figure 4.1 Network Node Distribution

Category	Name	Value
Structural Indicators	Number of Nodes	41,552
	Number of Edges	2,179,454
	Network Density	0.001175(0.12%)
	Avg. Out-Degree	84.40
Clustering Coefficient	Avg. Local CC	0.8449
	Global CC	0.4338
LCC	LCC Size	41,552
	LCC Ratio	99.97%

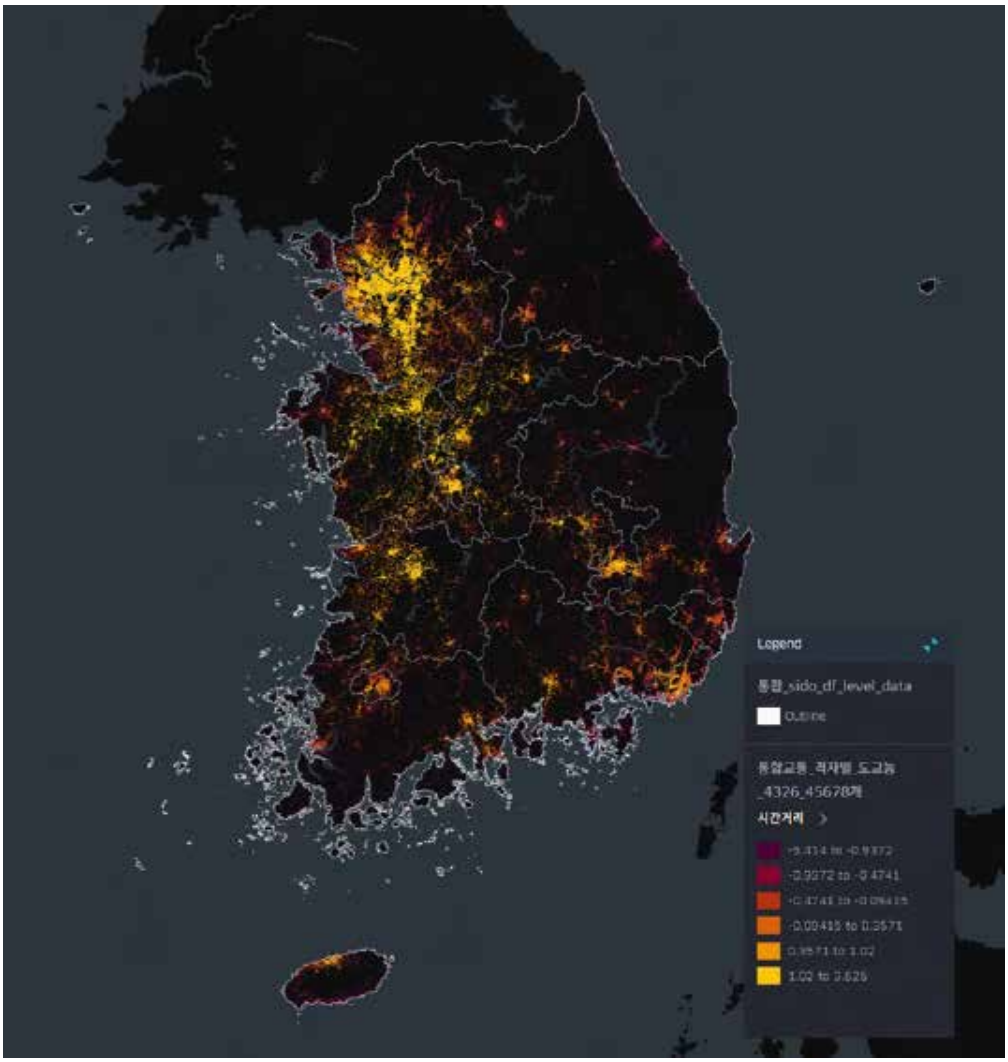

Figure 4.2 Distribution of Harmonic Closeness Centrality of PTNs

Network efficiency, indicating how quickly any point can be reached from a specific location via public transport, was measured by calculating the harmonic closeness centrality for each grid cell (node) based on the shortest path travel times to all other reachable cells.

The results reveal a concentration of overwhelmingly high efficiency in the Seoul Metropolitan Area (SMA), which appears as a broad yellow area on the map. This suggests a dense and rapid network of interconnected public transport modes, including subways and metropolitan buses. Similarly, other major metropolitan cities such as Busan, Daegu, Daejeon, and Gwangju exhibit high efficiency centered around their urban cores. In contrast, efficiency is markedly lower in non-urban and peripheral regions, including the mountainous areas of Gangwon-do, the northern and eastern parts of Gyeongsangbuk-do, and the southern and insular areas of Jeollanam-do. This indicates that travel to other regions via public transport from these locations requires significantly more time.

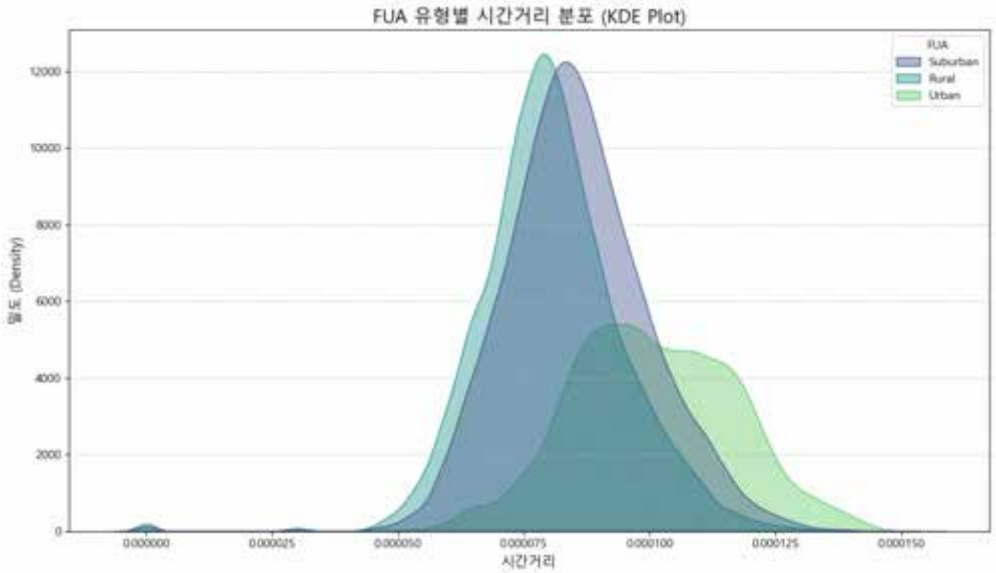

Figure 4.3 The distribution of public transport efficiency by FUA

The distribution of public transport efficiency across different Functional Urban Area (FUA) types is visualized using a Kernel Density Estimation (KDE) plot (Figure X.X). The plot indicates that urban areas exhibit a distinctly higher level of public transport efficiency, whereas suburban and rural areas show similar, lower-efficiency distributions. This suggests that, in terms of travel time, reaching other regions via public transport is substantially faster from urban areas compared to their non-urban counterparts.

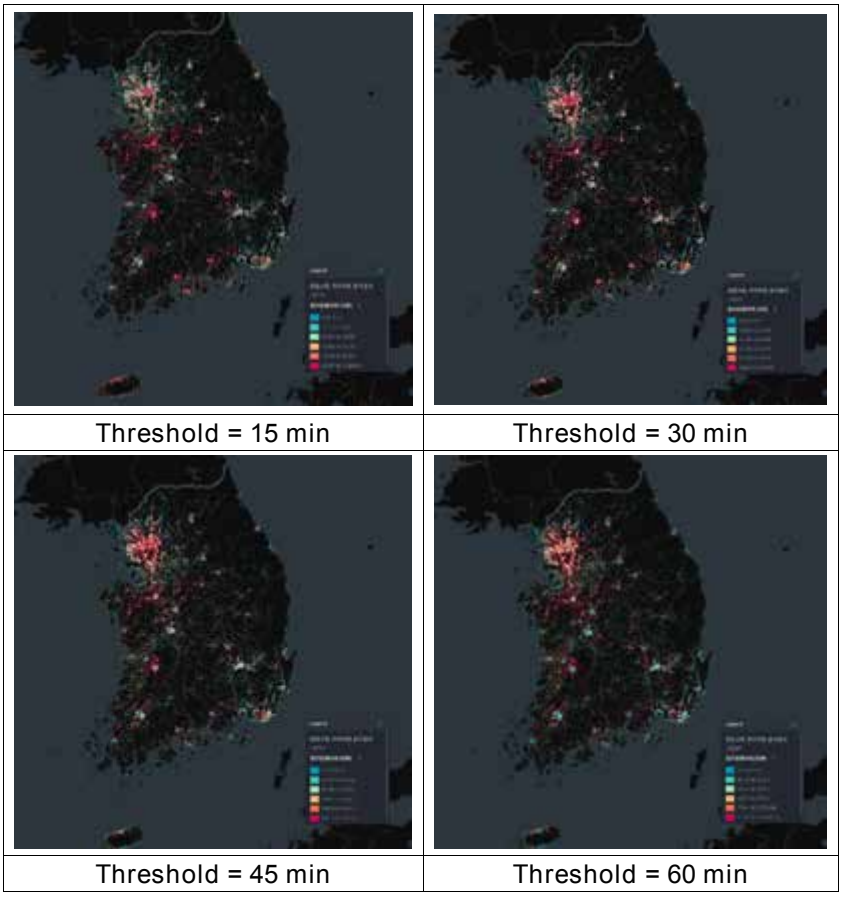

Figure 4.4 Distribution of Cumulative Opportunity Accessibility (Reachable Job)

The analysis of per capita accessibility reveals the number of jobs reachable by an average resident of each grid cell within specified time thresholds (e.g., 15, 30,45, 60 minutes). Unsurprisingly, areas encompassing Seoul's major business districts—the Central Business District (CBD), Gangnam Business District (GBD), and Yeouido Business District (YBD)—exhibit exceptionally high job accessibility within a 15-minute threshold. As this threshold expands to 30, 45, and 60 minutes, the number of accessible jobs per capita increases, altering the spatial landscape of accessibility.

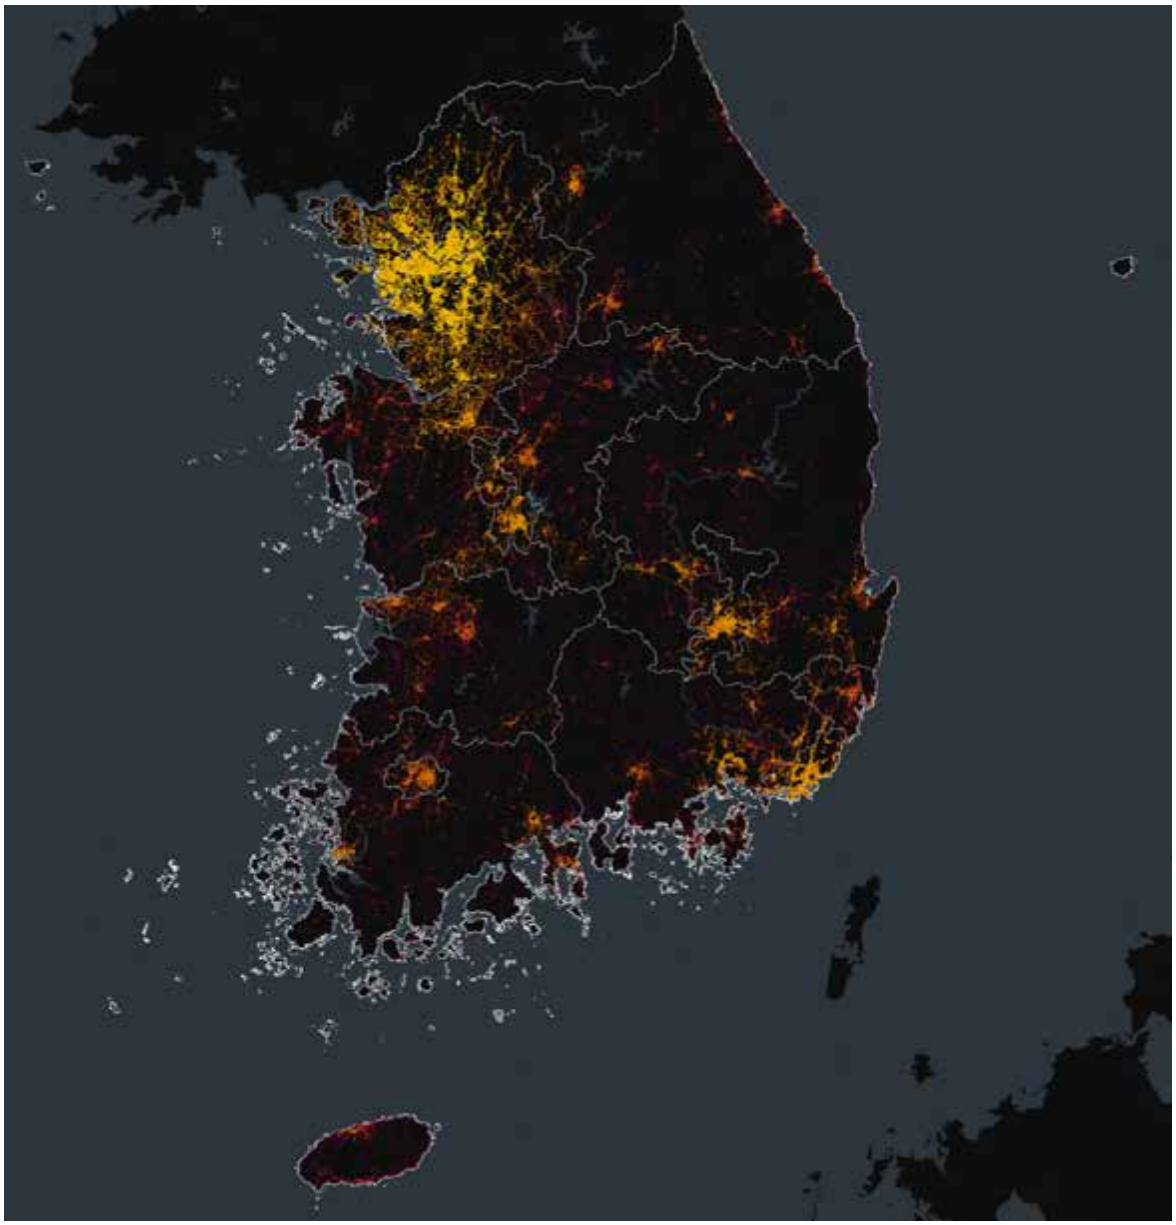

Figure 4.5 Distribution of Weighted Eigenvector Centrality (Oper capacity)

Transport capacity-weighted eigenvector centrality is an indicator that represents a node's influence within the flow of the public transport network's "people-carrying ability" (i.e., its transport capacity), rather than its influence derived from a simple count of connections or its position on shortest paths. A high score for a given node signifies that it is well-connected to other nodes that are themselves high-capacity hubs. In essence, it measures a node's access to the high-volume corridors of the public transport system.

5. Conclusion

5.1 Summary of Research and Key Findings

This study was initiated with the goal of expanding the paradigm of public transport service evaluation from a narrow focus on physical "access" to a broader understanding of "service level" and "equity" as experienced by actual users. To this end, we proposed and applied a novel analytical framework designed to overcome the methodological limitations of prior research, namely: analyses focused on single transport modes, the use of administrative units prone to the Modifiable Areal Unit Problem (MAUP), and the neglect of the quantitative dimension of service.

The core methodological contribution of this research lies in the construction of the "Grid-Based Multimodal Multiplex Network Framework," which is built upon GTFS big data. This framework conceptualizes various transport modes across South Korea—including buses, subways, and rail—as distinct layers in a network. It integrates the quantitative level of service into the model by utilizing the "Through-Route" concept and by employing service frequency and transport capacity as weights. Furthermore, by adopting a uniform 1km² grid as the fundamental spatial unit of analysis to overcome the limitations of MAUP, we established a foundation for analyzing the nationwide public transport system with unprecedented precision.

Our key findings reveal that while South Korea's public transport network exhibits a high degree of overall connectivity (LCC Ratio of 99.97%), its service level is distributed in a highly uneven manner. Both network efficiency, measured by harmonic closeness centrality, and the actual service supply, reflected in weighted centrality metrics, showed extreme spatial polarization, with services being overwhelmingly concentrated in the Seoul Metropolitan Area and the urban cores of other major metropolitan cities. In contrast, non-urban and peripheral areas, such as the mountainous regions of Gangwon-do and the outer regions of Gyeongsangbuk-do and Jeollanam-do, were found to be in a state of severe service deprivation. Notably, a comparative analysis demonstrated that our grid-based approach could empirically identify micro-level service disparities and genuinely transport-disadvantaged areas far more clearly than conventional analyses based on administrative units, which tend to mask such issues.

5.2 Discussion and Policy Implications

5.2.1 Theoretical and Methodological Implications

The findings of this study offer several important implications for the fields of transport planning and spatial analysis.

First, this research empirically operationalizes and validates the "Beyond Access" concept. By demonstrating quantitatively how inequities become more pronounced when service levels like operational frequency are integrated into the analysis, this study presents a clear direction for the future of transport equity research.

Second, this study makes a significant methodological contribution by fusing three previously fragmented fields of research—transport equity, network science, and spatial analysis—into a single, integrated framework. The proposed "Grid-Based Multimodal Multiplex Network Framework" serves as a robust and replicable model for analyzing complex, nationwide transport systems, and holds the potential to become a new standard for related research.

5.2.2 Policy Implications

This research provides concrete answers to Research Question 3: "What are the policy implications of incorporating the quantitative dimension of service level into network models?"

First, it challenges the traditional efficiency-oriented transport policy paradigm. Infrastructure investment decisions based primarily on cost-benefit analysis (B/C analysis) can exacerbate the kind of severe spatial inequalities identified in this study. Our findings strongly suggest that when allocating limited public resources, social equity criteria, such as guaranteeing a minimum level of service, must be employed as core evaluation standards alongside economic efficiency.

Second, it provides a practical tool for precise, data-driven transport policymaking. The high-resolution maps of service levels and vulnerability generated in this study can be used by policymakers as objective and scientific evidence to clearly identify which areas are genuinely transport-disadvantaged and to determine investment priorities.

Third, it contributes to the formulation of specific policy directions. Based on the analytical results, tailored, area-specific policies can be proposed. For instance, for high-density areas with low service levels, new bus routes or increased service frequency could be recommended. For isolated rural areas, an expansion of Demand-Responsive Transit (DRT) or public-purpose taxis that connect to core network hubs could be prioritized. For areas with high transfer potential but low network efficiency, improvements to transfer centers and enhancements to the connecting transport system could be implemented.

5.3 Limitations and Future Research

Despite its significant findings, this study has several limitations, which in turn open avenues for future research.

First, there is the static nature of the data. As this research is based on GTFS data, which contains scheduled timetable information, it does not capture dynamic fluctuations such as delays, cancellations, or traffic congestion. Future research is needed to integrate real-time transport data to analyze the dynamic reliability and stability of the network.

Second, the analysis has a supply-side focus. This study primarily analyzes the supply of public transport and does not explicitly model passenger demand. Future work could produce more sophisticated policy implications by integrating smart card or mobile phone data to analyze the interaction and potential mismatch between supply and demand.

Third, there is an absence of new mobility services. This analysis primarily deals with scheduled, route-based public transport and does not consider connectivity with emerging modes such as shared mobility or personal mobility devices (PMDs). Research that incorporates these services into the multi-layer network model to evaluate the integrated performance of the entire mobility system is required.

5.4 Concluding Remarks

This dissertation, under the guiding principle of "Beyond Access," proposed and validated a novel integrated framework for diagnosing the practical service levels and spatial equity of public transport. The analysis revealed the state of severe spatial imbalance within South Korea's public transport system at a high resolution, shedding light on micro-level issues that were difficult to capture with conventional analytical methods.

True transport equity is not achieved by simply providing identical infrastructure to all regions. It begins by guaranteeing an "adequate and sufficient" level of service tailored to the characteristics and needs of each region, so that all citizens have an equal opportunity to access the services they need. It is hoped that the data-driven, precise diagnostic methodology presented in this study can make a meaningful academic and policy contribution toward building a more sustainable and inclusive transport system in South Korea.

Abstract
Sustainable Urban Mobility Plans (SUMPs) are strategic planning tools to govern the urban mobility system for a better quality of life. However, their capacity in bringing about effective changes is limited, also due to the governance system in which they are embedded. This paper comparatively examines the multilevel governance framework of sustainable urban mobility planning in 8 case studies across Europe, considering SUMPs as part of their spatial governance and planning system. First, it analyses the interaction between the urban legal framework and the SUMP. Then, it analyses practices in one case study from the JUST STREETS project. The paper sheds light on the possibility of SUMPs as catalysts for transformative practices contributing to mobility justice, and the room for improvement in this respect.

Keywords: Sustainability Urban Mobility Plans (SUMPs), spatial governance and planning system (SGPS), Multilevel governance, mobility justice, JUST STREETS

1.Introduction

Sustainable Urban Mobility Plans (SUMPs) are strategic planning tools meant to improve mobility patterns in cities and their surroundings for a better quality of life. According to the European Commission, "A SUMP offers a comprehensive, vision-led, flexible and resilient approach by serving as a long-term mobility plan that includes packages of measures addressing short-term objectives and targets the reaching of which can be fast-tracked in response to changing needs." (EUR-Lex - 32023H0550 – EN). However, the capacity of SUMPs and other similar mobility planning instruments in bringing about effective changes towards more sustainable and just mobility practices has been questioned (Maltese, Gatta and Marcucci, 2021; Wågsæther et al., 2022; Hidayati and Tan, 2025) social, and environmental issues in transport policy at the urban scale from a long-term strategic perspective. Indeed, urban policymakers intend adopting measures to cope with the negative externalities generated by transport. The focus is on reducing traffic flows (number and length. Aiming to shed light on the matter, this paper starts from the assumption that in order to understand the effectiveness of SUMPs it is necessary to consider them as part of a spatial governance and planning system (SGPS). SGPSs reflect the complex and multidimensional interaction among the urban legal framework (Berisha et al., 2021). This interaction shapes and determines the possibility for SUMPs to improve urban mobility towards more sustainable and just mobility practices. By combining literature, policy and document analysis, the paper comparatively examines the multilevel governance framework of sustainable urban mobility planning across Europe, through the analysis of 8 case studies from the JUST STREETS project, analysing the multilevel frameworks in which the 8 SUMPs are developed and implemented, from the European to the local scale. The paper is organised as follows: first, in the next section, the concept of SGPS is briefly presented, together with a focus on the origin and aims of SUMPs and their supposed role in fostering more sustainable and just mobility practices. Section 3 analyses the multilevel governance frameworks that shape the development and implementation of Sustainable Urban Mobility Plans (SUMPs) across eight European pilot cities involved in the JUST STREETS project: Amsterdam, Braga, Cugir, Kozani, London-Wesminster, Metropolitan City of Milan, Riga, Vilnius. The interaction between the urban legal framework

(structure) and the SUMP (tools) is inquired. Section 4 brings the lens closer to practices, focusing on one local case study from the JUST STREETS project, the Metropolitan City of Milan – Corsico municipality. It analyses the mutual interactions between the Metropolitan planning tools (including the SUMP), and municipal planning and practices. Overall, the paper sheds light on the possibility of SUMPs as a catalyst for actually contributing to mobility justice, and the room for improvement in this respect.

2.SUMPs within Spatial Governance and Planning Systems framework

Spatial governance and planning systems (SGPSs) are institutional arrangements that guide and control spatial development in accordance with property rights, public interest, and market forces. They emerge from a complex and multidimensional interplay among several key components: the legal framework or structure, the tools for spatial planning, the practices that enact planning, and the discourses that shape and reinterpret them over time (Berisha et al., 2021). Sustainable Urban Mobility Plans (SUMPs) are among the crucial spatial planning tools within this framework, steering urban transformation by integrating land use, mobility, and environmental considerations into cohesive strategies.

The structure of SGPSs establishes the foundational legal and administrative rules for spatial development, providing a framework for decision-making and governance. Tools like SUMPs translate these rules into planning, setting out visions, goals, and regulatory instruments that respond to dynamic urban contexts and sustainability imperatives. Practices encompass the concrete ways in which these plans are implemented, adapted, or contested by various actors, from public authorities to private developers and community stakeholders. Meanwhile, discourses, i.e. narratives and debates surrounding urban planning, inform how these structures and tools are interpreted, negotiated, and legitimized, shaping shared understandings of public interest, urban futures, and governance priorities. Together, these interwoven dimensions of SGPSs determine the capacity of public authorities to influence urban change, manage development pressures, and promote sustainable, equitable, and resilient urban environments.

SUMPs, as key tools within SGPSs, exemplify the importance of strategic, integrative approaches to urban development and mobility in this broader governance landscape. Moving beyond car-centric paradigms, SUMPs embody the shift towards people-centered, low-emission, and equitable transport systems that address not only mobility needs but also broader environmental, social, and economic goals in urban and peri-urban areas (Jordová, 2021). In this sense, SUMPs are more than mobility strategies; they are integral instruments of SGPSs, embedded in and shaped by the interplay of legal frameworks, planning practices, and discursive narratives.

The European Commission (2019) defines the core objectives of SUMPs as enhancing accessibility and quality of life for all, including marginalized groups; ensuring environmental sustainability through pollution reduction and modal shifts; promoting social equity by recognizing the needs of disadvantaged populations; improving health and safety through active mobility; and fostering integrated policy and governance across sectors such as transport, land use, health, and energy. The SUMP process should follow a 12-step iterative methodology (European Commission, 2019) that spans preparation, visioning, implementation, and monitoring. It begins with establishing inclusive governance structures and stakeholder engagement to ensure that planning is transparent and participatory. Cities assess the current mobility context, identify spatial inequalities, and co-develop scenarios to envision inclusive futures. These scenarios should inform strategic visions, translated into SMART targets (i.e. Specific, Measurable, Achievable, Relevant, Time-bound), and operationalized through integrated policy packages that balance infrastructure investments and behavioral interventions. Implementation is phased, flexible, and subject to continuous review. Success depends not only on technical soundness but also on responsiveness to community feedback and urban dynamics.

To align SUMPs with the ideals of just transition, a shift to transformative governance is necessary (Schwanen, 2021). This includes i) actively dismantling automobility dominance and enabling inclusive active transport; ii) co-producing policies with underrepresented communities; iii) evaluating interdependencies between mobility, housing, and social systems; and iv) recognizing spatial and temporal inequities that affect access and agency. Ultimately, the success of SUMPs depends not only on achieving emission targets but on cultivating mobility systems that are resilient, inclusive, and co-owned by diverse urban communities.

However, while SUMPs offer a promising pathway for urban transformation, their justice implications must be fully addressed. More generally, the literature on SPGS shows gaps in the consideration of justice implications. Wågsæther et al. (2022) warn of "justice pitfalls" (ibid) in sustainability transitions, such as tolling systems or densification strategies that inadvertently burden low-income or marginalised groups. Schwanen (2021) expands this perspective, arguing that distributive justice alone is insufficient. Equally critical are procedural justice, which ensures inclusive and meaningful participation, and recognition justice, which acknowledges the diversity of mobility needs and lived experiences. SUMPs that narrowly focus on climate and efficiency targets risk marginalizing the very groups they aim to uplift. Further, Schwanen calls for attention to epistemic justice, i.e. valuing local and marginalised knowledge systems, requires expanding planning practices to include storytelling, participatory mapping, and deliberative forums that centre non-dominant voices.

3.The multilevel governance of sustainable urban mobility planning in JUST STREETS' cities

This section analyses the multilevel governance frameworks that shape the development and implementation of Sustainable Urban Mobility Plans (SUMPs) across eight European pilot cities involved in the JUST STREETS project and leveraging on the results of the CIVITAS' analysis of SUMPs (2018). These cities represent a wide range of governance systems ranging from strongly centralised systems with top-down decision-making to more decentralised or multilevel frameworks that rely on bottom-up collaboration, negotiation, and adaptive planning. The analysis also explores the legal frameworks (structure) in which SUMPs (tools) are conceived, shedding light on how authority and responsibilities are distributed among national, regional, and local authorities as well as the varying capacities of these levels to implement mobility strategies (Tables 1 and 2).

Considering their SGPS frameworks, JUST STREETS countries can be clustered into three main models: conformative systems, neo-performative systems, and performative systems (Berisha et al., 2021). Each model reflects a distinct approach to how public authorities manage spatial development and how they balance state control with market forces in urban planning, and this influences SUMPs development, as one of the main tools for mobility planning.

The conformative systems cluster includes Italy, Portugal, Romania, and Greece. These countries rely on comprehensive, binding general plans as the primary instrument for steering urban transformations. These plans are meant to establish a clear legal framework and guide spatial development decisions. In practice, however, they often incorporate mechanisms for modifications and adjustments, such as variants in Italy or amendments in Greece and Portugal, enabling flexibility in responding to shifting market demands or political pressures. This dual character of rigidity and adaptability underscores a dynamic interplay between formal structures and everyday practices. Despite their formal reliance on state-led planning, these systems have increasingly allowed market influences to shape development outcomes, particularly as urban growth pressures and private sector interests have grown stronger in recent decades.

The neo-performative systems cluster comprises the Netherlands, Lithuania, and Latvia. In these countries, general plans provide a broad framework for land use, but the actual allocation of development rights is negotiated in highly detailed plans. These negotiations typically involve close collaboration between public authorities, landowners, and developers. Such an approach reflects a planning culture that prioritises flexibility and responsiveness to market dynamics while still maintaining a degree of public control. The result is a more adaptive governance model that can accommodate development-led practices within the bounds of public policy objectives. In the Netherlands, for instance, negotiations ensure that spatial development aligns with broader public goals, even as market actors actively shape the details of projects. In Lithuania and Latvia, this neo-performative approach has emerged as a response to post-socialist transitions, combining new market pressures with inherited state frameworks.

The performative system is exemplified by the United Kingdom, where spatial governance is structured around discretionary decision-making rather than rigidly binding plans. In this model, the state manages urban development on a case-by-case basis, offering flexibility and negotiation space at the local level. While this performative approach can enable context-sensitive planning and adaptability, it can also create uncertainty for investors and developers. In the UK, successive reforms have retained the discretionary character of the system, with local authorities holding significant sway in development decisions.

However, this approach has also exposed the planning system to criticisms of excessive market influence, especially when broader social and environmental objectives are not robustly integrated into planning processes.

Collectively, these models reveal how SGPSs adapt to contemporary challenges, each reflecting a distinct balance of public control, market influence, and community participation in shaping urban futures, and this includes mobility planning tools, among which SUMPs are counted.

In the majority of JUST STREETS countries, i.e. Portugal (Braga), Romania (Cugir), Greece (Kozani), Latvia (Riga), and Lithuania (Vilnius), national authorities such as Ministries of Transport hold primary responsibility to define urban transport strategies, allocate funding infrastructure, and ensure compliance with international or EU-level commitments. Local authorities primarily serve as implementing agencies, with constrained autonomy and limited room for strategic innovation. Their roles are often confined to public service delivery, traffic control, and local roads and infrastructure maintenance. For instance, in Romania, the Ministry of Transport, Infrastructure, and Communication establishes the legal and procedural framework for mobility planning while requiring municipalities like Cugir to operate within a narrowly defined legislative framework (Framework Law no. 195/2006), by proving its conformative nature. A comparable dynamic is observed in Portugal, where the central government determines transport priorities while municipalities such as Braga manage urban services under strict administrative guidelines. These top-down highly centralised structure reflects the conformative nature of the Portuguese SGPS. Although this model ensures institutional coherence and streamlined vertical coordination, it often supresses local flexibility and weakens the transformative potential of SUMPs, particularly when plans are legally binding but procedurally rigid.

A particularly noteworthy case is Lithuania where the governance structure remains centralised with strong vertical coordination between national and local levels. Unlike other countries with established sub-national authorities, Lithuania lacks regional authorities that could facilitate coordination between central and municipal stakeholders. The absence of a regional authority hinders efforts to integrate spatial planning and mobility services across urban areas. The resulting meso-level governance gap undermines cross-jurisdictional alignment in the implementation of SUMPs.

In contrast, the Netherlands demonstrates a decentralised governance system grounded in horizontal coordination among local and regional authorities. Subnational actors such as municipalities and provinces are empowered to lead transport planning, public infrastructure, mobility management, and implementation while the national government provides solely strategic roadmap, proving its neo-performative nature. Although the Dutch planning system is framed by national policy objectives, it is inherently non-binding and operationalised through informal institutional trust and inter-municipal cooperation.

Italy and England, despite having a conformative and performative system respectively, embody more complex multilevel governance systems that combine vertical coordination where national and regional authorities set overarching strategic goals with horizontal cooperation mechanisms that promote inter-municipal integration and adaptive implementation. The Metropolitan City of Milan is an example of institutionalised multilevel governance, where the metropolitan city ensures the alignment of the SUMP with national, regional and metropolitan mobility objectives. London, within a performative SGPS, is particularly symbolic of a hybrid governance model in which the Department of Transport sets overarching regulations, and the Transport for London (TfL) functions as both a strategic and operational authority. Local boroughs such as Westminster develop their own transport strategies aligned with TfL's London Plan. In these contexts, SUMPs are formally binding, but their development often occurs through coordinated and flexible dialogues across levels.

Table 1 – Mobility planning structure in JUST STREETS countries/cities

Pilot cities	Authorities responsible for mobility planning
Amsterdam (NE)	***National authority*** **Ministry of Infrastructure and Water Management** – in charge of national transport policy (roads, railways, aviation, maritime, inland water transport) **Institute of Transport Policy Analysis** – supports policymaking with data and knowledge at the Ministry of Infrastructure and Water Management **ProRail** – a government-owned private-law body, manages rail infrastructure and operations **Dutch Railway** – has the sole right to operate passenger services on the main railway network | manages the train accessibility
	Regional authority **Provinces** - coordinate strategic transport planning, manage regional infrastructure (roads, railways, cycle paths) | regulate public transport concessions | oversee transport safety and logistics
	Local authority **Municipalities** – manage urban planning, local public transport, road and cycling infrastructure, parking management, and traffic regulation
Braga (PT)	***National authority*** **Ministry of Infrastructure and Housing** – defines and implements national transport policies **Ministry for the Environment and Energy Transition** – oversees urban transport and suburban passenger service **Ministry of the Sea** – coordinates maritime affairs, manages ports and maritime transport, oversees national and EU funding related to the sea **Ministry of Internal Affairs** – develops road safety policy **Infrastructure Portugal** – state company responsible for design, maintenance, modernisation of road and national rail networks **The Institute for Mobility and Transport** – a central administration body, regulates and coordinates inland transport, and ensures quality standards for the protection of consumer's rights **Bureau for the Prevention and Investigation of Aviation Accidents (GPIAA)** - incident aviation investigation authority
	Regional authority **Autonomous Regions of Azores and Madeira** - manage regional infrastructure, including roads, ports, airports, and sea, air, and land transport, with full responsibility for regional mobility and logistics
	Local authority **Municipalities** – responsible for urban transport, local road networks, municipal aerodromes and heliports, school and touristic transport **Intermunicipal entities** – manage abovementioned functions under agreement with the municipalities **Parishes** – responsible for maintenance of shelters, signage, roads, and pavements.
Cugir (RO)	***National authority*** **Ministry of Transport, Infrastructure, and Communication** – responsible for national legislative framework, strategy, infrastructure projects implementation, and international obligations | coordinates scientific research and SMART CITY strategies | Oversees state-owned transport companies and signs performance contracts with operators | Manages EU alignment and national-level projects
	Regional authority **Counties** – shared powers with the central government (e.g., management of roads of county interest), legal basis: Article 26 of Framework Law no. 195/2006 (revised)
	Local authority **Municipalities, towns, and communes** – responsible for local roads and local public transport shared competences with national authorities in managing the road infrastructures of local interest at commune level, legal basis: Article 21 & 24 of Framework Law no. 195/2006 (revised)

Kozani (GR)	***National authority*** **Ministry of Infrastructure and Transport** – develops national transport policy and legal framework, manages infrastructure projects at the national level, road safety
	Regional authority Extensive regulatory and licensing functions including licensing public transport vehicles, driving permits, new intercity and interregional bus services (KTEL), vocational training for transport managers, vessel licensing, fuel stations, taxi permits, and private roads | coordinates inspections, safety rules, and environmental regulations for transport
	Local authority **Municipalities** – in charge of urban planning, traffic regulation, local roads and public spaces | operate municipal public transport (particularly for social groups such as elderly, children, people with disabilities) | Issue transport-related licenses (driving training, vehicle maintenance)
London – Westminster (UK)	National authority Department for Transport (DfT) – a ministerial department, provides national transport policy, regulates roads, rail, aviation, and maritime; funds local authorities; regulates vehicle safety and licensing; and oversees national investigations Other central agencies - Highways England (roads), Network Rail (rail infrastructure), Office of Rail and Road (regulator), British Transport Police, Maritime & Coastguard Agency
	Regional authority Devolved authorities (Scotland, Wales, Northern Ireland) control most aspects of transport in their regions. In United Kingdom, regional coordination is more fragmented, but Transport for London (TfL) plays a major role in strategic regional mobility planning and delivery across Greater London | Strategic bodies coordinate some cross-border policies (e.g., North-South Ministerial Council with Ireland)
	Local authority **Westminster City Council** (a London borough) develops local transport strategies in line with **TfL's London Plan** | Responsibilities include traffic management, local roads, parking, active travel infrastructure, and neighbourhood public transport. Local authorities across the UK differ in powers, but in London, local and regional coordination is strong and driven through TfL and the Mayor's office
Metropolitan City of Milan (IT)	***National authority*** **Ministry of Transport and Infrastructure** – responsible for national transport systems (road, air) and water transport systems, traffic regulation, and major infrastructure | Keeps current competences with regions over ports, airports, and strategic networks
	Regional authority In charge of regional public transport, maritime infrastructure, inland vegetation, regional railways, inter-regional roads, and large-scale public works of regional interest
	Local authority **Provinces** – manage provincial transport, maintenance of provincial roads, and driving school licensing **Metropolitan cities** - ensure compatibility between urban mobility plans and local municipal plans **Municipalities** - manage local public and urban transport, traffic control, road maintenance, and land-use planning
Riga (LV)	***National authority*** **Ministry of Transport and Maritime Administration** – develops national policy on transport and traffic | oversees rail, maritime, inland water, and air transport systems | Coordinates EU legal alignment and advocates Latvian interests | Oversees the financial framework for inter-urban and regional public transport routes and unified ticketing systems | Manages public-use railway infrastructure
	Regional authority Responsible for regional public transportation networks and financial oversight | Proposes new or improved regional routes | ensures coordination between local and national actors | Oversees proper use of state and municipal transport budgets
	Local authority manages urban public transport planning and service delivery | maintains bus stops and related infrastructure, and coordinates with regional authorities | Responsible for maintenance and lighting of local roads, streets, and public squares
Vilnius (LT)	***National authority*** **Ministry of Transport and communication** – Development and implementation of national transport policy, coordinate logistics, manages infrastructure for all transport modes (road, rail, sea, air, inland waterways) | Oversees state-owned ports and airports, and develops national strategies including transit and combined transport
	Regional authority -------
	Local authority Local governments manage planning and maintenance of local roads, traffic safety, local route licensing, and compensation mechanisms for socially inclusive transport (e.g., rural school transportation)

Table 2 – The tools for mobility planning in JUST STREETS cities

Pilot Cities	Mobility planning tools - SUMPs
Amsterdam **(NE) | 2013**	**Title:** Mobility Approach Amsterdam 2030 **Objective(s):** Prioritising cost-efficient and space-saving modes of transport while optimizing the use of available infrastructure
Braga **(PT) | 2019**	**Title:** Sustainable Urban Mobility Plan for the City of Braga **Objective(s):** Promote soft modes (pedestrian, cycling), improve public transport, reduce car use, and support intermodality
Cugir **(RO) | 2023**	**Title:** Sustainable Urban Mobility Plan, 2022-2030 (PMUD) **Objective:** Provide an efficient and sustainable transport system to ensure accessible, safe, and sustainable transport to all in urban/periurban areas
Kozani **(GR) | 2020**	**Title:** Sustainable Urban Mobility Plan (SUMP) of the Municipality of Kozani (PMUD) **Objective(s):** Develop a sustainable, inclusive mobility system by shifting from car use to active/shared modes, improving quality of life, and integrating smart technologies
London – Westminster **(UK) | 2017/2014**	**Title:** Walking strategy - Cycling strategy **Objective(s):** Make Westminster a national leader in walking and cycling by improving safety, accessibility, and uptake of active travel modes
Metropolitan City of Milan **(IT) | 2021**	**Title:** Sustainable Urban Mobility Plan (SUMP) of the Metro city of Milan **Objective(s):** Satisfy the demand for mobility in urban and metropolitan areas
Riga **(LV) | 2020**	**Title:** Towards a better everyday life Riga mobility vision **Objective(s):** To create a sustainable, inclusive, people-centered mobility system that promotes equality of life, urban livability, public health, while addressing environmental and economic challenges
Vilnius **(LT) | 2018**	**Title:** Vilnius city sustainable mobility plan – action plan (SUMP) **Objective(s):** To create clean, safe, inclusive, and sustainable urban mobility systems, enhance quality of life, a modal shift from walking and cycling and support climate neutrality initiative

4.Multilevel planning in action: the Metropolitan City of Milan - City of Corsico case study

The Metropolitan City of Milan (CMM) is the second most populous metropolitan area in Italy (after Rome), encompassing 133 municipalities and over 3 million inhabitants. CMM was formally established in 2015 through the Delrio Law (Law No.56/2014), which reformed local government in Italy and instituted 14 "città metropolitane" in the country's largest metropolitan areas, in substitution of the respective provincial governments (Casavola et al. 2024). Metropolitan cities are responsible of three key planning instruments: the metropolitan strategic plan (PSM), the metropolitan general spatial plan (PTGM) and the sustainable urban mobility plan (PUMS). In more detail, they inherited the competences of the former provincial governments they substituted, and additional functions, such as strategic, spatial and mobility planning, organisation of coordinated systems for the management of public services, mobility and transport, promotion and coordination of digitalisation and economic and social development. While the PSM and the PUMS are non-binding strategic planning tools, the PTGM is a binding spatial planning tool. In essence, the PTGM assumes binding functions for land-use and urban planning, regulating the activities of municipalities regarding infrastructure and services under metropolitan jurisdiction, as well as land consumption. However, effective control over municipal land in the municipalities that are part of the metropolitan city is up to the municipalities themselves, through their land-use plan, a planning and land-use regulation tool that has no predefined time frame. As a result, the adjustment of municipal plans to what the metropolitan plan establishes depends on the willingness of municipalities to issue a new plan or a variant to it. In addition, it should be considered that Italian metropolitan cities are second-tier public bodies, that is, not directly elected. This results in weak political representation on the ground.

Within the metropolitan city, the municipality of Corsico emerges as a densely populated suburban municipality, located in the first belt, approximately 7 kilometres southwest of the city centre of Milan, with a resident population of around 34,000. Corsico is highly integrated into the metropolitan transportation and economic systems. It functions as part of the daily commuter belt and benefits both urban and regional public transport services.

This case study is analytically significant for two key reasons. Firstly, it demonstrates the dynamic between metropolitan-level strategies such as SUMPs and institutional capacities, political priorities, and operational constraints at the municipal level. Secondly, the Corsico pilot city provides a valuable lens to examine the mechanisms of multilevel governance in translating metropolitan strategies into localised implementation. This is particularly pertinent in suburban contexts, where disparities in urban density, socioeconomic context, political leadership, and administrative capacity among municipalities pose distinct challenges for coherent policy implementation.

The metropolitan city of Milan shows significant interest in active and sustainable mobility. Active mobility is treated as a strategic priority and deeply embedded with broader goals of environmental efficiency and modal shift. In particular, the SUMP of Metropolitan city of Milan supports its low-impact mobility strategy through the development of comprehensive cycling network via its dedicated Biciplan (Metropolitan Plan for Cycling Mobility), alongside safety improvements for pedestrian around key nodes particularly around schools, transit hubs, and public institutions. In doing so, the metropolitan city aims to support people in rethinking their mobility choices towards more sustainable forms, through both home-city centre connections and the strengthening of interchange functions between all transport networks. This change in behaviour is the main challenge of the Metropolitan City of Milan, especially in places where the concentration of people, mobility and functions is greater, such as in station areas, intended as modal interchanges centres.

As regards transit hubs, the metropolitan SUMP and the PTGM, approved almost simultaneously in April and May 2021 respectively, present a common vision and consistent indications with respect to the territorial role of the stations and the areas surrounding them. They identify, at the stops of the Milanese suburban railway lines and the other main modal interchange nodes, the so-called Luoghi Urbani della Mobilità - Urban Places for Mobility (LUM). LUMs are areas around the main public transport interchange stops within which, in view of their high accessibility, the location and strengthening of services and infrastructures necessary to enhance the interchange function and urban functions and services to people and businesses, aimed at improving the safety and liveability of the area, should be promoted. They provide for the regeneration and settlement of urban functions and services to people and businesses, as well as services and infrastructures necessary for the interchange function.

This coherence between metropolitan planning tools concerning settlement development and mobility creates fertile ground for TOD-oriented development and to promote more active and sustainable mobility. Although it may appear to be a reasonable coordination and present in all Italian metropolitan cities, the case of Milan is among the few to operate this synergy in Italy (Staricco and Vitale Brovarone, 2021, 2023).

As part of the JUST STREETS Project, the Metropolitan City of Milan intends to experiment by bringing the action of the metropolitan level closer to that of the municipal level, through a process of co-definition of guidelines and regulations for the development of LUMs. In this respect, the Corsico LUM would be considered as a pilot to experiment innovative multilevel planning practices. The guidelines for the organisation of inclusive and sustainable accessibility of the interchange nodes are then meant to be replicable in other mobility nodes in the territory of the Metropolitan City of Milan. They are also inspired by what has already been provided for and indicated in the planning tools of the metropolitan city. This initiative intends on the one hand to scale down the planning practices of the metropolitan authority, on the other hand to scale up local practices and instances, in particular with regard to the actions carried out by grassroot associations. The latter are the subject of investigation through interviews and focus groups, and will be involved in the process of co-creation of the guidelines. In this way it will be possible to integrate the perceptions and needs of the community, integrating them with the analysis of the territory and the regulatory framework through a process of listening and active involvement never before experienced by the metropolitan city in its planning tools.

Bringing the lens closer to the municipal level, the municipality of Corsico, although not formally involved in the partnership of the Just Streets project, has shown interest in the project and intends to cooperate in the co-definition of the guidelines for the development of the LUM. The LUM of Corsico poses particular challenges regarding accessibility and active mobility, being a minor suburban station in a car-oriented context, worsened by the presence, near the station, of two industries that provide for the continuous passage of heavy vehicles along a narrow road used by pedestrians and cyclists. This is therefore, in theory, an optimal opportunity to experiment with multilevel and multi-actor governance, involving different types of actors (public administrations, public transport operators, research centres, third sector associations) operating at different administrative levels (metropolitan city, municipality), in different sectors (urban and mobility planning, local development, advocacy of marginalised social groups) to improve mobility justice.

However, at the time of writing this paper, we cannot go further in the analysis, as the co-planning process, however promising, has been for several months breathed into institutional quibbles related to the signing of a formal collaboration agreement between the metropolitan city and the municipality, without which the metropolitan city is not authorised to carry out any initiative (not even intangible) within the municipality.

This suggests the challenges posed by a multi-level governance process of this type and, more generally, how much traditional metropolitan planning tools, including SUMPs, are able to catalyse and implement transformative mobility practices.

5.Discussion: lessons learnt from Corsico and the Metropolitan City of Milan

The governance structure and institutional dynamics observed in the Corsico case reveal critical insights into the transformative potential of SUMPs. While SUMPs are intended as strategic tools for sustainable mobility, their real impact is heavily influenced by the multilevel governance arrangements in which they are embedded. A key challenge emerging from the Milan-Corsico case is the persistent asymmetry between metropolitan and local governance levels. Although the Metropolitan City of Milan's SUMP and related plans like the PTGM and Biciplan offer robust visions for sustainable mobility, municipalities such as Corsico often lack the institutional and financial capacity to align local practices with these metropolitan objectives. The non-binding nature of strategic plans like SUMP, and the limited power of the metropolitan institution in implementing its plans at the municipal level, further complicates this dynamic, as it leaves room for local resistance or inaction, especially in municipalities with limited resources or conflicting priorities. This reinforces the observation that transformative mobility practices require not just visionary plans but also capacity-building mechanisms and funding streams that support local adaptation.

The Italian SGPS combines flexibility in municipal land-use planning with rigid binding frameworks at the metropolitan and regional levels. While this duality theoretically allows for local responsiveness, in practice, it

can produce institutional deadlock. In Corsico, the potential for active mobility improvements is constrained by the absence of a formal collaboration agreement, which delays project implementation and underscores the importance of procedural flexibility and trust-building in multilevel governance. This suggests that rigid legal frameworks (though essential for ensuring consistency) can inadvertently stifle local initiatives if not balanced with procedural flexibility and shared governance practices.

The case of Metropolitan City of Milan-Corsico in the JUST STREETS project highlights both the promise and the pitfalls of participatory co-production processes in mobility planning. The engagement of grassroots organisations and civil society actors through co-creation of LUM guidelines offers a powerful example of how SUMPs can catalyse more inclusive and context-sensitive mobility practices. However, the institutional inertia that has stalled formal cooperation also demonstrates that genuine co-production cannot be an afterthought; it must be embedded and institutionalised within planning processes and supported by governance structures that facilitate rather than hinder local experimentation.

The Corsico pilot also sheds light on the justice dimensions of mobility transitions. While the metropolitan SUMP framework prioritises active and low-carbon mobility, the challenges faced by Corsico, such as heavy vehicle traffic along narrow, pedestrian-inhabited corridors, underscore the need to address not just climate goals but also social equity and accessibility. Integrating community voices and ensuring that plans are sensitive to the everyday realities of disadvantaged or marginalised groups are essential steps towards realising mobility justice. Ultimately, the Corsico experience underscores that SUMPs' transformative potential depends on navigating the tensions between metropolitan strategies and municipal implementation, between binding legal structures and local adaptation, and between formal governance frameworks and community-driven practices. Future research should explore how these dynamics play out across other municipalities and how inclusive, flexible governance models can be strengthened to turn visionary plans into transformative, justice-centred urban mobility systems.

6.Conclusion and avenues for future research

The Corsico-Metropolitan City of Milan pilot underscores the complex interplay between SGPS and the transformative potential of Sustainable Urban Mobility Plans (SUMPs). While the multilevel governance structures in Milan-Corsico showcase innovative visions for active and sustainable mobility, they also reveal how rigid frameworks, capacity asymmetries, and fragmented implementation can undermine these ambitions. At the same time, the co-creation process involving local actors and communities hints at a promising pathway towards more inclusive and justice-oriented urban mobility transformations.

Future research could delve deeper into these critical tensions by explicitly integrating the conceptual framework of SGPS and the mobility justice lens. While SGPS literature has largely focused on how legal structures, planning tools, and institutional arrangements shape spatial development, it often falls short of interrogating how these systems interact with social inequalities and justice concerns. Conversely, mobility justice scholarship foregrounds questions of equity and inclusion but may not always fully engage with the institutional and procedural underpinnings of spatial governance.

Bridging these two domains could open fertile ground for understanding not only how SUMPs are developed and implemented, but also whose interests they serve and whose voices are excluded in the process. For instance, future studies could explore how the procedural dimensions of SGPS, such as participatory mechanisms, co-production of knowledge, and local negotiation, affect the realisation of mobility justice goals like equitable access, environmental sustainability, and recognition of diverse mobility needs. Comparative research across different metropolitan and municipal contexts could also help identify best practices and structural barriers in reconciling top-down planning with bottom-up initiatives.

Another promising direction involves examining the performative role of discourses within SGPS, i.e. how narratives around "smart" or "sustainable" mobility either enable or constrain justice-oriented planning. This could include analyses of how discursive frames shape priorities within SUMPs and how these narratives are contested or reinterpreted by marginalised groups. Embedding this focus within SGPS research would offer richer insights into how mobility justice can be more than an add-on goal, becoming an integral part of planning systems and governance structures.

Finally, the Corsico–Metropolitan City of Milan case study suggests that multilevel governance arrangements are not inherently good or bad for mobility justice; rather, their transformative potential depends on how they are activated through inclusive processes, shared visions, and flexible institutional frameworks. Unpacking these relational dynamics across SGPS components (structures, tools, practices, and discourses) can reveal pathways for fostering more equitable and resilient urban mobility futures.

Analysis of Regional Disparities in Public Transportation Accessibility: A Spatial Approach to Equal-Time Job Accessibility

Yoon Kyubin 1 Kang Myounggu2
Affiliation: University of Seoul, Department of Urban Planning and Design
Email: peter3574@uos.ac.kr, mk@uos.ac.kr

Abstract
This study empirically analyzes regional disparities in public transportation service levels between the Seoul metropolitan area and other South Korean regions, offering policy implications for balanced national development. Overcoming prior research limitations like reliance on administrative boundaries or a single-transportaion mode, this study utilizes nationwide direct-link transit data to evaluate mobility and accessibility at a fine 500m x 500m grid cell resolution. Mobility is defined as reachable grid cells and accessibility, as accessible jobs, both within one hour. Analysis reveals the Seoul metropolitan and Busan-Ulsan-Gyeongnam have the highest mobility and accessibility, while Gangwon ranks lowest. Notably, dense industrial clusters show high public transport job accessibility, underscoring that improving transit access to employment centers, not just attracting businesses, is key to enhancing regional competitiveness.

Keywords : Spatial inequality, Public transportation, Disparity, Spatial coverage, Job Accessibility

1. Introduction

In modern cities, public transportation is a crucial element that ensures individuals' ease of mobility to various destinations. Notably, in South Korea, public transportation accounts for a high modal share of 32.7% (Ministry of Land, Infrastructure and Transport, 2022) when considering travel distance and ridership, thus playing a pivotal role in mobility. The competitiveness of a city is influenced by the level of public transportation services, and efficient allocation can facilitate balanced development (Shabanam et al. 2024).

Public transportation has a greater societal impact compared to private vehicle use. This is because public transportation offers high road utilization efficiency and low usage costs, making its services accessible to diverse social strata. Specifically, low-skilled and economically vulnerable populations are more dependent on public transportation than private cars, necessitating the establishment of an adequate service level to provide them with employment opportunities (Elgeziry, M, 2022). Regions with inadequate public transportation systems face limited mobility, which degrades access to employment and educational services, leading to disparities in regional development and quality of life (Stewart, 2017).

Public transportation also contributes to industrial and economic development by enhancing labor market and consumer accessibility (APTA, 2022). An efficient public transportation system in a nation increases the likelihood of attracting various industries and businesses, and induces a higher volume of commuting and business activities (Lee et al., 2023). High values in indicators of public transportation infrastructure, such as bus stop density and public bicycle usage, enable urban residents to conveniently travel to various destinations like workplaces, schools, shopping, and cultural facilities. This, in turn, enhances accessibility to living infrastructure such as housing, education, and commercial facilities, thereby revitalizing the region (Kim, 2024).

The disparity in public transportation services between regions is identified as a representative factor of imbalance in urban and regional development in South Korea (Park, 2023). The establishment of a public transportation network involves not merely road construction but also substantial budgets, compelling the nation to make cautious investment decisions. In this context, there is a clear tendency for public transportation services to be primarily supplied to the Seoul Metropolitan Area, where population and jobs are concentrated.

In fact, the widening gap in regional public transportation infrastructure has accelerated even further since the COVID-19 pandemic (Korea Research Institute for Human Settlements, 2023). The increasing closures of local terminals and reductions in intercity bus routes and frequencies have drastically degraded convenience for local residents. In stark contrast, discussions for large-scale metropolitan railway projects, such as the GTX lines and Shinansan Line, are actively progressing in the Seoul Metropolitan Area, with continuous investment being made.

2 Professor, Department of Urban Planning and Design, University of Seoul

This contrasting situation in public transportation service levels between the Seoul Metropolitan Area and other regions further exacerbates the inter-regional accessibility gap, which directly translates into restricted mobility in local areas and can lead to significant problems such as an imbalance in regional revitalization and quality of life (Hwang et al., 2024).

Literature Review

Improving accessibility, a key indicator for evaluating public transportation service levels, is considered a core task for governments (Yoo et al., 2021). While various efforts are underway to enhance transport accessibility, the term "accessibility" is not uniformly defined, which can lead to ambiguity in evaluation. According to Cho (2014), public transportation accessibility can be largely categorized into three types: first, the ease of reaching public transportation facilities such as stops and stations; second, the geographical area reachable within a specific time using public transportation; and finally, the number of opportunities (e.g., medical services, education, employment) accessible via public transportation.

In this study, we define accessibility as the number of opportunities reachable by public transportation, specifically focusing on employment opportunities. The reason for prioritizing employment among various opportunities in a city is that commuting is the primary purpose for citizens using public transportation (Korea Transport Institute, 2014). In this context, the distance between one's workplace and residence is directly linked to life satisfaction; shorter commute times are associated with higher job satisfaction and quality of life for workers (Han.L, 2022).

ITF-OECD (2023) evaluated the level of public transportation infrastructure in the Seoul Metropolitan Area, comparing the number of accessible jobs when using a car versus public transportation. The analysis revealed no significant difference in the number of accessible jobs by mode in the central urban areas of the capital and some areas adjacent to railway lines. However, in most suburban areas with high commuting demand to Seoul, public transportation accessibility was found to be severely low, leading to high car dependency. Despite its insights, this study had limitations in clearly identifying the accessibility of public transportation itself, as it primarily examined the service level of public transportation relative to private vehicles.

Beyond Korea, studies in major U.S. metropolitan areas and recent EU cities highlight that a lack of private vehicle accessibility and inadequate public transportation services pose significant barriers to employment access and retention (e.g., Cervero et al., 2002; Korsu and Wenglenski, 2010; Sanchez et al., 2004). Fransen et al. (2019) confirmed that possessing a driver's license positively influences job accessibility. In the case of the Flanders region in Belgium, a positive correlation was observed between driver's license ownership and high job accessibility, suggesting relatively low job accessibility via public transportation. Furthermore, the importance of public transportation in the labor market is underscored by the significant negative correlation between job accessibility and the probability of long-term unemployment. However, this study indirectly revealed the high accessibility associated with private vehicle ownership rather than directly presenting job accessibility through public transportation. This limits its ability to ascertain the clear impact of public transportation.

Elgeziry (2022) revealed that job accessibility through public transportation has a greater impact on vulnerable populations. Through a case study in San Bernardino, California, the research analyzed the effect of affordable and convenient public transportation access on employment opportunities for low-skilled and economically vulnerable residents. The findings indicated that despite the availability of jobs for economically vulnerable and low-skilled residents, the existing public transportation system did not adequately cover their work hours and job locations, severely limiting job access. While this study is highly contributory due to its consideration of operating hours based on workers' job locations, its limitation lies in analyzing the mobility of specific social strata, making it difficult to grasp the overall effect of public transportation. Bastiaanssen (2022) confirmed that in urban areas of the UK (excluding London), employment elasticity showed a positive value when public transportation accessibility increased at the census tract level. This had a greater impact on people without cars and low-income individuals. This study is significant for using employment probability as a dependent variable to measure people's actual opportunities, but it has limitations in quantifying the number of opportunities.

Research Contribution and Differentiation

Previous studies evaluating public transportation accessibility based on the number of accessible jobs have primarily focused on the job accessibility levels of specific social strata or compared travel ranges within the same time using private vehicles. This approach has made it difficult to conduct a direct, region-by-region comparison of public transportation as a standalone mode. Therefore, this study aims to analyze job accessibility via public transportation for all citizens, not just specific groups, to understand the service level across all social classes. Furthermore, the analysis will focus exclusively on public transportation, excluding private vehicle use.

The key questions guiding this research are:
Within a given urban area in South Korea, what is the geographical range that can be reached by public transportation within a specific timeframe?
What are the disparities in the number of accessible jobs within the same timeframe across different regions?

This study will empirically analyze the regional differences in public transportation accessibility across South Korea, measured by the number of accessible jobs. We will also identify the number of jobs reachable by public transportation (Ma L. et al., 2021), which can serve as a metric for urban competitiveness. Understanding the number of jobs accessible in each region can help identify areas where public transportation needs improvement and contribute to establishing economic hubs by forming central transportation axes when planning new cities. Ultimately, this research will provide crucial foundational data for developing policies that foster balanced development and strengthen inter-regional cooperation.

2. Methodology

Previous studies on public transportation accessibility have faced several methodological limitations. For instance, Han Dae-ho (2016) evaluated public transportation levels in Seoul based on administrative dong units. However, these units often fail to reflect actual population distribution or area differences. In contrast, this study measured transport accessibility at a more granular spatial unit by employing a 500m x 500m grid-based analysis. This approach is advantageous for evaluating public transportation services based on actual residential areas.

Furthermore, studies by Yoo Kyeong-sang et al. (2020) and Jeong Yong-il (2021) utilized grid units but were limited to specific cities like Seoul or Cheongju, North Chungcheong Province, hindering the generalizability of their findings. This study overcomes this limitation by conducting a nationwide analysis. By classifying regions based on urban area categories officially announced by the government (Committee for Balanced National Development, 2023), rather than simple administrative districts, we enhanced the policy applicability of our research.

Finally, most existing studies primarily considered single modes of transportation like buses or subways (Rural Service Standards, 2023) and failed to incorporate actual public transportation usage characteristics such as transfer possibilities. To address this, our study attempted a more realistic assessment of public transportation accessibility by conducting a network analysis that considers integrated approaches across various transportation modes and transfer routes.

The data used for this analysis, as of December 2024, includes:
- GTFS direct section data for national regional buses, express/intercity buses, trains, subways, aviation, and maritime transport from TMAP.
- 500m x 500m grid SHP files from SGIS, along with population, household, business, and employee count data.
- Province and city/county shapefiles from the National Geographic Information Institute.

The direct section data can be considered as links connecting nodes (origin and destination). These nodes are spatially mapped onto the 500m x 500m grid files, transforming movement between stops into movement between grids.

Table 1: Example of Direct Section Data

Area	Agency Type	Route Name	Stop ID 1	Stop ID 2	Stop Name 1	Stop Name 2	Distance (m)	Time (sec)	Oper_ Count	First Depart	Last Depart
Gangwon	Express Bus	Express Bus : Gang-neung-Goyang	300070	300006	Gangneung Terminal	Goyang Terminal	184,663	10,200	5	7:00:00	19:40:00

For transfer calculations, a threshold distance of 800m was defined as the walkable range for transfers (Streb. M, 2022), assuming a walking speed of 1.2 m/s. Waiting times were also factored into the total travel time: 450 seconds for intra-regional movement and 900 seconds for inter-regional movement.

The analysis target area was set nationwide, and the spatial unit was structured based on a 500m x 500m grid cell system. Out of a total of 418,637 grids, 185,216 grids that actually contained population were selected for analysis to ensure relevance from a service perspective.

Table 2: Public Transportation Direct Section Data Structure (Grid-to-Grid Travel)

Agency Type	GRID ID 1	GRID ID 2	Dist (m)	Time (s)	Speed (km/h)	Oper Count
Transportation	Start	End	Distance	Time	Speed	Oper per day

· Spatial coverage
This study aims to analyze public transportation service levels within major metropolitan areas from the perspective of spatial accessibility. To achieve this, we evaluated public transportation-based mobility by combining the spatial range reachable within a set time (1 hour) via public transportation with the population size within that range.

For the mobility assessment, we adopted an accessibility analysis method based on travel time between origin and destination. This allowed us to quantitatively calculate the actual travel range provided by the public transportation network. For grids where a population exists, we evaluated the connectivity between all grids reachable within a maximum of 60 minutes using public transportation, starting from the public transportation stops located within each grid.

The public transportation direct section data used for this analysis totaled 5,772,986 records, from which 3,646,722 grid pairs reachable within 60 minutes were derived. To ensure the validity of the reachable range, cases where the destination grid had no population were excluded. This process resulted in the removal of 166,770 direct sections based on origin and 165,865 direct sections based on destination. Ultimately, only significant travel routes were extracted, and the range of movement possible within one hour was calculated for a total of 67,323 grids.
For spatial analysis, this study categorized the entire nation into seven major metropolitan areas: the Seoul Metropolitan Area, Gangwon Region, Daejeon-Chungcheong Region, Jeonbuk Region, Gwangju-Jeonnam Region, Daegu-Gyeongbuk Region, and Busan-Ulsan-Gyeongnam Region. Within each of these wider metropolitan areas, we analyzed public transportation accessibility and population distribution characteristics.

· Job Accessibility
In this study, accessibility is defined as the total number of jobs located within all destination grids reachable from a given origin grid within one hour, using the direct sections converted from grid-to-grid movements. We will then calculate the average number of reachable jobs per grid for each urban area to compare regional differences.

To compare regional accessibility, we will utilize the metric proposed by Allen et al. (2019), which is derived from the number of jobs reachable within a specific time in each region. The formula is as follows:

$$A_{ij} = \sum_{i=1}^{J} O_j f(t_{ij})$$

A_{ij} = Accessibility at location i

O_j = Number of opportunities at location j

$t_{i,j}$ = Travel cost (time or distance) from location i to j

$f(t_{ij})$ = Decay function based on travel cost

T = Threshold (travel time)

A_{ij} is a measure of accessibility for location i. O_j is the number of opportunities at location j. O_j can be interpreted as the attractiveness or gravity of location j. $f(t_{ij})$ is a decay function of travel cost t from i to j and threshold (T) for travel time or the number of transfers is set, meaning it is reflected if it is below the threshold and excluded if it exceeds it.

To understand the relationship between the level of public transportation service establishment and jobs, a correlation analysis was conducted between internal grid data (population, number of households, number of businesses, number of jobs) and the number of public transportations stops to enhance justification. The correlation analysis results, transformed into log values, showed a correlation coefficient of 0.35-0.38 between the number of stops and the intra-grid data. The number of stops has a significant correlation with socioeconomic indicators, and it can be seen that this should be considered when assessing public transportation service levels.

Table 3: Number of Stops within Grids

Metric	Value
count	71,830
mean	2.72
std	1.94
Min	1
25%	2
50%	2
75%	3
Max	27

Table 4: Population within Grids

Population	Grid
0	233,421
1-10	73,411
11-100	86,363
100-1,000	14,064
1,000-10,000	11,211
10,000+	166

3. Results

Spatial Coverage

We examined the percentage of grids reachable within 1 hour by public transport relative to the number of populated grids in each urban area. The Seoul Metropolitan Area showed the highest proportion at 47.2%, demonstrating its well-established transfer system, including bus-subway connections. Following Seoul, the Busan-Ulsan-Gyeongnam area (BUK area) also exhibited a high level of public transport service, likely due to its inclusion of two metropolitan cities and their larger populations.

Conversely, the Gangwon region had the lowest proportion at 27.1%, indicating that the spatial reach of public transport is significantly limited there. The Daejeon-Chungcheong, Jeonbuk, and Gwangju-Jeonnam regions showed similar proportions. Further analysis of factors like population and job numbers in these areas is necessary to determine if their current public transport distribution is adequate.

Table 5: Ratio of 1-Hour Reachable Grids to Populated Grids by Urban Area

Metropolitan Area	SIDO	Number of Populated Grids	Grids Reachable Within One Hour	Percentage
Seoul Metropolitan Area	Seoul	30,069	14,195	47.2
	Incheon			
	Gyeonggi			
Gangwon Area	Gangwon	18,529	5,029	27.1
Daejeon Chungchung Area	Daejeon	38,023	13,453	35.3
	Sejong			
	Chungnam			
	Chungbuk			
Jeonbuk Area	Jeonbuk	15,688	5,561	35.4
Gwangju Jeonnam Area	Gwangju	24,620	8,731	35.4
	Jeonnam			
Daegu Gyeongbuk Area	Daegu	31,229	10,273	32.8
	Gyeongbuk			
Busan Ulsan Gyeongnam Area	Busan	23,525	8,696	37.0
	Ulsan			
	Gyeongnam			

Job Accessibility

When analyzing by urban area, the Seoul Metropolitan Area consistently had the highest number of jobs reachable by public transportation. This region recorded more than twice the number of employees and businesses compared to the next highest-ranking area. Following the Seoul Metropolitan Area, the Busan-Ulsan-Gyeongnam area (BUK area) showed the next highest accessibility. The average number of reachable jobs in other regions was found to be similar across them.

Table 6: Average Number of Reachable Jobs and Businesses within 1 Hour per Grid by Urban Area

SIDO_NM	Number of job	Number of Businesses
Seoul Metropolitan Area	1202.4	265.3
Gangwon Area	200.6	60.4
Daejeon Chungchung Area	298.1	86.7
Jeonbuk Area	230.8	68.6
Gwangju Jeonnam Area	250.2	70.2
Busan Ulsan Gyeongnam Area	527.9	145.5
Daegu Gyeongbuk Area	266.2	77.5
Jeju Area	283.8	85.5

The Seoul Metropolitan Area shows high accessibility to jobs via public transportation. In most grids, it's possible to reach over 400 jobs within an hour. Specifically, areas like Yongsan-gu, Jung-gu, Gangnam-gu, Songpa-gu, Seocho-gu, and Yeongdeungpo-gu in Seoul demonstrate the highest accessibility, with over 5,800 jobs reachable per grid. Outside of Seoul, areas such as Bundang-gu in Seongnam City (including Pangyo Techno Valley), Suji-gu in Yongin City (home to a semiconductor cluster), Yeongtong-gu in Suwon City, and Giheung-gu in Yongin City also offer access to a relatively large number of jobs. This indicates that the presence of large industrial complexes or business districts near a grid leads to a high number of reachable jobs.

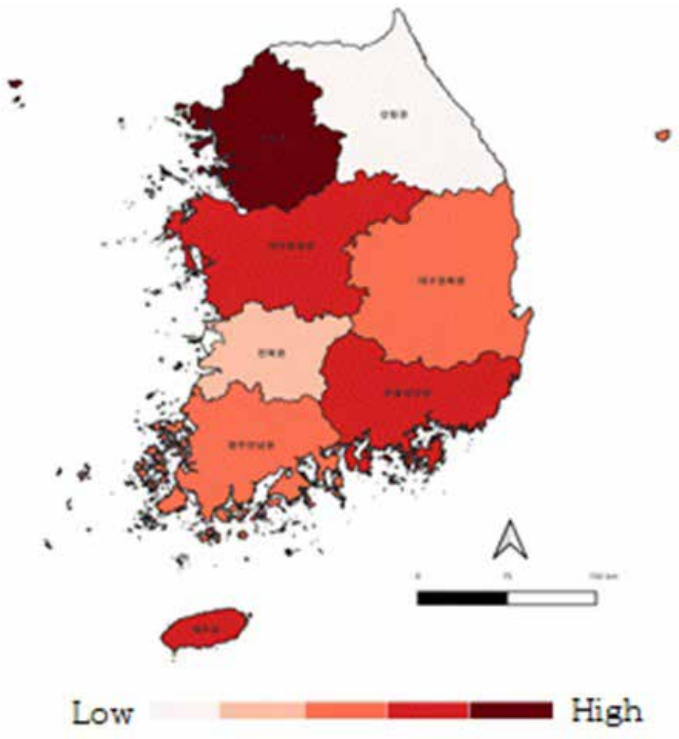

Figure 1: Average Number of Reachable Jobs per Grid within 1 Hour by Urban Area

In the Gangwon region, only Chuncheon City, Wonju City, Gangneung City, and Donghae City have grids where the number of reachable jobs exceeds 500. Most areas in Gangwon show limited accessibility via public transportation. This reflects the challenges posed by the Taebaek Mountains, resulting in insufficient public transportation infrastructure, and the lack of a proper industrial ecosystem development since the decline of mining.

The Daejeon-Chungcheong region also exhibits varying levels of job accessibility. Areas around Cheonan City's Seobuk-gu and Dongnam-gu, where Seoul Subway Line 1 passes, and Cheongju City's Heungdeok-gu, Seowon-gu, and Sangdang-gu, around Osong Station, have grids where approximately 1,000 jobs are reachable. Sejong City, with its active BRT system, also has grids where over 1,000 jobs are accessible via public transportation. Daejeon emerged as the region with the best job accessibility, largely due to its well-established public transportation system, including the subway, and the presence of numerous jobs in areas like the science research complex, which contributes to an increased number of reachable jobs per grid.

In the Gwangju-Jeonnam region, Gwangju Metropolitan City exhibits the best public transportation job accessibility, with the highest number of grids offering access to over 1,100 jobs. Additionally, Mokpo, Yeosu, Suncheon, and Gwangyang also show a high number of reachable jobs. Mokpo's strong performance is attributed to its KTX station and extensive accessibility via maritime transport, while Yeosu, Suncheon, and Gwangyang benefit from being major centers of heavy chemical industries, hosting numerous jobs.

Within the Jeonbuk region, Jeonju has the most grids with accessibility to over 1,000 jobs. Iksan, a KTX stop, and Gunsan, with its Saemangeum development and industrial complexes hosting automotive manufacturing plants, also show high job accessibility.

The Daegu-Gyeongbuk region finds Daegu Metropolitan City with the best accessibility. It boasts the most grids that allow access to over 1,300 jobs, with some grids offering access to a maximum of approximately 3,600 jobs. This high accessibility appears to be influenced by Daegu's subway system and Dongdaegu Station. Furthermore, Gumi City, home to production plants of large corporations, and Pohang, a hub for heavy chemical industries, also have numerous grids providing access to over 1,300 jobs. Most other areas in this region recorded similarly low accessibility levels.

In the Busan-Ulsan-Gyeongnam region, Busan has the highest number of grids with access to over 2,400 jobs, with some grids reaching up to approximately 8,600 jobs. Jinju and Changwon, both with concentrated KTX stations and industrial complexes, have many grids with access to over 1,500 jobs. Ulsan, a prominent industrial city, also has numerous grids offering access to over 1,500 jobs via public transportation.

Finally, in the Jeju region, grids providing access to over 1,100 jobs are predominantly concentrated in Jeju City, forming around the airport.

Integrated Results

The Seoul Metropolitan Area and the Busan-Ulsan-Gyeongnam Area (BUK Area) showed the highest numbers of reachable jobs per grid, relative to their populated grids. In the Seoul Metropolitan Area, this is due to the concentration of businesses and talent from metropolitan centralization, and the establishment of a public transportation system capable of accommodating a large population. Furthermore, the presence of KTX stations and the metropolitan subway system enhances job accessibility for citizens. In the BUK Area, the presence of KTX stations and industrial complexes, including Ulsan, provides a large number of jobs that are well-connected by public transportation.

The Jeonbuk Area and Gwangju-Jeonnam Area, which had similar proportions of reachable grids via public transportation relative to populated grids, also showed similar numbers of reachable jobs. In the case of the Daejeon-Chungcheong Area, despite having a similar proportion of public transport-reachable grids relative to populated grids as the Jeonbuk and Gwangju-Jeonnam Areas, its higher number of reachable jobs suggests that the public transportation service infrastructure might be relatively weaker compared to the abundance of jobs. Conversely, the Daegu-Gyeongbuk Area, which had a lower proportion of public transport-reachable grids relative to its populated grids, showed a higher number of reachable jobs than the Jeonbuk and Gwangju-Jeonnam Areas, demonstrating the significant impact of industrial complexes. Such industrial complexes contain a large number of jobs, and improving their accessibility through public transportation could lead to a more efficient transportation service establishment.

Lastly, the Gangwon Area recorded the lowest proportion of public transport-reachable grids relative to its populated grids, and also showed the lowest number of reachable jobs. This suggests that while public transportation services may be insufficient, the supply is proportionate to the smaller population.

Table 7: Number of Reachable Jobs within 1 Hour per Grid - by Urban Area

			Jeonbuk Area	Daegu Gyeongbuk Area	Busan Ulsan Gyeongnam Area	Jeju Area

4. Discussion

This study aimed to overcome the limitations of existing public transportation accessibility and mobility analyses. It did so by using nationwide empirical data to measure public transportation service levels at a precise spatial unit (500m x 500m grid). The research distinguishes itself from previous studies by integrating various transportation modes beyond single modes or administrative district analyses. It also quantified mobility and accessibility by constructing a direct section network based on actual usage data.

Public transportation mobility was defined as the "number of grids reachable within the same time," and accessibility was defined as the "number of jobs reachable within the same time." Based on these definitions, the study empirically analyzed inter-regional disparities in transportation services across urban areas. The results showed that the Seoul Metropolitan Area and the Busan-Ulsan-Gyeongnam Area exhibited the highest levels in both the number of grids and the number of jobs reachable within one hour via public transportation. This signifies that these regions possess well-established infrastructure and transfer systems. In contrast, the Gangwon region recorded the lowest figures for both public transportation accessibility and the number of reachable jobs, confirming the existence of a service gap between regions.

Specifically, it was confirmed that regions with economic hubs, such as industrial complexes, have more job opportunities when public transportation accessibility is high. This suggests that for regional areas, simply attracting businesses is not enough; the quality of transportation services that enable access to these jobs is crucial for enhancing regional competitiveness. To counter the concentration in the Seoul Metropolitan Area, it is essential to build competitive public transportation networks within each urban area. This can serve as an important strategic criterion for establishing regional balanced development policies.

5. Conclusion

This study moved past traditional administrative district-focused approaches by doing a grid-based, precise analysis. This let us assess actual service levels based on where people truly live. This method can provide helpful foundational data for creating public transportation policies that are practical for daily life and ensure fairness across regions.

However, this study has a few limitations. First, we didn't categorize reachable jobs by industry type, so we couldn't analyze which industries are more closely tied to public transportation accessibility. Second, even though different public transportation modes affect how people move in various ways, we didn't consider factors like transport capacity or service density. This might lead to a difference between the perceived and actual service levels. Third, we didn't re-integrate the grid-based analysis results back into administrative district units, which would have made them more applicable for policy.

This research is important because it used real-world, nationwide transportation network data to quantify and visualize the actual travel ranges and reachable opportunities for citizens. This clearly highlighted the imbalance in public transportation across different regions. In the future, we can expand this into more detailed policy-based research by adding analyses like job accessibility by industry, comparing the influence of different modes, and re-integrating data at the administrative district level. This will help us develop customized mobility policies.

Abstract
At present, most of China's population still lives in rural areas, and the allocation of health facilities in rural areas is generally weaker than that in urban areas. The factors affecting the healthy life of rural residents need to be studied. This study took six rural communities in Pujiang County, Chengdu, Sichuan Province as the research object, and randomly selected 172 residents as samples to investigate the relationship between the characteristics of daily travel activities and self-rated health level of rural community residents, in order to provide a scientific basis for the construction of healthy rural communities and their surrounding supporting facilities. In view of the difficulty of data collection in rural areas, such studies are relatively rare in China. The research comprehensively uses multi-source data, including GPS data obtained by wearable positioning equipment, health questionnaire data, POI data of Amap and building vector data of MapWorld. Firstly, this study uses AT-DBSCAN algorithm to cluster the travel trajectory points to obtain the location information of residents' stay points between 8:00-22:00, and divides the study area into 120m long grids. The TF-IDF algorithm is used to obtain the functional attributes of the grid based on the classified POI data, and then infer the type of stay point activities. For rural areas without POI data, the daily travel activity chain of rural community residents is constructed by combining building vector data. Then, the Word2Vec word embedding model is used to vectorize the activity chain data, and the K-means clustering analysis is used to obtain different daily travel activity patterns. Finally, combined with the residents' self-rated health data obtained from the health questionnaire, the Nonparametric Tests was used to analyze the differences between the self-rated health levels of different travel activity modes. The results show that there are significant differences in self-rated health level among rural community residents with different travel activity modes, which provides a reference for rural community planning and health management.

Keywords: Travel activity, characteristics, Rural community, Self-rated health.

Introduction

With the development of social economy, people pay more and more attention to the healthy lifestyle. In addition to basic physical and mental health, residents' daily travel contact with the living environment is also closely related to healthy life. Studying the relationship between the environmental characteristics and health status of residents' travel activities will help managers create a healthy living environment from the planning and design level. At present, the research on the relationship between the characteristics of travel activities and residents' health is relatively rich in urban areas, but insufficient attention is paid to rural areas. The prediction released by the United Nations in 2018 shows that China's urbanization rate will be 70.6% and 80.0% in 2030 and 2050, and the population in rural areas will be about 399million and 272million(United Nations Department of Economic and Social Affairs, Population Division, 2019)ΔAt the same time, China's 2021 census shows that 36.11% of the population still lives in the built-up environment in rural areas (National Bureau of Statistics of China, 2021)Δand the allocation of health facilities in these areas is generally weaker than that in urban areas, which significantly affects the health level of rural residents. In the past, China's research on rural health mostly focused on medical services (Gao *et al*., 2024; Yang *et al*., 2024) and environmental factors, but the link between residents' daily travel activities and health was rarely involved. In fact, daily travel activities have a direct or indirect impact on rural residents' access to medical care, leisure and social services, which can't be ignored in rural health research.

In view of this, this study selected some residents from six rural communities in Pujiang County, Chengdu, Sichuan, China to investigate and analyze the relationship between their daily travel activity characteristics and their self-rated health level, focusing on the characteristics of stay activity area and activity time allocation, so as to provide a scientific basis for the construction of healthy rural communities and their surrounding supporting facilities. Considering the difficulty of data collection in rural areas, relevant research in this field is relatively rare. In this study, multi-source data, including GPS data obtained by wearable positioning equipment, health questionnaire data, POI data of Amap and building vector data of MapWorld, were comprehensively used to explore the potential relationship between travel activity characteristics and health level, and provide beneficial reference for improving the health status of rural residents, optimizing rural community planning and health management.

Literature Review

Relationship between travel activity characteristics and health

Travel activity characteristics mainly include travel time characteristics, travel space characteristics, activity type, travel frequency, travel mode, travel destination, etc. Many studies have confirmed the correlation between travel activity characteristics and health, mainly through the built environment as the medium, from the aspects of physical activity promotion, environmental exposure, nature of activity sites, environmental healing (Frank *et al.*, 2019; Mahmoudi, 2022; Sharma and Jain, 2023). Choosing an active travel mode that can promote physical activity (such as walking, cycling, etc.) and increasing the travel time allocation of physical activity have many impacts on health promotion (Ali *et al.*, 2020, 2024; Dėdelė *et al.*, 2020; Foley *et al.*, 2018). Environmental exposure in travel activities has significant effects on health(Frank *et al.*, 2019; Poom *et al.*, 2021) , but such effects have duality. On the one hand, active travel modes such as walking and cycling make individuals more vulnerable to traffic related air pollution and noise, increasing the risk of respiratory and cardiovascular diseases. On the other hand, if the travel path passes through green space, it can have a positive effect on mental health by contacting nature and relieving stress (Le and Poom, 2024) . In addition, the role of environmental exposure and differences in travel mode, time period selection and personal perception vary, and there is a significant socio-economic imbalance (Briggs *et al.*, 2008; Ma *et al.*, 2021) . There are differences in the impact of staying in different places of activity on health. For example, leisure activities in places such as commercialservices, leisure and entertainment (Fancourt D *et al.*, 2021) and natural areas (Aerts *et al.*, 2018; Bratman *et al.*, 2019; Ewert and Chang, 2018) can promote health, while long-term activities in places such as office areas (Rasheed *et al.*, 2021) and industrial areas (Xu *et al.*, 2020) are generally considered to have adverse effects on health. In addition, Zhu and Fan et al. Found that travel mode, travel duration and distance, and destination choice were associated with emotional health (Zhu and Fan, 2018) . Bicycle travel has a psychological healing effect, while public transport travel has the opposite effect. The longer the travel duration, the lower the happiness and the higher the pressure. The positive mood of travel for the purpose of free activities such as leisure and entertainment is higher. The urban blue-green space and healing built environment that travel through have a certain healing effect on people's mental health and can relieve people's pressure and negative emotions (Vert *et al.*, 2020; Zhang *et al.*, 2019). To sum up, the characteristics of travel activities can affect health through a variety of mechanisms, and there is a theoretical basis for mining the correlation between rural residents' daily travel characteristics and health from the perspective of time distribution of travel activities and stay activity areas.

Travel activity characteristics and limitations of health research in rural areas

In the research on the relationship between residents' travel activity characteristics and health, the current literature mainly focuses on the relevant research in urban environment, while the research in rural areas is relatively less. The number and quality of transportation facilities, service facilities and travel activity places in rural areas are generally worse than the average level in cities, and there are also significant differences in the characteristics of residents' travel activities. At present, the research on the characteristics of travel activities in rural areas mostly focuses on travel distance, travel time, travel mode selection, etc. for example, Akinlotan et al. Revealed the differences in distance and time of rural residents in medical or dental care travel by using the data of the 2017 national family Travel Survey (NHTS) , and pointed out that the travel distance of rural residents is more than twice that of urban residents, and the travel time is also significantly longer (Akinlotan *et al.*, 2021) . In addition, Hearn et al. Also showed that the travel time of rural cancer patients is longer, which may be related to the lack of transportation facilities in rural areas (Hearn *et al.*, 2024).

In terms of the relationship between travel activities and health, some studies began to pay attention to the impact of travel activities on health of residents in rural areas. For example, Berga and Ihlström found that rural residents' daily activities and travel behavior were significantly affected by traffic conditions through qualitative interviews with rural residents in Sweden. In particular, the lack of Public Transport Services Limited residents' independent travel ability, thereby affecting their opportunities to participate in social activities and obtain health services (Berg and Ihlström, 2019)ΔIn addition, McCrorie's research in Scotland found that rural children have shorter sedentary time and longer time of mild physical activity than urban children, which may be related to the more spacious living environment and more opportunities for outdoor activities in rural areas (McCrorie *et al.*, 2020)ΔThese studies show that there is a complex correlation between the characteristics of travel activities and residents' health in rural areas, but at present, the relevant research is still relatively limited and needs to be further discussed.

In general, the existing literature has a certain foundation in the correlation between the construction of transportation facilities, service facilities, travel activity places and residents' travel activity characteristics in rural areas, but there is still a large gap in the research on the relationship between travel activity characteristics and residents' health. Future research should strengthen the research on the relationship between travel activities and health in rural areas, so as to better guide the traffic planning and health policy-making in rural areas and improve the quality of life of rural residents.

Data preparation

The data used in this study are from a travel trajectory and self-rated health survey conducted by the author's team in Pujiang County, Chengdu, Sichuan Province from July to August 2023 (Fig 1). This study surveyed 172 residents from six rural communities in the region, namely Hongfu Community, Dongyue Community, Shuangsh Community, Bajiaojing Village, Fuxing Community and Mingyue Village, and was conducted in two batches. The number of residents surveyed in each village is shown in Table 1.

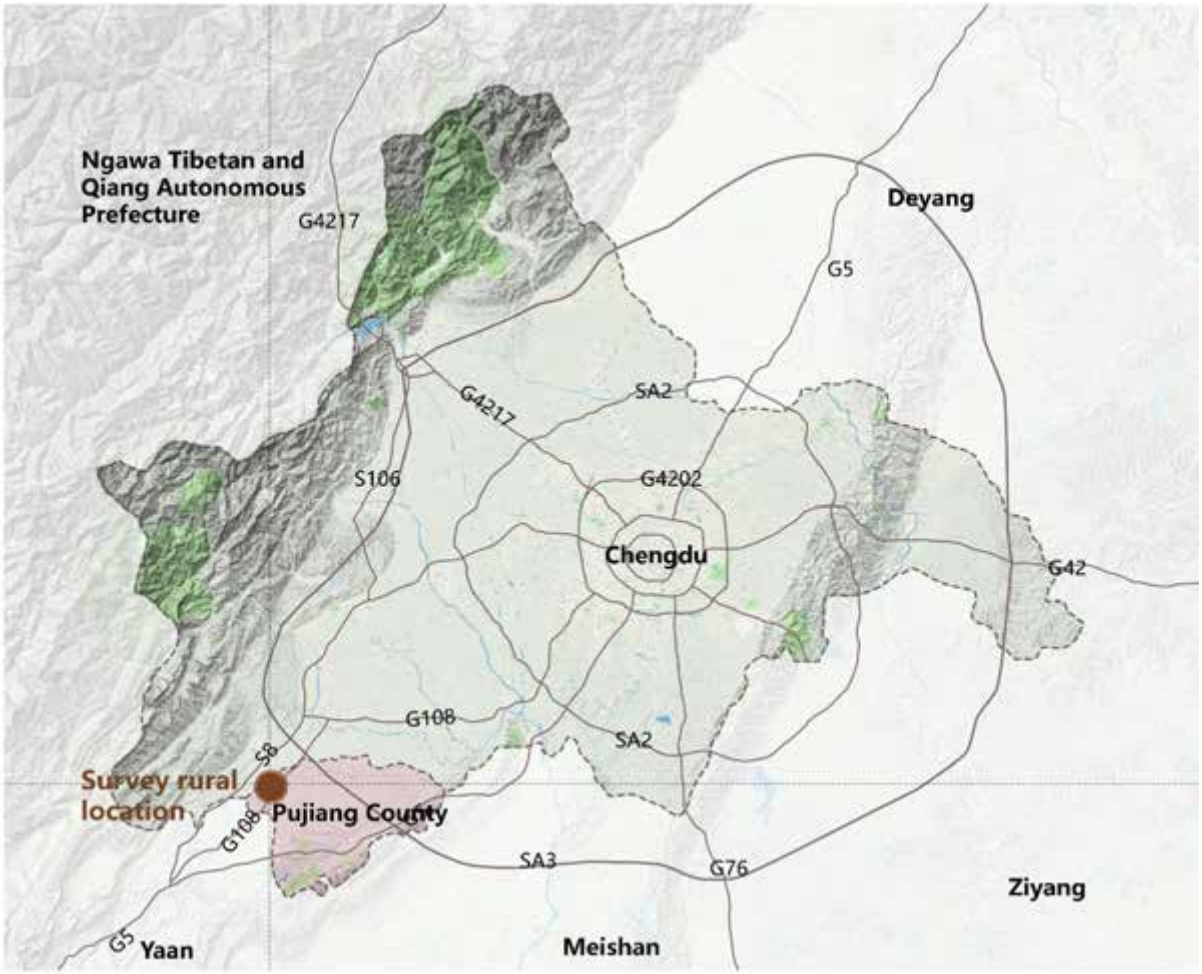

Fig 1. Study area scope and sample source

Table 1. Number of residents surveyed in each village

Number of residents surveyed in each village

Village name	Number of residents surveyed
Hongfu Community	31
Shuangshi Community	33
Dongyue Community	33
Mingyue Village	39
Fuxing Community	32
Bajiao Village	4

GPS positioning data

The GPS data used in this study was obtained by a smart watch with positioning function. The track data recorded by the positioning watch uses WGS 1984 geographical coordinate system, and the positioning accuracy can reach within 30 meters. During the collection process, all positioning watches are set to record trajectory data points every minute, and their information mainly includes longitude and latitude coordinate values, sample numbers, batch number, dates and times (Table 2). During the data collection process, participants were required to wear a positioning watch between 8:00-22:00 within 7 days, and were not allowed to remove the device without special reasons, so as to ensure the continuity of research data collection.

Table 2. GPS data sample

GPS data sample

date	time	sample number	batch number	latitude	longitude
2023-07-12	11:51:00	9617605926	1	30.278349	103.3772225
2023-07-12	11:51:00	9618007196	1	30.28061	103.3820817
2023-07-19	12:13:00	9618007145	2	30.26369	103.3239
2023-07-22	12:12:00	9618007135	2	30.27283	103.3311

As it is difficult for residents to fully cover the entire required number of days for wearing equipment, after screening, a total of 1116 daily behavior tracks were collected, including 584 in the first batch and 532 in the second batch. Fig 2 shows the main distribution range of the trajectories. Most of the data are concentrated in Pujiang County, Qionglai city and Mingshan District, Ya'an City.

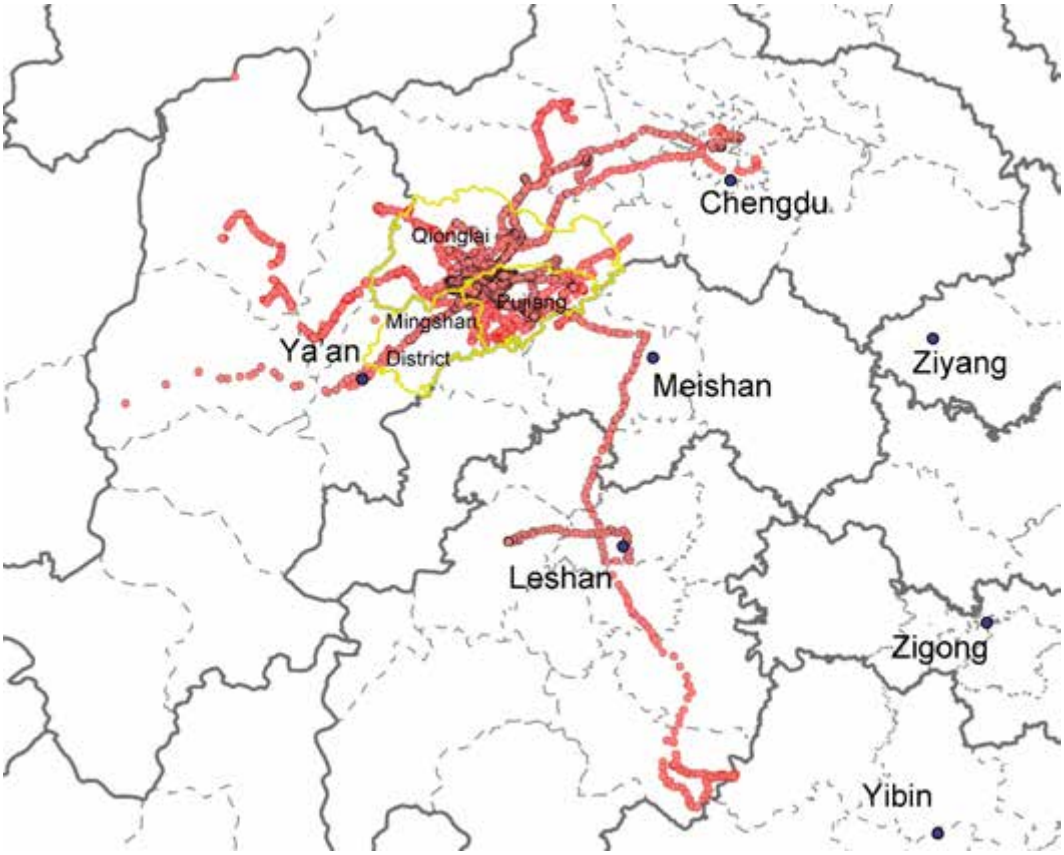

Fig 2. overall distribution of travel trajectories data

Health questionnaire survey data

Self-rated health has been proved to be able to effectively reflect the health level of individuals (Fayers and Sprangers, 2002) . The questionnaire used in this study mainly includes two parts: personal basic attributes and self-rated health scale. The basic personal attributes mainly include 10 items, including sample number, gender, age, occupation, marital status, address, length of residence, residential area, number of families, agricultural labor situation ,and annual family income. SRHMS v1.0 (Self-rated Health Measurement Scale V1.0) was used in the self-rated health scale. SRHMS v1.0 has good content validity, structure validity and calibration validity, which is more in line with the characteristics and habits of Chinese residents, and is suitable for all kinds of people over the age of 14. The content of the scale consists of three subscales of self-rated physical health, mental health and social health, as well as four parts of the overall self-evaluation, with a total of 48 items, which can be divided into nine dimensions: physical symptoms and organ function (B1), daily physical activity (B2), physical activity ability (B3), psychosocial symptoms and negative emotions (M1), positive emotions (M2), cognitive function (M3), role activity and social adaptability (S1), social resources and social contact (S2) and social support (S3). The overall self-assessment includes the overall physical self-test, the overall psychological self-test, the overall social self-test and the overall health self-test. The maximum score of each item is 10 points, the minimum is 0 points, and the maximum possible score is 440 points after removing the self-evaluation part of auxiliary verification. The scores of items 4, 5, 7, 24, 25, 26, 27, 28, 29 and 30 are scored in reverse to ensure the validity of the questionnaire (Xu *et al.*, 2000; Xu, 2001; Chuqun *et al.*, 2021)Δ

Due to potential problems such as residents' personal willingness to fill in, only 125 valid health questionnaire data were collected in this study. Table 3 shows the basic information data of the respondents, and Fig 3 shows the distribution of the total self-rated health scores of the sample population.

Built environment data based on Web Map

The built environment data used in this study mainly include POI data and building vector contour data within the scope of the study. POI data is obtained from Amap, which includes 22 categories and is limited within the administrative boundaries of Pujiang County, Lushan County, Mingshan District of Ya'an City and Qionglai City, with a total of 52784 items. In previous studies, the original POI data is usually reclassified according to the research purpose, such as taking the residents' service attribute as the core (Yang et al., 2021) and the urban functional area attribute as the core (Gu et al., 2018; Yang et al., 2020) . In order to meet the requirements for the identification of stay activity functional areas in this study, the POI of Amap is reclassified into 11 categories (Table 4) by focusing on the attributes of resident services, so as to facilitate the identification of subsequent residents' travel characteristics. The building contour vector data is obtained from the MapWorld, which mainly contains the outer contour vector shape data of all buildings in the three counties and cities, so as to help judge the resident stay activity category in the POI missing area.

Methods

Travel trajectory activity point acquisition

At present, there are four main directions for the research of stay activity point recognition in travel trajectory. First, based on the fitting of road network information and travel trajectory, the distance between trajectory points and road vectors is calculated to identify stay points (Du and Aultman-Hall, 2007). This method needs more detailed regional road network information as an auxiliary, which is suitable for use in urban areas with relatively complete road network data. It is not suitable for use in rural natural environment with insufficient construction of standard road network and serious lack of road network data. The second is to use the velocity characteristics of the trajectory points to judge and detect the trajectory points whose velocity approaches zero as the stay points (Zhang et al., 2013) . This method is aimed at the stay points in slow travel activities in rural areas, and requires equipment with high-precision speed collection ability. The third is to judge the stay point based on geographical semantics. For example, the SMoT (Stops and Moves of Trajectories) model first presets the locations of the points of interest that the samples often go to, generates appropriate geographic geometric entities based on such locations, and judges the stay activities through the residence characteristics of the sample motion trajectory in the geometric entities (Alvares et al., 2007). The fourth is based on density clustering to identify stay points. As the stay activities will be concentrated in a region for a long time, the stay point can be better found through density judgment. DBSCAN algorithm based on density clustering has a good performance in the identification of travel purpose. It only needs the location and time stamp data of trajectory points. By setting the clustering limit parameters such as EPS neighborhood and Minpts, it can expand the core points, divide the clusters by density reachability, and calculate the cluster center point as the stay point (Ester et al., 1996) .

On this basis, Zhou Yang and Yang Chao analyzed the shortcomings of existing ST-DBSCAN (Birant and Kut, 2007), TrigDBSCAN(Yan, 2011), C-DBSCAN(Gong et al., 2015) algorithms in the required data complexity, scientific threshold, core point search method, cluster merging method, and path overlap, and proposed the AT-DBSCAN algorithm (Zhou and Yang, 2018) The algorithm checks the internal trajectory points by setting a fixed length sliding window, so as to cluster and identify the core points, forming the initial cluster and cluster, and finally calculates the center points as the stay points after filtering the cluster according to the length of time. It requires the initial data and can better eliminate the influence of noise in the original trajectory data.

Due to the difficulty of data collection in rural areas, where residents' activities involve non built environments such as farmland and wilderness, it is difficult to manually determine the range of interest locations. In addition, the GPS data collected in this study has certain errors and noise effects. Therefore, this paper chooses to draw on the idea of AT-DBSCAN algorithm for identifying travel trajectory stay points. The AT-DBSCAN algorithm has five main parameters that need to be set, namely the sliding window length "k", time interval "I", spatial neighborhood distance "Eps", minimum trajectory point count threshold "MinPts", and minimum stay points duration "DU". Due to the fact that the GPS trajectory points data recording interval used in this study is 1 minute, considering that stay activities with a duration of too short are of little significance to this study, stay activity points with a duration of more than 15 minutes are included in the research scope. In this study, k=21, I=10min, Eps=60m, MinPts=10, DU=15min are set, and 172 residents' trajectories are respectively clustered to identify the stay activity points. Firstly, use a sliding window to mark trajectory points within the spatial neighborhood with a number of neighboring points exceeding the MinPts value as core points. Then, starting from random core points, traverse all unclustered core points and cluster the core points within the spatial neighborhood Eps range with a time interval of no more than 2 minutes as the initial cluster. Then start from the initial cluster with the highest density, merge other adjacent clusters with a time interval less than I, repeat this operation until all the clusters that can be merged are merged, and finally exclude the clusters with a duration less than Du. The final data includes the longitude and latitude coordinates of the stay activity point, the cluster number, the start and end time of the stay activity, the stay time, the date number, and the sample number (Table 5). An example of space-time diagram of clustered data trajectories is shown in Fig 4.

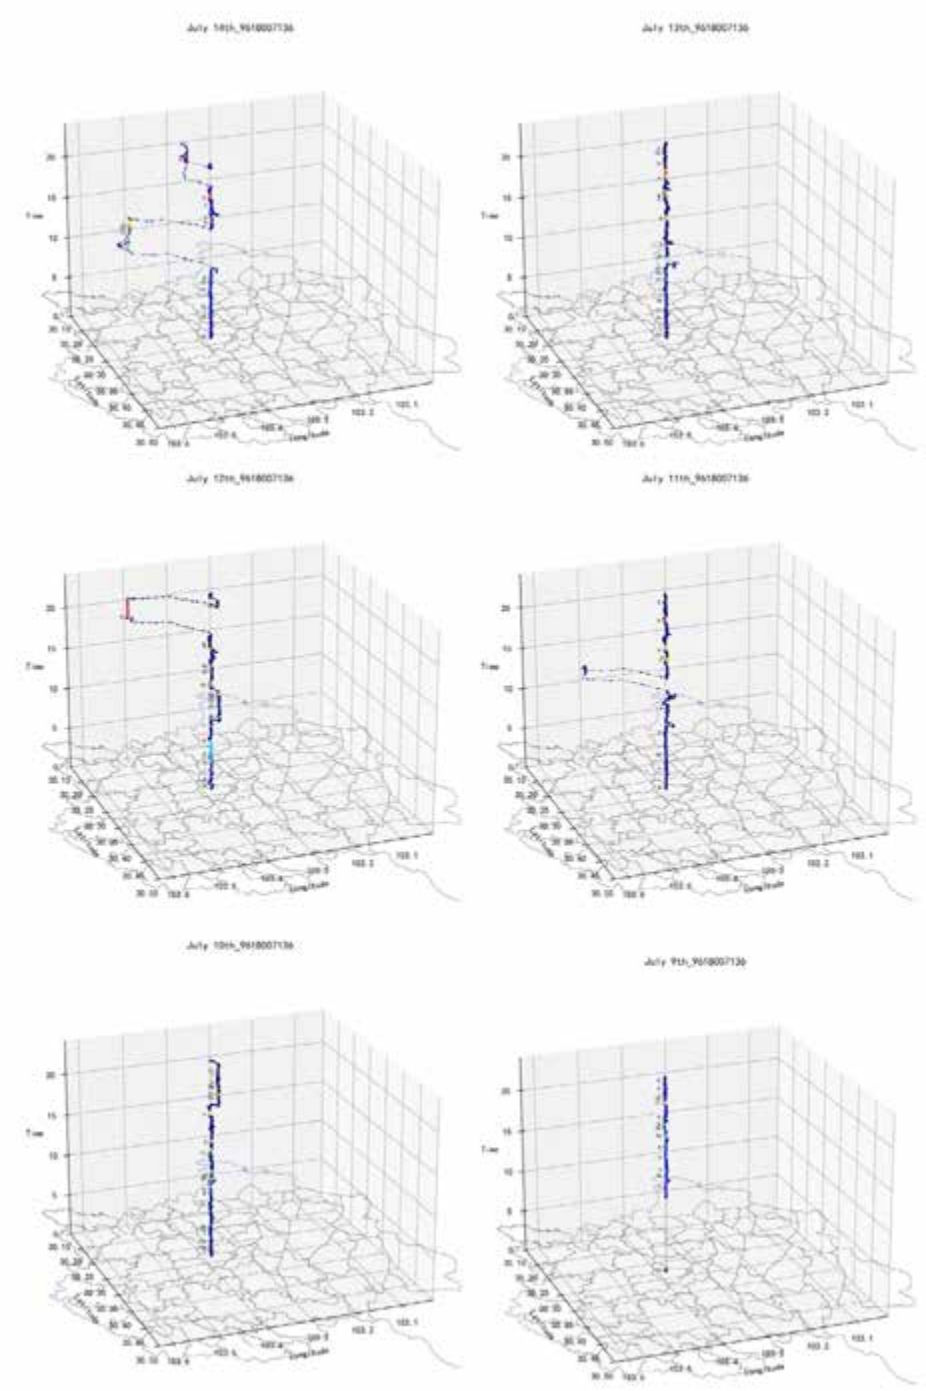

Fig 4. Example of Trajectory space-time diagram

Stay activity attribute judgment

After obtaining the stay activity point of the sample by clustering, it is necessary to infer its functional type. We choose to use POI data to judge, refer to the combination of TF-IDF algorithm and grid division method used in the related research of function area judgment, identify POI weights, determine grid function attributes, and further infer the type of stay activity points (Sparck Jones, 1972; Zhu, 2024). The specific method is to divide the area within the research scope into multiple grids according to the side length of 120m, and determine the weight

of each functional category in the POI data falling into the grid. In the weight calculation part, using the good classification ability of TF-IDF algorithm, each grid area is regarded as a single text, and the proportion of POI categories in a single text is regarded as word frequency. IDF (Inverse Document Frequency) is used to represent the importance of different POI categories, and finally the POI weights of each category in each grid are obtained. Then the weight proportion is calculated, and the function of grid area is divided according to the proportion. In this study, when the weight of a certain type of POI in the grid area accounts for more than 50%, it is considered that the functional category of the grid area is the same. When the weight of two types of POI is between 20% and 50%, it is considered that the function category of the grid area is a combination of two types of functions. When the weight of all POIs is 0%, the function category of the grid area is considered as no data area. Other cases are classified as comprehensive functions. After determining the function of the grid area, assign it to the function type of all stay activity points falling in the grid.

However, in rural areas, there are many grids that are judged as no data area due to the lack of POI. In fact, these areas include built-up environmental areas such as villages and settlements, as well as natural areas such as fields and mountains. Therefore, it is necessary to combine the building contour vector data to assist the judgment. In rural areas, areas without POI but with buildings are generally within villages where residents live, and these areas can be regarded as functional areas of "Residence". In this study, for the trajectory stay point marked as "no data area", judge whether there is a building outline intersecting with it within the 120m diameter of the section. If there is, change the functional attribute of the point to "Residence", otherwise, change it to "Natural area". Finally, the potential activity type characteristics of each stay activity points are obtained.

Travel activity chain clustering

After obtaining the functional attributes of the sample stay activity points, it is necessary to build the sample daily activity chain. We first divide the trajectory of each sample in the time range of 8:00-10:00 into 28 time blocks in 30 minutes. Then judge whether the time range of each time block is within the start and end time range of the stop activity point in order. If it is within the range, the function attribute of the stay active point is assigned to the time block. Then all time blocks that are not assigned the function attribute of the active point are identified as "moving" activities. Finally, the activity chain data with granularity of 30 minutes is formed. Due to the relatively small sample size of 124 data collected by the self-rated health questionnaire, in order to ensure the consistency between the subsequent analysis and the self-rated health questionnaire data, the activity chain without corresponding questionnaire data was deleted according to the sample number before the activity chain clustering, and 709 travel activity chain data remained.

In the part of activity chain clustering, this paper draws on the trajectory vectorization and clustering method based on word vector model (word2vec) proposed by liwenxiang et al. (Li et al., 2024) In this study, the activity unit is mapped to a word vector, and the activity chain is mapped to a sentence vector, so that the activity pattern recognition problem is transformed into the semantic similarity measurement between the sentence vectors of the activity chain. Through cluster analysis, user groups with similar activity patterns can be identified. This method shows good effect in multi day activity pattern recognition. The daily activity chain data of all samples are converted into comma separated sentence text composed of functional attributes such as "Residence", "Labor", "Work", "Transportation", "Finance", "Education", "Medical", "Tourism", "Entertainment" "Shopping", "Municipal", "Comprehensive", "Natural", "Move", in chronological order. Then use text data to train word2vec model, set the word vector dimension vector_size=19, the context window size window=20, and the minimum occurrence frequency of reserved words min_count=1, that is, words that appear at least once in the corpus will be retained. Finally, the daily travel activity chain sentence vector of each sample is generated, and SVD (Singular Value Decomposition) method is used to decompose the sentence vector to remove the main components in the data, so as to achieve normalization, which is convenient for feature recognition in subsequent clustering(Gargiulo et al., n.d.)Δ

After that, this study chose to use k-means algorithm to cluster the sentence vectors generated by the daily activity chain of samples. The algorithm has good interpretability for the results. The centroid of each cluster is the mean value of all data points in the cluster, which can directly reflect the central position and main characteristics of the cluster data (Li et al., 2020; Lin et al., 2009) . Because the k-means algorithm needs to specify the number of clusters in advance, the elbow method combined with the comprehensive judgment of contour coefficient can better distinguish the appropriate number of clusters (Humaira and Rasyidah, 2020), as shown in Fig 5. Combined

with the actual travel activities, elbow diagram and contour coefficient results, the preset clustering number k=7 is selected to obtain the final clustering data.

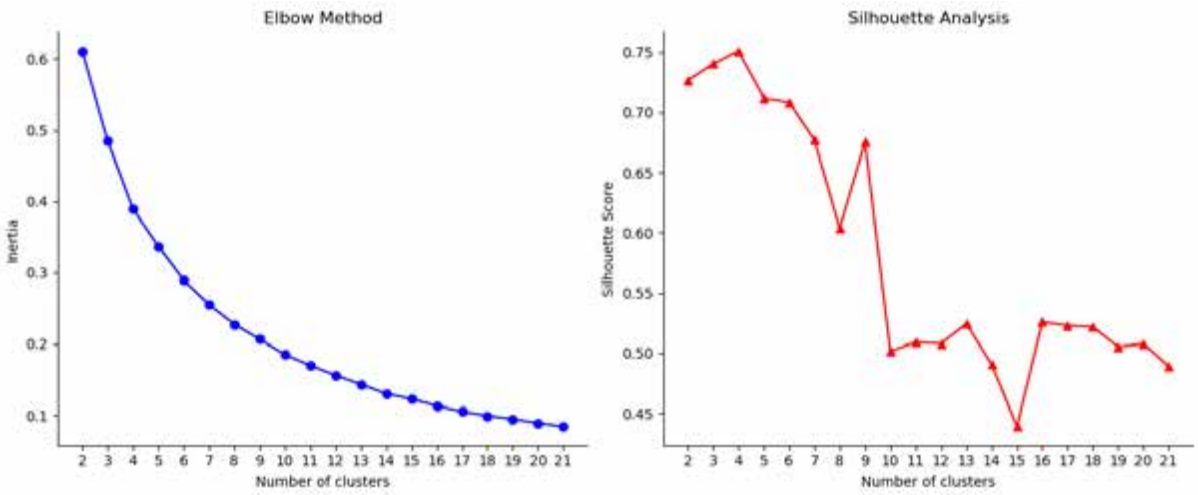

Fig 5. Elbow diagram and contour coefficient diagram Fig 6.

Analysis of health level differences among different travel mode

After mapping the self-rated health questionnaire data with the clustered activity chain data according to the sample number, it is necessary to analyze the difference of health level between different activity chain clusters. The commonly used statistical analysis methods for differences mainly include Analysis of Variance, Chi-Square Test, and Nonparametric test (le Cessie et al., 2020; Lee et al., 2013). Variance analysis requires that the dependent variable is a continuous variable and meets the homogeneity and normality of variance. Chi square test is applicable to the case where the dependent variable is classified variable. Using SPSSAU data analysis platform, the health score data corresponding to all travel activity chains were normalized and then tested for normality(SPSSAU, 2025). The results showed that the p value was less than 0.05, and the residents' self-rated health score data did not conform to the normal distribution (Table 6). Since the distribution of self-rated health data does not conform to the normal distribution, and the dependent variable is a continuous variable, this study uses a nonparametric test to analyze the difference of self-rated health scores between clusters in the activity chain.

Table 6. Analysis results of normality test

Results

In order to better analyze the activity patterns represented by each activity chain cluster, the functional attribute weights of all activity chains in each cluster are calculated and represented as images (Fig 6). It can be seen that the stay activities of the samples in cluster 0 are distributed in "Natural", "Comprehensive", "Residence" and "Shopping", and the weight of "Residence" is relatively high, but not more than 50%. The stay activities in cluster

1 are obviously concentrated in “Residence”, and a small part are distributed in “Natural”. The stay activities in cluster 2 are less distributed in “Residence “, relatively balanced in “Finance”, “Medical” and “Shopping”, and there are stay activities in some “Medical” areas. In cluster 3, “Medical” has the highest weight, followed by “Residence” and “Shopping”, and there are also a few stay activities in the “Medical” area. The stay activities in Cluster 4 are obviously concentrated in the “Comprehensive” area. The stay activities in cluster 5 are mainly “Work”. Cluster 6 is mainly distributed in “Natural”, “Tourism”, “Entertainment”, “Shopping” and other “Entertainment” areas, but in addition to “Residence”, there are also “Medical” areas in other activities.

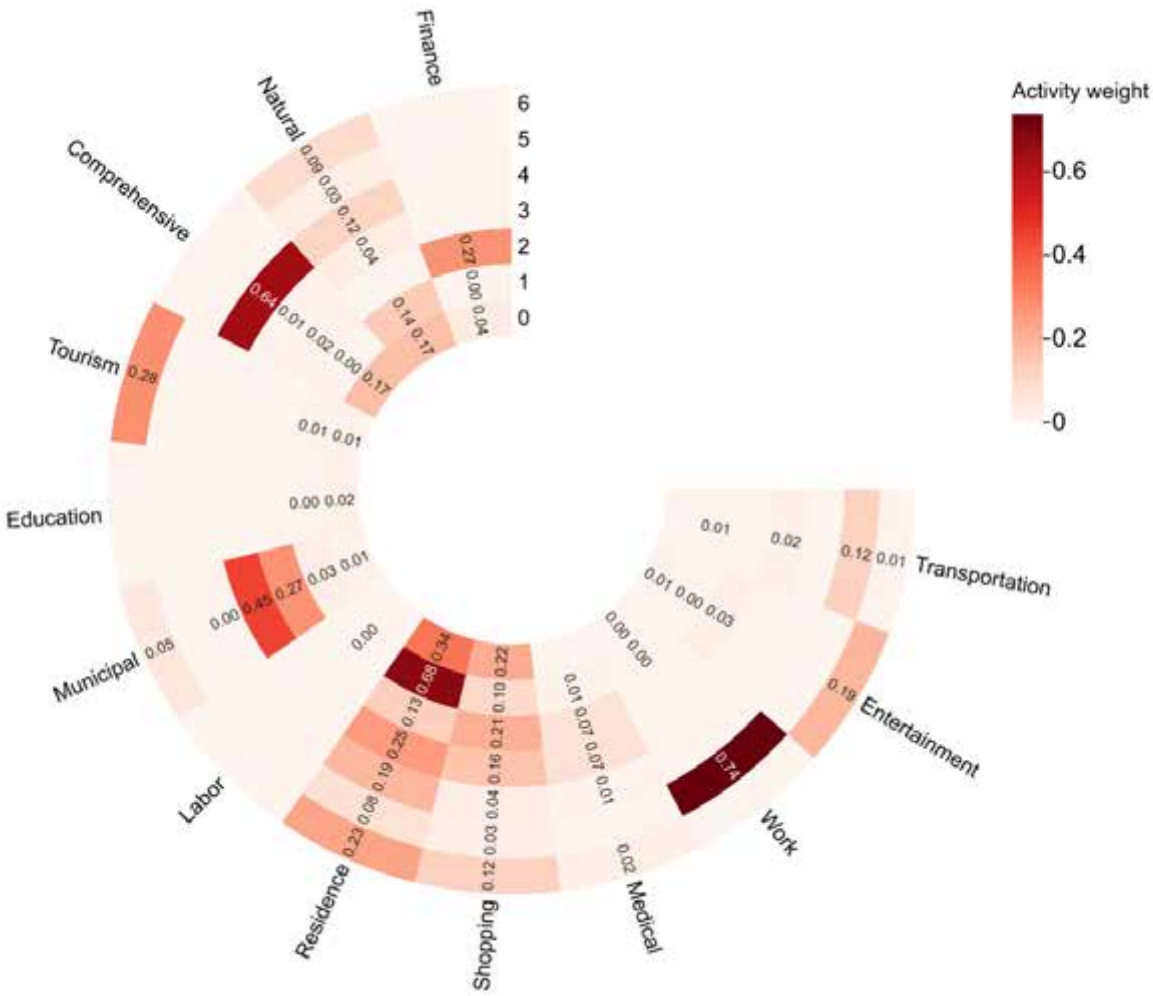

Fig 6. Feature weight of clustering activities

Nonparametric test was used to analyze the health differences among clusters of activity patterns. The results are shown in the table below (Table 7). The original hypothesis was that there was no difference in the self-rated health scores among the activity mode clusters. Since the p value was equal to 0.011 and less than 0.05, the original hypothesis was rejected and it was considered that there were differences in the self-rated health scores among the activity mode clusters. Draw a box plot to further analyze the specific differences in self-rated health scores among various activity modes (Fig 7).

The median of self-rated health score in cluster 2 is the highest 440, and the data distribution is relatively concentrated, with small variance, but the sample size is too small, and it shows an obvious left deviation distribution. The median of self-rated health score in cluster 0 was 403, which was at the second high level. 75% of the data were concentrated between 328 and 419.8, which had a certain concentration. The median self-rated health score of cluster 1 was 382.0, and the score distribution was between 339.5 and 414.0. Compared with cluster 0, the 75% data distribution was more concentrated. The median self-rated health score of cluster 3 was 373.0, and 75% of the scores were distributed between 271.0 and 420.0, indicating that the cluster had a wide range of health scores, and the self-rated health scores were not concentrated enough and showed a left skewed distribution, with more head data. The median self-rated health score of cluster 6 was 356.0, and 75% of the scores were concentrated between 294.0 and 385.0, which was significantly lower than that of cluster 0, 1, 2 and 4. The self-rated health score data of cluster 5 are all 352. Due to the small amount of data, it is considered as a special activity chain cluster with obvious characteristics. The median self-rated health score of Cluster 4 was 348.5, and 75% of the scores were distributed between 323.0 and 422.0, showing a right deviation distribution, with more tail data. Combined with the median and data distribution, the overall self-rated health score in this cluster is lower than that in clusters 0, 1, 2 and 3.

Discussion

This study found that in the daily life of residents in rural areas, the scope of activities of most people is relatively small, only staying in the village and its surrounding areas. According to the actual situation, cluster 0 is defined as "residential-mixed" travel activity mode, cluster 1 as "residential-natural" travel activity mode, cluster 2 as "commercial service" travel activity mode, cluster 3 as "municipal facilities" travel activity mode, Cluster 4 as "comprehensive functional" travel mode, cluster 5 as "office" travel mode, and cluster 6 as "entertainment" travel mode.

The health level of "commercial service" travel activity mode is the highest, and its activities are mainly concentrated in financial, municipal, commercial services and other areas, and a certain proportion of activities occur in medical areas. Commercial activities are usually associated with higher economic income and better living conditions, which may further promote the health status of residents (Contoyannis and Jones, 2004). However, the data volume of this cluster is small, and the data presents a significant left biased distribution, which may limit the universality of the results. Future studies need a larger sample size to verify this finding.

The self-rated health score of the "residential-mixed" travel activity mode is the second highest, covering activities in a variety of functional areas, including residential and related services, comprehensive functional areas, commercial service areas, etc. This diversified mode of travel activities may enable residents to access different types of resources and services, thus having a comprehensive positive impact on health. Residential areas usually provide basic living security, while comprehensive functional areas and business service areas may provide additional facilities and social opportunities. These factors work together to help maintain a high level of health.

The "residential-natural" travel activity mode has the largest amount of data, and the overall health level is widely distributed, and most of them are concentrated in the high score level, second only to "commercial service" and "residential-mixed". The stay activity of this mode are mainly concentrated in "Residence" and "Natural". According to the questionnaire, most rural residents need to go to farmland and woodland for labor in their daily life, and the moderate intensity physical activity brought by labor may promote their health level (Blair et al., 1992; Posadzki et al., 2020) . At the same time, the natural environment usually has a positive impact on mental and physical health, helping to relieve stress, improve mood and enhance physical activity (Ewert and Chang, 2018; Jimenez et al., 2021). However, there are still some residents with relatively low scores in this mode. This may be related to the quality of the living environment, the accessibility and utilization of natural areas, and the

sensitivity of individuals to the natural environment. In addition, the relatively single type of activities may limit the healthy development of residents to a certain extent. The sample size of this cluster is 626 samples, which is one of the clusters with the largest sample size. The results have certain representativeness and reliability, but the impact of individual differences on health still needs to be considered.

The stay activities of the "municipal facility" travel activity mode are mainly concentrated in the "Municipal", "Residence" and "Shopping" areas, and there are also a few stay activities in the "Medical" areas. The use of municipal service facilities provides residents with basic public services and convenience, and helps to promote the healthy lifestyle of residents. However, the cluster has a wide range of health scores, and the median advantage is not prominent, which may indicate that different individuals have different health benefits in the use of municipal facilities, which are affected by many factors such as individual health awareness, lifestyle, facility accessibility and so on. And the amount of clustering data is small, and the data distribution may also be affected by the sample characteristics. Further research is needed to clarify the specific mechanism behind it.

The "comprehensive functional" travel activity mode is mainly parked in the comprehensive functional area, and the overall level of self-rated health score is lower than the first few. Comprehensive functional areas usually integrate many functions such as residence, commerce, office and leisure. Although they provide convenient living and working conditions, such areas may also have adverse health factors, such as noisy environment, poor quality and high density, which will have a negative impact on the health of residents, and then affect their health. The amount of clustering data is small, and the data distribution may have large deviation. More research is needed to verify this hypothesis.

The stay of "leisure and entertainment" travel activity mode is mainly distributed in "Natural", "Tourism", "Entertainment", "Shopping" and other areas, as well as "Residence" and "Medical" areas. Leisure and recreational activities are generally considered to be beneficial to mental and physical health, and can relieve stress, enhance physical activity and promote social interaction (Fancourt D et al., 2021; Paggi et al., 2016). However, the health score of this cluster is not high, which may be related to the type, duration, frequency of leisure activities and the subjective experience and response of individuals to these activities, and may also be related to the stay activity of these data in the "medical" area. The amount of clustering data is small, and the data distribution has some limitations. More research is needed to explore the complex relationship between leisure and entertainment activities and health.

The self-rated health score of the "office" travel activity mode is the lowest, mainly in the "office" area. Long term office activities may lead to problems such as reduced physical activity, increased work pressure, and increased psychological burden, which may have a negative impact on health (Kouvonen et al., 2013) . However, the sample size is small and the source is single, which may be due to the small number of people in the daily regular office travel mode in rural areas.

Conclusion

The results show that there are differences in self-rated health level among rural community residents with different travel activity modes. Among them, the residents' health score of the "commercial service" model is the highest. It is speculated that social interaction and economic interaction in business activities have a positive effect on health, and may also be related to the higher economic level of people engaged in business activities; The health level of residents in the "residential-mixed" mode is second, and the diversified types of activities enable residents to contact multiple types of resources and services, which has a certain promoting effect on health. The "residential-natural" travel activity mode is the main mode of daily travel for residents in rural areas. In this type of travel activity mode, most residents' self-rated health level is relatively high, which may be related to the fact that some residents in rural areas are engaged in agricultural activities to promote physical activity. The residents' self-rated health score level of the "municipal facility" travel activity mode is relatively scattered, indicating that the travel mode has no obvious centralized health level characteristics, and the health level of the group may have more complex correlation with personal factors. The residents' self-rated health score of the "comprehensive functional" travel activity mode is lower than that of the first three activity modes. It is speculated that the comprehensive functional areas in rural areas may have poor environmental quality, which is not conducive to health promotion. The self-rated health score of residents in the "entertainment" mode is relatively poor, which is contrary to the generally believed promotion effect of leisure and entertainment

activities on health. This kind of activity mode has the activity stay in the medical area, which may indicate that these people's health level is poor, so they choose leisure and entertainment activities for treatment, leading to different conclusions. The health score of residents in "office" mode is the lowest, which is consistent with the conclusion that physical activity decreases and stress increases due to long-time office work in previous studies. In view of the differences between different travel activity modes and the self-rated health level of rural community residents, it is suggested to reasonably arrange various functional areas in rural community planning, encourage the development of commercial services and mixed functional areas, enhance economic vitality and social communication opportunities, and promote residents' health. In rural areas, the environmental quality of comprehensive functional areas should be optimized to avoid adverse effects on health. At the same time, increasing the planning and configuration of leisure areas should not only meet the residents' needs for treatment, but also consider how to enhance the health promotion effect of activities. In addition, when planning the office area, we should pay attention to the health status of office residents, reasonably arrange the working hours and environment, and reduce the health risks caused by reduced physical activity and increased stress, so as to comprehensively improve the health level of rural community residents.

However, this study also has limitations. The sample size is relatively small and concentrated in specific areas, which may affect the universality of the results; The data collection time is short and does not cover the impact of different seasonal changes on travel and health. Future research should expand the sample size and geographical scope of rural areas, extend the time of data collection, and combine more objective health indicators with travel monitoring methods to further verify and deepen the research conclusions, so as to provide more comprehensive and accurate guidance for rural community health planning.

Rethinking Policy Learning in Urban Policy Mobility

Abstract
Since the 'mobility turn', urban researchers have made important contributions to our understanding of the contentious and relational nature of cross-border policy learning. Yet, seldom has extant research explored the contextual influence of local policymaking on the localization process of a traveling policy practice beyond the initial encounters of policy elites with its simplified narrative. To fill this gap, this article investigates the link between policy learning and policy outcome by disaggregating its complex interactive and iterative process into distinctive policy stages of urban policy mobility. The case of participatory budgeting in Vienna adds an empirical dimension to this approach. The findings reveal how multiple types of learned lessons, drawn from diverse sources of knowledge, become enmeshed, streamlined and articulated into the local formulation and implementation of an international 'best practice' in a context-bound policy space. It concludes by highlighting some analytical advantages of this policy-oriented approach for researching urban policy mobility and directions for future research.

Keywords: citizen participation; participatory budgeting; policy learning; policy mobility; urban governance

Introduction

The question of how policy learning affects the localization of globally circulating policies has been central to our understanding of urban policy mobility. Within the policy mobilities literature, scholars from various disciplines, ranging from anthropology to geography and sociology to urban planning (see Harris and Moore, 2013; Healey, 2012; McCann and Ward, 2013; McKenzie, 2017), have captured the interconnected urban processes and outcomes of global policy circulation, wherein policy elites learn and move policy ideas from place to place through global networks of policy communities. Combined with new communication technologies and logistical means in transnational flows of knowledge (see Ward, 2024), existing works consider that such cross-border relationships between actors, institutions, instruments and ideas enable not only spatial, but also temporal compression of traveling policy practices (Peck and Theodore, 2015), featuring 'ready-made, quick-fix, off-the-shelf policies from other jurisdictions or from private consultants' (McCann, 2011: 121).

From a policy perspective, however, the current use of policy learning within the policy mobilities literature has some limitations to fully grasp its multifaceted dimensions and their varying influences on the urban process and outcome of policy travel. Of course, there is no doubt about the role of globally connected policy actors, including epistemic communities (Haas, 1992), in promoting transnational exchange of policy knowledge and selective adoption of 'best practice' solutions in different cities (see Stone et al., 2020). Yet, this understanding of policy learning in urban policy mobility only partially describes the policymaking behaviors and learning activities of policy elites that primarily occur in the earliest moments of its overall experience. In practice, their localization will feature more complex adaptive dynamics and interactions, in which various learned lessons and their (uneven) deliberation flow constantly between its constitutive stages. In other words, the travel, mediation and mutation of traveling policy practices through policy learning is more than ideological predispositions of partisan or self-interested policymakers. Rather, it entails multiple forms of knowledge exchange between a diverse range of policy actors from different governance levels with varying capacities to influence specific policy components. Together, they will have a specific consequence for the localized process and outcome of urban policy mobility.

In this article, we explore diverse patterns of policy learning and their implications for policy outcome as an international 'best practice' not only travels to and arrives in a city, but also lives through multiple interrelated stages of its life cycle. The purpose is to highlight how multiple types of learned lessons, drawn from diverse sources of knowledge, become differently enmeshed, streamlined and articulated into the local formulation and implementation of a traveling policy practice, extending beyond the initial encounters of policy elites with its simplified narrative of success. It argues that the way in which the specific capacities of policy actors intersect with prevailing contextual circumstances at the local level will have a significant influence on the translation of

learned lessons into concrete substances for policy outcome. Indeed, there are growing considerations into the 'topological' influences of local policymaking on urban policy mobility (McKenzie et al., 2021). However, the link between policy learning and policy outcome, influenced by context-bound social and political interactions in the iterative process of local policymaking, remains underexplored in the current policy mobilities literature.

The case of participatory budgeting for climate change mitigation (*Wiener Klimateam*) from Vienna, Austria, illustrates this theoretical approach empirically. In recent years, the global circulation of participatory budgeting (PB) has gained considerable attention within the policy mobilities literature and beyond (see Bartocci et al., 2022; Lehtonen, 2022; Montero and Baiocchi, 2022; Peck and Theodore, 2015; Wampler et al., 2021). While these studies have identified their diverging characteristics in terms of background, objective and design, less has been said about the critical role of their interactive and iterative policy processes within which policy actors build knowledge to frame issues, choose instruments, implement solutions and evaluate their outcomes. In this light, the empirical findings presented below zoom the relationship between policy learning and policy outcome in *Wiener Klimateam* into five separate – yet interrelated – stages of its overall policy cycle: 1) issue-framing; 2) instrument selection; 3) participatory process; 4) output implementation; and 5) evaluation. The discussion of these findings will connect the recent theoretical advances in policy studies on policy learning with extant research on urban policy mobility.

The proceeding sections are structured as follows. The second section outlines the current understanding of policy learning within the policy mobilities literature and identifies remaining issues and gaps. The third section sketches out the theoretical approach and the analytical framework of this article. The fourth section introduces the case study setting and describes the research methods used. The fifth section illustrates the varieties of policy learning and their implications for policy outcome in the localization experience of PB in Vienna. The sixth section discusses these results and their practical implications in reflection of recent studies on policy learning beyond the policy mobilities literature. It concludes by highlighting some analytical advantages of the presented approach to future studies of urban policy mobility.

Policy Learning in Urban Policy Mobility: Issues and Gaps

The current understanding of policy learning in urban policy mobility emerged from the call to rethink global policy circulation beyond simple cross-border emulation of policy solutions and to consider the power-laden process of their reproduction at the urban scale (see Cochrane and Ward, 2012; McCann, 2011; Peck, 2011). The conception of policy learning within the policy mobilities literature after this 'mobility turn' (Sheller and Urry, 2006) can be summarized as below.

First, powerful policymakers who strive to advance their political or personal agenda selectively choose and adopt from policies that circulate through growing transnational policy networks and exchange opportunities (see Baker et al., 2016; Peck and Theodore, 2015; Wood, 2015). In this process, policy experts beyond the immediate local policymaking circle, such as consultancies, think-tanks and universities as well as international, supranational and non-governmental organizations, play a crucial role in framing expert knowledge and promoting model practices across borders (see Andersson and Cook, 2019; González, 2011; Hudson and Kim, 2014). The underlying argument is that 'urban politics…is…global or international in a much deeper sense' (Ward, 2018: 279), invoking the mutually constituted and relational aspect of urban policy mobility.

Second, the change effect of policy learning on the actual process and outcome of local policymaking is therefore minimal. The content of policy learning that is drawn from policy expertise, designs and recommendations of epistemic communities is limited to 'success' narratives of abstract policy ideas rather than concrete institutional reform agenda and their specific policy mechanisms (see Montero and Baiocchi, 2022). Here, the selective definition of policy success becomes a rhetorical device to mobilize political support and resources for specific policy agenda, which may however falter amid various contextual constraints and – despite some generative effects (see Baker and McCann, 2020; Chang, 2017; Lauermann, 2016) – fail to materialize anticipated outcomes (see Stein et al., 2017).

Third, existing contextual barriers for urban policy mobility imply that many aspects of mobile policies are in fact immobile and thus non-transferable beyond their places of origin.

While most obvious examples include institutional and physical infrastructures that are fixed in place, the policy mobilities literature has increasingly reflected upon deliberate attempts by policy actors to purposefully render undesired elements invisible from the policy success – or failure – stories (see Lovell, 2017; Nciri and Levenda, 2020; Webber, 2015).

Therefore, policy learning in urban policy mobility is constructed not only geographically and historically, but also 'through socially contextualized means' (Peck and Theodore, 2015: 28), discursively forming policy imaginaries and specific learning patterns (see also Temenos and McCann, 2012).

Issues and Gaps

The 'mobility turn' in these recent writings has generated some important scholarly contributions to our understanding of urban policy mobility regarding its much contentious nature. However, a few issues and gaps remain in the current use of policy learning in the policy mobilities literature, which limit a more systematic reflection on complex interactions and processes between actors, institutions, instruments and ideas in the real-world context of policymaking.

The first concern is the limited consideration into the path-shaping role of the broader circle of policy actors in urban policy mobility, such as citizens, civil society organizations and street-level bureaucrats, whose influence stretches beyond the mobilization of support for or against traveling policy practices. Certainly, there has been growing attention to the intermediary role of diverse non-elite policy actors and their expertise to shape the translation of mobile policies into the local context (see Baker et al., 2020; Lauermann and Vogelpohl, 2019; Temenos, 2017; Weller, 2017). Yet, most of the discussion has been restricted to their activities in advocacy for or resistance to policy adoption outside the policymaking arena, failing to situate their actual roles for contributing to concrete policy components within the overall policy cycle.

Second, the diversity of policy actors who are – although unevenly – present across various moments of the policy process indicates that policy learning in urban policy mobility can occur in diverse forms about different aspects of policymaking with diverging effects that will be drawn from multiple sources of information. Recognizing the multiplicity of the sources, contents and timing of policy learning thus has an important implication for understanding the deliberate policy choices to select information from a vast amount of emerging knowledge, transform those lessons into policy instruments and utilize them in specific policy stages. Much is indeed said about how piecemeal learning about policy ideas and narratives frames and moves – or fails – traveling policy practices as a whole (see Bok and Coe, 2017; Borén and Young, 2021; Pitton and McKenzie, 2022). However, seldom has the literature touched upon the link between policy learning and the actual policy actions that puts together policy elements and implements them into effect.

Third, the localization of traveling policy practices, spanning from their initial encounter, selective lesson-drawing and instrument choice to final implementation, occurs in a context-bound policy space, which features place-specific – and varying – capacities and constraints for different policy actors within and across multiple governance levels. In policymaking, context refers not only to the geographical, institutional and social embeddedness of urban policy mobility within the relational politics of scale-making (see McKenzie and Aikens, 2021; Prince, 2017; Robinson, 2015; Savage, 2020). Also, and more importantly, it entails sets of multifaceted competences (skills) and capabilities (resources) that challenge the practical ability of policy actors to understand burgeoning social problems, formulate their policy solutions and put those decisions into action (see Wu et al., 2015; see also McLean and Borén, 2015). So far, the contextual understanding of urban policy mobility has revealed less about the political, organizational and technical conditions of local policymaking that may facilitate or obstruct the effective translation of learned lessons into the unfolding policy process.

Situating Policy Learning in the Local Policymaking Context

The main tenets of the policy mobilities literature draw from the limits of the earlier political science concepts for policy learning, namely policy transfer and diffusion (see Dolowitz and Marsh, 2000; Rose, 1991; Stone, 1999). Since then, however, a much wider literature on its multidimensional characteristics has emerged, aiming to decipher the ambiguous relationship between their contributing factors and generative effects for policy change (see Dunlop et al., 2018).

Contrary to the common assumption behind the innate capacity of policy actors to learn, these writings provide a more nuanced understanding of its diverse patterns and their implications for local outcomes of urban policy mobility along the following analytical elements: *actors*; *sources*; *types* and *effects*.

Actors of Learning
Broadly speaking, policy actors refer to all possible individuals, groups, organizations and networks who make both direct and indirect contributions to policymaking activities at any point in time (Howlett et al., 2020: 92). As the policy process moves forward, however, only a smaller number of them will be able to frame problems, make alternative solutions and convert them into outputs, each of whom will have a specific level of policy capacity to undertake their roles and tasks (Kingdon, 2011). As such, epistemic communities comprise an important issue-framing subset of the policymaking circle in cross-border policy learning (Dunlop, 2009).

Yet, their epistemic authority may not always extend to the rest of the key activities in urban policy mobility. Instrument selection, decision-making or output implementation – and their evaluation – require different sets of skills and resources to navigate through the political and technical complexities of policymaking at a collective level (see Capano et al., 2024). Furthermore, the increasing collaborative nature of urban policies points to the important relevance of citizens and civil society organizations and their deliberative power in knowledge production across multiple decision points in the policy process.

Sources of Learning
While not always rational, policymaking inevitably involves a deliberate act of decision-makers to process some kind of knowledge that will in one way or another influence the succeeding policy pathway (Chindarkar et al., 2017). Despite being an important one, international 'best practices' are not the only source of evidence and information in this process. As modern policy studies have already acknowledged, policy learning does not take place in a historical vacuum (see Hall, 1993). It occurs in a context-bound policy space with established actors, institutions, instruments and ideas, all of which feature significant enduring legacies, prompting decision-makers to utilize available knowledge about existing policy elements from their past actions (see Dussauge-Laguna, 2012).

This iterative nature of policymaking implies that policy learning in urban policy mobility is not a one-time event that is isolated from other stages of the policy process. As traveling policy practices become formulated into and implemented as local policies, decision-makers deal with a variety of new information about on-the-ground policy experiences through monitoring and evaluation of adopted, ongoing or finished interventions (Vedung, 2010). Although challenging, such a reflexive feature of policymaking can provide them a knowledge base from which to make in-process assessments, in-flight adjustments and *ex-post* changes to the next round of the policy process (see Nair and Howlett, 2016).

Types of Learning
Understanding how acquired knowledge becomes utilized across the policy process ultimately begs the question of how policy learning takes place by whom in what learning capacity. While 'learners' in policy learning are typically considered as those who hold decision-making power at any stage of the policy process (Dunlop and Radaelli, 2013: 606), a long line of research has theorized diverse types of policy learning that different 'learners' may undertake to varying extents (see Bennett and Howlett, 1992; May, 1992; Sabatier, 1988).

The first learning type concerns the acquisition of problem-centered knowledge to frame policy issues at stake and set corresponding objectives (*Problem Learning*), which can be sourced from diverse types of experts within epistemic communities (see Dunlop, 2010). The second type concerns learning about the means-ends connection between policy instruments and their anticipated outcomes (*Instrumental Learning*), gaining knowledge about technical details of policy tools from instrument experts (see Simons and Voß, 2018). The third type concerns accumulating lessons about the political complexities of the policy steering process (*Political Learning*) that pertain to the working relationships between relevant governmental actors toward effective policy delivery (see Howlett et al., 2015). The last type concerns the more fundamental form of learning that results from multi-stakeholder communication within the broader policy universe (*Social Learning*), influencing decision-makers' political-ideological frame of reference to make transformative changes (see Siddiki et al., 2017).

Effects of Learning

Regarding the complexity of translating learned lessons into policy outcomes, the policy mobilities literature has shown the negative and unintended results of policy learning in urban policy mobility, such as policy failure (see Temenos and Lauermann, 2020). Yet, a more detailed look at its entire process reveals more substantive effects of policy learning, which can occur at different levels of abstraction, influence various aspects of policymaking and thus go beyond the discursive framing of success or failure (see Howlett and Cashore, 2009; see also Moyson et al., 2017).

One, and the most typical, effect of policy learning is minor adjustments to existing policy instruments as well as their real-life use without modifying the policy objectives on the agenda (*Incremental Change*), struggling to move beyond the established mode of operation (see Baek et al., 2018). Another typical effect is major modifications to key policy instruments and specific program contents that are utilized to achieve existing policy objectives (*Program Change*), which, however, do not influence the overall policy goals and the belief system of decision-makers (see Voorberg et al., 2017). Lastly, although rare, policy learning can also generate a more systematic shift in the policy paradigm that fundamentally alters the main ideas, preferences and priorities of policymaking (*Paradigmatic Change*), resulting in radical changes to the decision makers' way of doing policy work (see Zaki et al., 2023).

Case Study Setting and Methods

Wiener Klimateam is Vienna's first citywide PB. It was launched as a pilot project of the city's energy planning department (MA20) in six districts between 2022 and 2023. It was developed through the collaboration between an international NGO and the City of Vienna within the EU's climate innovation initiative (EIT Climate-KIC). It shares a few design features that are common across the recent examples of PB in European cities, in terms of objective (democratic awareness-building/governance innovation), tool (digital participation) and resource (strong government support) (see Wampler et al., 2021). The participating districts in the annual budgeting cycle divide the budget of 6.5 million EUR depending on their respective population size, which are spent on citizen projects that are developed through the following stages: a) on-/offline idea submission; b) expert screening; c) co-creation workshop; and d) citizens' jury. Once the final projects are selected, the districts – based on the recommendations from the co-creation workshop – have the responsibility to reach out to the municipal departments with relevant jurisdiction to implement them, which are to be realized within two years.

The analysis below illustrates the link between policy learning and policy outcome in the localization experience of PB in Vienna, focusing on one of the first *Wiener Klimateam* pilot districts: Margareten. It highlights the interconnections and relationships between different actors, sources, types and effects of policy learning within and across its five core policy stages: 1) issue-framing; 2) instrument selection; 3) participatory process; 4) output implementation; and 5) evaluation (see Figure 1). The use of tailored methods reflects this stage approach: i) a qualitative content analysis of 13 expert interviews with the key stakeholders from the issue-framing and instrument selection stages; ii) participant observation of the co-creation activities and their systematic analysis along theory-driven process evaluation criteria; iii) two stakeholder workshops and 10 additional expert interviews with the district office and the municipal departments who are responsible for the implementation of the final projects; and iv) a comparative analysis of the participatory designs of the pilot and the current *Wiener Klimateam*, using the evidence from its internal evaluation, to assess the longer-term feedback effects.

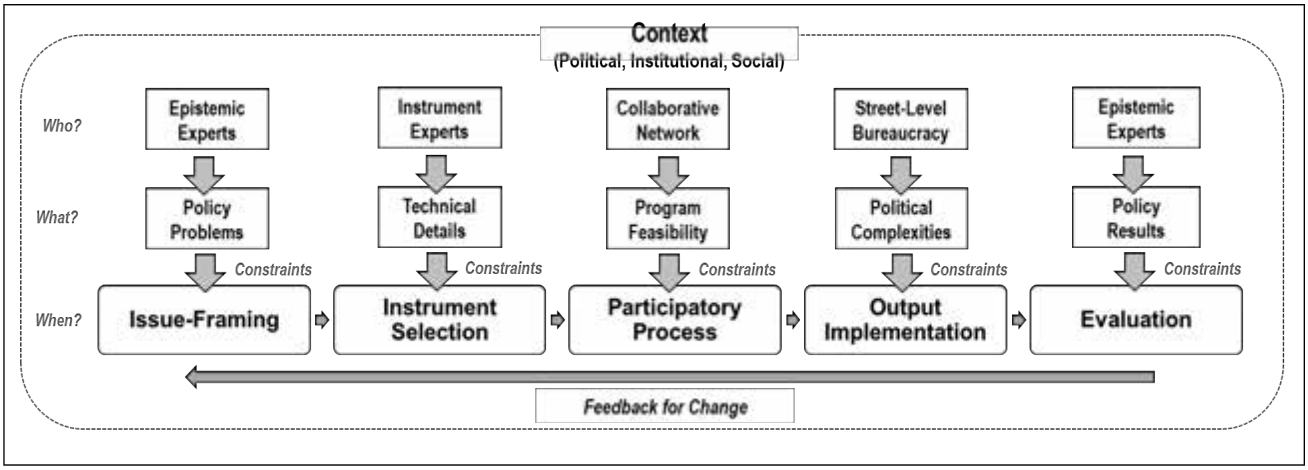

Figure 1. A Heuristic Model: The Flow of Knowledge in Policy Learning within Wiener KlimateamSource: Authors' own elaboration after Dunlop et al. (2024); Goyal and Howlett (2024); and Howlett et al. (2017).

Varieties of Policy Learning in Urban Policy Mobility

The collaboration between the City of Vienna and the partners of EIT Climate-KIC was a crucial milestone for *Wiener Klimateam*, resulting in a broad policy concept to mainstream citizen participation into climate budgeting in Vienna. One fundamental contribution was the new working relationship with an international NGO with multiple consulting experiences in other European PB projects, who was later commissioned to steer the formulation process of a concrete policy program. As we will see, however, the learning processes that shaped the core components of *Wiener Klimateam* and influenced their outcomes varied and occurred far beyond this cross-border partnership.

Policy Learning in Issue-Framing

For framing the issues to be resolved through PB, another set of policy actors with a different type of knowledge entered the preparatory phase of *Wiener Klimateam*. This comprised a group of local civil society organizations, scientific and public-sector experts who were mobilized by MA20 as an advisory board. Their main task was to guide the identification of the vulnerable social groups in the city's decision-making process and the strategies to activate their participation as well as the formulation of the key *Wiener Klimateam* objectives (climate protection; democratic awareness-building; governance innovation; and social justice).

The acquisition of expert knowledge on Vienna's social and environmental issues was accompanied by existing scientific evidence and past policy experiences among the members of the advisory group, whose expertise was related to specific local issues. On the one hand, the quantitative indicators that were developed in prior studies were used to identify the city's districts that are most affected by Vienna's socio-spatial inequalities. On the other hand, the district offices who had previously experimented with similar budgeting projects provided qualitative inputs about some practical criticalities, including the low participation rate of vulnerable social groups and the street-level implementation of participatory outputs (see Ahn et al., 2023).

The utilization of the acquired knowledge took place in two concrete ways. First, the varying levels of socio-spatial inequalities across the city's 23 districts were used to select the first *Wiener Klimateam* pilot districts with one of the highest vulnerability scores based on heat island effect, socio-economic inequalities, life satisfaction, and green infrastructure. Second, the perceived failures of the previous budgeting projects were used to set greater inclusion targets in an open-to-all participatory process as one of the main agendas, resulting in the additional selection of civil society organizations and public institutions to act as local multiplicators. These decisions to expand the representativeness of the wider public based on district-level inequalities marked the key difference with the democratic objectives of earlier PB cases, which had explicit rules for targeted participation of the urban poor at the neighborhood level (see Fung, 2006).

Policy Learning in Instrument Selection
The actual role of the international NGO, in contrast, was limited to developing the participatory instruments for *Wiener Klimateam* and informing the key program stakeholders, such as the municipal departments, the district offices and the local multiplicators, about their practical use to achieve the set agenda. This knowledge exchange drew from their prior experiences with similar instruments in the PB projects in Antwerp, Lisbon and Paris, which were, however, modified through stakeholder processes and brought in line with the main policy priorities of the City of Vienna and the program objectives of *Wiener Klimateam*.

Therefore, the transfer of expert knowledge by the international NGO focused not only on the successful instrument use in the 'best practice' examples of PB. Through multiple stakeholder workshops, involving some 70 local policy actors in total, the instrument selection process also kicked-off mutual learning about the applicability of the proposed participatory tools to the local governance environment and their compatibility with the specific needs of the program stakeholders. As such, the selection of the *Wiener Klimateam* instruments built on merging both international and local knowledge bases with the instrumental thinking of the knowledge holders about how the instruments could work in a practical setting and advance the anticipated program objectives.

The resulting effects of such two-way knowledge transfer can be traced in the application of new participatory instruments that set *Wiener Klimteam* apart from the 'best practice' examples considered. The first of these elements is the use of methodological toolboxes that were distributed to offline participants. These contained information about the environmental conditions and existing policy programs in the participating districts as well as interactive learning tools to facilitate their effective participation in the budgeting process. Second, greater emphasis was laid on face-to-face deliberation of citizens in the formulation of concrete participatory outputs through co-creation and their final selection by citizens' juries. This priority for real-time collaboration between citizens, scientific and public-sector experts in the participatory process showed a contrast with the strong reliance on online tools in other European PBs (Wampler et al., 2021).

Policy Learning in Participatory Process
The participatory process of *Wiener Klimateam* aimed at generating place-based climate actions from the bottom up. They were first gathered through on-/offline idea submission, which were then screened and selected by the municipal departments and the district offices according to their topical relevance and technical feasibility. The co-creation workshops were intended to refine these ideas into implementable projects based on the collaboration between the citizens whose ideas were selected in the screening phase, practitioners from the municipal departments and the officials from the participating districts.

While the main source of knowledge in the collaborative process originated from the citizen ideas in the initial submission phase, the importance of guiding information from MA20 must be acknowledged. The participating citizens and the public-sector experts of the co-creation workshops were given scores (from high to low) for the foreseen feasibility of each of the successfully screened citizen ideas based on the *Wiener Klimateam* selection criteria[1]. Based on this knowledge, they could voluntarily choose any submission of their preference, combine related ideas and provide new information about the content, location, tasks, cost estimates, anticipated climate and social benefits for the final projects.

The core contribution of the collaborative network was the creation of new policy outputs (five in Margareten), which were yet framed by the co-creation design based on the priorities of Vienna's existing climate policy framework. The effect of collaborative learning in the presence of strong public stewardship was thus connecting expert-led solutions from the expert-identified problems to the expert-formulated objectives. In turn, the participating citizens were given little structured guidelines and relevant information to make independent decisions for co-creation outputs based on previously identified climate needs and challenges from the bottom-up.

Policy Learning in Output Implementation
The five final *Wiener Klimateam* projects pertained to small-scale circular economy, urban greening and climate awareness-building measures: a) Repair Café; b) Superblock; c) Car-free Saturday; d) Street Greening; and e) Façade Greening. Since MA20, in charge of developing energy concepts and strategies, has no administrative

1 1) climate impact; 2) community orientation; 3) time feasibility; 4) legal feasibility; 5) cost feasibility; 6) maintenance feasibility; and 7) jurisdiction.

responsibility for such activities, these were first transferred to the district office of Margareten, which was tasked to contact the competent municipal departments and to steer their implementation. As the implementing agencies, the selected municipal departments on the other hand had a great level of freedom to reinterpret and redesign the final projects based on their own interests, competences and capabilities.

Once the implementation began, however, the different municipal departments faced a multitude of constraints to carry out the final projects as intended by the participants in the co-creation process. The first of these constraints was their ambitious and sometimes ambiguously formulated objectives and content, which made their realistic operation in the actual implementation setting difficult. Second, multiple municipal departments were assigned to jointly undertake the final projects without sufficient coordination mechanisms to oversee their effective communication and collaboration. They were left to self-determine their roles and responsibilities in the implementation process. Third, the incentives from taking on the implementation task were considered by the implementing departments as "minimal" both in political and financial terms. Moreover, they were competing with their running programs and putting an extra burden on their limited human resources.

The major lessons that were generated through the implementation activities therefore referred to the political complexities behind translating citizen ideas into actionable solutions. While the key actors within MA20 maintained informal communication with the implementing departments, the utilization of this new knowledge became highly restrained by the lack of their continuous involvement to monitor *Wiener Klimateam* beyond the participatory process and make *ad hoc* adjustments to the unforeseen challenges of implementation. As a result, several changes were made to all final projects, in terms of their designs and objectives as well as target groups and areas. This followed substantial negotiations between the district office and the implementing municipal departments, causing serious delays to the initial implementation plan. While the official Wiener Klimateam process in Margareten ended as of December 2024, only two of the final projects (Repair Café and Car-free Saturday) were fully implemented.

Policy Learning in Evaluation

The participatory activities of *Wiener Klimateam* were accompanied by an internal monitoring and evaluation process. In the first pilot year, 2022, a research team from a local university was commissioned by MA20 to develop evaluation indicators, which were used by a public agency of the City of Vienna to observe and review the next budgeting cycle in 2023. Focus groups, participant observation and participant feedback were used to elicit evaluation data.

Given the evaluation methods used and the type of questions asked, the acquired information about the operation of *Wiener Klimateam* was strictly limited to the perceived quality of the participatory process based on subjective assessment rather than the effectiveness and impact of the overall program against the set objectives. The qualitative indicators, such as informedness, satisfaction and willingness to participate in similar events, were less adequate to reveal the critical challenges to *Wiener Klimateam* that went much beyond the participatory process itself. As a result, for instance, it was not possible to verify if their activation strategies were indeed able to involve those who are most affected by climate hazards and democratic deficits. Similarly, the process evaluation, only involving the participating citizens, proved to be difficult in identifying the critical barriers that the implementing departments faced in order to implement the results of the participatory process at the street level.

Based on the evaluation results, the most recent *Wiener Klimateam* from September 2024 pays special attention to facilitate transparent and simple communication for potential citizen participants. One resulting change to the participatory design is the addition of open-to-all citizen participation at the screening stage, who now co-select citizen ideas for the co-creation workshops with public-sector experts. The feedback effect of learning from monitoring and evaluation therefore pertained to the minor modification of the participatory process that was deemed more open and inclusive. Consequently, there were no major changes to existing activation strategies and participatory instruments toward enabling explicit recruitment of disadvantaged social groups in climate change mitigation nor sustained engagement of most relevant policy actors throughout the whole budgeting cycle.

Discussion

The localization experience of PB in Vienna suggests that urban policy mobility is a complex multifaceted process. It involves more than just policy elites' selective reproduction of traveling policy practices based on professional know-how of transnational policy communities. Although globally circulating expert knowledge plays a significant role in this process, it is not the only source of inspiration for local policymaking. Rather, as shown, key decision-makers uproot various types of policy input from a diverse range of sources and actors throughout different stages of the policy cycle. Consequently, policy learning can take multiple forms according to who learns from whom, about what, and at what time. The specific type of learning that emerges will have a distinct effect on the overall policy process, contingent on the decision-makers' capacity and willingness to apply the lessons learned.

Table 1. Multistage Policy Learning and Outcome in *Wiener Klimateam*

Stage	Issue-Framing	Instrument Selection	Participatory Process	Output Implementation	Evaluation
Actors	Scientific/ Public	International NGO	Citizens/ Public	Street-Level Bureaucrats	Scientific/ Public
Source	Past Practice	Best Practice	Co-creation Process	On-the-Ground Experience	Internal Evaluation
Content	*Problems/ Failure*	*Instruments/ Practicality*	*Solutions/ Feasibility*	*Barriers/ Conflicts*	*Perception/ Success*
Type	Problem	Instrumental	Instrumental	Political	Political
Constraints	*Admin.*	*Design*	*Operational*	*Admin.*	*Design*
Effect	Program Change	Program Change	Program Change	No Change	Incremental Change

Source: Authors' own elaboration. See also Dunlop and Radaelli (2013) and Wu et al. (2015).

Table 1 summarizes the complex dynamics of such multistage policy learning and its link with concrete policy outcomes in *Wiener Klimateam*. The key decision-makers of Wiener Klimateam engaged in epistemic learning, where specialist knowledge is used to define uncertain problems and guide the selection of appropriate instruments (Dunlop and Radaelli, 2013: 609). This process, however, extended beyond abstract policy concepts and 'best practice' tools offered by international experts. They drew significant lessons from locally sourced evidence and information, which were crucial in framing specific policy issues and tailoring policy instruments to the local context. Continuous internal learning took place as *Wiener Klimateam* advanced through each stage. This learning emerged from ongoing interactions between decision-makers and local policy actors facilitated through stakeholder engagement, public-citizen collaboration, and process evaluation. Each actor contributed specialized knowledge based on their unique roles and responsibilities within the evolving policy process.

The effects of policy learning revealed many constraints on the *Wiener Klimateam*'s ability to acquire and use policy-oriented knowledge effectively in real-world policymaking (see also Ahn and Kazepov, 2024). The first of these constraints was *administrative*. Without explicit competence, MA20 was unable to effectively oversee and control the implementation activities, which otherwise would have been considered to breach the administrative autonomy of the implementing departments. This lack of competence provided the implementing departments with some discretionary power at the street level, for instance, by allowing them to make substantial modifications to the original participatory outputs. The second constraint pertained to *design*. The open-to-all participatory approach was inadequate to enhance the involvement of vulnerable groups experiencing climate vulnerability and a democratic deficit, which were the original objectives of *Wiener Klimateam*. Despite the genuine innovative outreach effort through local multiplicators, their working areas and target audience had less connection to the identified target vulnerabilities from the issue-framing stage. This led for instance to a spatial concentration of the submissions around the local multiplicators and offline events rather than the most needed areas with disadvantaged individuals and communities. Detection of such limitations was made difficult by the design of its monitoring and evaluation framework that was geared toward highlighting the subjective success factors of

the participatory process. Another critical constraint was *operational*. The lack of a clear collaborative structure in the co-creation workshop made it difficult for the participating citizens to deliberate their needs and interests from the bottom up to co-develop actionable solutions with public-sector experts. Many of the participants were not the ones who submitted the selected ideas and were not provided with sufficient knowledge about the practicalities around their implementation to make informed decisions based on group deliberation and collaboration. This resulted in highly unfocused participation dynamics that were dominated by individual expert participants who mostly created workshop outputs based on single citizen ideas.

Conclusions

Since the 'mobility turn', the policy mobilities literature has shed light on the highly politicized nature of urban policy mobility. Scholars in this debate argue that interest-driven policy actors selectively – and limitedly – draw lessons from international 'best practices' and modify them in line with prevailing economic pressures and anticipated political gains. Departing from the earlier positivist idea that lesson-drawing follows instrumental thinking of rational policy actors, they lay special emphasis on power-laden policymaking behaviors that frame particular narratives, contents and objectives of policy learning at the urban scale. So far, however, less effort has been made to consider the contextual influence of local policymaking on diverse patterns of policy learning and their varying implications for place-specific policy outcome by looking at the entirety of the policy process. This article, in contrast, links the dynamic process of policy learning with the actual learning effect on the policy process by disaggregating its complex relationship into the five core stages of the policy cycle. This analytical approach enabled a detailed assessment of the concrete learning processes and the flow of the acquired knowledge that together shaped the course of urban policy mobility in its truer local form. The results have illustrated that policy learning in urban policy mobility can occur in multiple forms and involve a diverse range of policy actors at different stages of its life cycle. However, the effects of this learning can vary depending on existing political, operational and analytical capacity constraints in policymaking.

Our policy-oriented approach, and the framework that we have put forward, presents a few analytical advantages over the current use of policy learning in the policy mobilities literature in the following ways. First, it captures the implications of the diverse roles and responsibilities, skills and resources of policy actors throughout the entire localization process of a traveling policy practice. This allows to disentangle the multiple objects of policy learning in urban policy mobility that emerge from their specific characteristics. Second, it locates multiple sources of policy learning and their movement across different stages of the policy process. This reveals the capacity and willingness of decision-makers to selectively extract lessons from emerging information, thereby determining the type of learning that ensues. Third, it helps to distinguish different types of learning and their generative effects on policy outcomes. It elucidates which policy outputs originate from specific learning activities at different levels of abstraction, as well as its political (in)ability to influence broader policymaking in the long run. Together, these elements enable a more systematic assessment of the expected policy effects from different types of policy learning under various policy circumstances. So far, this relationship remains elusive in existing research on urban policy mobility.

Within the policy mobilities literature, the interpretative lens on policy learning in urban policy mobility is considered to have been shaped by the 'discipline-specific specialization' of urban researchers, which differs from a more diagnostic approach in policy studies (Temenos and Lauermann, 2020: 1114). Yet, both strands of literature share a common ground: to uncover the complex social and political interactions that determine who teaches and who learns, which ideas become mobile and which ones remain immobile, and which lessons localize and which ones do not. What separates urban studies on policy mobility from other disciplines, however, is the strong thematic focus on urban policies that feature specific learning characteristics compared to national policies. These increasingly include, among others, learning from collaborative knowledge production through community-based participatory instruments within non-hierarchical network-based governance arrangements. Together, they can generate more complex patterns and processes of policy learning that do not always follow the traditional policymaking steps in a clear-cut fashion. Future research then may consider the policy-specific factors and effects of policy learning that shape the localization process of mobile 'urban' policies.

Actors in power networks: an institution framework of historic urban district renovation actors in China

RWTH Aachen University (Christa Reicher)
Email: xin.li1@rwth-aachen.de; reicher@staedtebau.rwth-aachen.de

Abstract
The powers, resources, motivations, and mindsets of actors play a critical role in shaping the conservation, renovation, and redevelopment of historic urban districts, as well as broader contemporary urban issues. Yet, understanding the roles of individuals and institutions remains challenging. Referring to bounded rationality hypothesis and Michael Mann's theory of power networks, this paper proposes a comprehensive analytical framework to examine the actor-institution landscape. It offers a panoramic view of the intricate and often chaotic interconnections among key actors as well as their power resources, institutional affiliations, interrelations, and action logics. This framework is then applied to the case of historic urban district renovation in China, providing insights from an actor-institutionalist perspective, such as the imbalanced power distribution and party-state authority fragmentation.

Key words: Actor; power network; institution; historic urban district; Chinese urban renovation

1.Introduction

Actor constellation plays a crucial role in urban renovation, conservation, and redevelopment. (Neugebauer, 2014, pp. 57–66; Imperiale et al., 2024; Li, 2025) Since the processes and the results of the urban interventions can be largely shaped by different actors' power, resources, motivations, and mindsets (Li, 2025), it is essential to recognize the intentions, capacity, and behaviour pattern of the actors, especially the key actors involved in historic urban district (HUD) transformation. However, it is far from an easy task to describe and understand the diverse array of individuals in real-world urban issues.

The paper adopts an actor-centred institutionalism perspective and bounded-rationality hypothesis, provides a descriptive framework that examines the power resources, interrelations, institutional organization, mindsets, and action logic of key actors based on Michael Mann's philosophy. Then the paper will apply this description framework in the context of residential and commercial-residential-mixed HUD renovation in China, describing the characters of four key power networks, namely political network, local community network, economic network, and expertise network based on extensive theoretical and experimental studies on representative organization studies and renovation cases. In the end, the study offers insights and critical reflections on the power distribution and the actor institutional contexts in the HUD renovation in China as well as the potential and limits of the descriptive framework. The proposed framework and contextual analysis aim to contribute to a foundational understanding for future research in HUD renovation and broader urban governance issues.

2.Literature Review

2.1Bounded-rational hypothesis and actor-centred institution

HUD renovation and regeneration typically involve a wide array of actors, varying significantly in capacity, mindset, and patterns of action. It is nearly impossible to analyse each individual actor in detail. A more feasible approach is to identify and focus on the shared characteristics, power resources, and decision-making logics that meaningfully influence urban renovation within specific groups of actors.

Several academic hypotheses and theoretical perspectives have been proposed to explain shared behaviours, decision-making patterns, and action logics that extend beyond the individual level. Two of the most influential hypotheses are (1) the rationality hypothesis and (2) the bounded rationality hypothesis. According to the rational hypothesis, individuals are assumed to make a rational choice and "systematically and purposefully do the best they can to achieve their objectives, given the available opportunities," (Mankiw, 2015, p. 6) or to say, actors can "order" the outcomes of the game according to their consistent preferences. (Lucchetti, 2011, p. 5) The "ordering" or "decision-making" always involves a comparison of marginal benefits and marginal costs (Mankiw, 2015, pp. 6–7), mathematically towards maximizing a certain utility or payoff function. While the rationality hypothesis remains prevalent in economic analysis and certain areas of social science, it can be limited when comes to urban studies. In the case of HUD renovation and other complex urban issues, the "bounded rationality" hypothesis (Simon, 1997;

Gigerenzer, 2020) can be a more referential framework. The bounded rationality hypothesis acknowledges that actors often face cognitive constraints (Simon, 1990), and are thus they may be unable to collect all the necessary information, calculate the marginal benefits, costs, and utility, and make an optimized or fully informed decision, even though sometimes they intend to act in a rational manner.

Institutional studies and "actor-centred institution" discussions serve as another referential perspective in understanding actors' mindsets and behaviours under the bounded rational hypothesis especially when actors are not fully informed or capable of purely rational decision-making. "Institution" can refer not only to organizations or agencies, but to a wider range under the New Institutionalism discourse, including "a set of formal rules, shared norms and understandings, and standard operating practices." (Sorensen, 2017, p. 251) It can be taken as "the rules of game... that shape human interaction" (North, 1990, pp. 38–40)Douglass North develops an analytical framework for explaining the ways in which institutions and institutional change affect the performance of economies, both at a given time and over time. Institutions exist, he argues, due to the uncertainties involved in human interaction; they are the constraints devised to structure that interaction. Yet, institutions vary widely in their consequences for economic performance; some economies develop institutions that produce growth and development, while others develop institutions that produce stagnation. North first explores the nature of institutions and explains the role of transaction and production costs in their development. The second part of the book deals with institutional change. Institutions create the incentive structure in an economy, and organisations will be created to take advantage of the opportunities provided within a given institutional framework. North argues that the kinds of skills and knowledge fostered by the structure of an economy will shape the direction of change and gradually alter the institutional framework. He then explains how institutional development may lead to a path-dependent pattern of development. In the final part of the book, North explains the implications of this analysis for economic theory and economic history. He indicates how institutional analysis must be incorporated into neo-classical theory and explores the potential for the construction of a dynamic theory of long-term economic change. Douglass C. North is Director of the Center of Political Economy and Professor of Economics and History at Washington University in St. Louis. He is a past president of the Economic History Association and Western Economics Association and a Fellow, American Academy of Arts and Sciences. He has written over sixty articles for a variety of journals and is the author of The Rise of the Western World: A New Economic History (CUP, 1973, with R.P. Thomas, which can structure the "courses of actions that a set of actors may choose" (Scharpf, 1997, pp. 38–40) and the departmental identities of actors shape their selective perceptions. Actors are likely to take into consideration the established, customary rules and traditions that form a cultural and normative institutional framework, including but not limited to as their roles in organizational structure, their interpersonal networks, path depending, traditional customs, etc. (Li, 2025) Even though the "rules of game" may not be the only determinant that influences actor choices and renovation results in all cases, they still provide meaningful insights into how social activities are organized and regulated. Moreover, they help render actors' decisions and behaviours intelligible—and even "predictable" to "those sharing in rule knowledge," albeit in a "limited conditional sense." (Burns, Baumgartner and Deville, 1985, p. 256; Scharpf, 1997, p. 40)

2.2.Power network: Michael Mann's studies

Michael Mann's "power network" framework (Mann, 2012, pp. 1–33) provides an insightful structure by examining actors' mindset and behaviour as well as their power and capacity within institutionalized "power networks." It can be highly referential to urban studies and HUD renovations for (1) it can enable a panoramic description framework out of the complex, chaotic and intertwined interconnections and interactions among diverse actors in the real world; (2) it can shed light on understanding the motivations and mindsets of the actors within social "rules of game;" (3) by situating the actors within the power networks, it can serve as a methodology for studying organizational power (Mann, 2012, p. 6) and help to elucidate actors' power, resources, and capacities, offering insight into how different actors can shape the real-world activities and impacts including HUD renovation processes and results.

Michael Mann interprets societies as "multiple "overlapping and intersecting socio-spatial networks of power" (Mann, 2012, p. 1) from an "organizational level of analysis." (Mann, 2012, p. 2) In his studies, these power networks are "overlapping networks of social interactions" as well as "particular organizational means each possesses to attain human goals." (Mann, 2012, p. 2) The power networks can be authoritative or diffused, intensive or extensive (Mann, 2012, p. 9), while they always feature real connections among people (Collins, 2006, p. 23) and functional

ends and means. (Mann, 2012, p. 12) The overall model presented in Mann's studies can be illustrated in Figure 1. It integrates power, institution, and actor motivation in a single conceptual framework. While it is worth noting that the highlighted "power networks" can only encompass some of "the broadest contours" of the messy human societies. (Mann, 2012, pp. 29–30) Identifying power networks can be tailored according to different scenarios and academic understandings. For example, when Mann applied this methodology framework to national and global history studies, he used identified four fundamental power networks, namely ideology, economy, military, and state(s). However, as for urban issues or HUD renovation at a relatively smaller scale, it remains necessary to re-define and reinterpret the key power networks.

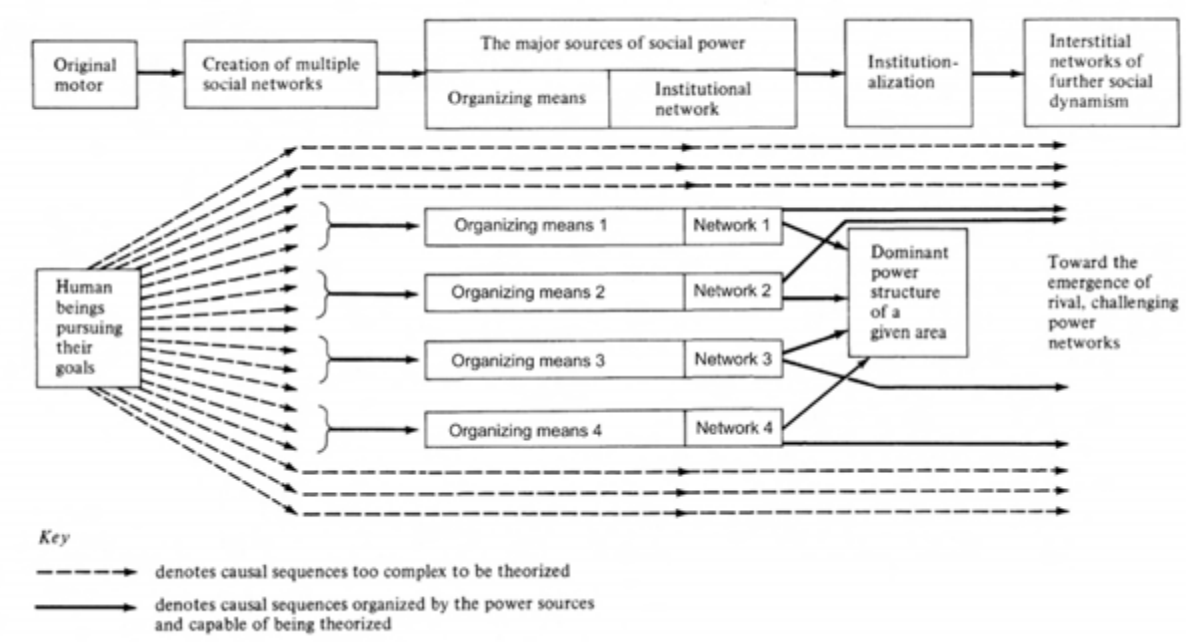

Figure 1: The framework of power network, adapted from (Mann, 2012, p. 29)

3.Create actor power networks in Chinese HUD renovation

3.1.Four key actor power networks in Chinese HUD renovation studies and actions

The paper adapts Michael Mann's theoretical approach to the Chinese residential and commercial-residential-mixed HUD renovation studies and proposes an actor power network framework building on the previous work of Li (2025). Four actor networks are highlighted in these scenarios, namely the political networks, local community networks, economic networks, and expertise networks. Table 1 provides a summary of the interpretation and key actors of each networks in the Chinese HUD renovation context.

Table 1: the four key actor power networks in Chinese HUD renovation studies (key reference (Mann, 2012; Li, 2025))

Power network	Power network interpretation in China	Key actors of the power network in China
Political network	Stem for "the usefulness of centralized, institutionalized, territorialized regulation of many aspect of social relations" (Mann, 2012, p. 26) beyond individuals.	The "party-state" system (Wu and Zhang, 2022) including different levels of government and the Chinese Communist Party (the Party)
Local community network	Stem for the basic requirement and desire on making a better living within a local quarter/ neighbourhood/ jurisdiction	Various local residents and communities in the neighbourhood
Economic network	Stem for "the satisfaction of subsistence needs through the social organization of the extraction, transformation, distribution, and consumption of the objects of the nature" (Mann, 2012, pp. 24–25)	Entrepreneurs, merchants, customers involved in circuits of production, distribution, exchange, and consumption and capital circuits, especially the chengtou platform and property management companies.
Expertise network	Stem for the pursue and recognition of expertise with "social-spatially transcendency" (Mann, 2012, p. 23)	Professional committees, planning institutes, educational and academic institutes, and some professional-based NGS, etc.

These four power networks interacting with each other can contribute to a foundational framework to understand the actor-institution landscape of HUD renovation in specific contexts, both within and beyond China. In the following sections, we would like to examine each of these four networks, depicting and analysing the power sources, institutional structures, mindsets and motivations of actors in Chinese HUD renovation. This part has been summarized from social governance studies, exemplified by the renowned scholars Zhou Li-an (2017; 2019), Zhou Xueguang (2017), and Wu Fulong (Wu, 2015; Feng, Wu and Zhang, 2022; Wu and Zhang, 2022). The research has also examined extensive HUD renovation case studies in big metropolises (such as Beijing) and small/middle-sized cities (such as Anyang).

3.2.Political Network

The power of the political network, primarily referring to the party-state in China, comes from both the state power, such as the administrative and adjudicatory power granted through the elected People's Congress, as well as the leadership of the Party. (Li, 2025) Key actors in the political network can possess extensive authority and extensive resources affecting various aspects of social lives including HUD renovation. They are always among the dominant players with "significant discretionary power." (Zhou, 2019, p. 409) In some cases, their influence can be far-reaching and ambiguously defined, especially when the local states act more as "development leaders" with an "entrepreneurial nature" rather than functioning solely as service-oriented administrators. (Zhao, 2021, p. 157) At the same time, the expansive political power also brings challenges. As the phrase suggests "unlimited power, unlimited responsibility" (Hu and Zhang, 2022, p. 92), heavy political power can lead to the overburden of the governmental systems, especially the ones operating at the grassroots communities.

In response to the challenges of managing a vast territory with diverse social affairs and a large population, the Chinese party-state has established a "hierarchical and multi-scalar" structure (Wu and Zhang, 2022), characterized by a matrix form extending vertically from central (the upper level) to local level (the lower level) and horizontally across a range of function sectors at each level. Scholars (Mertha, 2005; Zhang, 2013, p. 34) have also frequently described the structure of Chinese governance as "tiao (条)" and "kuai (块). "Tiao," or "line" in Chinese, refers to vertical clearances among functional bureaucracies;" while "kuai" captures geographic divisions of local governments" at one hierarchical level. In many, if not most, of the real-world cases in China, tiao-tiao management, that a functional sector is under the direct oversight of central or upper-level departments within the same vertical chain, and kuai-kuai management, that a functional sector is directly accountable to local leaders, are deeply intertwined, resulting in a highly intricate management system.

One other essential aspect of this system is that the political promotion of the lower-level governmental officer is always "determined or directly influenced" by the performance evaluation of the upper-level leaders or supervisors (Wei, 2024, p. 148). Such "upward accountability" (Zhou, 2013, p. 12; X. Zhou, 2017, p. 140) mechanism tends to induce a political-performance-orientated or personal-evaluation-oriented tendency in regeneration projects, such as pursuing fast and visible results without threatening social stability (Wang, Wu and Zhang, 2024; Wei, 2024). Since the state apparatus structured in "matrix form" with functional authority division and "the superior authorities have a strong personal influence in performance evaluation, governmental sectors tend to shrink their governance boundaries (Shi, 2022, pp. 209–228) Therefore, when it comes to highly intricated urban issues requiring interdisciplinary and inter-sector cooperation exemplified by HUD regeneration, the strategies or actions are often fragmented into diverse short-term sections within the shrank scopes of different functional authority and the performance indicators can be over-simplified or drop-dimensioned (Shi, 2022; Li, 2025).[1]

3.3.Local community network
