Reviving the relationship between community and local heritage to outline place-based and shared strategies.
The path towards a new place-based development strategy goes through a process of effective and sustained community engagement (Buuren, 2009; Cook and Nation, 2016). Communities must be largely involved in both the exploration of local potential and the design of actions to take. The starting point is establishing a dialogue with key local stakeholders (institutions, associations, active citizens, etc.): researchers must forge relationships with both the place and the community, develop a critical analysis of the internal dynamics that have eroded traditional ways of living, while identifying latent resources and values that could inspire new development trajectories.

The participatory process is structured around two main phases: co-exploration and co-design. The co-exploration phase is devoted to the collective construction of territorial knowledge based on the recognition by the community of its own values and resources, trying to identify links and potentials. Researchers act as mediators guiding the exploration of local histories, memories, and landscapes. Their role is to connect the existing cultural, social, and ecological values of the territory with emerging opportunities, helping communities rediscover the meanings embedded in their everyday spaces. Community mapping is especially valuable in this phase: it helps visualizing local assets – natural, historical, and cultural – and allows linking places with intangible heritage – memories, rituals, etc. This is particularly relevant to foster a renewed sense of shared responsibility for places. Community maps are not only descriptive tools but also political paths to express collective needs and spatialize potential transformation pathways (Perkins, 2007). The process can reactivate community cohesion, strengthen organizational capacity, and revive a culture of care toward the territory as a common good. It sets the stage for a transition toward a local self-determined development.

The community mapping process requires two fundamental preliminary steps: the establishment of a group of active citizens responsible for collecting materials and identifying other interested citizens to be involved in focus groups; the definition of thematic focuses to explore and map starting from brainstorming and clustering. Thematic focuses help the collection of data, materials, and information. Also, during the co-exploration phases relationships between thematic focuses and priority interests emerge. While the thematic focuses help concentrating common interests to collect available materials, the brainstorming favour the intersections between different interests, facilitate mutual exchange and create dialogue. The co-exploration and co-design phases are not clearly distinguishable. It is a cyclical process that is based on retroactivity. However, the parallel setting between Community-Spatial-Knowledge and Technical-Spatial-Knowledge (Larrain & McCall, 2019.) allows systematizing the results of each session from time to time and allows the initial frame to be updated.

Technical-Spatial-Knowledge includes both the neutral assessment of local resources and gaps, spatial dynamics, and future projections and the structured outcomes of insights generated by community through interviews, participatory workshops, walks, and storytelling.

Building upon the foundation laid in the co-exploration phase, co-design focuses on translating shared knowledge and values into strategies and actions. The phase has to be anchored in a collective vision of the future, place-based and collectively endorsed by the community. Researchers guide and support the design process by supporting the outlining of objectives, prioritization of actions, and alignment of strategic axes with the identified local potential. They introduce best practices, facilitate synthesis, and ensure scientific accuracy to the process, while also leaving the room for local creativity and ownership. In particular, when the co-exploration phase is primarily focused on mapping, the subsequent co-design phase benefits from a clearer spatialization of ideas, allowing the discussion to concentrate on areas with significant heritage value and on areas that are most in need—and most suitable—for enhancement.

This approach proves especially relevant in inner and rural areas where capacity building may be weaker due to depopulation, abandonment, and marginality. While the presence of researchers can facilitate the transfer of knowledge and best practices, effective empowerment requires that the community is willing and adequately equipped to independently lead and sustain the process and translate it into the capacity to organize actions around shared goals.

The co-design phase can be developed starting from a SWOT analysis, leading to the definition of general and shared goals, around which the focus groups are formed. Then, general goals can be further detailed in specific goals and actions and a territorial strategy can be outlined by answering three key questions: who? where? when? That is, subjects who might promote an action are identified, places that could be catalysts of transformation are mapped (Wilson and Sanyal, 2013), priority actions and their timeline are established, also by discussing the links with the other actions and the potential barriers to their implementation. As a result, the co-design phase becomes a launchpad for self-sustained development, driven by a community that has regained the sense of responsibility toward the future of its own territory.

The two-stage process briefly outlined is characterized by a cyclical nature and generates a spiral effect involving the community. The two main phases are closely related and intertwine with each other; moreover, community

engagement is not limited to the initial identification of the key actors but expands over time feeding both phases (Figure 1). This cyclical process also allows internal evaluation of the work through participant debate, influencing both the method and the outcomes.

An ongoing experience in Campania region: first outcomes and possible insights

The outlined methodological path is being currently tested on the municipality of Guardia Sanframondi, in the inner area Tammaro-Titerno, one of the NSIA project areas identified in the Campania region for the Province of Benevento (Figure 2).

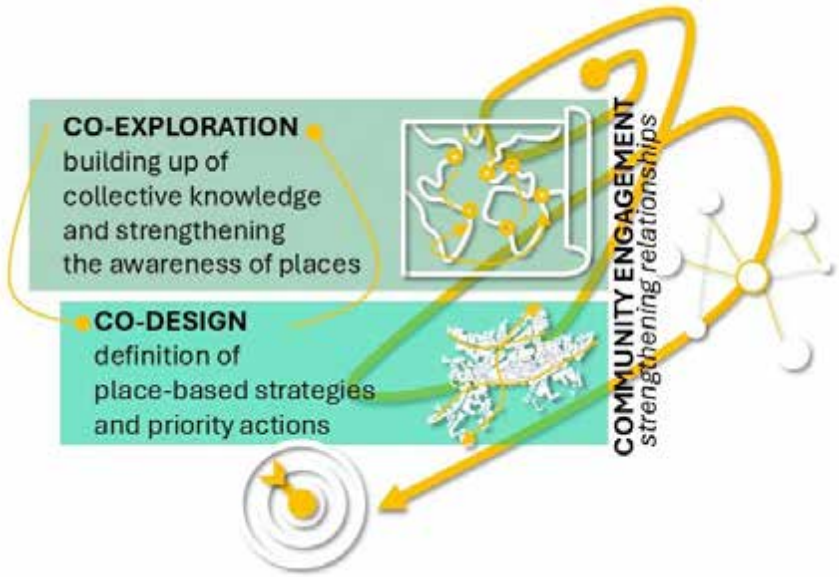

Figure 1. The methodological path
Source: Authors' elaboration

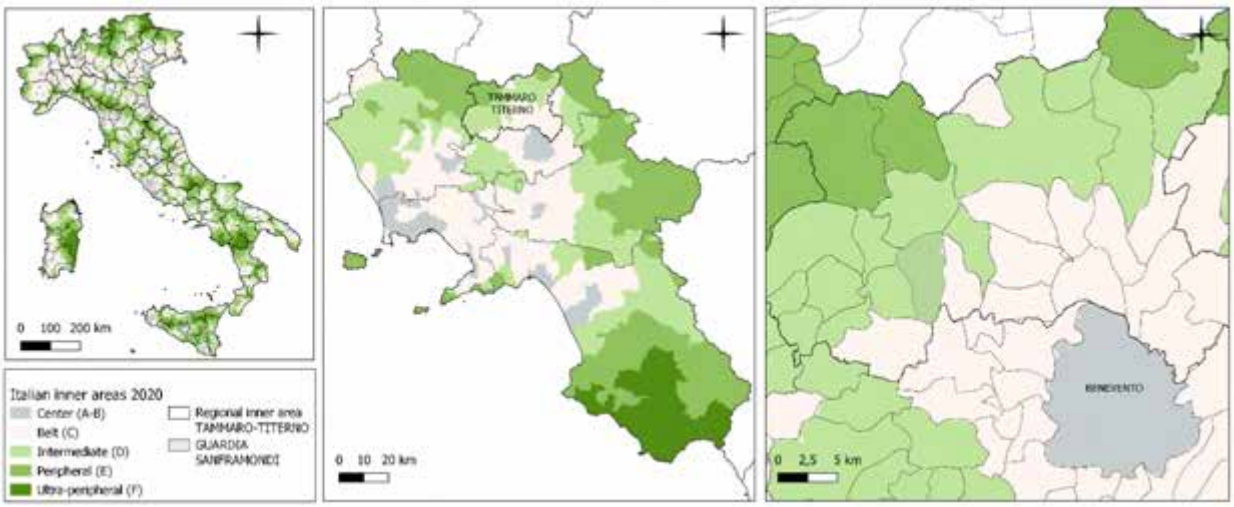

Figure 2. The Italian classification of Inner areas, the Tammaro-Titerno inner area in the Campania Regione and the Municipality of Guardia Sanframondi in the province of Benevento.
Source: Authors' elaboration

Guardia Sanframondi hosts a population of about 5,000 inhabitants and suffers from a chronic depopulation, like almost all the municipalities of the Tammaro-Titerno area. The municipality is characterized by a valuable, but almost totally abandoned, medieval center and a widespread presence of wine yards, olive groves, and other crops, being agriculture the main income source of the inhabitants.

The work started with the identification of an initial group of stakeholders to investigate the main problems of the place. In particular, the main concern is about the advanced state of abandonment of the historical center, shared both by the community and local institutions. Meanwhile, onsite inspections and desk analysis of demographic and territorial dynamics were started by the research group. The first active citizens already involved during the numerous onsite visits, representatives of local associations and the Mayor were invited to the kick-off meeting. The project was presented, and the main topics of interest were identified to start the co-mapping. After the first meeting, the others took place in small groups in relation to the topics of interest. The co-mapping was accompanied by informal interviews, walks, collection of materials such as photos, testimonies, local bibliography, and labs with high school students. As the knowledge of places and community's dynamics progressed, the meetings were more focused on specific insights and on the involvement of new citizens. The activities specifically focused on co-exploration lasted about six months. At the end, another general meeting officially launched the co-design phase. It should be emphasized that the two phases were not clearly distinct: during the first phase there were many references to possible strategies for the future, in particular for the revitalization of the historic center, and during the second phase the materials collected during the community mapping was further enriched with information especially regarding the places with a great heritage value for the community but underrepresented. However, despite the concerns about the critical issues related to depopulation and physical abandonment, co-exploration activities have attracted much more interest than co-design activities. Even about the involvement of heterogeneous groups of citizens, they welcomed the exchange of ideas in the co-exploration activities better than in the co-design ones, where the work carried out with small, already consolidated groups was more fruitful.

The process itself allowed the understanding of the main barriers for each group of citizens: they partly depend on their age and partly on their way of living the place. Young people show great pride about the history of the place and enthusiasm for a future revitalization, but they hardly think about long-term strategies for living there in the future.

The elderly have less confidence in the possibility of reversing current trends, but they are more open to outline strategies for the future. In general, intergenerational dialogue is difficult. In addition, a large community of foreigners, especially from the United States, lives in the historic center for a few months a year, some of whom have moved permanently. Despite this interesting migratory dynamic, the repopulation of the historic center is not such as to attract sociality. The new inhabitants also promote initiatives for the community, but dialogue with locals is limited by the language barrier.

As an initial reflection on the partial results of the ongoing research, it is worth highlighting the effectiveness of co-mapping tools in both phases of the process. The spatialization of narratives and the shared identification of heritage across the territory not only provided a comprehensive overview of the assets involved, but more importantly, enabled the collective recognition of relationships among places and between places and community. This approach significantly facilitated also the co-exploration phase, helping participants move beyond a focus on isolated physical interventions toward a more integrated territorial strategy, where each place and action is interconnected within a broader, cohesive framework.

Conclusions

The still ongoing research work already allows some considerations both regarding the effectiveness of the adopted methodology and the results for the case study area.

Guardia Sanframondi hosts a huge tangible and intangible heritage made up of natural resources, agricultural practices, traditions and religious rites, works of art, and literature. Therefore, the choice of rooting a possible revitalization strategy in renewing the relationships between local community and their own heritage is useful not only to provide the community with tools to support a sustaining process of revitalization, but also to strengthen these relationships in a proactive logic and not only in the safeguarding of the past. Also, the choice to accompany the co-exploration phase with co-mapping tools allows the spatialization of both tangible and intangible heritage and facilitate the identification of possible hotspots to trigger a revitalization strategy.

This is important especially for the specific case study because the place does not fully reflect the vitality of the inhabitants, the lively activism, the numerous cultural initiatives, although scattered, promoted by locals, new

inhabitants, university students, artists and scholars, the strong and transgenerational sense of belonging and the widespread knowledge of the past value of places.

An indirect effect of this process, perhaps more important than the outcomes of the two phases, is the reawakened awareness of some involved groups of being direct agents of change, who seized the opportunity and continued their activities independently of the research project.

Finally, it should also be noted that reinforcing the link between heritage and community can promote the effectiveness of public action in facing significant challenge such as securing significant portions of the historic centre.

Nevertheless, public interventions to redevelop buildings risk being ineffective unless they assume a role recognised by the community.

Silent evidence.
On nuclear mounds, craters and caves

Ludovico Centis
Affiliation: University of Trieste
Email: ludovico.centis@dia.units.it

Abstract
This essay focuses on three sites – the Niagara Falls Storage Site, NY, the Nevada Test Site north of Las Vegas, NV, and the Waste Isolation Pilot Plant, near Carlsbad, NM – where the ground still shows the scars of atomic testing and where nuclear waste is stored, shielded by artificial mounds or in deep underground caves. Sites that following the categorization proposed by Alois Riegl in his fundamental text on the cult of monuments would be defined as unintentional monuments.

The mounds, craters and caves that punctuate these sites, along with others dispersed both through the US and other countries that experienced nuclear testing and activity, testify of the great sacrifices that were inflicted upon territories that, realistically, will never return to their original condition.

Keywords: Atomic power, nuclear testing, nuclear waste, landscape, monument.

A new era

Dealing with the heritage of the Manhattan Project does not simply mean expressing one's position as being against or in favor of nuclear weapons or nuclear energy for civil use. Either we like it or not, and whether we accept it or not, the Trinity test held on July 16, 1945, ushered humankind into a new era (Figure 01).

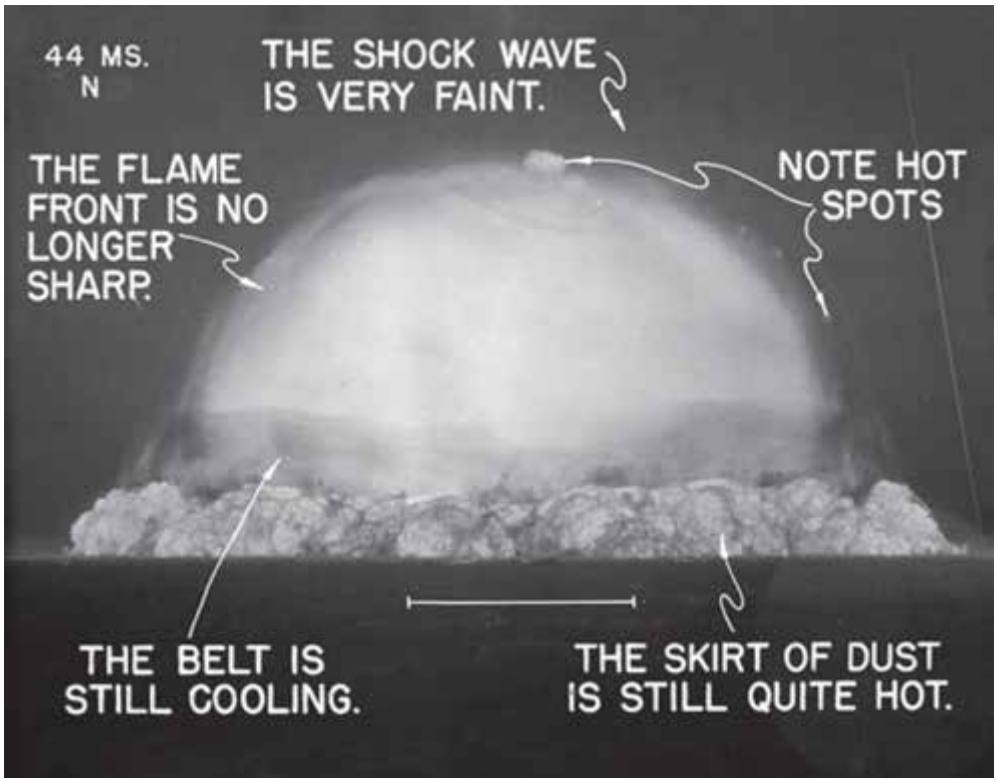

Figure 01: Annotated photograph of the Trinity test. Courtesy of Los Alamos National Laboratory.

We cannot pretend it never took place; we cannot simply go back to pre-atomic life. We should be aware that, as Günther Anders has stated, "we entered the Atomic Age in 1945 not because we fabricated three atomic bombs, but because we possessed the recipe for producing countless more."[1] We have to remember, and understand,

1 " . . . nicht dadurch sind wir 1945 in das atomare Zeitalter eingetreten, dass wir drei Atombomben fertiggestellt hatten, sondern dadurch, dass wir das nicht-physische Rezept für zahllose andere besassen" (Anders 1980, 37, auth. trans.).

what happened. Doing this is essential if we want to understand the world we live in today and avoid repeating the mistakes of the past, especially when it comes to the handling and disposal of nuclear waste and the safeguarding of the future of countless generations to come.

While historian Donald Worster has asserted that the Age of Ecology began with the Trinity test (1977, 339), philosopher Peter Sloterdijk (2002) further developed Anders's point of view, declaring that over the course of the twentieth century we have been led to question the man's existence as a Being in "breathable" space due first to poisonous gas and then to atomic bombs, for these offered means that could bring about a complete destruction of the environment human life requires. Arthur Koestler expressed a similar concept: "From the dawn of consciousness until 6 August 1945, man had to live with the prospect of his death as an individual; since the day when the first atomic bomb outshone the sun over Hiroshima, mankind as a whole has had to live with the prospect of its extinction as species" (Boyer, 2009, 3).

Unintentional monuments

If Alois Riegl had written his fundamental text on the cult of monuments today (Riegl, 1903), he would certainly see the test sites and mounds of nuclear waste as fascinating and exceptional examples of what he defined as unintentional monuments. Riegl made clear that it is we who define the value of unintentional monuments, and that there is a subtle and mutable threshold that divides what we want to preserve from what we allow to be destroyed. As Kurt W. Forster would remind us, for Riegl the very idea of the monument proved to be at once historically determined and relative to the values of each era. The Swiss historian has underlined that "Riegl's patient study of historic monuments raised issues other than scholastic distinctions [. . .] At the heart of the matter beats the destructive force of time; and beneath it, like a murmur of the Heart, the mortality of culture itself" (Forster, 1982, 31).

And while the historical value of a monument, which is based on scientific criteria and perceived through reason, is defined by a mutable threshold determined by the people and culture of a specific period, the age-value of monuments is more universal and enduring, touching the masses, regardless of their experience or education in the same manner as religious feelings do (Riegl, 1903). We should also remember that "Riegl had entitled his essay the modern cult of monuments. Under Riegl's dry prose one can find a belief that heritage in a secular society will fill the void left by religion. The cult of heritage would turn into a mass-movement that ignored borders and national identities" (Arrhenius, 2012, 103). Shifting from European theory to an American context, one could link the kind of religious feeling Riegl evokes to what David Nye has defined as the experience of the technological sublime (1994, XIII), something

that taps into fundamental hopes and fears [. . .] an essentially religious feeling, aroused by the confrontation with impressive objects [. . .] an integral part of collective consciousness [. . .] In a physical world that is increasingly desacralized, the sublime represents a way to reinvest the landscape and the works of men with transcendent significance.

It should come as no surprise that Nye himself mentions the Manhattan Project and the atomic tests in his work (1994, 224–56).

This essay focuses on three sites – the Niagara Falls Storage Site in Lewiston, NY, the Nevada Test Site north of Las Vegas, NV, and the Waste Isolation Pilot Plant, near Carlsbad, NM – where the ground still shows the scars of atomic testing and where nuclear waste is stored, shielded by artificial mounds or in deep underground caves. Following the fact that the nuclear waste will remain active for thousands of years, Riegl's notion of age-value is pushed to its limit, evoking a future so distant that our limited sense of time as human beings can barely grasp it.

Niagara Frontier mounds

In response to Colonel John Spence's request in 1982 for a list of where "radiological materials may have been left or buried on U.S. Army installations", Department of Energy public safety division director William Mott sent him a letter with several attachments (U.S. Department of Energy, 1982). Mott's reply indicates that forty years after the beginning of the nuclear program, even the U.S. Army did not know where all of the radioactive materials produced had been buried (Figure 02).

JUL 2 3 1982

Col. John D. Spence
U.S. Army Toxic and Hazardous
Materials Agency (DRXTH-AS)
Department of the Army
Aberdeen Proving Ground, Md. 21010

Dear Col. Spence:

In response to your letter of May 17, 1982, requesting the identification of sites where radiological materials may have been left or buried on U.S. Army installations, I am enclosing listings of military installations that may have been involved with the Manhattan Engineer District/Atomic Energy Commission (MED/AEC) activities. Enclosure 1 is a list and brief summary of all Army sites and Enclosure 2 is the list of military installations other than Army facilities. Enclosure 3 is the answers to the questionnaire as outlined in your letter for selected Army and former Army sites. The information presented is the best available to us at this time. A fourth list of sites containing names and AEC association is being prepared. Being formerly restricted data, this list must be handled as confidential data and will be forwarded under separate cover.

If there are any questions, please call me on 301-353-3016 or Mr. Arthur J. Whitman of my staff on 301-353-5439.

Sincerely,

Figure 02: Cover letter typed by William E. Mott introducing the List of Army sites that have or may have handled nuclear materials for the AEC or MED, 1982. Courtesy of U.S. Department of Energy.

While Mott declared with certainty that activities related to the Manhattan Project, and later to the Atomic Energy Commission, had taken place in specific locations, the information available about others—such as the Picatinny Arsenal, Dover, NJ, or the Twin Cities Army Ammunition Plant, New Brighton, MN—was either vague or conflicting. The list shared by Mott included several sites in Western New York State. This included the Lake Ontario Ordnance Works in Lewiston, NY, that along with the Linde Ceramic plant, located in the nearby city of Tonawanda, was among the facilities in the Niagara Falls area that made a significant contribution to the Manhattan Project. In fact, the abundance of hydroelectric power facilitated an unusually intense concentration of electrochemical plants in the area, including those of Union Carbide, Hooker Chemical, Carborumdum, Linde Air, and U.S. Vanadium. These

companies contributed to the uranium enrichment process and the production of other materials necessary for the construction of the atom bomb.
A few companies in particular, namely Linde Ceramics in Tonawanda and Bethlehem Steel in Lackawanna, played particularly key roles in the production process that led to the realization of the first atomic bomb. While this program did significantly boost the local economy at the time, it has left behind a serious and enduring threat, for it resulted in the creation of polluted areas and facilities that remain such for centuries to come.

Within this framework, the story of the Lake Ontario Ordnance Works is of particular interest, something Kevin Lynch acknowledges by mentioning it in his analysis of the waste we produce in his book Wasting Away (1990, 75). Originally conceived as a TNT production plant, from 1944 to 1952 the Manhattan Engineer District and the Atomic Energy Commission used the site as a radioactive waste deposit that later became known as the Niagara Falls Storage Site.

Looking at excerpts from local newspapers that refer to the Lake Ontario Ordnance Works site, it is revealing to see how in just a few months' time, the information printed in newspapers about this site went from being clear and transparent—as in the lengthy article on the TNT plant that had been located there since 1942 (Garnish, 1943)—to being vague and misleading, as is evident in the short article of October 1943 (Courier-Express Niagara Falls Bureau, 1943), stating that the TNT plant had been shut down and the land was to be returned to the farmers, when in reality the area was going to be transformed into a landfill for the burial of the radioactive remains generated by New York state's nuclear activities in Buffalo, Tonawanda, and Rochester, such as research byproducts from the Strong Memorial Hospital. In fact, from 1944 to 1952, first the Manhattan Engineer District and then the Atomic Energy Commission deposited radioactive waste in three areas at the Niagara Falls Storage Site, formerly the Lake Ontario Ordnance Works. In the years that followed, the Army Corps of Engineers consolidated the nuclear waste in a single area to allow the cleanup and repurposing of the rest of the site. In 1980, nearly twenty-five years after the intervention by the Army Corps of Engineers, the Department of Energy built an Interim Waste Containment Structure designed to work efficiently for a minimum of twenty-five and a maximum of fifty years (Figure 03).

Figure 03: The mound covering the Interim Waste Containment Structure designed by the Army Corps of Engineers to consolidate the nuclear waste from the Linde plant. Courtesy the author.

In the past decades, several landfills containing various types of domestic waste have been located around the

containment facility. The gas produced by the decomposition of waste is collected and used to heat some large greenhouses built in the vicinity. The greenhouses are particularly used to grow tomatoes that are sold across the state and probably beyond. Not far from the Niagara Falls Storage Site, 15 miles south as the crow flies, the Linde Ceramic plant processed uranium ore for the Manhattan Project. The radioactive remains of the building are now buried under a mound named Ashland site, enclosed by a fence and facing the Niagara River (Figure 04).

Figure 04: The Ashland site mound covered by a snow cap. Courtesy the author.

Desert scars

The U.S. conducted 1,054 nuclear tests from July 1945 to September 1992. Some of these were run by the Los Alamos scientists, some by the military, and others by the Atomic Energy Commission, which was established in 1946. Of these tests, 904 were carried out at the Nevada Test Site, 106 in the Pacific Ocean, 3 in the South Atlantic Ocean, and 17 in other U.S. locations (U.S. Department of Energy, 2000). The Trinity test, the first test run on July 16, 1945 in a remote desert area of New Mexico that was then part of the Alamogordo Bombing Range (today the White Sands Missile Range), was an atmospheric one. After this event and the release of the nuclear bombs on Hiroshima and Nagasaki in August 1945, the U.S. government decided to conduct over a hundred atmospheric and underground tests far from home in the Pacific Ocean—at the Marshall Islands, Johnston Atoll, and Christmas Island—as well as over the South Atlantic Ocean. This series of tests began in June 1946 and ended in November 1962.

Already in the early 1950s a sum of different factors, including the Cold War climate, the Korean War, and the logistical complications of carrying out atomic testing in the Pacific Ocean, pushed the U.S. government to select an alternative site. The location chosen was eighty miles northeast of Las Vegas and came to be known as the Nevada Test Site (NTS). The large majority of tests—both atmospheric and underground—carried out by the U.S. government between January 1951 and July 1962 were conducted at the NTS. From 1962, all experimentation was conducted underground, again mostly at the NTS, although some tests were also run at the Nellis Air Force Range, on Amchitka Island off the coast of Alaska, in central and northwestern Nevada, and in Mississippi, Colorado, and New Mexico.

Following the 1963 signing of the Limited Test Ban Treaty, which prohibited all but underground nuclear blasts, a series of tests was carried out to open the way for the civilian use of nuclear weapons. Military seismic tests were

run—first on the NTS and then all over the country—in order to distinguish natural earthquakes from underground nuclear tests. The Plowshare Program, terminated in 1975, foresaw the use of nuclear weapons for engineering projects, such as creating canals and harbors (Figure 05).

Figure 05: A permanent stable cavity formed by one of the underground nuclear tests as part of Operation Plowshare in 1961. Courtesy of Los Alamos National Laboratory.

The Sedan Crater, produced in 1962 as part of the Plowshare Program, measures nearly four hundred meters in diameter and is a hundred meters deep (Figure 06). The fallout generated by the explosion that created the crater exposed more than ten million people to radiation, raising serious doubts about the legitimacy of the program.

Figure 06: Sedan Crater. Courtesy of Los Alamos National Laboratory.

After decades of atmospheric tests that dramatically polluted large swathes of American soil with radioactive contaminants, the 1963 treaty accidentally could have served as the basis for underground pollution too, such as the diffusion of radiation through cracks in the earth and observation conduits in a gaseous form and the

contamination of groundwater and workers. Just imagine what would have happened if Project Gasbuggy, the first commercial application of nuclear explosions for natural gas stimulation (Zavattaro, 2005, 24), had led the way to nuclear fracking. Luckily, the high levels of radioactivity in the process's final product and the high cost of production halted further experimentation.

A nuclear oasis

A four-lane road wide enough to accommodate special trucks carrying transuranic nuclear waste[2] was built in the late 1990s in southern New Mexico (Lippard, 2014, 20). Since then, these trucks have used it to travel to the Waste Isolation Pilot Plant (WIPP), which was officially inaugurated in 1999 near Carlsbad, a city famous for both the Carlsbad Caverns (a part of the National Parks System) and Project Gnome.[3]The WIPP is a deep geological repository designed for the permanent disposal of transuranic radioactive waste—in other words, for ten thousand years (Figure 07).

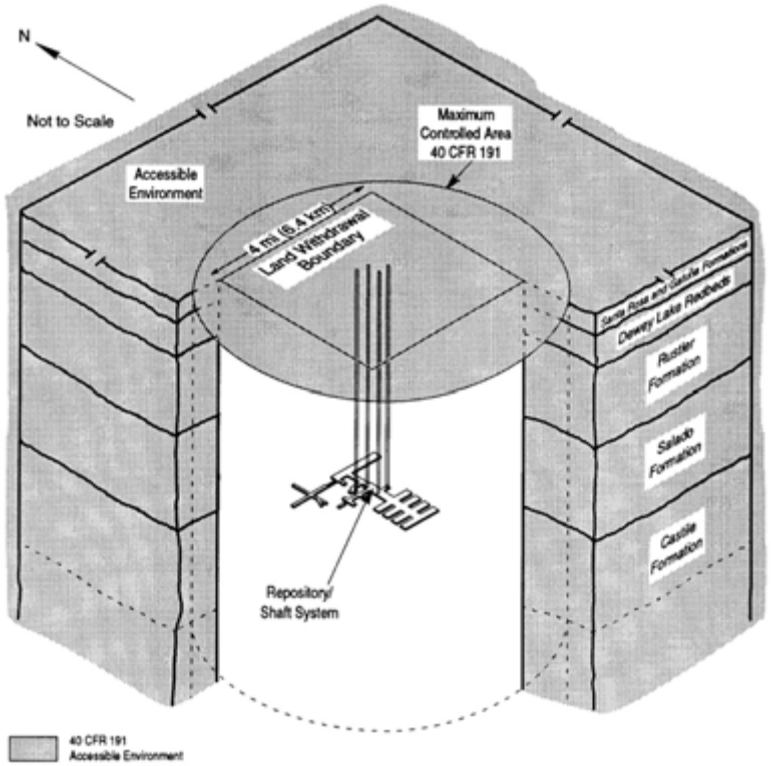

Figure 07: Artist's concept of the WIPP disposal system showing the controlled area and accessible environment tor 40 CFR 191, Subpart B, and the repository/shaft system. The repository/shaft system scale is exaggerated. On the land surface, the land-withdrawal boundary is shown at the same scale as the maximum extent of the controlled area. From Trauth et al. (1993).

The WIPP is one of what Andrew Blowers (1999) has named nuclear oases, often peripheral and remote landscapes

2 All stages of the nuclear cycle—the mining of radioactive ore, enrichment, fuel fabrication and reprocessing, the production of energy and the management of waste—involve risk. The radioactive life of spent fuel varies from thousands to several hundred thousand years, depending if it was generated by reprocessing (High-Level Waste [HLW]), reactor operations (Intermediate-Level Waste [ILW]), or different sets of routine operations (Low-Level Waste [LLW]). When the nuclear plants are decommissioned, several decades are usually required for the site's clean-up and restoration, as well as for the management of the waste it produced. Transuranic, or low-level, waste remains radioactive for approximately twenty-five thousand years. It usually consists of materials that have come into contact with uranium, plutonium, or other radioactive elements in the production of nuclear weapons or fuel, such as tools, gloves, and machinery.

3 The Gnome detonation, which was a part of Operation Plowshare, took place on December 1, 1961. A three-kiloton nuclear device buried in sedimentary salt was detonated before the physicist Edward Teller and more than five hundred other observers. Even if it had been planned as a fully contained explosion, radioactive smoke and steam quickly began to rise from the shaft and leaked out into the atmosphere. In the explosion cavity, the intense radiation created by the blast turned the salt shades of green, blue, and violet. It was only in 1977—sixteen years later—that the Department of Energy began the site decontamination process.

struck by economic marginalization and environmental degradation whose inhabitants are imbued with a sense of powerlessness and a culture of acceptance, thereby offering the ideal place for managing nuclear waste. These oases also became the places where conflicts over the future of the nuclear industry arise. Blowers divided the sites dealing with nuclear reprocessing and waste management into two groups: those that have been operating for several decades, such as the nuclear military reservations of Hanford, Washington, and the plant at Savannah River, South Carolina; and those he defines as "greenfield" locations, economically vulnerable areas where the nuclear industry is introduced for the first time generating patterns of spatial inequality, such as the WIPP itself, or the proposed deep disposal facility at Yucca Mountain, Nevada.[4]

Since 2014, when twenty-one workers at the WIPP were exposed to doses of plutonium sufficient to lead to cancer after an explosion, which caused an airborne release of radiological material, there are growing concerns about the safety of the repository. The safety of the facility was also a focus of studies carried out in the 1990s by the Sandia National Laboratories entitled Expert Judgment on Markers to Deter Inadvertent Human Intrusion into the Waste Isolation Pilot Plant (Trauth, Hora, and Guzowski, 1993). As Van Wyck has underscored,
for the WIPP, no one was particularly concerned that the interred waste be recoverable; the main concern was that the geological matrix be predictably stable over a (very) long period of time. The EPA [Environmental Protection Agency], which became responsible for the oversight of any nuclear waste disposal, subsequently added a layer of complexity to the decidedly material problem of stability and (relative) permanence. They decreed that any waste repository must be marked with signs—the "most permanent markers"—the purpose of which would be to deter "inadvertent human intrusion" into the repository for a regulatory period of ten thousand years (2012, 66).

The problem was not simply dealing with the enduring nature of the hazardous materials, or that of the structure of these markers. Rather, it was one regarding semiotics, signs, and memory, and concerned how best to transmit to future generations an awareness and understanding of the presence of the deadly materials buried in the underground repository—even in a future so remote that none of the languages spoken around the world at the time might still be comprehensible.[5] In the 1990s Michael Brill and Safdar Abidi conceived a variety of proposals – named respectively "Landscape of Thorns", "Spike Field", "Spikes Bursting Through Grid", "Leaning Stone Spikes", "Menacing Earthworks", "Black Hole", "Rubble Landscape", "Forbidding Blocks" (Trauth, Hora, and Guzowski 1993, F59–F75)– for a "monument to waste" that "perform[s] the threat that lies beneath" (Van Wyck 2004, 150). At the time of writing, none one of them has yet been realized.

Landscapes of Risk
The nuclear industry, whether put to civil or military use, represents a cornerstone of today's techno-scientific society, which Ulrich Beck defined in his book Risk Society: Towards a New Modernity (1992). According to Beck's thinking, we are individually unable to face or deal with nuclear activities and yet we collectively accept in a fatalistic way the consequences it brings.[6] What Beck articulates is not a recent phenomenon, namely the fact that nuclear energy has made mankind less free and more interdependent, and that nuclear energy's potential had to engender a race to military power was clear from the very beginning of the Atomic Age, as proven by books such as No Place to Hide.[7] The writer William Kittredge noted that the greater environmental awareness that came at the end of the twentieth century allowed us to understand that during the Cold War
we felt great destructiveness was permissible in defense of ourselves and our people . . . Great sacrifices were regarded as absolutely necessary, including the devastation caused by nuclear testing, and even the lives of luckless citizens who turned up downwind. Gonna bake a cake, gotta break some eggs. The Cold War was an

4 The deep disposal facility at Yucca Mountain was designed to contain seventy thousand tons of spent fuel. After an investment of ten billion dollars and many years of study that encountered irresolvable geological, environmental, and design problems, President Barack Obama canceled the program in 2010.

5 See Lynch (1990, 77).

6 Andrew Blowers has further elaborated on the role of nuclear industry in Beck's Risk Society: Towards a New Modernity: "Risk Society provides grand generalization on the mega risks which threaten to engulf us all. But, and again the nuclear oases make the point, risk is uneven, likely to be experienced by some communities more than others [. . .] Risk Society clearly identifies the nuclear industry as a key example, it is concerned with the problems of risk at the broad, abstract societal level rather than with the specific problems of risk facing local communities" (1999, 257).

7 See Bradley (1948).

orgy of mutual distrust and paranoia, and it was hard to think of a response, once we were in it, other than gearing up to defend ourselves. Now history has moved on and we are no longer compelled to maintain such vast military forces. But nothing has changed. (1997, 8)

It could be said that a good number of the great sacrifices that Kittredge referred to were inflicted upon territories that, realistically, will never return to their original condition. In the case of sites associated with the Manhattan Project and its legacy, aesthetic considerations permeated with nostalgia are much less important, considering that many of these landscapes are hostile or deadly to forms of life, and will continue to be for millennia to come. What scientists, engineers, and experts have been trying to do since the second half of twentieth century is "clean up" these territories, which means achieving the stabilization, removal, and long-term containment of the radioactive byproducts that have rendered them threatening. These efforts can prove satisfactory interventions when the initial level of radioactivity is low, but when the level is higher, we rarely have solutions to the dramatic environmental problems it poses, or at least, a properly in-depth cleanup with the means we do possess would prove prohibitively expensive. It also goes without saying that the only funding available for the cleanup of areas polluted with nuclear waste is public while it is usually private corporations that run the plants and create the pollution, making money in the process.

Considering the kind of impasse we are at today when it comes to dealing with atomic energy's byproducts, we might agree with Jacques Derrida's identification of nuclear energy as the most extreme pharmakon (1981; 1984), a type of substance that can both injure and be a remedy; we must not forget the contributions of nuclear medicine and the diagnostic abilities it affords. At the same time, we must recognize that we live in a society in which the threats generated by scientific development and technological innovation cannot be managed confidently (Anders, 1956; 1980), for it is now capable of exposing us to unprecedentedly large-scale and enduring environmental-pollution phenomena. In this respect, one need only call to mind the Three Miles Island, Chernobyl and Fukushima accidents, as well as the Manhattan Project's own dangerous legacy at sites such as Hanford. In the meantime, mounds, craters and caves that punctuate the US landscape in sites as the Lake Ontario Ordnance Works, the Nevada Test Site and the Waste Isolation Pilot Plant stand as silent evidence of the new era opened by the discovery of atomic power.

From Large-scale Modernist Planning to Small-scale Urban Blocks: Spatial Transformation Experiments in China's Large Gated Communities

Zihan Ke, Yongjie Cai
Affiliation: College of Architecture and Urban Planning, Tongji University, Shanghai, China
Email: kezan0526@gmail.com

Abstract
This study reconsiders large-scale gated communities in China shaped by modernist planning, which often lead to spatial inefficiency, social isolation, and unsustainability. Drawing on the theory of "urban cells," it explores spatial densification through theoretical analysis, case studies, and a design experiment in Shanghai's New Jiangwan Town. The proposed design restructures urban form through fine-grained grids, mixed-use blocks, and redefined plot hierarchies, enhancing both vibrancy and permeability. It also examines challenges of property adjustment and stakeholder coordination. The findings demonstrate the feasibility of transforming gated communities into open, sustainable urban fabrics. The study offers a transferable model with strategic implications for rapidly urbanizing regions across the Global South.

Keywords: Modernist planning; Large-scale gated communities; Urban cells; Scale optimization; Densification

1. The Prevalence of Large-Scale Residential Areas in China's New Towns

1.1 Emergence of a Homogenized Urban Model

Since the 1990s, Chinese cities have experienced unprecedented challenges brought by rapid urbanization. In response, extensive new town developments were launched across the country. Nearly all of these new towns adopted a standard model characterized by wide arterial roads, large-scale interchanges, superblocks, low-density land use, and generous spatial allocations. This formulaic approach has resulted in a repetitive spatial pattern across cities—manifested in new urban centres comprised of major roadways, expansive green landscapes, large gated residential enclaves, industrial parks, and mega commercial complexes (Sha, 2010, p. 3) These urban forms starkly contrast with the fine-grained fabric of traditional city centres, yet ironically appear highly similar to one another across different urban contexts.

This study focuses on one of the most representative units within this model——the large-scale gated residential community (Figure 1). First defined by Blakely and Snyder in 1997, gated communities are privatized residential areas enclosed by walls or fences, where services and amenities are internally managed and restricted to residents (Blakely and Snyder, 1997). In the Chinese context, these communities are often structured as "superblocks" characterized by functional monotony and structural uniformity. They reflect the spatial logic of modernist urban planning while exposing a growing disconnect between spatial form and contemporary urban lifestyles.

Figure 1. *Typical Large-Scale Gated Residential Community Module*

1.2 Structural Origins and Multidimensional Issues

The persistence of this urban form can be traced to two fundamental dimensions. Conceptually, it is a direct result of modernist urban planning principles, especially the concept of functional zoning, which promoted the separation and concentration of urban functions, leading to vast, single-use residential areas. Operationally, China's response to rapid urbanization relied on a real estate–driven model guided by regulatory detailed planning. Under this framework, urban plots tend to be oversized and isolated from each other, with planning and design focused on intra-parcel configurations while neglecting public space formation and the integration

of urban systems.

Although this model has supported rapid urban expansion and short-term economic gains, it has simultaneously generated interrelated problems in three critical areas: sustainability, quality of urban life, and social-cultural cohesion.

In terms of sustainability, these communities rely on a "wide-road, sparse-network" structure, which reinforces automobile dependency. Their spatial segregation and functional exclusivity reduce walkability and mixed-use potential, frequently necessitating long-distance travel for everyday needs—thus aggravating traffic congestion and obstructing efforts toward sustainable mobility.

In relation to quality of life, the most significant issue brought by this development model is the lack of urbanity. Professor Pu Miao from the University of Hawaii famously likens oversized gated blocks to "tumors," highlighting their destructive impact on urban space (Miao, 2004). These large gated communities are divided by wide roads and interchanges, forming isolated "islands" with limited connection to each other and to the broader city. As a result, urban vitality struggles to emerge. The streets between them are oversized, poorly defined, and functionally limited. Lacking human-scale design and everyday amenities, they fail to support active, livable public life.

At the socio-cultural level, this model diminishes the city's cultural identity. Modernist, copy-paste-style residential designs turn housing into industrialized products, producing uniform "new heritage" landscapes that erode regional uniqueness. The physical and social enclosures further intensify social segregation, hinder neighborhood interaction, and reinforce class divisions—posing serious challenges to social equity and integration.

1.3 The Need and Potential for Redevelopment

As urban development in China enters a more stable phase, the spatial, functional, and social shortcomings of large gated communities have become increasingly evident. With growing societal expectations for high-quality urban life, the traditional residential model can no longer accommodate the demand for diverse, open, and adaptable urban living environments. A transition toward more urban and resilient residential forms is urgently required (International Panel on Social Progress, 2018).

Despite their limitations, modernist planning legacies retain a degree of spatial plasticity. Their low-density, large-scale structure presents opportunities for transformation. With thoughtful planning and design, these inherited urban forms can be reconfigured to align with contemporary needs, unlocking both spatial potential and renewed social value.

2. New Jiangwan Town: Lifeless Streets and Living Units

2.1 Site Selection

This study takes New Jiangwan Town in Shanghai as its primary design site (Figure 2). As a representative of new residential areas within the central urban area, it exemplifies the broader urban issues previously discussed—despite its location within the inner ring, the district suffers from a lack of urban vitality. Its challenges and potential for transformation hold valuable insights and relevance for similar urban contexts.

Figure 2. *Status of New Jiangwan Town*

Located in the northeastern part of central Shanghai, New Jiangwan Town was developed on the former site of Jiangwan Airport—once known as "an ecological oasis in the city". In the early 2000s, the municipal government envisioned the area as a model "garden city" and ecological residential zone for the 21st century, oriented toward middle- and upper-income residents within a knowledge-based, international community (Figure 3).

This design research focuses on a 29.2-hectare site bounded by Zhengqing Road and Songhu Road, with Yinhang Road as its central axis. The site, measuring approximately 780 by 510 meters, encompasses the New Jiangwan Town metro station, ensuring convenient accessibility. It also reflects common issues of large gated communities, making it an ideal site for studying residential urban transformation. (Figure 4).

Figure 3. *Planning Context: Spatial Structure, Functions, and Transport Networks*

Figure 4. *Design Focus and Existing Site Issues*

2.2 Absence of Urbanity and Cultural Life

Despite ts designation as a "town," New Jiangwan Town lacks the spatial and cultural attributes expected of urban life. Influenced by modernist planning principles, its spatial organization is disconnected from everyday use, with limited continuity and permeability. In terms of spacial scale, wide roads and superblocks undermine human-scale connectivity; streets lack spatial enclosure, and elongated block edges create monotonous and fragmented pedestrian experiences. In terms of spacial form, residential compounds are developed independently with minimal attention to urban frontage. In pursuit of optimal orientation and floor-area ratios, buildings turn inward, and streets are flanked by blank walls or landscaped setbacks, lacking the spatial conditions needed for street life. Functionally, the area is dominated by residential use, with commercial and cultural facilities sparsely and unevenly distributed. workplaces and cultural institutions are virtually absent. As a result, urban diversity and the informal rhythms of everyday life are missing. New Jiangwan Town presents an urban façade but fails to perform as a true urban environment, functioning instead as a closed residential enclave devoid of socio-cultural depth.

esembles an urban form in appearance but functions as a mono-functional residential enclave—devoid of collective memory and civic culture.

The Yinhang Road site, for example, includes five gated residential communities, with an average building coverage of just 12.65%. The distance between buildings along main roads ranges from 65 to 91 meters, while secondary streets such as Ruida Road remain disproportionately wide. This functional monotony and disordered spatial form undermine both urban vitality and cultural expression (Figure 5).

Figure 5. *Analysis of Existing Site Problems*

2.3 Analysis Through the Lens of Urban Cells

To further understand the disconnection between space and culture, this study adopts the concept of the "urban cell" as a medium-scale analytical framework. The concept of urban cells, derived from biological metaphors, refers to the basic spatial unit of a city. Each cell is defined by its boundaries (walls, facades) and internal structure (courtyards, paths), which jointly determine its spatial performance and cultural capacity (Cai, Xu, Zhang and others, 2018).

In traditional urban forms, such as Beijing's siheyuan or Shanghai's lilong, urban cells are compact (typically 50–100 meters), fostering dense, permeable street networks and mixed-use environments (Cai and Xu, 2021). By contrast, modernist planning transforms these cells into isolated "functional warehouses," disconnected from their surroundings. New Jiangwan Town exemplifies this new urban cell typology, marked by two key deficiencies:

1-Oversized Cells: The excessive scale of residential blocks lead to functional fragmentation, low traffic efficiency, and weak social interaction.
2-Inactive Boundaries: The compound walls and adjacent buffer zones function merely as physical separators. While they provide basic spatial division, they offer little depth, serve no additional functions, and ultimately fail to sustain urban life. As a result, the street spaces between these cells remain lifeless and underutilized.

These two core issues correspond to two main transformation goals:
1-Optimizing the scale of urban cells to rebuild spatial and social connectivity.
2-Restructuring interstitial and boundary spaces to enhance street quality and activate public life.

2.4 Site Potential

At the macro level, New Jiangwan Town holds strong redevelopment potential. Its central location, robust public transit, and diverse population offer strategic, economic, and cultural advantages. Rich ecological resources further support high-quality, sustainable urban living.

At the site level, the existing low-density pattern leaves ample room for densification. Underutilized spaces between buildings and streets create opportunities to reconfigure urban cells, implement open community models, and revitalize street edges.

3. Research Objectives and Methodology

Despite extensive critique and revision of modernist urban planning concepts within academic discourse, practical applications for transforming large-scale and low-density residential areas remain scarce (Wu, Yang, Xu, Zhang and Antwi-Afari, 2021). This study seeks to bridge that gap by translating theoretical insights into actionable design methods, addressing the prevalent challenges faced by new residential areas in China.

Through theoretical analysis, case studies, and a spatial transformation design experiment in the core area of Shanghai New Jiangwan Town, this study investigates the theoretical significance and practical approaches to spatial transformation in contemporary large-scale communities.

At the design research level, this study focuses on the prevalent large-scale gated residential model in China's new towns. Taking the Yinhang Road area of New Jiangwan Town as a testing site, the core objective is to transform it from a large-scale, low-density, mono-functional residential zone into a network of small-scale, mixed-use, and street-oriented urban blocks that support greater urbanity. Importantly, the term urbanity here extends beyond physical form or centrality. It refers to the holistic spatial quality of the built environment, characterized by human-scale dimensions, legible urban form, programmatic diversity, and vibrant public life.

4. Theoretical Framework

This chapter establishes the theoretical foundation for the design strategies proposed in subsequent sections. It first traces the historical and cultural roots of gated community patterns in China, unpacking their spatial logic and sociopolitical underpinnings. It then reviews contemporary urban theories that advocate for openness, integration, and human-scale development. Together, these perspectives form a critical lens through which the challenges and potentials of reconfiguring New Jiangwan Town can be understood.

4.1 Historical Roots of Enclave Patterns in Chinese Housing

4.1.1 A Brief History of Residential Transformation in China

China's urban housing has undergone multiple stages of transformation, deeply shaping today's urban form.

During the planned economy period (1950s–1970s), residential development was primarily state-led, resulting in the widespread emergence of "danwei compounds" —enclosed residential blocks controlled by work units. In the absence of private property rights, walls served to delineate administrative boundaries, laying the groundwork for today's gated community model.

Since the late 1970s, reform and opening-up restored private property rights and introduced market-driven housing. Real estate developers emerged as dominant players, and under the influence of modernist planning paradigms, gated communities became the mainstream model emphasizing order, security, and property value.

In the 21st century, regulatory detailed planning became the dominant development mechanism, further entrenching the gated community model. However, this approach has been increasingly questioned. In response, the concept of open communities has gained attention, with pilot projects like Changde's Berlin International Community have shown the feasibility of fence-free designs in China (Wang, 2023).

4.1.2 Cultural DNA and the Shanghai Experience

Traditional Chinese housing has long favored inward-facing, enclosed environments, reflecting values of privacy and order (Deng, 2011). This is evident in the "lifang" system of ancient cities and residential types like Beijing's siheyuan or Shanghai's lilong. This spatial logic underpins contemporary acceptance of gated communities.

In Shanghai, a migrant city shaped by both indigenous tradition and Western modernism, hybrid housing forms such as "shikumen lilong". These typologies combined the privacy of Chinese courtyards with the density of European row houses. Their "closed outside, open inside" spatial logic fostered vibrant alleyway life and strong neighborhood cohesion, becoming a key element of the city's collective memory.

In older urban areas, mixed-use configurations like "shopfront-residence" and "store below, residence above" created high-functionality environments within walkable neighborhoods. By contrast, contemporary gated communities, though superficially resembling traditional forms, often lack the scale, form, and programmatic richness needed to sustain urban life, losing not just permeability, but also the cultural depth rooted in everyday spatial practices.

4.2 Spatial Strategies of Re-Urbanization

4.2.1 The Open Block Model

At the turn of the 21st century, French architect Christian de Portzamparc proposed the "Open Block" concept in Paris's Rive Gauche project, highlighting the street as the core of urban life (Portzamparc, 2015). He emphasized that the key principles of open blocks included small block size, mixed functions, and open circulation to foster accessibility and social interaction. In China, the Green Neighborhood Standard echoes these principles, promoting integration of public space and civic functions into residential areas. Unlike gated compounds, open communities aim to create lively, inclusive, and adaptable urban environments.

4.2.2 Small Blocks and Dense Streets Networks

The 2016 State Council Guidelines marked a paradigm shift by stating that new residential developments should adopt a block-based model and avoid constructing enclosed communities. It promoted the "narrow streets, dense networks" urban pattern.

The model generates a series of interrelated benefits. By subdividing large parcels and introducing shared street rights-of-way, it facilitates multimodal mobility and improves overall connectivity (Zhuo, Wu and Xu, 2017). Enhanced permeability and activated street frontages contribute to a more articulated and adaptable urban form. Simultaneously, the model fosters social integration by aligning with human-scale spatial perception and promoting frequent, informal interactions within the neighborhood context.

Nonetheless, the model poses design and operational challenges. Smaller blocks may reduce development flexibility and increase management costs. Perimeter block layouts may limit solar access, while denser street grids can increase noise and pollution (Zhuo, Wu and Xu, 2017). Therefore, local adaptation and site-specific strategies are essential.

4.2.3 Mixed-Use Development Theory

As a critique of functional zoning, mixed-use theory promotes integrating residential, commercial, educational, and recreational functions within walkable urban areas.

Mixed-use development promotes proximity, diversity, and efficiency by integrating varied urban functions within a compact spatial framework. It shortens spatial distances between living, working, and service activities, enhances temporal vibrancy through overlapping uses, and optimizes land and infrastructure utilization. By countering spatial segregation and curbing urban sprawl, it also reinforces socio-spatial sustainability (Jacobs, 2011).

Yet, the approach also demands careful spatial balancing. Conflicts in privacy, noise, and circulation must be resolved through refined architectural and programmatic design to harmonize vibrancy with livability.

5. Case Studies

Building on the theoretical framework, this chapter investigates representative urban spaces and residential areas to clarify the spatial logic of "Plot-Building-Block-District" and identifies the key characteristics of vibrant, sustainable districts. Furthermore, by examining cases of urban space reconstruction, the study explores densification strategies for spatial transformation and categorizes specific operational patterns.

5.1 Urban Blocks in Classic Cities

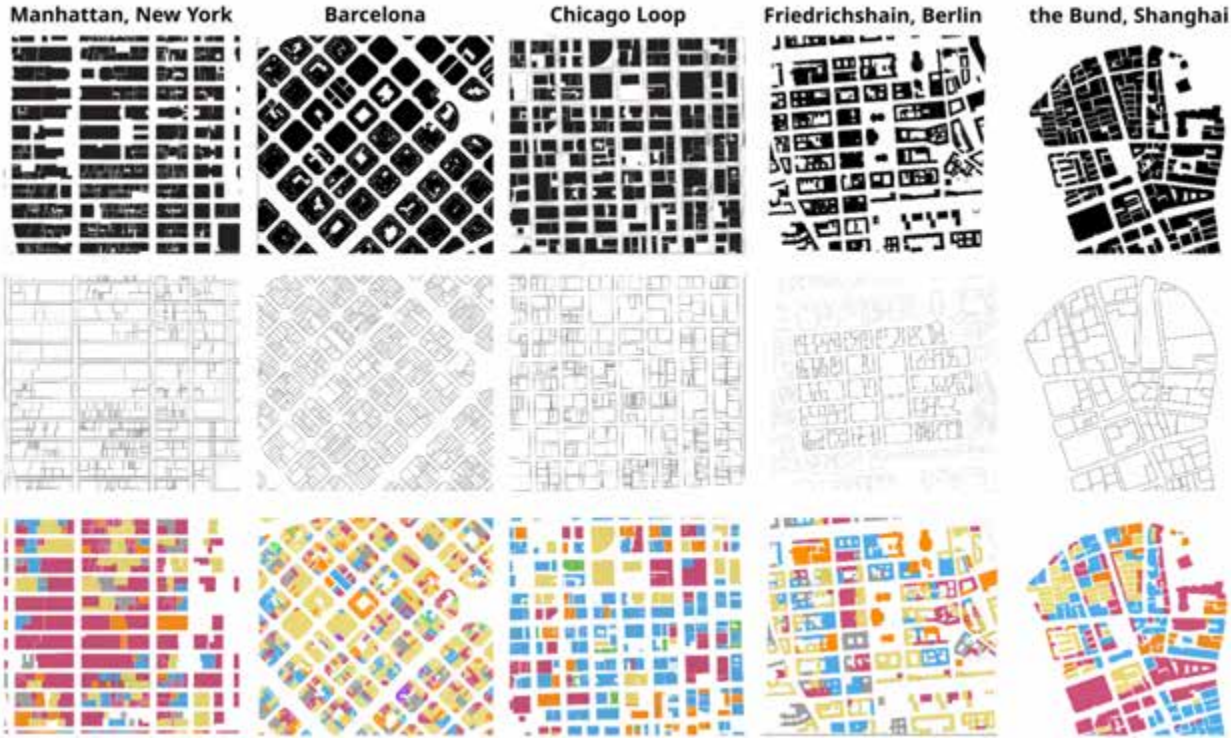

Figure 6. *Case Study of Urban Blocks*

This section examines 1 km² urban blocks in New York, Chicago, Barcelona, Berlin, and Shanghai's Bund to identify shared spatial traits (Figure 6). Comparative analysis of figure-ground patterns, parcel divisions, and functional layouts reveals a common logic: small blocks (70–160 m) within a coherent street grid, continuous frontages, fine-grained and flexible parcels, and diverse functions at the block scale. Together, these elements form a model of urban vitality marked by legibility, human scale, morphological richness, and integrated uses.

5.2 Urban Living blocks: The Case of Chuangzhifang

Located in Shanghai's Yangpu District, Chuangzhifang exemplifies the localized application of "small blocks" and "mixed-use" urbanism. The project integrates spatial, mobility, functional, and governance strategies to promote urbanity within a formerly underused area.

5.2.1 Spatial Construction: Small Blocks and Public Space

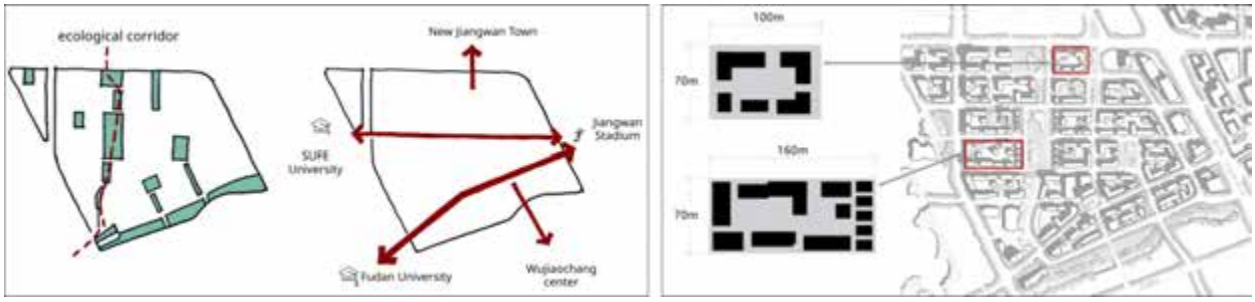

Figure 7. *Spatial Structure and Block Analysis of Chuangzhifang*

Figure 8. *Public Space and Building Height Analysis of Chuangzhifang*

The street grid is structured by a clear north-south ecological corridor and east-west urban axes (Daxue Road and Weikang Road), which connect key urban anchors including Fudan University, Shanghai University of Finance and Economic and Jiangwan Stadium, establishing a coherent spatial framework. Blocks adopt a compact scale (70–160 m), aligning with traditional urban grain and enabling seamless connection to surrounding neighborhoods. Public spaces are strategically placed at key intersections, with moderately scaled plazas (e.g., 40 × 50 m) that balance capacity with spatial intimacy (Qian, 2017). High near-line rate contributes to the integrity of the block form. Public space is closely tied to commercial functions, supporting a variety of events such as weekend markets and pedestrianized zones, enhancing spatial adaptability and user engagement (Figure 7, Figure 8).

5.2.2 Traffic Organization: Dense Networks and Pedestrian Priority

The district adopts a "narrow street, dense network" model, with open, shared streets seamlessly integrated into the city's broader traffic system (Yin, 2007). 8-meter-wide sidewalks are subdivided into outdoor dining, pedestrian, and furnishing zones, stimulating outdoor commerce and active street life. Tight corner radii (3–5 m) reduce vehicle speed, fostering a safer pedestrian environment (Figure 9).

Figure 9. *Street Layout, Sidewalk Zoning, and Road Section of Chuangzhifang (Qian, 2017)*

5.2.3 Functional Mix: Multi-Dimensional Integration
Functions are mixed across horizontal, vertical, and temporal dimensions. Horizontally, Plots are primarily mixed-use. Commercial functions line the main street while residential and office functions occupy interior plots. Residential units are preferentially arranged along north-south orientations, while non-sunlit areas are repurposed for offices (Wang, 2023). This horizontal integration is illustrated in the spatial organisation of Chuangzhifang. Vertically, buildings combine shops with "SOHO" (Small Office/Home Office) units, residences, or offices above, supporting ground-level activity without compromising livability (Figure 10). Temporally, LOFT-style SOHO units support dual-use functionality, accommodating shifts between daytime work and nighttime dwelling, exemplifying adaptable spatial design (Wang, Wang and Huang, 2023).

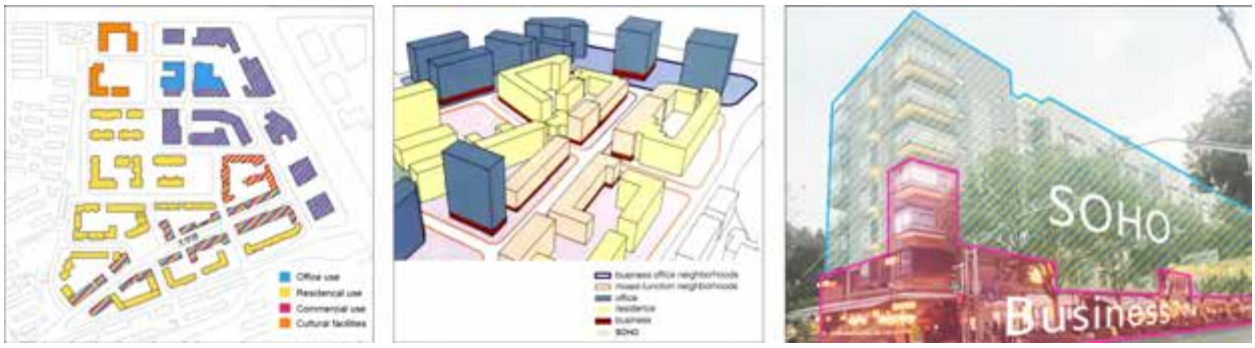

Figure 10. *Functional Mix Analysis of Chuangzhifang (Qian, 2017)*

5.2.4 Management Model: Flexible Governance through Subdivision
The district employs a decentralized governance model, subdividing the area into seven independently managed gated sub-blocks. Although this approach entails higher management costs, it enhances operational flexibility and security. In addition, these sub-blocks are physically and functionally integrated into a cohesive "super-block" through shared underground infrastructure, effectively balancing spatial openness with governance efficiency.

5.3 Densification: Strategies for Urban Block Transformation
In *Urban Transformations and the Architecture of Additions*, De Arce identifies three primary modes of urban transformation: extensive expansion, demolition-based reconstruction, and spatial densification (de Arce, 2014). In the context of land scarcity and rising demands for urban renewal, spatial intensification has emerged as a key strategy to activate existing urban fabrics and improve spatial efficiency. This section explores the mechanisms of densification at both the urban and residential scales.

5.3.1 Urban-Scale Densification
The fundamental strategy involves the insertion of new blocks into underutilized spatial voids without altering existing buildings, thereby preserving the original urban typologies. Based on Léon Krier's idea of urban space as composed of figure elements such as monuments and landmarks, and ground elements that form the spatial fabric of daily life, (Krier and Thadani, 2009) (Figure 11), this method overlays new "ground" elements onto modernist figure-dominated environments, resulting in a form of additive spatial repair.

For instance, de Arce's intervention in Chandigarh introduces 50m×50m blocks into the administrative district. These additions respect the axial order and iconic architecture while enclosing new communal spaces that enhance livability (Figure 12). Similarly, Rob Krier's interventions in central Stuttgart reinforce street edges and public squares through carefully placed infill (Figure 13), while Léon Krier's work in the Luxembourg suburbs re-establishes block perimeters and fine-grain urban texture, restoring spatial coherence at the human scale (Krier, 2010) (Figure 14).

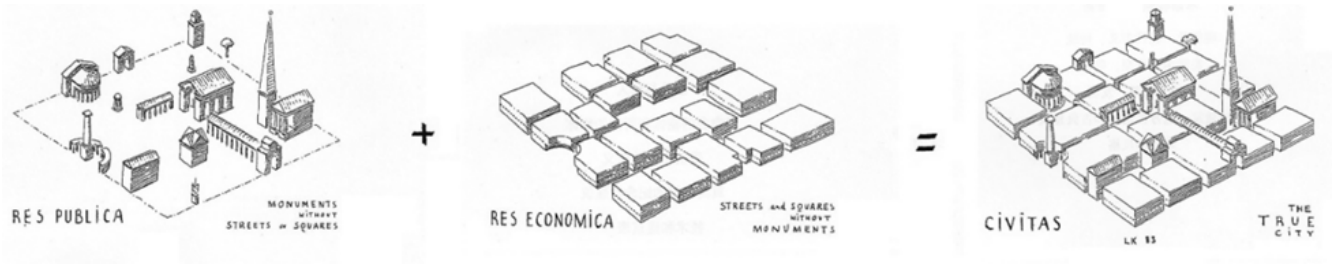

Figure 11. Typological Logic of Urban Spatial Structure (Krier, 2010)

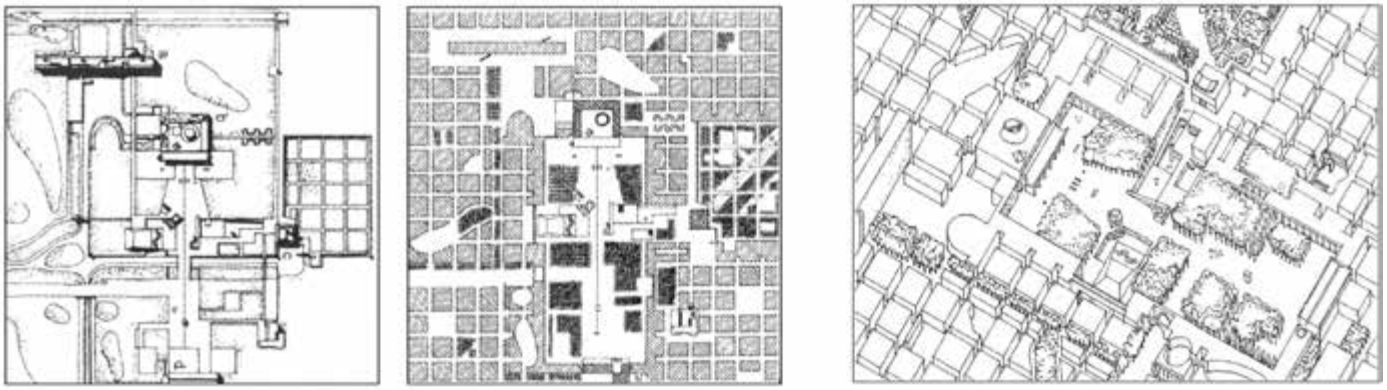

Figure 12. *Spatial Densification in Chandigarh New Town (Zhang, 2022)*

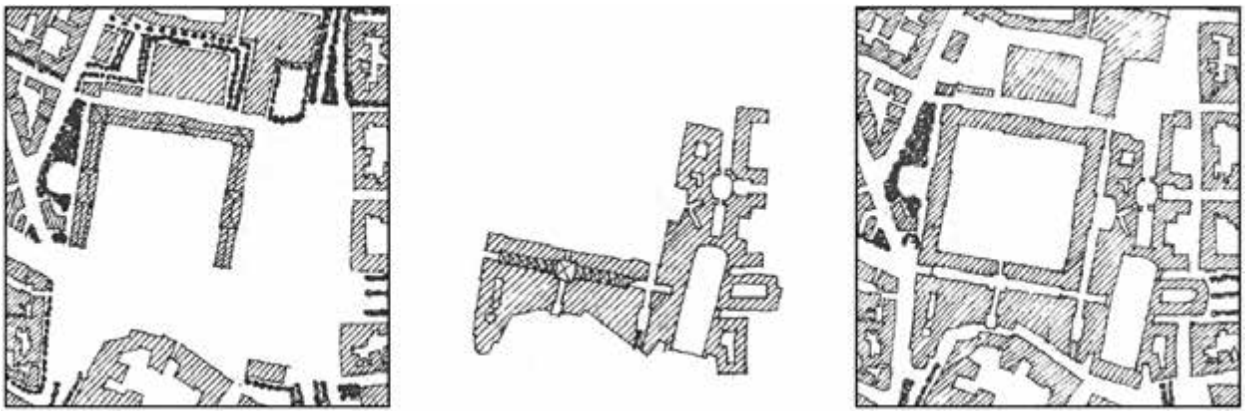

Figure 13. *Spatial Densification in Central Stuttgart (Krier and Thadani, 2009)*

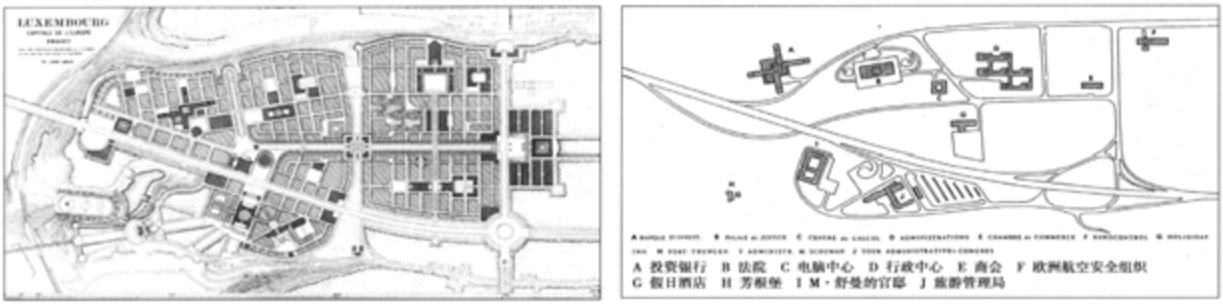

Figure 14. *Spatial Densification in the Suburbs of Luxembourg (Krier, 2010)*

5.3.2 Typological Transformation through Densification

Another strategy involves transforming existing building typologies through new additions. In the case of the Parliament Complex, de Arce's design infills street-facing volumes, converting isolated towers and slabs into a "enclosing block + tower" hybrid form (Zhang, 2022). This typological shift enhances enclosure, scale, and interface continuity, producing a more legible urban form (Figure 15). Such transformation represents a structural redefinition of urban form through densification.

This approach is echoed in Rob Krier's work in Runcorn New Town and Léon Krier's interventions in suburban Florence, where additions create cohesive and human-scaled urban environments through collaborative interplay between new and existing buildings (Figure 16).

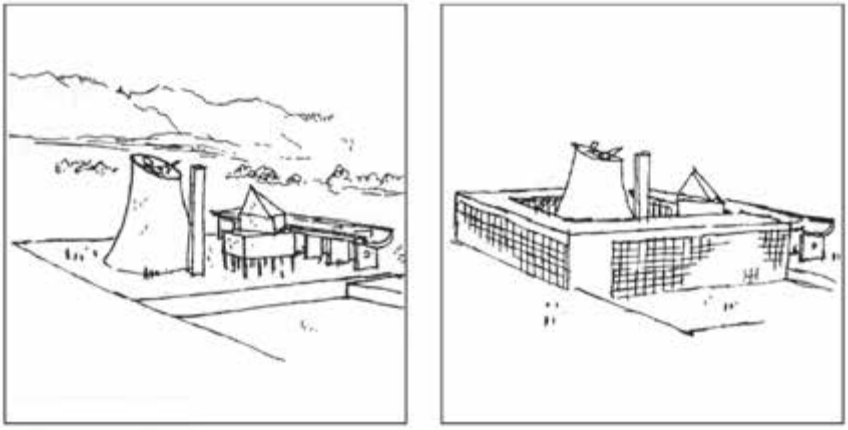

Figure 15. *Transformation of the Parliament Complex Into a Hybrid Form (Zhang, 2022)*

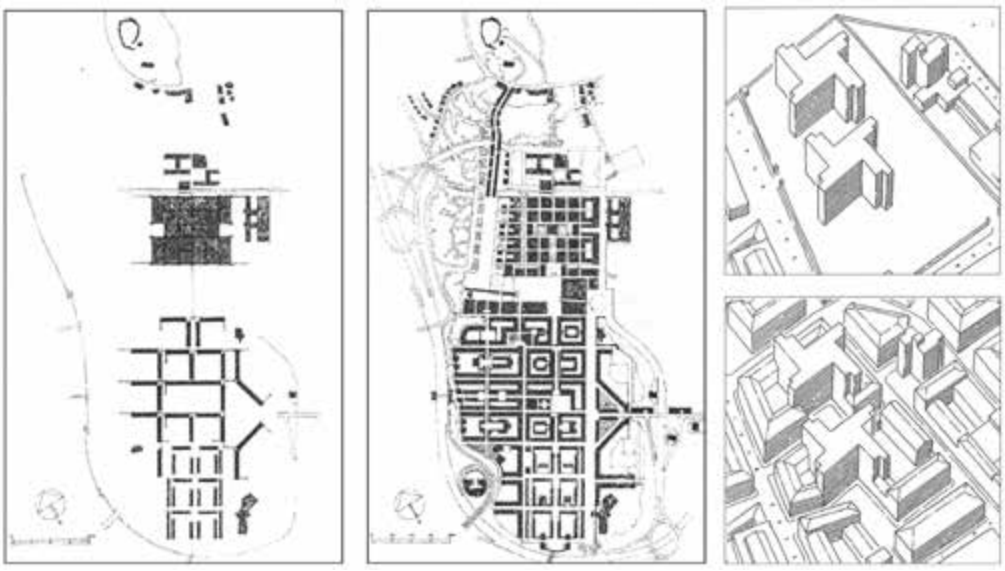

Figure 16. *Densification Strategies in Runcorn New Town (Krier and Thadani, 2009) and Suburban Florence (Krier, 2010)*

5.3.3 Residential Densification: A Prototype

While real-world examples of low-density residential densification remain limited, Léon Krier's experimental proposal for the St. Louis–Laurent Torres neighborhood offers a compelling model. In this scheme, formerly privatized land is re-parceled into traditional urban plots, reducing the public space ratio from 80% to 32% (Krier and Thadani, 2009). New low-rise additions (2–3 stories) are carefully integrated into the existing fabric, introducing housing, gardens, and civic amenities, while repurposing ground floors for mixed uses. This strategy of "small-scale accretions" demonstrates a viable approach to restructuring low-density environments by layering new spatial and programmatic complexity onto largely preserved built forms (Figure 17)

Figure 17. *Spatial Densification of the St. Louis-Laurent Torres Neighborhood (Krier, 2010)*

6. Design Experimentation

Building on the preceding analysis, this study proposes a strategic redevelopment of the core area of New Jiangwan Town. The design focuses on adjusting the scales of urban cells and their interstitial spaces, using spatial densification as a tool to restructure the urban framework and cultivate vibrant, resilient block patterns.

6.1 Three "Basics"

The design framework is anchored in three core aspects—Basic Task, Basic Strategy, and Basic Principle—which establish the foundation for targeted and responsive interventions.

6.1.1 Basic Task: Scale Adjustment

The design intervention addresses scale optimization at both the block and street levels, aiming to improve spatial functionality and social cohesion. At the macro scale, the current superblocks significantly exceed the optimal urban dimensions. Studies suggest that block sizes between 50 and 150 meters per side are most conducive to pedestrian accessibility and everyday convenience in central urban areas (Huang and Sun, 2012). However, all four study plots surpass this range, indicating the necessity of subdividing and reopening existing gated communities.

From a social standpoint, the household scale of residential clusters plays a crucial role in fostering neighborhood cohesion. Psychological research indicates that groups of 5–10 households encourage mutual support, 50–150 households cultivate a sense of belonging, while clusters exceeding 500 households tend to weaken interpersonal ties (Zhang, 2015). With current residential clusters exceeding 400 households, the need for finer subdivisions and more intimate social units becomes evident.

At the street level, the existing road network is characterized by excessive widths that undermine walkability and spatial articulation. The proposed design introduces strategic infill to reduce roadway dimensions, reconstruct fine-grain street interfaces, and enhance overall urban permeability.

6.1.2 Basic Strategy: Spatial Densification

Spatial intensification is the core design strategy. Studies show that vibrant urban districts typically achieve a built density of around 50% (Zhang, 2022), whereas the current average in New Jiangwan Town is only 12.65%, underscoring the need for densification development.

Following principles of spatial hierarchy, the site is divided into zones of differentiated intensity: The southern Wujiaochang node, designated as a city-level core, accommodates high-density, mixed-use development. The Yinxing Road area, identified as a community-level centre, is moderately densified to activate communal functions. The remaining sectors function as basic neighborhood units, subject to limited or deferred interventions.This gradient-based strategy seeks to produce a balanced urban fabric that integrates open space and functional intensity, aligning development with varying urban roles and scales.

6.1.3 Basic Principle: Contextual Adaptation

A critical challenge lies in integrating new interventions within the existing built fabric. The design adopts a strategy of contextual adaptation, in which existing structures inform the alignment, function, and articulation of new additions. Rather than imposing a uniform order, the approach leverages the irregularity of the current fabric to generate spatial variation within a coherent morphological logic. In this way, new and old elements co-produce block structures that are both legible and adaptive.

6.2 Spatial Reconstruction

At the structural level, the design introduces a reorganized framework to reshape the macro spatial logic of the site. To address the traffic and environmental burdens of Yinhang Road posed by the oversized scale, the design introduces a primary “urban vitality loop” that weaves through the site, interconnecting residential clusters. This loop extends westward to Ruida Road, integrating with the existing road network to establish a multi-dimensional street system. Additionally, a north-south ecological corridor is introduced to connect the waterfront edges on both sides of the site, forming a continuous green infrastructure. City-level public nodes are distributed along the primary loop, while secondary community-level nodes are embedded within residential clusters, forming a hierarchically structured public space network (Figure 18).

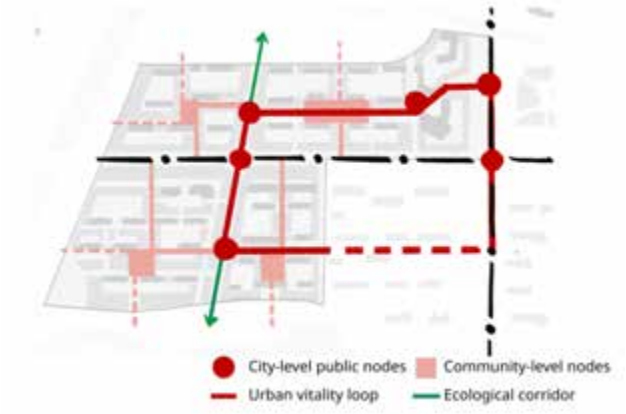

Figure 18. *Overall Spatial Structure Plan*

Building upon the structural reconfiguration, the macro-level strategy focuses on optimizing spatial scale and transforming gated communities into open urban blocks. This is achieved by dismantling and reorganizing the oversized, monolithic urban cells, introducing a finer-grained street network (Figure 19).

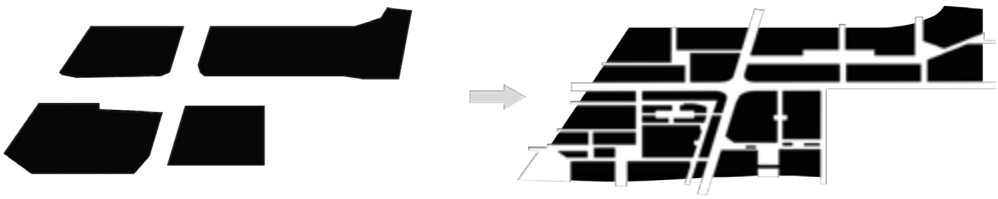

Figure 19. *Macro-Level Strategy: Before-and-After Comparison of Open Spatial Morphology*

At the micro scale, spatial infill is implemented through strategic insertions of new buildings that engage with existing structures to define new block perimeters and public interfaces. Three primary relationships are identified:

1-Full Intersection: New volumes overlap with existing buildings, often requiring ground-floor adaptation or replacement.

2-Partial Intersection: Including four subtypes—short-side intersection, inner long-side alignment, outer long-side alignment, and interlocking. Short-side contact entails minimal intervention, while the others require context-sensitive ground-floor modifications.

3-No Intersection: Including buffered spacing, enclosure, and juxtaposition, offering the least impact on existing structures.

These relationships are systematically categorized in a typological summary that guides design interventions (Figure 20). Based on these typologies, the design adopts a context-sensitive approach where new 3–4 story buildings are inserted in response to existing conditions. As a result, the district transitions from traditional slab-type blocks to a new hybrid model of “enclosing blocks + towers”, enabling dynamic dialogues between new and existing structures in terms of both scale and form.

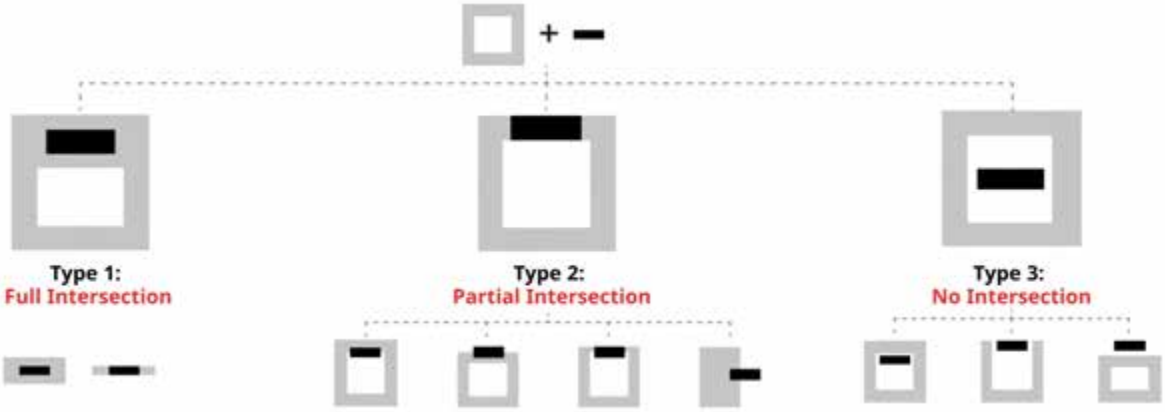

Figure 20. *Typological Summary of Spatial Relationships Between New and Existing Buildings*

The visual transformation of block morphology is illustrated through a series of before-and-after black-and-white diagrams, revealing changes in spatial structure and permeability (Figure 21). Building on a spatial hierarchy of "Plot–Building–Block–Cluster–District," the design introduces a multi-tiered public space system including city-scale nodes, community-scale nodes, and semi-enclosed courtyards embedded within blocks. This framework generates an "inward courtyard, outward street" configuration that transitions gradually from quiet and private to vibrant and public, accommodating diverse behavioral and psychological needs. Additionally, variations in building layout, height, and façade are used to shape and enrich spatial nodes, enhancing the overall experiential quality of the public space (Figure 22).

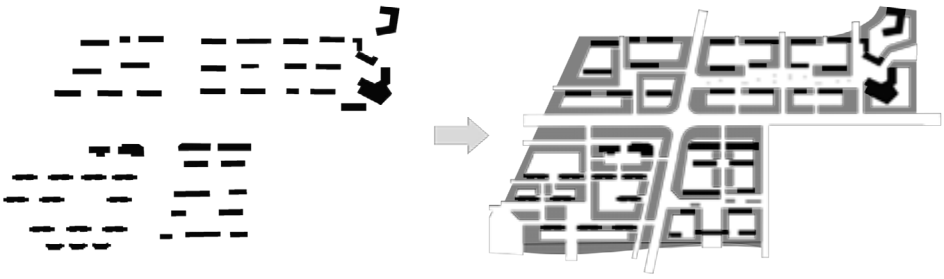

Figure 21. *Before-and-After Figure–Ground Comparison*

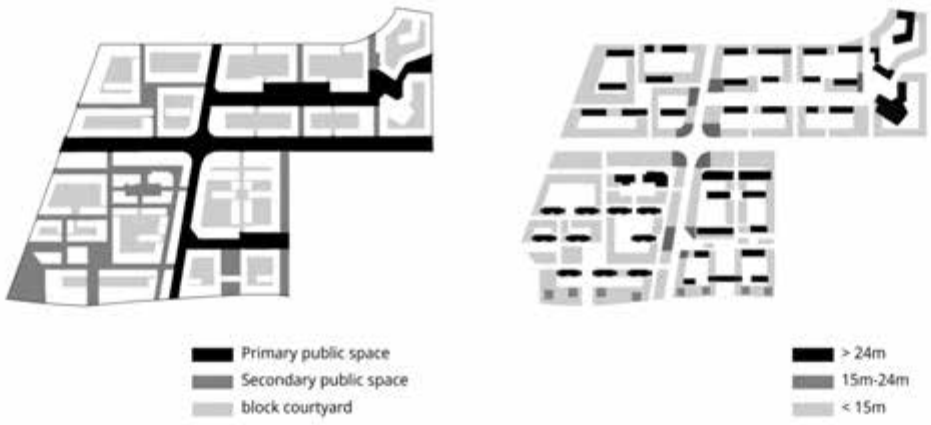

Figure 22. *Public Space Hierarchy Diagram (Left) and Building Height Control Diagram (Right)*

6.3 Traffic Reorganization

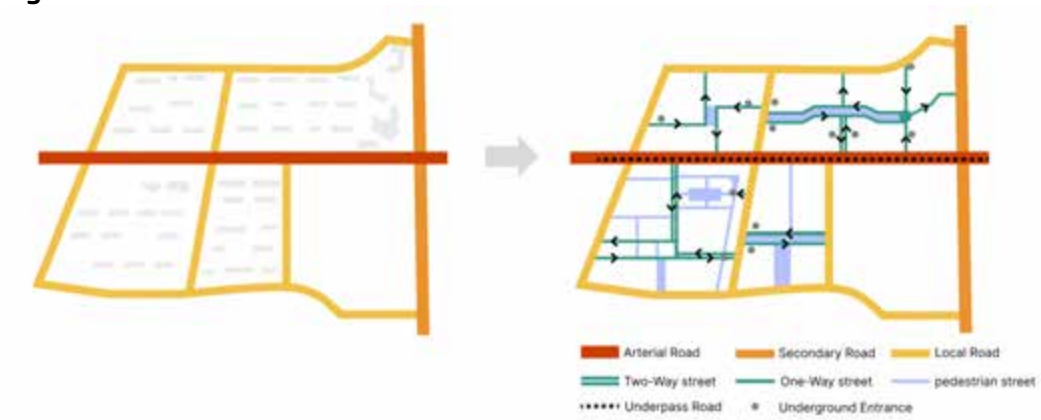

Figure 23. *Before-and-After Traffic System Comparison*

The reorganization of traffic operates at two levels: dealing with the existing urban road network and designing new intra-block circulation systems. The focus lies in coordinating the internal slow-mobility network with the external vehicular system while maintaining a clear distinction between the two (Figure 23).

For the external system, existing urban roads are retained as the foundational framework. While maintaining the primary traffic function of Yinhang Road, its scale and spatial form are optimized. A partially sunken traffic strategy is employed to redirect a portion of vehicular flow underground, thereby reducing the surface roadway width and significantly improving pedestrian spatial quality.

Internally, the newly introduced circulation system prioritizes pedestrian and low-speed traffic. In contrast to the external arterial roads, internal streets are narrower, consisting primarily of one-way lanes and pedestrian streets, with selective sections upgraded to two-way streets to ensure connectivity. To minimize disruption at points of integration, buffer lanes are added along both sides of major roads, alleviating the impact of the denser internal grid on regional traffic performance.

To further protect the residential environment, the design incorporates traffic-calming strategies, drawing from precedents such as Shanghai's Anting New Town. These include reducing vehicular lanes, introducing curved alignments, implementing one-way traffic patterns, installing roundabouts, and selectively closing intersections, thereby discouraging through-traffic and enhancing neighborhood tranquility.

6.4 Functional Supplementation

To transform the mono-functional residential area into a vibrant urban district, the design incorporates a mix of residential, commercial, and office functions into the newly inserted blocks. Drawing from mixed-use urban residential blocks in cities such as Berlin, where commercial functions generally occupy between 5% and 20% of the gross floor area (with up to 20% in central districts like Mitte and Kreuzberg), the proposed program the new buildings are assigned an approximate distribution of 55% residential, 30% office, and 15% commercial and community services. This ensures a residentially-oriented urban environment while differentiating from the regional commercial centre of Wujiaochang.

Functional layout is carefully aligned with the public space hierarchy. Continuous commercial and office frontages are positioned along the primary loop, forming a vibrant urban corridor comparable to the character of Daxue Road in Chuangzhifang. Community-scale public spaces are framed by smaller retail, cultural, and service facilities that support everyday life within each cluster. Along Yinhang Road, office functions dominate to strengthen its identity as a commercial corridor.

Functionally and spatially, the district adopts both horizontal and vertical integration strategies. A base typology emerges—commercial units at the ground corners, offices at middle levels, and residences above—offering flexible adaptation based on site-specific needs (Figure 24). This layered integration not only enhances daily

convenience and street-level vitality, but also positions the district for a gradual shift toward a more mixed-use, urban character, without compromising its residential identity.

The urban block adopts a both vertical and horizontal mixed-use typology, with a foundational model of "commercial units at the ground corners, offices at middle levels, and residences above" This model is flexible and adaptable to specific needs while maintaining a coherent logic.

Through this integrated approach, the design reinforces New Jiangwan Town's residential character while gradually transitioning it toward a more urban, multifunctional neighborhood.

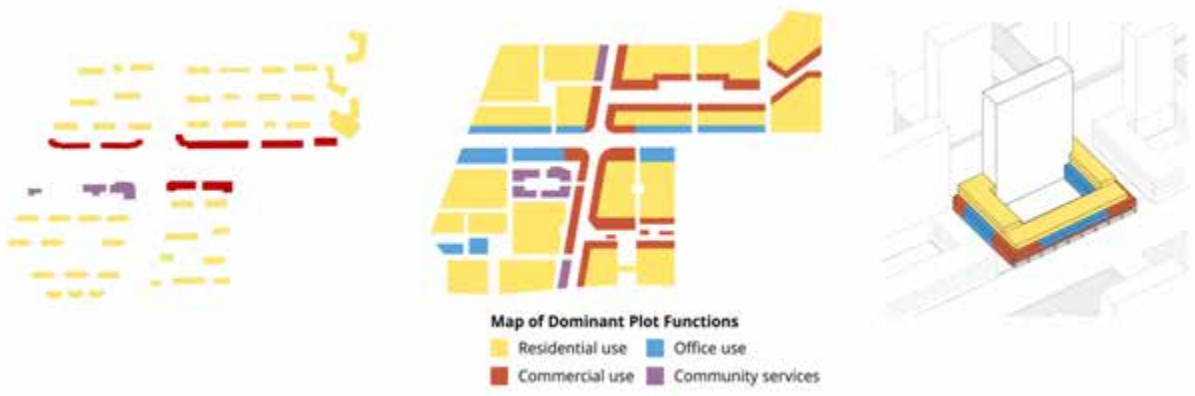

Figure 24. *Functional Layout: Before-and-After Comparison and Vertical Mixed-Use Typology*

6.5 Spatial Diversity Strategies

The creation of urban diversity is guided by a balance between spatial order and variation. At the urban design scale, new buildings align with existing structures while introducing articulation through axes, plazas, and T-intersections. These elements generate a rhythm of compression and openness, encouraging interactions across multiple scales (Figure 25).

At the block and cluster level, spatial patterns respond to both function and contextual character. Western clusters adopt inward-facing layouts for residential quietness, while eastern clusters open toward the urban edge to foster vibrancy. Northern clusters favor an ordered and structured layout to ensure clarity, whereas southern clusters use looser, fragmented patterns to create maze-like spatial experiences. These contrasting strategies collectively enrich the spatial texture of the district.

At the architectural level, future interventions will introduce further variation at a finer grain. Designers are encouraged to employ diverse architectural expressions, including pitched roofs, setbacks, arcades, and varied façade treatments, combined with a rich palette of materials. This flexibility supports architectural individuality while maintaining overall coherence, contributing to a layered and engaging urban environment.

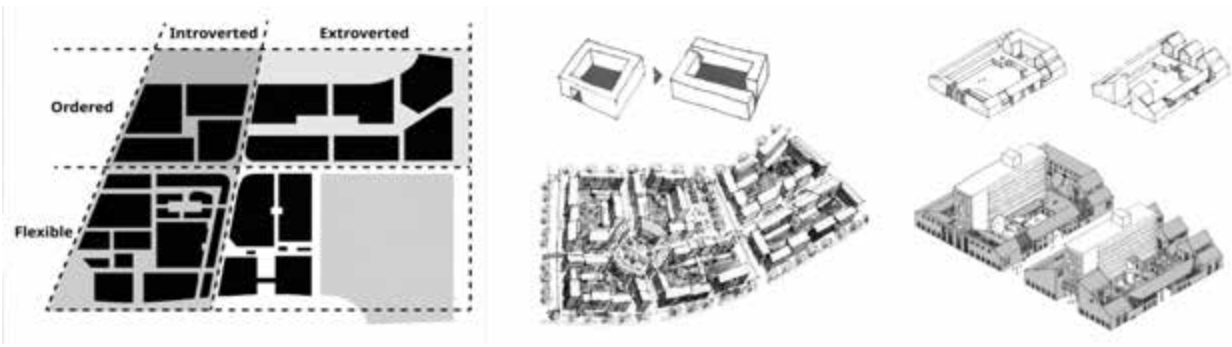

Figure 25. *Spatial Diversity Strategies*

7. Technical Challenges

The transformation from gated compounds to open communities involves not only physical spatial restructuring but also complex negotiations at the operational level such as land ownership, residential privacy, and socioeconomic equity. This chapter analyzes key technical challenges encountered in the implementation process.

7.1 The Change of Land Ownership

Extending urban streets into residential compounds and adjusting the scale of peripheral roads inevitably requires a reconfiguration of land ownership and plot boundaries. The design must therefore directly address how spatial densification strategies impact plots subdivision and property rights (Figure 26). Two primary approaches are identified:

Approach 1: While the primary loop inevitably subdivides the original parcel, other internal streets remain within existing property boundaries. These streets, though publicly accessible, are not designated as municipal roads and remain under community ownership. This minimizes legal transformation and avoids conflicts with current regulations, but may compromise long-term public governance.

Approach 2 designates all newly introduced roads as urban infrastructure, subdividing parcels into smaller units and requiring more extensive adjustments to land rights. Although more demanding in terms of implementation, this approach offers greater clarity in urban form and block structure. As a forward-looking urban design strategy, the second approach is considered as a more future-oriented and structurally coherent solution.

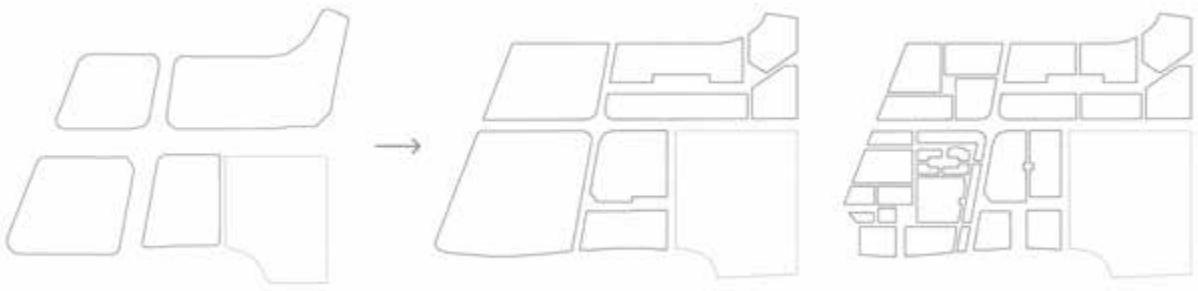

Figure 26. Before-and-After Parcel Subdivision Comparison

7.2 Avoidance: Negotiating New–Old Building Interfaces

While the design is guided by the principle of contextual adaptation, its technical implementation must address potential physical conflicts between new and existing structures, particularly with regard to residential buildings' needs for light and ventilation. To mitigate these impacts, the location and height of new additions are carefully controlled through staggered massing, spatial offsets, and deliberate gaps (Figure 27).

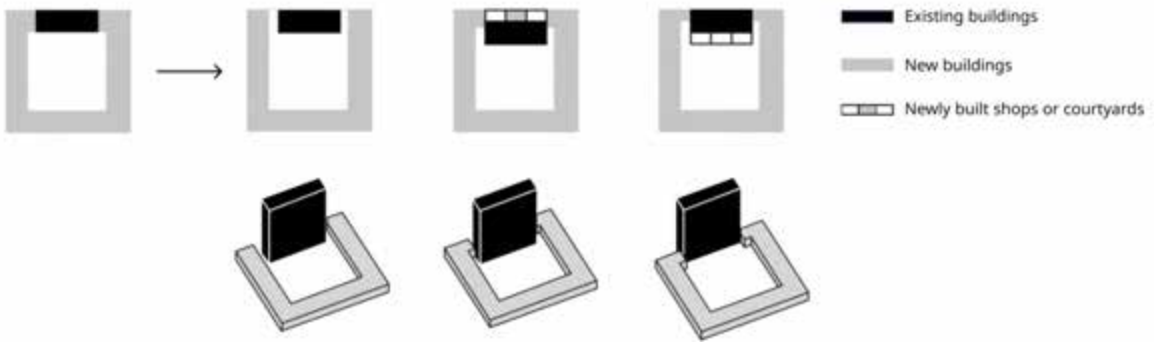

Figure 27. *Strategies for Managing Conflicts Between New and Existing Buildings*

7.3 Balance: Ensuring Privacy and Safety in Open Communities

To preserve privacy in a more open, mixed-use urban environment, the design incorporates spatial buffers such as building setbacks, ground-floor retail and courtyards (Figure 28). These elements create gradual shifts from public to private space. Although open communities inherently offer less privacy than gated compounds, the improved spatial quality and lifestyle afford greater long-term appeal .

Regarding safety, the scheme follows Jane Jacobs' principle of "eyes on the street." Active ground-floor commercial frontages replace blank compound walls, enhancing natural surveillance. The blocks become the fundamental unit of communal defence, contributing to both social cohesion and environmental security.

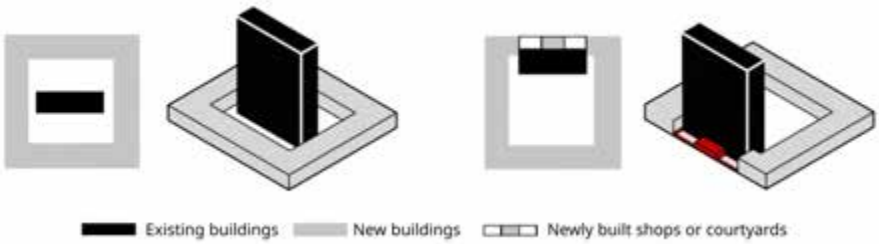

Figure 28. *Privacy Enhancement Strategies in Open Communities*

7.4 Compensation: Economic Viability and Social Equity

The proposed densification strategies may generate friction through shadowing, view obstruction, or reduced privacy, especially those living on lower floors. It is therefore essential to establish a multidimensional compensation framework. Compensation could be economic or spatial. Economic compensation refers to direct financial reimbursement. Spatial compensation can take the form of private gardens, balconies, or retail opportunities offered to affected residents within the new developments. Additionally, residents may be relocated to high-quality new housing units.

Beyond resident-level responses, a broader framework must define responsibility and benefit: who invests, who builds, and who gains. A public-led, multi-stakeholder renewal model is recommended to manage investment and ensure equitable value distribution. Additional floor area from densification should be used to generate returns that are reinvested locally, forming a closed-loop of value regeneration. This framework underpins not only financial feasibility, but also social acceptance and long-term sustainability.

8. Conclusions

Within the context of China's urban regeneration, this study critically examines large-scale gated residential communities shaped by modernist planning principles, directing the urban design perspective toward spatial quality and sustainable development.

Using New Jiangwan Town in Shanghai as a case study, it employs the concept of urban cells to examine the technical feasibility of transforming closed compounds into open communities. Through scale optimization and functional integration, the study demonstrates the feasibility of this transformation, offering a flexible and operable design framework. The spatial densification approach is shown to have broad applicability in urban regeneration.

Beyond its local context, the study contributes to the evolving discourse on urban renewal in comparable global contexts. It offers insights into redefining urban heritage and reconstructing public life, with strategic implications for Global South cities seeking sustainable approaches to legacy transformation.

Abstract:
The layering of historical spaces in Xi'an has led to the preservation and renewal of historical forms being maintained through the underlying structural control logic of residual forms,such as growth patterns along axes,partitioning relationships along enclosed structures,and isomorphic textures derived from fractal structures.As a representative of such historical cities,Xi'an's spatial text further reveals that the significance of architectural ruins as elements within the urban framework determines the linguistic structural characteristics of their formal value.

Based on the renewal cases of Xi'an's axial spatial morphology,this study explores how architectural forms,as extensions of urban morphology,rely on urban morphological research to sustain their historical significance in contemporary layered historical spaces,as well as the value continuity of East Asian urban heritage's unique morphological composition in the rewriting of contemporary urban forms.

Keywords: Typology, Xi'an, Historical axis, Urban morphology, Urban palimpsest, Architecture and city, Systemic transformation, Site rewriting

1. Architectural Fragments in Systemic Transformation

As urban forms evolve structurally over long historical periods, architectural elements from the previous era's structural system often face being captured and reorganized by the new structural system in the construction of a new layer of urban material text. These buildings or groups of buildings continuously integrate into the writing of the new urban fabric. The study of morphological typology becomes an indispensable premise for site research in architectural design during the renewal of such multi-layered, superimposed historical cities. It provides necessary systematic contextual analysis for architectural sites along the two dimensions of diachrony and synchrony, emphasizing the study and generation of architectural forms as linguistic elements of the urban morphological typology system through a textual organizational model. In terms of textual linguistic elements, context expresses the relationship between the whole and its parts, which only have complete meaning when understood as a whole. (Pezzetti, 2025) Whether surviving or renovated historical buildings or building clusters, or urban structural information hidden in city blocks and archaeological strata, they can be understood at the fragment or system level as layers of historical information within this overall superimposed collection that urgently need to be revealed and organized. It is worth noting that for traditional Chinese urban settlements: in the context of changes in urban morphological structure, buildings are not always subordinate to the urban structural system; rather, with structural evolution, most building forms continuously participate in or even determine the fractal occurrence and operation of urban structures at different fractal levels. For example, the architectural forms of city walls, gates, and towers themselves mark the same level of urban enclosure structure, while the forms of city towers and the centrally located bell tower arise from the urban axial spatial structural system. These buildings' "symbolic forms" are woven by a multidimensional systemic whole and are not fundamentally determined by themselves. Moreover, they do not participate in the adjustment of synchronous morphological relationships as "individual building" entities in relation to the continuously changing "residential fabric." Caniggia and Maffei, 2008 Rossi, 1966 This differs significantly from the European structural system, where streets and public spaces divide and juxtapose urban building plots, and at the level of architectural form operation. Compared to the expression of architectural form itself, the vast majority of important buildings in Chinese urban history have architectural significance because their form types reveal urban-level patterns. A typical example is the Xi'an Bell Tower, which, after urbanization, serves as the center of a road roundabout with a "symbolic form." Its representative construction form is unrelated to timekeeping functions or commemorating any event; it purely acts as a nodal element integrating the city and geographical environment structure. This nodal element is gradually integrated by urban cultural construction into a form of urban structural morphology; it strengthens the architectural form types of the same-level related elements to provide a reference system for

marking multi-level macrostructures in the urban landscape dimension.This also brings difficulties for Chinese historical urban renewal in borrowing European experiences.

The tremendous transformation of Chinese urban architectural typologies and site structural types has forced traditional architectural linguistic elements to continue in the contemporary urbanization context, where they have lost their systemic linguistic significance. In the capital-driven planning practices where linguistic elements lose their systemic function and the system context is completely segmented by plots, the traditional Chinese urban architectural typology, which originally spanned systems, can only be reduced to a convenient mode of "style experiments" decorating city streets as a subsidiary context for architects to choose from.

The classical Chinese city, whose urban system structure determines the architectural form types, has lost the cognitive context of architectural form types and the holistic connection of formal operations in the contemporary urban modernization movement; the typological combinations that lost control at the architectural dimension have been dismantled. While the classical language frees itself from typological constraints, it imitates the classical symbols competing under Western commercial trends, which in turn leads to the smearing and concealment of the city's deep historical structure in the preserved fragments carrying certain historical information. The superficial behavior that seemingly strives to reveal a certain historical layer's characteristics instead severely weakens the typological features of the remaining authentic historical form information. In 1985, Rossi described Japanese cities with characteristics similar to those of China: "I find it difficult to distinguish past civil buildings, religious buildings, and community buildings. Similarly, some more refined contemporary buildings are the same. My first impression of their reality is typological, that is, the principles followed by usually very different architectural structures."

2. The Transformation of the Site Context of Xi'an Urban Architecture

The continuous layering and superimposition of Xi'an's historical urban space have led to the preservation and renewal of historical forms being maintained in each era through the morphological control logic of the residual form's underlying structure. However, the morphological structure of the Chinese urban context has been in flux: what changes is the segmentation form of residential and commercial building land at the end of the macro-structural system (such as the transformation from "lilong" to "hutong alleys"); what remains unchanged is the mutually reinforcing relationship between the structural system and architectural form types, namely the typological organization of architectural forms and the construction of meaning (such as the gate tower system and city gate system). This unchanging control logic of urban form types, from top to bottom, from mountains and rivers to buildings, thoroughly creates the typical characteristics of East Asian layered historical cities as "rewritten editions." These characteristics include: fractal growth patterns of courtyard units along axial directions, division relationships along enclosed structures, and isomorphic textures derived from fractal structures(Miu, 1990).These typical structures of East Asian urban forms collectively define the attributes and form types of buildings and courtyards within the spatial framework. This cultural landscape information, formed by the synergy of interior and exterior spaces, is hidden in the "remnants" of the city's historical landscape and has a multi-level nested logic completely different from modern cities that emphasize the split relationship between buildings and road networks. This exacerbates the accelerated dilution of these historical landscapes at the morphological level and further dissolution at the structural level within the contemporary urban structural system.

3. Architectural Design's Revelation of the City's Historical Pattern

As a representative of this type of historic city, Xi'an's spatial text further reveals the significance of architectural sites as elements within the urban framework, determining the linguistic structural characteristics of their formal value. Since the beginning of this century, driven by urbanization efficiency, Xi'an's important historical sites have faced reorganization within the contemporary urban structure, generating new urban forms along their stratified historical axes. These new forms of spatial restoration not only attempt to reinterpret the historical significance of the site under a certain cultural construction but also provide buffering and self-protection mechanisms for the "important heritage" facing urbanization pressures; on the other hand, the axial forms of remnants at various levels in the city signify structural growth that goes far beyond the "symmetry" of architectural form and volume, existing within an environmental system beyond the "important heritage," and have long served as a control system for architectural types evolving with history. While new urban architecture plays a role in cultural narrative, it cannot avoid the systemic structural context revealed by these "important heritage" sites

as partial fragments of a potential historical whole. From the perspective of urban renewal, this excavation of renewal conditions determines the strategic direction of new architecture rewriting the historical structure of the urban dimension; from the perspective of heritage conservation, this awakening of design principles precedes architects' subjective formal experiments and their coincidental alignment with cultural narratives Rogers, 199 Through the analytical study of the evolution of Xi'an's urban historical morphology, within the urban pattern centered on axes, the axis serves as the main principle organizing the growth of architectural interior and exterior spatial layers through courtyard patterns. Architectural forms developed around this system are woven, concealed, repaired, or even dispersed within the stratified layers of the city's historical text. The architectural creation sites around urban heritage areas strictly accept the allocation of contemporary urban land, with historical axes being captured by the land-use logic of contemporary urban architecture, causing misleading misinterpretations and evasions in understanding the site's historical axes. The continuation of axes in new architecture related to ruins or historic buildings often stops at the inheritance of superficial symbols, leading to systemic isolation. In the formal strategies of such architectural designs, truly understanding and deeply conveying the value and significance of the city's historical structure, revealing the connotations of the site's multilayered system, generally relies on the following three experimental steps, here still exemplified by the architectural continuation of the historical axial pattern:

1) Morphological Analysis: Focus on the evolution process of the axial spatial forms in these areas, using the diachronic evolution of the figure-ground relationship of group buildings as an analytical element of the urban historical landscape system. The relational patterns of synchronic structures from various eras serve as the analytical basis for the diachronic evolution of architectural forms. In the East-West heritage value contest, respect the stratification process of the existing texture (including diachronic structural evolution and synchronic structural collage), dissecting the morphological texture of new architecture to organize and reveal opportunities to uncover hidden historical structures while respecting the existing complex structural system.

2) Site Decoding: Explore how architectural forms, as extensions of the urban landscape in contemporary stratified historical spaces, maintain historical significance through morphological studies, as well as the value continuity of East Asian urban historical landscapes in contemporary rewriting. Decode the spatial grammar of the site's historical stratification through morphological analysis and typological research.

3) Structural Verification: The fractal growth logic embedded in the axial structure constitutes the texture of Xi'an's urban historical landscape. Following the architectural volume under this structure naturally achieves its typological significance in form.

4. Practical Research on Interpretive Rewriting of Historical Axes

As a typical example of this type of site condition, the spatial text of Xi'an, represented by the Beilin Historical District, further reveals the significance of architectural landscape relics as elements woven into the hierarchical system of the city's historical landscape, as well as their linguistic structural characteristics that determine their formal value. The first case involves repairing the relationship between the new and old buildings of the Beilin Museum through landscape design. Since modern times, urban construction forms dominated by Soviet-influenced architectural entities have gradually interfered with the renovation and renewal of traditional neighborhoods originally dominated by courtyard patterns, under the pretext of seeking higher indoor utilization rates. The ancient inscription museum located in the core area of Xi'an's old city—the Xi'an Beilin—shares a historical texture similar to that of most Chinese and even East Asian cities, which unfold layer by layer along the north-south axis. Within it, vague pattern sequences and scattered individual buildings are submerged in the increasingly dense and morphologically changing urban fabric. Modern heritage workers, drawing on Western models of protecting individual buildings and groups of buildings, have allowed these remaining historical fragments to continue the traces of ancient civilization in the urbanization process by gradually expanding isolated individual buildings. Although this model formally repairs and continues the ancient texture, it causes a serious loss of the informational and value significance of these individual historic buildings at the group level of courtyard patterns. The newly completed north-side annex, half-embedded underground, continues this model in its strategy for updating the city's environmental historical information, despite the building's own design offering a new typological interpretation of the individual buildings housing the steles. The organizational structure of courtyard axes in ancient East Asian cities determines and constitutes the typological derivation of individual buildings; as nodes that "segment" the city's axial pattern, their significance usually precedes the

formal meaning of the buildings themselves. The new museum's repeated emphasis and focus on the typological interpretation of the building's own historical form instead intensifies its opposition to the city's contextual system. The limited landscape design task needs to structurally transform the axis and the spatial pattern of its two wings between the new and old buildings while connecting the traffic and evacuation routes of the new and old museums. (Figure 1)

1) Morphological Analysis: The design first organizes the basic logic of urban spatial segmentation by hierarchical levels. It then compares several courtyard generation methods based on "segmentation" as a spatial generation principle to assess their patching effect on the existing courtyard sequence and evaluate the opportunities revealed by this patching for the pattern to which the historical individual relics belong. The "preview" action of the new museum's building wall logic can simultaneously serve as the finishing and tidying of the preceding historical space dominated by courtyards. Thus, the "plaza" in front of the new museum building is understood as the "cross street" following the Confucius Temple courtyard at the end of the old venue. While organizing vertical circulation of the historical terrain, the landscape wall controls people's bidirectional understanding of the north-south structure as they stand between it.

2) Site Decoding: The new wall, matching the materials of the new and old venues, stands independently between the new and old buildings, constituting a linguistic type of "ruins" in the nostalgic sentiment of ancient Chinese literati. The converging and dispersing walls penetrate the grid between the new and old buildings, becoming an intermediate mediator that treats the new and old buildings—systems of different kinds—as exhibits to each other. Within the movement lines defined by the walls that are at once near and far, the perspective images of the new and old building landscapes complete the camera's transitions and edits through the organization of scene fragments.

3) Structural Verification: The landscape design on both wings around the axis forms spatial extensions adapted to the historical terrain under a symmetrical relationship, maintaining the growth of the courtyard axis at different levels. The Xi'an Beilin Museum complex, submerged in two different types of urban structures from ancient and modern times, transforms from an ambiguous and unclear structural relationship into a conclusion of the historical structure and a "camera transition" between the old and new Beilin through landscape mediation here. It realizes the originally mixed but overall museum and ancient temple complex, shifting from the single and strict whole of "Beilin as Confucius Temple" to a woven system of two opposing yet unified forms of "Beilin and Confucius Temple overlapping out of alignment." The city itself is a fabric formed by multiple systems layered through history. This both separates the historical venue from the new venue in terms of morphological type and maintains the structural integrity of the historical venue as a "historical building complex" heritage attribute.

The museum's landscape renewal ultimately respects the existing historical building complex by implanting a new "wall system" as a frame of reference for the historical space, organizing and integrating the scattered courtyard spatial sequence, highlighting the courtyard-dominated urban spatial order, and revealing the courtyard relationships to which individual building remains belong. At the same time, it also achieves the new venue building's own persistence and focus on formal innovation based on a certain historical type.

5. Conclusion: Structural Writing of This Time and Place

The "design site" in historical urban renewal activities is based on the standpoint of urban architecture, adapting both to the planning logic of contemporary Chinese urban renewal building land and serving as a meso-level research object for tuning the continuation of urban context on important urban heritage sites within a rapidly changing and complexly layered historical urban morphological environment. The Chinese character for "site" itself provides an accurate explanation of the synchronic and diachronic research dimensions of the historical attitude toward design land, representing a dynamic spatiotemporal concept of "this time and place." It signifies respect for the systemic meaning behind its own temporal condition and spatial state. The research emphasizes the principles and recognition patterns of architectural design interventions on the urban heritage landscape of the area but does not necessarily rely on strong intervention strategies involving urban architectural body conflicts. This intervention approach involves: revealing, protecting, and marking the core grammatical structure of the historical landscape; transitional buffering methods with morphological continuity research; and interpretive spatial language for contemporary interventions. The study shows that heritage landscape renewal in East Asian historic cities represented by Xi'an should establish a dynamic interpretive mechanism

while studying and continuing the deep structural genes of historical forms. Through typological experiments simulating the inherited urban context system, it comparatively discusses the reweaving and renewed contest of the urban structural systems in the area. This allows the city's "rewritten edition" to provide a readable formal sorting and structural inheritance for historical landscape fragments through the "site rewriting" model, enabling them to integrate into the future urban heritage system with dignity.

Abstract
This paper investigates the interplay of urban cultures, heritage, and spatial transformation through the case of the former Marsala Tito Barracks in Sarajevo, now redeveloped as the University of Sarajevo Campus. Developed within a research collaboration between the Universities of Ferrara and Sarajevo, it frames urban design as a critical lens for examining tensions between global urbanisation and local cultural identities. Challenging static conceptions of heritage, the study advocates for a dynamic, negotiated understanding shaped by evolving social relations. It highlights the complexities of reconciling heritage preservation with contemporary development in a post-conflict, multicultural city. The transformation of the Marsala Tito site exemplifies how urban interventions become contested arenas of memory and identity, calling for more inclusive, context-sensitive strategies that respond to both local narratives and global urban pressures.

Keywords: Post-Conflict Urbanism, Multicultural City, Urban Transformation Processes, Overlapping Urban Narratives

1.Theoretical and Methodological Framework

1.1 Introduction

The city of Sarajevo, the capital of Bosnia and Herzegovina, stands as a deeply stratified urban environment shaped by centuries of imperial, socialist, and post-conflict transformation. As a city at the crossroads of East and West and the *locus* of multiple modern conflicts — including the 1992–1996 siege during the Bosnian War — Sarajevo is more than a post-conflict city: it is a complex and unique urban palimpsest (Machado,1976). Each layer of its history remains legible, yet overlaid with subsequent uses, narratives, and ideologies. The city's contemporary condition is emblematic of the intersection of trauma, resilience, and re-imagination in the context of cultural heritage and urban regeneration.

In such a context, heritage is not simply an object of conservation: it is a medium of contested meanings. In Sarajevo's post-Dayton configuration, the politicization of urban planning and memory practices is embedded in fragmented governance and ethnic territorialization (Pickering, 2007). Projects like the transformation of the Marsala Tito Barracks into the University of Sarajevo Campus must be understood within this matrix of spatial symbolism and institutional negotiation.

Originally constructed in the Austro-Hungarian period and serving military functions through the Yugoslav era, the Marsala Tito Barracks were abandoned in the post-war years. They were later appropriated as the site for a civic and educational transformation — a shift from closed, military urbanism to an open, knowledge-driven environment. This evolution is the focus of a collaborative academic research effort between the University of Ferrara and the University of Sarajevo, initiated through the Erasmus+ program (2019-1-IT02-KA107-061336), which framed architectural design as a research tool and critical medium for understanding spatial transformation in complex, multicultural contexts.

This paper investigates three core research questions:
- How can urban heritage be understood not as static but as dynamic, particularly in post-conflict urban settings?
- What methodologies are suitable for reading and intervening in sites marked by overlapping historical, social, and architectural layers?
- How can transnational academic collaborations contribute to more inclusive and culturally sensitive urban development practices?

1.2 Conceptualizing Urban Heritage

Conventional approaches to heritage — especially those aligned with conservation charters and institutional frameworks — tend to prioritize tangible assets and monumental structures. These "authorized heritage discourses," as defined by Laurajane Smith, risk reifying the past and detaching it from lived experience. In contrast, critical heritage studies emphasize heritage as a dynamic, processual phenomenon, continuously constructed and reconstructed through social practices and spatial interventions (Harrison, 2013).

This shift is particularly relevant in cities like Sarajevo, where memory is politically charged and layered across ethnic, religious, and temporal axes. (Haidar, 2006). The Marsala Tito Barracks, for example, symbolize different things to different actors: to some, a relic of Yugoslav unity and military order; to others, a void awaiting reinvention. The act of transforming this site into a university campus involves not only physical redevelopment but also symbolic reinterpretation.

The concept of the urban palimpsest is instrumental here. As Rodolfo Machado (1976) argued in his seminal essay, the palimpsest represents a city where successive layers coexist, interfere, and reveal traces of prior occupations. Such layering does not imply a neat historical chronology but a complex, often conflictual assemblage of spatial meanings. In Sarajevo, the palimpsest condition includes Ottoman mosques, Austro-Hungarian boulevards, socialist apartment blocks, war ruins, and emergent neoliberal enclaves.

Solà-Morales further elaborates on this concept through his notion of "terrain vague," referring to ambiguous, residual urban spaces that resist definitive categorization. These spaces, often overlooked, hold the potential for new interpretations and interventions that acknowledge their layered histories. Engaging with these spaces thoughtfully, and avoiding aggressive impositions that erase their inherent complexities, is fundamental to promoting an effective and sensitive approach to urban and architectural design. (Solà-Morales, 1995).

Moreover, the importance of acknowledging the fragmented and layered nature of urban memory, advocating for interventions that respect and engage with the existing historical and cultural contexts rather than overwriting them, erasing them somehow (Haidar, 2006)

At the scale of the Marsala Tito Barracks, this palimpsest condition is especially visible. The barracks' architecture, planning geometry, and residual militarized landscape stand in tension with the civic and educational programs being projected onto them. The transformation project, as explored 3 years in a row by architectural and urban design students, does not seek to erase these traces but to integrate them critically within new urban narratives.

Importantly, this reconceptualization of heritage aligns with broader discourses on planetary urbanization, as theorized by Brenner and Schmid (2015). In an increasingly globalized urban system, local identities and cultural specificities are often subsumed by standardized development logic. Redevelopment projects risk producing homogenized spaces unless they are grounded in situated, culturally sensitive approaches. The work presented in this paper advocates for a model of heritage practice that resists such flattening — one that sees value in complexity, contradiction, and negotiated transformation.

1.3 Methodological Approach

The methodology employed in this research combines architectural design, critical heritage theory, and transdisciplinary pedagogy. At its centre is the overlapping methodology, developed within the design studios and workshops coordinated by the University of Ferrara in Sarajevo. This approach was articulated by Elena Guidetti in the context of LAP3 Architectural Design Studio as a "dual-paced didactic framework" designed to accommodate both synchronic readings of the present city and diachronic interpretations of its historical and cultural layers.

Overlapping refers to the simultaneous engagement with multiple temporal, spatial, and cultural layers in both analysis and design. It is opposed to reductionist models of urban intervention that seek clarity or linear solutions. Instead, it embraces ambiguity and contradiction as inherent qualities of real urban environments. In Sarajevo, this meant working with the existing barracks structures — not as obsolete relics to be replaced, but as active participants in shaping new spatial narratives.

Methodologically, the process was structured into two interconnected phases:

(1) Analytical Layering: students and faculty began with immersive site investigations, including photographic surveys, historical mappings, programmatic inventories, and spatial ethnography. The aim was to generate a multi-dimensional reading of the Marsala Tito site, incorporating both formal properties (geometry, structure, materiality) and informal dynamics (use patterns, social meanings, perceptual layers). These investigations culminated in visual "overlaps" that combined different timeframes and thematic perspectives on the site.

(2) Design as Inquiry: building on this analysis, students developed architectural and urban proposals that did not resolve the site into a single vision but instead allowed for multiple, often conflicting, interpretations. The design strategies — such as graft, box-in-the-box, parasite, and platform — were chosen for their capacity to negotiate between presence and absence, memory and innovation, stasis and transformation.

This iterative process was supported by collaborative critiques, guest lectures from Sarajevo-based scholars and public exhibitions that encouraged feedback from stakeholders. Importantly, the method emphasized pedagogical reciprocity: Italian and Bosnian students worked in mixed teams, producing knowledge across cultural and disciplinary boundaries. This not only enriched the design output but also enacted a model of shared authorship and mutual learning, crucial for operating in contexts of contested heritage (Guidetti, 2020).

The significance of this approach lies not only in its academic merit but also in its capacity to model a more inclusive, culturally grounded form of urban practice. The method produced a form of critical storytelling that respects the multiplicity of voices and spatial histories embedded in the site. Rather than imposing a single narrative, the designs allowed for overlapping meanings to be read, inhabited, and modified over time (Gardini, 2020).

Finally, the application of the overlapping methodology within LAP3 workshops resulted in more than 60 student design proposals and two major exhibitions in Sarajevo. These projects were not intended for direct implementation, but as speculative instruments that could provoke dialogue, critique existing paradigms, and suggest alternative futures for the Marsala Tito Barracks and similar urban sites. In this sense, design was mobilized not only as a tool of production but as a method of thinking-through-making, a way of generating knowledge about the urban condition through material and spatial speculation.

However, this design exercise sees the confrontation with the reality of urban transformation and planning. The project developed for this site and the current situation is still open to future transformations.

2.Case Study – Marsala Tito Barracks Transformation
2.1 Historical Significance of the Site
Overview of the Marsala Tito Barracks' military and political history.
Its symbolic and cultural relevance in the urban fabric of Sarajevo.

2.2 From Military Zone to University Campus
Description of the masterplan by ARUP London.
Phases of physical transformation: demolition, preservation, adaptation.
Integration with city planning and public space networks.

2.3 Actors and Stakeholders
Roles of architects, planners, local communities, and institutions.
Analysis of power dynamics and decision-making processes.
Tensions between preservation, redevelopment, and commercialization.

2.4 Urban Identity and Everyday Use
How the new campus is perceived and used by students, staff, and residents.
Shifts in social practices and spatial meaning.

Critical Reflections and Broader Implications
3.1 Heritage in the Age of Planetary Urbanization
How global urban models (e.g., neoliberal planning, university-driven gentrification) impact local heritage.
Homogenization vs. cultural specificity in post-socialist urban spaces.

3.2 Contested Memories and Narratives
Memory politics in Sarajevo and its role in shaping heritage discourses.
The site as a locus of competing narratives: reconciliation vs. erasure.
The role of critical storytelling and urban pedagogy.

3.3 Conclusion
Summary of key insights from the case study.
Reaffirmation of the need for nuanced, dynamic approaches to urban heritage.
Future research directions.

A Study on the Identification of Historical and Cultural Resource Carriers Oriented by Value: A Case Study of the Taihu Lake Basin

Guangfeng Zhai\Zuyue Liu\Yan Wang
Affiliation:Architecture College,Southeast University
Email:552049116@qq.com

Abstract
China's heritage protection system faces gaps as many historical resources remain outside legal frameworks due to inadequate classification standards. This study addresses legislative deficiencies by establishing systematic criteria to identify non-statutory cultural resources (e.g., place names, intangible skills). Combining international standards with domestic practice, it prioritizes conservation through value-based assessment—focusing on cultural genetics, intergenerational transmission, and regional identity. Using the Taihu Lake Basin as a case study, resources are analyzed across political, economic, social, technological, and geographical dimensions. The proposed recognition system clarifies resource value, enables timely protection, unlocks potential, and maintains cultural integrity within dynamic urban contexts. This approach sustains heritage significance while enhancing urban cultural resilience and exchange.

Keywords: historical-cultural value; urban dynamic development; historical-cultural resource conservation; element identification

Introduction

The 21st century has witnessed China's urbanization transition profoundly from quantitative expansion to qualitative advancement, elevating the imperative to preserve "collective memory" and cultural roots in urban-rural development. However, rapid urbanization has revealed a critical challenge: vast resources bearing historical memory and cultural genes—excluded from legally protected heritage categories (encompassing cultural relics sites, historic districts, and historic cities/towns/villages)—now face severe conservation gaps (Dong, 2022). These invaluable resources suffer from compartmentalization and fragmentation, undermining their integrity. Despite UNESCO's establishment of an Outstanding Universal Value (OUV)-based global assessment framework through the 1972 World Heritage Convention and its 2015 integration of sustainable development principles, China's conservation efforts confront persistent deficiencies. Current systems predominantly prioritize monumental ancient heritage with tangible forms, while inadequately addressing intangible elements (e.g., toponymic culture, traditional crafts) and dynamic cultural landscapes (e.g., polder systems, canal networks). This results in ineffective identification and preservation mechanisms (Wang et al., 2023). Value assessment remains reductive, overemphasizing the "antiquity" and "architectural integrity" of physical remains while neglecting the contemporary adaptability of cultural DNA and derivative values such as ecological wisdom.

The Taihu Lake Basin exemplifies these tensions. As the cradle of Wuyue culture and China's economic core since the Southern Song Dynasty, its networked aquatic settlements, engineered polder landscapes, and canal relics embody multidimensional historical, cultural, economic, and ecological values. Yet rigid classification frameworks and limited value recognition impede systematic identification and integrated governance.

Addressing these issues necessitates a value-oriented, dynamically integrated identification framework for historical-cultural resources. This requires transcending the material/non-material dichotomy and examining resources through dual analytical lenses: diachronic (temporal layering) and synchronic (spatial-network interactions) (Dong, 2022). Such an approach aligns with the holistic mandate of "spatial comprehensiveness, element inclusivity, and integrated conservation-transmission chains" in China's territorial spatial planning paradigm.

China's heritage conservation has evolved beyond adopting international models to develop distinctive frameworks. Since the 1982 Historic City System, a tripartite protection structure (cultural relics sites → historic districts → historic cities/towns/villages) has expanded to include industrial and agricultural heritage (Lü, 2008). The 2015 revision of China Principles for the Conservation of Heritage Sites marked a milestone by augmenting traditional "historical, artistic, scientific" values with "social" and "cultural" dimensions, emphasizing heritage's role in fostering contemporary identity (Lü, 2015). Recent policy directives, notably the CPC Central Committee's Opinions on Strengthening Historical-Cultural Conservation in Urban-Rural Development, explicitly advocate "spatial comprehensiveness and element inclusivity," demanding systematic integration from individual

structures to intangible cultural heritage (ICH).

Domestic scholars have pioneered context-specific methodologies: Shao (2019) proposed a "stratification-integrity-pluralism" assessment model, analyzing the Taihu water system to reveal spatiotemporal layering from the Tang-Song to Ming-Qing periods, and developed a stratified framework ("hydraulic base → ancient site → settlement → modern layers") for heritage integration. Jiang et al. (2024) employed a "value-characteristic correlation metric model" to quantify interactions among political, economic, social, technological-cultural, and geographical dimensions. Dong's (2022) "National Historical-Cultural Space" theory advocates integrated management through a "production-living-ecology" nexus.

Nevertheless, three interrelated challenges persist:
1.Coverage deficits: Material-focused registries overlook the Taihu Basin's polder systems, water-town networks, and intangible resources (e.g., toponyms, craft techniques).
2.Reductive valuation: Conventional "tripartite values" frameworks cannot accommodate cultural DNA's contemporary adaptability (e.g., silk craftsmanship in circular economies) or derived ecological wisdom.
3.Administrative fragmentation: Jurisdictional boundaries obstruct the formation of continuous cultural corridors (e.g., Taihu-Yangtze historic clusters), impeding holistic conservation. While Dong's (2022) theoretical framework provides direction, its implementation remains constrained by inadequate cross-regional coordination and limited community engagement.

Literature Review
(1) Theoretical Paradigm Shift in International Cultural Heritage Conservation
International cultural heritage conservation theory has undergone a paradigm shift from material-object preservation to value-based dynamic system governance. Early foundations emerged from the 1964 Venice Charter, which established "authenticity" and "integrity" principles emphasizing the transmission of civilizational memory through physical remains (Lü, 2008). The 1972 World Heritage Convention introduced six "Outstanding Universal Value" (OUV) criteria, framing heritage as testimony to shared human experience. While reinforcing authenticity and integrity, early implementation prioritized static conservation of tangible assets, overlooking intangible elements and dynamic interconnections. Evolving perspectives contextualized authenticity within cultural frameworks through the 1994 Nara Document on Authenticity and 2005 Xi'an Declaration, validating local knowledge systems (Lü, 2015). A pivotal advancement came with UNESCO's 2011 Recommendation on the Historic Urban Landscape (HUL), proposing "stratification" to balance heritage conservation and urban development. The 2015 revised Operational Guidelines for the World Heritage Convention further integrated Sustainable Development Goals, marking a transition from "freezing history" to "living heritage transmission."

ICOMOS's HUL methodology advocates multidisciplinary integration of natural-human elements. Cultural landscape theory conceptualizes natural substrates and cultural practices as symbiotic entities, exemplified by the Hani Rice Terraces' "forest-village-terrace-water" system (Jiao, 2002). The 1999 Charter on the Built Vernacular Heritage introduced "living heritage" principles, emphasizing synergistic conservation of traditional lifestyles and material spaces—providing theoretical foundations for protecting Taihu Basin's polder systems and Zisha pottery techniques. France's "Architectural, Urban and Landscape Heritage Protection Zones" (ZPPAUP) and Carl Sauer's cultural ecology theory further illuminate heritage-geography symbiosis (Shao, 2019). Australia's Ballarat Goldfields demonstrates "participatory change management" for functional regeneration, offering a global methodological framework.

(2) Characteristic Development and Challenges of China's Conservation System
China has developed a localized "national-provincial-municipal" tripartite conservation framework by synthesizing international experience. The 1982 Historic City System evolved into a three-tier structure (cultural relics sites → historic districts → historic cities/towns/villages), later expanded to include industrial and agricultural heritage (Lü, 2008). The 2015 revised China Principles for the Conservation of Heritage Sites augmented traditional "historical, artistic, scientific" values with "social" and "cultural" dimensions, emphasizing heritage's contemporary identity-building function (Lü, 2015). The CPC Central Committee's Opinions on Strengthening Historical-Cultural Conservation mandates "spatial comprehensiveness and element inclusivity," requiring integrated conservation from individual structures to intangible cultural heritage.

Domestic scholars propose innovative models: Shao's (2019) "stratification-integrity-pluralism cognition" framework deciphers the spatiotemporal layering of Taihu hydraulic systems from the Tang-Song to Ming-Qing periods; a four-tier system ("hydraulic base → ancient site → settlement → modern layers") integrates Jiaxing's heritage; Jiang et al.'s (2024) "value-characteristic correlation metric model" quantifies interactions among political, economic, social, technological-cultural, and geographical dimensions. However, three contradictions persist:

- Insufficient coverage: Statutory registers prioritize material heritage, neglecting intangible resources (e.g., toponyms, traditional crafts), leaving Taihu's polder systems and water-towns underprotected;
- Reductive value cognition: Overreliance on the "tripartite values" framework ignores cultural DNA's modern adaptability (e.g., silk craftsmanship in low-carbon economies) and derivative ecological wisdom (Dong, 2022);
- Fragmentation: Administrative boundaries impede holistic cultural corridor formation in the Taihu-Yangtze region. Dong's (2022) "National Historical-Cultural Space" theory proposes integrating natural-cultural resources via a "production-living-ecology" network, yet implementation faces cross-regional coordination and community participation deficits.

(3) Value-Oriented Theory Adaptation in the Taihu Lake Basin
As the core region of Jiangnan culture, the Taihu Basin pioneers localized innovations through value reconfiguration, technical integration, and governance synergy. Its heritage manifests multidimensional dynamics: governance wisdom in Southern Song tribute transport networks, global influences via silk trade, clan-structured water-town organizations, and hydraulic innovations in Lingang polder systems—collectively forming a "political-economic-social-technological-geographical" value matrix.

A three-dimensional framework ("cultural gene value-era-transmission value-territorial identity value") enables multidimensional identification:
- Cultural gene value focuses on core civilizational symbols (e.g., polder ecological wisdom), supported by diachronic analysis methodologies (Li, 1994);
- Era-transmission value emphasizes functional adaptation (e.g., low-carbon retrofitting of traditional architecture), aligning with UN Sustainable Development Goals (2015);
- Territorial identity value strengthens cohesion through festivals (e.g., Fishing Commencement Ceremony), guided by "cultural gene decoding" theory (Luo, 2023).

To counter fragmentation, dual integration strategies are implemented:
- Vertical: Cultural corridors (e.g., Grand Canal) link wharves and granaries;
- Horizontal: "Wetland-settlement-industry" ecosystems integrate polders and mulberry-dyke fishponds (Yang, 2016).

Technologically, the "Regional Correlation Metric Model" quantifies inter-element value relationships. Governance innovations include: dynamic tourist-capacity monitoring via digital platforms; revitalization of traditional silk-reeling techniques as cultural IP; intergenerational transmission of rituals (e.g., Silkworm Deity Worship) reinforcing identity (Han, 2024). These practices resolve the "conservation-development" paradox and establish a networked "natural-cultural ecological patch" system, contributing Chinese solutions to global living heritage transmission.

(4) Research Gaps and Innovations
Persistent limitations include:
1.Absence of classification standards for non-statutory heritage (e.g., toponyms, intangible techniques), delaying conservation of Taihu's polder systems;
2.Inadequate attention to adaptive evolution during urbanization (e.g., authenticity erosion in Zhouzhuang's tourism commercialization);
3.Cross-regional coordination deficits in the Taihu-Yangtze cultural zone.

This study innovatively proposes:

- A "five-dimensional value model" integrated with the HUL concept to establish a "cultural gene-spatial carrier-contemporary function" dynamic identification framework;
- Bottom-up pathways (e.g., specialized regulations for toponym conservation) complementing statutory systems;
- An "eco-conservation transmission" model combining "primitive ecological display" and "quasi-ecological inheritance" (Liu, 2022), demonstrated through intergenerational practices like Gaochun's Dongba Horse-Lantern Festival.

These innovations address gaps in dynamic landscape analysis (e.g., seasonal agrarian rituals) and offer globally transferable Chinese approaches to heritage conservation.

Framework Development for Historical-Cultural Resource Identification

Contemporary cultural heritage conservation confronts systemic deficiencies wherein resources embodying core cultural genes, adaptive continuity, and territorial recognition remain inadequately safeguarded due to fragmented protection frameworks. The dissolution of Beijing's historic hutong toponyms and jurisdictional ambiguities surrounding Southern Song shipwrecks in the South China Sea exemplify fundamental contradictions in non-systematic conservation: isolated interventions sever organic connections across temporal stratification, spatial systems, and multi-subject dimensions. This precipitates not only physical degradation but also ruptures in cultural gene transmission. Fragmented conservation undermines heritage's intrinsic value as integrated "structure-function-meaning" entities. Resolving these systemic challenges necessitates paradigm reconstruction through:

1.Dynamic correlation (dialectical unity of diachronic stratification, synchronic systems, multi-subject dimensions)
2.Value-oriented approaches (tripartite assessment of structural stability, functional adaptation, meaning cohesion)

$$(\text{RI}=0.58)\quad CR = \frac{CI}{RI} = \frac{0.0025}{0.58} = 0.0043$$

This study advances a dual-core theoretical framework integrating dynamic correlation with value orientation, structured through three weighted dimensions: cultural gene value (50%), era-transmission value (25%), and territorial identity value (25%). Quantitatively validated via Analytic Hierarchy Process (AHP; CR<0.1), this system establishes hierarchical metrics for assessing stratified, systemic, and pluralistic resources, targeting "comprehensive spatial coverage and inclusive element protection."

Dynamic correlation operationalization:
1.Diachronic stratification: Recognizes evolutionary patterns in cultural genes while establishing evaluation mechanisms accommodating continuity and adaptation.
2.Synchronic systems: Examines heritage embeddedness within geographical and socio-structural matrices to decipher natural-human interdependencies.
3.Multi-subject dimensions: Decodes coexistence logics of polycultural symbols across heterogeneous carriers.

Value-oriented architecture transcends static paradigms through tripartite assessment:
1.Structural dimension: Reveals historical-logical integrity beyond material persistence (e.g., Lingang polder system's Song-era "bamboo fencing–watercourses–sluice gates" technological chain preserving hydrological wisdom).
2.Functional dimension: Prioritizes adaptive regeneration (e.g., Lihu Wetland's restoration of traditional purification networks increased avian biodiversity by 100% through synergistic ancient-modern hydrology).
3.Meaning dimension: Activates cultural cohesion (e.g., Wuzhong's silvopastoral system transforming agricultural heritage into identity symbols via Hu sheep conservation centers).

Synthesizing dynamic correlation principles (dialectical integration of stratification, systemicity, multi-subjectivity) with value-oriented theory (structure-function-meaning assessment), we establish a three-dimensional framework centered on cultural gene value (50%), era-transmission value (25%), and territorial identity value (25%). AHP-quantified (CR<0.1) and hierarchically structured, this model enables integrated cognition through "historical stratification–systemic correlation–subject interaction" operationalization.

Weight Allocation Model of Three-dimensional Value Framework Based on AHP

1.Constructing a Hierarchical Structure Model

- Objective Layer (O): Maximization of Historical and Cultural Resources Value
- Criterion Layer (C):Cultural ($\Phi = \alpha \cdot S_{gene} + \beta \cdot I_{function} + \gamma \cdot D_{meaning}$ Identity Value (C3)
- Index Layer (P): 9 core indicators

2.Constructing Judgment Matrices

Using Saaty's 1-9 scale method for pair-wise comparisons to form judgment matrices. Take the criterion layer as an example:

	C1	C2	C3
C1	1	3	3
C2	1/3	1	1
C3	1/3	1	1

3.Weight Calculation and Consistency Test

Calculating Eigenvectors	$W_i = \sqrt[n]{\prod_{j=1}^{n} a_{ij}}$(Geometric Mean Method)	
Normalization Processing		
Consistency Verification	Maximum Eigenvalue	$\lambda_{max} = \sum \frac{(AW)_i}{nW_i} = \frac{1.803}{3 \times 0.600} + \frac{0.605}{3 \times 0.200} + \frac{0.605}{3 \times 0.200} = 3.005$
	Consistency Index	$CI = \frac{\lambda_{max} - n}{n-1} = \frac{3.005 - 3}{2} = 0.0025$
	Random Consistency Ratio	RI=0.58

4.Weight System of the Three-dimensional Value Framework

Value Dimension	Weight	Core Indicators	Sub-weight	Composite Weight
Cultural Gene Value	50%	Historical Stratification	40%	20%
		Civilizational Continuity	30%	15%
		Pluralistic Symbiosis	30%	15%
Time Inheritance Value	25%	Modern Adaptability	30%	7.5%
		Living Heritage Inheritance Ability	50%	12.5%
		Innovation and Transformation Ability	20%	5%
Regional Identity Value	25%	Geographical Relevance	40%	10%
		Ethnic Community Awareness	35%	8.75%
		Regional Representativeness	25%	6.25%

5.Priority Determination Equation for Cultural Heritage Protection, used to quantitatively assess the urgency of resource protection:

Φ	Priority Index
α	Weight coefficient of cultural gene breakage risk
S_{gene}	Cultural gene breakage risk
β	Weight coefficient of functional chain integrity
$I_{function}$	Functional chain integrity
γ	Weight coefficient of meaning production activity
$D_{meaning}$	Meaning production activity

Judgment Matrices of the Index Layer

	Historical Stratification	Civilizational Continuity	Pluralistic Symbiosis
Historical Stratification	1	2	3
Civilizational Continuity	1/2	1	2
Pluralistic Symbiosis	1/3	1/2	1

	Living Heritage Inheritance Ability	Modern Adaptability	Innovation and Transformation Potential
Living Heritage Inheritance Ability	1	2	3
Modern Adaptability	1/2	1	2
Innovation and Transformation Potential	1/3	1/2	1

	Geographical Relevance	Ethnic Community Awareness	Regional Representativeness
Geographical Relevance	1	1/2	2
Ethnic Community Awareness	2	1	3
Regional Representativeness	1/2	1/3	1

Formula for Historical Stratification:

$$D_t = \frac{1}{n}\sum_{i=1}^{k} \delta_i T_i$$

(δ_i is the stratum weight,is the chronological span)

Cultural Element Diversity: Calculated by the Shannon-Wiener diversity index to measure the coexistence degree of multi-ethnic symbols:

$$H = -\sum (p_i \ln p_i) \geq 1.5$$

Three-dimensional Value	Core Indicators	Quantification Criteria	Evaluation Method
Cultural Gene Value	Historical Stratification	Chronological Span: Number of historical stages covered by resources. Superimposition Density: Physical superposition layers of remains from different periods.	Combining archaeological reports, historical geography maps, and 3D modeling techniques (e.g., digital stratification analysis of Liangzhu Ancient City).
	Civilizational Continuity	Technical Iteration Cycle: Evolution frequency and span of key technologies (e.g., ceramic firing, water conservancy projects). Institutional Sustainability: Duration of institutional heritage.	Analyzing institutional texts through bibliometrics, combined with physical verification of technical archaeology.
	Pluralistic Symbiosis	Cultural Element Diversity: Number of coexisting multi-ethnic/cultural symbols. Interaction Frequency: Record density of cross-cultural exchange events in historical documents.	Based on ethnographic fieldwork and multi-source data fusion (GIS spatial overlay analysis).
Time Inheritance Value	Living Heritage Inheritance Ability	Intangible Heritage (ICH) Practice Frequency: Annual number of traditional festivals and craft activities. Inheritor Generational Span: Integrity of ICH inheritance and existing generational numbers.	Sociological statistics (questionnaire surveys) and oral history records of inheritors.
	Modern Adaptability	Functional Conversion Rate: Proportion of functional reuse of heritage spaces. Community Usage Rate: Daily usage frequency of heritage by contemporary communities.	Evaluation method: Spatial behavior big data analysis (WiFi hotspots, crowd flow heat maps).
	Innovation and Transformation Potential	Digital Coverage: Completeness and access volume of heritage digital archives. Cultural and Creative Economic Contribution: Annual sales of heritage-derived products.	Economic statistics models and intellectual property database analysis.

Three-dimensional Value	Core Indicators	Quantification Criteria	Evaluation Method
Regional Identity Value	Geographical Relevance	Landscape Coupling Degree: Spatial matching index between heritage and natural elements (water systems, terrain). Ecological Service Value: Contribution of heritage to regional ecosystems.	Landscape ecology models (e.g., InVEST) and remote sensing image interpretation.
	Ethnic Community Awareness	Number of Multi-ethnic Collaboration Cases: Quantity of historical and contemporary multi-ethnic co-construction projects. Cultural Identity Index: Community's recognition degree of the "Chinese Nation Community".	Ethnographic research and psychological statistics analysis.
	Regional Representativeness	Symbol Communication Breadth: Media exposure and online search volume of heritage as a local symbol. Economic Dependence: Contribution rate of heritage to local GDP.	Media big data crawling and economic input-output models.

Value-Oriented Identification of Historical and Cultural Resource Carriers: A Case Study of the Taihu Lake Basin
In the process of constructing a value assessment system for historical and cultural resource carriers, this study takes the Lougang water system in the Taihu Lake Basin as an empirical object. Through the quantitative application of a three-dimensional value framework, it systematically demonstrates the operational pathway and evaluation efficacy of value-oriented identification methods in practice. As a typical cultural-geographic unit in the Taihu Lake Basin, the Lougang water system's evaluation process fully reflects the organic integration of cultural gene inheritance, responsiveness to contemporary needs, and regional identity construction.

Based on the previously established evaluation model, the research team conducted multi-dimensional data collection and value decomposition of the Lougang system. In the dimension of cultural gene value, archaeological evidence and cross-referenced historical documents reveal that since the Song Dynasty's "longitudinal pujiang and transverse tang" water network formation, the system has undergone technological iterations through the Ming and Qing dynasties, culminating in the "one longitudinal pujiang every seven li and one transverse tang every ten li" weir system. The historical stratification is vividly demonstrated by the stratigraphic relationship between Song Dynasty wooden pile cofferdams and Ming-Qing stone embankments discovered at the Daxianlou site in Wuxing. The technological evolution trajectory confirms the millennium-long continuity of civilizational genes—from Song Dynasty bamboo-wood permeable dams to modern ecological hydraulic facilities—while the "Mulberry-Dike-Fish-Pond" system's wetland agricultural productivity, exceeding traditional cultivation by 200%, underscores the symbiotic wisdom of natural-human systems.

In assessing contemporary transmission value, field research and statistical yearbook analysis reveal modern adaptive features of traditional hydraulic functions: of the 62 existing waterways, 12 still maintain core irrigation and flood control functions, while Wujiang Pingwang Town's transformation of weir grids into modern ecological units has reduced nitrogen-phosphorus load by 42%. However, indicators of living heritage transmission show a 72% decline in traditional ritual frequencies over the past decade, reflecting practical challenges in intangible cultural heritage preservation. Notably, the 340% growth in silk cultural and creative industry output over eight

years demonstrates the economic potential of cultural gene innovation.

The quantitative analysis of regional identity value focuses on spatial correlation and cultural recognition. GIS spatial parsing indicates that the "waterway-settlement-weir field" tripartite spatial organization formed through water level regulation is perfectly exemplified in linear settlements like Yigao Village. The spatial distribution density of "Xu"-prefixed place names along the Xu River corroborates the waterway's historical role as a cultural exchange axis, while the agricultural proverb "When Suzhou and Huzhou thrive, the empire is fed" maintains 78% recognition among local residents as a regional economic identifier.

Through AHP analytic hierarchy process integration of third-tier indicator weights, the Lougang system received composite scores: 77 for cultural gene value, 62 for contemporary transmission value, and 76.5 for regional identity value. Core strengths lie in technological evolutionary continuity and spatial organizational integrity, though declining vitality in living heritage transmission warrants attention. These results directly informed dynamic adjustments to conservation priorities: urgent provincial-level intangible heritage rescue initiatives were launched given only seven living practitioners of the Mulberry-Dike-Fish-Pond techniques; smart monitoring systems were fully deployed in Wuxing sections with 68% hydraulic facility integrity; and cultural memory preservation platforms were constructed around dragon boat races attracting 23,000 annual participants.

This case validates the systemic efficacy of the three-dimensional value framework in resource inventorying, dynamic analysis, and conservation decision-making. By integrating historical stratification parsing, modern functional adaptation assessment, and regional identity construction within a unified evaluation framework, it avoids cultural fragmentation from static preservation while preventing value erosion through over-development. The methodology refined through Lougang evaluation—incorporating "technological gene continuity identification, spatial functional adaptability assessment, and regional network integrability construction"—provides replicable quantitative tools for similar heritage conservation efforts. Particularly within the context of integrated cultural heritage governance in the Yangtze River Delta, its trans-regional cooperation mechanisms and spatial integration enhancement strategies demonstrate innovative pathways for synergistic development between cultural preservation and regional sustainability.

Conclusion and Prospects

This study establishes a dynamic value-oriented identification framework for historical-cultural resources, advancing methodological approaches to systemic heritage conservation challenges. The synergistic integration of a five-dimensional value model (political, economic, social, technological-cultural, geographical) and three-dimensional value framework (cultural gene value, era-transmission value, territorial identity value) reveals heritage's multidimensional essence:

- Cultural gene value traces diachronic stratification of core civilizational symbols and technological evolution;
- Era-transmission value enables creative functional adaptation in contemporary contexts;
- Territorial identity value sustains community cohesion through living practices.

This system addresses critical gaps in conventional frameworks by:

1.Resolving cognitive blind spots regarding intangible resources and dynamic landscapes

2.Enabling comprehensive coverage through scientific identification of "implicit heritage" (e.g., toponymic traditions, artisanal techniques).

The validated multi-scalar protection strategy (cultural clusters corridors networks) offers transferable solutions to heritage fragmentation:

- Micro-scale: Precision identification of cultural clusters (e.g., settlement-ecological complexes) ensures unit integrity;
- Meso-scale: Linear heritage corridors (canals/ancient routes) integrate dispersed resources into functional systems;
- Macro-scale: Spatial integration of natural-cultural patches with industrial corridors forms regional cultural-ecological networks.

This hierarchical integration significantly enhances spatial connectivity and sustainable governance efficacy, transforming historical contexts from static artifacts into regenerative drivers of urban-rural development.

Future advancement requires tripartite innovation:
1.Theoretical: Machine learning-powered predictive modeling of value evolution to dynamically optimize identification criteria
2.Methodological: Integration of ecological resilience metrics and sociological community capital theory to quantify adaptive capacity
3.Practical: Transnational comparative studies (Taihu Lake Basin vs. Rhine/Mekong regions) to distill universal principles for living heritage transmission in hyper-urbanized contexts

Through integrated innovation—theoretical dynamization, transdisciplinary technologies, and collaborative governance—China's heritage conservation transitions from passive rescue to proactive stewardship, offering scientifically robust and culturally attuned solutions for global civilizational continuity.

Public emotions and visual perception of historic district : An AI approach using social media data

Chunye Ma, Lan Wang
Affiliation:Tongji university
Email:mcy0503@126.com

Abstract
Historic districts possess unique visual landscape features that can influence public emotional experiences. Advances in artificial intelligence, particularly multimodal large models, enable integrated analysis of image and text data, offering new possibilities for understanding the complex relationship between visual environments and emotions. This study focuses on Nanluoguxiang, a historic district in Beijing, using 2,851 text reviews and 13,553 associated images collected from the social media platform Dianping between January 2024 and January 2025. An AI-based emotion analysis framework was developed, and XGBoost was applied to examine the associations between seven types of visual scenes and emotional responses. Results indicate that joy dominates public sentiment; commercial scenes are highly perceived; and architectural and streetscape elements are linked to positive emotions, while storefronts correlate with negative emotions.

Keywords: historic districts: public emotions: visual perception

1. Introduction

Historic districts can offer positive emotional experiences to the public, enhancing well-being, place attachment, and psychological restoration (Bornioli et al., 2018; Scopelliti et al., 2019; Reece et al., 2022). Among the various factors that influence such experiences, visual perception plays a particularly important role, as it represents one of the most immediate and intuitive ways through which individuals engage with urban heritage environments. Therefore, the visual landscape characteristics of historic districts—such as architectural forms, streetscapes, commercial elements, and natural features—may significantly shape how people feel in these settings.

However, existing research often treats emotional responses and visual landscape features as independent topics, lacking a unified framework that links the two. In particular, while numerous studies have examined either the aesthetic value of urban heritage or the restorative potential of urban spaces, the specific influence of visual landscapes in historic districts on public emotional responses remains underexplored.

Recent advances in Artificial Intelligence (AI), especially in the domains of computer vision, natural language processing, and multimodal learning, provide new opportunities to examine this relationship. AI techniques are capable of extracting detailed visual features from images and detecting emotional content in text, making it possible to systematically analyze large-scale user-generated data. Accordingly, this study proposes to construct an AI-based analytical framework to explore the relationship between visual landscape characteristics and public emotional experiences in historic districts. By leveraging multimodal social media data and interpretable machine learning models, this research aims to bridge the gap between environmental perception and emotional response in the context of heritage planning.

2. Case study

2.1 Study area

Nanluoguxiang is a renowned historic district in Beijing, China, known for its well-preserved siheyuan (courtyard residences) dating back to the Ming and Qing dynasties. It holds a prominent position in the field of world heritage studies. Following multiple rounds of conservation and renewal efforts, Nanluoguxiang now features a mix of commercial, residential, and cultural functions. Whether the current spatial form and its visual perception are beneficial to the public's emotional experience is an important issue for policymakers to consider.

2.2 Social media data on NLG

The review data for Nanluoguxiang on the Dianping platform is relatively high in both quality and quantity. As a well-known tourist destination in China, Nanluoguxiang has accumulated a large volume of social media reviews across various platforms, including Xiaohongshu, Weibo, Dianping, and Ctrip. However, platforms such as Xiaohongshu and Weibo contain a significant number of promotional accounts and non-authentic user comments, which may not accurately reflect the public's genuine emotional responses, and were therefore excluded from this study. Although Ctrip is one of China's major travel platforms, the volume of available data on

Nanluoguxiang is comparatively limited. Considering factors such as data volume, the proportion of authentic users, and content quality, Dianping was selected as the primary data source for this research.

This study collected all publicly available reviews of Nanluoguxiang from Dianping between January 1, 2024 and December 31, 2024, including text reviews, associated images, and timestamps. A total of 2,818 text reviews and 13,986 images were initially gathered. After data cleaning, the final dataset comprised 2,460 valid text reviews and 12,770 images. The average length of a review was 106.8 characters (standard deviation: 86.7), with a median length of 105 characters. Notably, approximately 25% of the reviews exceeded 126 characters, indicating that users were generally willing to provide detailed narratives, thus offering a strong semantic foundation for emotion analysis.

3. Methodology

3.1 Overview

Text reviews from social media help understand people's emotional experiences with the built environment (Ghahramani et al., 2021; Park et al., 2020), and images voluntarily shared on social media serve as a rich resource for understanding people's visual preferences for environments (Chen et al., 2020). Although some studies have attempted to qualitatively explore the relationship between visual perception and emotional experience (Yang & Zhang, 2024), no quantitative analysis framework for this relationship has been established. In this study, we use Nanluoguxiang, a typical historic district in Beijing, as a case study. This study develops a multimodal deep learning framework to examine the impact of 6 environmental scenes in historic districts on public emotional experiences.

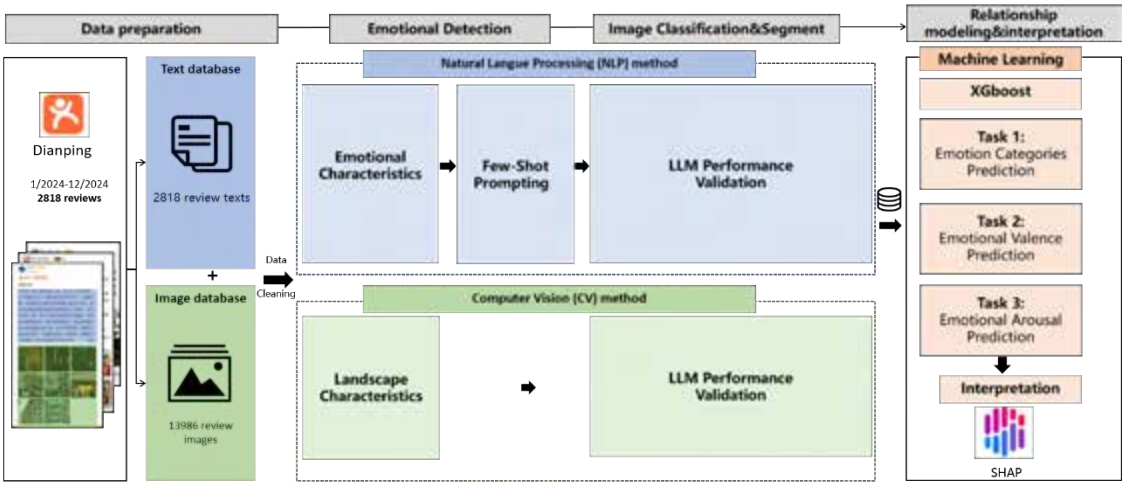

Fig. 1 Research Overview

3.2 Emotion Analysis Method

Aspect-Based Sentiment Analysis (ABSA) aims to identify specific spatial or managerial elements mentioned in user comments and determine their associated emotional tendencies. ABSA is a highly valuable technique in text analysis, as it allows the evaluation of sentiment across multiple dimensions within a single comment (Mehra, 2023; Viñán-Ludeña & Campos, 2024). Compared to overall sentiment classification, integrating ABSA into machine learning or regression models has been shown to significantly improve predictive performance (Li et al., 2023).

Based on the key dimensions typically emphasized in the conservation and renewal of historic districts, this study includes six analytical aspects:

- Material Form: Refers to the physical environment, including street surface design, street interfaces, and spatial morphology (e.g., sidewalks, building facades, architectural styles, and maintenance conditions).
- Commercial Functions: Encompasses commercial uses such as restaurants, entertainment, and retail businesses.
- Service Facilities: Includes public service amenities such as visitor centers, restrooms, parking areas, signage systems, and accessible infrastructure.
- Natural Environment: Covers elements such as vegetation, green spaces, water features, garden landscapes, and animals. Note: This does not include weather or air quality.

• Cultural Identity: Reflects the user's subjective appraisal and emotional identification with the district's historical value, cultural heritage, and ethnic character, including feelings of resonance, pride, and familiarity linked to heritage preservation and regional identity.
• Governance Mechanism: Relates to management practices such as crowd control, sanitation, shared bicycle regulation, ticketing systems, and public safety. ABSA enables fine-grained analysis and offers substantial value by providing insights for urban governance and decision-making.

In terms of emotional classification, this study draws on the basic universal emotions framework proposed by psychologist Paul Ekman, who identified seven core emotional categories: joy, sadness, anger, fear, surprise, disgust, and neutrality (Ekman, 1992). In this study, emotions are categorized into seven types: joy, pride, calmness, disappointment, fear, dissatisfaction, and mixed.

• Joy is defined as positive emotions such as happiness, relaxation, excitement, and satisfaction.
• Pride refers to expressions of admiration and identification with the district's historical or cultural background.
•Calmness indicates an absence of strong emotional fluctuation, often reflected in objective or neutral descriptions.
• Disappointment is characterized by a clear gap between expectation and actual experience.
• Fear involves concerns related to personal safety or social order.
• Dissatisfaction includes feelings of indifference, rejection, resistance, or negative judgment.
• Mixed emotion is used only when both positive (e.g., joy, pride) and negative (e.g., disappointment, fear, dissatisfaction) emotions are clearly expressed in the same comment with comparable intensity, making it difficult to determine the dominant emotional tendency.

3.3 Image Feature Extraction

Landscape type refers to the perceptual distinctions between one area and another, emphasizing the contextual differences that define distinct environments. Human perception responds more to holistic situations than to isolated elements, making landscape types—understood as cognitive situational units—more aligned with how people observe and experience their surroundings. Based on the principles of historic district conservation and renewal, and considering the typical scenes found in such areas, this study classifies visual landscape types into seven categories: historic architecture, streetscape, storefront façade, natural environment, signage and facilities, goods, and human activities.

In this study, a Mask2Former-based image segmentation model was employed to identify the visual landscape types embedded in user-generated images from social media. Mask2Former is a universal image segmentation framework capable of handling semantic segmentation, instance segmentation, and panoptic segmentation tasks (Cheng et al., 2022). The model was pretrained on the ADE20K dataset, which contains 150 categories of urban and natural scenes and broadly covers neighborhood elements and environmental features. ADE20K has been widely applied in studies of urban space recognition, landscape ecology, and visual perception (Zhou et al., 2019; Zheng et al., 2021; Zhao et al., 2023).

Compared with conventional convolutional neural network models such as U-Net or DeepLab, the key advantage of Mask2Former lies in its Transformer-based feature aggregation mechanism, which enables simultaneous modeling of both local details and global contextual relationships. This is particularly beneficial for interpreting images of historic districts, where spatial structures are complex and visually layered. In multi-label visual scenes, traditional models often struggle to differentiate highly co-occurring elements such as buildings, roads, and vegetation. Mask2Former, however, allows for fine-grained segmentation and accurate category recognition, thereby enhancing the detection of compositional structures in visual landscape types.

Accordingly, Mask2Former was selected for the interpretation of visual landscapes in historic districts. In this study, we extracted the top five segmented labels for each image, representing the dominant visual landscape types, and further analyzed their potential associations with emotional expressions identified in the corresponding textual comments.

3.4 Analytical Approach: Machine Learning Modeling and Explainability Techniques

In this study, XGBoost and SHAP were employed to analyze the relationship between emotional features and visual landscape characteristics. To investigate how users' emotional responses relate to the structural features of historic districts captured in images, we adopted Extreme Gradient Boosting (XGBoost), an ensemble learning method based on gradient-boosted decision trees. XGBoost is a supervised learning algorithm known for its strong capability in handling nonlinear relationships, robustness with high-dimensional sparse data, and high computational efficiency. It has been widely applied in urban research, affective computing, and geospatial data analysis, making it particularly suitable for modeling heterogeneous data that include image-derived landscape classifications and emotional variables.

To further interpret the contribution and directionality of each landscape feature in emotion prediction, we integrated the SHAP (SHapley Additive exPlanations) method. Rooted in game theory, SHAP assigns each feature a Shapley value, representing its marginal contribution to a particular prediction. It is widely recognized for its consistency and local accuracy in model interpretation. By applying SHAP analysis to the output of the XGBoost model, we identified key image-based structural features—such as the proportion of architectural elements, vegetation coverage, and frequency of human presence—that significantly influence emotional responses. Furthermore, SHAP enabled us to discern the positive or negative direction of each feature's impact on emotional outcomes.

4. Results

4.1 Overall Emotional Characteristics

The public's overall emotional experience in Nanluoguxiang is predominantly positive. Notably, the emotion of joy accounts for 68.7%, indicating that this historic district is generally successful in eliciting pleasant and satisfying emotional responses from visitors. However, negative emotions are still present to a certain extent. The proportion of dissatisfaction reaches 18.64%, followed by disappointment (5.89%) and calmness (5.44%). Emotions such as pride (0.97%) and fear (0.36%) appear infrequently and can be considered peripheral.

Monthly breakdowns of emotional distribution reveal notable seasonal variations. Joy remains consistently high during spring (March–May) and autumn (September–November), ranging from 67% to 73%. In contrast, its proportion drops significantly in the summer, reaching a yearly low of 61.24% in July. This decline is inversely correlated with a peak in dissatisfaction, which reaches 28.09% in the same month. This pattern may be attributed to increased tourist volumes during the summer holiday season, leading to greater spatial crowding and disruption of visitor rhythms, thereby influencing emotional perceptions.

By comparison, the milder climate and moderate foot traffic of spring and autumn provide more favorable spatial experiences, contributing to more positive emotional responses. These findings suggest that urban planners and tourism managers should pay particular attention to the emotional consequences of seasonal peaks in historic districts. During summer, strategies such as visitor flow control, enhanced service facilities, and spatial buffering may help alleviate the sense of overcrowding and emotional fatigue, ultimately improving emotional satisfaction and overall visitor experience.

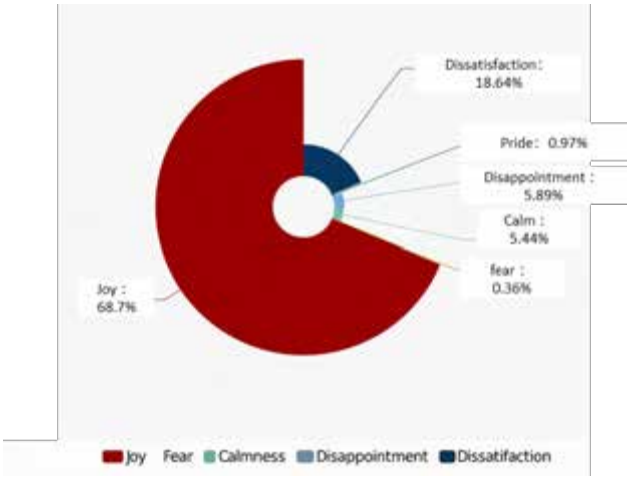

Fig.2 Distribution of Public Emotion Types in Nanluoguxiang

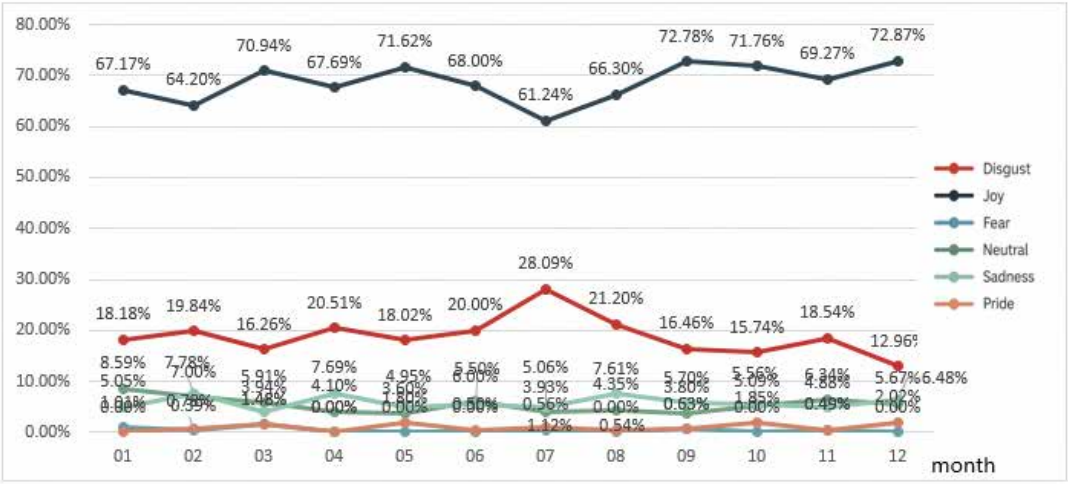

Fig.3 Annual Distribution of Public Emotion Types in Nanluoguxiang

4.2 Aspect-Based Emotional Characteristics

Overall, joy dominates across most aspects, reaching its highest proportion in the natural elements dimension (91.3%), followed by service facilities (82.5%) and functional formats (62.5%). This suggests that these aspects tend to elicit more positive emotional responses from the public. However, in the dimensions of management mechanisms and cultural identity, positive emotions are significantly diminished. The proportion of joy drops to 26.0% and 66.9%, respectively, in these two categories.

Notably, dissatisfaction accounts for as much as 52.0% under management mechanisms, the highest across all aspects, and considerably higher than its proportion under cultural identity (11.8%) and functional formats (24.8%). This indicates that institutional arrangements, regulatory measures, or managerial actions are more likely to provoke negative emotions among visitors. In addition, calmness also reaches a relatively high level under management mechanisms (18.8%), which may reflect a sense of passive acceptance or emotional neutrality among some visitors.

Among the less frequent emotions, disappointment is primarily associated with functional formats (5.5%) and cultural identity (4.8%). Pride appears slightly more often under cultural identity (11.8%) than in other aspects, suggesting that cultural elements can trigger a sense of emotional affiliation or resonance. Overall, this chart reveals substantial variation in emotional composition across different aspects, highlighting the need for differentiated optimization of landscape, functionality, and governance in historic districts based on their specific

emotional effects.

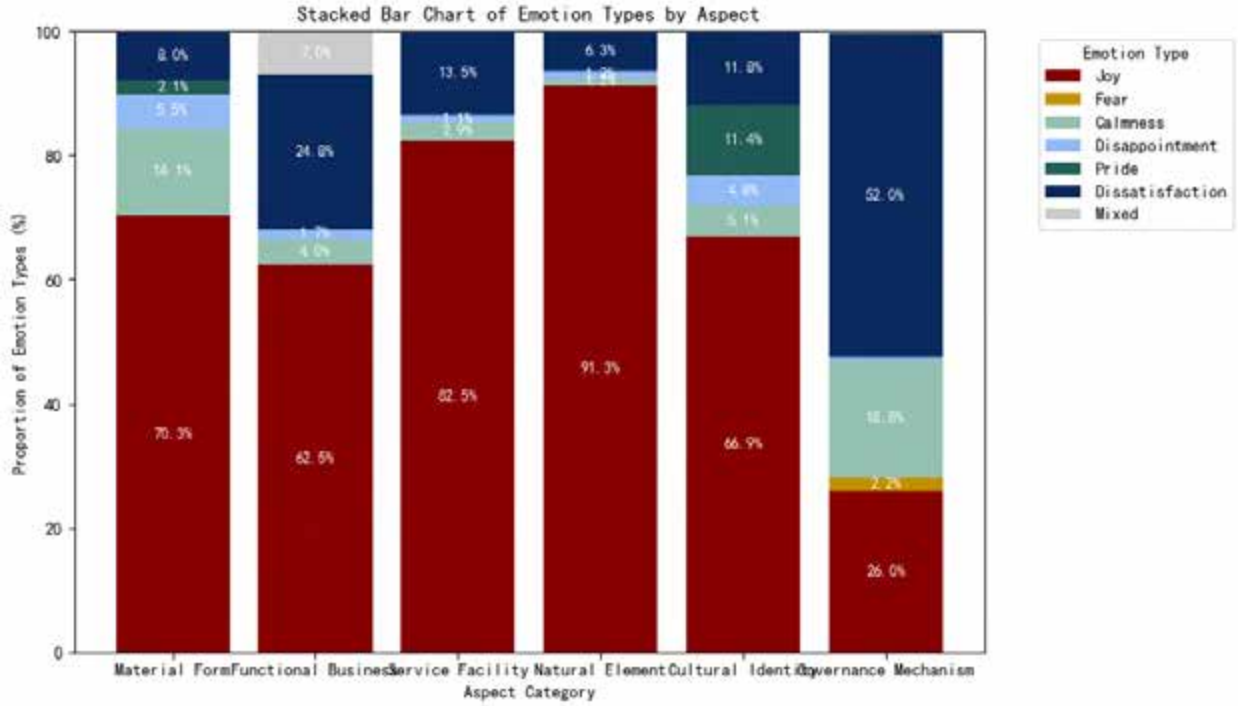

Fig.4 Aspect-Level Emotion Type Analysis

4.3 Visual Landscape Type Characteristics

Among the six categories, **commercial landscape** occupies the largest share at **48.5%**, suggesting that commercial scenes such as storefronts, signs, and retail displays are the most frequently photographed elements in this historic district. **Architectural landscapes** account for **23.7%**, indicating that built heritage and spatial enclosures remain important visual elements.

Streetscapes represent **15.2%** of the image content, while **facilities and signage** (8.7%) and **natural landscapes** (3.7%) appear less frequently. The **human activities** category accounts for only **0.3%**, implying either limited visible social interaction in the captured images or potential underrepresentation due to model classification limitations. Overall, the radar chart reflects a highly commerce-oriented visual landscape in Nanluoguxiang, with relatively low visibility of natural and sociocultural elements.

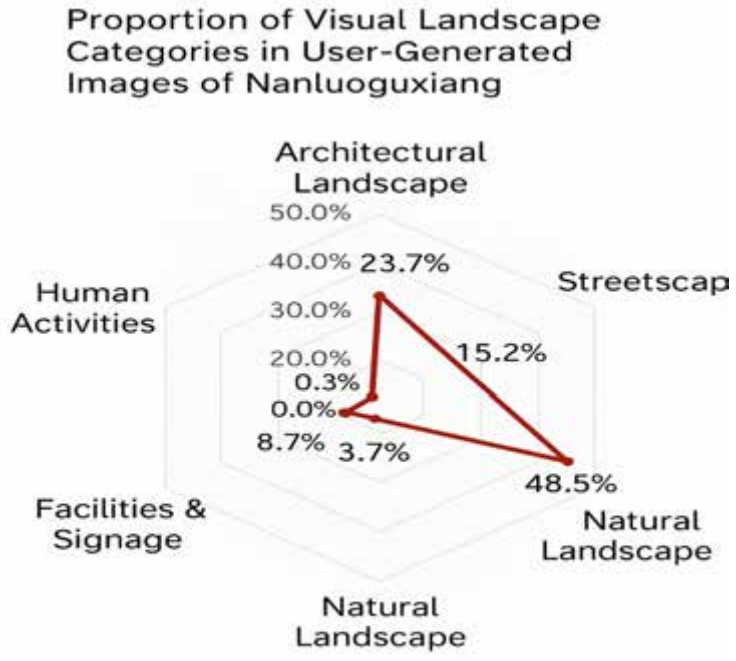

Fig.5 Proportion of Visual Landscape Categories in Nanluoguxiang

4.4 Relationship Between Emotional Characteristics and Visual Perception Types

The results are derived from an XGBoost (Extreme Gradient Boosting) model trained to predict public emotional responses based on visual landscape features extracted from images. To interpret the contribution of each feature to the model's output, SHAP (SHapley Additive exPlanations) values were employed. SHAP provides a theoretically grounded and visually interpretable method to quantify the marginal impact of each input variable on the prediction outcome.

Among the seven features, **Human Activities**, **Streetscape**, and **Historic Buildings** exhibit the widest spread of SHAP values, indicating they have the greatest influence on model output. High values of **Human Activities** and **Streetscape** (shown in red) are generally associated with positive contributions to the prediction, while higher levels of **Storefronts** and **Signage & Facilities** often reduce the predicted emotional positivity.

By contrast, **Natural Environment**, **Commercial Goods**, and **Signage & Facilities** show relatively narrow SHAP ranges, implying limited influence in the current model context—either due to low prevalence in the data or weaker emotional associations. This visualization provides a transparent global view of model interpretability, highlighting which physical elements in historical streetscapes are most strongly tied to emotional outcomes.

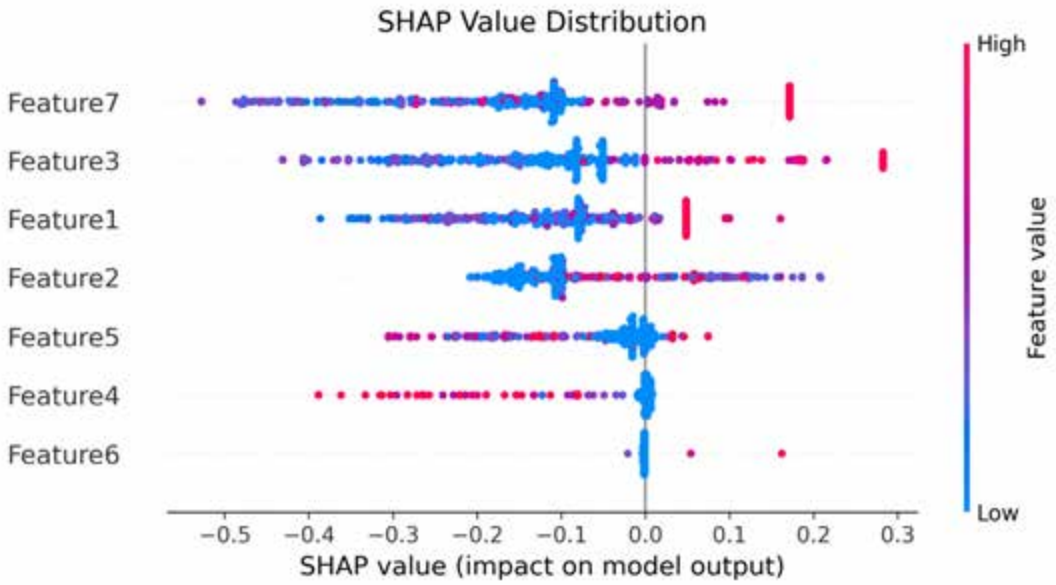

Fig.6 SHAP Value Distribution for Feature-Level Impact on Emotion Prediction Model

5. Discussion

This study demonstrates that text-based user comments and their accompanying images from social media platforms can serve as a valuable form of multimodal data for investigating the emotional effects of urban spaces. By integrating textual and visual content, the research reveals how public emotional responses are embedded within both narrative expressions and visual representations of historic districts.

Moreover, the findings highlight the potential of artificial intelligence (AI) in detecting and analyzing emotional experiences associated with urban environments. In particular, the AI models employed in this study were able to classify six distinct types of emotional responses with a relatively high degree of accuracy and consistency, illustrating their applicability to emotion analysis tasks in the urban and heritage planning context.

This research further confirms that it is feasible to integrate large language models (LLMs), computer vision techniques, and machine learning algorithms to jointly observe emotional signals and spatial landscape characteristics from social media data. Such integration enables a more comprehensive and scalable approach to understanding how people perceive and emotionally respond to historic urban spaces in real-world, user-generated contexts.

Nevertheless, certain limitations remain. A key constraint lies in the inherent biases of social media data. These datasets typically lack information on users' socioeconomic attributes, such as age, income, education level, or residential background, which may influence how different groups emotionally experience the same space. To address this limitation, future studies could incorporate experimental or survey-based methods to supplement and validate findings from digital trace data. Such triangulation would enhance the robustness and generalizability of emotion-oriented urban research.

6. Conclusion

This study is based on user-generated content (UGC) from the social media platform Dianping, using Nanluoguxiang (NLG), a representative historic district in Beijing, as a case study. It collected text reviews and associated images to construct an AI-driven framework for emotional analysis. Using XGBoost, the study investigates the relationship between six types of visual environmental scenes in the historic district and visitors' emotional experiences. The results reveal that specific visual scene types within historic districts have significant effects on public emotions. Meanwhile, the proposed multimodal framework proves effective in predicting the emotional impacts of visual

landscapes in historic district settings.

Abstract
Cafés have emerged as vital cultural and social anchors in contemporary cities, increasingly located in alleyways and residential neighbourhoods rather than traditional commercial centres. Focusing on Seoul's Hongdae district, this study uses semantic segmentation and deep learning applied to Street View Images to examine how streetscape attributes—both visual (e.g. enclosure, openness) and perceptual (e.g. liveliness, beauty)—influence café location patterns. Results reveal a shift away from conventional accessibility-based location towards environments that offer sensory richness and walkable appeal. These findings underscore the evolving role of cafés as everyday cultural spaces shaped by experiential consumption and image-based sharing. Accordingly, urban planners should consider streetscapes as active elements of lived heritage and place identity, rather than passive infrastructure.

1.Introduction

Modern consumer culture has expanded beyond the consumption of goods to encompass the commodification of space, emphasising the image and aesthetic distinctiveness of retail environments. Brands have adopted experience-oriented retail strategies, such as flagship stores and pop-up stores, or employed omni-channel approaches that integrate online and offline platforms. Offline stores, in particular, are being restructured as spaces where consumers can engage with brand identity and share their experiences with others. These experience-centred spaces have become a key foundation for consumer engagement, enabling them to share information through online communities or social network services (SNS), and visit cafés based on recommendations from others. Furthermore, location-based information on social media enables consumers to indirectly experience places they have not yet visited (Yuksel et al., 2016), thereby influencing their spatial preferences and consumption behaviour. In South Korea, retailers are making strategic location decisions that prioritise residential neighbourhoods over commercial centres, largely due to lower rents and improved access to spatial information. This tendency reflects a growing interest in individual consumer preferences, sense of place, and spatial experiences. Previously overlooked places and cafés have started to attract attention from consumers. Some of these areas—though not originally designed as commercial zones—are gradually recognised as commercial spaces, while others actively contribute to enhancing the perceived attractiveness of their surrounding urban space.

Among business sectors, the food and beverage (F&B) industry—particularly cafés, restaurants, and pubs—clearly exemplifies these spatial and cultural shifts. Cafés, in particular, are relatively easy to open with limited capital and preparation time, and are perceived as carrying lower risks compared to other food-related businesses, leading to greater locational flexibility. Moreover, as the millennial generation increasingly values experience and social sharing (Ryu et al., 2022), cafés are gaining recognition as places for unique experiences and social interaction. In South Korea, the café industry has expanded rapidly since the entry of the global franchise Starbucks in 1999. In Seoul, the number of operating cafés doubled from 8,638 in 2010 to 17,721 in 2019, making it one of the most active sectors for new business openings. Additionally, cafés are often among the first establishments to enter neighbourhoods undergoing a commercialisation process—including those associated with gentrification—and are known to attract external visitors, thereby demonstrating pronounced shifts in spatial distribution. With their rapid proliferation and flexible locational behaviour, cafés have thus played a leading role in shaping new commercial geographies across urban space.

While geographic location remains an important factor in retail location decisions, cafés have recently demonstrated patterns that diverge from traditional retail location models. In the past, cafés were typically concentrated in areas with high physical accessibility, such as near subway stations or along major boulevards. In contrast, newly opened cafés tend to be smaller in scale and more locally situated. Unlike conventional stores, these cafés position themselves as places offering distinctive experiences, enabling consumers to perceive their surroundings as unique and appealing, thereby overcoming less favourable locational conditions. This phenomenon is difficult to explain using traditional retail location theories, such as Christaller's (1933) central place theory, which suggests that new spatial patterns may emerge—patterns that are not solely based on conventional economic-geographic factors such as accessibility, land price, agglomeration, or population

density, but are instead shaped by changing consumer behaviours. However, most of the previous literature on café locations has focused on these traditional indicators (Gautama Himawan and Rahadi, 2020; Kim et al., 2015; Ko and Chiu, 2006; Sevtsuk, 2014; Zhao et al., 2023), often overlooking the influence of experiential attributes and visual appeal on location decisions.

In urban space, cafés have established themselves not merely as providers of food and beverages, but as everyday places of social and cultural interaction. They serve as places for optional activities (Gehl, 2013), and contribute to the vitality of public space (MacCormac, 1983). Zukin (1998) interpreted cafés not as simple consumption spaces, but as symbolic places that represent a new form of urban lifestyle. Similarly, Banerjee (2001) argued that public life becomes more enriched in third places such as cafés. According to Oldenburg (1999), third places refer to diverse public spaces beyond the domains of home and work, where people voluntarily and informally gather with the expectation of enjoyment. In South Korea, cafés have become representative examples of spatial consumption, functioning not as venues for the physical acquisition of goods at a specific moment in time, but as experiential places consumed and possessed through use. In this sense, cafés enable consumers to indirectly express their personal tastes and lifestyles through experiential consumption. Increasingly, people visit cafés not for the products themselves, but for the atmosphere of the surrounding area or the store. Ultimately, consumers have come to pay attention not only to the physical attributes of a place, but also to the emotional atmosphere and image it conveys.

Pedestrians' perceptions of place are shaped by the physical environment of the streetscape and the interactions among individual storefronts. Environmental elements that constitute the street function as part of the service setting that supports better customer experiences and contributes to the overall atmosphere of a café. At the same time, they offer personalised experiential spaces, allowing consumers to perceive a distinctive and appealing ambiance. A favourable service environment experienced at the time of use can trigger consumer behaviour and enhance customer satisfaction (Koo et al., 2023b). This, in turn, can attract potential customers, making it essential to understand the role of streetscape and walkability in shaping the attractiveness of commercial spaces in relation to café locations. Accordingly, this study examines the spatial dynamics of café location shifts in an area where traditional and emerging retail districts coexist, and analyses the influence of streetscape and walkability. Furthermore, it aims to assess the limitations of traditional theories in explaining café location decisions and to explore the evolving role of cafés in urban space.

The structure of this study is as follows. Section 2 reviews the relevant literature and theoretical background. Section 3 outlines the study area, data, and methodology. Section 4 presents the spatial patterns and influencing factors of café location shifts. Section 5 discusses the empirical findings, and Section 6 concludes the study.

2.Literature review

2.1.Retail location theories

Traditional retail location theories assume that retailers make location decisions that minimise transportation costs for consumers while maximising proximity to both competing and complementary stores. For example, Christaller (1933), in his central-place theory, posited that each retail store is equidistant from others selling the same goods and that stores offering more diverse products possess market areas of varying sizes. Later, Lösch (1938) modified this framework by excluding the concept of product range and instead focusing on the minimum market area required to maximise production value. In contrast, Hillier (1997) introduced the concept of movement in his movement-economic theory, emphasising that the fundamental logic of urban structure lies in movement itself. Ultimately, he emphasised that spatial advantages—such as streets with high pedestrian or vehicular traffic—are inherently more valuable.

More recently, the rising rents that often accompany commercial revitalisation have driven retailers to make location decisions in areas with relatively lower physical accessibility to reduce operational costs. In this context, producers increasingly choose locations with lower rents compared to commercial centres, thereby seeking greater economic efficiency. From this perspective, Smith (1979) proposed the rent-gap theory, suggesting that commercialisation occurs when disparities in rent emerge, even among areas with similar accessibility. Ley (1997), on the other hand, argued that when artists move into low-rent areas, they foster a consumption culture centred on aesthetic value.

Today, retail locations are increasingly chosen by consumers based not only on convenience but also on the unique characteristics of a district and the physical environment and atmosphere surrounding the store. Walkable streets provide positive sensory stimuli, contributing to more enjoyable and satisfying service experiences (Koo et al., 2023b). Building on this idea, Bitner (1992) introduced the concept of the 'servicescape', combining service and landscape to describe the physical environment in which the service experience takes place. The servicescape includes both the interior and exterior of a facility, as well as its surroundings, allowing consumers to indirectly perceive service quality and product value even prior to direct service engagement (Turley and Milliman, 2000).

2.2.Walkability and retail location

The built environment of a retail district plays a crucial role in attracting potential consumers, making walkability a key factor in determining the location and operation of retailers (Duncum, 2007; Handy et al., 2002). Streets serve not only as corridors for movement but also as social spaces that connect buildings and human activities (Carmona, 2021). Streets with high connectivity or those designed to encourage pedestrian movement tend to experience greater levels of foot traffic, which in turn contributes to drawing potential consumers (Sevtsuk, 2020).

Previous studies examining the built environment of retail districts from a street network perspective have employed Urban Network Analysis (UNA) to demonstrate that street-level accessibility and connectivity significantly influence the location and performance of retailers (Jeong and Yoon, 2017; Kang, 2016; Sevtsuk, 2014). For example, Sevtsuk (2014) analysed pedestrian accessibility from surrounding facilities and highlighted the importance of network-based measures such as the gravity index for public transit and building-level expected betweenness. Kang (2016) demonstrated that in pedestrian accessibility, betweenness and straightness are key predictors of retail sales in Seoul. From the perspective of urban spatial structure, Harvey et al. (2017) investigated cities such as Boston, New York, and Baltimore to explore how built features—such as street width and length—can be used to evaluate streetscape structure. Streetscapes enclosed by buildings or walls were found to contribute to perceived safety and imageability, offering more immediate stimuli for pedestrians and enhancing the effect of visual complexity.

2.3.Streetscape and retail location

Most literature on streetscape and retail location has primarily measured walkability from the perspective of pedestrian accessibility. However, walkability extends beyond accessibility to encompass pedestrians' perceived safety, aesthetic quality, and enjoyment of the environment at the landscape level (Koo et al., 2023b; Shields and Gomes da Silva, 2023). The architectural organisation of streetscape influences how pedestrians experience and perceive the space, contributing to increased safety, comfort, and enjoyment. Specifically, previous studies have assessed streetscape characteristics based on elements such as enclosure (Ewing and Handy, 2009; Harvey et al., 2017), openness (Ewing et al., 2013), and greenery (Li et al., 2018; Zhang et al., 2018). These micro-scale streetscape characteristics of walkability directly or indirectly influence pedestrian perception and emotion, shaping a human-scale environment that supports commercial activity by enhancing pedestrians' feelings of safety and comfort (Hahm et al., 2019). In previous literature, these features have been quantified through two-dimensional GIS-based analyses or extracted from street-level images using qualitative methods to identify visual factors (Ewing et al., 2006; Harvey et al., 2017; Hong et al., 2010; Purciel et al., 2009).

More recently, urban planning research has increasingly turned to machine learning techniques using street-level imagery, such as Google Street View, to estimate walkable environments from a human-eye perspective. Compared to two-dimensional GIS-based methods, Street View Images (SVIs) provide a more accurate representation of the built environment as it is experienced by pedestrians (Koo et al., 2022). For example, several studies have used semantic segmentation techniques to identify visual components of the streetscape from the perspective of pedestrian perception (Kim and Woo, 2022; Koo et al., 2023a; Lee et al., 2022). Common models include PSPNet, UPerNet, and HRNet, which have been applied in various studies to classify fine-grained visual features of the street environment. Furthermore, Dubey et al. (2016) proposed a Convolutional Neural Network (CNN)-based deep learning model that predicts six emotional responses to urban environments using the Place Pulse 2.0 dataset provided by MIT. This dataset contains 110,998 images collected from 56 cities across 28 countries and includes over 1.17 million pairwise comparisons evaluating six dimensions of perceived streetscape quality: Safe, Lively, Beautiful, Wealthy, Depressing, and Boring (Figure 1). Using this dataset, it becomes possible to identify how different SVIs elicit varying perceptions among pedestrians. In addition, Zhang et al. (2018) developed a deep learning model to predict emotional responses to streetscapes in specific study areas such as Beijing and

Shanghai. They examined the relationship between qualitative perceptual evaluations derived from image-based predictions and quantitative visual attributes obtained through semantic segmentation.

Figure 1. Example of Place Pulse 2.0 data collection

2.4.Café location

Cafés have been considered both spaces for community engagement (Ferreira et al., 2021) and indicators of gentrification (Zukin et al., 2009). Accordingly, previous studies on café locations have primarily focused on factors related to business performance, such as accessibility, economic viability, competitiveness, demographic characteristics, and store characteristics (Gautama Himawan and Rahadi, 2020; Kim et al., 2015; Ko and Chiu, 2006; Sevtsuk, 2014; Zhao et al., 2023). Table 1 provides an overview of these studies.

Table 1. Literature on café locations

Authors (Year)	Key variables	Findings related to location
Ko and Chiu (2006)	Accessibility, Physical characteristics	Key factors influencing customer satisfaction, ranking professional service, reasonable pricing, food quality, environment, other food drink, and promotion.
Sevtsuk (2014)	Accessibility, Competitions, Demographics, Store characteristics	Spatial clustering is a key determinant of retail location patterns, with restaurants exhibiting a tendency to be situated near similar stores. Additionally, proximity to subway stations is a significant positive factor influencing the store's location.
Kim et al. (2015)	Accessibility, Economic conditions, Competitions, Demographics, Store characteristics	Retail sales benefit from closer proximity to subway stations and a higher density of similar stores. Higher sales are observed in locations with lower footprint area but greater building volume.
Gautama Himawan and Rahadi (2020)	Accessibility, Physical characteristics	The built environment and ambiance of a café strongly influence customer satisfaction and revisit intention. Location and accessibility are critical factors in customers' choice of a particular café.
Zhao et al. (2023)	Accessibility, Economic conditions, Competitions	In Beijing's major urban centres, cafés tend to cluster in central business districts or along high streets.

However, today's consumers are increasingly willing to visit cafés with a desirable atmosphere, even if the locations are not physically accessible. As a result, the widespread use of digital platforms such as social media has brought about noticeable shifts in location patterns, even for stores situated outside traditionally optimal areas. Based on these insights, this study aims to examine how micro-scale environmental factors enhance the perceptual quality of streetscape while simultaneously making the pedestrian experience more enjoyable. In particular, aesthetic streetscapes increase the attractiveness of the walking experience and thus play a critical role in encouraging pedestrian flows. Given that such flows often translate into consumer footfall, it is essential

to investigate how walkable and visually distinctive streetscapes are associated with café location decisions.

Accordingly, this study explores the shifting patterns of café locations and investigates the role of streetscape and walkability in this process. Specifically, it employs a deep learning model to objectively evaluate physical streetscape conditions while also incorporating subjective pedestrian perceptions. By analysing new patterns in café locations, this study contributes to understanding not only the spatial transformation of retail districts and urban form but also the socio-cultural shifts driven by experiential consumption.

3.Methodology

3.1.Study area

This study focuses on the Hongdae retail district, one of the major commercial centres in Seoul, South Korea (Figure 2). The study area encompasses seven administrative districts (dong): Seogyo-dong, Seogang-dong, Hapjeong-dong, Mangwon-1-dong, Mangwon-2-dong, Seongsan-1-dong, and Yeonnam-dong. The term 'Hongdae' refers to the area surrounding Hongik University, which has developed into a central retail district around the campus. Covering an area of 8.15 km², the district includes six subway stations along two lines: Hongik University, Hapjeong, Mapo-gu Office, Mangwon, Sangsu, and Gwangheungchang. The district is characterised by human-scale streetscapes and a mixture of residential and commercial zones, which allows for the observation of retail activity not only within designated commercial zones but also in adjacent residential zones.

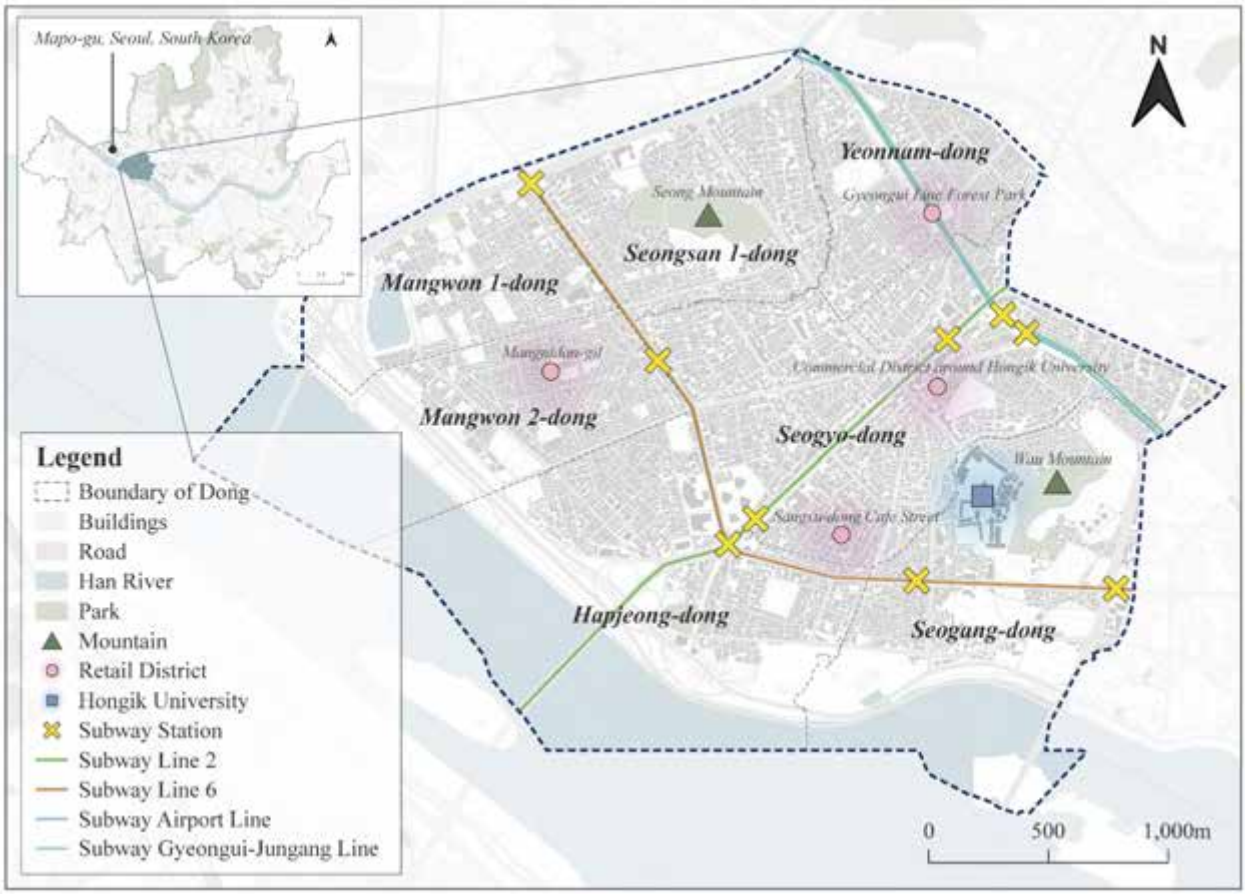

Figure 2. Study area

The Hongdae retail district began to take shape in 1955 with the establishment of the College of Fine Arts at Hongik University. As studios and galleries catering to art students began to cluster in the area, it gradually evolved into a culturally significant street. Over time, the area experienced continued retail growth as small shops became concentrated, and commercial businesses gradually penetrated residential zones, giving rise to newly developed retail districts (Hahm et al., 2017).

In the 2000s, foot traffic increased significantly due to two major factors: the 2002 Korea–Japan World Cup and the implementation of the Walkable Street Development Project, part of the broader Street Environment Improvement Project. These developments led to an influx of cafés, pubs, and restaurants into the university-centred retail district, solidifying its position as a central commercial district. In the early 2010s, the opening of new subway lines such as the Incheon Airport Railroad and Gyeongui Line improved accessibility from other cities such as Incheon and Gimpo. As a result, the area experienced gentrification driven by rising rents, which forced many young artists to relocate to nearby neighbourhoods such as Hapjeong-dong. This migration led to the emergence of new street-level retail districts, such as the so-called 'Sangsu-dong Café Street'.

In 2015, the Gyeongui Line Forest Park, an urban regeneration project that transformed an abandoned railway line into a linear park, was completed near Yeonnam-dong. It has been popularly dubbed 'Yeontral Park'—a reference to New York City's Central Park—due to its central location and the perceived improvement it brought to the surrounding residential and retail environment. The development of this green space contributed to another wave of retail expansion along the park corridor. That same year, the Beautiful Signage Street Project, a signage improvement initiative, was implemented to enhance the visual aesthetics of streets near the retail district. In 2016, the western part of Mangwon-dong—adjacent to the Mangwon Market—gained popularity and has been labelled as 'Mangnidan-gil'. The name was inspired by Gyeongnidan-gil, a well-known street-level retail district in South Korea. As the area attracted increasing attention on social media, it began to emerge as a new hotspot for younger consumers and independent retailers.

More recently, the broader Hongdae retail district has seen a rapid increase in foreign visitors, prompting the launch of the Cultural Tourism Destination Development Project for Walkable Street, a tourism initiative aimed at enhancing pedestrian-friendly cultural attractions. Figure 3 illustrates the spatial transformation of the study area over time.

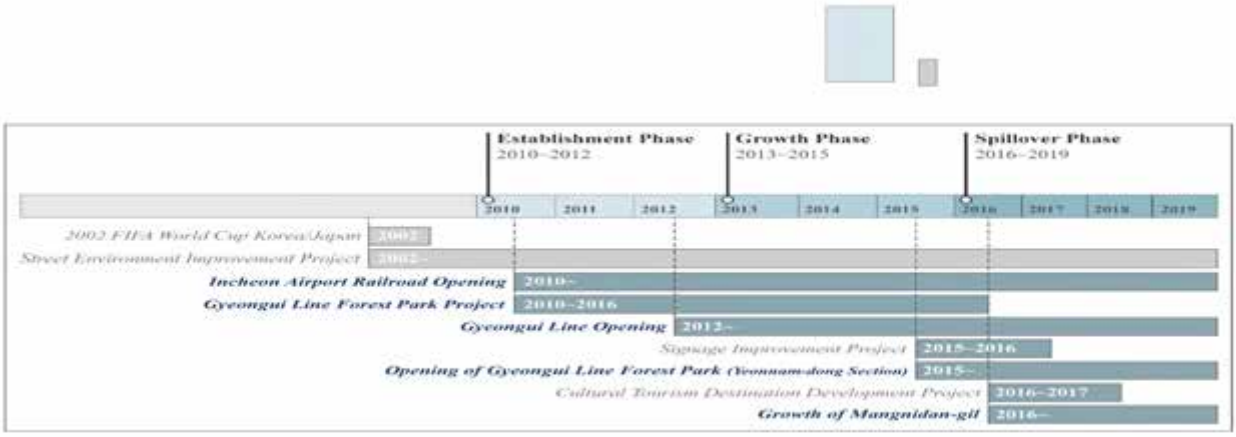

Figure 3. Evolution of study area

3.2.Definition of analysis periods

Due to limitations in the availability of SVIs prior to 2010, and in order to exclude the economic disruptions caused by COVID-19, the temporal scope of the analysis was set from 2010 to 2019. To examine the spatial shifts in café locations, it was necessary to define specific phases that reflect the evolution of spatial and commercial dynamics. This periodisation also helps to control for potential outliers in the annual opening data of cafés.

Based on the evolution of the Hongdae retail district, the study defines three distinct analytical phases. The Establishment Phase (2010–2012) corresponds to the initial formation of café clusters centred in Seogyo-dong, adjacent to Hongik University. The Growth Phase (2013–2015) is characterised by spatial expansion into surrounding areas along the edge of the core, while the Spillover Phase (2016–2019) captures the transformation

of retail activity extending beyond major boulevards into previously overlooked alleyways.

3.3.Measuring network-based walkability using UNA

The built environment that influences retail location decisions includes two key forms of accessibility: proximity to public transportation and specific facilities, and network-based accessibility derived from the street structure. In this study, three indicators were calculated using UNA: accessibility to subway station exits, accessibility to parks, and betweenness. UNA is a network-based spatial analysis method that incorporates buildings into the analytical framework; in this study, it was implemented using Rhinoceros 3D.

The Gravity Index quantifies accessibility by incorporating spatial resistance between origins and destinations. It captures the cumulative gravitational pull that destinations exert on a given origin within a specified network radius. The index assumes that accessibility increases when more destinations are located within the radius, when those destinations have greater weights (e.g. size or attractiveness), and when the network distance to them is shorter (Sevtsuk, 2020). The formula is given as follows:

$$Gravity[i]^r = \sum_{j \in G-i; d[i,j] \leq r} W[j]^{\alpha} / e^{\beta * d[i,j]} \quad (1)$$

where *W[j]* is the weight of destination *j*, indicating its size or attractiveness; *d[i,j]* is the shortest distance between origins *i* and destination *j* within the network radius r; α is a parameter that adjusts the influence of destination weight; and β is the distance decay coefficient that determines how accessibility decreases as distance increases.

The Betweenness measures the degree to which a building lies on the shortest paths between other buildings. A higher betweenness value indicates greater accessibility and ease of movement. As a probabilistic measure of how often a specific location is traversed within the street network, it serves as a proxy for estimating pedestrian flow (Figure 4). The formula is defined as follows:

$$Betweenness[i]^{r,dr} = \sum_{j,k \in G-i; d[j,k] \leq r*dr} (n_{jk}[i]/n_{jk}) W[j] \quad (2)$$

where n_{jk} [i] is the total number of shortest paths from origin j to destination k that pass by observer building i, $n_{jk}$is the total number of shortest paths from origin j to destination k, W[j] is the weight of origin j, and dr is the detour ratio, allowing for slight deviations from the shortest path, with j and k located within the network radius r of one another.

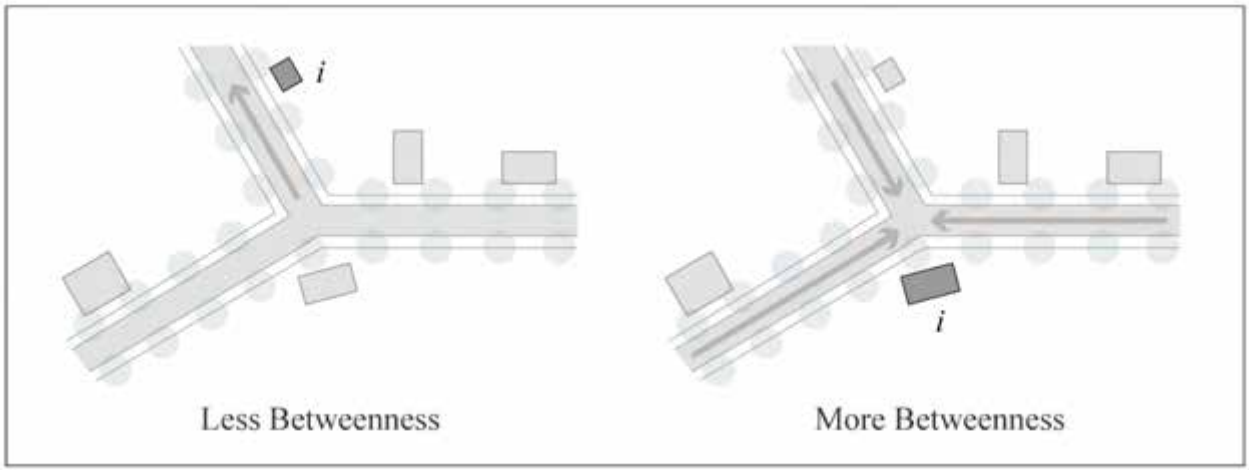

Figure 4. Example of betweenness (Adapted form Sevtsuk, 2014)

For the calculation of the Gravity Index, the network radius was set to 600 metres, which corresponds to a typical walking distance of 5–10 minutes. The distance decay coefficient was set to 0.00217, following the walking

distance-based value reported in Handy and Niemeier (1997). Betweenness was computed based on the full network of buildings within the study area. To account for differences in building size within the Hongdae retail district, each building was weighted by its volume. Accordingly, the resulting Betweenness values reflect the estimated volume of movement associated with each building, assuming that larger buildings generate more pedestrian flow than the smaller ones (Sevtsuk, 2014).

Given that urban structures such as roads and buildings tend to evolve gradually over long periods (Casali and Heinimann, 2019), it was assumed that the spatial configuration remained relatively stable during the analysis period. Therefore, spatial network data from 2019 were used for all time periods. For subway accessibility, changes were incorporated starting from the Growth Phase to reflect the opening of the Gyeongui-Jungang Line at Hongik University Station in 2012.

3.4. Measuring streetscape characteristics using SVIs

This study employed SVIs to extract streetscape characteristics as perceived by pedestrians. SVIs enable the quantification of pedestrians' subjective perceptions of the physical environment (Lee et al., 2022; Seo et al., 2021; Yin and Wang, 2016). This approach reduces statistical distortions and data biases, thereby improving measurement precision and enhancing the generalisability of results.

SVIs for the study area were collected using the Naver Street View (NSV) API. Naver is a leading Korean internet portal that provides both mapping and Street View services. In this study, a total of 21,101 panoramic 360° images were collected by generating points at 20-metre intervals along the road network in the study area. For visual attributes, full 360° panoramic images were used to assess the overall street environment. For perceptual attributes, only the front-facing portions of the panoramic images were extracted, as these reflect the visual field most relevant to pedestrians and were used as input for streetscape perception modelling (Figure 5). The SVIs used in the analysis correspond to the years 2010, 2014–2015, and 2016–2017. NSV data for the year 2013 were not available, as imagery for that year was not provided by the platform. In addition, the 2015 and 2017 images were included to supplement spatial gaps left by incomplete coverage in earlier years.

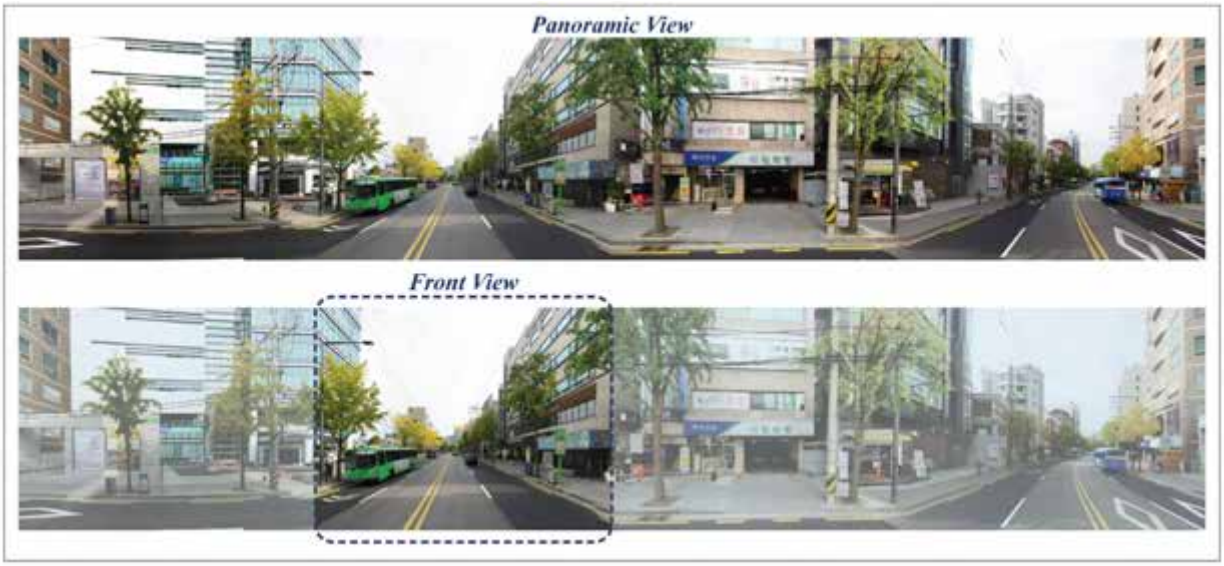

Figure 5. Example of a panoramic and front views extracted from SVIs

To extract the visual attributes of streetscape characteristics, this study employed a computer vision technique known as semantic segmentation. Semantic segmentation is a pixel-wise image classification method that distinguishes between multiple categories—such as buildings, trees, and sky—within a given dataset. We used the HRNet-V2-W48 model pre-trained on the ADE20K dataset to apply this technique. The pixel proportions of physical streetscape elements identified in each image were adopted as visual attributes perceived by pedestrians. Four indicators were ultimately computed: Enclosure, Openness, Pavement, and Greenness. Enclosure refers to the proportion of buildings and walls relative to roads; Openness indicates the proportion of sky area; Pavement reflects the proportion of sidewalks relative to road area; and Greenness quantifies the proportion of visible

greenery such as trees, grass, and plants (Figure 6).

Figure 6. Visual attributes extracted from a SVI using semantic segmentation

To measure pedestrians' perceptions of the streetscape, we trained a CNN model to predict perceptual attributes based on SVIs. In this study, we adopted VGG16 and applied transfer learning using a model pre-trained on the ImageNet dataset. For training data, we used the Place Pulse 2.0 dataset, a large-scale visual perception survey conducted by MIT Media Lab, which captures people's impressions of urban environments via an online platform. From the Place Pulse dataset, we extracted three positive perceptual dimensions—Safe, Lively, and Beautiful—as quantifiable street scores for each image. Other perceptual labels were excluded to ensure objectivity and reliability. First, the Wealthy dimension was excluded, as it tends to reflect high-income residential zones or areas with large boulevard-style street trees, which are not easily generalisable in typical retail districts. Second, the Depressing and Boring dimensions were excluded as negative emotional attributes, which may conflict with the selected positive attributes. Moreover, these mental health–related indicators are less applicable in the South Korean context, and difficult to interpret within retail environments.

Each variable was calculated as the average value of images within a 100-metre radius, to reflect the contextual streetscape characteristics of the surrounding area. During this process, 86 samples lacking image coverage within the 100-metre buffer were removed from the analysis due to missing data. Figure 7 illustrates the three stages of the machine learning–based analysis using SVIs conducted in this study.

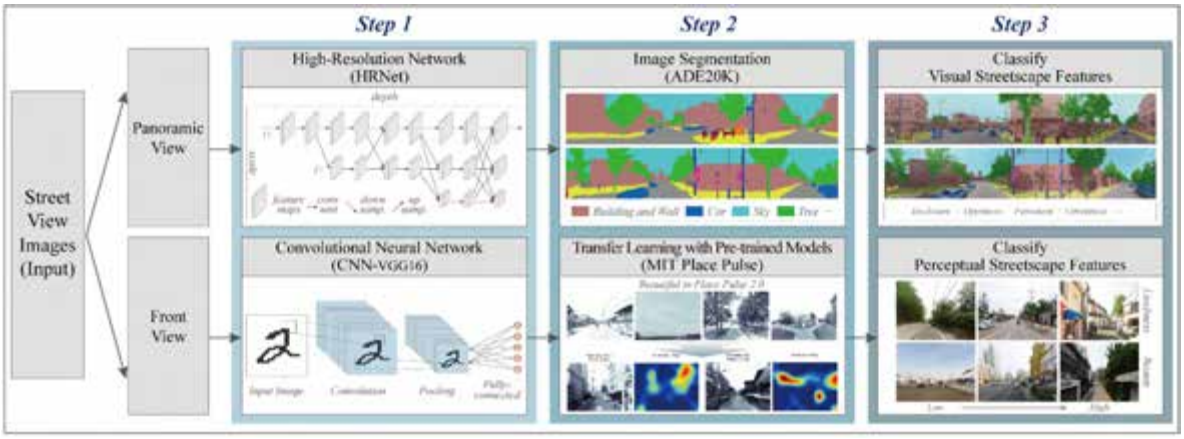

Figure 7. SVI-based process for classifying visual and perceptual streetscape features

3.5.Data

Point-of-interest (POI) data on cafés from 2010 to 2019 were collected from the Statistical Geographic Information Service (SGIS) using Python-based web crawling. From these data, we identified store openings, closures, and operational status for each year to construct the dependent variable: a binary indicator of store opening (0 or 1). Store opening was operationally defined as the appearance of a café in year t that did not exist in year t–1 (Figure 8).

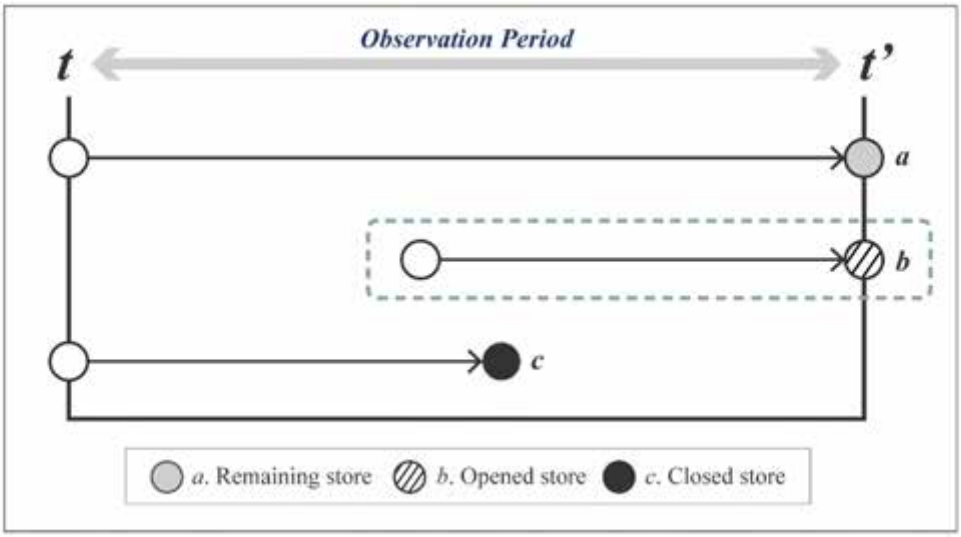

Figure 8. Classification of store status

To assess the prior presence of stores and café clustering before the time of opening, we used POI data from 2010, 2013, and 2016. Clustering was calculated using UNA with a network radius of 100 metres to capture the degree of competitive clustering as experienced by pedestrians.

Additional data on location factors were collected from various sources commonly used in previous studies. Information on building characteristics—including building footprint, building volume, building height, and parcel area—was obtained from the Ministry of Land, Infrastructure and Transport (MOLIT). Average land prices were collected from the Seoul Open Data Plaza and averaged for each analysis period. Population density and the number of millennial residents were retrieved from SGIS. Because population data prior to 2015 were only available in 5-year intervals, data for the Growth Phase were collected based on the 2015 census. Definitions of all variables used in the analysis and their data sources are summarised in Table 1.

Table 2. Description of variables

Variable				Description of variables	Source
Dependent variable			Open	Binary variable indicating whether a café newly opened (1=Yes; 0=No)	SGIS
Independent variable	Walkability characteristics		Subway	Spatial accessibility to subway entrance in the radius (gravity, r=600m)	MOLIT
	Park		Spatial accessibility to park in the radius (gravity, r=600m)		
	Betweenness		Connectivity between all buildings in the radius (r=n, weighted by volume)		
	Road width		Width of the road adjacent to the building (m)		
	Streetscape characteristics	Visual attributes	Enclosure	Average ratio of building and wall area to road in the radius (r=100m)	NSV
			Openness	Average ratio of sky area to road in the radius (r=100m)	
			Pavement	Average ratio of sidewalk area to road in the radius (r=100m)	
			Greenness	Average ratio of tree and plant area to road in the radius (r=100m)	
		Perceptual attributes	Safe	Average perceived level of safety of streetscape in the radius (r=100m)	
			Lively	Average perceived level of liveliness of streetscape in the radius (r=100m)	
			Beautiful	Average perceived level of beauty of streetscape in the radius (r=100m)	

Control variable	Store characteristics Agglomeration	Occupied	Binary variable indicating whether the store was already occupied in the previous year (1=Yes; 0=No)	SGIS
		Spatial proximity to other operating cafés in the radius (gravity, r=100m)		
	Built environment characteristics Building height	Building footprint	Footprint area of the building (m^2)	MOLIT
		Height of the building (m^2)		
	Parcel area	Area of the land parcel (m^2)		
	Land price	Average land price during the analysis period (won)	SODP	
	Demographic characteristics Millennials Employees	Residents	Residential population density in the census district	SGIS
		Number of millennials (aged 20–39) in the census district		
		Number of workers in the census district		

3.6.Research methods

To investigate the spatial distribution of café locations, we employed Kernel Density Estimation (KDE), a point pattern analysis method. KDE is a non-parametric technique that estimates the probability density of point distributions across space using point data. Unlike statistical clustering methods such as K-means, KDE accounts for spatial dependence and is particularly effective for identifying the spatial diffusion of events and visualising clusters of point features (Anderson, 2009; Węglarczyk, 2018). Due to its strengths, KDE has been widely used in various fields, including traffic accident and crime hotspot analysis, as well as studies of spatial utilisation patterns (Cai et al., 2013; Chainey et al., 2008; Xie and Yan, 2008; Yu et al., 2015). In this study, KDE was applied to the opening data of cafés during the Establishment, Growth, and Spillover Phases to examine spatial shifts in location patterns over time.

Subsequently, a binary logistic regression model was used to identify the determinants of café openings for each phase. Logistic regression is one of the simplest probabilistic modelling techniques and is used to estimate the likelihood of a binary outcome based on a set of independent variables. Rather than predicting whether an event will occur, it estimates the probability of its occurrence (Jin and Lee, 2017). The predicted value of the dependent variable is expressed as a probability between 0 and 1. If the predicted value exceeds a threshold (typically 0.50), the event is considered likely to occur. The logistic function is formulated as follows:

$$\ln\left(p\left(y=1\middle|x_1,\cdots,x_p\right)/\left(1-p\left(y=1\middle|x_1,\cdots,x_p\right)\right)\right)=\beta_0+\beta_1x_1+\cdots+\beta_px_p \quad (3)$$

where ln *ln(p/(1-p))* represents the logit, *p/(1-p)* is the odds, β_p is the regression coefficient, and x_p is the independent variable.

$$Odds=p_i/(1-p_i)=\exp(\textstyle\sum_{j=1}^{k}\beta_jx_{ij})=\exp(\beta_1x_1)\exp(\beta_2x_{i2})\cdots\exp(\beta_kx_{ik}) \quad (4)$$

where p_i represents the probability that event *i* occurs, β_k is the regression coefficient, and x_{ik} is the independent variable.

The odds indicate the ratio of the probability that an event occurs to the probability that it does not. When an independent variable x_{ik} increases by one unit, the odds ratio (OR) is given by exp(β_j), which quantifies the multiplicative change in odds. If the coefficient β_j is negative, the OR will be less than 1, indicating a decrease in odds as the independent variable x_{ik} increases. Based on this model, we examined the factors influencing café openings across the three temporal phases, thereby analysing the spatial dynamics of location shifts in the Hongdae retail district.

4.Results

4.1.Shifting patterns of café locations

Figure 9 presents the KDE results for café openings in the Hongdae retail district and reveals a pattern of spatial diffusion over time. During the Establishment Phase, openings were concentrated around Hongik University and Hongdae Station on Subway Line 2. Densely clustered openings appeared along Wausan-ro and the 'Walkable Street' near Hongdae, which had already established themselves as central commercial districts by the early 2000s. Several openings also occurred along higher-order boulevards such as Yanghwa-ro and Dongmak-ro.

In the Growth Phase, new openings emerged primarily around Hapjeong Station (Line 2) and Sangsu Station (Line 6). In particular, the alleyways adjacent to Hongdae Solnae-gil and the 'Sangsu-dong Café Street'—located roughly one block away from major boulevards—saw an increase in activity. This spatial relocation may reflect displacement due to commercial saturation or gentrification.

In the Spillover Phase, a significant increase in opening density was observed in the residential area of Yeonnam-dong near the Gyeongui Line Forest Park, suggesting a newly emerging location pattern. Additionally, opening density rose around Mangnidan-gil, indicating the expanding boundary of the Hongdae retail district. Notably, opening clusters during the Growth and Spillover Phases exhibited a linear pattern along the street network, suggesting that retail development and relocation tend to follow the structure of the street grid. Unlike the earlier phases, openings in Yeonnam-dong and Mangwon-dong extended beyond boulevards and into inner-block alleyways, highlighting the spatial shift into non-central areas.

The KDE results across the three temporal phases demonstrate an evolving spatial distribution of café locations. Unlike earlier periods, when cafés were concentrated in core commercial centres, recent openings have increasingly occurred in non-commercial or decentralised locations. These findings suggest a shift in the preferred locational attributes of cafés. To further investigate this trend, we apply binary logistic regression to quantify the factors that influence location decisions.

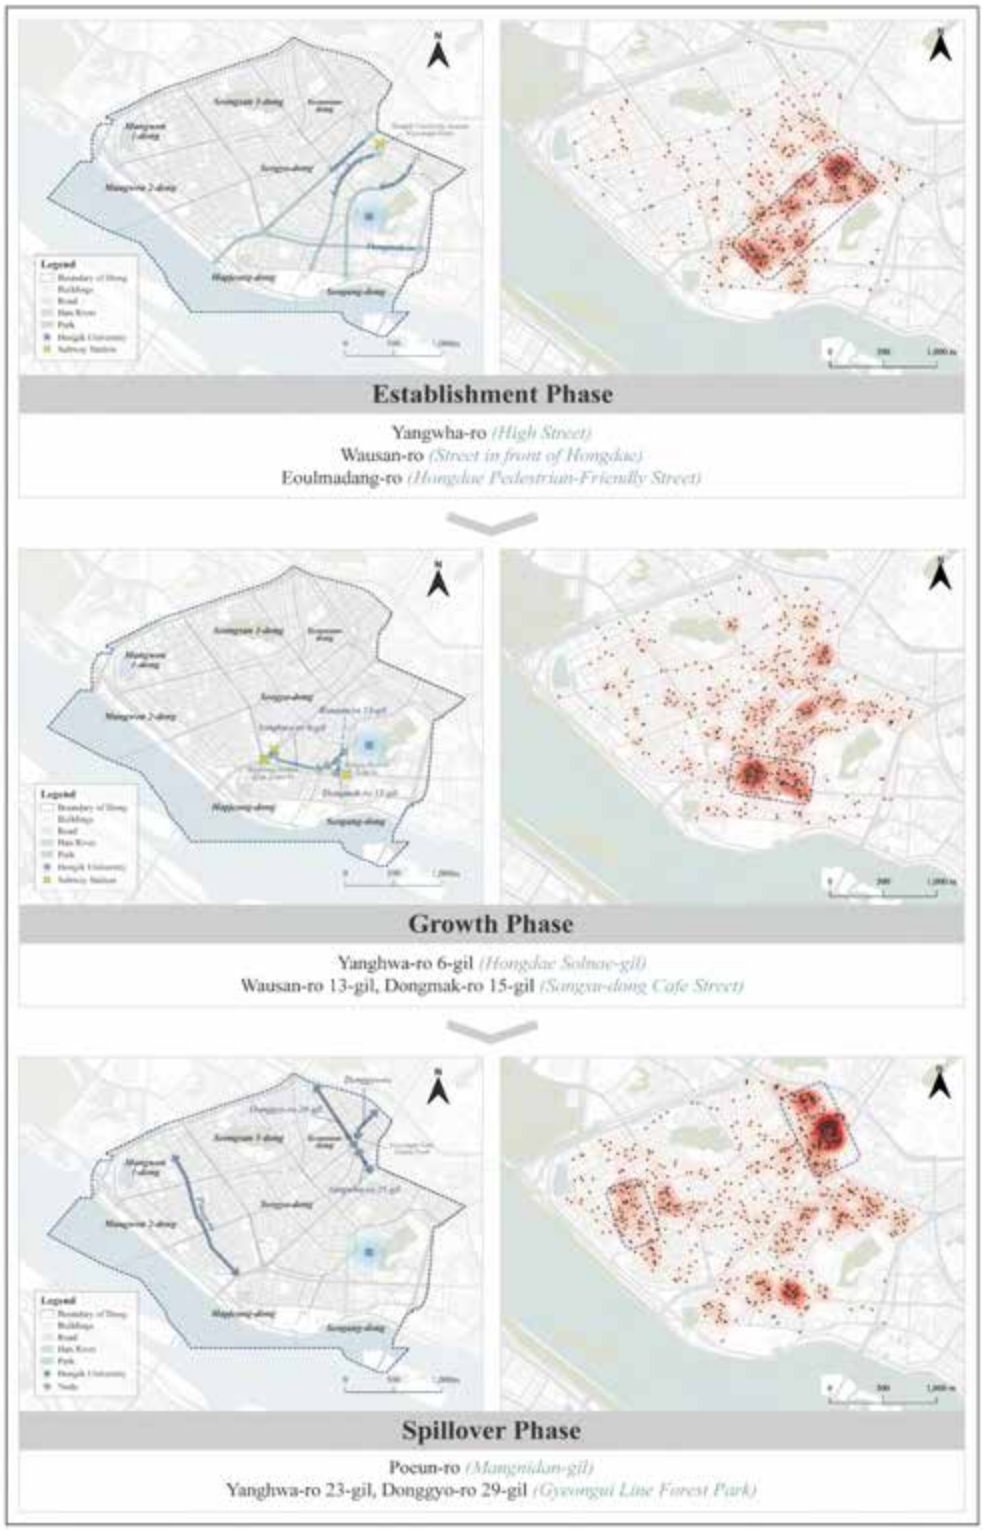

Figure 9. KDE of café openings by phase

4.2.Descriptive statistics

Descriptive statistics for the dependent and explanatory variables used in the binary logistic regression models are presented in Table 2. The unit of analysis is the individual building, and all variables were aggregated accordingly. Buildings deemed unsuitable for retail district analysis—such as apartments, schools, gas stations, and parking lots—were excluded from the sample. The final dataset includes a total of 13,439 buildings. Some variables were log-transformed or rescaled to improve normality prior to analysis.

4.3.Factors influencing café location choices

The Log Likelihood Ratio (LR) test results indicate that all three models are statistically significant ($p<0.001$). The Nagelkerke R^2 values were 0.23 for the Establishment Phase, 0.15 for the Growth Phase, and 0.11 for the Spillover Phase. However, it is widely recognised that R^2 values in logistic regression tend to be relatively low and vary depending on the distribution of the dependent variable (Cohen et al., 2009). Moreover, the Nagelkerke R^2 should not be interpreted in the same manner as R^2 in Ordinary Least Squares (OLS) regression, as the two statistics are not directly comparable (Azen and Traxel, 2009; Hu et al., 2006). To further assess the goodness-of-fit of the models, the Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC) values were also examined. Table 3 summarises the overall model accuracy.

Table 4. Model fit statistics for the three phases

Statistic	Model 1	Model 2	Model 3
Log likelihood	-1,405.53	-1,741.58	-2,413.44

BIC	3,010.68	3,682.78	5,026.50
*: p<0.1, **: p<0.05, ***: p<0.01			

The binary logistic regression results for the Establishment Phase are presented in Table 4. All variance inflation factor (VIF) values were below the conventional threshold of 10, indicating that multicollinearity was not a concern. Neither walkability nor the visual attributes of streetscape characteristics had a statistically significant effect on the probability of café openings.

By contrast, among the perceptual attributes of the streetscape, Lively—reflecting pedestrian perception of vibrancy—was negatively associated with the likelihood of opening (OR = 0.18). Regarding traditional location factors, both prior presence of cafés (OR = 9.49) and agglomeration (OR = 1.13) were positively associated with the odds of opening. In terms of building characteristics, larger footprint was associated with lower opening probability (OR = 0.79), while greater building height (OR = 1.38), larger parcel (OR = 1.00), and higher average land price (OR = 2.72) were associated with increased odds of opening. As for demographic factors, higher population density (OR = 1.44), larger millennial population (OR = 1.00), and higher number of employees (OR = 1.21) all significantly increased the likelihood of café openings. These results align with previous findings suggesting that the complementary relationships among similar stores contribute to agglomeration economies, and that building characteristics and population-based retail demand are critical for the efficient operation and location decisions of retailers (Porter, 1996; Sevtsuk, 2014; Small and Song, 1994; Teller et al., 2016; Um et al., 2009; Wu et al., 2021).

The logistic regression results for the Growth Phase are presented in Table 5. All VIF values were below the threshold of 10, indicating no multicollinearity issues. Compared to the Establishment Phase, the Growth Phase revealed a notable shift in the influence of locational factors, particularly in terms of walkability and streetscape characteristics.

Café openings were more likely to occur in areas with greater accessibility to subway stations (OR = 1.11) and nearby parks (OR = 1.27). Among the visual attributes of streetscape characteristics, higher Enclosure was associated with a slight decrease in opening probability (OR = 0.99), while higher Greenness also reduced the likelihood of opening (OR = 0.95). Conversely, a higher Pavement had a positive effect on opening probability (OR = 1.02). These findings support the interpretation that micro-scale visual streetscape factors enhance pedestrian visual preferences, thereby increasing the attractiveness of retail locations, in line with the results of Koo et al. (2023b).

Among the perceptual attributes, Lively continued to show a negative association (OR = 0.13), whereas Beautiful exhibited a strong positive association with café openings (OR = 9.89). In contrast, several traditional location factors—such as building footprint, parcel area, and millennial population—lost their statistical significance during this period. This suggests that, as the retail district expanded, large-scale parcels and fixed demographic groups such as young adult residents became less influential, while other commercial and spatial factors emerged as more influential in location decisions.

*: p<0.1, **: p<0.05, ***: p<0.01			

The binary logistic regression results for the Spillover Phase are summarised in Table 6. All VIF values were below 10, indicating no multicollinearity concerns. While the influence of traditional retail location attributes remained similar to the previous phase, the impact of walkability and streetscape characteristics shifted notably.

Accessibility to subway entrances (OR = 0.89) and wider roads (OR = 0.98) were associated with decreased probabilities of café openings. This suggests that improved access to spatial information has weakened the traditional locational advantages of highly accessible central areas. Meanwhile, higher Enclosure (OR = 1.27) and higher Openness (OR = 1.09) were positively associated with opening likelihood, whereas higher Pavement was negatively associated (OR = 0.98). These findings align with Nasar's (1990) study, which argued that people prefer open spaces with clearly defined boundaries, rather than simply wide-open areas.

In addition, Lively, one of the perceptual attributes of streetscape, was positively associated with café openings (OR = 14.15). This reflects the fact that areas with slower pedestrian speeds and frequent foot traffic—such as alleyways with small-scale spatial units and multiple storefronts—are perceived as more vibrant (Gehl, 2013; Kickert and Talen, 2022; Yun and Choi, 2013), and play a crucial role in retail operation and location decisions. Overall, these results suggest that under the rise of experiential consumption, consumers increasingly value the emotional and aesthetic appeal of surrounding environments. As a result, visually and perceptually attractive areas—as experienced by pedestrians—are becoming more important in café location decisions.

5.Discussion

The spatial shift in café locations in the Hongdae district reflects the evolving nature of urban consumer culture and highlights the growing influence of streetscape quality and place perception on location preferences. Figure 10 illustrates the streetscape characteristics of areas that satisfied the preferred locational conditions for each phase. In the early stages, location decisions were primarily shaped by traditional characteristics of commercial centres, such as accessibility and centrality. However, as the core area became increasingly saturated and experiential consumption gained prominence, new locations—such as surrounding alleyways—emerged as preferred sites. These findings align with previous research suggesting that during commercialisation, retail districts tend to expand into adjacent areas with relatively lower rents or land prices once the core becomes saturated (Ley, 1997; Smith, 1979; Zukin, 1987). Furthermore, beyond traditional location characteristics, spatial features closely tied to consumers' experiences of place should be considered as increasingly important in café location decisions.

More specifically, the results can be interpreted in two ways. First, the relationship between café locations and walkability differed by phase. During the Growth Phase, openings were concentrated near subway stations and parks, reflecting a continued preference for traditional commercial centres with high transit accessibility and public amenities. These results align with prior studies that emphasise the positive impact of public transportation on retail activity by serving as anchors of pedestrian flow (Lee and Kwon, 2016; Wu et al., 2021; Yoshimura et al., 2021) and highlight how parks attract consumers and generate synergies with surrounding businesses (Sim, 2019). However, in the Spillover Phase, locations with lower subway accessibility and narrower street widths became more favoured. This suggests that café location decisions were no longer dependent on minimising

distance to a fixed destination or locating in walkability-optimised central areas.

Second, the visual and perceptual quality of streetscapes had a significant influence on café location decisions, and this influence varied by phase. During the Establishment Phase, cafés tended to locate along major boulevards with relatively low perceived vibrancy. As the retail district expanded, new openings increasingly concentrated along pedestrian-friendly streets and eventually shifted towards narrower, human-scale alleyways. In particular, during the Spillover Phase, vibrant and visually attractive streets—as perceived by pedestrians—became preferred locations for café openings. While wide streets may appear empty even when populated, narrow streets with clear visibility of building facades are perceived as more active. Cafés located along such streets not only contribute to perceived safety and imageability (Harvey et al., 2017), but also enhance the spatial appeal by encouraging optional activities such as lingering and spending time (Gehl and Svarre, 2013). This shift in location—from closed boulevards with limited social interaction to open alleyways that support informal encounters—ultimately contributes to neighbourhood transformation and strengthens the vitality of the broader urban space. Moreover, as cafés begin to cluster along pedestrian-friendly and aesthetically pleasing streets, the resulting streetscapes can promote gradual urban growth and enhanced vibrancy (Cox and Streeter, 2019; Jacobs, 1961; Kickert and Talen, 2022). Outdoor cafés that utilise terraces in highly walkable areas, or shops embedded in alleyways that foster active interaction with the street, serve as extensions of public space (Montgomery, 1997; Sim, 2019). These findings suggest that urban planners should aim to improve the streetscape environment and encourage small-scale commercial activity in alley-based retail districts.

While traditional location attributes have long been considered important in café location decisions, their influence has diminished over time. This result underscores the limitations of traditional location theories and highlights the need for ongoing monitoring of consumer preference shifts—particularly by incorporating streetscape-oriented locational trends.

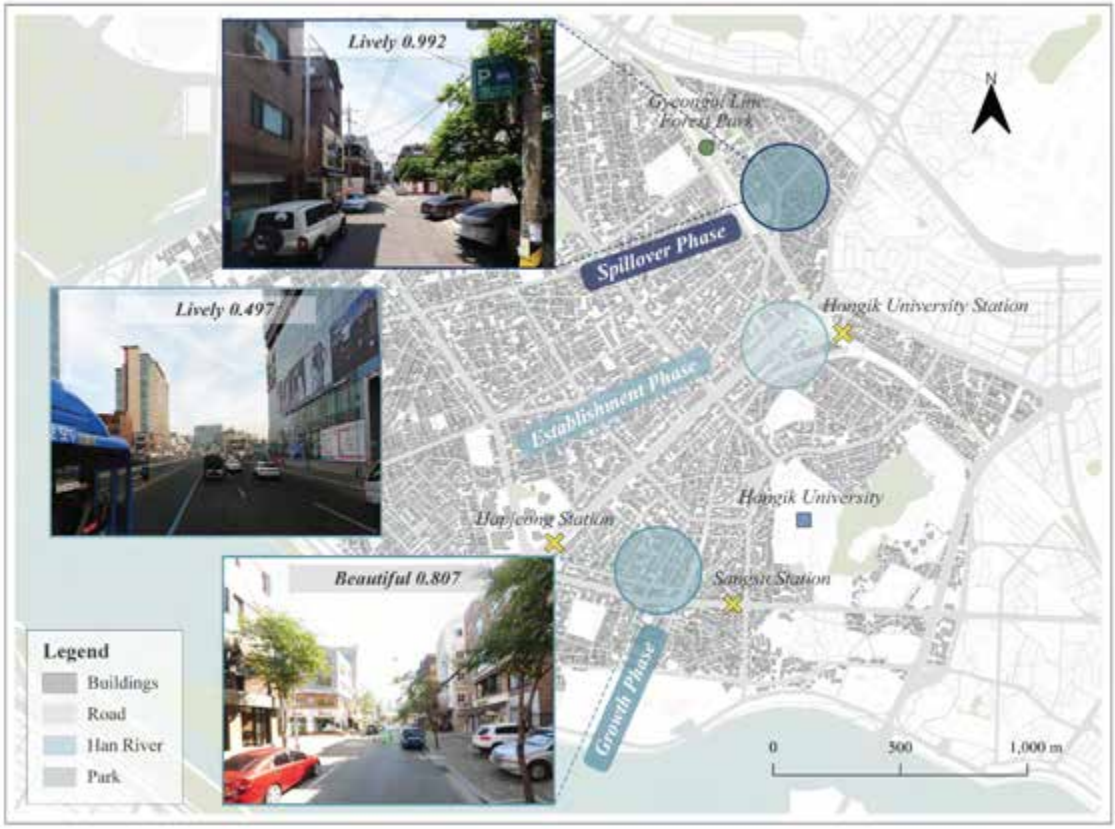

Figure 10. Locational preferences and streetscape indicators by phase

6.Conclusion

This study empirically demonstrates the complex interaction between café location decisions and urban spatial conditions, particularly emphasising the significance of streetscape quality. It highlights the dynamic and

interrelated processes through which sense of place, urban culture, and everyday heritage evolve. In the Hongdae retail district, traditional commercial location characteristics were more influential during the Establishment Phase, while walkability became more important during the Growth Phase, and visual and perceptual streetscape characteristics were emphasised during the Spillover Phase. Historically, small-scale retailers such as cafés have tended to locate in highly visible areas—physically central streets with heavy pedestrian and vehicular traffic—to benefit from agglomeration economies or gain competitive advantage. However, in contemporary urban consumer culture, consumption has evolved towards everyday life, and cafés have become key social spaces where individuals share in one another's daily routines (Horton and Kraftl, 2013). Place, as Carmona (2021) notes, is constructed through lived experience; it becomes meaningful as individuals, communities, and societies attach emotions and memories to space. These social activities are embedded in the street, where the streetscape becomes a medium for memory, experience, and emotional resonance.

Moreover, the rise of small-scale experiential spaces, omni-channel retail, and social media has made it possible for people to indirectly experience spaces without physically visiting them, thereby increasing the importance of the environment surrounding a store. User-generated content and information sharing on social media platforms can shape the identity and attachment to place (Farrelly, 2017). In particular, with the growing culture of image-based sharing, users now actively tag locations and upload images in real time, even from lesser-known alleys or newly discovered destinations (Lee et al., 2018). From this perspective, streetscapes that facilitate visual engagement and offer sensory experiences provide retailers with new opportunities to attract consumers (Kickert and Talen, 2022). Therefore, urban planners are encouraged to cultivate a localised sense of place in retail districts by designing environments that offer differentiated experiences for consumers within the everyday urban landscape.

This research not only assesses the continued relevance of traditional commercial location theories, but also highlights the overlooked connection between recent shifts in café locations and streetscape characteristics—an aspect that has received limited attention in previous research. The findings emphasise that, in determining retail locations, the perceived quality of the surrounding service environment has become increasingly important for consumers. Specifically, the study shows that preferred location conditions have changed over time, from both the retailer's and the consumer's perspectives. These results point to the need for long-term monitoring of spatial changes in retail districts to support sustainable commercial operations. Notably, considering the role of cafés in enhancing quality of life and contributing to urban vibrancy, the findings suggest that streetscapes should be viewed not as passive elements, but as active components in evaluating and promoting urban vitality. In this sense, the study offers insights into retail dynamics driven by evolving consumption patterns and the changing role of cafés, moving beyond a mere examination of locational shifts.

There are some limitations that need to be explored in future research. First, as this study focuses on a single case study area, the generalisability of the findings is limited. Future research should expand the analysis to include multiple cities. Second, to ensure consistency across the dataset, the SVIs used in the analysis were collected by vehicle-mounted cameras, meaning that the images were captured from a driver's perspective. In streets with clearly separated roads and sidewalks—such as boulevards—this may lead to discrepancies from the pedestrian point of view. As such, there may be subtle differences between the visual perception captured in the SVIs and the streetscape as experienced by pedestrians. Addressing this limitation in future studies may help to more precisely capture changes in how urban spaces are subjectively perceived.

Abstract:
Human-Habitat World Heritage, as a form of living heritage, embodies dual attributes of "heritage" and "habitat." Driven by economic restructuring and urbanisation, it is transitioning from "everyday residential use" to "tourism-driven development," facing challenges of conservation and development. This study, based on Pingyao Ancient City, employs the triadic dialectics of spatial production alongside policy analysis, historical archives, field surveys, and oral histories to construct its transformation narrative. Findings reveal that Pingyao achieved physical space reproduction through planning and business adjustments, strengthened cultural identity via conservation policies and cultural festivals, and expressed social space through community participation and visitor interaction. This process has enhanced cultural and social values while driving sustainable development. Through Pingyao's practical paradigm, this study establishes a theoretical framework for balancing conservation and development, offering insights for managing similar heritage sites globally.

Key words: space production; human-habitat world heritage; living heritage; Pingyao Ancient City; tourism development

1 Introduction

Pingyao Ancient City, located in Shanxi Province, China, was built in the 14th century and inscribed on the World Heritage List in 1997. It is a quintessential example of Human-Habitat World Heritage, possessing dual attributes of "heritage" and "habitat." First, its heritage characteristics are significant, featuring abundant tangible and intangible heritage. It preserves a traditional urban layout, streets, and architectural remains, reflecting over five centuries of evolution in Han Chinese urban architectural styles and planning (Centre). Additionally, it embodies traditional spatial organisation principles, materials, structures, and construction techniques, as well as traditional aesthetics, folklore, religious practices, political systems, commercial culture, and production methods (Shao et al., 2016). Second, its habitat characteristics are evident; historically, it served as a living space and continues to accommodate daily life, undergoing constant development and change (Shao, Hu, and Xu, 2019). These dual attributes underscore its "Outstanding Universal Value" at the global level" ('Convention concerning the protection of the world cultural and natural heritage', 1973) and highlight its significance for stakeholders (Li and and Su, 2020), heritage communities, and cities at the local level. The interplay between traditional spaces and lifestyles illustrates the wisdom of addressing "human-place relationships" in traditional urban planning, offering unique value (Shao et al., 2016).

With the progression of urbanisation in China and economic restructuring, Pingyao Ancient City has witnessed rapid tourism development in recent decades. Commercial activities and spatial forms within the city have diversified, improving and advancing the local economy (Long, 2016). However, the form and function of the heritage site have been irreversibly affected (Rezaei, 2017). The deepening connection and escalating conflict between visitors and indigenous residents have driven Pingyao's transformation from an "everyday residential" model to a "tourism-oriented" one. Overuse and excessive demand on the heritage site have revealed issues unanticipated during its construction (Li, Wu and Cai, 2008). Heritage conservation faces dual challenges: safeguarding the authenticity and integrity of the heritage, respecting the material spatial authenticity and lifestyle of indigenous residents, while promoting tourism and modern livelihoods to drive tourism-induced spatial and economic transformation (Wang, 2012). The Protection and Revitalisation Plan for Pingyao Ancient City was approved in 2014, with the overarching goal of enhancing heritage conservation and livability while fostering sustainable social and economic development (Centre). The conservation, preservation, reconstruction, and management of Pingyao have evolved from a "material-centric" approach focused on architectural restoration and tourism to a "people-centred" model of community co-creation (Sun and Nakajima, 2023).

Current research on the governance of Pingyao Ancient City, a Human-Habitat World Heritage site, primarily focuses on analysing its intrinsic value and conservation methods, as well as its development from the

perspective of heritage tourism. Studies on intrinsic value and conservation methods encompass value assessment and characteristic evaluation(Shao, 2018), conservation management mechanisms(Miao, 2014), spatial and morphological studies(Tao, He and Jiang, 2014; Xie, 2015), comparative analyses of ancient urban planning concepts and urban expansion through conservation and planning(Li et al., 2022), and research on the protection and analysis of street facade spaces (Li and Wang, 2015).From the perspective of heritage tourism, research covers spatial-functional analyses (Liao et al., 2022), resident and community participation(Ju, 2022; Liu et al., 2022; Sun and Nakajima, 2023; Liu et al., 2023; Cui, Cheng and Shang, 2024), stakeholder framework studies (Li and and Su, 2020), application frameworks for urban historical landscapes(Hu, 2011; Wang and Gu, 2020), tourism industry analyses (Gao et al., 2017), sustainable development assessments(Weng et al., 2019), and visitor data tracking(Li et al., 2024).In summary, there is limited focus on the spatial production and renewal mechanisms of Pingyao Ancient City. Few studies adopt a comprehensive framework to integrate and analyse the relationships among the material, social, and spiritual dimensions.

This study focuses on the spatial patterns and production processes of Pingyao Ancient City as a Human-Habitat World Cultural Heritage site, employing Lefebvre's triadic dialectical framework of spatial production for a narrative construction of its transformation pathway. Lefebvre's theory views urban space as both a product and a means of production, shaped by social and interpersonal relationships (Fuchs, 2019). It conceptualises urban space as a triad: (1) Spatial practice (perceived space); (2) Representations of space (conceived space); (3) Representational space (lived space) (Lefebvre,1991). Through historical-sociological analysis and spatial investigation, this study aims to construct a comprehensive framework of spatial production. It analyses the interplay among material space (buildings, streets, districts), planning and policy frameworks (conservation plans, relevant policies), and everyday life and values (local culture, resident experiences). The objective is to elucidate the processes and outcomes of spatial production and heritage governance during the tourism transformation of Pingyao, thereby offering valuable theoretical and practical paradigms for the humanistic tourism development of Human-Habitat World Heritage sites.Specifically, this research seeks to address the following questions:

1.How have the material, social, and spiritual spaces of Pingyao Ancient City changed under heritage tourism?
2.How do stakeholders and key policies collectively influence and shape the spatial production of Pingyao Ancient City?
3.What integrated strategies can be identified to guide the tourism transformation of Human-Habitat World Cultural Heritage sites?

2 Literature Review

2.1 Human-Habitat World Heritage and Living Heritage

Human settlement refers to all types of inhabited aggregations and their environments, including rural areas, towns, cities, and regions. It encompasses five key elements: nature, society, humans, dwellings, and supporting networks. Human settlement consists of two main components: firstly, humans, including individuals and the societies they form; secondly, the tangible settlements and their surrounding environments composed of natural or artificial elements (Wu, 2014). Research on Human-Habitat heritage sites began in the late 1990s ('The spatial coupling and its influencing mechanism between rural human-habitat heritage and key rural tourism villages in China', 2025) and is interdisciplinary, covering both tangible and intangible heritage (Su, 2011; Wang, 2016; Amit Cohen and Sofer, 2017). The inheritance and development of Human-Habitat heritage sites demonstrate continuity (Poulios, 2011), with an emphasis on the functional role of "habitat" where residents, as key participants, continuously engage in shaping heritage spaces (Chapagain, 2013). Heritage sites and communities are closely interconnected, forming a form of "living heritage" (Zhang and Lu, 2025).

Academic literature on Human-Habitat World Heritage emphasises the concept of "living heritage", focusing on its sustainable development (Landorf, 2011; Weng et al., 2019). The heritage management process has shifted from a centralised, exclusionary approach to a participatory and holistic one, with "community", "residents", and "co-creation" becoming key terms in heritage governance (Li et al., 2020). A "community co-creation" governance model has been developed to address conflicts in living heritage, particularly the tensions between modern socio-economic development and the daily needs of local heritage communities (Ju, 2022; Sun and Nakajima, 2023). Additionally, conflicts among stakeholders have become a major focus in heritage tourism research, prompting the proposal of frameworks to resolve such disputes (Li and and Su, 2020). Furthermore, tailored

assessment frameworks have been established to evaluate China's management practices in promoting community participation in cultural heritage (Li et al., 2020).

2.2 The Applicability of the Theory of Spatial Production

The theory of spatial production originated from Marxist sociology, with Henri Lefebvre as its founding figure. Lefebvre posited that "space is a product of social relations," emphasising that social space is produced through social practices. He categorised the production of space into three dimensions: spatial practice, representations of space, and representational space (Lefebvre, 1991).

In recent years, the theory of spatial production has been increasingly applied to research on cultural heritage sites and industrial heritage. In the context of industrial and urban heritage renewal, scholars have employed the perspective of spatial production in analysing cases of Chinese industrial heritage and urban redevelopment. For example, Song Yongyong, Zhang Tongyu, and others investigated urban old industrial zones, analysing their renewal mechanisms and pathways within the framework of spatial production theory (Song et al.). The theory has also been introduced into the protection and governance of historic urban districts. The conservation of inhabited heritage must balance heritage value with the needs of residents' daily lives. Ma Xiaowen and Li Bin analysed the renewal process of Qingdao's Zhongshan Road Historic District within the theoretical framework of spatial production and place-making (Ma and Li, 2024). Moreover, spatial production theory has been applied to heritage spaces in tourism contexts. Wang Mingfeng and Zhou Yuan studied the production and evolution of Shanghai's Tianzifang as a creative tourism space (Wang and Zhou, 2022).

For Pingyao Ancient City, as an inhabited World Heritage Site, Henri Lefebvre's theory of spatial production offers a valuable perspective. The triadic dialectics of spatial production organically integrate the physical, social, and mental dimensions. This theory facilitates an understanding of how state-led conservation plans (conceived space) interact with tourism-driven market forces (social space) and cultural attachment (lived space).

3 Materials and Methodology

This study examines the transformation pathway of Pingyao Ancient City, a World Cultural Heritage Site, through methods such as policy review, historical archive analysis, field surveys, and oral history collection. Using Henri Lefebvre's triadic dialectics of spatial production as a theoretical framework, it analyses the spatial production mechanisms of Pingyao Ancient City.(Figure 1)

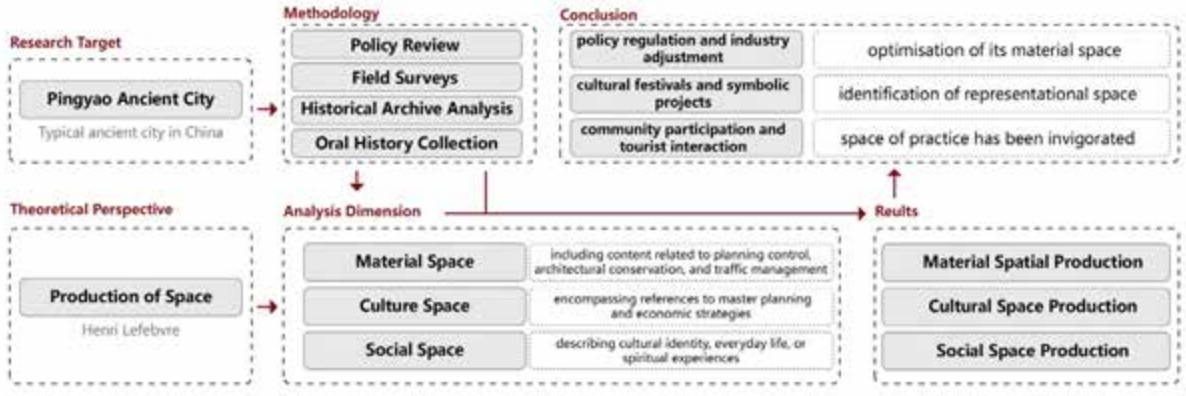

Figure 1.Research Framework

3.1 Study area

3.1.1 Pingyao Ancient City

Pingyao is located on the central plains of Shanxi Province, adjacent to the Fen River, the region's principal waterway-Figure 2-. Pingyao Ancient City lies in the northwest of Pingyao, covering an area of 2.25 km². The protected zone encompasses "one city and two temples"—Pingyao Ancient City and the nearby Zhenguo Temple and Shuanglin Temple. Within the city, there are over 20 ancient temples and nearly 4,000 historical residential units. Built in the 14th century, Pingyao Ancient City is one of the four well-preserved ancient cities in China,

reflecting Han cultural characteristics(Su, 2018; Tang, Zheng and Ng, 2019). Its urban fabric illustrates five centuries of evolution in Chinese imperial architectural styles and urban planning, with its "piaohao" buildings, associated with banking, being a distinctive feature.

Pingyao City is shaped like a turtle poised to move but remaining still-Figure 2-. The "turtle's" head points south and its tail north, with its four gates on the east and west symbolising the turtle's legs. Outside the southern gate, there were originally two wells, metaphorically representing the turtle's eyes. This configuration has led to the city being colloquially referred to as the "Turtle City," symbolising eternal life, perpetual youth, unyielding strength, and everlasting stability (Government, 2015).

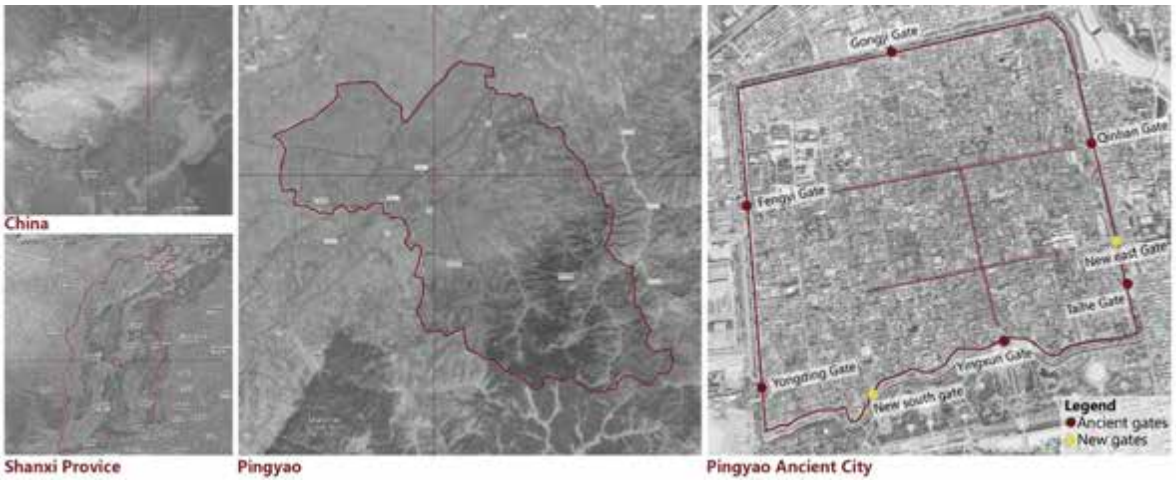

Figure 2. Location and the plan of Pingyao

The functional layout within the ancient city of Pingyao exemplifies the typical characteristics of a traditional county town in the Central Plains region of the Han ethnic group. On the left is the Chenghuang Temple, while the county office is on the right; the Confucian Temple is located to the left and the Martial Temple to the right. The Qingxu Taoist Temple is situated on the eastern side, and although the Jifu Buddhist Temple on the western side no longer exists, the City Tower remains centrally positioned, creating a symmetrical functional distribution. Pingyao's street network is renowned for its "Four Main Streets, Eight Minor Streets, and Seventy-Two Winding Lanes." Most streets and lanes are organised in straight north-south or east-west alignments, with distinct hierarchies and systematic organisation. Particularly prominent is the inverted "干" shaped primary commercial street system formed by South Street, East and West Streets, Chenghuang Temple Street, and County Office Street, whose scale far exceeds that of typical traditional county towns(Xie, 2015). Flanking the main streets are historical shop buildings dating back to the 17th to 19th centuries. The well-preserved architectural ensembles vividly illustrate the historical urban landscape and commercial cultural heritage of Pingyao Ancient City.

3.2 Research design

3.2.1 Theoretical Framework

Henri Lefebvre's core triadic dialectical structure of spatial production consists of: (1) Spatial Practice, which refers to the material practices in production and everyday life, such as daily activities and social reproduction processes. (2) Representations of Space, denoting the conceptualised space created by ruling classes, planners, and professionals, including urban planning, architectural design, and maps. (3) Representational Space, indicating the lived space characterised by people's subjective experiences and symbolic meanings, encompassing cultural imagination and symbolic inscriptions. (Lefebvre, 1991). These three dimensions are dialectically interconnected: spatial practice reproduces space through social actions, representations of space shape spatial forms via planning and design, and representational space reflects people's utilisation and emotional investment in space. Within this framework, Lefebvre asserts that every social formation exhibits this "triadic dialectical" structure(Lefebvre, 1991).

3.2.2 Analytical Dimensions

Using Lefebvre's triadic dialectical theory of spatial production, the surveyed texts are categorised according to the spatial dimensions they reflect, specifically: (1) material space, including content related to planning control, architectural conservation, and traffic management; (2) cultural space, encompassing references to master planning and economic strategies; and (3) social space, describing cultural identity, everyday life, or spiritual experiences. The analysis results are further integrated to form a comprehensive examination of Pingyao's spatial production process, revealing how the material, social, and spiritual dimensions interact under the influence of various stakeholders and policies to collectively shape the spatial characteristics of the heritage site.

3.3 Data and methods

This study employs a combination of qualitative research and case study methods, supplemented by policy and historical document analysis, on-site observations, and semi-structured interviews. To visually present the findings, the study uses tables to illustrate the research content: Table 1 lists the major policies of Pingyao Ancient City, and Table 2 marises the timeline of significant events, providing historical and policy context for the study.

Heritage tourism projects involve numerous stakeholders, and existing literature presents different models of relevant stakeholders across various cases (Aas, Ladkin and Fletcher, 2005; Sheehan and Ritchie, 2005; Cheng et al., 2012). However, there are still shared and overlapping stakeholder groups. Local residents, governments, tourists, tourism entrepreneurs, non-governmental organisations, and mass media are identified as key and indispensable stakeholders in heritage tourism projects (Communicating heritage – a handbook for the tourism sector, 2011) .-Figure 3-This study's oral history interviews involved five categories of key stakeholders: government officials and planners, local residents within the ancient city, tourism entrepreneurs, and visitors. The interviews were structured around the following themes: living conditions, perceptions of heritage value, views on the benefits and costs associated with tourism, and understanding of conservation policies. All interviews were conducted in Mandarin.

Figure 3-Stakeholders and Their Interrelations

4 Empirical Analysis of Spatial Production in Pingyao Ancient City

4.1 Pingyao Ancient City

Pingyao is located on the trade route between Beijing and western China, serving as a longstanding administrative and market centre (Wang and Gu, 2020). Its historical evolution encompasses three morphological periods: the pre-industrial period (before 1949), the socialist period (1949–1997), and the recent development period (post-1997). Each period represents a distinct cultural-historical phase, marked by the emergence of unique spatial configurations and forms that adapted to the socio-economic demands of their time (Conzen, 1960; Conzen and and Whitehand, 2012; Wang and Gu, 2020).

Before 1949, Pingyao Ancient City experienced a period of trade prosperity, even emerging as a financial centre of China. During this time, historic buildings were subjected to repurposing, such as the conversion of the Confucian Temple into a modern school in 1904 and the use of Qingxu Taoist Temple for military purposes in 1926. Additionally, key traditional structures suffered damage during wartime (Wang and Gu, 2020).

Between 1949 and 1997, the development of Pingyao Ancient City was shaped by socialist policies, leading to the construction of industrial-related buildings such as factories and staff dormitories within the ancient city

(Wang and Gu, 2020). Additionally, modern structures like prisons, police stations, and juvenile detention centres emerged, which contrasted sharply with the traditional architecture (Su, 2018). During the late 1970s, a team from Shanghai Tongji University conducted multiple field surveys and mapping projects in Pingyao, strongly advocating for the preservation of the ancient city. They appealed to the local government to halt demolition activities, marking the beginning of Pingyao's heritage conservation efforts (Ruan and Pan, 2019). In 1986, Pingyao Ancient City was designated as a National Historical and Cultural City. By 1997, the city, including its "ancient city walls," "government offices," "markets," "residences," and "temples," was inscribed as a unified entity on the World Heritage List. Recognised as a "living specimen" for studying the development of Chinese politics, economy, culture, arts, and religion.

After 1997, the local government prioritised tourism as a key focus for the conservation and development of Pingyao Ancient City. Over years of planning and implementation, the ancient city gradually evolved into an isolated landmark within the urban area. (Li et al., 2022). The local government's objectives for urban conservation and heritage development included: first, restoring the historical features of the walled city; second, reducing population density within the city walls; and third, creating an ideal environment for tourists (Wang, 2012). By the time this study commenced in 2005, the local government had largely achieved these goals. Historical buildings within the city walls had been restored, and functional transformations had been completed to serve tourism purposes. (Wang and Gu, 2020).

4.2 Dimension of Material Spatial Production

The "spatial practice" within the dimension of material spatial production constitutes its primary level, with production outcomes manifested as tangible and perceptible spatial forms. The incorporation of tourism attributes into the spatial fabric has become a key aspect of the tourism development process in Pingyao Ancient City. The intervention of tourism elements has led to significant transformations in the material spatial morphology. External driving forces, represented by the government and planning experts, have gradually replaced the endogenous impetus based on the natural development of the local community, thereby assuming a dominant role in the production of heritage tourism space (Zhang and Li, 2024). As a model of cultural heritage conservation in China, Pingyao Ancient City has realised a spatial transformation from a traditional town to a cultural tourism destination through functional relocation, business adjustment, restoration of traditional residences, and the introduction of cultural industries. The urban pattern has undergone a diachronic evolution from the "Ming and Qing layout" to a "tourism pathway", while spatial functions have experienced a topological reconfiguration from "residential and productive" to "commercial and cultural."

Functional relocation and spatial vacancy have provided the spatial foundation for the transformation of the ancient city. Prior to the World Heritage nomination, the ancient city housed approximately 45,000 residents. Following the successful inscription, the county government, originally located in the old county yamen, was the first to relocate outside the city walls. Subsequently, schools, hospitals, public security, prosecution, and judicial institutions—functions less related to the cultural context of the ancient city—were gradually moved out. The resident population within the city decreased to about 20,000 permanent inhabitants (Wang, 2012; Wang and Gu, 2020). This measure not only alleviated spatial pressure within the ancient city but also freed up space for cultural exhibitions and activities. It furthermore provided opportunities for the restoration and conservation of historic buildings occupied by institutions.

The reshaping of commercial functions and the optimisation of the landscape constitute important means for the transformation of the ancient city. The production of material space in Pingyao Ancient City is profoundly influenced by policies and planning at international, national, and local levels. The restoration and conservation of the city walls and the strict planning of traffic in historic districts have resulted in the core area becoming a pedestrian zone, with motor vehicles restricted to peripheral circulation to reduce environmental impact on the heritage site. The adjustment of commercial functions centred on South Street is a key example of spatial functional reproduction, where shops originally serving local residents were relocated, and the core street was transformed into a tourism-oriented commercial district themed around cultural antiques, calligraphy, paintings, and intangible cultural heritage (Wang, 2012). Through the restoration of courtyards, revival of traditional styles, and establishment of intangible cultural heritage exhibition centres, this area has become a spatial node of both cultural and economic value. Infrastructure within the ancient city has been repaired, and some private residences have been converted into tourist-oriented guesthouses, boutique hotels, and restaurants (Whitehand and Gu,

2007; Wang et al., 2022). In this process, traditional spaces have been redefined as venues for cultural display and consumption. However, this phenomenon is distinctly marked within the ancient city, where buildings on main streets and heritage nodes have been restored and revitalised, whereas backstreets and peripheral areas receive comparatively less attention, revealing an uneven distribution of resources during heritage conservation and spatial redefinition.

Non-profit restoration and industrial innovation have injected vitality into the production of material space. Under the guidance of policies such as the "Control Plan" and "Management Rules," the restoration of traditional residences, the rehabilitation of significant historical buildings, and the functional adjustment of industrial buildings and land have further reinforced the cultural display function of the ancient city (Government, 2015; Regulations on the Protection of the Ancient City of Pingyao in Shanxi Province). The non-profit restoration of residential buildings in Pingyao Ancient City has achieved remarkable results, with restoration funding jointly undertaken by the Pingyao County Government, the Global Heritage Fund, and property owners. Meanwhile, some industrial and warehouse lands that have been relocated were repurposed for cultural exhibition and creative industry functions, providing venues for the presentation of intangible cultural heritage and cultural research activities, such as lacquerware decoration techniques and Sha Ge opera performers.

The spatial transformation of Pingyao Ancient City demonstrates a policy-driven model of heritage conservation and tourism development. Through the combination of functional relocation, targeted restoration, and innovative cultural industries, it illustrates that heritage sites can achieve a balance between cultural preservation and economic vitalisation.

4.3 Dimension of Cultural Space Production

The second dimension of spatial production is the "representation of space," that is, the production of cultural space. Its outcome is manifested in conceived and symbolised spatial forms that carry specific knowledge and ideology. Building upon the embedding of material tourism elements, the interpretation and reinterpretation of heritage values endow the physical space with spiritual and cultural connotations, which is key to emphasising the heritage attributes and their value significance (Zhang and Li, 2024), thereby promoting the incorporation of cultural connotations and the spirit of place into heritage tourism spaces. Cultural festivals, artistic activities, and symbolic architecture in Pingyao Ancient City are critical carriers of this dimension.

Cultural interpretation and policy implementation constitute the foundational controls ensuring the reliability of spatial representation. The central and local governments of China have successively issued multiple policy documents that provide clear guidance for the preservation of Pingyao Ancient City's spatial pattern, restoration of its historic appearance, and environmental improvement, with strict enforcement at the implementation level (Shao et al., 2016). For instance, in 1998, Pingyao initiated the "blue brick and grey tile" renovation project, removing incongruous colourful buildings to restore the traditional visual characteristics of the ancient city. In 2017, the local government further implemented the "illegal construction removal, disorder rectification, and quality enhancement" campaign, clearing over incompatible building materials such as coloured steel sheets and polycarbonate panels, thereby improving the overall visual impression of the ancient city. The "Management Regulations for the World Cultural Heritage Pingyao Ancient City" strictly specify the renovation styles and procedures for traditional residences (Sun and Nakajima, 2023).

Cultural festivals and narrative reconstruction have deepened the cultural expression of Pingyao's spatial environment. Pingyao Ancient City realises the reproduction of cultural space through festival activities. These include representative events such as the Pingyao Chinese New Year, Pingyao International Photography Festival, Pingyao International Film Festival, and Youjian Pingyao Performance (Again See Pingyao) (Li et al., 2022), which integrate traditional culture with contemporary art, thereby reshaping the city's cultural imagery (Sun and Nakajima, 2023). These cultural projects and festive celebrations not only enhance the attractiveness of Pingyao Ancient City but also inject new narrative dimensions into the city, strengthening public recognition of the heritage site's cultural value.

The demands of different stakeholders have shaped the cultural spatial representation of Pingyao Ancient City. Around 1994, Pingyao proposed the "Three-City Plan," aiming to establish a "Tourism City," "Film and Television City," and "Commercial City." In 1995, the local government introduced a "Private Sector Strategy," seeking to enhance

the cultural spatial value through market-based approaches by encouraging private capital to participate in the renovation of South Street, transforming it into a cultural district themed around "antique trading." The government further reinforced the cultural value of the ancient city through symbolic naming, for instance, in 2017, roads near Pingyao Ancient City were renamed as Ruan Yisan Road and Zheng Xiaoxie Road, commemorating experts who contributed to the heritage conservation efforts. Additionally, the establishment of the "See You Again in Pingyao" theatre exemplifies the heritage management's control over cultural space production, as well as the driving role of private capital and creators. This representational space combines traditional narratives with contemporary art to provide visitors with a unique cultural experience, while simultaneously reinforcing the heritage's contemporary value.

The cultural spatial production of Pingyao Ancient City reflects an organic integration of policy and practice. On one hand, the government provides strong assurance for the cultural conservation of the ancient city through the implementation of policy documents and concrete measures. On the other hand, cultural festivals, symbolic architecture, and narrative activities serve as key carriers that enrich the cultural connotation of the ancient city and enhance public heritage recognition.

4.4 Dimension of Social Space Production

The third layer of spatial production is the "representational space," referring to the production of social space, whose outcome combines both reproducibility and authenticity in spatial form. As a space of practical living, experience, and engagement, its primary producers are the local residents and visiting tourists of the heritage site. During the transformation of heritage tourism, local residents often occupy a passive position due to relatively weak discourse power (Sun and Nakajima, 2023). With the dominant intervention of power holders, heritage communities typically undergo a process of resistance, adaptation, and eventual acceptance (Su, 2018). Ultimately, through participation in tourism services and heritage education, they gradually identify practical fields for intervention in spatial production, thereby personalising and normalising the power-led spatial representations and the spirit of place, resulting in a perceivable representational space with distinctive local community cultural characteristics (Zhang and Li, 2024). In Pingyao Ancient City, heritage serves both as a material carrier and a reproduction of living narratives, with community participation and tourist experience forming the core of this dimension.

Community spatial participation and social feedback enhance the vitality and cohesion of heritage communities. Residents of Pingyao Ancient City are deeply engaged in building renovation and commercial operations, achieving a win-win situation for heritage conservation and economic development through the synergistic guidance of private capital and government policies. For example, the former site of the Rishengchang Draft Bank was transformed by private capital into the "China Draft Bank Museum," which not only fully preserves its historical and cultural characteristics but also effectively stimulates the local economy, injecting endogenous dynamism into the heritage area. Many residents have converted private residences into guesthouses, shops, or exhibition venues, actively participating in the city's operation through commercial means. Under a "government-led + resident self-help" model, community members have completed the restoration of privately owned courtyard houses, gradually becoming key actors in heritage space management and operation (Sun and Nakajima, 2023). Furthermore, intangible cultural heritage such as Pingyao lacquerware decoration techniques is widely exhibited within the heritage zone, revitalising traditional craftsmanship and effectively addressing employment issues for some local youth (Sun and Nakajima, 2023). Heritage community residents also participate in local governance through roles such as "grid members," contributing to the administration of the ancient city community.

Tourist experience and the reproduction of representational space. Tourists, as perceivers and participants of heritage representational space, shape their unique heritage narratives through heritage education, cultural experiences, and subjectivised evaluations (Su, 2018). Various guided tours, cultural activities, and heritage education programmes provide tourists with opportunities for an in-depth understanding of the cultural significance of Pingyao Ancient City. Modern technological means, such as digital light shows, museum development, and intangible cultural heritage transmission, reproduce the ancient city's culture within virtual spaces, creating novel visitor experiences. The diversified interpretations of heritage by tourists enrich the cultural connotation of the heritage and simultaneously raise new spatial production demands for heritage managers and local communities, thus forming a dynamic balance between heritage conservation and tourism development.

As a World Cultural Heritage site, Pingyao Ancient City has established a dynamic and interactive social space between the community and tourists. The community achieves self-empowerment through active participation and social contribution, while tourists inject new narrative dimensions into the heritage through their experiences and reproduction.

5 Conclusion

This study attempts to reveal the heritage revitalisation of ancient city heritage with distinctive Chinese traditional cultural characteristics through the protection and transformation practices of Pingyao Ancient City. From Lefebvre's perspective, it analyses the dynamic interweaving and mutual shaping of material space, space of representation, and representational space within heritage sites: through policy regulation and industry adjustment, the ancient city has achieved optimisation of its material space; by leveraging cultural festivals and symbolic projects, the city has strengthened the identification of representational space; and through community participation and tourist interaction, the space of practice has been invigorated. This virtuous cycle not only injects sustainable development momentum into the heritage site but also provides a referential model of spatial production for other heritage sites (Figure 4).

From the perspective of spatial practice, political power, professionals, capital, and non-governmental organisations have been deeply involved in the remaking of Pingyao's space: government planning and financial investment have shaped tangible spaces such as the city walls, roads, and utility networks (including the continuous removal of illegal constructions and the construction of underground corridors); market forces have introduced modern tourism functions, promoting the synchronous development of pedestrian districts within the ancient city and the surrounding areas (for example, guiding private capital to renovate South Street). Social strata and various interest groups have also played a role in this process: the authorities have constructed Pingyao as a site to exhibit Jin merchants' culture and emphasised the protection of indigenous residents' rights by positioning them as the "remaining residents of the old city"; meanwhile, investors and external developers pursue tourism profits, leading to a reconstruction of commercial space content, but this has also resulted in inappropriate "false prosperity," raising concerns about the authenticity of the space.

At the level of representational space, the preservation blueprint designed by the government and experts has provided guidance for the transformation of the tangible space: the official policy's principle of "minimal intervention" and the subsidy mechanism have directed conservation and repair practices; cultural and creative projects along with promotional narratives have reconstructed the public's interpretative understanding of Pingyao's spatial significance.

At the level of spatial representation, the interaction between residents and tourists endows the ancient city's space with multiple cultural significances: it is both a historical relic and a modern living environment. The community progressively strengthens its role through active participation in management, education, and governance, while tourists, through their experiences and reinterpretation of the heritage, inject new cultural narratives and meanings into the site.

The spatial production of Pingyao Ancient City is a complex process involving multiple actors and layers: national policies and planning establish the baseline for protection and development positioning; capital investment presents challenges. Lefebvre's framework reminds us to focus on the contestation among different forces in the process of spatial production. The transformation practice of Pingyao Ancient City demonstrates that through the integration of government, capital, and community, alongside a protection-prioritised approach, these conflicts can be mitigated to some extent, providing a valuable reference for the management and planning of similar heritage sites worldwide.

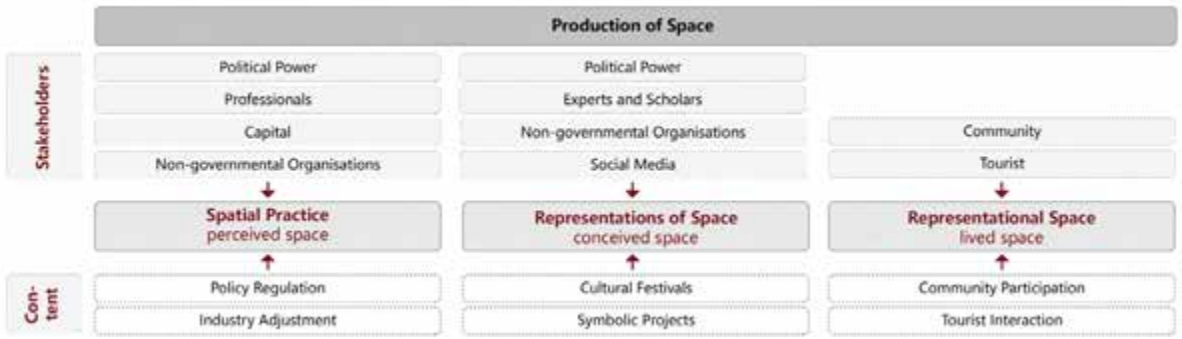

Figure 4-Framework Model

Based on the present study, future research could be further expanded in the following directions:
(1)The balance mechanism between heritage authenticity and commercialisation: Conduct in-depth analyses of the impact of commercialisation on the cultural value of heritage during the production of heritage space, and explore regulatory approaches through policies and management methods to maintain the authenticity and sustainability of heritage sites.

(2)Collaborative heritage conservation models involving multiple stakeholders: Investigate the modes of collaboration and power distribution among government, capital, and community in the spatial production of heritage sites, with a focus on the evolving roles and dynamic relationships of each stakeholder in heritage protection and utilisation. Further exploration should be made on the long-term mechanisms of multi-stakeholder collaboration for sustainable heritage development.

(3)Strategies to enhance visitor experience and cultural identification: From the visitor's perspective, examine the relationship between heritage spatial representation and visitor cultural identification, analysing how cultural experiences and narrative construction influence visitors' understanding and attitudes towards heritage, thereby providing new insights for the future development of heritage tourism.

(4)Comparative heritage management from a cross-cultural perspective: Through comparing the conservation and management practices of Pingyao Ancient City with other cultural heritage sites, especially under different national and cultural contexts, explore universal principles and localisation strategies for heritage site management in a global context.

Table 2. Main Events

Year	Main Participants	Event Description
1963	Dong Jianhong, Ruan Yisan (Tongji University)	Conducted a survey of Pingyao
1976	Pingyao County Construction Bureau	After the Reform and Opening-up, Pingyao was designated as a small to medium-sized city focusing on light textile and machinery industries
1981	Pingyao County Government, Tongji University	Surveyed and formulated the Overall Plan for Pingyao County; new urban area developed outside the old town; Pingyao was designated as a nationally protected tourist county with a complete ancient cityscape
1986	State Council of the People's Republic of China	Listed as the second batch of national historical and cultural cities
1992	Ministry of Construction, UN-Habitat	Organised training courses on ancient city protection planning
1994	National Committee of Historical and Cultural Cities	Passed a proposal to support the prompt nomination of Pingyao as a World Cultural Heritage Site
1997	UNESCO	Officially inscribed Pingyao Ancient City along with Shuanglin Temple and Zhenguo Temple on the World Heritage List
2006	Global Heritage Fund, Pingyao County Government	Jointly funded and completed the overall conservation plan and residential repair projects in Pingyao
2011	Pingyao Jiucheng Cultural Tourism Investment Co., Ltd., Wang Chaoge Team	Youjian Pingyao Performance (Again See Pingyao) designated as a benchmark project; Pingyao Film Festival became a signature event
2017	Jia KezhangdirectorPingyao International Film Festival Co., Ltd.	Pingyao Crouching Tiger Hidden Dragon International Film Festival
Since 2019	State Administration of Cultural Heritage, Shanxi Provincial Bureau of Cultural Heritage	Conducted protection and repair of heritage units; constructed public service spaces; implemented operational regulation
Since 2020	Pingyao County Government	Implemented infrastructure improvement and renovation projects in Pingyao Ancient City

Digital Platform for Accessibility and Cultural Enhancement of Inner Areas in Italy

Abstract
Heritage plays a central role in territorial cohesion and development policies, as well as in the activation of urban transformation processes. This interdisciplinary project experiments with a virtual platform to explore small historic centres, enhancing cultural and landscape heritage and promoting inclusive accessibility. The objective is to guarantee the right to know and share this minor heritage, eliminating accessibility barriers and serving as a shared archive for local communities. Focused on Stigliano (MT) in Basilicata, the project aims to preserve memory and local identities in areas affected by depopulation and hydrogeological risk. It also aims to promote cooperation between different levels of government and local actors, also through virtual interactions, and to encourage potential investments. The platform becomes a tool for cultural regeneration, stimulating dialogue on the future of these communities.

Keywords : Inner areas, cultural heritage, digital tools, public engagement, accessibility.

1. Introduction

More than 60 percent of Italy's territory is made up of fragile and poorly accessible rural territories, i.e., inner areas, yet they are home to less than a quarter of the national population and continue to depopulate. These figures are indicative of a clear territorial imbalance impoverishing cultural continuity and integrity, especially in rural areas.

European policies have increasingly focused on social cohesion and cultural enhancement to strengthen these marginalised contexts. Public debates reflect a shift from static conservation to dynamic place-based development, in which cultural and natural heritage – both tangible and intangible – acts as a driver of territorial cohesion and sustainable growth. In Italy, 'inner areas' are defined as areas far from service centres, characterised by systemic inequalities that lead to progressive demographic decline, accelerating depopulation and the impoverishment of local economies (Barca et al., 2014). This weakens the bond between inhabitants and their territory, also threatening the survival of cultural and historical-architectural heritage – a legacy of stratified histories, vernacular architecture, and landscape elements now at risk (Vigotti, 2020).

While the importance of developing services that address the essential needs of the inhabitants of inner areas is well known, there is also a growing recognition of the need to initiate processes of knowledge-building, conservation, and enhancement of territorial capital in its various dimensions – material, cultural, and cognitive – in order to define effective intervention strategies. The Hangzhou Declaration (2013) already addresses the contribution of culture to the social, environmental, and economic pillars of sustainable development, as well as its role in creating sustainable cities and building resilient societies. Although not explicitly stated, the cultural aspect is underlying, transversal, and implicit in all the actions of the 17 goals and 169 targets of the 2030 Agenda. This is because each pillar – environment, society, and economy – has a cultural dimension. Some scholars claim that this lack of explicit recognition has led many conservation-focused projects to concentrate efforts and resources on physical preservation, often at the expense of cultural, social, and intellectual drivers of sustainable management (Vandesande, 2021), and that this approach has frequently proven ineffective. As a result, public participation, community involvement, and civil society engagement are increasingly promoted in the context of heritage interventions to ensure the long-term sustainability of management, valorisation, and development processes (Faro Convention, 2005; Tomka, 2013). In this sense, digital technologies can foster cultural innovation and participation, considering deeper forms of participation that go beyond mere interaction

with predefined content. The idea of democratising heritage (Taylor, Gibson, 2016) through digital access has promoted a number of Europe-wide initiatives and funding programmes for the digitisation of cultural heritage (European Commission, 2019).

In Italy, in line with the Faro Convention and the European Framework for Action on Cultural Heritage, the National Recovery and Resilience Plan (NRRP) of the Ministry of Culture includes, among its investments under Mission 1 (Digitisation, Innovation, Competitiveness, Culture and Tourism) - Component 3 (Tourism and Culture 4.0), a specific measure for the implementation of 'Digital Strategies and Platforms for Cultural Heritage'. These developments represent a valuable opportunity for fragile and marginalised territories, in continuity with what was already envisaged by the National Strategy for Inner Areas (SNAI) during the 2014–2020 programming period. Information management through open and interoperable platforms provides valuable tools for decision-making and heritage monitoring. Indeed, by offering data and digital content to a wide range of users, these platforms promote collaborative networks between stakeholders and open new possibilities for knowledge sharing and cultural innovation. Digital tools allow both physical and virtual accessibility, which is also functional in promoting sustainable forms of cultural tourism; sustainable cultural tourism is indeed one of the pillars for the local development of inland areas, as highlighted by various scholars (Bizzarri, 2024).

The aim of this contribution is to explore how digital resources can significantly support the understanding, protection, and enhancement of cultural heritage, through the conceptualisation and first experimentation of a digital platform in a real case study, i.e. the Italian small town of Stigliano (MT) – leading municipality of the action plan for the inner area "Montagna Materana" – characterised by a rich cultural landscape but also by strong environmental fragility due to hydrogeological instability. The article is structured as follows: Section 2 presents a literature review and a selection of best practices related to the use of digital platforms for the enhancement of cultural heritage, with a focus on inner areas and minor historical centres; Section 3 illustrates the methodological framework for the development of a virtual platform, enabling its replicability, and an initial experiment in a pilot area of Stigliano; Section 4 discusses open issues, including feedback obtained from the pilot case application, implementation possibilities, and the structural limitations identified. Finally, Section 5 reflects on how the experimentation fits into a broader public and scientific debate, as well as on the future scalability and replicability of the research.

2. Literature review and best practices on social digital tools for inner areas

There are several examples of experimentation and application, both institutional and non-institutional, that use digital platforms to enhance cultural heritage and promote sustainable cultural tourism. Although most of these good practices refer to medium-to-large urban contexts or specific heritage institutions (art collections, museums, etc.) and are focused on particular sites (monuments, archaeological areas, historic buildings, rural areas, museums), some experiments address marginal territories and smaller historical centres – together with their tangible and intangible heritage – in a more integrated way, including through the involvement of so-called "heritage communities" (Faro Convention, 2005). The experiences presented below, at European, national, and local levels, were selected for their methodological similarities and alignment of objectives: they all involve the development or use of digital tools and platforms for the valorisation of cultural heritage, both tangible and intangible, in marginal and underrepresented areas, with the active involvement of local communities in the various stages of the knowledge and management process. Digital platform thus becomes a 'space' for exercising shared responsibility in the protection, enhancement, and promotion of collective memory and heritage (Longo et al., 2020), also through virtual interaction between users and the digital environment, as well as among users themselves. Furthermore, some of these initiatives focus on expanding the concepts of accessibility and inclusiveness in smaller historic centres through virtual reality or digital twins (Bacci et al., 2021; Lombardo et al., 2023). However, awareness of the actual effectiveness of these initiatives in producing tangible transformations in public space remains limited (Caselli et al., 2025).

At the European level, the Horizon 2020 Programme has promoted numerous projects in which digitisation, and the enhancement and sharing of cultural, environmental, and social heritage, served as key drivers for reducing territorial and social inequalities, with a focus on rural, mountainous, and peripheral areas. One example is the REACH project (Re-designing Access to Cultural Heritage for a Wider Participation in Preservation. Reuse and Management of European Culture, 2017-2020), a European initiative aimed at creating a Digital Social Platform. Its purpose was to bring together a wide range of stakeholders and audiences and offer meaningful participatory

experiences through pilot projects. One of these focused on rural heritage in Spain, exploring participatory approaches to its conservation, particularly in relation to historical irrigation systems and rural areas affected by change or natural disasters. The project continues the work begun by the FP7 MEMOLA project (Mediterranean Mountainous Landscapes, 2014-2017), which led to the development of a collaborative map of historical irrigation systems[1]. The resulting dataset, now available online, is presented to the public as a map; registered users can contribute new entries and comment on existing ones. This approach not only constitutes an example of active community involvement in the process of knowledge production and subsequent "maintenance" of heritage but also highlights the importance of using open online platforms to ensure the visibility and usability of data collected through research projects. It also facilitates collaboration between researchers and civil society in the collection and validation of data, opening new opportunities for cooperation (Toscano, 2018).

In Italy, the National Plan for the Digitisation of Cultural Heritage (PDN) for the five-year period 2022-2026, sub-investment 1.1 of the NRP Culture, defines a platform as "any hardware and software system used to host applications or services and serves as a basis for the development or management of other applications, processes or technologies [...] and may be equipped with different interfaces both for the display of data and for interchange with other platforms". This includes applications designed with different interfaces and structures to ensure access to cultural heritage and to enable any user to participate in, experience, interact with, disseminate, and reuse public cultural assets. Forms of participation are often activated through online crowdsourcing of ideas, memories, personal stories, and other data (Ridge, 2014), depending on the thematic focus of each initiative. Such is the case, for instance, of the "Archivio Atena" community archive and the "Qui Val di Fiastra" project[2]. The former aims to digitally archive the architectural and cultural heritage of the historic centre of Atena Lucana (SA), to trigger processes of adaptive reuse and urban regeneration by leveraging socio-spatial relationships. The process is based on mutual participatory learning between experts and community members, with the goal of co-identifying shared values through the spatial, social, cultural, and environmental dimensions of the context (Rocca et al., 2023; Somma et al., 2024). The latter project seeks to revitalise the social, economic, and cultural fabric of the municipalities of Ripe San Ginesio, Loro Piceno, and Colmurano (MC) through an integrated strategy of social and cultural regeneration and the creation of a Digital Valley Ecosystem (Giacomelli, Calcagni, 2022). The initiative includes 15 interventions concerning the development of Territorial Infrastructures (networks for slow mobility and enhancement of socio-cultural services), Intangible Infrastructures (an interactive web platform and museum network), Cultural Activation and Events, and the Narrative of the Valley. This reflects a broader intent to promote more inclusive forms of cultural tourism. Nevertheless, such experiences demonstrate that mapping information and making it widely accessible – e.g. through GIS tools – is a way to operationalise and make use of it, both for the sake of knowledge and to stimulate planning that considers local identity and memory. Moreover, these experiences address the need to work on the encoding of heritage, especially intangible heritage. While digital interaction (such as interpretation or expression of values) during the decoding phase has become increasingly polyvocal, the decision about what constitutes "heritage" and what is selected for digitisation (encoding) is not necessarily part of this democratisation (Taylor, Gibson, 2016).

3. Testing a metodological framework for a virtual platform on the pilot case of Stigliano

Within the broad framework of the experiences summarised above, the national research project "GO-IN! Digital Platform for Inner Areas" (funded by Next Generation EU in the framework of the Italian NRRP) explores the application of new digital technologies to the cultural heritage of small historical centres in inner areas for the enhancement of local resources, supporting innovative approaches in tourism, housing, and sustainable mobility (Savi, 2019).

The main objective of this inter-university and interdisciplinary research project is to assess the potential of

1 The collaborative map of historical irrigation systems has the primary goal of making both these productive landscapes and the irrigation communities that manage them visible. This initiative was born in collaboration with the European FP7 MEMOLA project and the Association of Historical and Traditional Irrigation Communities of Andalusia. To support this effort, we have received funding from the Spanish Foundation for Science and Technology (FECYT) within the framework of the participatory science program. https://regadiohistorico.es/

2 "Archivio Atena" and "Qui Val di Fiastra", are a winning projects of the public notice, "Attractivity of the villages", part of the National Recovery and Resilience Plan (PNRR M1C3) financed by the Next Generation EU.

Web site Qui Val di Fiastra: https://www.quivaldifiastra.com/ (last accessed: 13/05/2025)

3D reality-based models integrated into GIS environments and virtual platforms for the enhancement and conservation of small historical centres in vulnerable contexts. The project aims to develop an innovative and replicable methodological protocol for the creation of a 3D GIS databases and an interoperable virtual platform (Figure 1). The protocol also focuses on evaluating the technical and economic feasibility required for managing and implementing digital systems in contexts that typically lack resources, personnel, and digital skills within public administrations.

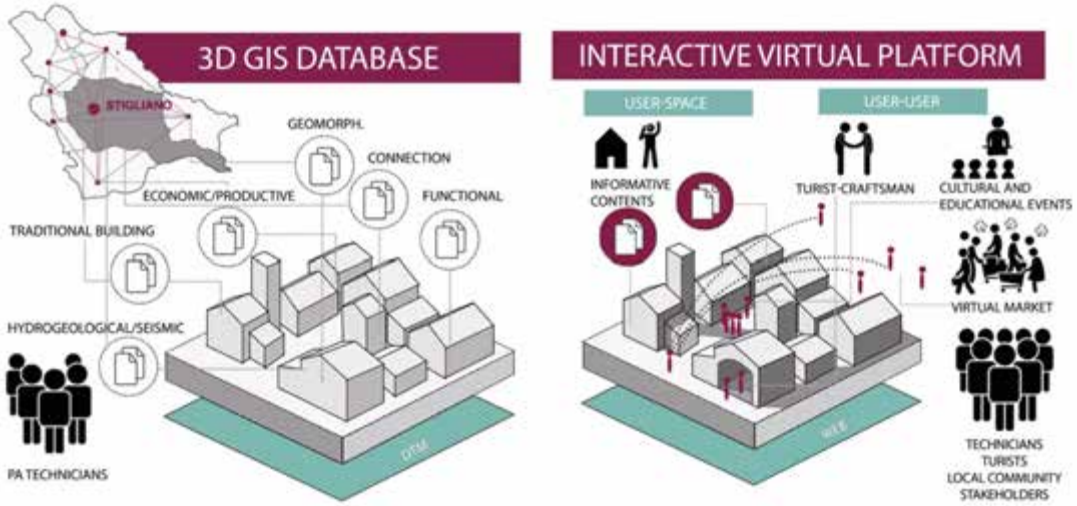

Figure 1. Graphic diagram summarising the objectives of the GO-IN! project. On the left, the 3D GIS database targeted to technicians of the Municipality of Stigliano; on the right, the interactive virtual platform addressed to scientific and non-scientific community. Image produced by DAda Lab, University of Pavia.

This contribution focuses on the development of the interoperable virtual platform, which include a photorealistic 3D model made publicly available online through the project website. The concept is developed starting from the case study of Stigliano, which had been thoroughly documented in the first stages of the GO-IN project.

The platform enables the archiving, processing, and visualisation of open and interoperable data available in various formats (3D models, images, texts, videos, interactive contents, etc.) and collected from diverse sources (traditional archives, digital libraries, real-time content, open dataset databases, open-access research data repositories of scientific results, social networks, etc.). Users, including tourists, will be able to navigate the digital environment, interact with virtual content, and engage with other users. The platform helps guarantee the right of access to culture by removing barriers to accessibility – both physical and informational.

3.1 Contextual Analysis of Stigliano and the Montagna Materana inner area

The experimentation of the virtual platform focuses on the case study of Stigliano (MT) in Basilicata. The region, characterised mainly by small municipalities, comprises four inner areas designated by the SNAI: Montagna Materana, Mercure - Alto Sinni - Val Sarmento, Marmo Platano, and Alto Bradano. Of these, the inland area "Montagna Materana", of which Stigliano is the leading municipality, is described by SNAI as an archipelago of eight "landscape towns"[3] : Accettura, Aliano, Cirigliano, Craco, Gorgoglione, Oliveto Lucano, San Mauro Forte, and Stigliano (Figure 2). All eight municipalities are considered ultra-peripheral, and the main demographic indices confirm the typical symptoms of demographic contraction, accompanied by a rapid ageing of the population (Figure 3). This leads to a progressive erosion of the everyday infrastructure (Coppola et al. 2021), and of the material and immaterial resources of these areas. Further exacerbating this condition of territorial fragility are widespread forms of hydrogeological instability, which in some municipalities have led to the relocation of parts of the settlement at

3 Area Strategy, pilot project 'Montagna Materana'. Website: www.agenziacoesione.gov.it/strategia-nazionale-aree-interne/regione-basilicata-aree-interne/montagna-materana/ (last accessed: 03/06/2024)

risk to newly built areas, amplifying “dispersions, slights, pains, fractures, dissensions, forms of resistance” (Teti, 2024).

Urban/connective criteria (conditions of isolation from reference service centres), morphological criteria (conditions of geological or hydrogeological risk), and cultural criteria (presence of tangible and intangible cultural heritage) were particularly influential in identifying the case. But that is not all. Among all of them, the municipality of Stigliano was certainly the one that best lent itself to experimentation, because although it is among the municipalities most affected by ageing and by a constant rate of decline – in the last 19 years it has lost 14% of its population – it is still the most demographically significant, with 3,586 inhabitants (as of 1 January 2023). Moreover, although since 2017 Stigliano, together with the other municipalities in the inland area, has signed a convention for the associated exercise of activities and services with the delegation of functions to be exercised in a coordinated manner, it still has a more solid administrative apparatus, with the management of urban and building planning at the municipal level as well as participation in territorial planning at the supra-municipal level. Technical-administrative capacity was considered an essential condition for achieving the objectives that the project had set and for hypothesising possible future developments and further activations.

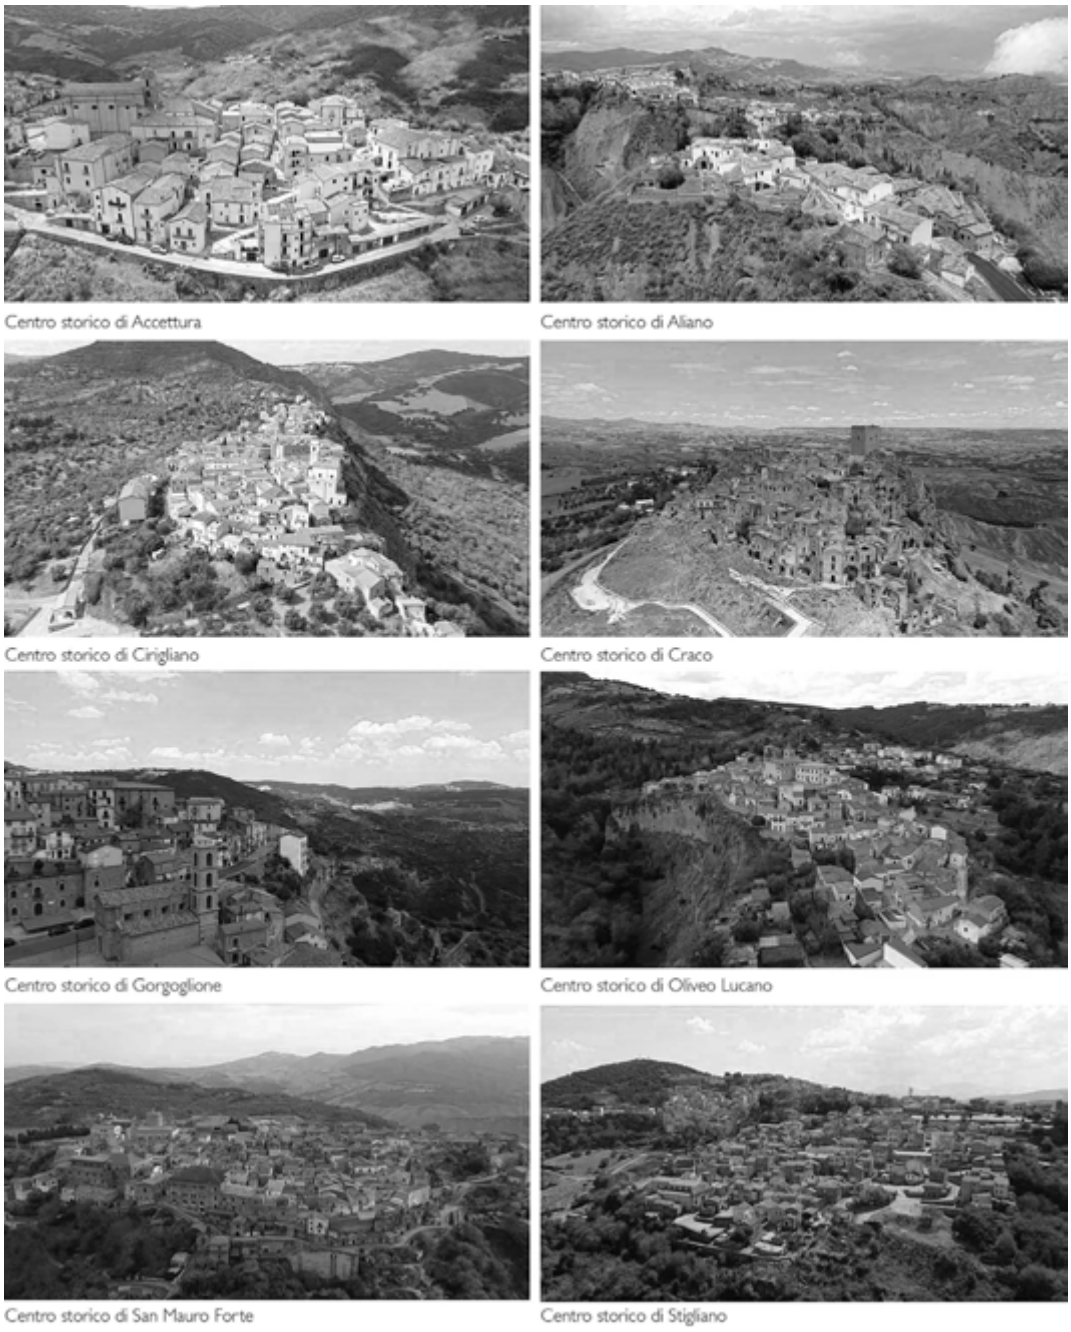

Figure 2. Aerial photos of the eight municipalities that make-up the 'Montagna Materana' inner area. Authors' elaboration.

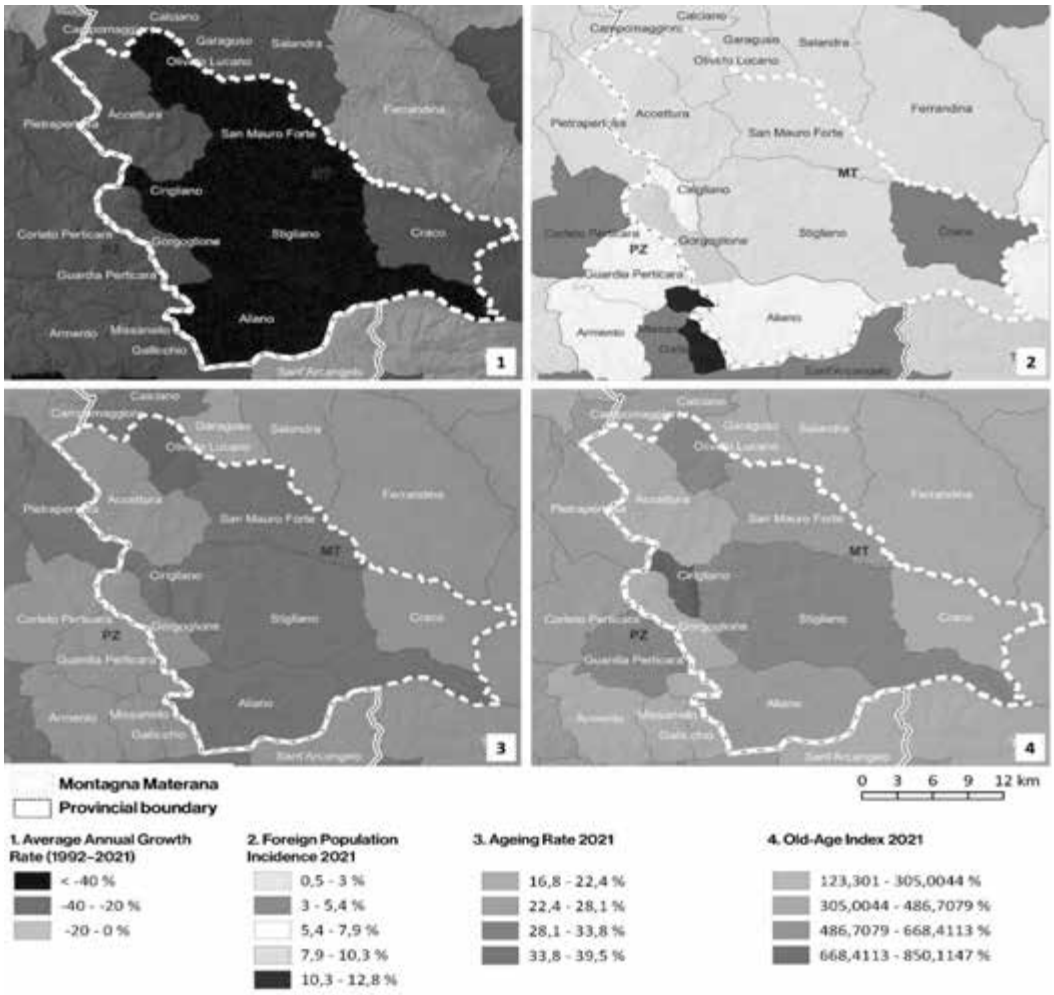

Figure 3. Main demographic indicators: growth rate, incidence of the foreign population, ageing rate, and old-age index. Original elaboration based on Istat data, Statistical Atlas of Municipalities 2021. Authors' elaboration.

In this framework, the experimentation for the GO-IN virtual platform focuses on the portion of the historic centre of Stigliano included in the perimeter of the "Transfer Plan" following the disastrous flood of 1973 and the identification of an area subject to high hydrogeological risk. The area coincides with the oldest part of the settlement, the Rione Terra known as "Chiazza", in which there are sections with severely degraded units that are no longer habitable, including buildings of considerable historical and architectural value (Figure 4). The "Transfer Plan", which has been in force in the area for more than fifty years, prevents any hypothesis of functional recovery/reconversion, consigning the buildings to progressive erosion, accelerated by preventive demolition interventions carried out for public safety reasons.

Figure 4. Collage of photos depicting the Chiazza district of Stigliano. The Mother Church of Santa Maria Assunta stands out within the urban fabric, which is mostly made up of minor historic architecture. The urban voids visible in some of the photos are a direct consequence of preventive demolitions. The historic center overlooks the badland landscape of the Basento valley. Authors' elaboration.

The exposure of historical-artistic artefacts, as well as cultural landscapes, to calamitous environmental events – aggravated by anthropic intervention – highlights the need for new forms and policies for the protection of cultural heritage, both tangible and intangible, and opens up experimentation with new tools for the preservation of knowledge and memory, also taking into account the possibility that this heritage may disappear over time (Parrinello et al. 2024). The project has developed digital documentation of tangible and intangible heritage, analysis of the state of conservation of buildings and open spaces, a census of services and territorial resources, as well as an update of hydrogeological and geomorphological vulnerability assessments. Part of these data will also be included in the virtual platform currently under construction in the framework of the GO-IN project, which will allow their free use.

3.2 The methodological framework for a Virtual Platform

The identification of site-specific needs and resources of the inner area Montagna Materna, Stigliano and the chosen historic neighbourhood helped the conceptualisation of the virtual platform whose main objectives, as

already mentioned, are to integrate and disseminate knowledge on historical and architectural heritage; make information on territorial resources easily accessible; promote a network that connects environmental landscape and cultural assets, small businesses, associations, and local cultural initiatives.

The methodological approach is therefore based on an in-depth, multi-scalar knowledge of the study area and on the principles of making the platform accessible - with freely available content - scalable and reproducible. The proposal involves the creation of a web interface that enables access to digital documentation and interactive contents including a 3D model of the selected historical neighbourhood of Stigliano designed to establish connections and networked routes at multiple scales. This strategic 'node' thus act as a catalyst, trying to extend its impact across a wider territorial extension.

The conceptualisation of the platform is given in the following subsections, which present four main strategic axes, accompanied by a description of the main objectives of each axis, expected results and main tools and procedures to be adopted.

3.2.1 3D digital reconstruction and participatory mapping

The interactive 3D model represents the main innovation of this proposal. This is integrated into an easily navigable web interface, enriching it with informative content and narrative elements that make navigation more engaging. The process starts with a digital survey and 3D modelling, in parallel with designing data architecture – supported by the digital documentation of the site through heritage mapping and cataloguing – multimedia and user interaction methods.

The use of an integrated data acquisition campaign involving both range-based technologies (terrestrial and mobile laser scanners) photogrammetry and image-based tools improves the accessibility of user-digital interaction once the model is published online because the model can be enjoyed from different pint of views: 2D map, 3D perspective, street-level with the guidance of a 2D navigator.

The implementation of the model into a software for the management of interactive 3D models - i.e. 3DVista – allows users to navigate the online space and interact with "hotspots" located on specific objects or areas. The interactive hotspots consist of multimedia content related to the area's cultural and touristic heritage. These contents can be collected through different collaborative mapping tools, as well as, structured and semi-structured interviews.

This phase is preceded by an exploratory effort aimed at engaging different stakeholders and, as much as possible, the local community, in order to identify and bring to light shared, plural, and cultural values. These values may serve as key elements both in shaping visitor itineraries and in constructing a community archive.

3.2.2 Community Digital Archive

The construction of community archives, as previously mentioned, can represent a significant advantage in terms of active involvement in urban regeneration processes (La Rocca et al., 2023). The goal in this case is the construction of an open and evolving archive, accessible online, built together with the community, to document and preserve the cultural heritage of a small town in the internal areas. The process of community involvement and activation begins with the planning of meetings, participatory workshops and focus groups, during which themes and values recognized as shared emerge and are "mapped", subjects bearing knowledge and "interest" for the construction, maintenance and implementation of this tool. The tools used to collect material on the identified themes include the use of more or less structured interviews, the use of questionnaires, participatory mapping and participatory GIS (PGIS), integrating top-down and bottom-up approaches. The database produced is digitized and uploaded to the platform, where it will be freely available for consultation and download. It can be expanded over time by users through forms of online crowdsourcing, subject to appropriate moderation processes. Through the implementation of this system with interactive features such as forums, surveys and the integration of mobile apps for data collection, it can constitute an opportunity not only in terms of memory preservation and support for urban and territorial planning, but also in stimulating the birth of innovative startups, social enterprises, local networks and associations engaged in the territory.

3.2.3 Tourism interaction and immersive storytelling

Mapping this information and making it accessible to all is a way of operationalizing it – making it available not only for general knowledge but also as a tool to support planning efforts, particularly within the framework of cultural-based tourism promotion.

This approach aims to enhance even lesser-known places, creating alternative routes to mainstream circuits. The archive thus becomes an active resource for the development of thematic itineraries that require a methodological framework capable of integrating both expert knowledge and knowledge rooted in the local context. Building on these principles, intangible heritage – such as rituals, dialects, oral histories, and culinary traditions – was also "mapped" through the collection of images and testimonies. To ensure ease of interpretation, the data were organized into thematic clusters and integrated into the 3D model. The grouping follows either a logic of spatial proximity or one of conceptual continuity: in the first case, it is directly highlighted on the model through interactive hotspots; in the second, it is organized within a dropdown menu. The selected thematic layers activate a selective display of hotspots, guiding their exploration according to a defined sequence – either linear or open-ended. The 3D platform includes virtual tours (of both indoor and outdoor spaces) created using 360° photographs, allowing users to immerse themselves and interact with public spaces, historic buildings, handcrafted objects, and artefacts. In this context, the platform will be integrated with physical systems connected to multimedia content (such as QR codes, information panels, and visitor centers), acting as a tool to promote and connect local guides and interactive experiences (e.g., community-recorded audio guides, participatory tours, thematic festivals).

The itineraries may also engage small accommodation facilities, farms, and local producers, helping to create a hybrid network – both physical and digital – that offers immersive experiences, including those related to the region's traditional products. With the aim of promoting virtual forms of interaction – between user and space, and between users themselves – that also have a tangible impact on the physical world, remote experiences will be developed to complement in-person ones (such as virtual markets, educational events, and outreach activities). This is made possible by activating crowdcasting methods of interactive live streaming, enabling people to participate remotely in live events and interact through text comments and reactions via social media platforms (e.g., YouTube Live, Facebook Live, Instagram Live) or through video conferencing software and interactive remote workshops (Rodriguez-Gil et al., 2018). To enhance interaction with the 3D model, encourage community participation during crowdsourcing phases, and stimulate learning and recognition of this heritage among new generations, the platform can also be integrated with gamification tools (such as hotspots with game logic).

3.2.4 Open digital infrastructure and local governance

The Platform, if conceived as a dynamic digital ecosystem, must ensure the active involvement of the community, particularly in terms of the continuous updating and enrichment of its contents over time. For this reason, it is essential to define in advance the management model to be adopted – one that is as sustainable as possible in relation to the technical, economic, and human capacities of those responsible for its operation. In contexts such as inner or marginal areas, the most sustainable model is one that brings together and fosters dialogue between public administration and local stakeholders – associations, third sector organizations, and community-based actors. On the one hand, it is crucial for a local public authority – either independently or in partnership with others – to take responsibility for the platform's operational, technical, and legal management, formally recognizing it as part of its institutional digital services and territorial information systems. On the other hand, placing the full burden of management on such small-scale administrations risks quickly slowing down platform updates and development processes. An integrated management model – shared between public, private, third sector, and local community actors – can instead ensure the presence of dedicated and skilled personnel, enhancing the capacity to access funding through national (e.g., PNRR, Borghi, Cultura Digitale) and European programs (e.g., Creative Europe, Interreg, Erasmus+). This approach leverages complementary expertise and the ability to adopt new tools and languages. However, an integrated model also requires a strong coordination structure to avoid dispersing efforts and to mediate between stakeholders whose interests may not always align.

3.3 Pilot application on the case of Stigliano.

Regarding the pilot application in the case of Stigliano, work is still ongoing. The web interface for the 3D platform has been completed, the photogrammetric model has been optimized for remote access and use, and the

selection and insertion of informational content has begun.

More specifically, with respect to the 3D modeling of the site, an integrated data acquisition campaign (Picchio et al., 2024) was conducted, involving both distance-based technologies (terrestrial and mobile laser scanners) and image-based tools (portable reflex cameras, 360-degree cameras, and UAV systems – DJI Phantom Pro and Mavic Mini). After appropriate metric verification and scaling, photogrammetric altimetric data were produced and further decimated using CloudCompare. These data form the basis of the virtual 3D platform. The model was then imported into the 3DVista software and enriched with multimedia content related to the cultural and tourist heritage of the area. This content was collected through collaborative GIS mapping (ArcGIS Survey123 and Field Maps) and semi-structured interviews with local stakeholders.

The GO-IN website (www.goinprin2022.com) was configured as a multidimensional interactive platform designed to provide access to a variety of multimedia content (some of which is available for download) related to the cultural and tourist heritage of the pilot area. It is accessible from smartphones or tablets without the need to download specific applications and is available in both Italian and English. The content is organized into three sections: Home, Resources, and 3D Platform. The 3D Platform is the main component of the website and consists of a 3D model that functions as an interactive interface: by selecting areas, points of interest, or itineraries, users can directly access contextualized content (Figure 5). The platform demo has currently identified five thematic clusters: Historical Architecture, Murals, Rural Culture, Historical Itinerary, and Online Market. In this case, the design of cultural itineraries and the identification of key themes have benefited from the work of the research group at the University of Basilicata in the Montagna Materana area. For many years, this group has carried out research projects involving the active participation of communities, institutions, cultural operators, and citizens. Through workshops, laboratories, and meetings, values, themes, and places linked to collective memory and community identity have been jointly identified.

The inclusion of a dedicated "online marketplace" cluster allows for the networking of local producers, small artisans, and creatives, fostering the creation of shared itineraries, narrative paths, and showcases designed to promote local creativity and diverse forms of cultural and experiential tourism.

Figure 5. 3D Virtual Platform with thematic interactive hotspots visible on the model; on the side, an example of an interior virtual tour – Museum of Rural Life – and an information sheet from the Architectural itinerary. Developed by Metaheritage srl.

4. Discussion on application in the pilot case

The pilot application, although still under development, already provides valuable insights into the opportunities and limitations of implementing a virtual platform in a peripheral and internal area such as Stigliano.

One of the most significant opportunities is the ability to document and preserve a fragile heritage through digitalization – particularly in contexts where material and immaterial cultural assets are at risk of erosion. Building on this premise, initial demonstration tests of the prototype – conducted with the involvement of the municipal administration and both internal and external technical experts – have shown that interactive features are capable of generating renewed curiosity and engagement with a heritage often "unseen" or unrecognized even by the local community. To further enhance this engagement, particular attention has been paid to the integration of game dynamics and an exploratory dimension within the 3D model. The possibility of creating gamified narrative tours, virtual/physical treasure hunts, thematic quizzes, and collective challenges opens up new educational opportunities and fosters intergenerational interaction. These features facilitate connections between traditional knowledge holders and younger generations, helping to create meaningful bridges across age groups. As a result, new actors and stakeholders emerge at both local and territorial levels, including schools, libraries, educators, and students. In parallel, another promising development lies in the creation of a network of local producers and artisans. Within the platform, these stakeholders can narrate the deep connection between land, people, and production – using tools such as historical documentation and digital storytelling, and providing links to their commercial activities. This fosters an integrated vision of cultural and productive heritage.

However, to draw more robust conclusions, further testing will be conducted once the platform is complete. These tests will involve a broader and more diverse user base – students, tourists, and residents of all ages – to assess the clarity, emotional engagement, and overall usability of the digital narratives. The feedback gathered will be integrated into an iterative refinement process, enabling continuous improvement and contextual adaptation of the platform (Camarda, 2021).

That said, the success and longevity of the platform rely heavily on meaningful community involvement through structured participatory and co-design processes. Without this, there is a risk that the outcomes achieved during the research phase may fade at the end of the project. Participation must therefore be designed in relation to the community's actual capacities, with attention to overcoming a variety of structural and social barriers – including limited human, financial, and infrastructural resources; latent conflicts and misaligned interests among stakeholders; and a general distrust toward time-consuming or politically-driven processes.

In this regard, the choice of participatory techniques and tools for data collection and archiving becomes crucial. When tools are overly technical or not truly collaborative, they may discourage community participation and compromise the platform's future sustainability – particularly its ongoing maintenance and content updating by local stakeholders.

To address this challenge, and to ensure long-term sustainability, the virtual platform and website will be formally handed over – after testing and evaluation – to the technical department of the Municipality of Stigliano, or to other local, regional, or national bodies. Recognizing the digital skills gap that emerged during the project, a series of tailored training programs is planned for municipal staff, professionals, cultural operators, and young people in training. These courses aim to create a local pool of digitally competent individuals capable of maintaining, enriching, and managing the platform, as well as facilitating participatory content creation and knowledge sharing.

5. Conclusions

The use of digital platforms and systems to revitalize inner and peripheral areas through the enhancement and promotion of their cultural and environmental heritage, as well as their cultural and creative scenes, is becoming increasingly widespread and structured. It has demonstrated a strong potential to stimulate new forms of entrepreneurship.

The ongoing pilot in Stigliano fits within a local context that shows certain potential. The historic center, in fact, receives a moderate influx of tourists only during the summer period, mainly due to cultural promotion activities organized by the public administration and local associations (for example, "AppARTEngo" https://www.appartengo.com/). However, these initiatives alone are not sufficient to counter the depopulation trend. It is necessary to connect these cultural realities with others operating at the local, national, and even international levels – actors that can act as external enablers (Milone, Paolucci, 2025). The new opportunities that could emerge would benefit both the local community and potential external stakeholders.

At the core of the GO-IN project lies the idea that, through the replicability of the model proposed for Stigliano, it is possible to activate collaborative networks among neighboring territories that are historically interconnected through shared landscape, social, and economic systems. To achieve this, it will be essential to build alliances with the ecosystem of projects, organizations, and cultural programs that have flourished across the region – especially following Matera's designation as European Capital of Culture in 2019, which gave both the city and the region significant international visibility and strengthened their identity as a prominent cultural destination. Moreover, in a broader multi-scalar perspective, this pilot initiative could also contribute to and integrate with a national network of villages aimed at improving economic, ecological-environmental, and welfare systems.

The Value of Suqian Water Culture heritage from the Perspective of Cultural Landscape

Ying Yuning
Affiliation:Southeast University
Email:1030427599@qq.com

Abstract
The perspective of cultural landscape echoes the trend of regionalization, holistic, and dynamic protection of cultural heritage. From this perspective, this study constructs a value cognition framework based on three dimensions, aiming to explore the water culture value of Suqian area. According to history, Suqian formed its unique water network and field patterns under different human-water relationships. Therefore, the value of the water cultural heritage can be distilled into four aspects: the evolutionary history of the coexistence and integration between villages and water, the formation of characteristic water networks and conservancy, the witness of the iteration of modern rural governance and the spirit of water management. Finally, this article proposes strategies providing experience for the protection and revitalization of Suqian area.

Keywords: cultural landscape; Water cultural heritage; Value; Suqian area

1. Introduction

In recent years, the concept of international heritage protection tends to be regionalized, holistic and complex. From the first attention paid to the connection between individual heritage sites and their surrounding environment in the Venice Charter, to the concept of historic towns and urban areas proposed in the Nairobi Recommendation and the Washington charter, and then to concept of cultural landscape, rural landscape and cultural routes proposed in the 1990s, the focus of international heritage protection gradually shifted from individual sites to the whole, and the scope of protection gradually expanded. Meanwhile, the natural and cultural complex heritage has attracted much attention, and the elements of heritage protection are constantly superimposed.

Since the 19th century, the West has carried out extensive investigation and Research on landscape, forming the branch fields as landscape geography and human geography, and laying the foundation for cultural landscape(Xu&Han,2016). Among them, Ratzel systematically expressed the concept of cultural landscape with the word "historical landscape" for the first time, providing an early framework for the studies of cultural landscape(Tang&Jin,1998). In the 1920s, American geographer Carl Sauer created the theory of cultural landscape, claiming that cultural landscape is the result of culture acting on nature, and emphasising the systematic interaction between natural and human society, which formed the core theory of cultural landscape(Sauer,1925). In 1992, the 16th meeting of the UNESCO World Heritage Committee was held in Santa Fe, the United States. The word "cultural landscapes" was proposed for the first time, making it formally different from the cultural and natural heritage, and becoming one of the world cultural heritage types. The word "cultural landscape" was written into the Convention Concerning the Protection of the World Cultural and Natural Heritage(UNESCO World Heritage Centre,2019).

Conceptually, cultural landscape is a complex of the natural landscape and human activities attached to it. It encompasses the overall characteristics within the region, such as the site selection, form and distribution of settlement groups, providing a basis for the regionalization and holistic protection of rural heritage. In terms of value cognition, cultural landscapes emphasize the integration of nature and humanity, and pay attention to the comprehensive value of heritage in multiple aspects such as ecology, culture and society, which can provide a framework for the multi-dimensional value identification of rural heritage. Therefore, taking Suqian area as an example and water culture as a clue, this paper studies the exploration of heritage value from the perspective of cultural landscape. It is of great significance for the regional value identification of general village remains (village clusters without characteristic resources), and is conducive to the implementation of contiguous protection and utilization work of villages.

Based on the current research and literature review, although experts and scholars have long proposed the necessity and urgency of the regional holistic protection and utilization of rural heritage, the protection theories

and methods at the regional scale have not yet formed a universal system, especially in terms of value identification. There is a lack of universally applicable and operational guidance. In the research on heritage protection at the rural regional scale, there are a relatively large number of studies conducted with cultural landscapes as the entry point. The research contents mainly involve the formation mechanism and evolution mechanism of village cultural landscapes, gene identification and map construction of village cultural landscapes, and research on the protection and development strategies of cultural landscapes. For example, Hao Naiyi took the tea culture landscape of traditional settlements in Zhejiang as the research object. Through the analysis of its geographical environment characteristics, such as hilly terrain, humid climate, tea culture activities, traditional architecture centered on courtyards, and beautiful environment, she deduced the formation and evolution process of the local tea culture landscape(Hao,2024). Zheng Wenwu proposed the concept of landscape group genes based on the theory of cultural landscape, identified the common characteristics of traditional villages in Hunan Province through clustering, and constructed a gene map(Zheng,2021). However, the objects of these studies mainly focus on national and provincial key protected villages, and general villages not included in the protection system are rarely involved. Therefore, the conclusion could be drawn that in the vast rural areas of China, villages that have not been included in the protection and inheritance system are rarely studied. Furthermore, most of these villages have remnants rather than heritage. With no value exploration been carried out, the heritage value has not been identified, and few protection and utilization measures have been taken. This further explains the necessity of conducting research on the general village of Suqian in this paper.

In addition, the research on the heritage value system from the perspective of cultural landscapes is relatively detailed. Studies tends to be combined with issues such as comparisons among landscape heritages of the same category, heritage protection and sustainable development. The discussions on its heritage value focus on material aspects such as mountain terrain, water systems, farmlands, and residential settlements, as well as intangible resource elements such as production techniques and folk culture. For instance, Wang Lin pointed out that the constituent elements of the Longji Terraced Fields cultural landscape heritage include topography and landforms, air, unique mountain microclimate and characteristic cuisine(Wang,2009). Shen Xiuying conducted the research on Settlement cultural landscape area. By means of disciplinary methods such as geography, biology and anthropology, she identified and extracted elements including topography, climate, ethnic identity, production and lifestyle, religious beliefs, customs and conventions, building materials and aesthetic concepts and establishing the genetic map of cultural landscapes of different regional settlements.(Shen,Liu&Deng,2006) Spencer JE summarized the heritage elements of agricultural cultural landscapes into six aspects, namely the psychological elements of environmental perception, the political elements of land resource allocation, the historical elements of ethnicity, religion and customs, the technical elements of the ability to utilize land, the agronomic elements of varieties and cultivation, and the economic elements such as the law of value(Spencer,1963). These studies provide a good theoretical and methodological basis for this paper to construct the cognitive framework of heritage value from the perspective of cultural landscape, and help clarify the angles and dimensions of the analysis. This study will construct the framework of value cognition on this basis.

Finally, regarding the research on water cultural heritage, relevant scholars from disciplines such as water conservancy engineering and landscape architecture have respectively explored the value and protection and utilization of water cultural heritage in recent years. Chen Haiying explored the connotation and value of water cultural heritage from the perspective of tourism discipline(Chen et al,2019). Wang Cheng fang explores the value of Guangzhou's waterway cultural heritage from the perspective of spatio-temporal integration and constructs an overall protection system for heritage interpretation(Wang,Wu&Zhang,2021). Kong Fan'en studies the differences in the quantity and type distribution of water cultural heritage in different regions around the world and analyzes its value from the disciplinary perspective of landscape architecture(Kong&Liu,2022).These studies have sorted out and analyzed the value of water cultural heritage in terms of form and culture, but their research objects mainly focus on ancient water conservancy projects. There are relatively few studies and protection practices related to modern and contemporary water conservancy projects, and there is still a research gap.

In conclusion, this paper selects Suqian area as the research object. Firstly, through the analysis of historical archives and the translation of historical maps, combined with field investigation, this study sorts out the

historical evolution of the human-water relationship in Suqian area, especially the historical turning point of water management in modern times. Then, it attempts to construct a value cognition framework from the perspective of cultural landscape. Under this framework, the material space, social governance and Spiritual and culture dimension values can be recognized, along with corresponding carriers of water culture heritage in Suqian area. Finally, based on the above results, this paper proposes strategies for the protection and utilization of contiguous areas. On the one hand, this paper expects to take Suqian as a template, providing an empirical analytical framework for the exploration, protection and utilization of the heritage value in general villages. On the other hand, as the research on modern time water cultural heritage in China is still incomplete at present, it is hoped that this research can supplement and expand the systematic understanding of water cultural heritage in China's cultural heritage protection system. This is also of positive significance for regional ecological protection and the healthy development of the human living environment.

2. The Value Cognition Framework from the Perspective of Cultural Landscape

UNESCO has proposed that cultural landscapes represent the "combined works of nature and of man", and have dynamically evolved along with human activities, witnessing the evolution process of human settlements under the constraints and influence of the natural environment(UNESCO World Heritage Centre,2019).The perspective of cultural landscape emphasises the continuous interaction between human and nature and the regional protection scope. Reflected in the representation of village clusters, it can reflect the common value attributes of villages within the region from three dimensions: material space, social governance and spiritual culture, which enables general villages to be identified, protected and inherited as a cultural landscape as a whole. It constitutes the basic framework of regional value cognition from the perspective of cultural landscape (Fig. 1.).

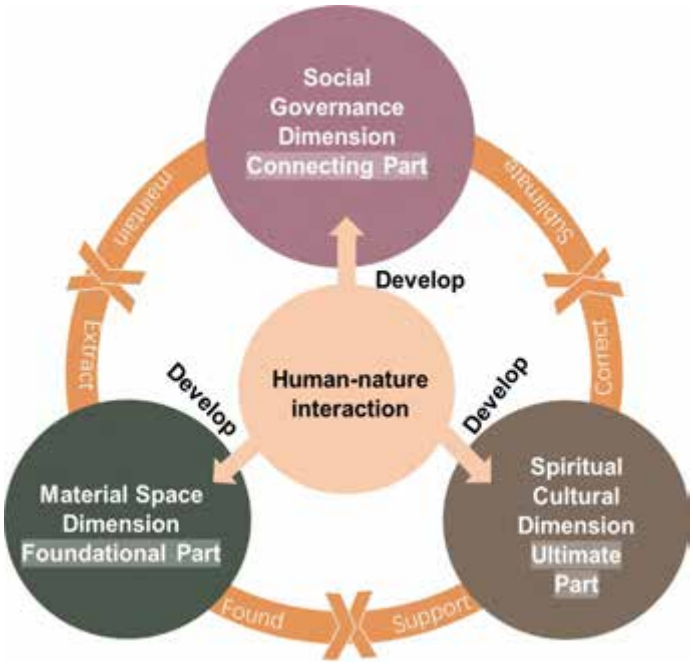

Fig. 1. The Value Cognition Framework from the Perspective of Cultural Landscape. Using a circle to explain the interrelationships among the three dimensions. The value of each dimension is generated due to the interaction between human beings and nature. On the surface, it is the development of material value into social governance value and then into spiritual value. In fact, both social governance value and spiritual value will have a feedback effect on material value.

2.1 Material Space Dimension

The material space dimension is the surface value of the villages. The carriers are usually various material

elements of the village. On the one hand, it includes the characteristics and evolution of the natural environment and settlement forms. On the other hand, it also includes the material interaction between human beings and nature. Such as water network systems, land use patterns, technologies and measures for life, production and ecology which adapted to local conditions (ANTROP,2005). These two aspects above constitute the value of material space dimension.

Furthermore, when constructing the value cognitive framework of general village clusters, in addition to emphasising the value of the human-land relationship, attention should also be paid to the collaborative value of general village clusters from a regional perspective, which focuses on regions with roughly the same cultural characteristics (Wu,1999). On the one hand, the regional perspective identifies the consistency or integrity of the spatial structure, resource environment, and even the cultural structure of villages. On the other hand, it can also grasp the structural relationship of "village-unit-region" in the village cluster. Through the spatial scale division of regions, units and specific villages, it recognizes the consistency or integrity at the regional scale level and the differentiation of the village structure at the unit scale level(Zhang,2015).The value in the material space dimension is the most foundational. On this basis, the value of social governance, as well as spiritual and cultural dimension can be further explored.

2.2 Social Governance Dimension

Based on the material space, with the development of society and the conduct of social activities, people carries out the spatial governance on nature and villages, which has formed the second level of value——the value in the dimension of social governance. The value of this dimension is generally reflected in carriers such as the social governance system, economic and social policies, production models, and social organizational relations. The spatial governance of rural areas is not only the key to maintaining the material interaction between human and nature, but also an important component of the local knowledge system. The human-land interaction in this dimension not only can maintain or correct the value of the material space, but also serve as the basis for extracting spiritual and cultural values.

2.3 Spiritual and Cultural Dimension

The spiritual and cultural value of a village is the cultural and spiritual significance bestowed upon nature and society by human beings in their interaction with nature. Village clusters take cultural commonalities as the main line, by integrating resources, they connect scattered cultural carriers and clarify the ambiguous cultural context. From the perspective of cultural landscape, the value cognition of the spiritual and cultural dimension of ordinary villages carries the regional place identity, cultural identity and ethnic identity. It is a significant part of maintaining community cohesion and pride, and also the basis for community support for the protection of rural landscape(Walker&Ryan,2008).

3. The History of Water Culture in Suqian

3.1 Before the Ming and Qing Dynasties: thrived and declined due to water

In ancient times, with dense water network and numerous rivers and lakes, Suqian was a fertile place suitable for farming, fishing and hunting and living. Ancient cities such as Sizhou City were born due to the Sishui waterway and the Southern Canal.

In 1194, the Yellow River burst its banks in Yanghwu, Henan Province, and changed its course to the southeast, divert the way towards the Huai River.Later, the Yi River flowed into the Yellow River and accumulated to form the Luoma Lake, which was almost unable to discharge floodwaters normally. Therefore, the bottom of the lake gradually silted up and overflowed to the downstream areas, causing disasters. The "Yellow River's diversion of the Huai River" has completely changed the original pattern of the water systems in the Huai and Si River basins, causing the siltation of rivers and the rise and fall of lakes. This has led to soil desertification and alkalization, along with significant changes in the structure of rice crop cultivation. Frequent floods and drought occurred, making the once fertile land turning into a flood-stricken-area. The folk sayings such as "Afraid of both flood and drought, nine out of ten years without harvest" and "If there is rain, there will be flood; if there is no rain, there will

be drought" have become the true portrayal of Suqian.

3.2 From the Ming and Qing Dynasties to the founding of the People's Republic of China(1949): The predicament of water control

During the Ming and Qing Dynasties, the rulers were constantly striving to construct water conservancy projects, hoping to solve the long-standing flood drainage problem. In 1644, the Ma Ling Mountain Ridge was excavated to the north of Suqian County, allowing the water of Luoma Lake to be discharged. It was thus named the Lanma River. In1680, the general governor of the river, Jin Fu, presided over the construction of six dams on the Lanma River. It was thus named the "Liutang River", which serves as the main flood discharge outlet for the Luoma Lake. During the reigns of Emperor Kangxi and Emperor Qianlong, they paid particular attention to the water-control projects in Suqian and both made six Tours of investigation. Emperor Kangxi inspected the projects of the Yellow River, Huai River, Grand Canal, Luoma Lake and Hongze Lake for several times. He went to the sites to measured the water levels in person and discussed water-control strategies with his ministers. Emperor Qianlong issued hundreds of river engineering orders and conducted many projects. It can be seen that during the Ming and Qing dynasties, the rulers played an important role in water-control projects. These deeds also became the poetry of Suqian and formed a part of the local water culture.

In conclusion, From the Ming and Qing Dynasties to 1949, although the Chinese government had initiated some water conservancy projects, due to the limitations of social technology and scientific levels, it was unable to fundamentally solve the problems of floods, waterlogging and droughts. During this period, there were 32 major floods in Suqian, averaging once every four years. Moreover, due to the inability to store and utilize rainfall, only drought-resistant crops could be grown, which was with low and unstable yields. In the event of floods or droughts, the government is powerless, and the common people can only resign themselves to fate and fight against water.

3.3 After the founding of the People's Republic of China(1949): Two peaks of water control laid the foundation for the water network and farmland pattern

After the founding of the People's Republic of China, a wave of water-control campaign has swept across the country. In April 1951, under the leadership of the county committee, the heroic people of Suqian launched the vigorous "Guiding Yi river and regulating Shu river" project. Centering on flood problem, they opened up the New Yi River, a channel for the flood of Luoma Lake to flow into the sea, and built the south embankment of Luoma Lake and the Zaohe Control Gate, Zaohe Small Boat Gate, Yanghetan Gate, forming the first-line flood-control barrier of Luoma Lake (Zaohe Control Line). It became the first large-scale water-control battle of the country after the founding of the People's Republic of China. Since 1957, the government has led the construction of water-control projects of the Middle Canal and the Liutang River, and extended the south embankment of Luoma Lake to the west and north, basically completing the large-scale control project in Suqian. This was the first water-control campaign under the leadership of the government initiated by Suqian people after1949. Centering on flood-control and security, a water-control engineering system was established to solve the flood problem of Luoma Lake. The five major engineering systems and layouts of flood control, drainage, irrigation, waterlogging reduction and water supply in Suqian were basically formed. The human-water relationship also shifted from defense to governance. In addition, the people of Suqian have renovated the old river channels, excavated new rivers for flood drainage, and carried out supporting projects for branch rivers as well as large, medium and small ditches. They have built a cascade river network that is interconnected and coordinated with the ditch network, laying the foundation for the water network system in the Suqian area.

After the flood problem was solved, aiming to address the food issue, government of Suqian made the decision of " Conversion of dry fields to paddy fields "projects, developing irrigation agriculture to increase agricultural output and the living standards of farmers. From the winter of 1958 to the spring of 1959, Suqian gathered more than 100,000 farmers to dig the Second main Canal, the Third main Canal, as well as the first and second branch canals in the Lailong Irrigation District. They carried out meticulous and dense river network construction to transform farmland water conservancy and used lake water for gravity irrigation.Since then, the area of paddy

fields in the region has expanded rapidly, the basic construction of farmland has been improved rapidly, and the number of major agricultural producers has increased. The dry fields in rural areas have been transformed into high-yield and stable fields that guarantee harvests in both drought and flood.This is the second peak of water-control campaign in Suqian. Centering on the transformation from dry land to paddy fields and the construction of irrigation and drainage areas, it developed irrigation agriculture, and laid the foundation for the water system and field pattern in the rural areas of Suqian. Through unremitting efforts to transform nature, the human-water relationship have shifted from people struggling with water to people coexisting with it, from managing water to utilizing it.

Based on the utilization of water, Suqian people have further adjusted their industrial structure around agriculture and industry through the renewal of governance measures. They drew on outstanding cases across the country and attempted the "all-round contract" program in agriculture, starting to grow economic crops mainly including mulberry, and using the silk industry to drive the adjustment of the agricultural planting structure. In industry, the "Gengche Model" was created, where township enterprises led communities and family workshops to develop together, promoting social and economic progress(Fig. 3.).

Fig. 3. The different stages of water history in Suqian area. In Figure a, Suqian has experienced the Yellow River's diversion of the Huai River and the accumulation of Luoma Lake. In Figure b, during the Ming and Qing dynasties, the general managers of the Yellow River dug the Middle Canal and the Liutang River under the emperor's order, attempting to divert the floodwaters. Figure c shows that after the founding of the People's Republic of China, Suqian area experienced two peaks of water control campaigns. Therefore, Suqian gradually formed a tiered water network, laying the foundation for the current water network pattern and farmland layout.

4. The Value and Carriers of Water Cultural Heritage in Suqian

From the perspective of cultural landscape, the human-water relationship in Suqian area is a dynamic process from defense to governance and then to utilization. In this interactive relationship, they jointly constitute the value and carrier system of the village cluster in Suqian area(Fig. 2.).

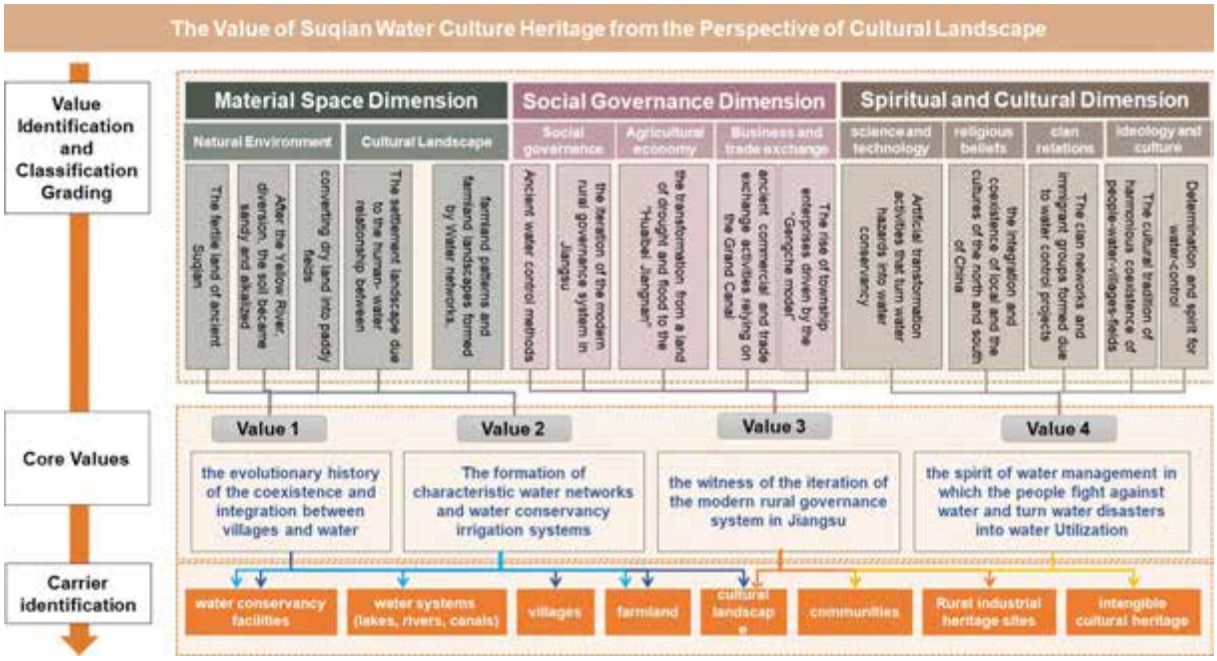

Fig. 2. The Value of Suqian Water Culture Heritage from the Perspective of Cultural Landscape. By classifying and grading the three dimensions, the value of Suqian area in each dimension is comprehensively expounded, and through refinement, the three core values are ultimately determined

4.1 Material Space Dimension: The evolution history of the coexistence and integration between villages and water

In ancient Suqian area, the natural background with its dense water network and fertile land, gave Suqian an thrive in agricultural. At this time, the relationship between people and water in Suqian area was harmonious. The settlements were built along the water and gradually developed into ancient cities. After the Yellow River's diversion, the soil in Suqian rapidly became sandy and alkaline. Coupled with frequent floods and droughts, the people began to fight against water, mainly by excavating the river course to promote the diversion of water from the river. For instance, the Lanma River and the Middle Canal was dug to divert water from the Yellow River system. At this time, due to the tense relationship between people and water, most settlements were distributed in farmlands and forests, maintaining a certain distance from rivers to reduce the losses caused by floods.

After the founding of the People's Republic of China, the relationship of struggle between humans and water continued. However, due to the increasingly improved scientific level, it gradually shifted from defense to governance. Not only did the people continue to excavate for flood diversion, but they also constructed a flood control engineering system with new technologies. In addition, converting dry land into paddy fields and developing irrigation agriculture around Luoma Lake have significantly increased agricultural output, and the relationship between humans and water has further evolved towards utilization and symbiosis. At this time, the newly established settlements showed a trend of distribution along water, which is banded distributed and divided by water systems, forming a settlement landscape where water and villages blend, demonstrating the harmonious coexistence of human and water relations.

Therefore, in the material form dimension, the changes in river systems and the evolution of villages connect different historical periods, witnessing the human-nature interaction and the changes in the human-water relationship, as well as the evolutionary history of the coexistence and integration of villages and water.The carriers of this part of the value mainly fall into two categories. One is the water system in Suqian area, including lakes, rivers and canals. Another category is aquatic cultural landscapes, that is, farmlands and villages that emerged and changed because of water.

4.2 Material Space Dimension: the formation of characteristic water network and water conservancy irrigation system

In this regard, the heritage value of Suqian area mainly lies in the formation of a distinctive water network and water conservancy irrigation system, whose carriers are mainly the water conservancy facilities, artificial water network systems and drainage and irrigation areas after the founding of the People's Republic of China. In Suqian area, a water network system composed of large and small rivers, canals and reservoirs has been artificially excavated, and branch rivers, branch canals and large, medium and small ditches have been artificially divided in the farmland. The water from Luoma Lake is drawn through a tiered water network to serve as Irrigation water source, which was transformed by regular and dense farmland water conservancy in the field. Thus, the water network system and farmland complement each other in the process of human transformation of nature. They not only form a regular grid-like pattern of water system, field pattern and farmland landscapes, but also demonstrate the material interactive value in terms of production technology in the process of human transformation of nature.

For instance, in the Lai Long Irrigation District, before its construction, the land within the district was compacted and alkalized, allowing only drought-resistant crops to be grown, and the people's lives were extremely poor.In 1958, under the leadership of the county government, the broad masses of the people built channels, constructed culverts and sluices, leveled fields and prepared land, and began to switch to growing rice. And through the engineering support, the Yanghetan Gate draws water from Luoma Lake for gravity irrigation. One year later, the rice and crops in the irrigation area gradually increased, and the average annual agricultural output value reached 35 million yuan.

4.3 Social Governance Dimension: Witness to the Iteration of the modern governance System in rural area of Jiangsu

After water control, the material utilization of nature gradually stabilise. People of Suqian established social interaction and began to update and innovate the governance system, pursuing development. This is the value of Suqian's water culture history and its remnants in the dimension of social governance, witnessing the iterative process of the modern governance system in Jiangsu's rural areas.

On the one hand, as for agriculture, Suqian has implemented an "all-round contract" program based on the existing paddy fields, carried out agricultural structure adjustment, by planting economic crops like mulberry. In the industrial field, Suqian has created the "Gengche Model", which has driven the development of township industries through a group and serialized operation mode at the township, village and household levels, witnessing the history of exploring modernization in Jiangsu's rural areas. The main carriers are the industrial sites of the "Gengche model", such as Xiaodian Winery, Daxingchao Silk Factory, Suqian Glass Factory , as well as the related Caoji People's Commune and Xinzhuang People's Commune.

On the other hand, Suqian has merged scattered natural villages and administrative villages based on the renovated water network, and transformed them into new rural communities. Based on the common memory of water control, these natural villages and administrative villages have similar farmland cultivation history and folk cultures. By utilising the cohesion generated by water culture, villagers can well adapt the transformation from different villages to the common rural community shared together. Furthermore, through the joint management of village cadres and community social organizations, combined with the innovative grid-based management approach, the community guaranteed the collaborative governance of multiple subjects.This transformation has facilitated the transformation from traditional villages into new rural communities, highlighting the social governance value of updated models and system based on Suqian's water culture. The main carriers are emerging rural communities such as Liyuanwan Community and Shuangheli Community. This also the important manifestation of Suqian's implementation of the national rural revitalization strategy

4.4 Spiritual and Cultural Dimension: The water-control spirit of Suqian people during their struggle against water and their efforts of turning water disasters into water conservancy

In terms of the cultural and spiritual dimension, the water culture history of Suqian demonstrates values in various aspects such as science and technology, religious beliefs, clan relations, and ideological and cultural categories.

In terms of science and technology, in the face of the floods caused by the Yellow River's diversion of the Huai River, Suqian people have reshaped the water network through projects such as "Guiding Yi river and regulating Shu river" and " Conversion of dry fields to paddy fields ", transforming the threat of floods into irrigation resources, demonstrating the spirit of transformation and the wisdom of technology .

In terms of religious beliefs, since ancient times, the Grand Canal and the well-developed north-south canal transportation have not only generated the circulation of goods and materials, but also facilitated the integration of dialects, folk customs and skills, giving birth to an open and inclusive cultural mindset and cultural genes.In the belief system of Suqian people, they not only Revere the Mazu belief introduced from Fujian, but also worship the canal god of wealth, Guandi, which was brought from Shanxi. All these belief are closely related to water culture. In addition, waterfront customs such as the Zaohe Temple Fair, Dingzui Donkey Running, and Daxing Boat, are also the intangible cultural heritage created in the integration of local cultures and cultures from northern and southern regions of China. They embody the unique personality and character of Suqian region, demonstrate the cultural identity and common beliefs that the people have gathered because of water.

In terms of clan relations, early Suqian predominantly consisted of traditional Chinese villages organized along kinship ties.After the founding of the People's Republic of China, due to the large-scale water control project, the Luoma Lake Mass Migration Incident occurred. The migrants around Luoma Lake settled in communes such as Lailong community, Caoji community and Xinzhuang community, which prompted the collaboration between the clan organizations and the immigrant groups. People build collective identity within water management and establish a new social collaboration network with water as the bond. This not only enhanced the cohesion and sense of belonging of the village clusters in Suqian area, but also enriched the local clan network in Suqian, which was reflected in the names of the roads, factories built at that time.

In terms of ideology and culture, with the continuous changes in the human-water relationship, Suqian area has gradually formed a layout of "ponds-canals-fields-villages", achieving a sustainable cycle between water, fields and people, and solidifying the ecological concept of respecting nature and harmonious coexistence that has been passed down from generation to generation. In addition, throughout the long history of water control, from the 180,000 voluntary labor in the "Guiding Yi river and regulating Shu river"Project in 1951, to the migrants of Luoma Lake who Abandoning their own house to build a reservoir in 1958, not to mention the ten years of continuous efforts in the " Conversion of dry fields to paddy fields "project. Suqian people have never stopped their efforts to transform nature in the struggle against water, showing their determination of making sacrifices and contributions.This indomitable spirit of resistance has become a spiritual symbol of collective resistance against nature, as well as the cornerstone of the spiritual culture of Suqian people.

These spiritual and cultural values are not only the survival wisdom of Suqian people in dealing with natural challenges, but also the core driving force for uniting the community and carrying forward traditions.

5. Strategies of Concentrated and Contiguous Protection

Based on the analysis of the value of Suqian area and its carriers, the strategies are proposed from the perspectives of human-water relationship and village governance, aiming for the concentrated and contiguous protection and utilization of Suqian area

5.1 Reorganizing the water-control cultural routes in the river basin

Taking the history of water control as the clue, a cultural route with the theme of "Transforming water hazards into water utilization " could be constructed in the Lailong Irrigation District. Relying on the water network system of "Lake (Luoma Lake Reservoir)-River (Zhongyun Canal Liutang River)-Canal (Ergan Canal)", the historical story of the development and evolution of the relationship between humans and water will be told in sections. Along the Liutang River to the Second Main Canal, from the starting point of water-control, to the water-control predicament of the Ming and Qing Dynasties, and finally to the two peaks of water-control campaign. Water-control cultural landscape nodes could be set up based on the remaining relics and the main line of historical narrative.

At the micro-scale level, in combination with cultural routes, water-control theme activities can be set up. For instance, water management cultural parks can be created by integrating the remains of water conservancy facilities such as water conservancy heritage parks. River-digging experience activities can be carried out in conjunction with the farmland water conservancy in villages, and related science popularization and education can be conducted. Moreover, water management history exhibition halls can be set up based on new agricultural communities built along water. Showcase and explain the history of water-control in Suqian District and the fighting spirit during the years. In addition, as for villagers, through water pollution control and ecological transformation of ditches and rivers, the original hard revetments can be classified and softened to create various types of waterfront platforms and riverside walkways, recreating the harmonious interaction scene between humans and water, and also providing activity venues for waterfront folk customs during special festivals.

5.2. Jointly building a governance system

Continue to optimize the governance system of the community. From the flexible governance dimensions such as behavioral norms and cultural inheritance, guiding farmers to transform from the traditional geographically oriented village identity and familiar society action model to the modern community citizen behavior model. In this process, the improvement of villagers' self-governance ability and identity empowerment should be guided. It is also necessary to Lay a psychological foundation and provide flexible guarantees for the reconstruction of governance order in new rural communities. Furthermore, through the integration of clan etiquette and legal norms, the governance system of the new rural community has become more practical. While conforming to the humanistic traditions of the settlement, it can also operate in a coordinated and efficient manner.

6. Conclusion

Based on the trend of the regionalization, holistic and complexity of international heritage protection, this paper introduces the perspective of cultural landscape to construct a value cognition framework based on three dimensions: material space dimension, social governance dimension, as well as spiritual and cultural dimension, hoping to expand the focus of heritage protection from individual and typical villages to general village clusters in the region.

Under this framework, this article takes water culture as the clue, sorting out the history of the Suqian area along with the evolution of human-water relationship, and identifies the common values and their carriers in four aspects of the Suqian area, which can be distilled into four aspects: firstly, the evolutionary history of the coexistence and integration between villages and water; secondly, The formation of characteristic water networks and water conservancy irrigation systems; thirdly, the witness of the iteration of the modern rural governance system in Jiangsu; fourthly, the spirit of water management in which the people fight against water and turn water disasters into water Utilization. On this basis, this paper proposes concentrated and contiguous protection strategies such as reorganizing the water-control cultural routes in the river basin and Jointly building a governance system.

The value cognition system constructed in this paper provides a universal method for the value identification of general villages from a regional perspective, and has enlightenment for the protection and revitalization of vast rural areas. Based on this study, more specific regional protection planning methods and technical paths still need to be discussed on a thematic basis in subsequent studies, such as the demarcation of protection areas and so on.

Research on the Revitalization Modes and Mechanisms of Historical Buildings in High-density Cities: A Case Study of Hong Kong

Dan Ye[12], Yu Zhuang[1], Xin Li[2]
Affiliation: [1]Tongji University, [2]City University of Hong Kong
Email: Danye@tongji.edu.cn

Abstract
The conservation and revitalization of historic buildings constitute a critical challenge for high-density cities in balancing urban development with cultural continuity. Hong Kong's practice in this domain offers paradigmatic insights. This study systematically examines the evolutionary trajectory and defining characteristics of heritage revitalization in Hong Kong, identifying three prototypical modes through the analytical framework of multi-stakeholder interest coordination. This study reveals that negotiable interest commonality serves as the inherent driver shaping these differentiated models, with governance processes involving interest concession, value co-creation, and benefit-sharing mechanisms. Hong Kong's experience provides actionable references for Asian megacities undergoing urban regeneration, such as integrating differentiated incentives with rigid protection, synthesizing cultural inheritance with innovation, and strengthening whole-process public participation to forge preservation consensus.

Key words: Revitalization; historical buildings; Benefit coordination; Diverse entities; Hong Kong

1 Introduction

As non-renewable resources in cities, historical buildings' conservation and adaptive reuse yield economic, socio-cultural, and environmental benefits (Gražulevičiūtė and Urbonas, 2011). However, urban central areas in high-density cities frequently confront acute land scarcity (Wang et al., 2015). Conserving historical buildings may reduce government revenue, limiting its ability to allocate resources for other policies (Liu and Tang, 2014), and also restricts land development rights. Thus, historical buildings are often demolished under high development pressure (Yung and Chan, 2016). Hong Kong exemplifies such urban contexts, where historical neighborhoods in Hong Kong Island and Kowloon Peninsula—key development zones—operate under severe land constraints (Ye, 1998). Therefore, how to maximize their socio-spatial value and regenerate aging urban districts remains a pressing scholarly inquiry, particularly regarding balancing conservation imperatives with developmental necessities, thus constituting a critical research imperative.

Hong Kong's historic building regeneration operates within a demolition-redevelopment paradigm, where conflicts arise among governments, developers, and the public over competing conservation and revitalisation agendas. Urban renewal, predominantly driven by real estate interests and governmental land reclamation needs, subjects heritage revitalization to dual pressures of capital accumulation and political prioritization (Xu et al., 2022). Transferring urban development rights to conservation initiatives inevitably diminishes potential economic returns from market-driven redevelopment (Urban Renewal Authority, 2008). Thus, achieving equilibrium between demolition and adaptive reuse fundamentally hinges on institutionalized interest coordination among stakeholders. This positions interest coordination as the critical nexus for resolving revitalization dilemmas in land-constrained metropolises, where optimized institutional arrangements mediate tensions between heritage integrity and urban growth imperatives.

Existing studies predominantly address socio-political dimensions of heritage conservation in Hong Kong, such as public engagement awareness and urban renewal conflicts (Yung et al., 2015). However, systematic examinations through an interest coordination framework remain scarce, particularly regarding dynamic interplay among governmental, market, and societal actors in resource allocation, as well as the stakeholder interest configurations underlying diverse revitalization models. Institutional barriers hinder social institutions' resource access and decision-making participation (Chan and Yung, 2004), while market-driven revitalization exacerbates developer-community conflicts (Lee and Chan, 2008). Community-led initiatives often require external interventions to establish interest equilibrium due to weak endogenous capacities(Ng, 2002), resulting in superficial project evaluations that inadequately dissect power dynamics and resource distribution inequities.

Present research also pays insufficient attention to the operation phase, predominantly centering on preliminary planning and transformation (Langston et al., 2008) but overlooking the dynamic operational processes. Critical issues like functional compatibility of revitalized historical buildings gradually emerge during this stage, yet lack

systematic scrutiny, undermining long-term impact assessments and practical guidance. Moreover, Eurocentric studies on low-density urban contexts inadequately address Hong Kong's high-density specificities. As a typical high-density city, Hong Kong faces unique challenges, such as functional hybridization driven by land scarcity (Cheung and Chan, 2014), complex community networks fostering competing interests (Yung et al., 2014), and necessity for context-specific conservation technologies (Yung and Chan, 2012), which existing studies have inadequately addressed.

From a lens of stakeholder engagement, this study employs a tripartite methodology integrating case studies, in-depth interviews, and documentary analysis to systematically examine core interest coordination mechanisms in historic building revitalization within Hong Kong's urban renewal context. It particularly investigates how institutional configurations mediate interactions among the government, market, and societal actors, elucidating pathway formation processes for balancing multi-stakeholder interests. Based on the interest-balancing logic of different stakeholders, it proposes optimization strategies for high-density cities, aiming to solve the dilemma of historical building protection and urban development coexistence.

2 Revitalization of Historical Buildings in Hong Kong: Evolution and Overview

2.1.Evolution of Historical Building Revitalization in Hong Kong under Urban Renewal Context

Hong Kong has evolved through four stages, reflecting the dynamic interaction of urban renewal and cultural awareness. 1)The Inception Stage (Before 1970). Hong Kong, dominated by economic development and pragmatism, focused on infrastructure and housing construction due to the post-1894 plague demolition and post-war housing shortages. As a borrowed place (Gallagher, 2021), weak public place attachment and an underdeveloped local identity (Lin, 2015) marginalized conservation concerns. 2)The Scattered Conservation Stage (1970–2000). During rapid economic growth, the Land Development Company was established to drive urban renewal, with demolition and new construction becoming the norm. The release of the Antiquities and Monuments Ordinance in 1976 and the formation of related committees marked the government's conservation efforts, but commercial interests still led to widespread demolition of historical buildings, with only limited preservation due to public conservation struggles. 3)The Reflection and Adjustment Stage (2000–2010). Demolition-dominated renewal caused housing rights conflicts(Wu, 1996) and community network disruption(Lai et al., 2018). In 2001, the Urban Renewal Authority (URA) replaced LDC and introduced the 4R strategies, including Redevelopment, Rehabilitation, Preservation and Revitalization, integrating conservation into policy. Post-SARS public resistance to high-density development (Lin, 2015)and conservation movements at places like Wan Chai's Lee Tung Street and Queen's Pier(Audit Commission, 2013) prompted the government to launch the Revitalising Historic Buildings Through Partnership Scheme (Revitalisation Scheme, R-Scheme) in 2008 and the Central Conservation Plan in 2009, significantly enhancing public conservation awareness. 4)The Pro-Active Inheritance Stage (Post-2010).The Hong Kong 2030+ plan established goals of Sustainable Development and Cultural Inheritance. The government explored Conservation through Design and Development strategies (Development Bureau, 2012; Legislative Council, 2011). Projects like the Blue House Cluster and Tai Kwun, winning UNESCO awards, proved conservation-revitalization and economic-development compatibility. By setting up conservation funds and cultural activities to encourage public participation (Development Burea, 2025), society's perception of historical buildings has shifted from physical elements protection to social-cultural inheritance, creating a diverse development pattern with the government, community, and NGOs working together.

This evolution shows Hong Kong's transformative journey from initial neglect of historical buildings to valuing conservation due to social conflicts and public awakening, and then achieving a preservation-development balance via policy innovation. It offers a paradigmatic case study for cultural continuity in high-density cities. Overall, Hong Kong's urban renewal focuses on historical conservation after large-scale demolition and redevelopment. Within this context, Hong Kong's historical building conservation and revitalization reflects a sustained negotiation to balance socio-cultural values under a strong economic-interest orientation.

2.2 Historical Building Revitalization in Hong Kong

In Hong Kong, historical buildings are categorized as Declared Monuments and Graded Historical Buildings. The first is protected under the Antiquities and Monuments Ordinance[1]. The Antiquities Advisory Board (AAB) assesses

1 This legal designation enables the Authority to prohibit any alterations to the monument or, at its discretion, impose conditions that must be complied with when alterations are made, ensuring statutory protection measures are enforced for the protection of the monument.

historical buildings using six criteria: historical, architectural, group, rarity, social and regional values, and integrity (Antiquities and Monuments Office, 2005), grading them into Grade 1, 2, or 3[2]. These graded buildings lack legal protection, and owners can demolish them (Gallagher, 2021). From Hong Kong's published list of 1,444 historical buildings (Antiquities Advisory Board, 2025a) and supplementary list (Antiquities Advisory Board, 2025b), over 70% are privately owned.

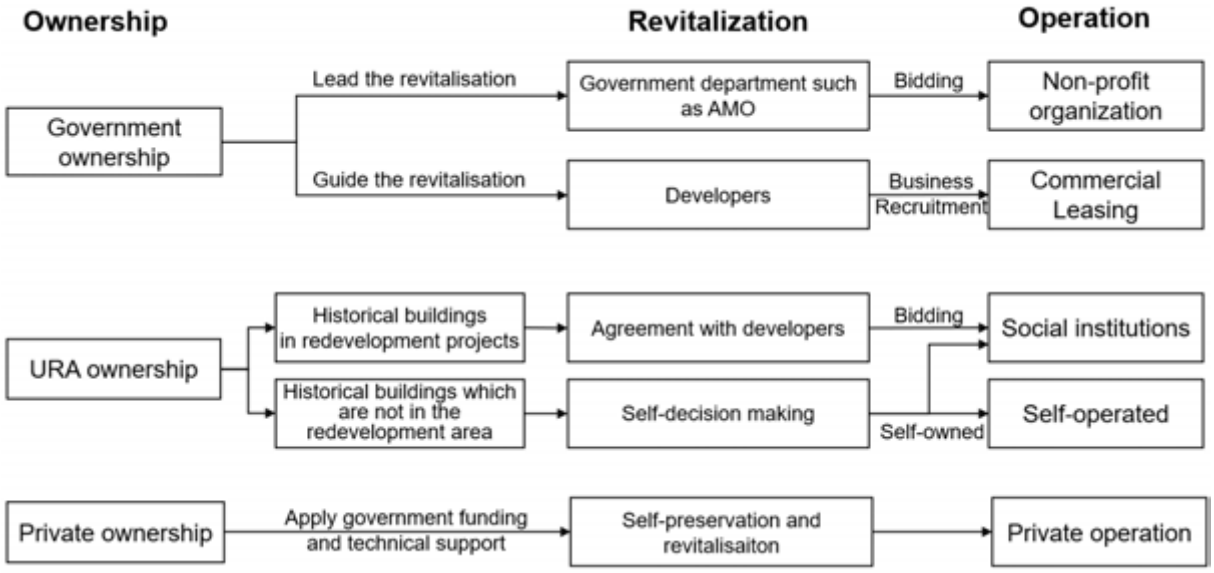

Figure 1. The Revitalization Pathways of Historic Buildings in Hong Kong
Source: By author

Hong Kong's historical building revitalization operates through three property-rights frameworks, forming multiple revitalization paths based on government, URA, and private ownership (Figure 1). Government-owned buildings are revitalized through the R-Scheme, where non-profit organizations are introduced to create public cultural spaces. For buildings with commercial potential, market capitalization is brought in via public bidding. The former Marine Police Headquarters (1881 Heritage) exemplifies heritage-commercial integration, transforming cultural assets into commercial value (Rong et al., 2017). Additional strategies include adaptive reuse as public museums (e.g., Kom Tong Hall as Dr. Sun Yat-sen Museum) or governmental offices (e.g., Old Supreme Court Building as Court of Final Appeal), ensuring functional continuity.

URA-owned buildings are managed with ownership control. Tenant compensation follows district-based property valuation standards(Urban Renewal Authority, 2024), and special projects (e.g., Wing Lok Street) get targeted subsidies like the Home Improvement Allowance (Press Release, 2010). URA executes two typologies: Preserved Buildings in Redevelopment Projects, i.e, contextual conservation integrating heritage elements within redevelopment zones, and Pure Preservation and Revitalisation Projects. From now on, URA has preserved over 60 buildings (Urban Renewal Authority, 2025)through self-operated or leased cultural and commercial programs.

In privately owned historical buildings, owners can revitalise cultural heritage through independent functional transformation. For instance, the Grade III historic residential building at 11 Yuk Sau Street was converted into the F11 Poto Museum, focused on photographic art. The Nan Fung Cotton Mills, an industrial heritage site, was revitalised into an experiential retail and textile art complex. Owners of graded buildings can apply for the Financial Assistance for Maintenance Scheme on Built Heritage with a maximum of HKD 6 million per project. However, grantees must commit to not demolishing or transferring ownership during repairs and allow reasonable public access (Commissioner for Heritage's Office, 2024).

2 Grade 1: Buildings of outstanding merit, for which every effort should be made to preserve if possible. Grade 2: Buildings of special merit; efforts should be made to selectively preserve. Grade 3: Buildings of some merit; preservation in some form would be desirable and alternative means could be considered if preservation is not practicable.

As historical buildings are bundles of cultural heritage, economic resources, and living spaces, their revitalization involves conflicting interests of the government, markets, residents, and civil society. These conflicts manifest in tripartite value contests: authenticity preservation, economic viability, and community equity (Aigwi et al., 2021). Thus, regardless of revitalization pathways, core challenges stem from divergent stakeholder interests and their dynamic interplay. In Hong Kong's high-density context, land scarcity intensifies the conflict between conservation and development. Market-led commercialization can cause gentrification and squeeze public cultural rights (Yung and Chan, 2016). Top-down planning, lacking participatory mechanisms, often disconnects from communal cultural aspirations (Ng, 2018). Mandatory public access requirements in privately-owned heritage spark private-public domain boundary disputes over residential privacy and usage restrictions(Luo and Wen, 2025). These tensions not only hinder revitalization but also undermine social consensus, highlighting the urgency of establishing interest-coordination mechanisms among different entities. Moreover, the long-term sustainability of historical building revitalization requires full-cycle investment, yet high costs deter market, social, and resident participation (Fang and Wu, 2025). Therefore, only by using interest coordination as a starting point and identifying the root of conflicts among entities can we protect cultural authenticity while accommodating diverse interests. This can transform historical buildings from conflict arenas to symbiotic value platforms, ensuring sustainable revitalization of cultural heritage in high-density cities.

3 Revitalisation Modes Under Different Interest Coordination Mechanisms and Case Studies

From the perspective of interest coordination, Hong Kong has established three typical stakeholder collaboration modes in the historical buildings revitalization: the government-social institution collaboration mode, the market-led with benefit recirculation mode, and the community-engaged co-creation mode. These modes balance the demands of multiple stakeholders, achieving coordinated conservation and development.

3.1 The Government-Social Institution Collaboration Mode

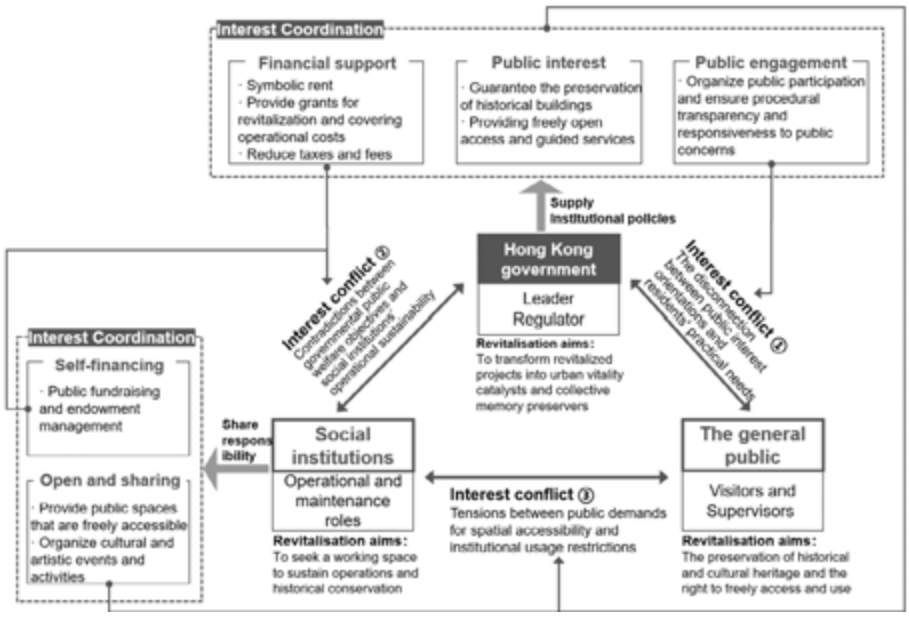

Figure 2. Operational mechanism of the government-social institution collaboration mode Source: By author

This mode is commonly applied in revitalizing government-owned historical buildings. As illustrated in Figure 2, this mode prioritizes government funding and policy-driven initiatives, focusing on public domains such as cultural exhibitions and community services while strictly limiting commercial development. Within this framework, the government assumes the leading role in overseeing and regulating the revitalization process, aiming to transform

revitalized projects into urban vitality catalysts and collective memory preservers. Social institutions, such as non-profit organizations (NPOs), assume operational and maintenance roles, seeking a working space to sustain operations and architectural conservation. The general public, as the visitors and supervisors of these projects, is mainly concerned with the preservation of historical and cultural heritage and the right to freely access and use the spaces. Divergent stakeholder interests arising from distinct roles often trigger three types of conflicts, including contradictions between governmental public welfare objectives and social institutions' operational sustainability, tensions between public demands for spatial accessibility and institutional usage restrictions, as well as the disconnection between public interest orientations and residents' practical needs. To address these, the government coordinates the interests of different parties through institutional arrangements. It offers symbolic rent and tiered financial support to NPOs, such as providing grants for revitalization projects and covering operational costs for the first two years (Commissioner for Heritage's Office, n.d.). The government also implements stringent application reviews and supervision mechanisms to guarantee reasonable preservation, freely open access and guided services. Furthermore, the government organizes public participation to ensure procedural transparency and responsiveness to civic concerns. Selected social institutions collaborate with the government to fulfill obligations, alleviating financial burdens through public fundraising and endowment management while proactively opening historical buildings. In this way, a collaborative mechanism that balances the interests of all stakeholders is established.

The Former Explosives Magazine(Asia Society Hong Kong Center)

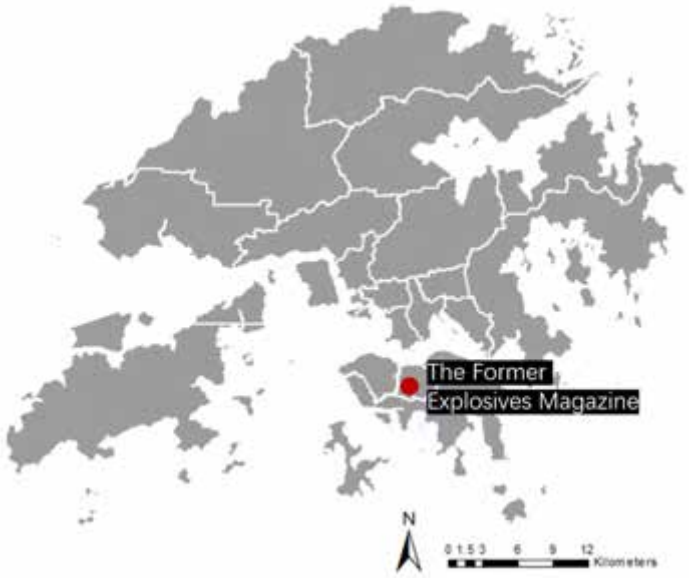

Figure 3. The location of The Former Explosives Magazine
Source: By author

The Former Explosives Magazine, located in Admiralty, Hong Kong Island(Figure 3), is part of the Victoria Barracks, one of Hong Kong's oldest military camps. It comprises four historical buildings, three of which are Grade I and two are Grade II[3]. In 2002, the Hong Kong Government, in collaboration with the non-profit Asia Society Hong Kong Center, leased the former depot site via Private Treaty Grant[4] at a nominal rent of HKD 1,000 to revitalize it

3 A mid-19th century explosives magazine (Magazine A, Grade 1 historic building), an early 20th century explosives magazine (Magazine B, Grade 1 historic building), a mid-19th century laboratory complex (Old Laboratory, Grade 1 historic building), and a 1930s military barracks (the GG Block, Grade 2 historic building).

4 Private Treaty Grant: Land allocation in Hong Kong primarily occurs through public auction for private residential and commercial developments. Under exceptional circumstances, specific projects aligning with established policies and contributing to Hong Kong's socio-economic needs may obtain land through private treaty grants. https://www.landsd.gov.hk/en/land-disposal-transaction/land-transaction/private-treaty-grant.html

as the Asia Society Hong Kong Center's headquarters and a cultural museum. After formally taking possession of the site in 2005, the Asia Society initiated the revitalization project in 2006, completing it in 2012(Figure 4). In the adaptive reuse of these buildings, A and B Warehouses were converted into an exhibition hall and a 100-seat multifunctional theater. The old laboratory was repurposed into meeting rooms and offices. GG Barracks became the administrative office space for the center. To meet modern functional requirements, the project added new service buildings and linked the historical structures with a contemporary bridge (Figure 5), merging old and new elements into a cohesive cultural space.

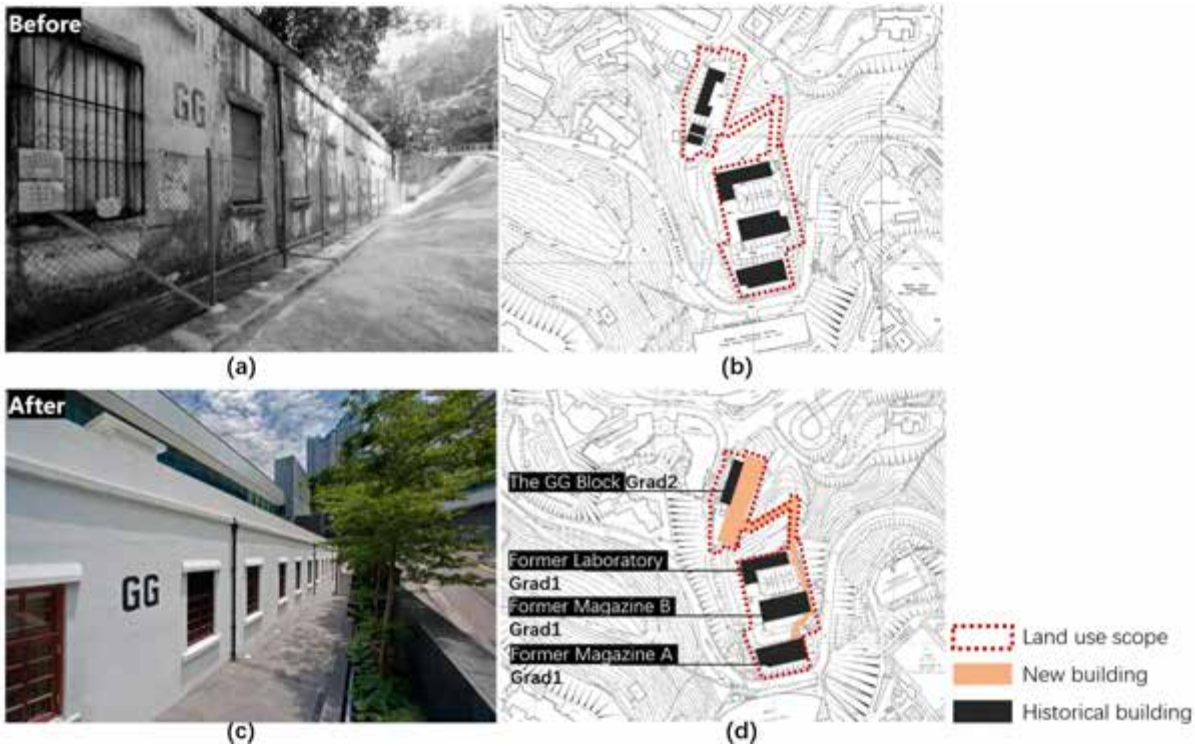

Figure 4. The Former Explosives Magazine before and after revitalization
Source: (a)(c)Asia Society Hong Kong Center;(b)(d)by author

Examining the Asia Society Hong Kong Center revitalization project through the lens of interest coordination reveals a dynamic interplay of competing demands and reconciliation mechanisms among multiple stakeholders. Initial conflicts primarily arose from public and conservation groups concerned about potential compromises to the historical authenticity of the ordnance depot and its ecological context (The Conservancy Association, 2002). These objections delayed project implementation, extending the timeline from the 2002 agreement to a 2005 groundbreaking, prolonging the construction period to 13 years. Concurrently, the budget doubled from HKD 200 million to 400 million, with sustained high operational costs (HKD 30-40 million annually), exposing resource allocation challenges for social institutions in heritage revitalization (Cummer, 2021). The government's symbolic lease arrangement (HKD 1,000 for a 21-year term) and the Asia Society's reliance on philanthropic donations drew public criticism as elitist, perceived as creating a private club for Hong Kong's elite (Chan, 2016).

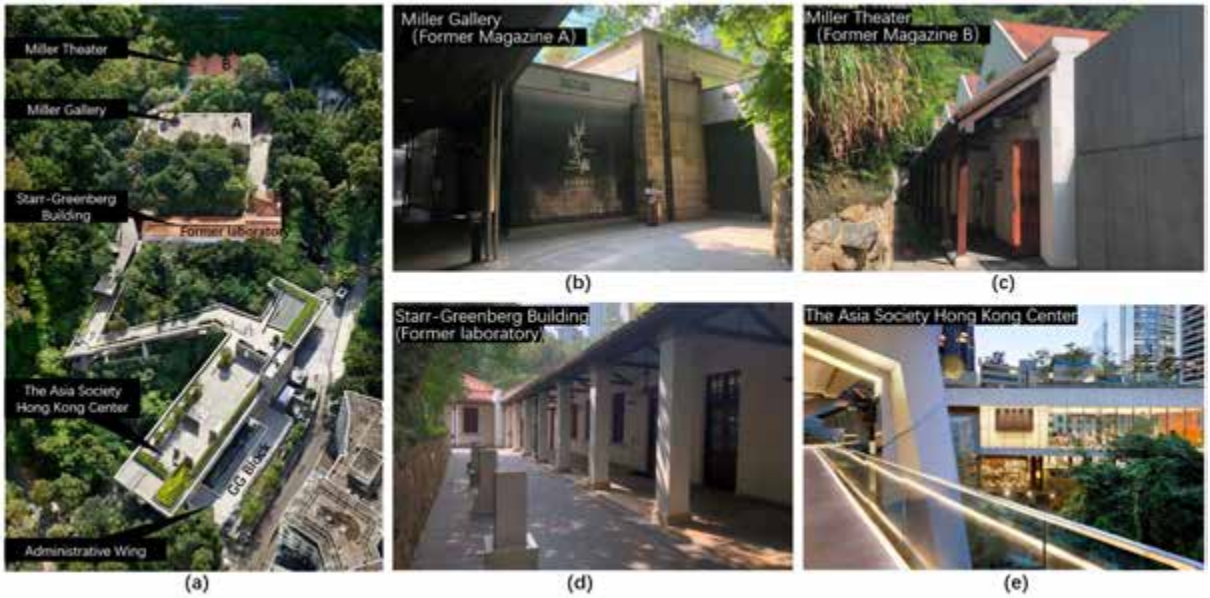

Figure 5. The revitalized former explosives magazine has become the headquarters of the Asia Society Hong Kong Center
Source: (a) K.Cummer;(b)(c)(d)(e)Asia Society Hong Kong Center

Facing initial public skepticism, the ASHKC later eased tensions through multi-dimensional cooperation. Financially, it established a mechanism led by social capital with government support. All HKD 400 million construction funds came from private donations, including HKD 102.5 million from the Hong Kong Jockey Club (Legislative Council, 2005). The government only offered maintenance subsidies in 2023-2024 via the Historic Buildings Maintenance Sponsorship Scheme, reinforcing the non-profit mandate by allocating all revenues to operational upkeep and enhancing resource allocation transparency. In terms of space use, the Center implemented inclusive measures such as complimentary guided tours(Asia Society, 2023) and public art exhibitions, transforming the revitalized heritage site from an elite enclave to a socially shared space, thereby gradually dispelling public distrust. The adaptive reuse of the Former Explosives Magazine, including the conversion of Buildings A/B into exhibition halls and a theater, achieved a balance between historic preservation and contemporary cultural functionality. This approach garnered professional acclaim, demonstrating practical value in reconciling philanthropic funding, governmental oversight, and public demands.

3.2 The Market-Driven with Benefit Recirculation Mode

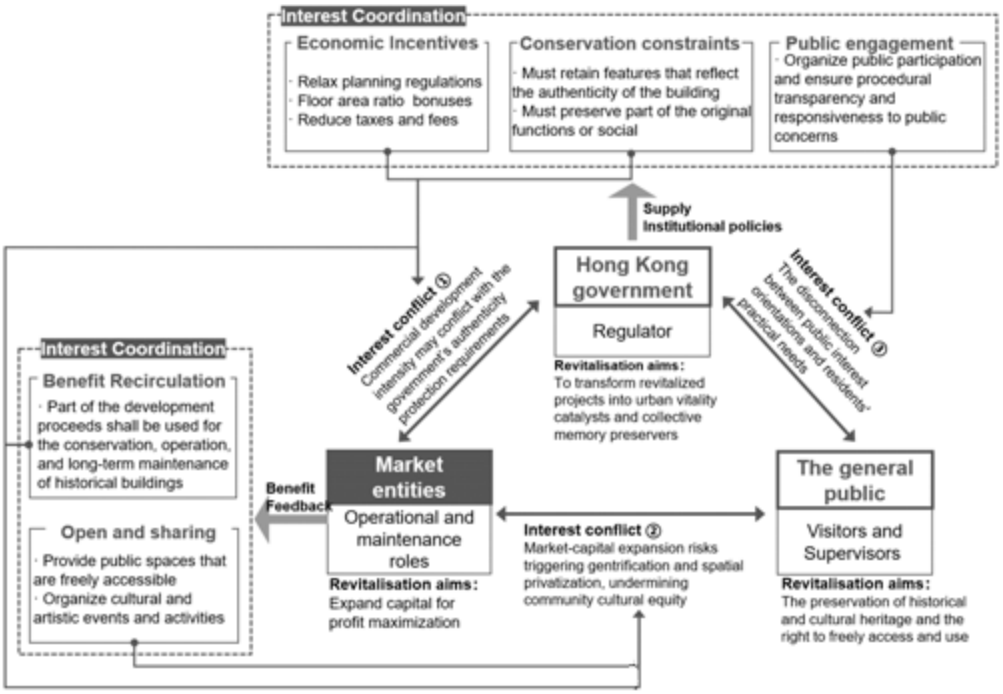

Figure 6. Operational mechanism of the market-driven with benefit recirculation mode
Source: By author

This mode is primarily applied to private historical building revitalization, a developer-led process. As Figure 6 shows, market entities, as operators and maintainers, leverage the building's cultural value to expand capital space for profit maximization. The government assumes a regulatory role, enforcing conservation obligations while promoting these projects as new urban vitality drivers. The public, as users and supervisors, prioritizes heritage continuity and equitable access to revitalized spaces. This mode also faces multiple stakeholder conflicts. Market-capital expansion risks triggering gentrification and spatial privatization, undermining community cultural equity. Commercial development intensity may conflict with the government's authenticity protection requirements, potentially degrading historic fabric through over-renovation. Insufficient profit margins may deter market participation, compounded by misalignments between regulatory efficacy, public expectations, and functional mismatches with community needs. To reconcile these conflicts, the government implements dual regulatory mechanisms. Policies like floor area ratio (FAR) bonuses and relaxed planning regulations reduce revitalization costs and enhance commercial feasibility. Technical conservation guidelines limit development intensity, enforce adaptive reuse standards, and embed authenticity protection in plans. Concurrently, a portion of commercial revenues must be allocated for building maintenance, with designated public access zones to mitigate the impact of capital expansion on public interests. Market entities reciprocate by reinvesting profits into conservation, environmental improvement, and public cultural services, fostering a symbiotic cycle where commercial operations sustain conservation efforts, which in turn enhance commercial viability.

The former headquarters building of CLP (CLP Pulse)

Figure 7 The location of CLP Group Headquarters
Source: By author

The former headquarters of China Light and Power Company (CLP), situated on Argyle Street in Kowloon (Figure 7), was originally constructed in 1940 and embodies profound urban historical significance. This three-story reinforced concrete building features brick-patterned ceramic tile cladding, exemplifying distinctive Art Deco architectural motifs. In 1959 - 1968, two adjacent residential buildings were converted into offices (Figure 8) and linked to the headquarters, expanding the complex. The building's clock tower once served not only as a critical public timekeeping facility but also as a local landmark, silently bearing witness to Kowloon's developmental trajectory. Historically, residents frequently paid electricity bills on-site, forging an enduring connection between the building and community life, thus solidifying its role as a living repository of collective urban memory (am730, 2023).

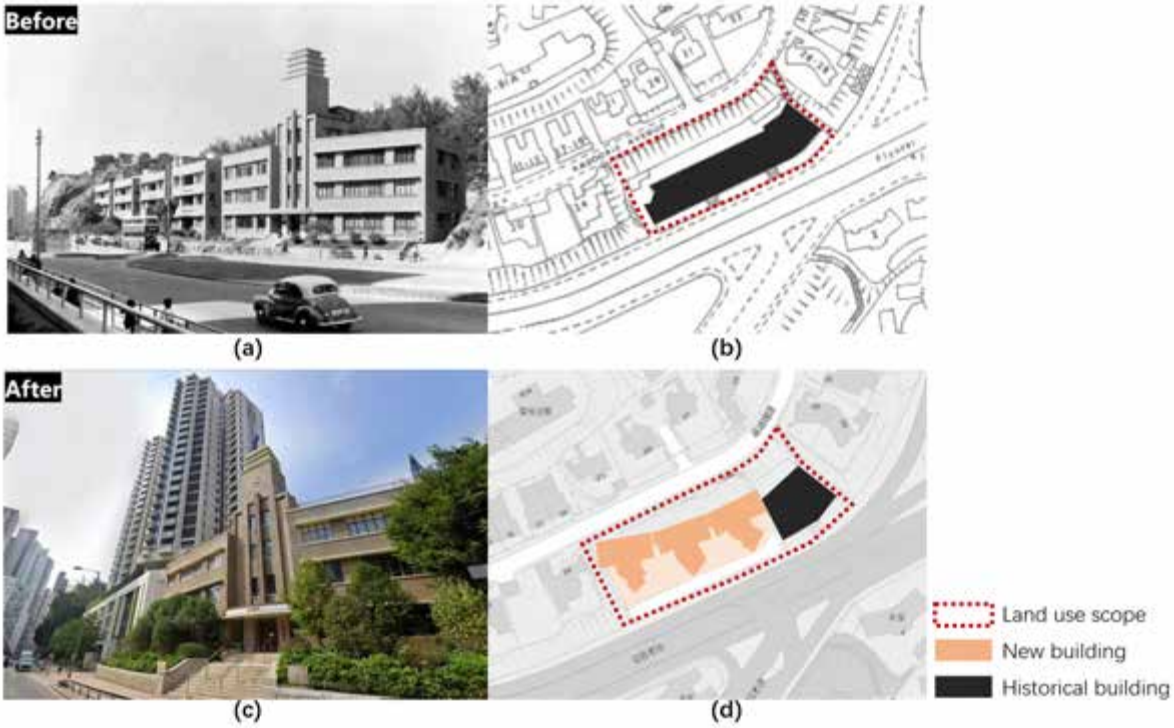

Figure 8. The former headquarters of CLP before and after revitalization
Source: (a)CLP Pulse;(b)(d)by author; (c)Google Street Map

From the lens of interest coordination, the revitalization of CLP Group's former headquarters has been marked by conflicts and coordination among multiple stakeholders. The initial contradiction between redevelopment returns and cultural preservation emerged when the government-approved 43-story residential redevelopment plan (2001) directly clashed with authenticity preservation demands following the building's proposed Grade 1 heritage designation in 2009.CLP contested the heritage status based on commercial priorities, suspending the redevelopment plan. In 2011, CLP provided a proposal for partial conservation with partial redevelopment, sparking new disputes. Local residents raised concerns that three residential buildings, forming a 70-metre-long and 100-metre-high screen wall, might cause canyon effects and trap vehicle exhaust fumes (Green Sense, 2011), highlighting tensions between high-density development and environmental rights. Conservation groups insisted on preserving the entire building and opposed only keeping the clock tower, criticizing the fragmented protection approach (Oriental Daily, 2011), exposing fundamental disagreements over commercial development intensity versus authenticity preservation.

In response to these conflicts, the government facilitated interest balancing through policy adjustments. Development rights were transferred to market entities. The Town Planning Board approved CLP's partial demolition plan, relaxing building height restrictions from 80 meters to 100 meters and increasing the FAR to 5.5 (Oriental Daily, 2012). These measures compensated for floor area losses due to heritage retention, incentivizing corporate conservation participation. Simultaneously, conservation clauses enabled a 23% reduction in land premium payments for China Light and Power in 2018 (Ma, 2018), further motivating market engagement through fiscal concessions. CLP reciprocated by fulfilling social responsibilities through functional adaptation. The clock tower was revitalized as a cultural center (Figure 9), hosting free public exhibitions such as Power World and Humanity & Intangible Heritage, alongside multilingual guided tours (English, Cantonese, and Mandarin). This transformation established a hybrid space for historical interpretation, cultural education, and community interaction. By reallocating commercial profits to public cultural services, the company addressed demands for equitable cultural access, demonstrating responsiveness to civic rights.

Figure 9. After revitalization, the former headquarters of CLP has been transformed into a public space integrating historical display, cultural education, and community interaction
Source: CLP Pulse

3.3 The Social-Engaged and Community Co-Creation Mode

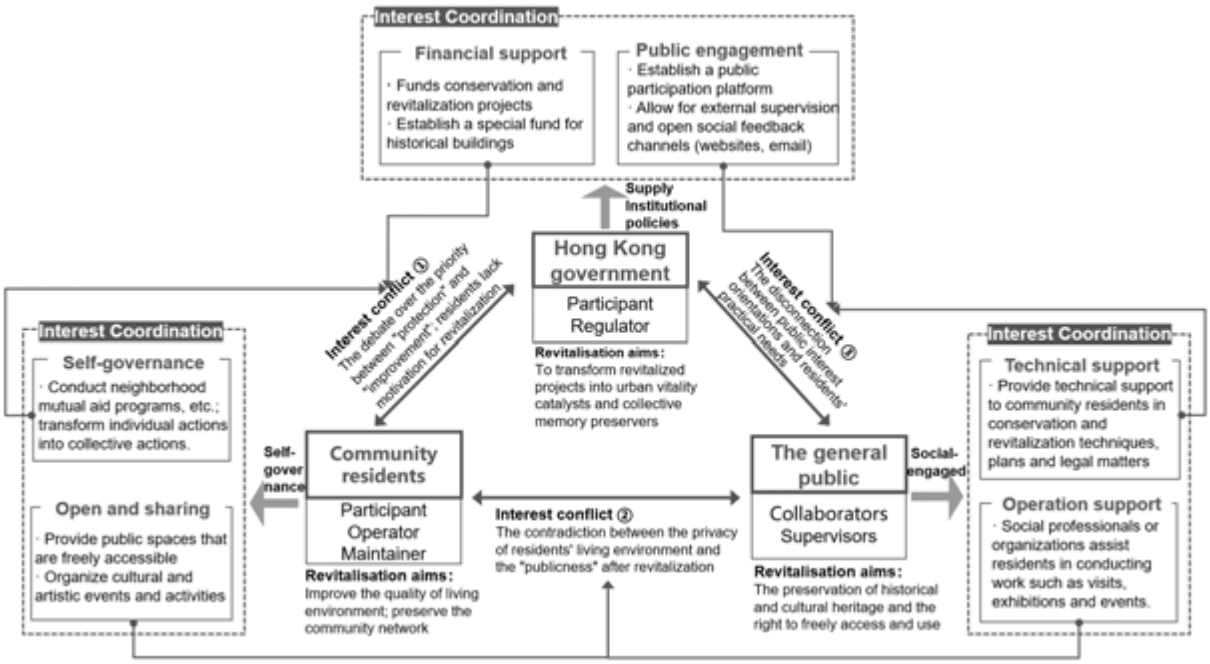

Figure 10. Operational mechanism of the social-engaged and community co-creation mode
Source: By author

In this mode (Figure 10), residents, merchants, and tenants within historic buildings serve as core participants who act as both operators and maintainers of revitalization projects. Their primary objectives involve improving residential environmental quality while preserving their essential social networks (Ng, 2018). The public transitions from traditional users to co-creation participants, while the government assumes dual roles as both participant and coordinator, striving to stimulate new dynamics for regional development while preserving urban historical and cultural heritage. Key conflicts of interest manifest in four dimensions: 1) the tension between residents' privacy requirements and the post-revitalization publicization of buildings; 2) the divergence between governmental prioritization of historical environmental authenticity and residents' practical needs for environmental improvements; 3) diminished participation incentives due to high revitalization costs; and 4) cognitive disparities between governmental revitalization objectives and public perceptions regarding resource allocation and participatory rights. To reconcile these conflicts, the Hong Kong government has implemented institutional support through financial mechanisms and public engagement strategies. This includes direct funding for conservation projects and the establishment of special funds to alleviate residents' economic burdens. Residents, tenants, and merchants engage in co-construction through neighborhood mutual assistance and community self-governance, while appropriately opening shared spaces to facilitate public access to historical-

cultural resources. Social stakeholders, including experts, scholars, and professional institutions, provide technical support in revitalization strategies, design solutions, and legal consultation. They assist in organizing cultural activities such as guided tours and exhibitions, fostering collaborative efforts between residents and social forces to establish a "living community" that achieves integration of historic building preservation, community quality enhancement, and cultural inheritance.

Staunton Street/ Shing Wong Street(H19)

Figure 11. The location of Staunton Street/ Shing Wong Street(H19) Source: By author

The Staunton Street and Shing Wong Street community, located in the Central District, Hong Kong Island (Figure 11), traces its origins to mid-19th century commercial development. Initially evolving into an international lower and middle class settlement where Chinese-Portuguese labor families established roots, Staunton Street gradually developed into 30 tenements, namely Tong Lau (唐樓)[5], by the late 19th century. These buildings collectively formed the culturally and historically significant landmark known as Thirty Houses (卅間). During the early 20th century, Dr. Sun Yat-sen frequented the area, which became a significant hub for Hong Kong's early educational institutions, revolutionary networks, and newspaper industry, marking its critical role in the city's printing history. Post-World War II reconstruction transformed it into a vibrant community characterized by wet markets, restaurants, and close-knit neighborhood ties. Since the 1990s, urban road planning initiatives have enhanced community vision, preserving historical heritage while elevating community identity(SVhk, 2019). As such, this neighborhood embodies not only layered historical narratives but also a cultivated cultural distinctiveness (Figure 12).

5 Tong lau were historically inhabited only by Chinese people, hence they are commonly referred to as "tong lau". This architectural style was quite common in towns and cities of southern China during the 19th century.

Figure 12. H19 before and after revitalization
Source:(a)(c) URA; (b)(d)by author

Examining the H19 community revitalization project through the lens of interest coordination, its progression demonstrates a characteristic trajectory of conflict eruption, multi-stakeholder negotiation, and mode innovation. Intense conflicts of interest emerged since its launch. The 2003 commercial-residential redevelopment plan proposed by URA triggered dual opposition from residents and conservation advocates. Residents demanded fair compensation (referencing property appraisal values in the same district), tenant rights protection, and transparent communication mechanisms, citing severe building dilapidation and prolonged project stagnation due to litigation (Legislative Council, 2004). Concurrently, civic groups and conservation organizations advocated preserving the historical fabric and community culture embodied in this tenement community (Press Release, 2010), directly challenging URA's initial high-density oriented redevelopment. The 2010 film Echoes of the Rainbow, using Wing Lee Street as its backdrop, amplified public demands for preserving urban memory (Lui, 2022), exposing fundamental contradictions between commercial development and cultural conservation, as well as between residents' livelihood rights and urban renewal efficiency.

To reconcile the interests of all parties, the government and the URA adjusted the plan and introduced community-engagement initiatives. URA abandoned the original high-density development scheme, reducing the plot ratio from 8 to 4.5 (Press Release, 2010). Aligned with the revitalization policy for the former Hollywood Road Police Married Quarters, Wing Lee Street was rezoned as a Comprehensive Development Area in 2011 and further designated for cultural-historical community use in 2020, shifting from demolition-redevelopment to preservation of historical-cultural ambiance(Legislative Council, 2012).In terms of implementation, URA introduced a community-engagement mode in 2019, commissioning Social Ventures Hong Kong (SVhk) to establish a multi-stakeholder platform integrating residents, conservation groups, and professional institutions. Through sustained dialogue, this collaborative process developed an inclusive revitalization framework(SVhk, 2019). The plan transformed tenement buildings into mixed-functional complexes featuring "co-living units + retail units + community-making units," preserving the terrace-style urban fabric while providing housing improvement options.. Socio-culturally, residents' self-organized activities, such as community nurseries and plant-sharing programs, strengthened neighborhood bonds. Intergenerational integration was fostered through youth-elderly co-working spaces, while economic sharing concepts revitalized community vibrancy (Figure 13). Concurrently, URA implemented a building rehabilitation program with owners' associations to enhance environmental quality, and commissioned professional organizations to manage co-living projects. This approach achieved multidimensional progress encompassing physical restoration, social network cultivation, and cultural value regeneration.

4 Discussion

4.1 The comparison of the three modes

Hong Kong's three interest coordination modes for historic building revitalization in high-density urban contexts demonstrate distinct strategic responses to revitalising costs and public interest preservation, with marked operational divergences in practice. The government-social institution collaboration mode, as a top-down public welfare approach, leverages government-owned property rights through symbolic rents, fiscal subsidies, and policy instruments to enable non-profits delivering cultural exhibitions and community services. While ensuring authentic preservation and safeguarding public accessibility under governmental stewardship, this mode's heavy reliance on public financing raises sustainability challenges in balancing non-profit operational costs against their social missions. The market-driven with benefit recirculation mode, operating through public-private bundling mechanisms, centers on developers, receiving planning incentives, such as FAR bonuses and planning concessions, to integrate heritage conservation with commercial projects. Exemplified by the CLP Clock Tower's conversion into a free cultural venue, this approach effectively mobilizes private capital while mandating profit-sharing for conservation. However, its commercial orientation risks gentrification and privatization of communal spaces (Yung and Chan, 2016), frequently triggering community dissatisfaction regarding benefit distribution. Contrastingly, the social-engaged and community co-creation mode initiates bottom-up revitalization through multi-stakeholder negotiation, exemplified by URA's acquisition-based community making in the H19 project. While effectively preserving cultural identity and achieving high social acceptance (Yung et al., 2015), it requires sustained governance to reconcile immediate livelihood improvements with long-term conservation goals.

In the three modes, the government dynamically shifts from a leader to a regulator and then to an enabler, yet it remains the defender of historical buildings' public attributes. Across all paradigms, governments employ institutional frameworks encompassing funding regulations, conservation mandates, and participatory mechanisms to safeguard core objectives of cultural continuity and public accessibility against commercial encroachment or individual interests. Concurrently, authorities bear ultimate regulatory responsibilities through controlling commercial development intensity and monitoring fiscal subsidy allocation, thereby mitigating risks of authenticity erosion and benefit inequity during revitalization processes. Notably, URA, with a semi-governmental and semi-market identity (Zhang and Wang, 2024), leans differently in various modes. In market-led, benefit-feedback revitalization, its market role dominates, and its governmental role weakens, as seen in the Johnston Road Project (J Residence) involving the revitalization of 60 - 66 Johnston Road and Woo Cheong Pawn Shop (URA, 2008). Conversely, its governmental identity prevails in community co-creation initiatives through programs like H19, where market considerations become subsidiary to participatory governance.

The resolution of stakeholder conflicts fundamentally lies in innovative institutional designs for interest concessions and benefit-sharing mechanisms across different modes. In government-social institution

collaborations, this mode reconciles contradictions through public resource transfers. The government relinquishes historical building usage rights via symbolic rents and directly funds initial revitalization costs, such as covering restoration works and two-year operational expenses in revitalization schemes, thereby addressing high conservation expenditures. Social institutions then assume public service delivery through nonprofit operations. The market-led benefit-recirculation mode resolves funding constraints through development profit redistribution. Market entities gain planning concessions (e.g., plot ratio incentives) and commercial premiums from heritage cultural value (Licciardi and Amirtahmasebi, 2012), while contractually reinvesting partial profits into public space enhancement or conservation. The government essentially "purchases" conservation outcomes through regulatory incentives, achieving a commercial-public interest exchange. The community-engaged co-creation model establishes community value co-creation scenarios where residents sacrifice short-term redevelopment profits in exchange for improved living environments, community identity preservation, and social network maintenance, establishing shared value co-creation (Zheng et al., 2020). Governments and social institutions transform heritage conservation into tangible quality-of-life enhancements through community placemaking initiatives.

4.2 Revitalization Policy Optimization and Implications

To address existing challenges across these modes, the Hong Kong government should refine heritage conservation policies through four dimensions: funding system construction, economic incentive design, balanced rigid-flexible governance, and deepened public participation.

Funding system construction

The government should establish a multi-stakeholder funding framework. This requires expanding support for public education, academic research, and maintenance projects within existing heritage conservation funds while strengthening the coordinating role of heritage trusts to enhance fiscal efficiency. Concurrently, a dedicated heritage revitalization fund should be established to support vulnerable groups' adaptive transitions during revitalization processes(Yung et al., 2015). Policy instruments like tax incentives and honorary recognition should channel social capital from corporate donations and lottery surpluses into heritage conservation (Liu and Tang, 2014). NPOs should be encouraged to manage government-owned historic buildings through social enterprise models (Antiquities Advisory Board, 2014), permitting revenue reinvestment from low-impact commercial operations, such as cultural experiences and creative retail. This approach would ultimately form a sustainable financial ecosystem integrating fiscal allocations, social capital, and project-generated income, ensuring economic viability for revitalisation.

Economic incentives design

The government should integrate policy instruments (Antiquities Advisory Board, 2014), establishing a transparent tiered incentive system. Based on evaluations of historical significance and adaptive reuse potential, differentiated incentives, such as maintenance subsidies and plot ratio concessions, should target high-adaptability projects to enhance market participation (Langston et al., 2008). Concurrently, mandatory benefit-reinvestment rules must institutionalize profit-sharing clauses in redevelopment agreements, requiring market entities to proportionally allocate value-added benefits from rental premiums and asset appreciation to heritage maintenance, public space enhancement, or community services. This ensures commercial developments reciprocally replenish public interests while securing economic returns, fostering a virtuous cycle between conservation efficacy and developmental benefits.

Governance System Optimization: Balanced the rigid-flexible

Governance frameworks must reconcile mandatory conservation requirements with adaptive management. The government should legislatively mandate compulsory public access provisions for revitalization projects (Lang et al., 2018), resident retention incentives, and social obligations like public space allocation ratios (Yung and Chan, 2012). Collaborative governance with social institutions necessitates strengthened procedural oversight, requiring periodic submission of visitor statistics (Audit Commission, 2013), long-term viability assessments, and dynamic adjustments to funding caps(Audit Commission, 2020) to safeguard the public attributes of historic buildings. Meanwhile, policy adjustments should relax overly restrictive modern regulations (e.g., fire safety codes) on heritage buildings by exempting non-critical safety standards. Technical adaptations should enable flexible integration of conservation techniques with contemporary functionalities (Yung and Chan, 2012). Local service priority clauses must further ensure community welfare, requiring commercial tenants to

prioritize neighborhood employment and services (Cheung and Chan, 2014). This hybrid governance framework institutionalizes both regulatory safeguards and adaptive flexibility, addressing heritage-specific operational challenges while maintaining public accountability.

Public Participation and Educational Innovation

The government could innovate heritage education through digital platforms such as QR-code-guided tours and virtual reality experiences, enhancing owners' awareness of timely maintenance while leveraging public engagement to constrain excessive commercialization (Yung and Chan, 2016). Participation channels should be expanded via District Councils and NGOs, incorporating resident consultation mechanisms for functional needs during planning phases(Lam et al., 2022). Operational agreements should embed free community workshops and multilingual revitalization documentation (Cheung and Chan, 2014), with independent heritage management bodies facilitating bottom-up participatory planning to optimize transparency in balancing diverse interests. A tiered public access policy should be implemented: government-owned historic buildings maximize physical accessibility, while private properties adopt 3D archival sharing as a non-intrusive alternative to onsite visits (Antiquities Advisory Board, 2014). This approach safeguards cultural rights while respecting owner privacy, forming a comprehensive public engagement network spanning education, planning consultation, operational involvement, and access management.

5 Conclusion

This study deciphers three core revitalization modes through the lens of interest coordination, elucidating governance logics for multi-stakeholder equilibrium in high-density cities. These modes institutionalize negotiable interest commonality by translating development profits, cultural preservation, and community well-being into tradable governance metrics, establishing a "benefit concession, value co-creation and outcome sharing" governance cycle. This framework offers localized references for cities like Shenzhen and Shanghai to address challenges of exorbitant conservation costs, development conflicts, and weak public engagement. However, limitations arise from the exclusive focus on Hong Kong's singular context, insufficient analysis of adaptive mechanisms under divergent property regimes, such as mainland China's land tenure system, and inadequate exploration of latent factors like quantified community identity assessments and social capital allocation efficiency. Future research should extend comparative analyses to Tokyo, Singapore, and other high-density cities, prioritizing dynamic interest mediation mechanisms in multi-actor negotiations. Integrating surveys and benefit models could empirically evaluate the efficacy of these models across dimensions like cultural continuity, resident satisfaction, and commercial sustainability.

Abstract
We examine the integration of cultural heritage into climate adaptation and flood risk governance through comparative case studies in Norway and Italy, undertaken within the AGREE project. Using a relational analytical framework to assess the policy portfolios connecting these fields, we analyse how heritage is framed in adaptation and risk policies, how vulnerability is conceptualised, and how integration unfolds across sectors and scales. Norway provides formal definitions and planning tools for heritage vulnerability, yet implementation remains inconsistent. Italy demonstrates diagnostic awareness of heritage risk, but operational integration is lacking. Our findings highlight persistent gaps in vertical and horizontal policy alignment, while identifying entry points for transformative change. Reframing cultural heritage in terms of its relational capacities may support more integrated, adaptive, and resilient approaches to climate risk governance.

Introduction

Flood protection is a growing priority in local adaptation strategies across Europe (Cumiskey et al., 2019). Over the past two decades, urban flooding has intensified due to shifting precipitation patterns and temperature fluctuations (Bueno Rubial et al., 2024). Extreme rainfall events, although statistically rare, are becoming more frequent and severe, posing increasingly significant risks to cities. Regional climate projections indicate these trends will intensify by century's end, especially in Norway and Italy (Amundsen & Dannevig, 2021; Vitale et al., 2022), underscoring the rising importance of flood risk management (FRM) in climate change adaptation (CCA).
While technological innovations have improved hazard control and set safety standards, FRM has evolved beyond a technical field. It increasingly intersects with governance, spatial planning, and societal concerns. Risk-based approaches emphasize reducing exposure and vulnerability (IPCC, 2022); however, the practical integration of spatial policies into FRM remains limited.

Meeting today's climate challenges requires transformative adaptation—structural shifts in governance logics, regulatory norms, and institutional values (UNFCCC, 2024). Climate risk management (CRM) frames this as a long-term, non-linear process that addresses the root causes of vulnerability across scales, from communities to national regimes (Deubelli & Mechler, 2021). Although promising, this transformation remains difficult to operationalise due to entrenched policy silos and institutional inertia (Hölscher et al., 2019).

CCA measures, such as water reservoirs and flood infrastructure, rely on multi-level governance (Termeer et al., 2017) and diverse policy instruments (Cumiskey et al., 2019) This mix of policies also presents significant governance and implementation challenges. Their inherent complexity, stemming from multiple, often conflicting goals and instruments across sectors and governance levels, can result in fragmentation, redundancy, or institutional lock-in. The variation of policy mechanisms to address CCA and increased climate risks often evolves incrementally rather than through deliberate design, complicating optimization and integration (Lesnikowski et al., 2019). Additional challenges include blurred responsibilities, inconsistent policy timeframes, and difficulties in aligning spatial and administrative boundaries (Nilsson & Persson, 2003). Thus, we analyze the policy mixes employed at national, regional, and local levels according to a policy-mixes structured approach to understanding how governments combine various goals and instruments. Examining how these two cities integrate CCA and cultural heritage conservation policies amidst escalating flood risk offers valuable insight into the complexities of policy frameworks and the challenges of systemic and landscape-based cross-sectoral integration.
Adaptation strategies require coordinated policy mixes across levels of government. Local actions are shaped by broader institutional frameworks, and practical strategies often combine instruments such as spatial planning,

infrastructure standards, and financial incentives (Cumiskey et al., 2019). Yet this complexity can lead to fragmentation and institutional lock-in, especially when policy instruments evolve incrementally (Lesnikowski et al., 2019), or when responsibilities and spatial jurisdictions are poorly aligned (Nilsson & Persson, 2003).

This paper analyses policy mixes for CCA and FRM across national, regional, and local levels. We focus on how governments combine diverse instruments and goals, and how these combinations impact the integration of cultural heritage. Examining how two cities—Lillehammer in Norway and Moncalieri in Italy—navigate climate adaptation and heritage conservation amidst increasing flood risks offers valuable insight into the challenges of systemic, cross-sectoral governance.

The AGREE (Advancing Cultural Heritage Governance for Resilient Climate Adaptation) project investigates the intersection of FRM and cultural heritage management—two domains where adaptation is often operationalised. It asks: What is the role and effectiveness of cultural heritage governance frameworks in advancing climate action across countries and governance levels? We compare two contrasting governance contexts: Italy's centralized, sector-based model with strong civil protection traditions, and Norway's decentralized, participatory planning model that emphasizes vulnerability assessments (Amundsen & Dannevig, 2021). Despite these differences, both countries face intensifying flood risks to heritage, creating a shared ground for comparison.

Moncalieri, in the Piedmont Region, is part of Turin's metropolitan area and lies along the Po River. The city has experienced several flood events, notably in 2000, revealing systemic vulnerabilities linked to ageing infrastructure and fragmented governance. Lillehammer, in Norway's Innlandet region, has a long history of floods, including the devastating "Storofsen" flood of 1789 and another major event in 1995 that severely affected heritage areas. Both cities illustrate complex interdependencies between water systems, urban development, and historic environments.

To assess how adaptation and heritage objectives interact within policy discourses, we combine policy-mix and discourse analysis. We map the portfolios of planning, regulatory, and capacity-building instruments for FRM and heritage management, then analyse how they frame climate risk, resilience, and heritage values. This approach uncovers discursive misalignments or synergies and helps identify capacities and gaps that shape cross-sectoral coordination. Applying this to Turin and Lillehammer reveals how climate adaptation is—and is not—being integrated with cultural heritage governance in flood-prone urban areas.

Theoretical Framework

Sustainability transformations require a shift in how we conceptualise relationships between humans, nature, and governance systems. West et al. (2020) call for a relational turn in sustainability science, arguing that dualistic thinking—such as the separation of nature and culture—hinders our capacity to address complex socio-ecological challenges. Relational approaches instead view systems as dynamic and co-constituted, shaped by continuous interactions. This shift enables more inclusive and transformative governance by emphasising the relationships and processes that underpin decision-making and lived experience.

This relational perspective offers a foundation for addressing climate risks to cultural heritage. It moves beyond siloed, asset-based approaches and recognises heritage as a socially embedded and evolving element of place, memory, and identity—capable of contributing to climate adaptation, not just requiring protection.

Recent convergence between landscape and heritage discourses reflects this shift. Both emphasise place-based, long-term stewardship and promote participatory, cross-sectoral governance (Galan et al., 2023). Landscapes are increasingly understood not only as physical environments but also as cultural and emotional infrastruc-

tures—deeply embedded in how communities relate to place (López Sánchez et al., 2020).

The Historic Urban Landscape (HUL) approach embodies these principles. It seeks to embed heritage management within wider territorial development goals (Bandarin & van Oers, 2012), moving away from static conservation towards adaptive governance models that integrate ecological, social, and cultural values (Veldpaus & Pereira Roders, 2017). HUL thus supports systems thinking in heritage governance, aligned with broader adaptation agendas.

This convergence prompts key questions: How is cultural heritage framed in adaptation and risk policy? How can relational approaches like HUL inform governance mechanisms that integrate climate, heritage, and spatial planning? To answer these, we apply an analytical framework combining three interrelated lenses: (1) cultural heritage as a relational actor in policy discourse; (2) climate risk management (CRM); and (3) policy integration (PI).

Cultural Heritage as a Relational Actor in Policy Discourse

We build on Guzman (2025), who proposes a framework for analyzing how cultural heritage is conceptualized and operationalized within national climate policy portfolios. This analytical framework serves to trace discursive shifts, from portraying heritage as a vulnerable asset to recognising it as a relational actor that contributes to adaptation processes. This repositioning opens new roles for heritage in enabling cross-sector collaboration, adaptive planning, and inclusive decision-making.

Through discourse analysis as defined by (Hajer, 1993), this framework examines how policy narratives shape the framing of heritage, define policy problems, and legitimise governance responses. It identifies three key dimensions through which cultural heritage becomes integrated in adaptation governance:

- Paradigm shifts: how heritage discourses evolve from preservation to adaptation;
- Policy cycle integration: whether heritage is addressed from planning to implementation and monitoring;
- Collaborative governance: How heritage facilitates coordination across sectors.

This approach allows us to examine not only whether heritage is included in policy, but how it is framed—as passive or active, static or dynamic, vulnerable or adaptive. It also highlights heritage's potential to mediate between technical systems and lived experiences of place and change.

Framing heritage as a relational actor thus repositions it as more than a sectoral concern. It becomes a vehicle for transformative change, capable of mobilising shared values, institutional innovation, and context-sensitive knowledge. This conceptual shift aligns with recent calls in adaptation and heritage literature to treat cultural assets not as isolated monuments, but as embedded within evolving socio-spatial systems that both shape and are shaped by climate risks.

Climate Risk Management (CRM)

The second lens builds on climate risk management as a governance framework that integrates climate adaptation and disaster risk reduction. CRM moves beyond reactive, hazard-based models typical of traditional disaster risk management (DRM), and instead emphasises proactive, systemic approaches that address the root causes of vulnerability (Leitner et al., 2020).

CRM recognises that risk is shaped not only by exposure and hazard, but also by governance responses. Poorly

designed interventions may inadvertently increase risk, particularly when they ignore social values, historical context, or community capacities (Andrews et al., 2023). For cultural heritage, this highlights the importance of engaging with the meanings of place, identity, and continuity in climate strategies.

By applying CRM to cultural heritage, we extend beyond technical assessments of material degradation. This lens highlights how vulnerability is socially constructed and historically situated, and how heritage can serve as a resource for building resilience, particularly when planning frameworks acknowledge its symbolic, experiential, and adaptive dimensions.

CRM thus reinforces the relational framing of heritage. It calls for integrated, long-term planning approaches that consider cultural systems as both at risk and part of the solution. In the context of this study, CRM provides a means to assess whether risk policies adequately account for the multifaceted nature of heritage vulnerability and whether heritage is being effectively activated in building adaptive capacity.

Policy Integration (PI)

The third lens addresses policy integration as a strategy for overcoming fragmentation between cultural heritage, spatial planning, climate adaptation, and disaster risk management. Following Lafferty and Hovden (2003) and Tosun and Lang (2017), we adopt a dual perspective: horizontal integration examines the extent to which cultural heritage is linked to climate and environmental sectors through regulatory, planning, and institutional instruments. It asks whether heritage is treated as a cross-cutting concern or confined to sectoral mandates. Additionally, vertical integration examines whether heritage-related adaptation objectives are consistently addressed across different scales and whether feedback mechanisms exist between national frameworks and subnational implementation. Inconsistent integration across these levels can undermine both climate resilience and heritage protection.

Effective PI supports mutual reinforcement of policies and enhances collaboration between actors. It also enables cultural heritage to function as a bridge between technical planning, institutional structures, and community-based knowledge.

This is particularly relevant in flood risk governance, where overlapping responsibilities, divergent planning cycles, and fragmented data systems often challenge implementation. Policy integration can help align adaptation and heritage goals, reduce duplication, and open space for transformative governance approaches.

By combining the lenses of CRM and PI with the discourse-oriented analysis of heritage as a relational actor, we aim to assess not only whether and where heritage appears in policy, but also how it is conceptualised and what capacities it brings to governance systems.

This framework enables a more nuanced evaluation of whether heritage is positioned as a passive object of protection or as an active contributor to resilience and systemic adaptation. Together, the three lenses provide the conceptual foundation for our comparative analysis of how cultural heritage is integrated into climate adaptation and flood risk planning in Norway and Italy.

Methodology

This study adopts a qualitative, comparative case study approach to examine how cultural heritage is conceptualised and integrated into climate adaptation and risk frameworks across governance levels in Italy and Norway. The analysis focuses on multi-level governance arrangements, flood risk management, and the degree of policy

integration—both vertical (across scales) and horizontal (across sectors). Case selection is based on the AGREE project's empirical focus on urban heritage historically exposed to flood hazards, situated within distinct planning cultures, institutional architectures, and heritage governance frameworks.

Data sources

The empirical analysis draws on a broad set of policy documents related to climate adaptation, disaster risk management, flood risk planning, and cultural heritage management at national, regional, and municipal levels in Italy and Norway. To structure the document collection, we applied the policy portfolio framework developed by Hurlimann et al. (2024), which includes two main components:

- A policy instrument typology, covering laws, regulations, strategies, and guidelines;
- A built environment policy setting, capturing the institutional and spatial contexts in which instruments are deployed across cultural heritage, CCA, and CRM (including DRM).

This framework provided a systematic basis for identifying and comparing the planning and governance instruments that influence the positioning of cultural heritage within climate and risk policies.

Coding and Analytical Procedure

The policy portfolio framework provided the foundation for targeted content retrieval. A structured codebook, aligned with the three conceptual dimensions—heritage as relational actor, climate risk management (CRM), and policy integration (PI)—was optimised using Large Language Models (LLMs), specifically NotebookLM.

Drawing on Guzman (2025), the analysis applies prompting techniques to extract, cluster, and refine relevant text segments from a large volume of documents. These prompts guided the identification of both explicit and implicit framings of cultural heritage, climate risk, and vulnerability. They also supported the mapping of institutional responsibilities, coordination mechanisms, and cross-sectoral linkages.

This hybrid method, combining structured policy mapping with AI-assisted discourse analysis, enabled a systematic comparison of the coherence, effectiveness, and transformative potential of national and subnational policy portfolios. Thematic synthesis and interpretation were manually verified to ensure analytical rigour and contextual sensitivity. The resulting insights contribute to understanding how cultural heritage governance can support more transformative approaches to climate adaptation and flood risk planning according to the cases' policy context (Fig 1).

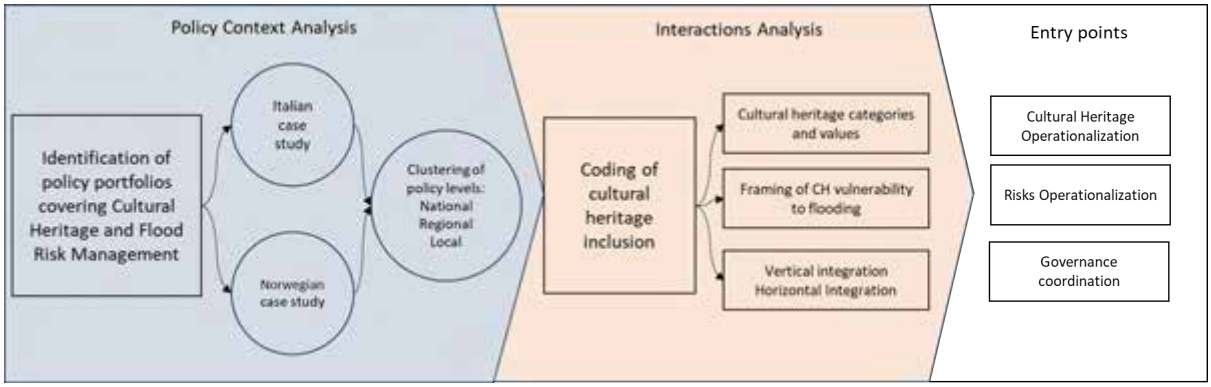

Figure 1. Methods overview for case study analysis.

Case Study Analysis

Lillehammer, Innladet region in Norway

The Norwegian policy portfolio (figure 2) for cultural heritage management (CHM), climate change adaptation (CCA), and flood-related disaster risk management (DRM) comprises 38 documents: 26 at the national level, 5 at the regional level, and 7 at the municipal level. These span regulatory, planning, and guidance instruments relevant to heritage in the context of climate risk.

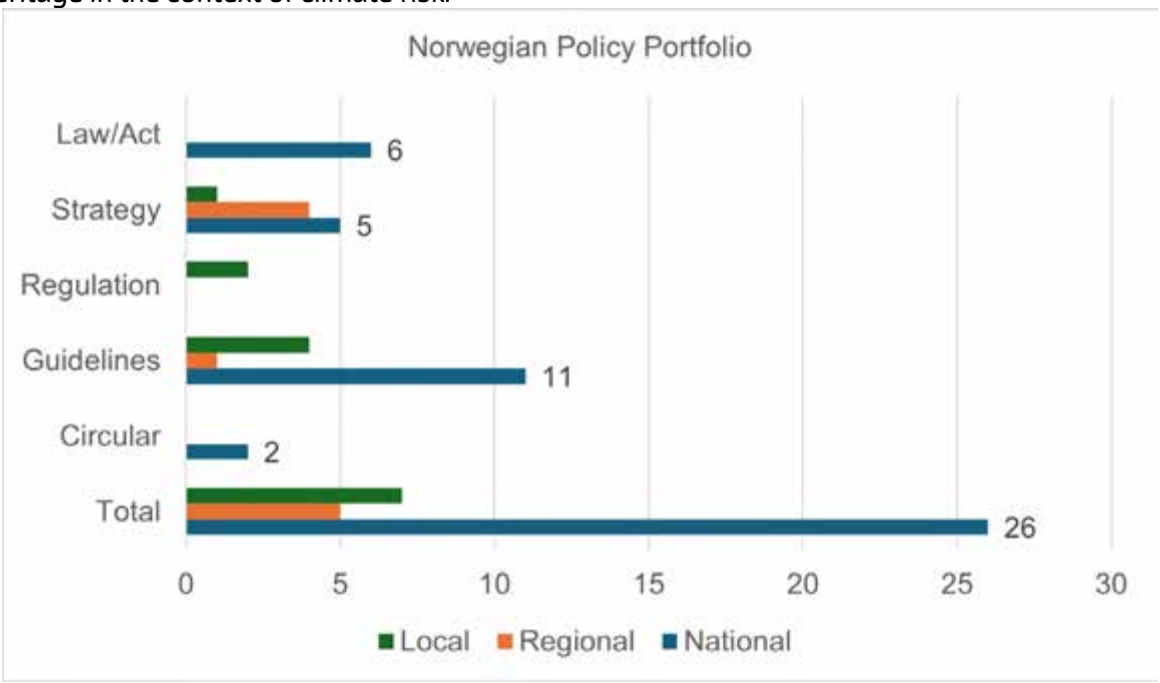

Figure 2. Norwegian policy portfolio for cultural heritage in FRM for CCA and DRM

National policy documents

Nationally, key responsibilities are defined by the Planning and Building Act (2008), the Water Resources Act, and the Civil Protection Act. The Norwegian Water Resources and Energy Directorate (NVE) leads on flood hazard mapping, spatial planning guidance, and emergency coordination. The Directorate for Civil Protection (DSB) oversees broader disaster preparedness. Within the Risk and Vulnerability Analysis (ROS) framework, cultural heritage is explicitly identified as a vulnerable asset. Vulnerability is defined in terms of a cultural environment's capacity to retain value under prolonged stress, encompassing physical degradation, symbolic and institutional fragility, and threats from climate-driven hazards such as flooding, erosion, and biological decay.

Regional policy documents

Innlandet County translates national priorities into spatial strategies via mandatory four-year Regional Planning Strategies and supporting thematic plans. The county's FylkesROS (Regional Risk and Vulnerability Analysis) incorporates cultural heritage under the categories of "Nature and Environment" and "Material Values." This framework uses scenario-based assessments to identify indirect flood impacts on heritage sites, such as water infiltration, soil saturation, and erosion.

Although this value-based risk framing elevates heritage within the regional discourse and encourages the preparation of emergency plans, its application remains mainly generic and advisory in nature. Cultural heritage is treated as an asset at risk rather than as a contributor to adaptive spatial planning. Its role is referenced in environmental and emergency strategies but is not embedded in instruments that guide spatial decision-making or long-term resilience planning.

Local policy documents

At the municipal level, Lillehammer integrates cultural heritage into risk governance through planning instruments such as the Municipal Master Plan and binding Zoning Plans, as well as its municipal ROS (Risk and Vulnerability Analysis). These tools consider cultural heritage among long-term risks and apply concepts such as "sensitivity requirements" and "tolerance thresholds" to regulate development and conservation activities.

Despite this formal inclusion, flood-related heritage risks are typically rated as "very small," reflecting low perceived urgency and limited consideration of evolving climate dynamics. While regulatory mechanisms safeguard heritage against inappropriate development, they do not consistently address climate-induced risks or promote proactive adaptation. Design standards and oversight processes remain focused on static protection rather than anticipatory or systemic responses to future climate impacts.

Table 1. Cultural Heritage Vulnerability in Flood Risk Governance – Norwegian Case Study

Comparative Point	National level	Regional (Innlandet)	Local (Lillehammer municipality)
Formulation of Vulnerability	Focused on material and structural susceptibility to climate parameters (moisture, temperature, rainfall).	• Part of broader sectoral/territorial assessments (FylkesROS); • highlights exposure and emergency preparedness gaps.	• Embedded in land use plans and heritage protection strategies (Kommundelplan); • expressed through tolerance and sensitivity criteria.
Focus of Vulnerability	Physical degradation of heritage due to site-specific climate conditions and structural/material weaknesses.	Emphasis on hazards like flooding and landslides and their potential to damage heritage.	Emphasis on architectural character, cultural landscape features, and urban form coherence.
Mechanism / Approach	Uses scientific data, national registers (Askeladden), risk matrices, and expert-based assessments.	• Integrated into ROS analyses; • focuses on qualitative assessment of exposure and event-based risk.	Planning tools define acceptable change thresholds (scale, structure, terrain, form) and guide development to protect heritage significance.
Types of Heritage Considered	Mostly listed and mapped heritage assets, including buildings, archaeological sites, and landscapes.	Includes settlements, infrastructure, and sectoral assets, often aggregated into risk categories.	Broad inclusion: historic buildings, gardens, walls, paths, and visual experience of heritage environments.

Vulnerability Dimensions Addressed	Primarily physical/material dimensions.	Some institutional and preparedness dimensions included in civil protection planning.	Focuses on morphological, experiential, and aesthetic dimensions of vulnerability.
Integration in Risk Planning	Partial – addressed in sectoral strategies and adaptation studies; generally limited to state-owned or protected heritage.	• Present within ROS frameworks, but not always heritage-specific; • often generalized within infrastructure or building risk.	Stronger integration in planning documents and municipal regulations; less in hazard-specific risk assessments.
Quantification / Monitoring	Lacks comprehensive quantitative indicators; knowledge base relies on expert input and fragmented registries.	• Risk often qualitatively graded; • lacks specific vulnerability metrics for cultural heritage.	Uses qualitative tolerance definitions and design prescriptions rather than measurable vulnerability indicators.
Limitations / Gaps	Cultural heritage vulnerability is largely framed as a technical conservation issue, with less emphasis on systemic or societal dimensions.	• Heritage is not consistently or specifically disaggregated in risk data; • Limited technical detail.	• Emphasis on planning compliance rather than climate resilience; • No systematic tracking of climate-related vulnerability at the site or community level.

Turin, Piedmont, Italy

National policy documents

Italy's FRM system spans multiple levels of government and integrates civil protection, environmental planning, and water governance. The legal framework is long-established and supported by technical experience in hydrogeological risk management. The national policy portfolio comprises 37 documents relevant to cultural heritage management (CHM), CCA, and DRM, with a particular focus on FRM. Policy documents (shown in fig.3) include nine national-level instruments (laws, strategies, and programmes), 16 regional documents, and 12 at the municipal level, reflecting Italy's hierarchical structure and the division between strategic planning and regulatory implementation.

Despite the availability of planning tools such as Flood Risk Management Plans (FRMPs) and hazard maps, cultural heritage is not systematically integrated into national or basin-scale FRM strategies. While risks to heritage, particularly in historic centres, underground assets, and coastal or archaeological sites, are increasingly recognised, they are typically addressed in isolated assessments. Diagnostic studies often explore material sensitivity, environmental conditions (e.g., fluctuating water tables), and anthropogenic stressors such as neglect or tourism. However, these insights are not yet embedded into FRM protocols, early warning systems, or emergency preparedness plans. Although the 2023 National Adaptation Plan (PNACC) acknowledges the vulnerability of heritage, it has yet to produce enforceable mandates or mechanisms for implementation.

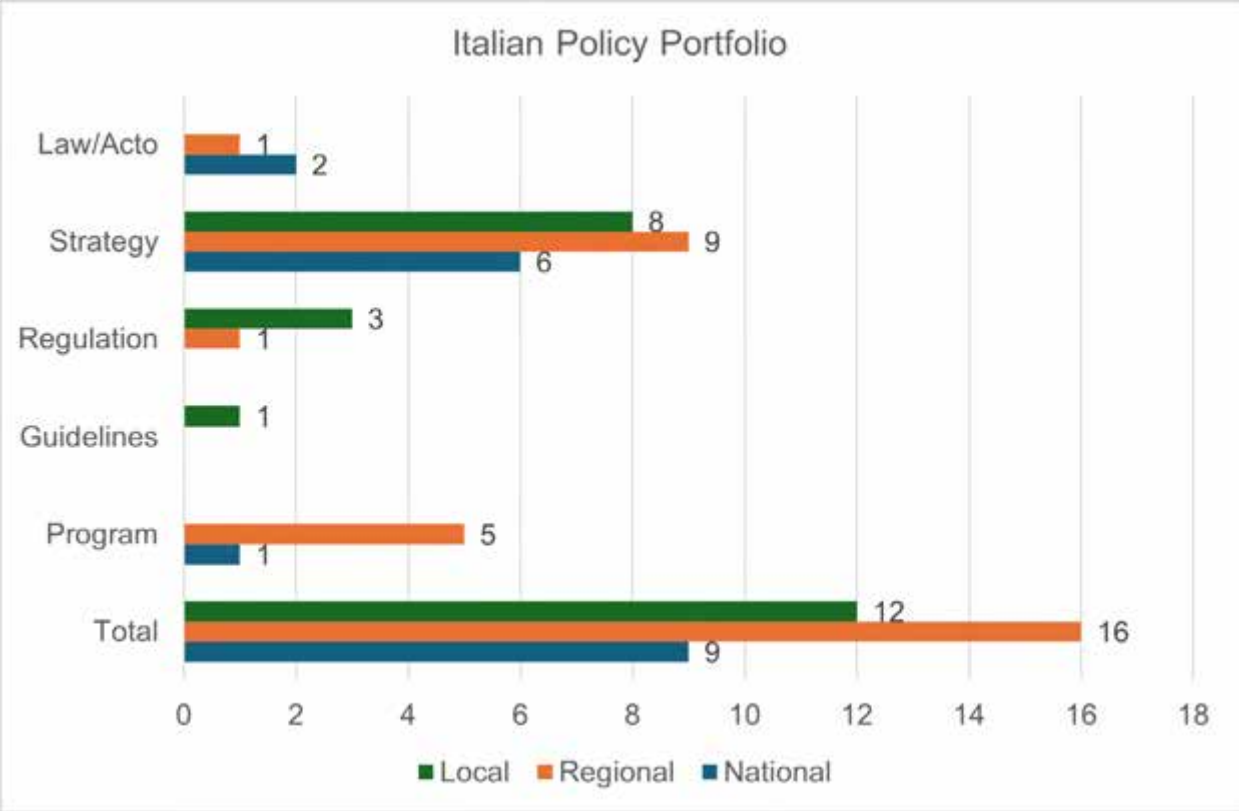

Figure 3. Italian policy portfolio for cultural heritage in FRM for CCA and DRM

Piedmont region policy documents

Following constitutional reforms, Italian regions such as Piedmont have gained significant autonomy in spatial planning and civil protection. Flood risk governance is integrated into Territorial Coordination Plans (PTRC/PTCP), supported by a Regional Functional Centre that collaborates with the national Department of Civil Protection (DPC) on real-time hazard monitoring, early warning, and prevention strategies. River Basin Authorities provide hazard maps that inform regional land-use restrictions and guide planning in areas prone to risk.

Despite the formal embedding of flood risk planning into regional governance, cultural heritage remains largely absent from these instruments. Historic centres, subterranean structures, and culturally significant landscapes are visibly exposed to hydrological hazards, but this exposure is rarely reflected in risk assessments, hazard mapping, or emergency planning.

Where heritage is considered, the regional approach reflects a multi-dimensional view of vulnerability. Physical risks arise from degradation, ground instability, and maintenance deficits. Institutional fragilities include fragmented mandates, weak coordination, and the lack of strategies linking heritage protection and promotion. Territorial inequalities persist, particularly in inland and mountainous areas, alongside chronic capacity gaps, underfunding, and outdated infrastructure that limits adaptive reuse. However, these issues are mostly recognised in assessments and reports, rather than operationalised in governance instruments.

Moncalieri municipality and Turin metropolitan area policy documents

Municipalities and provinces are responsible for local risk governance. Each municipality must prepare a Piano Comunale di Protezione Civile (Municipal Civil Protection Plan), which outlines hazard scenarios, such as floods and landslides, and sets out emergency procedures and guidance for citizens. Mayors act as the highest civil protection authorities in emergencies. The Metropolitan City of Turin coordinates among municipalities, supports planning, and consolidates local risk data.

Land-use restrictions in flood-prone areas are enforced through municipal planning instruments based on hazard maps from regional and national sources. Functions such as drainage and local water management are often delegated to land reclamation consortia, reflecting Italy's decentralised implementation model.

Cultural heritage is acknowledged within civil protection and urban planning frameworks but lacks dedicated risk methodologies. It is referenced in Strategic Environmental Assessments (VAS) under general environmental or landscape categories, without clear criteria for vulnerability or exposure. The Cultural and Environmental Assets Observatory in Turin improves data availability by cataloguing and mapping heritage assets and constraints. However, its use in vulnerability assessment or flood risk planning remains limited.

Table2. Cultural Heritage Vulnerability in Flood Risk Governance – Italian Case Study

Comparative Point	National Level	Regional Level (Piedmont)	Local Level (Turin)
Formulation of Vulnerability	Generic and implicit in FRMPs; heritage vulnerability is not methodologically defined	Multi-dimensional diagnosis covering physical, institutional, territorial fragilities	Implicit in civil protection and environmental assessments; not heritage-specific
Focus of Vulnerability	Damage to exposed assets; heritage seen as one of many sectors	Sectoral fragilities and systemic weaknesses across institutions and landscapes	Emergency impact on heritage assets; indirect inclusion in urban planning
Mechanism / Approach	General guidance in FRMPs and civil protection policies	Diagnostic assessments in regional plans; preliminary integration in spatial and adaptation planning	Strategic Environmental Assessments (VAS); local protection plans; civil protection frameworks
Types of Heritage Considered	Broad: monuments, archaeological sites, landscape heritage (not disaggregated)	Historic buildings, archaeological sites, rural landscapes	Cultural and environmental assets, including archives and museums
Vulnerability Dimensions Addressed	Physical exposure; limited institutional or societal framing	Physical, institutional, societal, infrastructural, and data-related vulnerabilities	Exposure to hazard; infrastructural and data constraints; societal access barriers
Integration in Risk Planning	Limited; cultural heritage weakly embedded in FRMPs or hazard maps	Partial; not systematically translated into FRM or adaptation instruments	Fragmented; planning tools acknowledge heritage but lack targeted vulnerability assessments
Quantification / Monitoring	Minimal; no dedicated indicators or recovery protocols	Economic valuation and scoring tools used diagnostically; not linked to FRM	Observatories and asset mapping exist, but not integrated with risk assessment
Limitations / Gaps	Weak operational link between heritage and FRM; fragmented responsibility	No formal mechanism for integrating heritage in hazard mapping or emergency preparedness	No dedicated methodologies for heritage-specific vulnerability; underutilized data systems

Comparative Discussion

This section compares the integration of cultural heritage into flood risk and climate adaptation governance in Norway and Italy. While both countries acknowledge heritage vulnerability, they differ in how it is framed, operationalised, and linked across governance levels.

Norway adopts a formal and multi-dimensional definition of vulnerability, embedded in national civil protection and planning tools. Cultural heritage is explicitly included in the ROS (Risk and Vulnerability Analysis) framework and reflected in spatial planning regulations. However, this framing is not always translated into practice at the local level, where climate-specific risks to heritage are often rated as low.

In contrast, Italy is showing an increasing awareness of heritage vulnerability, particularly at the regional and municipal levels. Diagnostic assessments in Piedmont, for example, highlight physical, institutional, and territorial fragilities. Yet, this knowledge is not systematically integrated into national FRM instruments, emergency planning, or spatial policies. To consolidate the comparative insights across key governance dimensions, Table 3 summarises the main findings:

Table 3 Comparative Summary – Cultural Heritage in Flood Risk and Adaptation Governance

Analytical Dimension	Norway	Italy
Heritage Categories & Values	Tangible assets (e.g. buildings, sites); some recognition of functional and experiential value in planning tools.	Focus on tangible heritage (monuments, archaeology); limited articulation of social or functional roles.
Vulnerability Framing	Defined nationally (ROS); includes physical, symbolic, and institutional aspects.	Diagnosed regionally; multi-dimensional but lacks national methodology.
Operational Integration	Heritage included in national tools; local uptake limited, risks often downplayed.	Heritage rarely integrated into FRMPs; awareness growing but not formalised.
Vertical Integration	National frameworks guide subnational levels; implementation varies.	Weak vertical coherence; local and regional efforts not fully supported.
Horizontal Integration	Some coordination between heritage, planning, and risk sectors.	Institutional silos persist; limited cross-sectoral governance.
Transformative Potential	Emerging in discourse; heritage recognised as a potential resilience asset.	Seen largely as a passive asset; not yet activated in resilience strategies.

Conclusions

This study examined the integration of cultural heritage into climate adaptation and flood risk governance in Norway and Italy. While both countries recognise heritage vulnerability, integration remains limited and uneven. Norway benefits from clear national frameworks, but local uptake is inconsistent and often downplays climate risks. Italy demonstrates growing diagnostic awareness at regional and municipal levels yet lacks operational tools and formal mechanisms for integration.

In both contexts, heritage is still largely framed as a passive asset at risk, rather than an active contributor to resilience. Policy integration—both vertical and horizontal—remains weak, constrained by fragmented mandates, limited coordination, and underdeveloped methodologies for heritage-specific risk assessment. These findings point to the need for relational governance approaches that see heritage not just as an object to protect, but as a medium for connecting people, places, and institutions. Advancing this perspective can support more inclusive, adaptive, and systemic responses to climate risk.

Within the AGREE project objectives, we will further explore how integration unfolds in practice by engaging with the actors and institutions shaping adaptation and heritage governance on the ground.

Exploring the Emotional Dynamics of Beyoğlu's Transformative Urban Atmosphere Through Music Ecosystems

Abstract
This study traces how music-related everyday practices have shaped Beyoğlu's affective atmosphere in the wake of spatial changes since the 1990s. Although emotions began gaining ground in urban research in the early 2000s, they had long been excluded or marginalised. Empirical research has often relied on methods that objectify emotions, rather than engaging with their embodied and affective dimensions. Drawing on field observations, in-depth interviews and sensory methods, this study proposes an approach that treats subject and method as an integrated whole—treating emotions as spatially entangled and grounded in embodied ways of knowing. Addressing a gap in the local context, it offers a case from Turkey and contributes both theoretically and methodologically to the expanding field of affective geographies.

Keywords: Emotions, Atmosphere, Beyoğlu, Music, Sensory Methods

<This research is conducted as part of the author's ongoing doctoral thesis supervised by Prof. Dr. Murat Cemal Yalçıntan at Mimar Sinan Fine Arts University.>

1. Introduction

The relationship between individuals and places is inseparable from emotions. Emotions may be conceptualized as a connective tissue that integrates the embodied geographies of the self with broader social and spatial formations. Emotions have long been marginalized in urban studies. Within the framework of Cartesian dualisms and modern scientific conventions, emotions were framed as irrational, subjective, and incompatible with value-free knowledge production (Bondi, 2009; Thien, 2005; Thrift, 2004). This perspective has been sharply criticized by those who argue that it replaces the complex nature of social relations in space with a logic of reproduction necessary for the survival of the system (Lefebvre, 1994; Hochschild, 2012). The emergence of literature on concepts such as sense of place and place attachment marked an early attempt to engage with the emotional relationships people form with their environments (Proshansky, 1978; Altman and Low, 1992). However, tended to reduce rich conceptual insights frequently falling short of capturing the full complexity of such relationships (Manzo, 2003). Since the early 2000s, however, a growing body of scholarship, frequently described as emotional geographies, has challenged previous assumptions (Anderson and Smith, 2001; Davidson and Milligan, 2004; Davidson, Bondi, and Smith, 2007), calling for approaches that "take emotions seriously" (Bondi, Davidson and Smith, 2007) not only as content but also as method. Responding to this call, this study traces how music-related everyday practices have shaped Beyoğlu's affective atmosphere in the wake of spatial transformations since the 1990s.

Atmosphere is conceived as a space that mediates between emotion and affect or integrates them; and serves as a central analytical tool for exploring how place is affectively charged (Riedel, 2019; Anderson, 2009). In a similar vein, this study does not take sides in the conceptual divide between 'emotion' and 'affect', but instead uses the term 'emotion' to refer to relational, embodied, and spatially situated experiences that co-constitute place. Applied to the case of Beyoğlu, the term affective atmosphere allows the study to trace how emotional relationships to place are shaped and transformed through music-related everyday practices, particularly within the context of spatial and cultural change. In doing so, it offers a situated contribution to emotional geographies by showing how space, affect, and emotion co-produce one another through embodied urban life.

Viewed through the lens of emotions and affective atmosphere, Beyoğlu offers a rich and complex field of research. Despite the district's layered history; its central role in Istanbul's cultural, social, political life and its prominence in studies on urban change, nightlife, and music; research addressing the role of emotional and sensory dynamics in shaping people's relationships to place is still limited (Ural, 2017; Öz and Özkaracalar, 2021; Türkün, 2021). Focusing on the period following the 1990 pedestrianization of İstiklal Avenue this research examines how music-related everyday practices have shaped and been shaped by the affective atmosphere of Beyoğlu. Pedestrianization of İstiklal Avenue initiated a period of cultural revitalization in which idle spaces were reclaimed by art institutions, bars, and civic organizations (İBB, 2023; Türkün, 2021). During this period, the district emerged as a major hub of musical and artistic activity. This period catalyzed the formation of the district's contemporary cultural memory and atmosphere, while simultaneously triggering processes of gentrification, spatial privatization, and intensified state intervention in cultural life. These shifts deeply affected the district's music spaces—its venues, informal performance zones, recording studios, artists' homes as spaces of both production and recreation, among others—reshaping music-related practices in everyday life. More importantly, they disrupted the functioning of numerous actors both within and beyond the music sector, and signaled profound transformations in the city's musical culture. These transformations not only call for a deeper understanding of how emotions are entangled with urban change, but also underscore the importance of studying space through its affective and sensory dimensions, alongside its physical or institutional shifts. In this research, the focus is on Beyoğlu not as defined by the boundaries of the district municipality, but rather as the area commonly evoked in contemporary debates and everyday personal narratives—an axis beginning at Gezi Park, passing through Taksim Square, Galatasaray Square, and Tünel Square, and ending at Galata Square, along with its many branching side streets.

This study addresses that gap by offering both a theoretical and methodological contribution to the growing field of emotional geographies, and by providing a locally situated perspective on the interplay between affective atmospheres and place. This research adopts an ethnographic approach, combining in-depth interviews, field observation, and sensory methods to understand how urban space is lived not only cognitively, but affectively. This article is part of a multi-layered research project conducted within the scope of my doctoral dissertation, carried out under the supervision of Prof. Dr. Murat Cemal Yalçıntan.

2. Literature Review

The marginalization of emotions in urban studies is by no means a new concern. Around half a century ago, a conceptual distinction between space and place began to take hold—one that emphasized meaning, affect, and emotional relationships with place (Tuan, 1974; 1977; Relph, 1976; 1985; Buttimer and Seamon, 1980). Nearly two decades have passed since emotional geographies emerged as a field committed to exploring how emotions are entangled with spatial processes (Anderson and Smith, 2001; Davidson and Milligan, 2004; Davidson, Bondi, and Smith, 2007; Bondi, Davidson and Smith, 2007). Still, many of the foundational questions remain unresolved.

As the literature on emotional geographies has expanded, the growing dissatisfaction with representational approaches has led to a conceptual division between 'emotion' and 'affect' (Parr, 2014), often presented as a theoretical and methodological rupture. Emotions are typically seen as nameable, conscious states tied to individual subjects, while affect refers to pre-personal, non-cognitive intensities that circulate between bodies, spaces, and materials (Pile, 2010). This distinction emerged largely from non-representational theory's critique of the limits of language, reflexivity, and cognition in capturing embodied experience (Anderson, 2015; Anderson and Harrison, 2010; Thrift, 2004). This research resists such an ontological split. Instead, it approaches emotion and affect as entangled registers of experience, co-produced through bodily and sensory encounters that unfold within specific spatial and social contexts. Within this framework, the concept of affective atmosphere offers a way to rethink emotion and affect not as phenomena located within bounded individuals, but as dynamics that emerge across bodies, environments, and relations.

The term atmosphere predates its introduction into recent debates by Anderson (2009). In human geography, affective atmospheres are conceived as emergent, relational, and collectively sensed—hovering between subjects

and spaces, never fully subjective nor entirely external (Anderson, 2009; Böhme, 1993; Thibaud, 2014). Importantly, affective atmospheres resist reduction to either stable emotional categories or abstract affective forces (McCormack, 2008; Anderson, 2009; Riedel, 2019). They are registered through movement, rhythm, material presence, and bodily orientation—shaping how space is sensed and lived without always being linguistically captured (Bissell, 2010; Pink and Mackley, 2015; Sumartojo and Pink, 2019; Riedel, 2019). This study draws on the concept of affective atmosphere not merely as an interpretive tool, but as a central analytical lens through which the emotional and affective texture of urban transformation is examined. Rather than treating affect as pre-cognitive intensity or emotion as representational expression, it explores how these registers operate together in shaping everyday spatial experience. Affective atmosphere as a concept provide a way of attending to the dynamic, ambiguous, and often ineffable qualities of the change in Beyoğlu—especially as it unfolds through music-related practices with space.

Riedel (2019) highlights a parallel between atmospheres and musical experience, highlighting their rhythmic, mereological, and immersive qualities. A number of recent works that approach music practices and space through the concept of atmosphere (Riedel and Torvinen, 2020; Tan, 2023; Järviluoma and Murray, 2023) shed light on both the relational nature of musical practices and their affective dimensions. There is a growing body of research on the spatial, social, cultural, and economic contributions of music to cities (Behr et al., 2014; Martin, 2017; Van der Hoeven et al., 2022; 2023). Recognized as tools within international development and resilience agendas (UN-Habitat 2020; United Nations General Assembly, 2016), they play a role in city branding (Botta, 2008; Wynn ve Yetis-Bayraktar, 2016; Brunow, 2019) and contribute to urban economies (Florida ve Jackson, 2010). But one should not ignore the fact that while music-led development can foster urban revitalization (Kronenburg, 2020; Gibson and Homan, 2004; Jakob, 2013; Seman, 2010), it may also render urban spaces more exposed to market-driven dynamics and economic pressures (Bennett, 2020; Brown et al., 2000; Flew, 2008). When legitimized solely through its economic benefits, it may lead to problems such as gentrification and displacement (Gibson and Homan, 2004; Holt, 2013; Lobato, 2006). Literature increasingly emphasizes the need for urban policies, legal frameworks, and planning tools to address such outcomes (Brown et al., 2000; Flew, 2008; Grodach, 2012; Hitters and Mulder, 2020; Homan, 2010; 2017; Lobato, 2006; Martin, 2017). Although the gentrifying power of culture has been well documented, some studies offer comparative examples of legal and planning mechanisms that mediate the positive and negative outcomes of music in urban contexts. In the case of Beyoğlu, the failure of policymakers to implement protective strategies led to the loss of the district's character.

3. Methodology

Incorporating emotion and affect into social, cultural, and spatial research necessitates a shift in methodological approaches. Beyond conventional frameworks, the integration of perspectives such as empathy, reflexivity, and sensory or embodied ways of knowing into fieldwork has been widely emphasized. Edited volumes that aim to bring together theoretical foundations and empirical studies on emotional/affective methodologies (Flam and Kleres, 2015; Knudsen and Stage, 2015) also stress the importance of conceptual, methodological, and epistemological alignment. A range of conventional methods have been employed in empirical research, including surveys (Hubbard, 2007; Korpela and Hartig, 1996; Hernandez et al., 2007), mapping (MacKian, 2004; Lazarenko, 2020), discourse analysis (Ural, 2016; 2017; Bennett, 2013), narrative analysis (Tokdoğan, 2018; 2019), and interviews (Demirkol, 2023; Karmann et al., 2023; Tang, 2021; Bissell, 2010). Alongside this diversity, most studies focus on interviews to access emotions, drawing on participants' or researchers' observations. A significant portion of these studies adopts an ethnographic approach (Boğaç, 2020; Navaro, 2009; 2016; Ellington, 1998; Korjonen-Kuusipuro and Marilainen-Hyvaranen, 2016; Laurier vd., 2012). Given that ethnography can encompass multiple methods, its use in studies exploring emotions in space may offer advantages through its potential to integrate diverse research practices. Since this study aims to explore aspects of emotional experience that lie beyond what can be verbally articulated, the chosen methodology is expected to be capable of capturing atmospheres as spatially non-representable affects and spatial ambiguities. In line with similar concerns, visual (Duru, 2019; Wilson et al., 2020; Lorimer, 2010; Pink and Mackley, 2015) and sensory methods (Bingley, 2003; Wise, 2010), which foreground emplacement, reflexivity and embodied experience, will form the methodological basis of this research.

The design of my research on Beyoğlu, which adopts visual/sensory methodologies, is grounded in the principle that visual ethnography is inherently multisensory rather than merely visual, as emphasized by Pink (2001), adopts visual/sensory methodologies. There is now an extensive body of literature on empirical visual research (Grimshaw ve Ravets, 2005; Knowles ve Sweetman, 2005; Pink vd, 2004; Bates, 2013; Laurier ve Philo, 2006). In recent years, sensory methods have been increasingly integrated into spatial empirical research (Adams ve Guy, 2015; Crang, 2003; DeFazio, 2011; Garrett ve Hawkins, 2000; Low, 2015; Paterson, 2009; Urry, 2003). These studies are grounded in the idea that visual methods have a capacity to encompass embodied/sensory research.

As previously stated, this paper covers the part of a broader research project—my doctoral dissertation—that I have carried out so far, along with its preliminary findings. In my dissertation, I propose a research design that enables a bidirectional perspective—from today to the past and from the past to the present. The comprehensive study involves conducting ethnographic interviews with individuals from Beyoğlu and deepening these interviews through the photo elicitation method, using photographs selected from their personal archives to access the past; while to approach the present from today, I designed a participant observation process. At the intersection of these two methods, I aimed to create a space for re-articulating emotions related to these sites by walking through the streets of Beyoğlu with the interviewees and spending time together. The preliminary findings presented in this paper are based solely on the participant observation and ethnographic interview phases of the research. While the participant observation process spans the last year, my personal relationship with Beyoğlu dates back to the 1990s, and these past experiences have contributed significantly to developing insights into the space and making sense of my observations.

During this process, I made periodic visits to the spatial contact points, tracing them backward from the present, while also conducting general observations on the current state of Beyoğlu. I conducted ethnographic interviews with individuals who have longstanding ties to Beyoğlu, using various audio-visual materials related to specific places, times, and events. In these interviews, I recorded not only verbal expressions but also affective components such as facial expressions, gestures, and moments of silence, using both audio and video. During my visits, I focused on documenting the sensory qualities of Beyoğlu through my own embodied experience. I collected and analyzed all these data using MAXQDA, a data analysis software that allows for the systematic coding, analysis, and visualization of not only textual but also visual, audio, and video data in qualitative and mixed-methods research. I chose this software because it allowed me to evaluate my field and interview notes together with other types of data.

4. Beyoğlu

Since its emergence as the new center of Istanbul in the 19th century (Üstdiken, 1994), Beyoğlu has been a space that has continually transformed under the influence of ideological, political, and economic dynamics, marked in every era by an atmosphere distinct from tradition. Beyoğlu has established a strong connection with the culture, arts, and food and beverage sectors, evolving alongside them and undergoing transformations over time.

In the decades preceding the 1990s, Beyoğlu underwent significant transformations due to political unrest and military interventions, leading to the loss of its formerly vibrant, energetic and multicultural atmosphere. The 1942 Capital Tax, Istanbul Pogrom, curfews, military rule, and ongoing national tensions lead to a significant decline in interest toward restaurants, taverns, and other dining venues, many of which consequently shut down. In the 1980s, Istanbul's urban spaces underwent significant transformation as part of neoliberal renewal campaigns aimed at integrating the city into global networks. In 1988, following mass demolitions, Tarlabaşı Boulevard was officially opened. Subsequently, İstiklal Street was pedestrianised in 1990 in order to increase the area's attractiveness for both the business sector and tourists.

The identity of Istiklal Street has changed significantly since the pedestrianisation. Although İstiklal Street was pedestrianised in 1990, it was still not a preferred area for many, its lower rents compared to other central neighborhoods in Istanbul began to attract "bohemian" individuals once again, who started opening cafés, bookstores, and stationery shops (Türkün, 2021). This movement signaled the beginning of a new period of revival

for Beyoğlu. The multicultural and multi-layered composition has resurfaced with the co-emergence of different actors (Erkut and Shirazi, 2014; Tekin and Gültekin, 2017). One of the more ironic and symbolically rich moments in İstiklal Street's transformation from the 1980s to the 1990s was the impromptu Sun Ra Arkestra concert performed atop a moving truck in 1990. Taking place shortly after the pedestrianisation of the street, the performance marked an early cultural intervention in an area that had not yet regained its former vibrancy (Url1). Through such interventions, İstiklal Street slowly began to evolve from a space of transition and abandonment into a renewed cultural axis.

In the 1990's, notable urban planning decisions included designating Beyoğlu as a conservation area, and classifying various parts of it as Tourism Development Zones (Güney, 2015). These policies contributed significantly to the revitalization efforts of that period and laid the groundwork for the developments seen in the 2000s. From the second half of the decade onwards, new types of cafés, bookstores, and music venues that were particularly popular among high school and university students began to emerge (Türkün, 2021). The revival of cultural and high-quality commercial activities on Istiklal Avenue also accelerated the gentrification of nearby residential areas like Cihangir and Galata, known for their historic building stock (Türkün, 2021).

Throughout the 1990s, Beyoğlu emerged as a key hub for both independent music scenes and institutionalized cultural production. Performance venues such as Hayal Kahvesi, Jazz Stop, Kemancı, Peyote, Roxy, and—toward the end of the decade—Babylon, became central to the city's diverse musical landscape (url3). At the same time, art institutions funded by private companies, such as Aksanat and Borusan Sanat, contributed to the area's cultural diversification on a more institutional level. Istanbul Jazz Festival played a crucial role in bringing contemporary music to the city, with most concerts at the time taking place in and around the Taksim area. The backstreets of Beyoğlu were rediscovered. During this transitional period, streets intersecting or running parallel to Istiklal Avenue witnessed the coexistence of workshops, cabarets, rock bars, and pubs. The transformation of Mis Street in the 1990s became an important symbol of the broader changes in Beyoğlu. Venues offering cheap beer operated side by side with artist-frequented cafés, maintaining a vibrant, mixed-use environment. Rock music and rock venues became nearly mainstream on Istiklal Avenue (Akay et al., 2021).

In the 2000s, Beyoğlu's popularity increased significantly (url3). This decade marked also a sharp increase in rental and property values. There was a notable diversification in dining, entertainment, and cultural activities. One of the most striking developments of the 2000s was the revitalization of the area between Galatasaray and Tünel. This area began to attract higher-income groups (Eder and Öz, 2015). The transformation of Asmalı Mescit, marked by the emergence of more upscale retail and dining establishments, drew many from the middle and upper classes to Beyoğlu (İnce, 2011). During this period, Istiklal Avenue experienced its peak in terms of tourism. In response, large-scale urban projects targeting these areas were promoted under the local government's vision (Adanalı, 2011).

Within the framework of Istanbul's selection as the 2010 European Capital of Culture in 2006, developments in tourism and the cultural sector accelerated. It has been observed that the policies implemented during this time triggered a rapid gentrification process along Istiklal Avenue (Türkün, 2021). As the tourism sector expanded and inflation rates—previously high due to the 2001 economic crisis—dropped, the real estate market in Beyoğlu began to flourish, leading to a sharp rise in property values. This, in turn, deepened the gentrification process, and many businesses were forced to close due to rising rents (Eder and Öz, 2015). The years following 2010 marked a turning point for the fate of many venues in Beyoğlu. A series of events —including changes in the district's vision, the release and subsequent annulments of the 2011 zoning plan, bans on outdoor seating, the enactment of the Turkish Code of Obligations No. 6098 in 2012 (implemented in 2014), the Gezi Park protests of 2013, the terrorist bombing in 2016, and the economic crisis—collectively triggered Beyoğlu's decline.

During the COVID-19 pandemic, Beyoğlu underwent one of the most dramatic periods of silence and inactivity in its recent history. Following the announcement of Turkey's first official case, a series of nationwide closures and restrictions were imposed, severely impacting the district's vibrant ecosystem of restaurants, bars, nightclubs,

and cultural venues. İstiklal Street, once known for its round-the-clock activity, became nearly deserted, with most businesses—including those offering delivery services—shutting down. Entertainment venues were particularly hard-hit, as establishments with bar and nightclub licenses were not permitted to reopen even during phases of controlled normalization. Iconic spots such as Zencefil, Leb-i Derya, Anahit permanently closed, while others relocated or changed ownership. The collapse of this cultural infrastructure deeply affected musicians within the nightlife economy, many of whom lacked access to government support mechanisms. Reports of widespread financial hardship and even suicides among musicians revealed the depth of the crisis.

Since the early 2000s, Turkey has been governed by the Justice and Development Party (AKP), and during this period, Beyoğlu was consistently administered by AKP-affiliated mayors. Especially over the last fifteen years, the transformations discussed in this section were largely shaped by interventions jointly implemented by the central government and the local municipality, often reflecting a shared political vision. In the 2024 local elections, a notable shift occurred when the district was won by İnan Güney, the candidate of the opposition Republican People's Party (CHP). This political change was interpreted by many people of Beyoğlu as a sign of emerging expectations for a different model of local governance, one that might be more responsive to the area's cultural diversity and civic demands. Post-election celebrations, including street parties and widespread engagement on social media, pointed to a renewed public interest in Beyoğlu's potential and a hopeful re-engagement with its urban life.

5. Belonging, Creativity, and Cultural Continuity in Beyoğlu: Everyday Practices, Musical Spaces, and Affective Memory

Participant narratives reveal that the sense of belonging to Beyoğlu is not solely constructed through frequency of visits or physical proximity, but rather through everyday practices, emotional orientations, and social encounters. Especially during high school and university years—when daily responsibilities were minimal—Beyoğlu emerged as a space that was repeatedly visited, intuitively navigated, and eventually felt "like home." Expressions such as "the place I spent the most time outside home," "more than at home itself," or "like my own neighborhood" positioned Beyoğlu as an extension of everyday life. A participant whose actual residence was neither located within the administrative boundaries of Beyoğlu nor in a neighborhood typically associated with proximity to İstiklal Avenue nonetheless described the area as "very close to our home," referring to it as "like our street." This account illustrates how strong affective attachments can reshape spatial perception, producing a sense of proximity that is emotionally rather than geographically grounded. The statement "we would sit and drink beer in front of one of its apartment buildings" illustrates a strong sense of spatial appropriation. The same participant recalled, "I once left saying I was going to the corner shop, but ended up just going there, wandering around in my flip-flops and shorts. We wouldn't do anything. We'd go there for the sake of going." This non-instrumental orientation was further articulated through the analogy: "It's like going home—you don't know exactly what you'll do in which room, but you go anyway."

Experiences of Beyoğlu often lacked clearly defined spatial boundaries. While İstiklal Avenue appeared as a shared axis, participants' spatial practices extended into surrounding side streets and informal gathering spots. "We spent a lot of time on the streets... the streets were much freer," one noted. Spaces such as the steps near the Galatasaray public bath, in front of TRT, or the backstreets were remembered not as places of consumption but of lingering, inhabiting, and informal interaction. Social ties were sometimes formed with those working in these venues: "We would go to places because people working there became our friends." The sense of belonging varied across micro-locations in Beyoğlu. The Tünel–Asmalımescit area was often perceived as "posh" and associated with adulthood, whereas the axis between Taksim Square, Galatasaray High School, and Odakule felt more comfortable and familiar. The presence of "our people" in certain areas—an expression used by the participant—was a strong determinant of emotional attachment, reinforcing a form of socially coded spatial orientation.

Beyoğlu was not only a place for socializing but also for solitude, self-reflection, and escape from daily routine. Visits to Beyoğlu were often spontaneous and purposeless. The metaphor of "going home without knowing

what you'll do there" illustrates how the attachment was grounded in a habitual rhythm. Encountering someone familiar or remaining alone were equally plausible outcomes, and this ambiguity did not weaken one's sense of place. Activities described as "aimless wandering" or "going to loiter" positioned Beyoğlu as a space of open-ended potential, not limited to consumption. Participants described their navigations as shaped by an embodied familiarity: "knowing where to look" or "having nowhere else to go." The social encounters forged in this context often transcended the immediate moment, reemerging in later life phases and shaping enduring personal or romantic relationships. Shared memories of Beyoğlu, its venues, and the people within them acted as a unifying emotional reference point, even long after the spatial context had changed.

Another affective tone is the sense of safety. However, this sense of security did not stem from institutional infrastructure or formal policing, but from familiarity and emotional resonance with the space. "I never had any problems—I didn't even consider that I might," one participant remarked. While participants did not deny that negative incidents occurred, they generally framed them as exceptions rather than generalizations. Words like "my people were there" described a social landscape composed of familiar, unnamed faces. One participant referred to a man known by many as "Sedat Abi," a homeless figure who was widely recognized in the neighborhood and affectionately described as "everyone's Sedat Abi." He was nonetheless attentive to others, once asking the participant if something was wrong when they appeared upset. This anecdote exemplifies a horizontal form of care and social cohesion grounded in everyday familiarity and mutual recognition. For individuals with non-normative appearances or lifestyles, Beyoğlu functioned as a rare zone where their presence was not policed: "If you went to Ümraniye dressed like a punk, people would stare or say things, but in Beyoğlu you could express yourself freely." In this sense, safety was not just about avoiding harm, but about the right to be seen without judgment. In a similar vein, Beyoğlu also served as a site of personal formation. It functioned as a "laboratory" for experimenting with tastes, interests, and identity orientations. One participant described themselves as "formless," initially attracted to "a bit of an 'apaçi' aesthetic," underscoring Beyoğlu's role in processes of aesthetic and social discovery. Yet this process of "finding oneself" was never purely individual—it was shaped by spatial affordances and limitations. The participant noted, "you need to find the part that includes you," suggesting that inclusivity was not evenly distributed. Places like Asmalımescit were never experienced as accessible or welcoming, revealing the classed and culturally coded exclusions that coexisted within the broader inclusivity of Beyoğlu. Over time, this spatial learning led to a form of confidence—knowing "where to go, what to do there, and what I liked"—which reflected not only a stable relationship with place, but also a solidified relationship with the self.

All these layers of experience converge in a distinction participants make between merely "being in Beyoğlu" and "truly going there." The latter implied not a momentary or instrumental visit but a sustained, repetitive, and immersive engagement with the space. This pattern, often interrupted by life changes such as relocation or the pandemic, was most severely disrupted by the shrinking diversity of venues and increasing inaccessibility. Participants mourned the loss of spontaneity and mobility between venues, noting that today's Beyoğlu often resembles "a tunnel of memories." The shift from lived to remembered experience coincided with the gentrification of previously accessible spaces. Venues once defined by low cost and openness had either closed or been replaced by fine-dining restaurants and boutique shops. "Many places feel like souvenir shops now," one participant said, underlining the transformation from dynamic, relational space to commercial spectacle.

Within this broader context, music emerges as a particularly powerful medium through which cultural engagement and personal transformation were made possible. Participant narratives reveal that Beyoğlu was not merely a space where music was consumed as a listener, but also a site where music production, creative expression, and personal transformation were directly experienced. Particularly during high school and university years, practices such as renting studios went beyond casual engagement and evolved into collective forms of production. These studios were not simply rental spaces offering technical equipment; they functioned as expressive environments where observational learning, and the right to make noise were actively explored. Statements such as "We did everything there—someone would play guitar, someone else would just sit in the corner, but we were there" emphasize the value of being present, spending time together, and learning collectively just as much as producing music itself. Participants noted that the development of similar musical tastes occurred

through shared aesthetic preferences and the places they frequented together. The expression "We used to go there not knowing who we might run into" underscores the culturally generative nature of Beyoğlu's encounter regime, which was not only social but also directional. The relatively low cost of studio rental, the shared nature of expenses, and the accessibility of music production rendered Beyoğlu an inclusive space not only physically, but also economically and affectively. Participants' recollections highlight how Beyoğlu once offered not only physical but also economic inclusion. Moreover, the density of opportunities for spontaneous encounters directly shaped individual musical orientations. Listening to similar genres was not merely an aesthetic preference but was enabled by shared spatial trajectories and a broader regime of encounters. These moments—whether a spontaneous street interaction with Harun Tekin, an unposed photograph taken by Ara Güler, or an unexpected meeting with a musician in a studio—were not simply memories, but affective and cultural inflection points that contributed to the formation of identity and orientation. Over time, however, these dynamics began to shift. Processes of gentrification, genre transformations, institutionalization, and rising economic thresholds rendered these spaces more exclusive, more expensive, and less accessible. Although emotional attachments to the past persist, participants noted that spontaneous encounters and unplanned creative production have diminished. In this context, Beyoğlu continues to exist not only as a former site of cultural creation but also as a cultural potential that persists in memory.

The types of music participants connected with were shaped by the diversity of genres and styles that Beyoğlu made accessible. Particularly in their youth, connections with punk, rock, metal, and other alternative subgenres were formative in shaping both individual identities and interactions within social groups. Participants reported that their musical preferences evolved over time, often in parallel with shifts in their spatial circulation and vice-versa.

These experiences contributed to a shared spatial memory of venues that left collective traces: places like Yeni Melek, Haymatlos, GarajIstanbul, Karınca, Klan, Ağaç Ev, Ghetto, and Dorock were not only concert spaces, but also stages for everyday socializing, relationships, discovery, and the formation of belonging. Some venues, such as Klan—where high schoolers gathered on Fridays, surrounded by film posters and drinking banana-flavored instant coffee—offered tangible expressions of "alternative" identities in everyday life. Participants' continued emotional connection to the songs they once listened to—felt with the same intensity today—demonstrates that their musical engagement was not limited to personal taste. Rather, it was grounded in spatial, cultural, and affective continuity. This continuity persists, even as spaces themselves change, sustained by the power of memory and the affective force of remembering.

6. Conclusion

This study has explored how the emotional and sensory dimensions of everyday musical practices shape and are shaped by the transforming urban atmosphere of Beyoğlu. By foregrounding the role of emotions not only as content but also as method, it contributes to the expanding field of emotional geographies with a situated, multisensory perspective. Through participant observation and ethnographic interviews, it becomes evident that Beyoğlu has functioned not merely as a spatial backdrop, but as a relational and affective environment where belonging, identity formation, and cultural expression are co-produced.

Participants' narratives reveal that musical engagement in Beyoğlu operated as a mode of spatial appropriation, emotional continuity, and collective meaning-making. As informal musical encounters, studio practices, and venue-based interactions became increasingly constrained by gentrification, economic pressures, and political interventions, the district's affective atmosphere also shifted—moving from a lived, inclusive openness toward a more fragmented and nostalgic terrain. Yet, the persistence of affective memory, and the emotional intensity associated with past spatial rhythms, indicates that place continues to exert influence even after its physical and social textures have changed.

Methodologically, this research demonstrates the value of integrating sensory and visual approaches in capturing the elusive qualities of urban transformation. The concept of affective atmosphere—neither wholly repre-

sentational nor entirely pre-cognitive—proves to be a productive lens for tracing how emotions circulate through bodies, places, and practices.

In sum, Beyoğlu's musical past is not simply remembered; it is felt, embodied, and enacted through emotional orientations that endure beyond spatial loss. The findings not only illuminate how music and place co-construct affective geographies, but also underscore the need for urban scholarship to engage with the ephemeral, affective, and embodied layers of spatial experience—particularly in contexts marked by cultural displacement and contested memory.

Participatory living heritage planning in practice: Lessons from Balıkçıköy, Istanbul

Busra Nur Gundogdu

Urban and Regional Planning Doctoral Program, Graduate School, Istanbul Technical University, Istanbul, Turkey, gundogdubu21@itu.edu.tr

Imge Akcakaya Waite

Urban and Regional Planning Department, Faculty of Architecture, Istanbul Technical University, Istanbul, Turkey, imgeawaite@itu.edu.tr

Abstract
This study examines the participatory process of an ongoing conservation-oriented urban planning initiative in Balıkçıköy, a registered cultural heritage site in Maltepe Istanbul, through the conceptual lens of the living heritage approach. Drawing on in-depth interviews with local residents and planning professionals, it investigates three interrelated dimensions: the acknowledgment of local values, the translation of community knowledge into planning decisions, and the equity of representation across the process. Although a range of participatory tools was employed, the findings indicate that participation largely remained at a consultative level, with limited influence on strategic outcomes. While local values were documented, their integration was constrained by expert-driven frameworks. Rather than evaluating final outputs, the study focuses on participatory dynamics, arguing that meaningful heritage planning requires transparent dialogue, shared authority, and a sustained commitment to co-producing decisions with communities.

Key words: Heritage planning, community participation, knowledge integration, conservation planning, urban governance

1. Introduction: From material- and value- based conservation to the living heritage approach

After World War II, approaches to cultural heritage conservation became institutionalised, leading not only to technical advancements but also fundamentally transforming knowledge production, accuracy criteria, and decision-making authority. A brief analysis of cultural heritage conservation in a historical context suggests three distinct periods, first defined by Poulios, 2014: positivist–materialist period (1960-1980s), interpretivist–evaluative period (1990-2000s), and participatory–community-oriented period (post-2000s). Understanding these periods with their differences and shifts is important to describe the living heritage approach, which is the main topic of this study.

During the positivist–materialist period, conservation was framed as a scientific-technical field. The 1964 Venice Charter established this approach by emphasizing the documentary value of heritage and endorsing scientific methods as the sole valid basis for intervention. Knowledge was seen as measurable, objective, and universal. Authenticity was defined through material components, applying uniform criteria regardless of cultural or geographic context. Although UNESCO's concept of the "common heritage of mankind" (1972) and the "integrated conservation" approach of the 1975 Amsterdam Declaration expanded the focus from individual monuments to urban areas, the core paradigm remained unchanged (Muñoz Viñas, 2005). Material authenticity continued to dominate (Jokilehto, 1999), and decisions were led by experts. This approach was criticized for forcing cultural diversity into a uniform model.

By the 1990s, the limitations of the earlier one-dimensional approach had become evident. UNESCO's development of the concept of Outstanding Universal Value shifted the focus of conservation from purely physical attributes to the values embodied in heritage (Bortolotto, 2015). Beyond aesthetic and historical dimensions, social, economic, symbolic, and spiritual meanings began to be considered. A turning point came with the 1994 Nara Document on Authenticity, which emphasised that authenticity must be understood within its cultural context—marking a shift from a Eurocentric to a multicultural perspective. Similarly, the 1999 Burra Charter restructured the conservation process into the stages of understanding–deciding–intervening, centred on the notion of cultural significance.
During this period, knowledge production became more multidisciplinary, and stakeholder perspectives started

to be acknowledged. Yet, value assessments continued to be shaped primarily by expert opinion, and meaningful community participation remained limited. Smith (2006) critiqued this value-based approach through the concept of authorized heritage discourse, arguing that experts tend to prioritise certain values while marginalising others. This highlights how heritage definitions remained constrained within a narrow framework and how genuine public involvement was still largely absent.

The growing emphasis on locality, shaped by globalisation and post-colonial critiques (Poulios, 2014; Ndoro and Wijesuriya, 2015), challenged the expert-dominated conservation paradigm (Waterton and Smith, 2010). These critiques revealed that conventional conservation theory relies on hegemonic knowledge systems and often disregards local cultural contexts. In the emerging paradigm, valid knowledge derives not only from technical expertise but also from the real-life experiences and everyday practices of local communities (Wijesuriya et al., 2013).

As Harrison (2013) argues in his notion of dialogical heritage, the pluralistic nature of heritage values necessitates democratic conservation processes. Decision-making has thus evolved into a multi-actor practice involving experts, community members, managers, and users. This community-oriented paradigm positions local communities as key stakeholders in heritage conservation (Wijesuriya, 2015; Labadi and Gould, 2016) and views change as a sign of vitality rather than a threat (Poulios, 2014).

ICCROM's 2015 People-Centred Approaches document provides a structured framework for translating the emerging principles of living heritage into practical strategies (ICCROM, 2015). As dialogical, community-driven heritage practices gained prominence, the document offered concrete methodologies to support inclusive, locally grounded conservation efforts. By reframing conservation as a collaborative and continuous process of 'living together,' it foregrounds local agency, values, and capacities, and supports the shift toward participatory and pluralistic governance. In line with Healey's (1997) communicative planning theory, which emphasises inclusive dialogue and the co-construction of meaning in spatial governance, the document contributes tools to facilitate negotiation and mutual understanding among diverse heritage actors.

2. Making living heritage participatory: potentials and challenges

2.1. The importance of the community-oriented perspective brought by the concept of living heritage

The concept of living heritage, which enabled the transition to a community-oriented conservation paradigm, brought about a fundamental shift in perspective for conservation practice. The main contribution of this perspective is to change the ontological definition of heritage: Heritage is no longer a static 'object' to be preserved, but a dynamic 'process' that is constantly reproduced in the everyday life practices of communities (Wijesuriya, 2015). This ontological shift is driving fundamental changes in conservation practice. As Waterton and Smith (2010) emphasise, heritage is no longer understood as a collection of physical objects, but as the social practices and value systems constructed around them. The shift from passive beneficiary to active subject, as described by Jigyasu (2015), highlights how communities are now positioned as central actors in the conservation process.

The continuity–change balance, as conceptualised by Poulios (2014), provides the operational framework for the living heritage perspective. This approach redefines change not as a threat to heritage, but as a sign of its vitality. It asserts that decisions about what kinds of change are acceptable can only be made by the communities that sustain the heritage. In response to Smith's (2006) critique of authorized heritage discourse, this perspective centres the value systems, priorities, and meaning-making practices of communities within conservation processes. Heritage is thus no longer viewed as static objects to be preserved and displayed, but as dynamic spaces where collective memory is sustained and social dialogue is fostered.

This community-oriented perspective brought about by the concept of living heritage makes participatory approaches in planning processes mandatory. This necessity stems from the nature of the living heritage perspective and manifests itself in three main dimensions. The need for knowledge production stems from the definition of living heritage as a process. Heritage knowledge, continually reproduced through the lived practices of

communities, can only be accessed from within those practices. In this context, Healey's (1997) communicative planning theory is crucial: without integrating diverse forms of knowledge, the dynamic nature of heritage cannot be reflected in planning. This renders the traditional 'informing' and 'consulting' levels of Arnstein's (1969) ladder of citizen participation insufficient. Instead, a co-production of knowledge becomes a necessity rather than a choice. The need for inclusive decision-making arises from the fact that the continuity–change balance cannot be maintained through external interventions. Since this balance emerges from lived practices, only the communities that sustain these practices can manage it. Fishkin's (2009) deliberative democracy models highlight the importance of democratic dialogue in such decision-making. Similarly, Ostrom's (1990) co-management approach emphasises that the ongoing processes of maintenance, reproduction, and adaptation essential to heritage survival require genuine community ownership. On another note, the legitimacy imperative stems from the institutional need highlighted in Harrison's (2013) concept of dialogical heritage. If heritage is constantly renegotiated, such negotiation must occur under democratic conditions. Fairclough's (2009) notion of democratic heritage stresses that these processes are essential for ensuring social legitimacy.

The living heritage perspective faces a key paradox in practice. While community knowledge and participation are essential, existing institutional structures often limit this involvement. This gap reflects an underlying interest in preserving existing power relations. Chitty's (2017) community-based heritage management approach addresses this paradox by enhancing community autonomy and control over heritage. It offers a way to reconcile the democratic participation required by living heritage with institutional sustainability. This highlights three key questions for implementing participatory living heritage planning: How do communities assess their heritage, and how can these assessments be systematically integrated into planning? How should participatory planning processes be designed and conducted? What are the main barriers to implementation, and how can they be addressed? The following literature review examines existing research and theoretical frameworks that address these questions.

2.2. Transferring community knowledge to the planning process

Recognising the role of community attitudes in sustaining living heritage raises a core question: How can the diverse values that communities assign to heritage be systematically integrated into planning? Transferring community-centred heritage knowledge into planning requires systematic data collection and participatory methods. Community-based mapping combines local knowledge with expert cartography by visualising spatial perceptions. Focus groups enable comparison across demographic groups' heritage views. Participant observation reveals how communities engage with heritage in daily life. Oral history captures the lived knowledge of older generations and supports intergenerational transfer. Digital ethnography and social media analysis explore younger groups' heritage perceptions and content production. Crowdsourced inventories, social media mapping, and virtual reality tools complement traditional methods. Online platforms offer access for those unable to join in person—such as remote communities, the elderly, disabled individuals, or working parents—though digital exclusion risks must be addressed. Community-based inventories promote local involvement in identifying, classifying, and prioritising heritage. Narrative research and storytelling workshops help communities express their heritage through their own concepts. Defining the role of community knowledge through procedural transparency is essential. It ensures that how community insights shape planning outcomes is traceable and supports the sustainability of participatory governance.

Sustainable participatory living heritage planning depends on three key conditions. First, capacity building (Simpson, 2008): strengthening communities' technical knowledge, organisational skills, and leadership. Second, flexibility (Brown et al., 2013): establishing regular evaluation and adaptation mechanisms. Third, egalitarian power sharing (Logan, 2012): ensuring balanced decision-making where no single stakeholder dominates. When these conditions are met, participatory planning becomes a responsive and effective tool that aligns with both community needs and the dynamic nature of heritage. Urban cultural heritage sites offer examples of these principles in action. In Barcelona's El Raval neighbourhood, inclusive representation brought together residents, artisan groups, municipal actors, and conservation experts on equal footing—preserving the historic fabric while preventing social exclusion (Degen and García, 2012).

2.3. Implementation challenges to participatory heritage planning

The implementation of participatory heritage planning, despite its theoretical appeal, encounters various practical barriers. Research examining real-world applications has identified recurring challenges that limit the effectiveness of participatory approaches.

Participatory heritage planning faces several interconnected challenges, particularly within institutional and legal frameworks. As Taylor (2016) points out, heritage institutions are often shaped by traditional, expert-led models. Conflicts between conservation boards and local governments, stemming from overlapping authority, can obstruct the implementation of community-driven projects. Ndoro and Wijesuriya's (2015) research in Africa shows that colonial-era institutional structures continue to limit community participation. In many site management plans, community input remains consultative, while decision-making power is retained by expert boards.

Power imbalances and issues of representation also hinder meaningful participation. In traditional neighbourhood meetings, older men tend to dominate discussions, while the voices of women and youth are often sidelined. Ethnic and religious minorities similarly face structural barriers to being heard. Cooke and Kothari's (2001) concept of the "tyranny of participation" highlights how such processes may reproduce existing hierarchies. For example, when dominant community actors or interest groups claim to speak for the entire community, the perspectives of tenants and other less visible groups often go unrepresented.

A lack of resources and capacity further complicates participation. Chirikure et al.'s (2010) study in Africa shows that communities often lack the technical knowledge and financial means required for heritage management. They may be unfamiliar with traditional repair methods or conservation project planning. Even basic needs—such as organising meetings, hiring facilitators, or securing venues—may remain unmet, deepening dependence on experts and limiting community control.

Conflicts of interest and diverging priorities also create challenges. As Logan (2012) notes, heritage stakeholders often have conflicting goals. For example, the tourism sector may push for increased visitation, while residents raise concerns about noise and congestion. Similarly, luxury real estate projects can clash with tenants' fears of displacement. Short-term, project-oriented funding models also undermine participatory continuity. As Leask and Fyall (2006) highlight, heritage initiatives often rely on time-limited funding. Community committees formed during 2–3-year EU projects are usually dissolved once the project ends, leading to the abandonment of participatory mechanisms and loss of social capital. Cultural and contextual differences further complicate implementation. Caftanzoglou (2001) and Landorf (2009) show that participatory approaches face distinct challenges across settings. In some cases, traditions that prioritise elder authority may conflict with egalitarian participation models.

Systematically understanding and adapting these challenges to local contexts is essential for effective participatory living heritage planning. How such universal challenges manifest within Turkey's institutional structure and social dynamics must be examined within the framework of the local planning system.

3. A brief review of the local planning system: Turkey's legislative capacity for participatory living heritage

After identifying key challenges in implementing participatory living heritage planning, it is essential to assess how well Turkey's current planning system supports the participatory processes this approach requires in order to effectively understand the case study context.

Turkey's cultural heritage planning system is grounded in Law No. 2863 on the Protection of Cultural and Natural Heritage (1983), supported by additional laws such as No. 5366 and 6306. However, this legal framework shows limited alignment with the three core principles of the living heritage approach: integrating community knowledge into decision-making, power sharing, and democratic legitimacy. The practical implications of these limitations arise not only from legal texts but also from complex dynamics, including institutional structures,

professional culture, participation practices, and political priorities. Articles 6 and 7 of Law No. 2863 require "necessary examinations and investigations" in identifying and registering protected areas, yet these procedures rely solely on technical expert assessments. The law includes no provisions for systematically incorporating community knowledge. Conservation Boards base their decisions on technical reports and plans, excluding the experiential knowledge of local communities. Although Annex Article 2 envisions consulting relevant institutions, NGOs, and property owners during the area management plan process, this remains limited to a consultative level. Moreover, the regulations lack binding procedures for systematically collecting and processing community knowledge.

The most explicit participation provisions appear in the Conservation-Oriented Development Plan (CODP) process. While the 2005 regulation required public meetings, a 2019 amendment made them optional—held only "when deemed necessary." This shift weakened public influence in decision-making. Similarly, Law No. 5366 on the Conservation by Renovation and Utilization by Revitalization of Deteriorated Historical and Cultural Properties, and Law No. 6306 on Transformation of Areas under Disaster Risk contain no explicit participation requirements, leaving implementation to central authorities. This undermines the living heritage principle of "managing change with the community" and enables rapid, investment-driven planning.

In Turkey, participation remains at the "information" and "consultation" levels of Arnstein's (1969) ladder of citizen participation, lacking the legal and institutional foundations needed to support equal public involvement in decision-making. Conservation Board members are appointed solely by the Ministry, with no institutionalised mechanisms for local citizen representation, social balance, or civil oversight. Also, while legislation defines the framework for participatory planning, differences in practice cannot be explained by legal texts alone. The emergence of varied practices across cities under the same laws reflects the influence of institutional, professional, and social factors. In Turkey, planning and conservation education and practice remain largely technical and physically oriented. This limits experts' engagement with community knowledge and creates distance from participatory methods (Kayasü and Yetişkul, 2014).

The capacity of municipalities—in terms of staff, expertise, and budget—shapes the quality of participatory processes. Well-resourced municipalities can support more meaningful engagement, while others conduct participation superficially. The success of such processes also depends on local communities' organisational strength and prior experience. Some neighbourhoods mobilise effectively, while others lack this capacity. In areas under tourism, investment, or redevelopment pressure, participation is often side-lined. Cases like Tarlabaşı, Sulukule, and Fener-Balat show how economic priorities have overridden community needs (Kuyucu and Ünsal, 2010).

4. Methodology

This study evaluates the effectiveness of the participatory planning process conducted in Balıkçıköy urban conservation area located in the Maltepe District of Istanbul, during the preparation of the Balıkçıköy CODP. Balıkçıköy was selected because the planning process explicitly aimed to implement participatory methodologies in heritage conservation, providing an opportunity to critically examine the application of participatory principles within Turkey's institutional context.

A qualitative methodology was adopted, structured through a two-stage data collection process. The first stage involved content analysis of participation reports and documents to examine how community inputs were recorded, framed, and who was involved. In the second stage, semi-structured interviews were held with local residents and planning experts to explore their experiences and perceptions in depth. Data were analysed thematically using MAXQDA software. Coding followed an inductive approach, informed by literature on participatory heritage planning and spatial practices.

Purposive sampling was used to reach individuals residing in Balıkçıköy who were involved in the participatory planning process. A total of seven interviews were conducted: four with local residents and three with planning experts. Resident selection considered age, gender, occupation, and length of residence to capture diverse social

profiles and experiences. Participants ranged in age from 37 to 67 and included artisans, journalists, and others. Their ties to the area varied from lifelong residents to artisans with 25 years of experience. Planning experts were selected based on institutional roles—such as coordinator, assistant branch manager, and project staff—and experience with participatory planning.

Interviews with local residents focused on three main themes:

1. Translating community views into planning decisions: Participants were asked about opportunities to participate, how their views were reflected in the plan, the clarity of communication, integration of community demands into decision-making, and the existence of feedback mechanisms.
2. Representation of neighbourhood values: Questions explored perceptions of Balıkçıköy's cultural and historical values, how these were conveyed to planners, the role of everyday experiences in the planning process, representation of intangible heritage, and the balance between conservation and change.
3. Inclusiveness of the participation process: Participants evaluated how accurately their views were reflected in reports, whether participation barriers were addressed, if diverse opinions were equally considered, and whether outcomes were shared transparently.

Institutional interviews were structured around five core questions, addressing:

1. identification of cultural values,
2. participatory planning methods used,
3. criteria for evaluating community input,
4. diversity and inclusiveness of participants, and
5. recommendations for improving future participatory processes.

The raw interview data were first reviewed to identify common themes and outliers, followed by discourse analysis of the coded content. The three main themes aligned with the question sets developed through field observations and were further broken down into secondary categories (Table 1). Observation notes from the researcher's open participation were incorporated where relevant. Finally, findings from the literature review and case study were evaluated together to revisit the research questions and overall topic.

Table 1. Coding themes

Main Themes	Sub themes
Local values and patterns of daily life	• Physical environment and structural memory • Spatial memory and identity construction • Social practices and collective rituals
Transforming local people's views into planning decisions	• Disconnect between demand and decision • Technical knowledge and local knowledge and experience • Institutional complexity and jurisdictional ambiguity
Representation of all views	• Participant composition and demographic diversity • Temporal and spatial dynamics of participation • Information sharing and process traceability

5. Results

5.1. The Balıkçıköy conservation area and its planning process

The case area is located in Yalı Neighborhood, Maltepe district, Istanbul, lying between the E-5 (D100) Highway and

Turgut Özal Boulevard, bordered by the E-5 to the north, the coastal road to the south, Hasan Polat Stadium to the east, and Orhangazi City Park to the west (Figure 1). Originally a traditional fishing settlement with strong ties to the sea, its coastal connection weakened after the construction of the coastal road in the 1970s, resulting in a spatial structure increasingly disconnected from the shoreline.

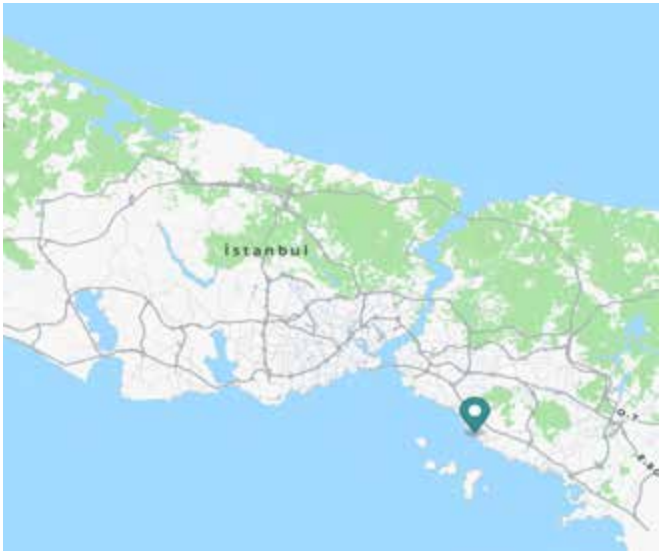

Figure 1: Location of the planning area in Istanbul (Source: Istanbul Metropolitan Municipality, 2024a)

Key features of the area include Beşçeşmeler Square, İskele Square, Feyzullah Mosque, traditional houses, and narrow streets, which together define its distinctive urban character (Figure 2). Beşçeşmeler serves as both a functional hub and a symbolic focal point. The organic street layout reflects typical coastal settlement patterns, but growing development pressure and functional changes have led to a gradual deterioration of the urban fabric.

Figure 2: Balıkçıköy Urban Conservation Area (Source: Istanbul Metropolitan Municipality, 2024b)

The area was designated as an Urban Conservation Area in 1990 by Istanbul Cultural and Natural Heritage Conservation Board No. II. It covers a total of 12.5 hectares, including the protected zone and its buffer area (Figure 3). The 1/500 and 1/5000 scale Conservation Plans approved in 1998 remain in effect. The plan revision process began with a 2019 decision by the Regional Conservation Board.

Figure 3: The boundaries of the planning and urban conservation area, (Source: Istanbul Metropolitan Municipality, 2024b)

In 2021, the 1/5000 scale Balıkçıköy Conservation-Oriented Revision Master Plan received presidential approval from the Istanbul Metropolitan Municipality (IMM). Later that year, following the transfer of planning authority from the district municipality to the IMM, the 1/1000 scale Implementation Plan was also approved. By early 2022, the planning process actively commenced, with opinions sought from relevant institutions. Analyses on natural structure, land use, built environment, transportation, and technical infrastructure were conducted based on 2022 data and made available digitally. Between 2022 and 2023, analysis–synthesis studies, conservation zoning plans, and the Urban Design Guide were completed with input from institutional stakeholders, fieldwork, and participatory processes. In 2023, the plan was approved by the IMM Assembly and submitted to the Regional Conservation Board in 2024. That same year, the plans were returned with revision requests, and revision efforts are currently ongoing.

The Balıkçıköy CODP implemented a participatory planning methodology based on six core principles.

- Transparency ensured openness from start to finish, with all activities shared publicly;
- Objectivity promoted equal and fair treatment of all participants;
- Inclusiveness aimed to represent diverse social groups and foster dialogue;
- Needs assessment focused on identifying and discussing stakeholders' on-the-ground needs;
- Deliberation encouraged open discussion of conflicting views and expectations;
- Feasibility emphasized evaluating proposals in light of their practicality and public benefit.

Various data collection methods were employed to operationalise the participatory approach. Public meetings supported information sharing, awareness raising, and consultation. Surveys, spatial marking exercises, and a participation desk were used to gather input from local residents, shopkeepers, and visitors. Additional methods included focus group meetings, one-on-one interviews, city councils, and exploratory walks to sustain dialogue and consultation throughout the process (Figure 4). The following activities were carried out as part of the participatory planning process:

- Balıkçıköy introductory forum (June 9, 2022): An open-air forum was held in Beşçeşmeler Square, where residents, shopkeepers, and users were informed about the conservation area, planning process, and urban design guide. A Q and A session followed.
- Cultural centre meetings (June 23–25, 2022): Over three days, meetings were held with five neighbourhood cultural centres to discuss street revitalisation through cultural functions, public space improvements, infrastructure needs, and ways to enhance social interaction.
- Participation desk and spatial marking: One-on-one interviews were conducted at a participation desk in Beşçeşmeler Square, while participants marked problems and suggestions on a digital map via an online tool.
- Urban design guide meeting (September 9, 2022): Held at the Chamber of Architects, this meeting presented the draft urban design guide. Alternative scenarios for square and street layouts were evaluated through design criteria.
- Interviews with local actors (March 9, 2022): Representatives from BEKSED and the Katılımcı (Participatory) Maltepe Newspaper were consulted to gather views on local challenges, opportunities, and recommendations.

Figure 4: Participatory planning activities by IMM (Source: Istanbul Metropolitan Municipality, 2024b)

5.2. Local values and daily life patterns

Physical environment and structural memory

Local participants perceive Balıkçıköy's physical environment as a strong anchor of collective memory. Old buildings are associated with personal memory cues such as "the coffee left by the Greeks," "tandoori smells," and "Communist Kenan's house," reflecting both the area's multicultural past and the spatial grounding of individual memories (İ, 67, local resident). Beşçeşmeler, in particular, is identified as a key focal point with both nostalgic and symbolic significance (N, 43, NGO representative; M, 64, local journalist).

Expressions like "silently being demolished" and "abandoned to its fate" reflect widespread concern over the loss of physical heritage. Participants associated the street texture with a past characterized by low-density, gardened, countryside living. The transformation over time was voiced critically through remarks such as "it was a summer place" and "now we cannot see the sea."

In planners' discourse, the physical environment is framed primarily as a site of technical intervention. Tools such as registration fiches, 3D models, façade arrangements, and circulation schemes are used to enhance the visibility and accessibility of historic buildings (Planner M; Planner N). References to Beşçeşmeler focus on functionality rather than emotional meaning. Emphasis on circulation and visual continuity reflects a technical optimisation of the street texture, with limited attention to its cultural significance.

Spatial memory and identity construction

Interviewee narratives indicate that local identity in Balıkçıköy is shaped not only by the physical environment but also by personal histories and shared community memory. A sense of belonging is reinforced through long-term residence and being born and raised in the neighbourhood, transforming the place into a carrier of biographical identity. İ's (67, local resident) remark, "we are the ones who have the real say," reflects a claim to legitimacy grounded in both historical continuity and lived experience. Beyond daily use, this sense of belonging is deeply tied to individual and collective memories. N's (43, NGO representative) remark, "we used to play on

these streets," reflects the spatial imprint of childhood, while M's (64, local journalist) statement, "this fountain connects me to life," shows how physical elements become emotional anchors. Temporally, participants idealise the past, constructing a "golden age" narrative with expressions like "it was like Bodrum" and "it was a tourism town." These narratives express both criticism of current changes and a sense of loss, marking ruptures in the experience of belonging.

Local identity in Balıkçıköy is shaped by both micro-level personal references and macro-level historical narratives. Phrases like "Communist Kenan's house" and "Hacı Kahve's house" reflect how individual memory is embedded in the physical fabric of the neighbourhood, while statements such as "this is where Maltepe was born" emphasise the historical depth of collective identity (İ, 67, local resident; G, 46, shopkeeper). In planners' narratives, belonging and memory are often treated as externally observed behaviours or data sources for planning. Planner E's remark that "a protectionist attitude was observed among the participants" reflects an understanding of belonging as an object to be identified, rather than a lived experience. Similarly, Planner N's statement "citizens shared their memories and we tried to reflect this in the planning decisions" suggests that memory-based inputs are mediated through a planning lens. From this perspective, identity tends to be shaped through physical interventions, supported by tools such as pedestrian connections, public focal points, and façade arrangements.

Social practices and collective rituals

Local participants describe Balıkçıköy's social fabric through past neighbourhood relations, shared rituals, and daily practices. Statements like "everyone knew each other," "you couldn't go home without having tea at 5 p.m.," and "there was a culture of helping each other" reflect sustained forms of social interaction (İ, 67, local resident; N, 43, NGO representative). Among ritual practices, the Turkish Republic Day celebrations stand out. Narratives such as "local dances used to be played" and "people walked around in war costumes" highlight both the vibrancy of the tradition and its spatial requirements (M, 64, local journalist). However, this continuity has been disrupted, as expressed by G (46, shopkeeper): "the square cannot accommodate it in its current form." Social belonging is said to persist in small-scale spaces such as modest cafés, street conversations, and fountainheads. These places strengthen individual and collective bonds, as reflected in expressions like "it connects me to life" and "we are on very good terms with the shopkeepers" (M, 64, local journalist).

Planners tend to view social practices as sources of observation and data. The decline of rituals like the October 29 celebrations is attributed to spatial issues, such as "winter gardens blocking public space." The lack of playgrounds and inadequate public gathering areas were noted in reports under the category of social needs. Past social practices—such as the "tavern and raki culture"—were treated by planners as historical references derived from observation and archival sources, rather than as lived local experiences (Planner M). However, most local residents noted that the tavern culture in Beşçeşmeler Square is not a unique value of the area's past. Overall, official correspondence and institutional opinions appear to have been the primary sources guiding the planners during the process.

5.3. Transforming the insights of local people into planning decisions

Disconnect between demand and decision

During the Balıkçıköy planning process, local participants were able to share their demands in meetings and engage directly with planners. While they acknowledged that their views were noted and recorded, there was little clarity on how much these inputs influenced actual plan decisions. N (43, NGO representative) reflected a sense of limited impact with the remark, "even if we object, not much changes. Planner N stated that data collection was systematic, with field observations and meeting notes analysed thematically. However, she did not clarify how this information was communicated or shared with local stakeholders.

The tension between local demands and planning objectives is clearly reflected in the debate over winter gardens. Shopkeepers defended them for their economic value, while residents complained that they limited access to the square. In response, the planning team recommended their removal, citing disruption of public space continuity and obstruction of historic buildings. Planner E's remark— "the frequency of requests was important, but

public interest was also taken into account"—indicates that while local demands were considered, final decisions were ultimately guided by the principle of public interest.

Technical knowledge vs local knowledge-experience

The planning process reveals an asymmetry between technical expertise and local experience. In Balıkçıköy, technical knowledge largely shaped decision-making, while local knowledge was primarily used during data collection. Planners noted that input from residents was categorised under thematic headings in plan documents (Planner E). However, how this information was translated into specific decisions and shared with stakeholders remained unclear. Local participants noted that they were able to share their experiences, but were unsure whether this input influenced outcomes. Statements like "we told them, but the decision is still the Board's" (N, 43, NGO representative) and "I attended the meeting, but we couldn't see what happened afterwards" (M, 64, local journalist) highlight a disconnect between participation and decision-making.

Planners explained that the process relied on institutional opinions, archival records, registration slips, and technical analyses by BİMTAŞ (Planner M; Planner N). These sources, drawn from official documents, were directly incorporated into the planning materials. Local knowledge—such as neighbourhood memory, usage patterns, and oral narratives—was included only after being filtered through technical evaluation. The presentation of technical information also limited access. Although plan documents were made available online, this was insufficient for users with low digital literacy. M (64, local journalist) noted that she accessed the documents through her own efforts, while other participants struggled to obtain them. The complexity and technical nature of the language used also emerged as a barrier. M (64, local journalist) remarked, "I had difficulty understanding some parts," while N (43, NGO representative) described the participation desk as "like a touristic place," criticising the information as superficial. Planner E acknowledged this issue, noting that efforts were made to simplify terms—for example, saying "zoning" instead of "Master Plan" to improve understanding.

Institutional complexity and ambiguity of authority

The Balıkçıköy planning process involved multiple actors, including the Conservation Board, Istanbul Metropolitan Municipality, and Maltepe Municipality, all exercising overlapping authority. Most local participants viewed the Conservation Board as the final decision-maker. N (43, NGO representative) expressed this perception, though the quote was incomplete in the original input—please feel free to provide the rest if you'd like it included.

Institutional authority conflicts were made tangible by the failure to implement an approved project. G (46, shopkeeper) noted that a project developed by the artisans' association was approved by the Conservation Board but not implemented by Maltepe Municipality. The lack of clearly defined institutional responsibilities left local residents without a clear point of contact, resulting in unresolved expectations. İ (67, local residents), M (64, local journalist), and G (46, shopkeeper) stated that despite collecting numerous signatures to pedestrianize Küçükyalı Street, they received no definitive response from any authority. Some participants remarked, "the Metropolitan Municipality has the authority, but we're left dealing with the local municipality." Participants noted their exclusion from the Urban Design Guide process. N (43, NGO representative) stated, "we were not invited to some technical meetings," while M (64, local journalist) remarked that technical experts deliberately avoided involving local residents, which led to their exclusion.

5.4. Representation of all insights

Participant composition and demographic diversity

Participants offered varied reflections on the demographic composition of stakeholders involved in the Balıkçıköy planning process. İ (67, local resident) remarked, "I was the only local," highlighting the underrepresentation of long-term residents. Regarding age groups, Planner M noted, "children could have been worked with, and the night population could have been interviewed," indicating limited inclusion of children and evening users. Socio-economic and interest group disparities were also evident. Commercial actors—especially shopkeepers—were well represented, likely due to debates over winter gardens. In contrast, the voices of non-commercial users, such as families, public space users, and recreational visitors, were less visible. Planner E acknowledged

this imbalance, stating, "the diversity of participants could have been wider," suggesting that institutional actors were aware of representational gaps.

Temporal and spatial dynamics of participation

Several observations were made about the timing and spatial organisation of participation activities. Planner E noted that "the area becomes more crowded in the evening," suggesting that scheduling meetings primarily in the morning may exclude evening users and the working population. Concerns were also raised about how meetings were announced. N (43, NGO representative) stated, "we found out later that some meetings were held," while İ (67, local resident) recalled, "suddenly a crowd came to the square, and when I saw there was a plan meeting, I joined." These accounts highlight how the timing and communication strategies of participation events can unevenly affect access for different user groups.

Information sharing and process traceability

Participants reported contributing to the process but receiving little information about the final outcomes. İ (67, local resident) noted, "we did not see the final version of the plan," while N (43, NGO representative) stated, "we participated but no one informed us afterwards." G (46, shopkeeper) highlighted the lack of traceability with the remark, "no feedback was given." Some participants said they were unaware of the plan's approval status and were only told it had been uploaded online. M (64, local journalist) pointed to digital inequalities, saying, "I was able to access it, but not everyone can." From the institutional side, Planner E emphasised the timing of feedback, observing that "if it is not responded to in a short time, belief decreases."

6. Discussion and conclusions

The participatory living heritage planning process in Balıkçıköy drew attention for its methodological variety and institutional involvement. Despite this, it faced key limitations regarding the influence of participation on decision-making and its perceived legitimacy among the community. Various tools—such as introductory forums, cultural centre meetings, participation desks, online mapping, thematic public meetings, and design guide workshops—were employed to create a formally inclusive model. Yet, participants often questioned whether these tools led to meaningful participation or shaped actual planning decisions. For instance, many participants were unclear about how activities like the participation desk in Beşçeşmeler Square or the mapping of local issues influenced planning outcomes. Remarks such as "We participated, but then no one provided any information" (N, 43, NGO representative) and "We couldn't see the final version of the plan" (İ, 67, local resident) highlight a lack of feedback and process transparency. These concerns indicate that participation was largely limited to data collection and aligned more with the "consultation" level in Arnstein's (1969) ladder of participation.

Although the process followed participatory principles, the integration of local knowledge into planning decisions was limited. This is especially relevant to the study's second theme: how community knowledge informs decision-making. While local input was included in planning documents, it was filtered through technical frameworks, and the details of this transformation were not communicated back to the community. In cases like the exclusion of winter garden proposals for "public interest," technical priorities prevailed over community demands. This reflects the reproduction of what Smith (2006) terms 'authorised heritage discourse,' where local knowledge served a supplementary rather than central role.

Participant narratives reflect not only information but also expressions of identity and belonging. Statements like "This fountain connects me to life" (M, 64, local journalist) and "We are the real decision-makers" (İ, 67, local resident) illustrate that spatial memory and local values imply both physical and social ownership. This aligns with the study's first theme: local values and everyday life patterns. However, in the planning process, these values were often reduced to functional elements, stripped of their cultural context within the technical discourse. According to Healey's (1997) communicative planning approach, such values should inform decisions, yet in Balıkçıköy they remained largely illustrative rather than operative.

The third main theme, "representativeness and equality," becomes central when examining participant experi-

ences. Access to meetings, the selection of invited groups, and the ability to follow the process directly shaped the inclusiveness of participation. Comments such as "I was the only local person there" (İ, 67, local resident) and "some meetings were held in the morning, so workers couldn't attend" (N, 43, NGO representative) reveal how temporal and social constraints limited representation. Although planners acknowledged that "participant diversity could have been broader," this issue was not addressed through structural changes.

At the institutional level, the involvement of multiple actors—such as the Istanbul Metropolitan Municipality, the district municipality, and the Conservation Board—created confusion and weakened participants' focus on solutions. Comments like "the Board approved it, but the municipality did not" or "we went to the local municipality, but the authority lies with the metropolitan municipality" illustrate a lack of clarity in the chain of authority. This ambiguity reduced public motivation to engage. According to Healey's governance-based model of participation, this case highlights the need to strengthen both horizontal and vertical communication mechanisms.

When these findings are evaluated through the lens of Court and Wijesuriya's (2015) three-stage cyclical participation model in living heritage planning, the Balıkçıköy planning process appears to have been relatively effective in the first phase, "Discovery and Understanding." A variety of tools were employed to explore community perceptions, local values, and priorities; rich qualitative data were collected through activities such as community forums, participation tables, and online mapping. However, during the second phase, "Visioning and Strategy," the integration of this local knowledge into decision-making processes remained limited, as the planning vision was primarily shaped by expert-driven definitions. In the third phase, "Implementation and Monitoring," the absence of participatory feedback mechanisms and the inadequate dissemination of the final draft plan outcomes to the public hindered the development of a cyclical and adaptive planning process. This indicates that participation was largely confined to an initial data collection exercise, falling short of the principles of continuous learning and shared governance central to the living heritage approach. The Balıkçıköy case thus highlights the importance of not only engaging communities in the discovery phase, but also ensuring inclusive collaboration throughout strategy development and implementation in order to fulfil the transformative potential of living heritage planning.

In conclusion, while the Balıkçıköy planning process adhered to formal participatory principles, it fell short in key areas such as influence on decision-making, the integration of local values, and equitable representation. Technical tools alone were insufficient to establish democratic legitimacy. The process underscored the need for deeper structural changes—particularly in decision-making authority, information transparency, and representational balance. Taken together, the findings reveal structural tensions between participatory ideals and practical implementation in the Balıkçıköy case. The study's three core themes—(1) recognition of local values, (2) the link between information and decision-making, and (3) representational inequalities—offer a valuable lens for evaluating the transformative potential of participatory planning, not only in Balıkçıköy but across other protected areas in Turkey. Future research should assess the long-term impacts of these dimensions through broader case studies to determine whether participatory mechanisms function as effective tools for equitable governance or remain constrained within procedural boundaries.

Digital platforms, regulatory planning and heritisation: Airbnb and discourses around courtyard houses in the medina of Tunis (2011 to 2024)

Iman Batita
LARSH – UPHF, Université polytechnique des Hauts de France

Justin McGuinness
LACNAD Langues et cultures du Nord de l'Afrique et sa diaspora, INALCO – Paris and AUP, American University of Paris)

Abstract
This paper is concerned with historic houses in the old city or médina of Tunis as sites of memory. We take three case studies of courtyard houses (diyar, sing. dar) which were restored or adapted for use as guest accommodation in the 2010s. While the sample is small allows us to explore some of the main features of the discourses of belonging developed around the historic house in old Tunis. Such guest accommodation can now be seen across the world thanks to digital service platforms like AirBnB. Our interviews with guesthouse owners suggest a strong intellectual and emotional commitment is present in the restoration and reuse of a history property. While digital platforms are importants as sites via which individuals can communicate ideas about the built heritage of a city, there are other important discourses underlying the veneer. The paper thus reveals how family pasts are important in a form of activist engagement with a particular city's past.

Key words: heritisation, urban conservation, guesthouses, urban memory, médina of Tunis

This paper is concerned with historic houses in the old city or médina of Tunis as sites of both memory and forgetting. We take three case studies of courtyard houses (diyar, sing. dar) which were restored or adapted for use as guest accommodation in the 2010s. The sample is small but in the short space of an oral conference paper, it allows us to suggest some of the main features of the discourses of belonging developed around the historic house in old Tunis. Such guest accommodation can now be seen across the world thanks to digital service platforms like AirBnB. We suggest that such platforms are growing in importance as sites on which individuals can communicate ideas about the built heritage of a city, to an extent competing with or even weakening the discourse of public institutions. While we believe that actors providing tourist services play an increasingly important role in the historic built environment, we are not sure how this might be measured. Its impact is certainly clear in numerous cities where residents are driven out by rising rents and the general decline in deep rooted urban ways of living which occurs as tourism expands.

In this short study on old Tunis, we hope to show something of the way in which houses are made appealing, displaying historic features and playing a part in narratives of the old city. Such narratives are developed – at least for the houses discussed here – by individuals with a strong sense of the value of Tunis' historic architecture and of their place in the scheme of the city's past.

Both the authors of this paper are concerned with questions of regarding the heritisation of urban space, housing and planning. Iman Batita is the author of a doctoral thesis on the different users who have restored houses in the médina of Tunis for different uses; Justin McGuinness, having originally worked on planning for precarious social groups in multi-occupancy housing is interested in the techniques used in the transformation of historic homes and in the planning frameworks for médinas in North Africa.

The old city of Tunis has been the focus of conservationist discourse since at least the 1920s when two central areas whose architecture was held to require special protection were defined (Ammar 2010, p.116). The details of the development of heritage planning from that decade onwards are well covered by Jellal Abd el-Kafi in his La Médina de Tunis, espace historique. Since the late 1960s, the historic urban fabric has had a place in Tunisia's national political discourse. The médina has also been the object of numerous professional interventions by

architects and urban planners, for the most part working for an unusual body, the Association de sauvegarde de la Médina de Tunis, established in 1967. The more distinctive spaces of the old city have also proved attractive to entrepreneurs in the tourism and hospitality industries, a turning point being the opening of a high-quality restaurant in 1989, the Dar el-Jeld. A further turning point in the old city's trajectory was the completion of a major public realm project in the north-west section of the Médina, one of the areas with a particularly high concentration of historic buildings, religious, residential and educational. Through a subtle series of interventions on façades and sometimes on whole buildings, this project, completed in 2010 and often referred to as le Circuit, rendered several kilometres of streetscape far more 'historic' – and certainly more attractive thanks to the careful selection of colours and materials. Arguably this project 'primed the pump' for private investment for tourist activity in the western médina. The route from the Zitouna Mosque through to the rue du Tribunal had become immensely more pleasing to both residents and visitors. Note that actors in the tourist industry comprise individuals and businesses ranging from the highly professional to the amateur.

Since the 1980s, the medina has been subject to a specific town planning code that the municipality was able to enforce fairly effectively until the Jasmine Revolution – as it was often dubbed in the media – of 2011. Façade improvement operations like le Circuit continued in the early 2010s while a municipal programme to improve owner-occupied private housing continued over the same period. However, the control by the municipality over building use and new build / restoration works weakened considerably after 2015. Notably, the wholesale trade in imported garments, footwear and accessories gained considerable ground in a large swathe of the south-eastern central médina. This phenomenon has yet to be studied in detail either by researchers or by the municipality's services. There are several reasons which may account for the lack of investigation here, the most important one being the instability of municipal government since the 2011 Revolution. For a long period, municipal councils across the country operated under a special régime; there being no municipal elections, caretaker city councils were put into place. Short of funds and without strong leadership, such councils were unable to undertake any major decisions on the future of the built environment.

Methodological framework: discovering discourses of the house as site of meaning

Indispensable to human survival in settled areas, the material forms of the house are strongly invested with meaning. This has been explored by numerous theorists and a reflection of the contemporary debates about the question of the house can be found in journals like Home Cultures. The present paper draws on the authors' work on houses in Tunis, and notably on Batita's doctoral thesis which was based on numerous direct interviews with the actors of the heritage and tourism sectors in Tunis. In order to build her knowledge of the functioning of guesthouses, Batita also undertook short stays in several of them, giving her work a particular level of nuance.

McGuinness worked on the trajectories of precarious, low-income households during his doctoral research in the early to mid-1990s. Between 1992 and 2000 he lived in a nineteenth century house in the Bab Menara district. Through his network of friends and acquaintances, he has been able to follow the changes in a number of historic homes, some of them which are now used as guest accommodation. He is also well aware of the challenges and unforeseen hurdles of historic house restoration, having undertaken ethnographic work in that area in Fès – where he also restored a house.

Such familiarity with this particular aspect of the médina's functioning is not easily acquired. Some informants are prolix, to say the least, in a discussion of the médina. Others whom one would have expected to have much to say are not interested in the researcher's themes. But it is an old truism of ethnography that good insights are not always to be found where one would expect them – and that a discussion with informants will necessarily take a hoped-for direction. But this is all part of generating insights into a world with which the researcher may only have limited familiarity.

Before moving on, the authors recognise that the business of researching other people's homes can be sensitive. The informants who provided material for our case studies are in a sense public figures, either by dint of their interventions on the Web or by their professional activity which is based on the provision of well run short-stay

accommodation.

Changes in residential patterns in the médina, 1960 to 2000

In terms of residential use, the Medina underwent major changes, starting in the 1950s. Fleeing the poverty of the countryside, large numbers of rural migrants settled in the old city. As of the 1960s, elite families began to move out of the old city to settle in neighborhoods vacated by departing French, Italian and Tunisian Jewish families. There was a change in meaning and ways of living apparent in the Medina. Old Tunisois (beldi) families whose jobs and aspirations were tied up with the country's drive to modernity longer no wanted to live as part of extended families in the labyrinthine courtyard houses.

It became difficult for such families to live alongside the rural folk who were living in historic houses where rooms were rented out to individual families. The beldia found the northern coastal suburbs to be more congenial for a middle-class 'modern' family and they began to live in their summer residences all year round. There was a definite mimicry here.

When a family moved out, the old courtyard houses faced two options: abandonment or rental through agents as rooming houses (oukala-s). Architecturally important houses like Dar Belhassen and Dar Hedri on rue du Trésor, just a few minutes' walk away from the central Zitouna Mosque, were left to crumble. As certain individualism took root in the extended families, it became impossible to finance the maintenance, generally costly and often complex, of a typical large médina dar. The rental of rooms to families desperate for somewhere to live in the city was a stop-gap solution which became permanent.

Nevertheless, in some neighborhoods, the old ways of life continued to an extent into the late 1990s. In that decade, a number of families – the Baccouches and the Bou Hajbas, along with members of the Bayram and Lakhoua families were still resident in the Bab Menara district. Even today there are old beldi families living on the rue Sidi Ben Arous. One such family, the Belhaouanes, were the very first to transform their home on this street into the médina's first guest house, the Dar el-Médina, which opened in 2005.

The 1990s also saw artistically minded artistically minded folk, both Tunisian and foreigners, acquiring historic properties in the central Medina. The Algerian artist Rachid Koreïchi restored a house. The restoration of a fine seventeenth century courtyard house, just off Rue de la Kasbah, was conceived by the London-based Minimalist architect John Pawson. This house has featured on several occasions in decoration magazines like Nest and Architectural Digest (Withers 2008, Tomasini 2024). By about 2000, the possibility of the médina becoming a place where a relatively wealthy person might have a tasteful retreat, restored so as to preserve and enhance its original architectural features, was circulating among a handful of architecturally minded Tunis residents. That the médina might become a place where old houses were upgraded to function as guest houses – as was the case in Marrakech from the mid-1990s – did not seem likely, however. (By 2000, that city had at least three agencies specialised in the purchase, restoration, rental and management of upgraded historic houses).

The development of the *maison d'hôte*: obstacles and opportunities

As just mentioned, the first fully functioning guesthouse was the Dar el-Médina on the Rue Sidi Ben Arous. We discuss this case in detail because it provides a base-line from which to discuss the factors enabling the phenomenon of individually owned guest houses to develop. (Not least of these was Web 2.0)

Originally the family home of a family close to the Tunisian nationalist movement, Dar el-Médina opened in 2005. All family members had agreed that a guesthouse was an appropriate use for the home. The restoration project saw a skilled architect with years of experience in working on historic buildings reinforce the house's character with the careful insertion of extra rooms and the judicious addition of decorative features.

Nevertheless, few other families in the early 2000s were ready to make the leap. The question of indivision (Muslim law lays down scrupulous rules for the division of an inheritance) can stymie a project should there be absent

part-owners or a family member unwilling to sell their share to the promoters of a project for a house. Then there is the question of cost. To put in the fluid and electric networks is a costly job, as is the construction of new rooms to give a house the number of rooms – generally considered to be seven – necessary for a guesthouse to be cost effective. The city planning regulations are stringent on security and on quality requirements for utility networks.

Despite a major delay due to a shortage of funds, Dar Belhaouane was opened as the city's first officially authorised guesthouse and continues to function as such today.

The Belhaouanes had seen a business opportunity. Familiar with developments in Morocco, they had realised the potential of their home. Because the other elements necessary (available loans, a good architect and suitable contractors) were present, they were able to move forward. Many other projects for guesthouses and small hotels remained at embryonic level, however, for reasons not always clear. Some of the most ambitious projects, launched by major business figures simply stalled, seemingly from lack of interest.

European buyers were also few – a major difference with Morocco and other Mediterranean countries. The Tunisian State requires that foreigners buying property outside designated tourist zones obtain an authorisation to purchase. The procedure for obtaining this document from the regional authorities (governorate) is slightly opaque in character and would seem to have discouraged individual foreigners from buying property and eventually moving into the guesthouse business.

The market for property with historic character and potential as tourist accommodation thus remained dominated by Tunisian buyers. So it was that when the digital travel platforms appeared in the 2010s, there was an opportunity for individuals and families with attractive houses to reach a global market for their newly created guest accommodation. The Revolution of 2011 saw people taking liberties with municipal regulations in a way which would have been unthinkable during the years of the Ben Ali regime (1987-2011), not least of which through the construction of new rooms on roof terraces or the transformation of street-facing rooms into shops or depots. While the Revolution may have not ushered in a new republic firmly based on respect for the rule of law, it did open up opportunities in various areas where regulations were unclear or had yet to be drafted on a new activity, i.e. the family-run guesthouse.

To return to our theme, in this short paper, we are exploring the discourse around three well-known maisons d'hôte, namely the Dar Jellouli, La Chambre bleue and Dar Ben Gacem. All are in the central médina, all are well known in one way or another. Located on Rue du Riche, the first-floor patio apartment of Dar Jellouli was occupied by one of the Médina's most emblematic figures, Si Ahmed Jellouli, a true dignitary of the city whose home was a point of call for many a diplomatic visitor. La Chambre bleue, situated on Rue du Divan, was established by a Tunisian couple, descendants of an old Tunis family, both of whom had studied abroad. One was a dancer and actress, the other a university lecturer. Located on the Rue du Pacha, our third example, Dar Ben Gacem, is run by a woman entrepreneur of a family of the same name. This family has no historic ties to the médina.

All these maisons d'hôte are centrally located. We take them each to be representative of a certain approach to presenting the life of the médina – and to making a narrative of the past and the city's culture available to the foreign visitor. In Dar Jellouli, the family once resident in the house is explained through references to a prestigious lineage. La Chambre bleue is a conversion with a strong contemporary aesthetic charge; at least one of the owners is always present. The owners of Dar Ben Gacem grew up abroad, and had restoration works conducted by an experienced architect. This is the most heavily promoted guesthouse of the three. Owner Leïla Ben Gacem's good works in the médina have been the subject of many a media article; she appears to be the main force in a private-sector initiative, Tunistoric, promoting the sale and restoration of historic houses.

We propose now to examine more closely the discourses produced around different elements in these restoration projects. How did their owners establish a relationship with their houses – and through them, with the city's past?
Motivations. What makes couples or families decide to set up a *maison d'hôte*?

As indicated earlier, the present authors are both well aware of the vicissitudes of historic house restoration. The process is rarely smooth. A building may have unforeseen defects; appropriate materials may be in short supply or extremely expensive; a suitable contractor can be unavailable without explanation. In the light of these factors, we should turn to our small selection of guest-houses, first providing brief descriptions of their character before turning to the thinking which led the owners to take on restoration projects.

All three guest houses are at least two and half centuries old. Dar Jellouli is mentioned in 'the Revault' (1978, p.140) on account of its striking main entrance framed in the dressed stone so typical of the Tunis streetscape. However, only a small part of the house is used – or was used in the early 2000s – for guest accommodation. The main patio, referred to in the family as Dar et-Talyana ('la Maison de l'Italienne') was in multi-occupancy until recently. Similarly, the Chambre bleue is in fact the guest quarters of the much larger Dar Bel-Cadhi (Revault 1978, pp.347-348). Dar Ben Gacem, on the other hand, is a full courtyard house which may go back as far at the seventeenth century. All these houses have the decorative features so typical of buildings in old Tunis: polychrome wall tiles, marble or cut-stone floor paving, painted ceilings and carved stucco.

To go into depth regarding Dar Jellouli, this house was the Tunis residence of a family originally from Sfax. The Jelloulis were involved in corsair activity, a form of legalised piracy practiced in the Mediterranean in the seventeenth and eighteenth centuries. As of the nineteenth century, the family provided administrators for the Beylicate of Tunis (see Binous 2001, pp.62-69). The last of these figures, Si Ahmed Jellouli, was a well-known figure in the Médina. After his death in 2011, his apartments on the first floor of Dar Jellouli were preserved as he left them. It was here that he would receive, in an unofficial capacity, important visitors to the city. Family members' respect for Si Ahmed had allowed him to continue to enjoy the use of the upstairs apartment; the question of indivision was not evoked.

Given the cost of maintaining the property, two of Si Ahmed's relatives started a small-scale guest room operation on AirBnB. One of the present writers (I.B.) stayed in the house and was struck by the extent to which a visitor was immersed in the family's story. At least in the first decade after Si Ahmed's death, members of the family felt invested by a mission to conserve the memory of the family and its place in Tunisia's history. But the revenue generated through the rental of a guest room was inadequate to cover the cost of maintaining the house. In 2025, it seemed that Dar Jellouli was for sale.

In the case of the Chambre bleue, the relationship with the house was different. Sondès and Marouan Ben Miled, the couple who acquired the property at the Rue de l'Aga end of Rue du Divan knew that they wanted to live in the Médina. They had the advantage that Marouane's father had restored a property and that an uncle, Tarik Ben Miled, is a highly respected architect in Tunis, aware of the difficulties of restoration. The motivation was more diffuse than in the case of the owners of Dar Jellouli. There was a strong attraction to the ways of life still present in the médina; Sondès felt a need to hand on the house to future generations. But as works proved expensive for the couple, medium term rentals became a way of generating some extra income to help cover costs. Eventually, this activity turned into short stay holiday rentals which Marouane Ben Miled manages extremely effectively – as is illustrated by comments on the Chambre bleue's AirBnB page. A will to transmit a feel for old Tunis to clients, both in the spaces and through the food prepared for guests, is strong in this guest house.

In contrast, in the case of Dar Ben Gacem, the motivation for restoring the house is more definitely commercial. Possibly because she is not from Tunis and does not actually live on the premises, the owner has had to put effort into developing a discourse which demonstrates her affective link with the house. This can be discerned in the promotional booklet, Dar Ben Gacem, the Story, where much is made of the 'noble' origins of the Anun family, the original owners of the house. (The connotations of the term 'noble' as used in European languages cannot be easily applied in a city like Tunis). Arguably, in the case of Dar Ben Gacem, the business of selling accommodation in a beautifully restored house is linked to a desire for recognition.

Thus our three guesthouses, partly through their striking décor and interesting locations, but also through their

owners' affection for the medina and their sense of responsibility, can be described through the metaphor of a deeply felt 'rootedness' in the city's long history. To move further theoretically, these owners, heritage activists as they are – without ever using that term about themselves - are people who have succeeded in creating places where certain qualities of old Tunis are presented and even enhanced. One cannot doubt their sincerity in this task. The récits of the city are an essential part of their practice. After all, anecdotes please; one cannot just say here is a stone-flagged courtyard with four rooms.

What does a guest house mean?

Through a small number of cases – to be expanded upon further in the fuure, this short paper illustrates the way in which the Tunisois courtyard house, that most intimate of dwellings, has shifted from being the living space of extended families to a place for receiving a regular flow of short-stay visitors. While similar mutations in the function of housing have taken place in thousands of historic neighbourhoods across the world, in the case of Tunis – and Arab-Muslim cities like it - the shift marks a major break with the deep-rooted cultural practices, in the meaings of place. While the owners of some houses work to generate income allowing the built fabric to survive, in other cases the house is very much a place to purvey commodified 'experiences' of an old way of living. Below the (extremely agreeable) veneer of the heavily restored courtyard house, the profit motive is at work. That said, there are different degrees with respect to this motive.

To return to our closing question, 'how do guest houses mean?', there is much more than immediately meets the eye on the Internet when discovering these Tunisois homes through images and the flow of comments on a digital platform. Both the Belhaouane and Ben Miled families had a deep-rooted commitment to the broader life of Tunis. The grandfather of the owner of the Chambre bleue was one of the city's first European-trained Tunisian doctors and a public figure, as was his grandmother. The uncle of the Belhaouane brothers who set up Dar el Médina in the early 2000s, Ali Belhaouane (d.1958) was a figure in the Tunisian independence movement. The nuances of such pasts are not easily explained to the short-stay visitor. But for those who are curious, further tales of the city are there.

The historic *dar*'s place in the processes of heritisation – and commercialisation

In this paper, we have attempted to bring out the discourses which are part of the general fabric of meaning offered by our three emblematic guesthouses. In future work, we would like to situate them firmly in the broader processes at work in residential life. The récits offered by the owner-promoters of these guest houses are lucky in a sense that their homes are both aesthetically pleasing and are part of strong traditions in public life.

Encouraged with technical advice provided by trained architects sensitive to the qualities of the Tunisois house, sometimes assisted financially by local government, these entrepreneurs are actually just a handful of people among the numerous actors at work buying, selling, transforming property in the médina. Praiseworthy as they are, central to the revitalization of the city's historic building trades, such initiatives are a small part of the broader pattern of urban change – the médina's population is declining, the residential function is being driven out by pressure from garment wholesale businesses, the centre of Tunis gravity has moved north-east to new suburbs.

But via digital platforms, the guesthouse owners – and the guests through their comments - offer a particular take on the historic house. In effect, the house is used to state who the owner is and above all what their attitude to the material traces of the past are.

But there are other 'house-stories' to be seen in historic Tunis: the early twentieth century apartment stone-built immeuble, entirely demolished, replaced by a concrete frame low-rise building. There are the houses which go back to the seventeenth century, completely abandoned; for those who knew them before the family left, they are still imbued with memories. And there are the shrines and mausolea, every year a little more decayed after the heavy September rains – and mostly far off the tourism industry entrepreneur's radar. And there are the fine houses on key streets – rue Sidi Ben Arous, rue des Andalous, for example – where works were started on ambitious restoration projects, only to stall for years. To take a normative stance, these are worthy of the

researcher's gaze, given their place in the unique texture of the city. They will certainly need attention should stringent conservation plans be put into place.

Canal Imperial de Aragón, the functionality of a water infrastructure and the inheritance of a traditional agriculture landscape in Spain

Marcos Marina-Castello, Gabriel Marro-Gros, Ana Ruiz-Varona

Affiliation: Universidad San Jorge

Email: mmarinac@usj.es, gmarro@usj.es, nruiz@usj.es

Abstract
Canal Imperial de Aragón is one of the most significant hydraulic infrastructures in Europe and probable one of the most ambitious projects in the history of Aragón region. This work analyzes the main elements that characterize this infrastructure, including symbolic constructions such as locks and historic buildings, to provide objective reasoning of how these elements have shaped the region's cultural heritage. In addition, this study reconstructs the hierarchy and topological dependencies of the elements that comprise the canal's current irrigation network. The findings contribute to clarify the canal's role as a cultural and territorial asset, while also identifying current actions aimed at ensuring balanced water management without compromising this peri-urban landscape.

Keywords: Agricultural landscapes; GIS; Hydraulic infrastructure; Traditional Irrigation; Aragón

1. Introduction

The Imperial Canal of Aragon — Canal Imperial de Aragón in Spanish — is not only a major hydraulic infrastructure but also one of the main cultural heritage assets of the city of Zaragoza. Water-related assets hold deep cultural significance for the entire region of Aragón, especially for the Ebro River valley, where vast arid areas require the development of large-scale infrastructure to harness the river and its tributaries. The canal was initially conceived to bypass the meanders of the Ebro River in its middle course, making it navigable and providing a connection to the sea for the exchange of agricultural products. It was integrated with existing irrigation canals and extended their reach. Its role as a transportation route became obsolete with the development of railways. Today, the canal is no longer used for navigation; instead, it serves purposes such as irrigation, urban water supply, and electricity generation (CHE, 2025a). Its geographical trajectory is shown in Figure 1.

Figure 1: Geographical location of the Imperial Canal of Aragon in Spain. The map shows the trajectory of the canal and its irrigated region, which runs from the region of Navarre to Aragon, in parallel to the Ebro River, within the northeastern quadrant of the Iberian Peninsula.

1.1 History and Tradition of the Canal

Since ancient times, the use of water resources has played a central role in the development of the Ebro Valley. At least two dams from the Roman Imperial period are known in this area (Beltrán Lloris & Willi, 2012). The dam at Almonacid, on the Aguasvivas River—a tributary of the Ebro—has considerable dimensions and must have been capable of irrigating a vast area between the present-day towns of Quinto and Belchite. Moreno Gallo (2022) believes that the abandonment of the Celsa colony in 70 AD was due to the early failure of this dam, likely caused by rapid siltation. As a result, Caesar Augusta, now Zaragoza, replaced it as the most important city in the region. Of course, it also had a major hydraulic infrastructure for irrigation. In this case, a dam was built on the Huerva River, in Muel. Thus, the availability of irrigation water shaped both the settlement and development of the region.

There is even evidence of irrigation activity prior to the founding of Caesar Augusta. A bronze plaque found in Botorrita, known as the Tabula Contrebiensis, records the first documented legal dispute on the Iberian Peninsula, and the subject of contention was none other than water channeling rights, disputed by the inhabitants of Alaun and Salduie, the two Iberian settlements that once occupied the areas of present-day Alagón and Zaragoza (Giusto, 2006). Dated to 87 BC, it demonstrates, on one hand, the importance of irrigation water in the region since ancient times, and on the other, the extent of Roman resource management, which led them to arbitrate disputes between local populations. Later than this bronze plaque is the so-called lex rivi hiberiensis—the law of the Ebro canal—which documents a similar dispute in the 1st century AD and refers to a canal used jointly by several communities in the valley (Beltrán Lloris, 2006).

During the period of Islamic rule, which lasted for four centuries in this region until the conquest of Zaragoza by the Christian kingdom in 1118, irrigation systems and water channels were also developed. These infrastructures were of a smaller scale than those established by the Roman Empire, yet they left a significant cultural legacy. The invaders brought hydraulic technologies and new crops. Even today, most Spanish terms related to irrigation and water channeling originate from Arabic (Roldán Cañas, Moreno Pérez & del Pino, 2008). For instance, cisterna—like in Latin—means water tank, but when referring specifically to irrigation water, the word aljibe, from the Hispano-Arabic al úbb, is preferred. This is just one example of the Arab legacy in the culture of water and irrigation. They also influenced management practices, administrative systems for water rights, and many other aspects of irrigation activities.

To properly discuss the history of the Imperial Canal of Aragon, starting with its direct antecedents, we must go back to the year 1125, when Alfonso I the Battler, who had reconquered Zaragoza for Christendom, began granting irrigated lands to various knights. Thus, a new network of noble estates and large landholdings began to emerge as part of the colonization of the newly conquered territory (Laliena Corbera, 2011). Other irrigation channels are also known to have existed during the 12th century (Bosque Maurel, 2011: 112). As for the city of Zaragoza, the earliest surviving documents that mention them date from 1184, in which Alfonso II grants the Templars custody of the Celtén Canal—now called Centen.

Zaragoza had undergone significant growth and, by the early 16th century, had become a wealthy Renaissance city. Some texts from the period refer to it with terms alluding to its opulence (Bas Carbonel, 1999: 138). Spain was experiencing a period of splendor in technology, art, and culture, driven by the voyages to the Americas. Advances in navigation and cartography stimulated technological innovation, modern thinking, and the ambition that fostered grand projects. It was in this context that a faction of Zaragoza's municipal leaders, the Jurados, petitioned King Ferdinand the Catholic in 1510 for authorization to divert a navigable and irrigational canal from the Ebro River.

That project formally began in 1528, when Charles I of Spain—also known as Charles V, Holy Roman Emperor—commissioned three architects to study the diversion dam for the canal. The proposal by Gil de Morlanes was selected, recommending the dam be built at Fontellas, in the neighboring Kingdom of Navarre. Construction began in 1529, resulting in the El Bocal dam, but the canal never reached Zaragoza, halting just 15 kilometers from the city. This canal, known as the Acequia Imperial (Imperial Ditch), encountered numerous operational and maintenance issues. Among them, the original design included a large siphon to cross the Jalón River, which caused leakage and sedimentation problems and had to be replaced with an aqueduct supported by massive walls (Gallardo Pérez, 2024: 104). The challenges were so severe that King Philip II demanded a loan from Zaragoza for its upkeep (CHE, 2025a). The project was ultimately abandoned when a flood from the Ebro River destroyed the dam.

After several failed attempts to launch a new project to replace the Acequia Imperial, responsibility for overseeing the construction of a new one was entrusted in 1772 to Ramón de Pignatelli, with Pedro Herranat appointed as chief engineer (Fernández de Córdoba, 1791). This marked the beginning of the construction of the present-day Imperial Canal of Aragon, which remains in operation to this day.

This project also faced serious challenges during its execution. However, unlike the Acequia Imperial, all of them were ultimately overcome, and it can be regarded as a success in civil engineering. Initially, the canal's diversion dam was to be located upstream of Tudela, but due to technical issues, the new dam was ultimately built slightly higher than that the previous one. A remnant of this early attempt still survives: the ruins of a palace known as Casa de la Obra, constructed near Tudela to serve as the project's headquarters (Carrasco Navarro, 2013). The greatest risk of failure came when a flood from the Ebro River cast doubt on the project's viability. In 1784, engineer Agustín de Betancourt was appointed to inspect the site and evaluate the project. His report was highly favorable, and work resumed. Nevertheless, public opinion had begun to see the canal as a doomed venture. The failure of the earlier Acequia Imperial and the recent destruction of part of the works were seen as ominous signs.

When the water finally reached Zaragoza, Pignatelli ordered the installation of a monumental fountain near the mill and the San Carlos locks. A stone plaque was affixed to it with the inscription INCREDULORUM CONVICTIONI ET VIATORUM COMMODO (For the conviction of the incredulous and the relief of travelers). Today it is known as the Fountain of the Incredulous (Fuente de los Incrédulos). Shortly thereafter, Pignatelli died, having extended the canal beyond Zaragoza. He was succeeded in the project by the Count of Sástago, Vicente Fernández de Córdoba, who did not fulfill the dream of reaching the sea. Ultimately, the canal ends at the Ebro River near the town of Fuentes de Ebro. The Count of Sástago's contribution to the project was less significant, as the major works and engineering feats had already been completed. However, he left behind a highly valuable document: a detailed report on the canal and its construction, containing extensive information on the engineering solutions that had been implemented (Fernández de Córdoba, 1791).

Not long after, the canal and its bridges in Zaragoza became part of the front lines. The sieges that the French army inflicted upon the city in 1808 and 1809 caused damage to the canal infrastructure. Further destruction occurred during the French retreat in 1813. The 19th century was a time of reorganization and restructuring for the canal. In 1813, the Junta del Canal Imperial was established to manage and maintain it. From that point on, the administration and oversight of this hydraulic infrastructure remained under public authority. Since 1985, the Ebro River Basin Authority (Confederación Hidrográfica del Ebro) has been its managing body. Water users, organized into irrigation communities, form the General Community of Users of the Imperial Canal of Aragon. These two entities are today responsible for the infrastructure's maintenance, management, and the allocation of water quotas.

1.2 The Imperial Canal today

The 108 kilometers of the canal's course run parallel to the Ebro River along its right bank. At its origin, the intake dam has a flow capacity of 30 m^3 per second, diverted through eleven sluice gates installed beneath the large building known as San Carlos, which has remained operational since the 18th century. Approximately 265 km^2 (around 65,500 acres) of land are irrigated using this infrastructure. For this purpose, more than 300 water intakes are assigned to irrigation communities, each feeding one of the main ditches (CYA, 2025).

In terms of productive use, irrigation is primarily dedicated to extensive herbaceous crops (alfalfa, maize, cereals, etc.), although there are also areas devoted to fruit and vegetable cultivation (artichokes, cauliflower, onions, etc.). The average annual water demand for irrigation is 417 hm^3. Although most of the canal remains unlined earth, a hydrological plan has been approved that includes the modernization of several sections among other improvements (CHE, 2025).

The numerous intakes for irrigation and other services are supplemented by additional infrastructure. Two aqueducts allow the canal to cross the Jalón and Huerva rivers, both tributaries of the Ebro, near Zaragoza. Additionally, a diversion near Gallur channels water to the La Loteta reservoir, which is also fed by other watercourses (Lafuente Dios, 2004).

Regarding hydropower, four plants operate along the canal. In Gallur, where the elevation difference with the river exceeds 20 meters, 20 GWh are generated annually. In Zaragoza, the drop at the Casablanca lock was originally used as a mill in the 19th century. In 1901, a Kaplan turbine was installed in its place, enabling the generation of 650 kW, and it is still used today as an auxiliary system. This small power plant made Zaragoza the first city in Spain—and the second in Europe—to receive high-voltage alternating current. The other two power stations in operation are the Jalón plant, producing 3 GWh annually, and the Valdegurriana plant, near Zaragoza, generating 1.1 GWh.

The total elevation drops along the entire length of the canal is 125 meters. Since it was originally designed for navigation, the gradient of all sections is only 0.08%. The elevation is overcome by a system of lock groups installed in three locations on the outskirts of Zaragoza, although one of these areas has since become a highly developed urban neighborhood. This reflects how the rest of the canal's route successfully bypasses the natural terrain

using well-engineered valleys and aqueducts. The first group, located in the Casablanca neighborhood, consists of two locks known as the San Carlos locks. Adjacent to them is the sluice house, which diverts water toward the urban center of Zaragoza. It is also at this location, taking advantage of the drop in elevation, where the first hydroelectric power station was installed. Eight kilometers downstream lies the Valdegurriana lock group, situated in the Torrero hills. These are imposing oval-shaped locks, built with ashlar masonry and flanked by stone staircases. The final group is the Torrecilla locks, which overcome a vertical drop of 9.75 meters. Due to the abandonment of navigation and lack of maintenance, they had fallen into disrepair. Currently, a system of four sluice gates has been installed to allow navigation once again, serving as a replacement for the original locks.

2. Canal Elements and Cultural Heritage

2.1 Architecture and Engineering

Most of the buildings and major engineering works of the Canal have been preserved. As expected for an infrastructure that has remained in continuous use for 225 years, many of these elements have been modernized or adapted. Only those components dedicated to navigation have suffered significant general deterioration, in some cases reaching total ruin. This is also understandable after more than a century of neglect of that activity. Nevertheless, especially in recent years, restoration efforts have been undertaken to recover what is now a recognized and highly emblematic cultural heritage site for the region.

All elements of the canal —locks, guardhouses, ditches— form part of an integrated system, whose coherence is not only hydraulic but also topological. Their spatial and functional interdependence allows the infrastructure to be understood and managed as a network, with upstream and downstream relationships that reflect both physical flow and institutional coordination. This systemic logic can be mapped and studied using GIS and historical cartography, offering tools not only for conservation, but also for maintaining operational continuity in the face of change. This network logic becomes especially evident when analyzed using Geographic Information Systems (GIS), which allow mapping the hierarchy and interconnections of primary and secondary ditches, sluices, and intake points. Understanding these dependencies is essential for both conservation and adaptive management, particularly in times of increasing climate uncertainty and regulatory demands. The canal is not a linear infrastructure, but a spatially distributed and functionally interlinked system, shaped by both hydrological and social flows.

The list of elements we present here to highlight the legacy of the Canal is based on information gathered by the authors during numerous visits to the facilities and analysis of three key documentary sources. First, the document prepared by the Count of Sástago (Fernández de Córdoba, 1791) is undoubtedly the most detailed description of the Canal at the time, including highly precise technical and graphic information. The second source is primarily visual: in 1833, a collection of landscape engravings of the Canal was published by order of King Ferdinand VII, accompanied by a descriptive text of the construction project and its uses (Blanchard & Alexis, 1833). It includes 37 plates, showing the state of the facilities and buildings during the first third of the 19th century, each with an explanatory caption. The most recent source is a publication offering a detailed account of the Canal's current elements (Pallarés Jiménez, 2011).

The Casa de la Obra is a palace built as the Canal›s headquarters at the start of the project, when the dam was initially planned to be located upstream from Tudela. Although this location was ultimately abandoned, some structures remain at the site (Carrasco Navarro, 2013). The palace is considered one of the finest examples of Baroque architecture in the city of Tudela. Its imposing facade adorned with noble coats of arms and its interior with carved stone columns reflect the magnitude of the project. This is one of the so-called Canal Palaces. The term also refers to two large buildings that can be admired at El Bocal dam, both of which are well preserved. The so-called Palacio de Carlos V was the seat of the Acequia Imperial, home to its governor and the access point to the dam's four sluice gates. Built in the 16th century, it was renovated in the early 19th century. Of Aragonese style, it combines ashlar masonry on the ground floor with Mudéjar brickwork on the upper two floors and side towers. It forms a complex with other structures, such as the neoclassical Chapel of San Carlos Borromeo (Pinilla Gonzalvo, 2022). A few meters upstream, the Palacio de Compuertas is the building associated with the current Canal dam.

The El Bocal dam includes additional buildings, and an important settlement developed around it at the beginning of the Canal's construction. Families of the construction workers settled in the area, which still retains residential buildings, a school, and workshops maintained and periodically restored by the Ebro River Basin Authority (CHE, 2022).

Less monumental than the palaces but no less important as heritage is the San Carlos Mill in Casablanca. Today, Casablanca is a district within the city, and its name—meaning the white house—derives from this building, which was coated and painted white. A visual comparison of its historic and current state is provided in Figure 2. The mill serves multiple functions. It houses the Community of Users of the Imperial Canal of Aragon (CYA) and was formerly part of the Canal›s management infrastructure. Located next to the dock and locks, it also served as the administrative house for these facilities. It harnessed the water drop to grind wheat and today contains a small hydroelectric plant. Beneath the building, a structure of large ashlar blocks forms the sluice gates that once supplied Zaragoza with water—its only source for many years. The building also has significant historical value: it was here that the capitulations of the city of Zaragoza were signed in 1809, ending the second siege during the Peninsular War against Napoleon›s army. Currently, the building also houses a Canal museum featuring historical artifacts and interpretive models. Next to it is the Fountain of the Unbelievers.

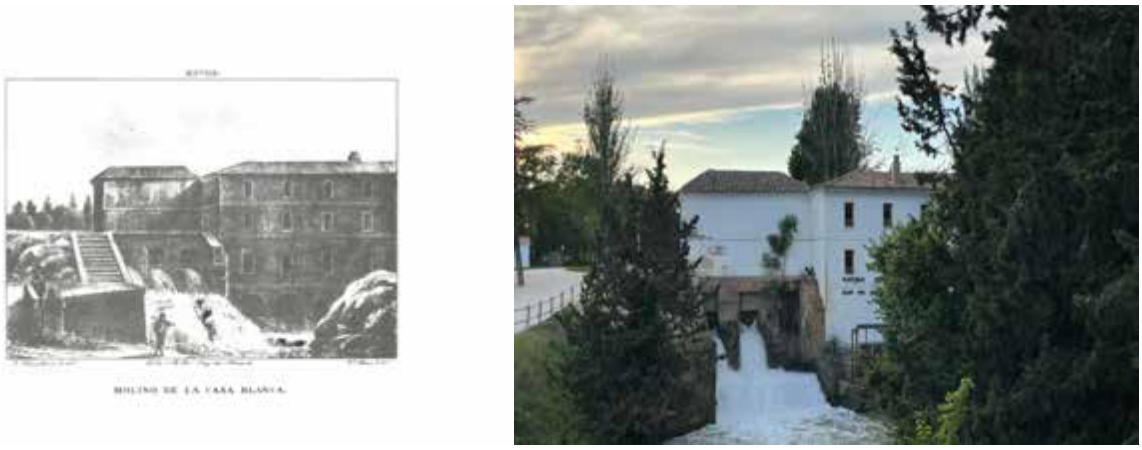

Figure 2: Historical and current view of the San Carlos Mill. Comparison between an archival image and a contemporary photograph of one of the key buildings linked to the Canal's infrastructure, located in the Casablanca district of Zaragoza. Sources: archival print (Blanchard & Alexis, 1833); authors' photography.

Currently, the Canal has 300 sluice gates that divert water into irrigation ditches. Initially, there were fewer, and the oldest ones feature access buildings used to manage the infrastructure. Twenty of these structures, known as almenaras, are preserved along the Canal. As the water has been spordically used for industrial projects, industries powered by water can be found at its side. The most important are the Imperial Flour Mill of Zaragoza and the Imperial Ceramics of Ribaforada.

2.2 Landscape and Cultural Heritage

Both Zaragoza's population and public institutions are increasingly aware of the value of the Canal's facilities as cultural heritage. In recent years, significant efforts have been made to restore all the locks to make navigation possible once again (CHE, 2025b).

Along the Canal, historical bridges built from various combinations of ashlar masonry, brick, and concrete are still preserved. Some stand out for their elegant arches, such as the Formigales Bridge, Cortes Bridge, and Clavería Bridge in Garrapinillos. Some bridges remain incomplete or in ruins, often because they had wooden decks, sometimes temporarily constructed. A good example is the Jubo Bridge in Pinseque, which preserves only its side plinths. These old bridges are an essential part of the Canal's landscape, as shown by their inclusion in the

1833 collection of picturesque views (Blanchard & Alexis, 1833).

Also notable are the aqueduct segments. In the section crossing the Jalón River, the Canal runs elevated over a monumental ashlar wall known as Las Murallas de Grisén (The Walls at Grisén). Nearby is a natural area called El Caracol, where tourism is encouraged to enjoy the landscape formed by the immense aqueduct, a large tower with a spiral staircase that leads to the elevated Canal, and the slender gate San Martín almenara, which, being on the elevated canal, rises like a tower on the horizon. The water flowing from it cascades down a stepped channel. These visible walls conceal earlier ones built for the Acequia Imperial that provided access to the siphon (Saenz Ridruejo, 2004: 356). The nearby crossing over the Jalón River, with the large openings of the aqueduct, is also part of this setting. Other elevated aqueducts on large walls exist in Zaragoza, such as the Barranco de la Muerte.

Elsewhere, the Canal's contribution to the landscape is less monumental but no less significant. Its route through Zaragoza is especially visited where it integrates with the city's large park. In this area, it crosses the Huerva River via another elevated aqueduct known as El Ojo del Canal (the eye of the Canal). Less integrated into the city is the linear PLAZA park, a newly created green space bordering a large industrial and business area, where the Canal plays a key role in shaping the park's landscape.

The Canal's contribution to the urban landscape goes beyond parks. As mentioned earlier, the Casablanca district grew around the Canal's facilities. Another major urban district, Torrero, is also closely tied to the Canal. The large América Bridge connects this district with its southern area and the rest of Zaragoza. Torrero's initial growth was driven by Canal-related construction. Pignatelli commissioned the construction of a large church for the workers, the Church of San Fernando. Today, located within a military compound, the 19th-century district was then connected to the city only by a rural road. The church marked the consolidation of this new population center and it features a large dome and two towers, reflecting the importance of the growing community. The commission for the interior paintings went to Francisco de Goya y Lucientes (Marías et al., 1984). During the sieges of Zaragoza, French troops looted the church, and the paintings were lost. However, Goya's preparatory sketches are still preserved.

The ecological value of the Canal is indisputable. It has helped sustain a vast irrigated area on the southern side of the Ebro River. Although irrigation has existed since ancient times, the Canal's infrastructure and steady flow ensures the ecosystem's maintenance. Notably, the water serves as a reservoir for endangered species such as Margaritifera auricularia, a rare freshwater mussel also known as the river pearl (Araujo & Ramos, 2000).

As presented, the Imperial Canal of Aragón is a cultural asset of special significance for the region due to its connection with the water culture, a recognized part of the region's identity. In such an arid area of Aragón, yet rich in difficult-to-access water resources, it is no surprise that the region closely identifies with its rivers and canals. This water and irrigation culture, inherited from Romans and Arabs, survives in local traditions affecting both irrigation techniques and water governance. For instance, in a town near Zaragoza, an ancient system of irrigation rights allocation known as El Trallo is still in use. It involves throwing a bundle of plants into a ditch and depending on which direction they take at a fork, water is allocated to one village or the other (Pérez Viñuales, 1989).

The Imperial Canal traverses a highly dynamic peri-urban area where rural practices, metropolitan expansion, and ecological values intersect. This landscape is not a passive buffer but a space of tension, where different land uses and temporalities coexist —productive agriculture, infrastructural heritage, and urban transformation. The canal, by sustaining agricultural activity and offering ecological continuity, becomes a structural element of resilience in this context. Its preservation is not only a matter of heritage, but of territorial balance and environmental justice as well.

Zaragoza, as the regional capital, embraces and promotes this legacy. In 2008, it hosted an International Exposition whose central theme was water and sustainable development. The event addressed the challenges of water under climate change and its role as a shared resource, while supporting a landscape intervention and

management project that has contributed to improving the city's environmental quality (Alday, Jover y Dalnoky, 2009). Today, Zaragoza has a vast riverside park dedicated to water and water resource issues often shape the region's political discourse. The Imperial Canal of Aragón remains one of the most cherished assets, representing Aragon's heritage of traditional and responsible water use.

3. Challenges to traditional practices amidst Peri urban dynamics

The irrigation system is managed through a shared institutional structure. While the physical infrastructure is owned and maintained by the Confederación Hidrográfica del Ebro (CHE), the distribution and operational management of water is carried out by the user community, represented by the Canal Imperial de Aragón entity (CYA). CYA is the organisational body that brings together the various irrigation syndicates along the canal, coordinating the use of water resources and ensuring compliance with the regulatory framework established by the CHE. Within this model, CYA is responsible for implementing irrigation schedules, mediating local governance, and maintaining the traditional practices that structure daily water management. The main structure of this irrigation system and its extent can be seen in Figure 3.

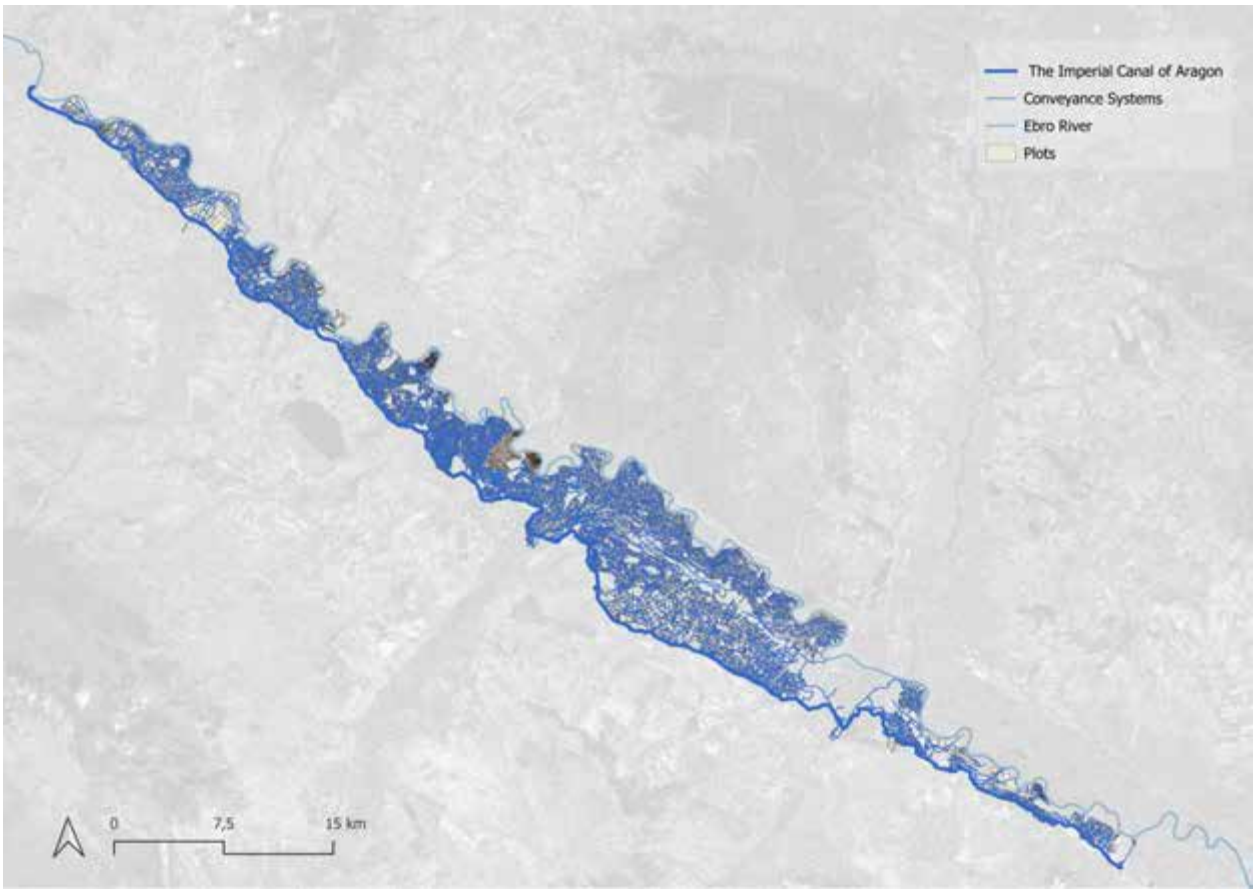

Figure 3: Irrigation infrastructure of the Imperial Canal of Aragon. The map shows the main canal, the network of conveyance systems, and the agricultural plots it serves. This layout reflects the extensive spatial organization of the irrigated area.

The uniqueness of CYA lies not only in its technical scale but in its organisational model. Governed by communities of irrigators, grouped into irrigation syndicates (sindicatos de riego), the system operates according to a set of practices developed through centuries of shared use. At the heart of these practices is the notion of equity, embedded in a rotation-based method of distribution—known as adores—that assigns water to users in a cyclical and public manner. Each day, the head canal guard oversees water distribution, records which plots have received water, and ensures compliance with the schedule. This structure has generated a strong sense of

collective responsibility and reciprocity, contributing to the social resilience of the communities that depend on the canal.

This model of self-managed irrigation, developed long before the rise of contemporary resource governance theory, provides an exemplary case of what Elinor Ostrom termed a "common-pool resource institution" (Ostrom, 2002). It is governed by rules devised by the users themselves, enforced through mutual monitoring, and adapted to environmental fluctuations. Yet, despite its adaptability and effectiveness, the CYA system is increasingly seen as insufficient from the perspective of modern water management standards and regulations.

3.1. The Need for Water Consumption Management

Across Europe and other parts of the world, the discourse on water governance has shifted significantly over recent decades. The focus has moved from access and equity toward efficiency, accountability, and technological innovation. This transition is linked to broader concerns over climate change, water scarcity, and environmental sustainability. Under new regulatory frameworks, irrigation communities are now expected to provide detailed data on consumption, report crop types and schedules, and demonstrate improvements in water use efficiency. These expectations arise from both legal requirements —such as the EU Water Framework Directive— and growing public pressure to justify the use of shared natural resources.

In this context, the traditional operational logic of CYA appears increasingly out of step with institutional demands. Water is not allocated based on volumetric measurement or per capita quotas. Instead, distribution is guided by historical entitlements associated with plots of land, and turns are coordinated through informal negotiations and routine practices. While this system has ensured equitable access over centuries, it offers limited capacity for real-time monitoring or precise accounting.

The disconnect between traditional logic and regulatory expectations poses both technical and political challenges. From a technical standpoint, it becomes difficult to evaluate the relative performance of CYA in terms of water efficiency or productivity. Statistical comparisons with pressurised or automated systems often favour the latter, especially when data availability is unequal. From a political perspective, the lack of data can be interpreted as a sign of opacity or inefficiency, reinforcing the notion that traditional systems must be replaced or overhauled to meet contemporary standards.

Yet, such assumptions overlook the complexity and functionality of systems like CYA. Despite its informality, the canal's distribution mechanism operates with remarkable precision, guided by generations of experience and local knowledge. The guards responsible for opening and closing the main gates often know each plot, user, and ditch intimately. Their role, though rarely digitised or standardised, ensures the system's daily operation and reflects a form of expertise that cannot be reduced to sensor readings or remote monitoring dashboards.

The need to manage water consumption more effectively is not denied within the community. Many users and administrators of CYA recognise that the pressures facing the system today are different from those of the past. They are aware of the demands for transparency, the importance of sustainability, and the necessity of adapting to a changing climate. However, they also argue that solutions must be adapted to the context. What works in drip irrigation schemes or highly mechanised farms may not apply to a flood irrigation system rooted in collective action and territorial history.

Moreover, the scale and heterogeneity of the CYA system further complicate the implementation of standardised monitoring tools. The network of ditches and secondary canals is complex, and many plots receive water from more than one intake point, depending on the topography, the time of day, and the specific irrigation cycle. The idea of installing a flow meter at each individual gate is not only financially unfeasible, but also socially disruptive, as it would alter the balance of trust that underpins the existing order.

In this scenario, the goal is not to reject the call for better water management, but to reframe it in ways that

respect the system's cultural and operational integrity. What is needed is a form of adaptive governance that improves data availability and reliability without undermining the principles of collective management. Such an approach would seek to enhance, rather than replace, the mechanisms already in place, and to work from within the system's logic instead of imposing an external model.

The adoption of new tools and methods must be aligned with the principle of subsidiarity—where decision-making is kept as close as possible to the local level. This means recognising the guard's observations as valid inputs, structuring the existing libros de adores (ador logbooks) in ways that allow for systematic analysis, and combining this information with basic hydrological models that account for the physical characteristics of the network. In doing so, CYA could generate more accurate estimates of water consumption while maintaining the community-led structure that has sustained it for centuries.

3.2. Challenges of Measurement in Traditional Systems

The traditional structure of the CYA irrigation network presents inherent limitations for measuring water consumption using conventional technical tools. Unlike modern irrigation systems that rely on pressure lines, digital meters, and automated control, CYA operates entirely through gravity-fed flow, distributed via open ditches of varying construction types and dimensions. This complexity is illustrated in Figure 4, which shows the dense conveyance system and the parcel fragmentation. The physical configuration of the network, along with the rotational logic of water allocation, makes precise and continuous measurement a difficult task.

Each intake along the main canal diverts water into a local conveyance system, which then branches into numerous ditches and ultimately reaches individual plots through gates operated manually by irrigators. These gates are not fitted with meters or sensors, and their opening levels are rarely recorded with engineering precision. Instead, guards and users rely on experience, visual inspection, and habitual knowledge to manage the distribution. This results in a system that is functionally effective, yet difficult to capture in standardised data formats.

Water losses between the canal intake and the destination are significant and variable. They depend on several factors, including the material and age of the ditches, the slope and distance of the flow path, and weather conditions that affect evaporation. Conveyance losses are generally assumed to be high —sometimes exceeding 40%— (Serra, 2016) but no direct measurements are made on a daily basis. The inability to account accurately for these losses complicates efforts to assess how much water each plot receives.

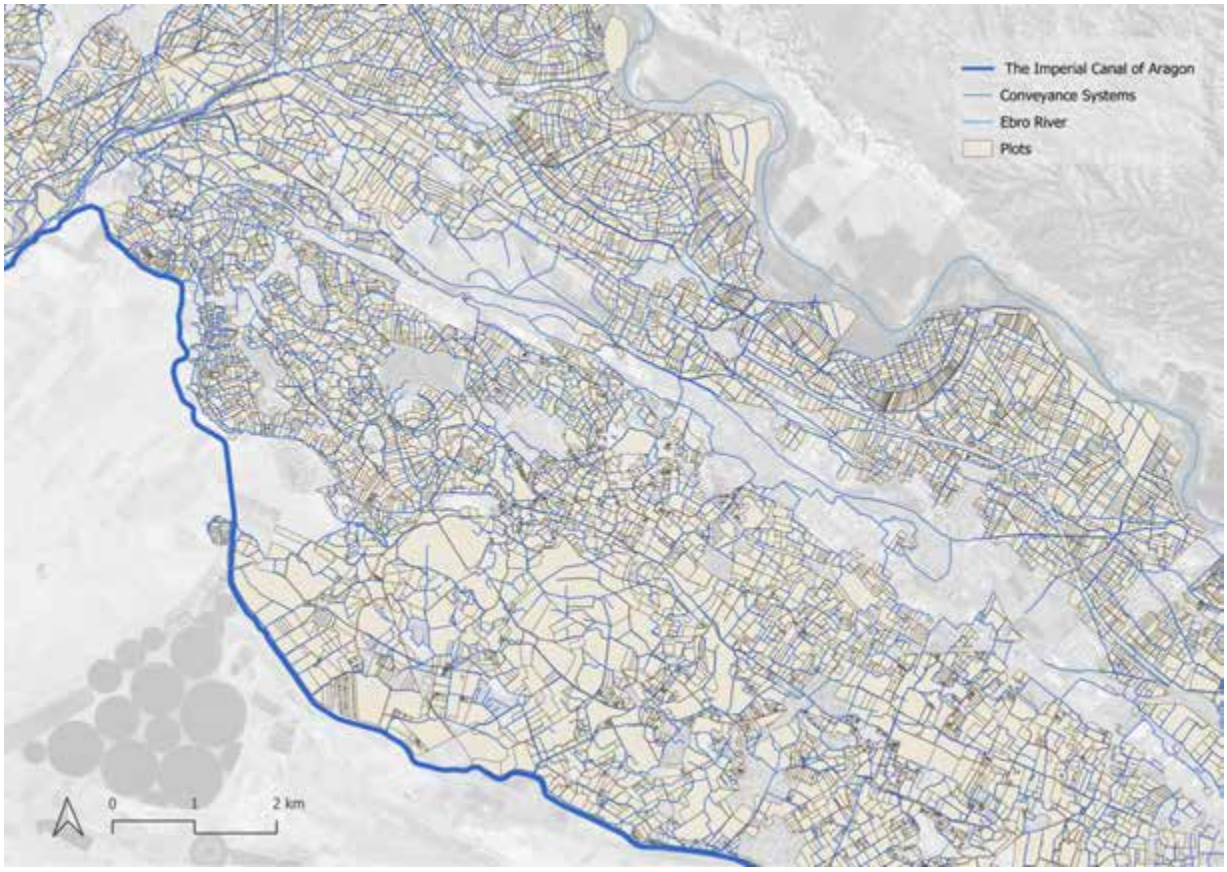

Figure 4: Detailed partial view of the irrigated area. The image illustrates the high density and complexity of the conveyance system and the parcel fragmentation.

Another issue is the temporal dimension of flow. Because of the slow movement of water through the ditch system, there is always a delay between the moment water exits the main canal and the moment it reaches the plot. This delay, known as conveyance time, can range from 90 minutes to over two hours, depending on distance and conditions. As a result, any time-stamped measurement at the canal level does not immediately correspond to what happens downstream. Synchronising flow data with plot-level activity requires not only physical modelling but also reliable information on irrigation schedules—information that, in the CYA context, resides primarily in the daily notes of the guards.

The adores logbook is the only consistent record of water distribution in the system. It is maintained manually, often with limited detail, and varies from one syndicate to another in structure and style. Despite this, it offers valuable insights into how water is used: which plots were irrigated, in what order, and for how long. However, because the data is subjective, based on observation or user reports, and not standardised, its reliability for estimation purposes is variable. Some entries are precise, while others may be incomplete or rely on assumptions. The lack of systematic archiving or digital transcription further reduces its analytical potential.

The core issue concerns the coexistence of two distinct approaches to managing irrigation. One is based on lived experience, observation, and collective coordination; the other relies on measurement, standardisation, and external monitoring. Bridging these perspectives requires not just methodological innovation but also institutional awareness of the system's cultural and operational specificities. Traditional data should not be dismissed as unreliable, but rather understood in its context and translated into forms that can inform practical decision-making. Ultimately, the goal is not to quantify every detail, but to generate sound and consistent estimates of water consumption—estimates that reflect both the physical dynamics of the system and the way it is used and governed.

CYA presents a powerful case for rethinking how we define and measure water use. It invites a broader reflection on the role of tradition in contemporary water management, and on the need to adapt our tools to the systems we are working with, not the other way around.

3.3. Heritage Dimensions and Pathways for Protection

Beyond its operational challenges, the CYA irrigation system must be understood as part of a broader cultural and territorial heritage. Its ditches, gates, pathways, and guardhouses form part of a historical landscape shaped by centuries of interaction between people and water. The rules of rotation, the figure of the guard, and the communal management model are all expressions of intangible heritage that reflect a collective memory and a shared sense of belonging.

These dimensions are often overlooked in conventional water policy, which tends to favour efficiency over continuity and data over meaning. Yet, safeguarding traditional irrigation systems is not only about preserving old techniques. It is about recognising the value of a way of managing land and resources that remain socially relevant and ecologically adapted. Systems like CYA have persisted precisely because they respond to the complexities of their environment with flexibility, embedded knowledge, and low-cost operation.

However, this heritage is increasingly under threat. Regulatory frameworks rarely account for the specificity of traditional systems, and funding programmes for irrigation modernisation often prioritise technical upgrades that are ill-suited to the logic of collective governance (OECD, 2006). Meanwhile, generational renewal is limited. Young people are less involved in farming and less connected to the values and practices that sustain traditional water management. Without targeted support, much of this knowledge may be lost within a generation.

To address this risk, heritage protection should be redefined to include not just monumental structures or historic canals but also living practices and institutional arrangements. Recognising the ador rotation system, the adores logbook, and the figure of the guard as heritage assets could open new possibilities for institutional support. This recognition does not mean freezing the system in time. On the contrary, it involves empowering communities to adapt their practices while maintaining their identity. It also involves documenting existing knowledge, promoting intergenerational transmission, and creating spaces for dialogue between users, researchers, and policymakers.

The future of CYA depends on the capacity to evolve without losing its core. Protecting the system means more than preventing physical decay. It requires creating conditions for social, institutional, and technical continuity. Only then can the canal continue to irrigate not only crops, but also the cultural and civic fabric of the territory it sustains.

Striking a balance between technological innovation and traditional knowledge is essential. Maintaining the canal's use should not imply transforming it into a mechanised or hyper-technified system at the cost of its ecological and cultural integrity. Rather, adaptation must work within the system's own logic, respecting the territorial and environmental values that give meaning to its operation. The canal is not only an infrastructure. It is a socio-ecological ecosystem shaped by collective practices and historical memory. Any modernization strategy must recognize this complexity and avoid interventions that might simplify or fragment it. Protecting this equilibrium is the real challenge of contemporary water governance.

4. Conclusion

The Imperial Canal of Aragón constitutes a unique case of territorial continuity, where an infrastructure designed in the 18th century remains both operational and socially embedded in the contemporary landscape. Heritage, ecology, and agricultural functionality intersect in the peri-urban fringe. Its hybrid nature —as both a functioning irrigation system and a cultural-historical landscape— challenges conventional modernization approaches that often prioritize technical metrics over historical resilience and socio-ecological integration.

The peri-urban context of Zaragoza plays a crucial role in this complexity. As urban pressures intensify, the canal landscape has become a buffer zone between agricultural persistence and urban expansion. This spatial tension must be addressed not only through land-use regulation, but also through policies that recognize the cultural, ecological, and social functions of traditional irrigation landscapes.

Efforts to modernize water management must be carefully adapted to these specific contexts. Rather than imposing volumetric control through high-tech systems, governance frameworks should pursue compatibility with the collective, experience-based logic of flood irrigation. Adaptive models that integrate community records, observational practices, and targeted monitoring can improve accountability without dismantling historically grounded practices.

Protecting the canal requires more than preserving its physical elements. It demands a commitment to maintaining the social fabric that gives it life: the irrigation communities, the guards, the rotation schedules, and the lived knowledge embedded in each ditch and gate. These are not relics, but assets of a flexible, robust, and living rooted system.

In a time of climate uncertainty, biodiversity decline, and urban sprawl, infrastructures like the Imperial Canal offer a roadmap for ground sustainability. It demonstrates that resilience can be built not only through innovation, but also through memory, reciprocity, and rootedness in territory. It stands as evidence to how infrastructure, tradition, and landscape can coexist in dynamic balance. Recognizing and supporting these qualities will be key to ensuring their continuity into the future.

Heritage and Community. Strategies for a sustainable change of the mid-Adriatic coastline

Andrea Di Cinzio, Lorenzo Morelli

Abstract
The study analyzes the coastal landscape of the mid-Adriatic coast of Abruzzo, from Pineto to Vasto, interpreting the heritage processes connected to the dynamics of territorial transformation. The focus is on new forms of development aimed at enhancing the coastal heritage, understood as an accessible resource.

The research deals with heterogeneous territories: the Adriatic city, squeezed between the coastline and the infrastructure that crosses the Adriatic dorsal of the country, and the Costa dei Trabocchi, where the rural landscape clashes with the pressures of urbanization and tourism.

The coastal heritage, consolidated and in need of reinterpretation, is understood here as an environmental infrastructure and a laboratory for experimenting with policies to mitigate the risks posed by climate and social change, capable of developing sustainable enhancement strategies.

Keywords: Trabocchi coast, tangible and intangible heritage, heritage community, mid-Adriatic coastline, Coastal Landscape.

Introduction

The coastal areas of the Mediterranean are currently undergoing profound environmental, social, and territorial transformations, triggered by intense urbanization, climate change, and increasing pressure from tourism.

In this scenario, the stretch of the mid-Adriatic coast of Abruzzo between Pineto and Vasto represents an emblematic laboratory for investigating the tensions between development and conservation, between heritage and innovation. The study focuses on the mid-Adriatic coast of Abruzzo, interpreted as a privileged space of connection between cultures, economies, and emerging territorial dynamics. Abruzzo now plays a strategic role as a gateway to the eastern coast of the Adriatic Sea, strengthening its vocation as a bridge to the Balkan peninsula, which is currently undergoing economic, cultural, and social upheaval.

The study aims to analyze the coastal landscape of the mid-Adriatic coast of Abruzzo, interpreting the processes of heritage preservation linked to the dynamics of transformation currently underway. The goal is to identify new forms of sustainable development capable of protecting and enhancing heritage, understood as a living and shared resource.

The Costa|Med research, conducted by the research unit of the University "G. d'Annunzio" Chieti-Pescara, aims to create a cognitive atlas of the mid-Adriatic coastal heritage, focusing on the coastal heritage of Abruzzo to create a territorial analysis tool that can provide a comprehensive picture of the characteristics and potential of this specific geographical area. The research is part of the PRIN 2022 project "COSTA | Med – Catching Opportunities for Strategic Transformation and Adaptation of Mediterranean Coasts," which involves the research units of Roma Tre University and the University "G. d'Annunzio" Chieti-Pescara.

The paper is divided into four main sections. The first section presents the theoretical and methodological context of the research. The second section describes the study area, highlighting the specific characteristics of the Abruzzo coastline between Pineto and Vasto. The third section illustrates the results of the territorial analysis and the atlas as a tool for reading and studying the territory. Finally, the fourth section looks at the impacts of climate change and some good practices.

The Mid-Adriatic between identity and transformation

The Adriatic Sea, with its qualities and history that have defined the characteristics of the peoples inhabiting the territories bathed by its waters, is one of the basins of the Mediterranean Sea that has perhaps contributed most to our understanding of the Mediterranean world, its dynamics, and its events. This is despite the historical complexity of the basin and its "marginal" position, with which we are accustomed to identifying it today.

This basin, defined by Franco Farinelli (2024) as "the sea of domesticated complexity," encompasses three of the main civilizations of the contemporary world, identified by Samuel P. Huntington: Islamic, Orthodox, and Western civilizations, which together make up the soul of the Adriatic.

The work of the research unit at the University "G. d'Annunzio" Chieti-Pescara fits into this context rich in communities and tangible and intangible heritage, where geographical proximity has fostered processes of exchange, comparison, and cultural hybridization. The activity is developed within the Costa|Med project, focusing on the stretch of the mid-Adriatic coast of Abruzzo, along the western coastline.

The macro-context of the research is part of a much larger geographical context that extends for about 400 km, covering an area that stretches from Emilia-Romagna to Molise, crossing the Marche and Abruzzo regions. These regions share similarities in their urban and social characteristics along their coasts, such that the mid-Adriatic can be considered a single territorial entity.

The territory is structured as an urban filament that runs continuously along the entire coastal strip (Pignatti, 2014). In its components, which will be described in more detail below, the mid-Adriatic manifests itself along this strip of land, intersecting perpendicularly with the valleys. These natural, urban, and infrastructural intersections give rise to the characteristics and "situations" that shape the identity of the central Adriatic territory.

This coastal landscape, including the Abruzzo coastline, is a vacation destination par excellence, an identity for which it is famous abroad, generating substantial tourism from Europe. It is characterized by endless rows of beach umbrellas which, like the urban fabric, seem to stretch uninterrupted along the mid-Adriatic coast. This is a tourist image that over time has become a distinctive feature of the mid-Adriatic landscape, an identity that today, however, threatens the very existence of this territory. The Abruzzo coastline under consideration is in fact subject to strong expansionist pressure from tourism, which threatens the territories, the communities that live there, and their tangible and intangible heritage.

Coastal heritage as environmental infrastructure: sustainable development of the mid-Adriatic coast of Abruzzo

The coastal heritage is interpreted here as environmental infrastructure (di Venosa, et al. 2022), alive and dynamic, overcoming the traditional static view to embrace a perspective that recognizes it as an active resource, capable of redefining itself through social practices of enhancement. It thus takes the form of a value-generating resource, through its daily use by the communities that inhabit it, through practices capable of keeping it alive and mitigating the risk factors that threaten its existence.

This dimension is particularly important in the coastal areas of the mid-Adriatic region of Abruzzo, where traditional practices, from fishing along the Trabocchi coast to settlement patterns and relationships with the territory, now constitute an intangible heritage that manifests itself through places and rituals. This is the same heritage that local artists have always represented, such as the painter Francesco Paolo Michetti and the "circolo michettiano" with their evocations of everyday life in Abruzzo.

These testimonies show how heritage in its various forms is articulated in complex relationships between the natural and built environment, knowledge, and traditions, where landmarks such as the trabocchi or the more recent oil and gas extraction platforms take on the value of identity symbols capable of guiding territorial development.

Heritage is constructed through the adoption of social practices of attribution of meaning, a particularly fruitful perspective for coastal heritage, where transformations require a continuous renegotiation of meanings and values. The European Landscape Convention introduces a democratic concept of landscape, defining it as "a specific part of the territory, as perceived by the population" and emphasizing that "landscape is a key element of individual and social well-being." This link between quality of life and landscape is a fundamental principle, particularly significant for coastal areas where environmental quality is a factor of attractiveness and a resource for the well-being of communities.

Coastal heritage must be seen as a privileged laboratory for policies to combat climate crises, a territory where innovative and sustainable solutions can be tested that effectively integrate heritage protection with contemporary environmental challenges.

The Faro Convention (2005), and in particular its Article 8 on "Environment, heritage, and quality of life," provides the theoretical and operational framework to support this project vision. The article establishes the importance of using all dimensions of cultural heritage to enrich development processes and promote an integrated approach to policies concerning cultural, biological, and landscape diversity. Heritage enhancement is achieved through the ability to understand the virtuous link between heritage itself, improvement of quality of life, and sustainable development.

The concept of "heritage communities" therefore takes on a central role, identifying groups of people who value specific aspects of cultural heritage and wish to support and pass them on to future generations. This approach does not replace institutional logic, but promotes structured collaboration between public institutions and heritage communities, creating the conditions for participatory governance of coastal heritage that can respond to the needs of conservation as well as those of climate adaptation and sustainable territorial development.

It is important to highlight some fundamental aspects of the Convention that are essential for research and its future developments. The first concerns democratic participation, which provides for the active involvement of communities in decisions relating to the cultural heritage of their territory. This is followed by the integrated approach, according to which heritage protection must be considered across all sectors of public policies, recognizing the strong connection between heritage and development. Finally, shared responsibility establishes that the identification, study, protection, and conservation of cultural heritage do not belong exclusively to institutions but are a collective responsibility of citizens.

To paraphrase Alberto Magnaghi, in this perspective, designing means creating a "stable home", i.e. establishing virtuous relationships between the settled community, the environment and the territory. Building the future means reconnecting differences, where diversity becomes a resource rather than a source of fragmentation. At the heart of this vision, the community is not just a social aggregation, but becomes the active subject of territorial transformation, capable of imagining and building concrete alternatives.

The prospects for the mid-Adriatic coast of Abruzzo in this research are outlined through the integration of these theoretical dimensions into operational strategies capable of enhancing the existing heritage, orienting transformations towards environmental and social sustainability.

Characteristics of the coastal urban fabric between Pineto and Vasto

The stretch of coast between Pineto and Vasto is an emblematic fragment of the so-called linear Adriatic city, where the urban fabric is continuous along the coastline, intertwining with transport infrastructure and the local landscape. The urban morphology of this area is the result of a predominantly recent and widespread development, in which medium-sized urban centers, such as Pescara, Ortona, and Vasto, alternate with smaller towns.

This sequence of settlements is characterized by a dual nature: on the one hand, heavy anthropization along

the coastline, reflecting a process of urbanization that alternates between residential areas, beach resorts, and tourist infrastructure; on the other hand, a significant presence of agricultural and coastal landscapes, residual green areas, and portions of territory that still reflect a more direct relationship between the community and the natural environment.

The Adriatic sea, defined by Matvejević (2006) as the "sea of intimacy", has played a crucial cultural role in the formation of these settlements, not only as a route for trade and connection, but as a fundamental element of identity. If we were to look at Europe from above at night, we would immediately notice that "the two coasts of the Adriatic show an irreducible diversity. "On one side, the dense layer of lights" (Bianchetti, C. 2002) that highlight the western part, dotted and illuminated by the conurbation of the linear Adriatic city, and on the other side, "a black border in a Mediterranean full of lights" (Bianchetti, C. 2002). A sort of exception, decipherable from the landscape and history.

The medium-sized western Adriatic cities that dot this coastal strip, often with between 50,000 and 200,000 inhabitants, are now central nodes in the redefinition of sustainable urban development models. According to the reflections of A. Rodríguez-Pose (2018), these cities, once considered "places that do not matter," are acquiring a new prominence, demonstrating a capacity for resilience and innovation that large metropolises struggle to maintain.

In the section between Pineto and Vasto, the urban fabric significantly expresses the tension between consolidation and transformation. This segment of the so-called linear Adriatic city is a complex landscape, where established infrastructure and new coastal centers intertwine. The Trabocchi coast, with its architecture suspended over the water, coexists with tourist and industrial ports such as those of Pescara and Vasto, while protected areas of nature, such as the Torino di Sangro holm oak forest, offer an ecological counterpoint of great importance. In this scenario, the interaction between settlements, infrastructure, and landscape provides a privileged observatory for interpreting territorial transition processes and imagining a new development paradigm based on the integrated enhancement of cultural, environmental, and built heritage.

The Trabocchi coast: natural landscape and development processes

Along the Adriatic coastline, between land and sea, ancient structures stand out, their roots sinking into the water: the trabocchi, bearers of a deep local history and authentic symbols of the genius loci of the mid-Adriatic. It is no coincidence that the 42 km stretch of coastline between Ortona and Vasto has been named the Trabocchi coast, in recognition of their central role in redefining the collective imagination and the specificity of the Abruzzo region.

These fishing machines on stilts, built entirely of wood and anchored to the rocks by long arms that support the nets, are widespread along the central Adriatic coast and represent a unique architectural and engineering feat, skillfully modeled on the irregular morphology of the coastline. At once vernacular, evocative, and fragile (Cambi, C. et al. 2017, Di Mascio, D. 2009, Carolis, D. 2020), trabocchi embody traditional technical knowledge deeply rooted in local culture and the millennial relationship between man and the sea. According to some studies, their origins date back to the Phoenician era, but it was mainly between the 18th and 19th centuries that trabocchi established themselves as a means of subsistence for coastal communities, enabling them to fish even in adverse weather conditions.

The Trabocchi Coast, an emblematic stretch of the mid-Adriatic coastline, is a cultural landscape in which the natural and anthropic dimensions merge in a delicate but meaningful balance, representing not only an architectural and functional asset, but above all a symbol of identity rooted in the collective memory and local maritime culture. The heritage value of this coastline lies in its heterogeneous morphological composition: rocky promontories, sandy coves, protected natural areas, and stretches of spontaneous vegetation coexist in a continuum that conveys an image of a coastline that is still authentic, despite anthropogenic and tourist pressures. In this context, the perception of the landscape takes on an affective and relational character, as

recognized by the European Landscape Convention and, more recently, by the amendment to Article 9 of the Italian Constitution, which explicitly includes the protection of the environment, biodiversity, and ecosystems among the duties of the Republic.

The landscape of the Trabocchi Coast has been transformed over time from a marginal and productive area to a place of cultural and tourist rediscovery, where the trabocchi have been restored and reinterpreted as heritage sites, often converted into restaurants or exhibition spaces. This process, however, is not without its contradictions: on the one hand, there is a strengthening of the sense of belonging among local communities and an appreciation of intangible heritage; on the other hand, there is a risk of turning the landscape into a museum or triggering tourist consumption dynamics that distort its original value.

The recent development of the "Greenway" cycle path, a cycling route built on the dismantled track of the Adriatic railway between Ortona and Vasto, represents an emblematic example of sustainable and heritage oriented territorial regeneration. The intervention not only restored accessibility to the coastline, reconnecting urban centers to the littoral, but simultaneously transformed landscapes, trabocchi, and historic stations into heritage assets to create slow and conscious tourism. This type of cultural infrastructure, which integrates with a historic landscape matrix, contributes to consolidating the understanding of heritage as a living resource, capable of generating economic development and social cohesion, in line with the principles of the Faro Convention.

The Greenway is configured today as a strategic resource for experimenting with integrated development models, based on environmental sustainability, heritage enhancement and the involvement of local communities. However, even in this case some critical issues emerge: while on one hand territorial identity is strengthened and a virtuous model of enjoyment is promoted, on the other hand the project implementation methods did not pay full attention to the environmental context in which it was inserted. In particular, the coastal strip within 300 meters of the shoreline is subject to landscape constraints and, in some cases, to absolute construction prohibitions, which would have required greater design caution and more careful evaluation of impacts.

Ultimately, the Trabocchi coast presents itself today as a laboratory of territorial practices in which environment, identity and development intertwine. Its protection cannot ignore an integrated vision that considers the landscape not only as an asset to be protected, but as a lived space, in which local communities play an active role in transformation processes.

Cognitive Atlas of the mid-Adriatic Abruzzo Context

The coastal stretch of the mid-Adriatic Abruzzo region constitutes a territory of extraordinary complexity, characterized by a rich interweaving of landscape, environmental and cultural values that today confront the growing pressures arising from climate change and ongoing anthropogenic transformations.

The objective in this phase of the research is to identify, map and enhance the different forms of heritage present, highlighting their potential in mitigating risk factors related to climate and social change.

The project is based on a mixed methodological approach, which integrates qualitative analysis of readings, attributed meanings and interpretations of the territory that come from local communities with quantitative analysis of environmental, territorial and socio demographic data.

Through this methodology, a multilevel reading of the mid-Adriatic coastal stretch is enabled, which relates the physical, social and cultural aspects of the territory under examination.

The atlas is therefore configured as a multi scalar knowledge tool, articulated on three levels of analysis:
1 - mid-Adriatic macro-context: a large scale vision of the Abruzzo coastal territory and its main environmental, morphological and settlement characteristics;
2 - in depth contexts: the first context (C1), the northern one with the municipalities of Pineto and Silvi and the

southern one (C2) with the municipalities of Fossacesia, Torino di Sangro, Casalbordino and Vasto;
3 - a synthesis of the critical issues and opportunities identified within the previous study levels, with the construction of a risk map interpolated with the environmental and socio demographic factors identified, which will allow the construction of design scenarios in the analyzed areas.

In this reference framework, the research aims to highlight the knowledge necessary to make it possible to re heritage the coastline, understood as an active resource for sustainable territorial development.

Specifically in the mid-Adriatic Abruzzo stretch, heritage manifests through heterogeneous forms, which are the result of a multitude of settlement histories, urban and infrastructural transformations.

The two contexts taken into analysis in their heterogeneity, when compared, fully manifest the territories that can be encountered along the Abruzzo coast.

To the north, in the territorial area of the municipalities of Pineto and Silvi, the presence of a compact urban fabric is evident, a typical expression of the so called "Adriatic city". This settlement model develops between the coastline and the infrastructural bundle that runs longitudinally along the Adriatic dorsal, composed of railway, highway and state road. In an apparently paradoxical way, this urban density has favored the conservation of original and identity characters in the municipalities located beyond this infrastructural bundle. This linear system, while on one hand representing a strategic resource for regional and national mobility, on the other hand significantly affects the continuity and accessibility of the coastline.

The southern context includes the municipalities of Fossacesia, Torino di Sangro, Casalbordino and Vasto, which together represent that natural and rural landscape that composes the Trabocchi coast area, a territory that represents an environmental heritage of great landscape value.

The atlas proposes to map in an ecosystemic manner the coastal territories of this region, identifying the characterizing elements, today subjected to strong pressures due to rapid urbanization and seasonal tourism.

Towers, Platforms and Reserves: Anatomy of a Coastal Landscape
In this delicate and complex scenario, the mid-Adriatic Abruzzo coastal heritage is characterized through different interconnected dimensions.

The atlas, through territorial analysis, studies hydrogeological and climatic vulnerabilities. The integration of this data with social vulnerabilities allows for the construction of a complex and dynamic framework of relationships between human and environment, useful for guiding management and territorial enhancement plans and policies.

The context analysis is oriented toward an integrated reading of territories that start from the hinterland, cross the coastline and extend into the sea. This research emphasizes the necessity of considering all these environments to obtain a complete understanding of the mid-Adriatic Abruzzo stretch, since the coastal territory requires a holistic approach to be effectively understood and enhanced.

The built coastal heritage is distinguished by the stratification of elements belonging to different eras, which function as distinctive landmarks and which, as previously observed with the trabocchi structures, define the identity of the littoral landscape. An emblematic example of these territorial signs is represented by the Torre del Cerrano, located between the municipalities of Silvi and Pineto within the homonymous marine protected area. This ancient fortification, dating back to the Kingdom of Naples period, constituted a strategic node of the extensive network of coastal towers designed to counter Turkish and Saracen incursions coming from the sea.

From the summit of the historic tower it is possible to glimpse the ENI oil and gas extraction platforms that today characterize the Adriatic maritime panorama. These industrial structures, which appeared along the Abruzzo coast starting from the 1970s until the first decade of the 2000s, represent a new generation of landmarks that defines the marine horizon, often positioned within 12 miles from the coast.

The presence of these infrastructures in the mid-Adriatic stretch configures an emblematic scenario that solicits reflections on possible paths of reconversion and innovative reuse. The critical analysis of these industrial artifacts opens questions about their transformative potential: from extractive elements with controversial environmental impact, they could evolve into spaces dedicated to new cultural, scientific or eco touristic functions. Such transformation would contribute to the construction of a contemporary narration of the coastal landscape, capable of integrating historical memory and future projection in a sustainable vision of the territory.

Exposed to strong pressures and anthropic impacts, the natural heritage in the mid-Adriatic Abruzzo instead is composed of green infrastructures that also in this case want to be read, preserved and enhanced through a bidirectional reading from the hinterland to the sea and vice versa.

Representative in this case is the Natural Reserve of the holm oak forest of Torino di Sangro which, with its approximately 180 hectares of surface, connects the Abruzzo coastline to the hinterland and represents one of the few testimonies of natural forest still present in the Mediterranean area. Within it is contained an extraordinary biodiversity that needs to be preserved and enhanced: from sea level it reaches up to 115 m of altitude, collecting flora and fauna in some cases unique in the world, as in the case of the terrestrial turtle population (*Testudo hermanni*), symbol of the reserve.

A little further south we find yet another example of natural heritage in the context of the mid Adriatic Abruzzo: the Punta Aderci Natural Reserve. With an area of approximately 285 hectares that reaches 400 hectares counting the external protection area, it extends from the beach of Punta Penna to the mouth of the Sinello river. Within it shows some peculiarities to preserve such as the dune environment or some bird species like the Kentish plover (*Charadrius alexandrinus*), which also in this case has been chosen as the symbol of the reserve.

The atlas, therefore, collects this and much other fundamental information to construct a complete knowledge framework of the territory, allowing for the mapping of significant places and knowledge and distinguishing those consolidated from those that need reinterpretation. This analysis offers the basis for developing operational tools aimed at territorial enhancement, through an integrated vision of heritage capable of requalifying and restoring value to the coastline.

Climate Change Impacts on Coastal Heritage. The Vulnerability of the Mid Adriatic Abruzzo Coast

In 2014, the Trabocco Turchino, following a storm surge, collapsed. One of the symbols of Abruzzo coastal heritage was damaged by extreme events. The Abruzzo coast hosts elements of great cultural and landscape value, such as the trabocchi, today exposed to the growing effects of climate change. More intense and frequent weather marine events are already having tangible impacts on heritage: “climate change has, already today, visible impacts in terms of damage to cultural heritage” (Mascitelli, A. et al. 2023). This emblematic case demonstrates how phenomena such as sea level rise, coastal erosion and marine storms represent concrete threats to coastal assets. Recent studies on the mid-Adriatic stretch highlight “significant changes in recent decades, which pose a serious threat to cultural heritage due to climate change (sea level rise, erosion, storms, floods and salinization)” (López Campos, L. I. et al. 2024). Faced with such risks, it becomes crucial to integrate heritage protection into climate adaptation strategies, ensuring management that considers new weather climatic scenarios.

The Abruzzo coast between Pineto and Vasto presents marked geomorphological vulnerability, particularly regarding erosive processes. Studies conducted on the coastal stretch between Pescara and Ortona report an advancement of erosion due to scarce sedimentary input and intense anthropization of the littoral zone. (Tarragoni et al., 2015) Detailed analyses confirm how the Abruzzo Region falls among the Italian coastal areas most exposed to erosion phenomena and hydrogeological risk. (Cavuta et al., 2018, Zullo et al., 2022). In the Italian context, beach erosion increased by 63% between the 1970s and 2000, with Abruzzo showing one of the highest rates at the national level (Zullo et al. 2022). The coastalization of the coast and the loss of dune systems – today severely reduced – have altered natural sedimentary dynamics, contributing to the intensification of the erosive phenomenon.

Beyond erosion, the mid-Adriatic littoral is subject to local hydrogeological instabilities, with cliffs and coastal slopes unstable in some points. For example, along the Chieti coast there are landslides and ground movements that threaten infrastructures and settlements on the littoral edge (López Campos, L. I. et al. 2024). Accessibility also suffers from these critical issues: in the past the presence of coastal railway and industrial areas limited access to the sea, while today erosion reduces the usability of some beaches and imposes costly periodic beach nourishment. Beyond erosion, the coastal stretch is subject to landslides and hydrogeological instabilities linked to intense weather events and the fragility of the hills behind. An emblematic case concerns the extreme rains that occurred in 2007, 2011 and 2012, which caused strong erosion phenomena of surface coverings on Abruzzo hillsides, with average values between 0.8 and 3.1 cm per event (Piacentini et al., 2018).

These multiple vulnerabilities highlight the necessity of integrated planning and sustainable coastal management measures, capable of balancing environmental protection, territorial safety and public use of the littoral.

Adaptation and Mitigation Strategies: Design Examples and Practices

On the adaptation front, diversified approaches are being experimented along the Abruzzo coast. "Traditional" coastal engineering interventions remain important in some critical areas: for instance, new defense works such as groynes, breakwaters and submerged barriers are being designed to protect the most exposed points of the Costa dei Trabocchi (Mascitelli, A. et al. 2023). However, there is consensus that solutions must not be limited to rigidly contrasting phenomena, but rather accommodate them intelligently. "All proposals must adapt to the problem and not go against it. The keyword is adaptation: adapt the affected areas, make them resilient, adjusting to environmental changes" (Mascitelli, A. et al. 2023).

From this perspective, nature based solutions are gaining importance. For instance, the restoration of coastal dunes and backdune wetlands is promoted to reactivate natural defenses against storm surges and flooding, as well as to conserve littoral biodiversity. In non urbanized areas, the possibility of retreating or relocating infrastructures away from erosion risk zones (the so called strategic retreat) is evaluated, avoiding fighting the sea where it is not sustainable to do so in the long term. Territorial planning increasingly incorporates these approaches: the new Trabocchi coast plan, for example, prescribes considering different scenarios of sea level rise and increased hydrogeological risk, estimating the potential costs of damages associated with each scenario. This denotes a growing institutional awareness of future uncertainty and the necessity to pre adapt territorial transformations.

Even at the European level there are virtuous examples of coastal adaptation from which to draw lessons. In the Netherlands, where low coasts are particularly exposed, the innovative Sand Motor project was implemented. This is a gigantic artificial sediment nourishment implemented in 2011 along the Delfland littoral, which formed a hook shaped sandy peninsula destined to be gradually distributed by wave motion on surrounding beaches. This intervention, equivalent to about 20 years of traditional beach nourishment concentrated in a single solution, "has formed a peninsula to protect the coast, mitigate sea level rise and create recreational and ecological spaces... is achieving its objectives of coastal conservation, habitat creation and recreational opportunities" (Climate ADAPT, 2022). The Sand Motor is considered a successful example of the Building with Nature approach, in which one works with natural processes rather than against them, obtaining coastal protection together with environmental and social benefits.

Parallel to adaptation measures, mitigation remains a fundamental pillar of territorial climate strategies. Reducing climate altering emissions in Abruzzo means, for example, promoting sustainable mobility, energy efficiency and renewable sources. The transport sector, in particular, can contribute significantly through green interventions from the hinterland to the coast and vice versa and along it: such as the transformation of the former railway route into a cycle pedestrian path; incentivizing the use of soft mobility and enhancing rail mobility. This would help reduce both local atmospheric pollution and the carbon footprint of tourism.

Conclusions

The Atlas has brought to light, through the reading of the land water heritage and the construction of an articulated knowledge framework, a complex system of heritage, environmental, cultural and settlement values, which are configured today as a territorial laboratory of great interest for experimenting with enhancement and sustainable adaptation strategies. The articulation of its landscapes, the richness of natural and cultural heritage and the presence of rooted communities make it an ideal context for reconnecting protection instances with those of sustainable transformation.

The research highlights how the coast, if reread in an ecosystemic key, can become a strategic area for experimenting with alternative development models capable of integrating environmental resilience with the quality of life of settled communities. The coastal heritage, consolidated but in need of reinterpretation, thus proposes itself as environmental infrastructure and active laboratory for adaptation policies, where heritage communities, understood as collectivities that preserve and transmit stratified territorial knowledge, become active protagonists in the co design of sustainable enhancement strategies, transforming the memory of the place into a resource for adaptive innovation.

Furthermore, the integration of adaptation and mitigation measures results in a further essential action: it is necessary to adapt to impacts now underway, protecting coastal heritage and local communities, but at the same time act to limit the extent of future changes. Only through coordinated strategies on both fronts will the mid Adriatic Abruzzo coast be able to successfully face the climate and social challenges of the coming decades, transforming potential crises into opportunities for innovation and sustainable development.

The future of Costa|MED research will be further articulated along three main operational directions. The first will concern public restitution and completion of the knowledge Atlas, through validation of collected data, integration of new territorial information and dissemination of results to communities, local authorities and professionals. The second direction aims at the construction of climate and sustainable development scenarios, capable of anticipating coastal territory transformations and orienting adaptation policies on local and territorial scale, integrating environmental data with socio economic dynamics. Finally, the third direction provides for the elaboration of a design guidelines agenda, structured as an operational tool for administrations and designers, aimed at guiding future interventions in a resilient, participatory and regenerative key.

In this perspective, the mid-Adriatic coast is no longer only a fragile margin to be preserved, but is configured as a strategic space for the contemporary project: a habitable, sensitive and adaptive territory, in which environmental challenges can be transformed into opportunities to rethink the relationship between heritage, communities and innovation.

Complex System Conservation Technology for Spatial Cultural Heritage Networks: A Case Study of Qinghai Province, China

Chao Ma, Zuobin Wu, Yimin Wei

Affiliation:Xi'an University of Architecture and Technology

Email:12225341@qq.com

Abstract
Qinghai Province, on the Qinghai-Tibet Plateau, hosts 517 national/provincial heritage sites across 720,000 km², with spatial dispersion challenging conservation. Shifting from single-site models, current research stresses interconnectedness and systemic risks but lacks dynamic modeling and value quantification. This study uses ArcGIS, spatial syntax, and AI-driven multidimensional models (cultural value, environmental vulnerability, social connectivity) to analyze spatial distributions. For the first time, we identify hierarchical structures and vulnerability patterns, yielding three outcomes: (1) a five-tier vulnerability classification framework; (2) a "Three Cores, Three Belts" conservation network; and (3) pathways for heritage activation. These findings advance UNESCO's "Cultural-Natural Symbiosis" agenda, addressing plateau conservation challenges through an integrated technical system (spatial analysis, risk simulation, decision support), positioning Qinghai as a potential International Demonstration Zone for plateau heritage conservation.

Keyword: Cultural Heritage Spatial Network: Cultural Value Index: Synergistic Conservation: Qinghai Province, China

Introduction:

Qinghai, a multi-ethnic province, has accumulated a rich tapestry of historical and cultural heritage shaped by generations of diverse ethnic groups. These assets serve as critical pillars for fostering a sense of shared identity among the Chinese nation and safeguarding national ecological security.

As an integral component of China's pluralistic civilization, Qinghai's cultural heritage embodies both distinctive ethnic characteristics and ecological fragility. The province boasts 1 National Historical and Cultural City, 1 National Historical and Cultural Town, 5 National Historical and Cultural Villages, 4 Historical and Cultural Blocks, and 183 Chinese Traditional Villages—ranking first among China's five northwestern provinces. It also houses 51 national-level protected sites, including the Sakyamuni Pagoda in Sangnang and the Gyasa Monastery, along with 466 provincial-level sites such as the Zhujiazhai and Hanzhuangzi ruins. Many of these cultural treasures suffered catastrophic damage during the 2010 Yushu earthquake, with nearly 100% of immovable cultural relics impacted, exposing the vulnerabilities of traditional conservation models. Current challenges in cultural heritage protection include:1 Simplified Value Assessment: Overemphasis on physical carriers while neglecting intangible cultural dimensions.2 Reactive Risk Management: Predominantly post-disaster rescue rather than proactive mitigation.3 Fragmented Conservation Strategies: Lack of systemic coordination and holistic planning.

Complex system theory offers a novel approach to overcome these limitations. By conceptualizing cultural heritage as a dynamically interconnected system, this theory analyzes node relationships to reveal inherent structural patterns—a methodology widely applied in micro-scale spatial layout studies such as community public spaces. This study innovatively applies complex network theory at the provincial scale, examining the spatial distribution of cultural heritage through a network topology perspective. Utilizing data on heritage sites, road networks, and points of interest (POIs), we establish a five-tier vulnerability classification system for Qinghai's historical and cultural heritage network. By integrating historical information, spatial coordinates, and fuzzy boundary processing, we construct a multi-layered heritage typology framework that interweaves points, lines, and planes. This framework provides a reference for heritage conservation, transmission, and adaptive reuse. While international applications—such as resilience assessments for Italy's cultural heritage corridors—exist, this study represents the first practical implementation in China's plateau regions, filling a critical research gap.

1 Study Area Overview and Research Methodology

1.1 Study Area Overview

Qinghai Province, located in northwest China (89°35′–103°04′ E, 31°9′–39°19′ N), spans 720,000 square kilometers (7.5% of China's territory) with an average elevation exceeding 3,000 meters. Bordering Gansu to the east, Sichuan to the south, Tibet to the southwest, and Xinjiang to the northwest, it serves as a transitional zone between the Qinghai-Tibet Plateau and the Loess Plateau, as well as a historical crossroads of the Tang-Tibet Ancient Road and the Henan Corridor of the Silk Road. Dubbed the "Water Tower of China," it is the birthplace of the Yangtze, Yellow, and Lancang rivers, and hosts Qinghai Lake (China's largest inland saltwater lake) and hundreds of salt lakes. The province's topography is defined by the "Three Mountains, Two Basins" configuration: the Kunlun Mountains traverse its center, the Qilian Mountains guard its northern flank, and the Tanggula Mountains dominate the south. As one of the cradles of Yellow River civilization, it nurtures the Hehuang cultural complex—centered in Haidong City—which blends Central Chinese agrarian, steppe nomadic, and Western regional commercial traditions into a "pluralistic integration" cultural model, earning designation as a national cultural ecosystem conservation zone.

The province boasts a robust intangible cultural heritage (ICH) system, with 2,361 entries across four protection tiers, including 88 national-level items (e.g., Regong Thangka, Hua'er folk songs, Huangzhong Duiu embroidery) and 238 provincial-level items, supported by 3,160 designated bearers. Its tangible heritage is equally remarkable, comprising 6,411 immovable cultural relics (51 national-level, 466 provincial-level protected sites), 1 national historical and cultural city, 1 national historical and cultural town, 5 national historical and cultural villages, 123 Chinese traditional villages, and 1 archaeological site park. The province's 41 registered museums and memorials safeguard 310,000 movable cultural artifacts.

1.2 Research Methodology

1.2.1 Kernel Density Analysis

This study employs kernel density analysis to process the POI data of cultural heritage sites in Qinghai Province. As a widely adopted non-parametric estimation method, kernel density analysis calculates density values within spatial point/line element domains to simulate continuous density distributions. The mathematical expression for the conventional kernel density estimator is:

$$f_n(X) = 1/N\pi/^{2} \bullet \sum_{j}^{n} =_1 k_j(1 - D_{ij}^2 \ /h^2)^2$$

Here, K denotes the kernel function; *h* represents the bandwidth of the selected region; D_{ij} signifies the distance between spatial point *i* and study object *j*. Even with a relatively small *h*, sufficient sample capacity ensures adequate data points for probability density calculation. The optimal bandwidth relationship is defined as $h=c \cdot N-1/5$, where c=1.05 under normal distribution conditions.

1.2.2 Quantitative Evaluation Framework

The integrated quantitative evaluation methodology combines single-factor assessment with comprehensive density analysis, forming a hybrid evaluation technique that merges independent single-element analysis with spatial aggregation characteristics. This framework is applicable to cultural heritage conservation, environmental assessment, and regional planning. Its core logic involves:Single-Factor Evaluation: Independent quantification of critical impact factors (e.g., heritage value, ecological sensitivity, social engagement) using standardized scores within a 0-1 range:

$$S_i = \frac{X_i - X_{min}}{X_{max} - X_{min}}$$

where S_i is the standardized score for factor *i*, X_i denotes the actual value, and X_{min} /X_{max} represent the minimum/maximum values within the evaluation scope.

1.2.3 Comprehensive Resistance Model Analysis

The comprehensive resistance model (CRM) evaluates a complex system's capacity to maintain functional stability under internal/external disturbances. Originally proposed by Dutch ecologist Knappen for species dispersion studies, this model has been extended to ecological conservation and landscape pattern analysis. By quantifying "resistance" generated by internal structures, external environments, and their interactions, CRM identifies systemic vulnerabilities and optimizes resilience strategies. The Minimum Cumulative Resistance (MCR) calculates the minimum energy expenditure or cumulative cost for movement from "sources" through heterogeneous landscapes:

$$MCR = \int_{\min} \sum_{j=n}^{i=m} (D_{ij} \times R_i)$$

where *MCR* represents the minimum cumulative resistance, D_{ij} is the distance from heritage site *j* to landscape element *i*, and R_i denotes the resistance value of location i for heritage corridor development. Higher resistance indicates lower corridor suitability, and vice versa.

1.2.4 Application of Complex Network Theory in Cultural Heritage Conservation

Rooted in the principles of system science—including holism, hierarchy, openness, teleology, stability, mutability, self-organization, and irreversibility—and governed by fundamental laws such as structure-function correlation, information feedback, competitive synergy, fluctuation-induced order, and optimization-driven evolution, systemic principles exhibit universal applicability to the material world. Systems permeate all facets of human society, encompassing entities of varying scales, natures, and attributes. Cultural heritage networks exemplify such complex systems, integrating social, cultural, and natural dimensions. These networks comprise foundational natural ecosystems, anthropogenic structures, and the socio-economic activities of local communities and visitors, encompassing aspects such as neighborhood social interactions and regional cultural bearing capacity. The material spaces shaped by temporal-spatial evolution, regional cultural bearing capacity, and environmental factors demonstrate significant overlap and integration, with ubiquitous complex interconnections existing among elements and hierarchical levels within the system. Alterations in one system element trigger cascading effects across interconnected components, collectively shaping the system's holistic behavior. By treating historical sites as complex adaptive systems and employing systems thinking to investigate dynamic interactions among system, environment, and elements, this approach enables targeted analysis of specific system components to address emergent practical challenges.

Complex network theory elucidates systemic complexity through node-edge topological relationships. In cultural heritage contexts:Nodes represent individual heritage entities.Edges encode spatial connections, cultural lineages, or functional dependencies between heritage elements.

Recent methodological developments highlight two research trajectories:Network Resilience Analysis: Identification of critical heritage nodes through centrality metrics (e.g., degree centrality, betweenness centrality). Multi-Layer Network Integration: Emergence of coupled network models, such as Italy's hybrid framework overlaying sacred architecture networks with tourist mobility patterns for proactive risk management.

2 Multi-level analysis of cultural heritage in Qinghai Province

2.1 Three Principles for Cultural Heritage Conservation in Qinghai

(1) Authentic and Effective Protection of Historical and Cultural Resources

Adopting a value-oriented approach, this principle emphasizes the implementation of scientific methods and appropriate strategies to safeguard the authenticity of historical and cultural resources. Destructive practices such as demolishing authentic heritage to construct replicas or engaging in fraudulent restorations are strictly prohibited. Emergency conservation and repair measures are promptly undertaken for historical and cultural resources facing severe deterioration or existential threats.

(2) Holistic Conservation of Resource Entities and Landscape Patterns
This principle underscores the integrated preservation of historical and cultural resources, their associated landscape patterns, natural vistas, and cultural environments. It encompasses the protection of ecological elements such as mountains, rivers, ponds, and pastoral landscapes. Conservation efforts must avoid altering the topography surrounding heritage sites, refrain from felling ancient trees, and preserve morphological contours, street networks, architectural textures, axial sightlines, and spatial landmarks that reflect indigenous construction wisdom. Exploration of river-basin and corridor-style regional heritage conservation approaches tailored to Qinghai's geographical context is actively encouraged, emphasizing holistic and systemic preservation.

(3) Systematic Conservation of Historical and Cultural Resources Across Eras
This principle advocates for the harmonious coexistence of historical and cultural resources from different periods, opposing the overshadowing of diverse cultural information by singular thematic or stylistic representations. It emphasizes understanding the evolutionary trajectories of heritage assets, integrating their temporal stratification and spatial interconnections. Conservation strategies should ensure continuity and legacy across spatial configurations and physical heritage entities, vividly preserving historical traces and collective memories from various epochs.

2.2 Evolution of Cultural Heritage Conservation Policies in Qinghai
The policy framework for heritage conservation in Qinghai has undergone continuous refinement. In 2022, the provincial government enacted the Regulations on the Identification of Historical and Cultural Cities, Towns, Villages, and Districts in Qinghai. Subsequently, in 2023, it designated 4 cities, 9 towns, and 33 villages as the first batch of provincial-level historical and cultural entities. An additional 3 historical and cultural districts were added to the reserve list in 2024, establishing the foundational structure of the provincial heritage conservation system. Key legislative milestones include the Regulations on the Protection of Intangible Cultural Heritage in Huangnan Tibetan Autonomous Prefecture (February 27, 2025), alongside the formulation of the Qinghai Provincial Urban-Rural Historical and Cultural Conservation and Inheritance System Plan and the Huangnan Prefecture Concentrated Conservation and Utilization Special Plan. The Approval Regulations for Conservation Planning of Qinghai's Historical and Cultural Cities, Towns, Villages, and Districts have been implemented, with all national-level conservation plans having secured provincial government approval. Collaborative efforts with the Provincial Publicity Department and relevant bureaus have resulted in the 2024 Key Tasks for Urban-Rural Historical and Cultural Conservation and Inheritance, alongside the issuance of standards such as the Qinghai Provincial Guidelines for Village Appearance Enhancement and the Qinghai Provincial Standards for Traditional Village Conservation and Utilization. A comprehensive regulatory mechanism has been established through the introduction of identification protocols, management regulations, accountability measures, planning approval procedures, inspection systems, and expert advisory committee frameworks, supplemented by annual assessments, patrol inspections, and public interest litigation initiatives. This multi-pronged approach has engendered a deterrent effect against heritage damage, ensuring robust protection and oversight.

2.3 Spatial Distribution of Cultural Heritage in Qinghai
2.3.1 Regional Distribution of Cultural Heritage
Table 1 summarizes the distribution of cultural heritage sites across Qinghai's 8 prefecture-level cities. Based on administrative boundaries, Haidong City holds the highest count of both national and provincial-level protected sites, while Golog Tibetan Autonomous Prefecture has the fewest. Huangnan Tibetan Autonomous Prefecture is home to Qinghai's sole national-level historical and cultural city, while Haidong City contains the province's only national-level historical and cultural town and the majority of traditional villages.

Aggregating all categories, Xining City boasts 98 heritage sites; Huangnan Prefecture, 62; Golog Prefecture, 30; Hainan Prefecture, 81; Haidong City, 245; Haixi Prefecture, 43; and Yushu Prefecture, 106. The ranking of prefecture-level cities by heritage site quantity is as follows: Haidong City, Yushu Prefecture, Xining City, Hainan Prefecture, Huangnan Prefecture, Haixi Prefecture, and Golog Prefecture.

Table 1 Administrative distribution of cultural heritage in Qinghai Province

order number	City	Cultural heritage sites		settlement						
		National Geopark	Provincial tourism	National historic city	A provincial historical and cultural city	A famous historical and cultural town in China	Provincial historical and cultural town	A famous historical and cultural village in China	Provincial historical and cultural villages	Traditional Chinese villages
1	Xining City	1	72	0	1	0	2	0	4	23
2	Tibetan Autonomous Prefecture of Huangnan	4	55	1	1	0	1	1	4	24
3	Tibetan Autonomous Prefecture of Golog	3	13	0	0	0	1	1	1	0
4	Tibetan Autonomous Prefecture of Hainan	7	43	0	1	0	2	0	0	0
5	Haidong City	16	139	0	0	1	2	1	10	19
6	Hainan Mongolian and Tibetan Autonomous Prefecture	2	27	0	0	0	1	0	0	0
7	Tibetan Autonomous Prefecture of Haibei	4	26	0	0	0	0	0	0	0
8	Tibetan Autonomous Prefecture of Yushu	7	65	0	1	0	1	2	3	22
9	total	51	440	1	4	1	11	5	24	107

Figure 1 spatially locates cultural heritage sites in Qinghai Province using ARC GIS geographic information data, revealing distinct geographical distribution patterns between cultural resources and natural landscapes within the region.

Historical and cultural cities, towns, villages, and traditional villages predominantly cluster in basin and valley regions. The Hehuang Basin exhibits particularly high density, while valley areas along the Tongtian River (Yangtze River), Yellow River, and Zhaqu River (Lancang River) also serve as critical settlement zones for these heritage communities.

Protected cultural relics similarly concentrate in basin and valley terrain, with the Hehuang Basin remaining the most densely populated area. Substantial numbers of protected sites also line the river valleys of the Tongtian River, Yellow River, and Zhaqu River.

Scenic areas demonstrate strong correlation with mountainous and fluvial geomorphology, typically following mountain ranges and river courses. The Yellow River corridor hosts exceptionally high concentrations of scenic sites, with additional significant clusters in the Qilian Mountains and Kunlun Mountains regions.

The Qinghai section of the Silk Road cultural belt primarily extends through valley and basin zones, with the Hehuang Basin constituting its core distribution area and the Qaidam Basin serving as another key component.

The Qinghai-Tibet Railway cultural belt predominantly follows basin areas and railway corridors, maintaining high density in the Hehuang Basin while also exhibiting significant resource distribution along the Qinghai-Tibet Railway route.

The Tang-Tibet Ancient Road cultural belt similarly favors basin and valley topography, with the Hehuang Basin as its densest concentration zone and valley areas along the Tongtian River, Yellow River, and Zhaqu River forming additional critical distribution regions.

Other heritage remains broadly distribute across basin, valley, and transportation corridor zones, showing highest concentration in the Hehuang Basin while also appearing in valley areas along the Tongtian River, Yellow River, and Zhaqu River, as well as along the Qinghai-Tibet Railway.

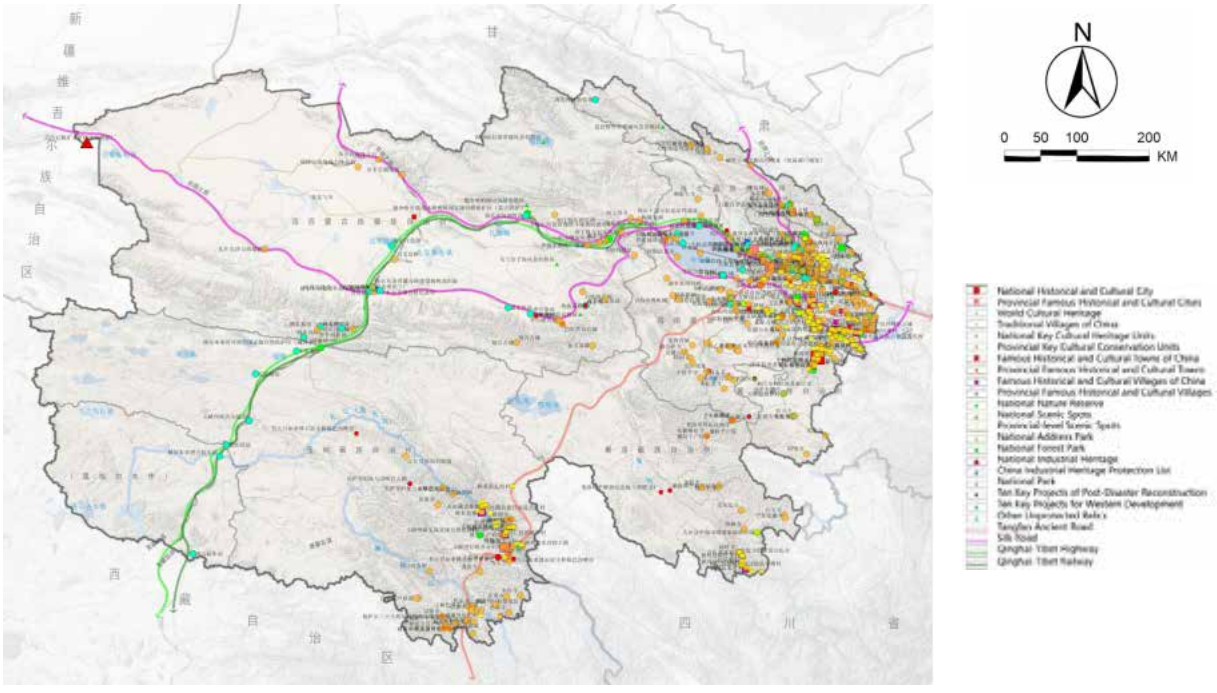

Figure 1 Distribution Map of Historical and Cultural Heritage Sites in Qinghai Province

2.3.2 Analysis of Cultural Heritage Conservation and Utilization Efficiency in Qinghai Province

An integrated analytical framework for historical and cultural heritage conservation-utilization efficiency was developed by synthesizing: (1) An integrated resistance surface model incorporating natural factors (elevation, slope, land use type, road proximity, river proximity) (2) Specialized assessments of heritage site vulnerability, environmental threats, and management efficacy.This framework enables the demarcation of five vulnerability tiers and the formulation of tiered conservation strategies.

Single Factor	Category	Grade	Weight
Elevation (m)	1500	1	0.1
	2750	2	
	4000	3	
	5250	4	
	Above 5250	5	
Slope (°)	3	1	0.1
	8	2

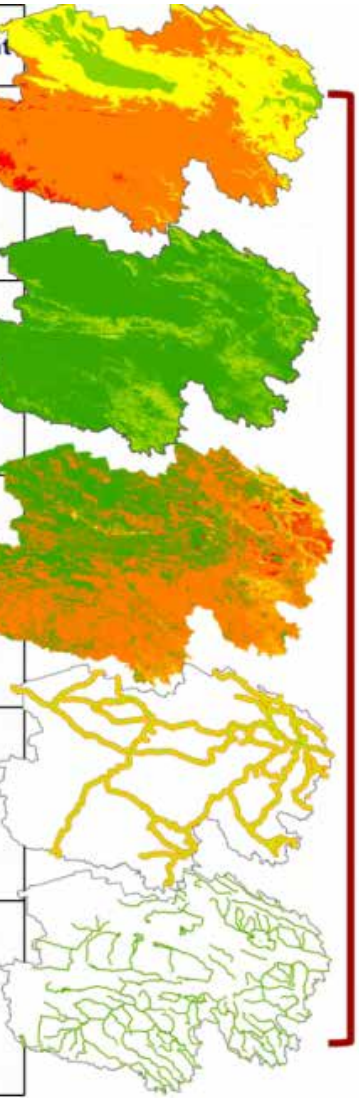

Figure 2 Comprehensive resistance surface model diagram

(1) Cultural Heritage Vulnerability Assessment and Tier Classification

Through the integration of natural factor resistance surfaces with specialized assessments (heritage asset vulnerability, environmental risks, management performance), a five-tier vulnerability classification system for Qinghai's cultural heritage sites was established (Table 2). This tiered structure clarifies conservation priorities and management focuses across different vulnerability levels.

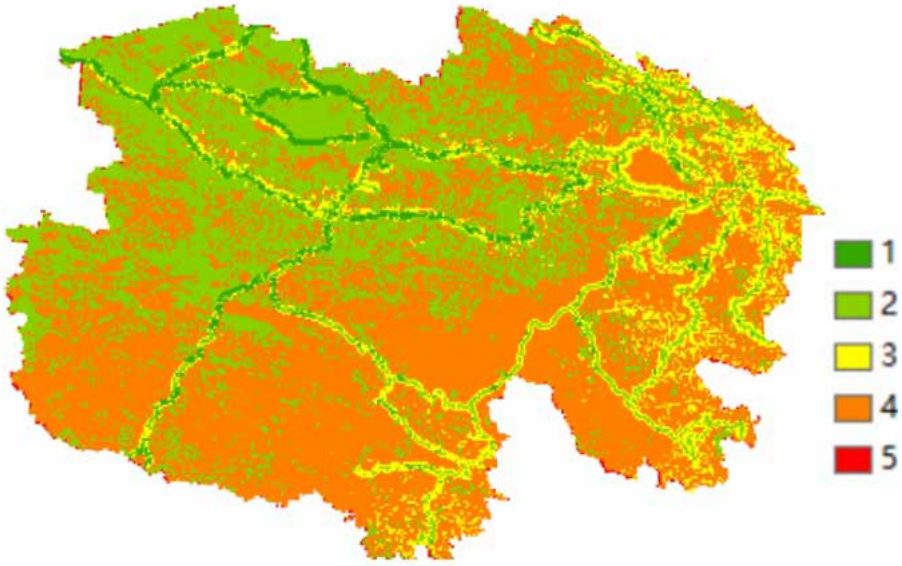

Figure 3 Cultural Heritage Vulnerability Assessment and Grading Diagram

Vulnerability Level	Natural Resistance Characteristics	Preservation Status of the Object	Environmental Threat	Management Efficacy	Typical Case
Level I (Slightly Vulnerable)	Low-resistance area	The object is intact, with a disease rate <5%	Low risk of natural disasters, weak human activity interference	High protection level, monitoring coverage >90%	Dongguan Mosque in Xining, Zhenda Temple
Level II (Mildly Vulnerable)	Lower-resistance area	Slight disease (5%-15%)	Relatively low risk of natural disasters, controllable human activity interference	Relatively high protection level, monitoring coverage 70%-90%	Kumbum Monastery murals in Haidong
Level III (Moderately Vulnerable)	Medium-resistance area	Structural stability decline (disease rate 15%-30%)	Moderate risk of natural disasters, significant human activity interference	General protection level, monitoring coverage 50%-70%	Zongri Site in Hainan Prefecture
Level IV (Severely Vulnerable)	Higher-resistance area	Endangered state (disease rate >30%)	High risk of natural disasters, strong human activity interference	Low protection level, monitoring coverage <50%	Jia Mani Stone Carvings in Yushu Xinzai
Level V (Extremely Vulnerable)	High-resistance area	Urgent need for rescue protection (disease rate >50%)	Extremely high risk of natural disasters, severe human activity damage	No effective management measures	Red Army Long March Inscription in Golog

(2) Integrated Conservation-Utilization Analysis

Superimposing cultural heritage vulnerability tiers onto the integrated resistance surface model reveals spatial patterns of conservation-utilization efficiency, categorized into five levels:

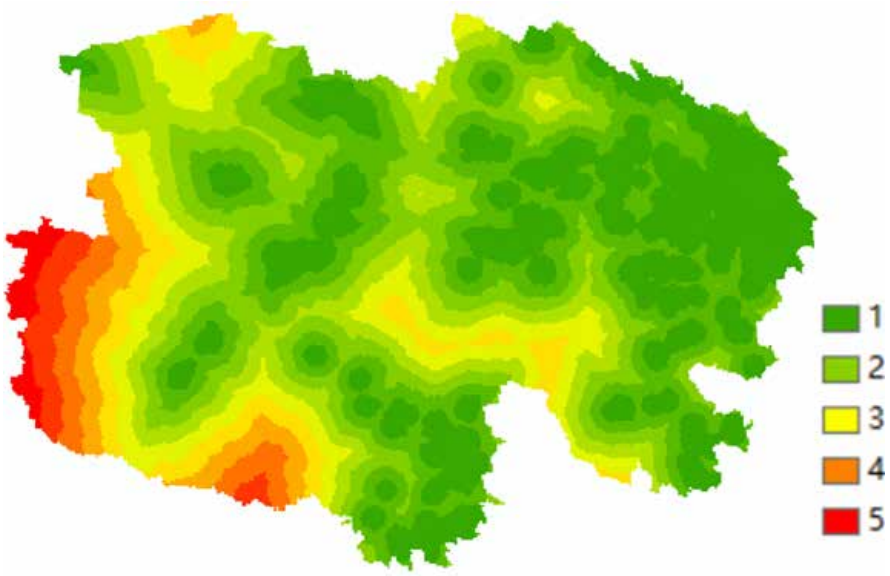

Figure 4 Comprehensive protection and utilization degree analysis diagram

Priority Conservation Zones (Tiers I-II): Predominantly located in the Hehuang Valley and eastern agricultural regions characterized by low natural resistance and minimal-to-mild heritage vulnerability. Strict in-situ preservation measures and development controls are mandatory.Stringent Conservation Zones (Tier III): Concentrated in the Loess Plateau-Qinghai-Tibet Plateau transition zone with moderate natural resistance and medium heritage vulnerability. Visitor capacity limits and enhanced monitoring/maintenance protocols are required.Conservation-Oriented Utilization Zones (Tier IV): Dispersed across the Three-River Source core zone and periphery, marked by high natural resistance and severe heritage vulnerability. Limited cultural experience projects may be permitted under stringent construction intensity controls.Moderate Development Zones (Select Tier V Areas): Restricted to rare areas with extremely low natural resistance and extreme heritage vulnerability. Digital exhibition formats represent potential conservation modalities.

Cautious Development Zones (Most Tier V Areas): Characterized by high natural resistance and extreme heritage vulnerability, these zones prohibit development in principle, restricting access to scientific research and emergency conservation activities.

(3) Spatial Adaptability and Management Recommendations
Qinghai's cultural heritage conservation-utilization efficiency exhibits a spatial pattern of "concentrated protection in the east, prudent utilization in the west," necessitating differentiated management strategies aligned with regional realities.

① Hehuang Valley: Living Heritage Preservation in Cultural Hubs
As Qinghai's most densely populated heritage region, the Hehuang Valley hosts national-level protected sites like the Lajia Ruins and Machangyuan Ruins, alongside intangible heritage such as Regong Arts and Hehuang Hua'er folk songs. Conservation priorities include:Living Heritage and Community Engagement: Transitioning from isolated preservation to mass participation, as demonstrated by the Huangzhong District "Eight-Petal Lotus" ICH Experience Center. Programs like Xining's "ICH in Schools" initiative (recognized as a national best practice) enhance community involvement.

Ecomuseum Model: Expanding the Regong Arts Ecological Protection Zone concept across heritage-rich areas, integrating cultural landscapes, traditional villages, and natural environments while resisting over-commercialization.

Digital Conservation and Dissemination: Leveraging digital technologies for heritage documentation and exhibition, exemplified by digital archives for 128 historic structures and traditional villages, coupled with online ICH dissemination platforms.

② Three-River Source Region: Ecological-Cultural Synergy
As China's "water tower," this region's heritage intertwines with alpine ecosystems (e.g., Qumalai alpine nomadic systems, Gesar epic traditions). Conservation strategies emphasize:Eco-Friendly Utilization: Balancing heritage preservation with ecosystem integrity, such as Qumalai County's integration of pasture resources through ecological livestock cooperatives, merging traditional nomadism with modern management to restore grasslands.

Traditional Knowledge Databases: Documenting nomadic cultural lexicons, proverbs, and ecological ethics (e.g., "The grassland is our mother; livestock are our children") to strengthen cultural identity through educational outreach.

Eco-Management Integration: Incorporating heritage conservation into the Three-River Source National Park's ecological management framework, training herders as dual cultural-ecological stewards through "cultural ranger" positions.

③ Southern Qinghai Plateau: Emergency Conservation in High-Vulnerability Zones
Regions like Golog and Yushu face challenges from high natural resistance and management difficulties (e.g., fading Red Army slogans, aging Gesar epic custodians). Interventions include:Emergency Documentation and Restoration: 3D scanning of endangered rock art and stone inscriptions, coupled with conservation laboratories for weathered artifacts.

Custodian Support Programs: Increasing stipends for ICH custodians and offering subsidies for apprenticeship training (e.g., Qinghai's ¥10,000 annual grants to provincial-level custodians).

Cross-Regional Collaboration: Joint protection mechanisms with Tibet and Sichuan for trans-regional heritage (e.g., Gesar culture), including shared databases and cooperative frameworks.

④ Policy and Institutional Safeguards
Regulatory Enhancement: Revising the Qinghai Provincial Intangible Cultural Heritage Protection Regulations to clarify rights/responsibilities and strengthen enforcement.Dynamic Monitoring System: Establishing a heritage spatial database for real-time environmental (seismic, flood) and anthropogenic threat monitoring, with vulnerability tiers subject to dynamic adjustment.Diversified Funding: Supplementing fiscal allocations with social capital participation, such as ICH protection funds and heritage lottery programs.

2.3.3 Kernel Density Analysis of Cultural Heritage and Spatial Network Construction for Heritage Conservation in Qinghai
(1) Kernel Density Analysis of Heritage Distribution
Based on the spatial distribution characteristics, significance, and internal relationships of historical and cultural heritage, kernel density analyses were conducted for six categories: historical and cultural cities, towns, and villages; traditional villages; protected cultural relics; scenic areas; revolutionary heritage sites; and cultural route heritage sites. These analyses revealed the comprehensive spatial distribution patterns of provincial historical and cultural resources. Key findings include: an absolute concentration zone in the Hehuang Basin, which benefits from favorable natural conditions and transportation accessibility; secondary density belts along

the valleys of major rivers such as the Tongtian River, Yellow River, and Zhaqu River; aggregation zones along transportation corridors (e.g., Qinghai-Tibet Railway, historical Silk Road Qinghai section, Tang-Tibet Ancient Road) and connected basins like the Qaidam Basin; and a distinct distribution pattern for scenic areas, which primarily align with mountain ranges (Qilian Mountains, Kunlun Mountains) and river courses, particularly the Yellow River. Overall, basins, valleys, and transportation arteries are identified as the three critical geographic factors shaping Qinghai's cultural heritage spatial structure.

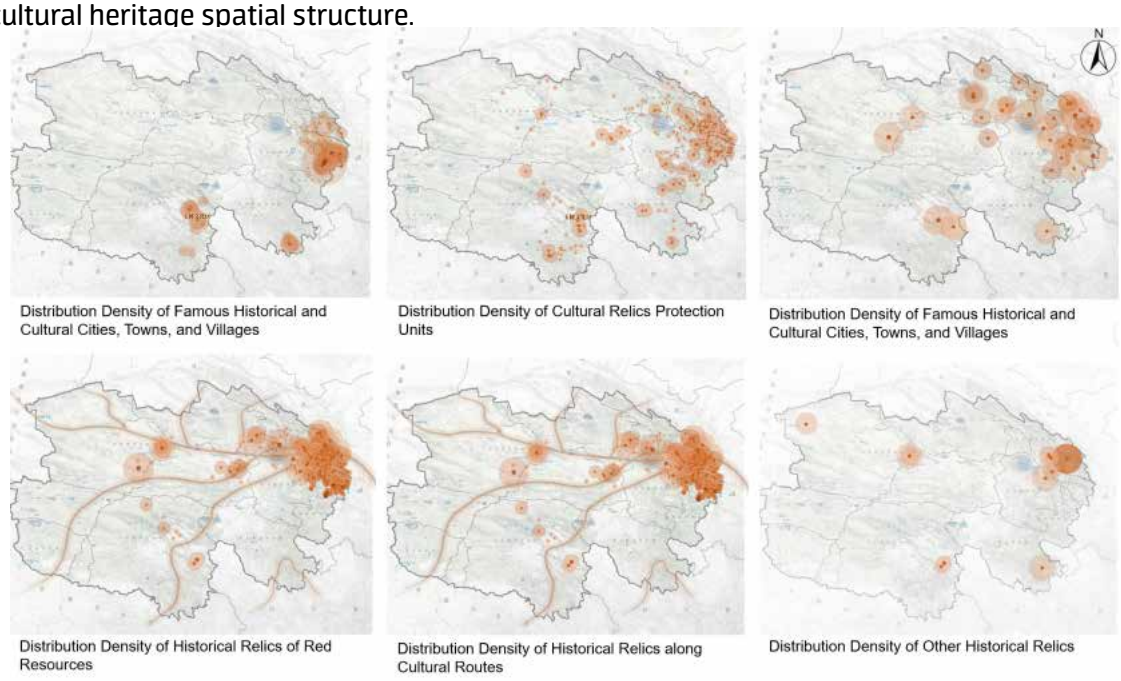

Figure 5 Analysis diagram of kernel density by type

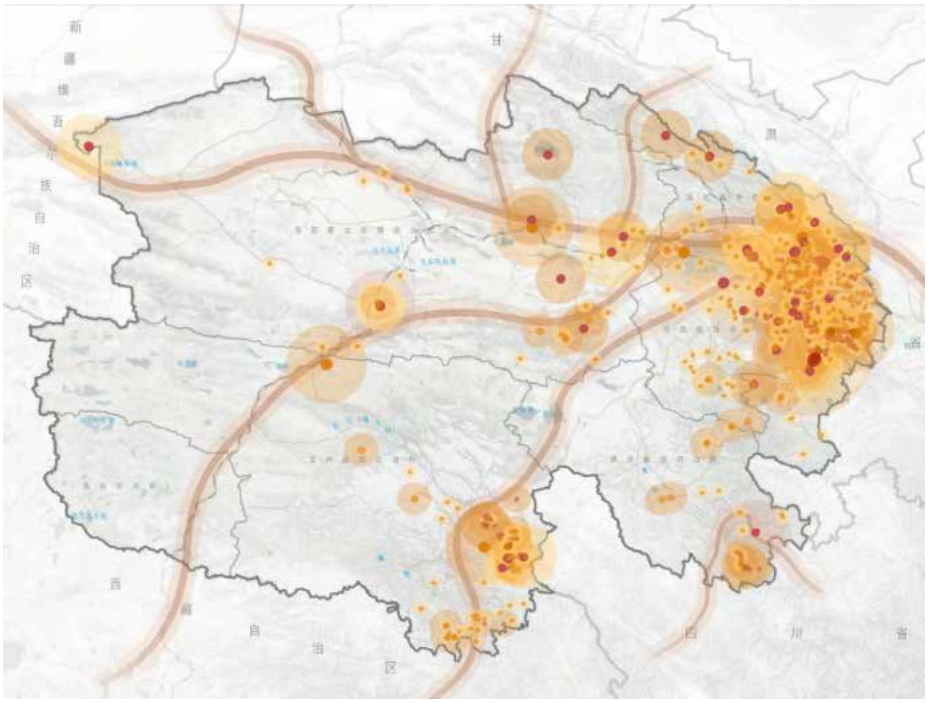

Figure 6 General diagram of nuclear density analysis

(2) Construction of the "Three Cores, Three Corridors" Heritage Conservation Spatial Network
Based on kernel density analysis results and the intrinsic connections among heritage sites, a spatial conservation network was constructed.

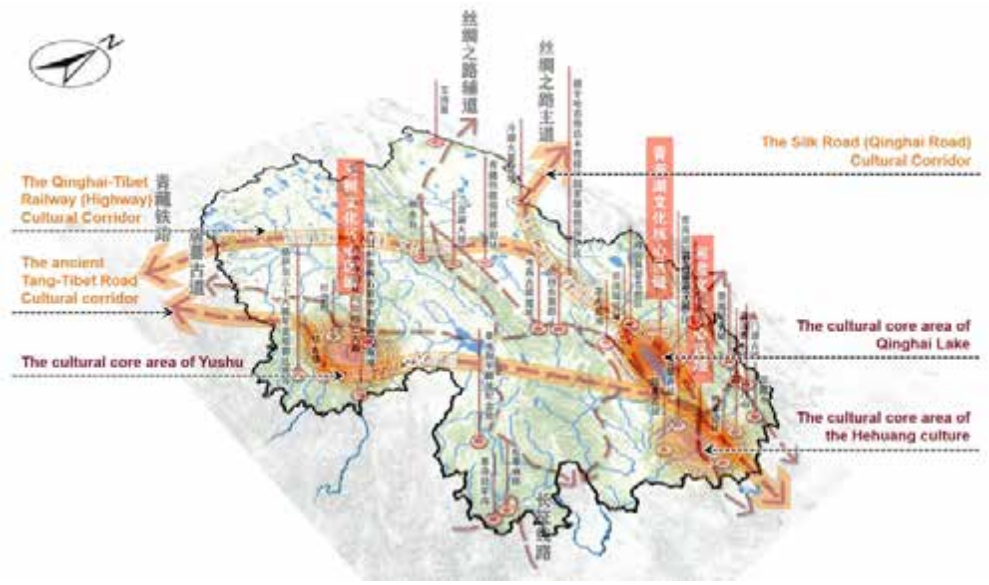

Figure 7 Spatial network structure diagram for Heritage protection

This network integrates the natural and cultural geographic patterns, historical and cultural context elements, and provincial heritage value priorities. It comprises three cultural cores and three cultural corridors: the three cores include the Hehuang Cultural Zone (encompassing Xining, Haidong, Haibei, and Huangnan prefectures), the Qinghai Lake Cultural Zone (including Haiyan, Gonghe, Tianjun, and Gangcha counties), and the Yushu Cultural Zone (covering Yushu Prefecture); the three corridors include the Tang-Tibet Ancient Road Cultural Belt (along National Highway 214), the Qinghai-Tibet Railway Cultural Belt (along National Highway 109), and the Silk Road (Qinghai Route) Cultural Belt (along National Highway 315).

3 Cultural Heritage Conservation Strategies for Qinghai within Complex Systems

For a prolonged period, the field of historic urban conservation has been trapped in a monolithic mindset, excessively focusing on conservation methodologies themselves while relentlessly pursuing technical perfection and flawless planning outputs. However, insufficient attention and research have been directed toward understanding the fundamental attributes and inherent operational mechanisms of historical-cultural heritage carriers. This fragmented approach has hindered our ability to comprehensively examine conservation and development issues within historic cities under the macroscopic framework of spatial complex systems.

In practical implementation, these limitations manifest prominently. During urban renewal processes, drastic demolition-and-reconstruction approaches have severely disrupted the traditional urban fabric, gradually eroding historical values and cultural functions. Conversely, when formulating conservation plans, an overemphasis on preservation controls often neglects the developmental and renewal needs of historic cities, resulting in planning frameworks that struggle to adapt to evolving realities and urban growth dynamics.

Confronting this dilemma, the heritage conservation community faces a critical challenge: how to respect the fundamental characteristics of historic cities while adhering to general urban development patterns, thereby identifying viable pathways for their conservation and evolution. Fortunately, this discourse is gaining increasing global attention.

The 2005 Vienna Memorandum offers valuable insights, particularly through its exploration of World Heritage conservation and historic landscape preservation amid rapid urbanization—a document commended by the 29th session of the World Heritage Committee. It explicitly identifies the paramount challenge of balancing modern development, urban transformation, and socio-economic harmony when introducing new constructions into historic environments. The memorandum underscores the necessity of prioritizing cultural and historical factors in such contexts, ensuring the integrity and authenticity of heritage structures while achieving synergistic outcomes for both conservation and urban advancement.

The 2011 UNESCO Recommendation on the Historic Urban Landscape further deepens our comprehension of historic city conservation, asserting that historic urban areas represent humanity's richest and most diverse cultural heritage expressions—critical testaments to collective human endeavors and aspirations. Simultaneously, urban heritage constitutes not merely social, cultural, and economic assets but also bridges connecting past and future. That same year's Valletta Principles for the Conservation and Management of Historic Cities, Towns and Urban Centres positions heritage as a vital component of urban ecosystems, emphasizing that conservation entails not only preservation, protection, reinforcement, and management but also harmonious integration with contemporary life.

These international instruments provide crucial theoretical frameworks and practical guidance for exploring effective models of historic city conservation and development. Moving forward, deeper inquiry into the fundamental attributes and intrinsic mechanisms of historic cities is essential to adopt a more holistic, scientific perspective in addressing conservation and development challenges.

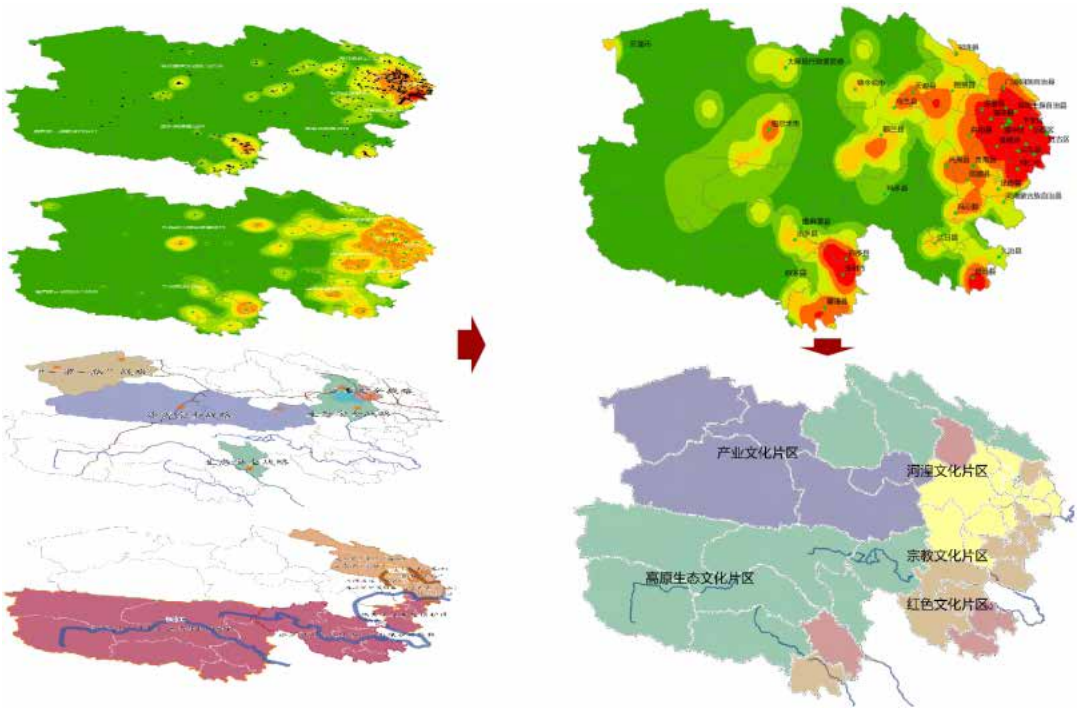

Figure 8 Path of revitalization and utilization of cultural heritage

4 Conclusions

The integrity of protection and transmission urgently needs strengthening. The work of protecting and transmitting urban and rural historical culture lacks overall provincial coordination and vertical linkage. A

provincial-level historical and cultural value system has yet to be established, resulting in unclear direction and focus for protection and transmission efforts. A collaborative protection mechanism between the province and cities/counties is absent, leaving the specific responsibilities, missions, and priorities of different cities and counties undefined, preventing the formation of a unified provincial effort ("playing chess as one province").
The coverage of protection work urgently needs expansion. Currently, Qinghai Province possesses only 1 National Famous Historical and Cultural City, 10 Famous Chinese Historical and Cultural Towns/Villages, and 4 Historical and Cultural Districts, significantly lagging behind other provinces. In reality, many urban and rural heritage sites bearing important historical and cultural value remain unlisted for protection. Heritage resources reflecting historical memories and values from key periods like the 100th anniversary of the CPC, the 70th anniversary of the PRC, and the 40th anniversary of Reform and Opening-up have not been fully explored or protected. Cross-regional and cross-jurisdictional historical and cultural corridors and routes, such as the Tang-Tibet Ancient Road and the Qinghai-Tibet Railway, lack integrated protection.

The scientific rigor and rationality of protection and transmission urgently need enhancement. There is a widespread tendency to focus on protecting individual heritage buildings or historical structures while neglecting the preservation and continuity of the overall urban/rural landscape pattern, traditional regional character, and cultural environment. In some urban construction projects, the destruction of original topographic features and the overall setting of historical and cultural heritage has occurred, damaging the protection of overall townscape, height control, and visual corridors, resulting in "bonsai-style" protection (isolating relics from their surroundings). Protection and renewal efforts in some historical and cultural districts or areas have severed the original social fabric and living networks.

In the contemporary era, urban and rural cultural heritage, as a vital component of a complete cultural ecosystem, is experiencing continuous expansion and deepening of its connotation and extension. It is no longer confined to singular cultural elements or physical carriers but extends to the complex interactions between different cultures, and between culture and the natural environment, along with their profound impacts. This comprehensive expansion endows urban and rural cultural heritage with diversified values, encompassing profound historical value, unique cultural value, captivating aesthetic value, significant social value, and potential economic value, among other dimensions.

Given the richness and complexity of urban and rural cultural heritage values, protective actions have far surpassed the scope of traditional cultural relics preservation, evolving into a complex social systems engineering project involving multiple domains such as politics, economy, society, culture, and management. This necessitates comprehensive, multi-level expansion and exploration in our protection efforts.

Cognitively, we need to re-examine the value and significance of urban and rural cultural heritage, deepening our understanding of its cultural essence and ecological value.

Theoretically, a more robust theoretical system for the protection of urban and rural cultural heritage should be constructed to provide scientific guidance for practice.

Technically and methodologically, innovative conservation techniques and methods must be continuously developed to enhance the scientific rigor and effectiveness of protection work.

In terms of implementation and strategy, long-term, systematic protection plans need to be formulated to ensure the continuity and stability of conservation efforts.

Simultaneously, the protection of urban and rural cultural heritage must transcend the singular concept of space and be considered within a broader cultural-ecological context. This implies a shift from specialized technical fields towards integrated domains where society, economy, politics, and culture intersect, requiring interdisciplinary and cross-sectoral collaboration.

To achieve this goal, we need to conduct comprehensive and in-depth integrated surveys and assessments of value, current status, and management, accurately grasping the situation and challenges of urban and rural cultural heritage. Based on this, establish a core-value-based protection system for urban and rural cultural heritage to ensure targeted and effective conservation work.

Furthermore, urban and rural cultural heritage protection should emphasize a people-oriented philosophy, focusing on strengthening the formulation and implementation of public policies. By establishing coordination mechanisms involving multiple departments and public participation, we can fully mobilize the initiative and proactiveness of all stakeholders – government, enterprises, social organizations, and the public – fostering a positive atmosphere of collective participation and protection. Only in this way can we steer urban and rural cultural heritage protection towards a dynamic, proactive, inclusive, and diverse path of sustainable development.

Spatial Development Strategies and Policy Recommendations for Social Development in Shenzhen

Mao, Weifeng
Affiliation:Guangzhou Urban Planning & Design Survey Research Institute Co., Ltd.
Email: weifeng.mao29@gmail.com

Abstract
This paper examines the current challenges in the spatial dimensions of our city's social construction efforts, including the low level of resource allocation efficiency, inadequate expression of urban characteristics, and shortcomings in management systems. It offers reflections on the issues and underlying causes affecting social construction in our city. Drawing on successful practices in social construction from both domestic and international contexts, the paper proposes relevant spatial strategies aimed at activating existing spaces, expanding incremental development, prioritizing community engagement, supporting vulnerable groups, enhancing citizens' well-being, and innovating institutional mechanisms.

Keywords: Social Development; Spatial Strategy; People-Oriented; Sense of Well-Being

Looking back at the history of Shenzhen's reform and opening up over the past 40 years, economic construction has always been the centre of development, while the development of social construction has lagged , becoming a 'bottleneck' that further restricts Shenzhen's sustainable economic and social development. As a pioneer city of China's reform and opening up, Shenzhen has long faced challenges in integrating economic development with social construction, as the lack of effective synergy has led to high property prices, congested traffic and increasing social pressure, seriously affecting the sustainable development of Shenzhen. Urban planning, as a tool for regulating urban development and construction, plays an important role in guiding coordinated economic and social development. Looking at developed cities at home and abroad, all of them give full play to the comprehensive, macroscopic and holistic role of urban planning to promote the sustainable development of cities.

1. The top-down social construction model is difficult to adapt to the requirements of Shenzhen's transformation and development

In the 40 years since the establishment of the Shenzhen Special Economic Zone, while creating a world miracle of economic development, urban social construction has also made remarkable progress. However, in terms of spatial support for social construction, it is basically a big deal for the government, and there is still a gap between its top-down spatial allocation model and that of advanced cities, which is mainly reflected in:

1.1 Spatial resource allocation for social construction needs to be optimised

There is a shortage and a waste of spatial resources for social construction. There is a shortage of community-level service facilities compared with the relatively well-developed urban-level service facilities. Shenzhen has highlighted some of its large-scale facilities, completing the construction of public facilities with a high starting point and high standards, such as the Shenzhen International Convention and Exhibition Centre, the Universiade venues and the Shenzhen Concert Hall. However, there is a relative shortage of community-level service facilities compared to urban-level facilities. The population served by social service centres in Bao'an District, Luohu District and Longhua New District, where community population density is high, is 2-3 times that of other districts, and the service carrying capacity of community facilities is relatively weak. The network of grass-roots cultural and sports facilities is not yet complete, with only seven districts having cultural centres and two streets having cultural stations; cultural centres and libraries outside the original Special Administrative Region are not up to standard, and the construction of grass-roots sports facilities needs to be stepped up.

On the other hand, existing facilities, whether in education, health care, elderly care or housing, are being used inefficiently and resources are being wasted to varying degrees. Concerning medical and health facilities, large and medium-sized hospitals are overcrowded and operating at excessive capacity. Primary healthcare facilities, on the other hand, are cold and quiet, and are even struggling to survive. With regard to elderly care facilities,

the total occupancy rate of institutional elderly care facilities is only 49.3%, with the occupancy rate of privately-run elderly care facilities at 18.9%, and a large number of facilities and equipment lying unused; whereas the total number of elderly people on the waiting lists of the Luohu Welfare Centre and the Nanshan District Welfare Centre at the end of 2023 amounted to 1,700, and the distribution of beds does not match the distribution of the elderly population. Social welfare facilities such as social welfare homes for vagrant mental patients and children are lacking. With regard to cultural and sports facilities, the efficiency of the use of some of the large cultural and sports facilities is generally low, such as the low utilisation rate of the Universiade venues, the yearly number of visitors to the Guanshanyue Museum of Art in Shenzhen is around 100,000, and the annual number of visitors to the Hexiangning Museum of Art is no more than 80,000, for example.

1.2 Social construction needs to be elevated

The current social construction is based on the protection of people's basic needs, and it is difficult to meet people's ever-increasing material and cultural needs. Aristotle once said: 'People gather in the city in order to live, in order to live better in the city.' People living in cities not only need to solve the basic problems of food, clothing, housing and transport, but also need to live a happy and joyful life.

However, Shenzhen's urban space shaping has yet to fully reflect the characteristics of a coastal city and multiculturalism, and residents lack a sense of belonging and identity. As a coastal city with a long coastline in the east and west, Shenzhen has good conditions for building a coastal eco-city. However, these natural conditions have been neglected in the development process, resulting in the distance of the sea, the reduction of mountains and the pollution of rivers. The proportion of living shoreline is low. Shenzhen has a total of 260.5 kilometres of shoreline, of which about 63 kilometres are living shoreline, accounting for only 24%. Referring to the proportion of public shoreline to the main waterfront shoreline in advanced cities (regions) in the world, Chicago is 68.9% and Sydney is 36.3%, which are both over 30%. Shenzhen's multi-cultural characteristics are not fully perceived by the public. Firstly, history and culture are not sufficiently visible, and protection and utilisation are fragmented. Shenzhen has 1600 years of urban history in Dongguan County and Bao'an County, and 600 years of castle history in Nantou and Dapeng. Although the protection of historical and cultural resources is increasingly important, but the government passively delineates the purple line for strict protection, and can not fully realise the value of historical and cultural resources. The combination with the cultural and creative industries is not high, and in the end, but is not conducive to the protection of cultural resources themselves. Secondly, the implementation of the reform and opening-up culture is less content. At present, the culture of reform and opening up is mostly protected through museum exhibitions; this static and single way of protection can not be a comprehensive display of the reform and opening up of the culture of Shenzhen.

1.3 Institutional mechanisms for social construction need to be improved

There is no clear distinction between the responsibilities and roles that the Government and the market can assume. At present, in the area of social construction, the Government 'takes care of everything', with all types of social resources being allocated by the Government from the top down. In terms of construction and investment channels, the government's financial resources are predominant. Social capital, especially social organisations and charitable organisations, does not have good channels for donating funds and land for the construction of various welfare facilities. In social organisation management, the slow development of private organisations has made it impossible to effectively alleviate the social contradictions brought about by the sharp increase in social pressure and the imbalance in income distribution.

There is a lopsided emphasis on disaggregating and implementing responsibilities, and there is a lack of platforms for effectively integrating resources and coordinating interests. As the city's social construction is dispersed among various functional departments, the implementation of vertical 'article management', each grassroots community hangs dozens of signs, the community more from the perspective of meeting the requirements of the assessment of the higher level of government rather than from the perspective of meeting the actual needs of the community to carry out the various tasks. The lack of effective coordination among various functional departments makes it difficult to form synergies, and public properties completed often lack follow-up management and supervision; various departments are unable to share resources, and the public has no way of understanding the social facilities around them. Inadequate mechanisms for acceptance and supervision,

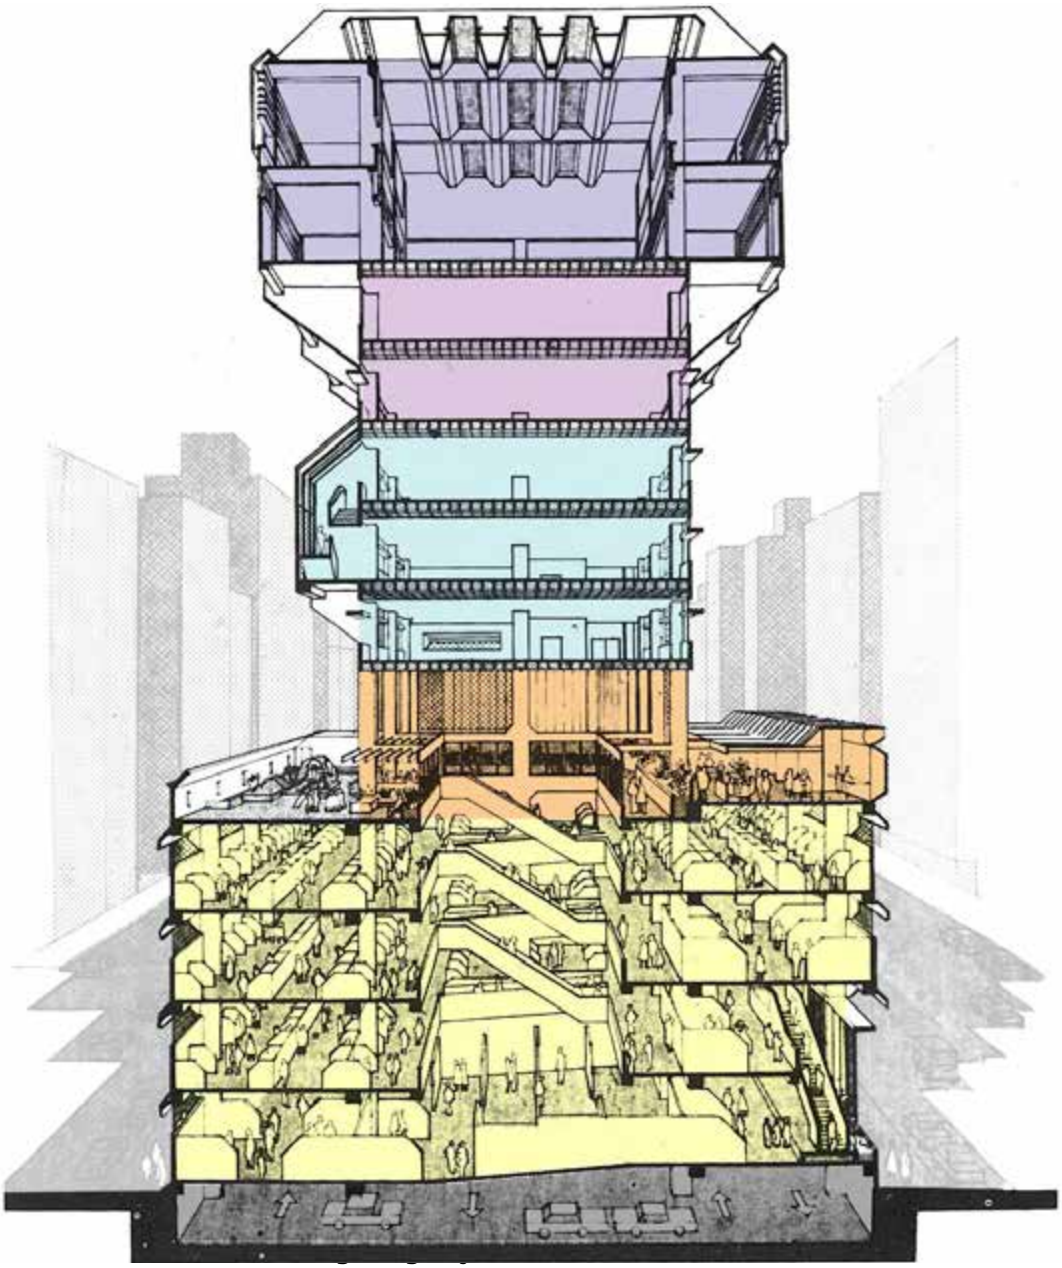
which require the participation of multiple departments, have made it difficult to implement planning for social facilities. Mainly reflected in the completion of the transfer of the community, community public facilities are not in accordance with the requirements of the planning and construction, or do not meet the requirements of the sectoral industry norms, resulting in the phenomenon of 'goods do not match the board', resulting in low utilization of social facilities, problems also have no feedback or accountability. Existing public welfare facilities, due to mismanagement or being in the hands of developers, are privately contracted for closed operations, losing their original public welfare purpose and becoming 'tasteless. For example, the Starlight Home for the Elderly has been converted into a mahjong teahouse in many communities.

2. Successful explorations in the field of social construction both at home and abroad have centred on 'human development' to organise all kinds of social resources.

Although Shenzhen's social construction is in a leading position in the country, there are still certain gaps in terms of space, level and institutional mechanism. Strengthening social construction is an important part of Shenzhen's construction of a modern, internationalised and advanced city, and is also a basic guarantee for the social and urban transformation that Shenzhen is facing. We must look to the developed countries and regions and learn from their successful experience, focusing on human needs and organising all kinds of social resources around human development.

2.1 Efficient and Intensive Spatial Allocation for Social Construction - One-Stop Service in Hong Kong's Municipal Services Buildings

The Hong Kong Municipal Services Building (HKMSB) is a multi-purpose integrated municipal building in Hong Kong, which generally comprises a loading and unloading yard on the basement level, a market on the ground and first floors, a cooked food centre on the first floor, a public library on the third floor, a swimming pool from the fourth floor to the fifth floor, and a gymnasium on the sixth and seventh floors. The LCSD and the FEHD now manage some of the facilities separately. At present, there are 39 municipal services buildings in Hong Kong. Vibrant municipal services buildings not only accommodate a wide range of social activities and provide diversified choices for the community, they are also valuable historical monuments in their own right. At least one community cultural complex is encouraged to be provided in each urban living cluster, where the basic needs of life, such as markets, catering, libraries, activity rooms, and so on, are concentrated in a single building, so that residents can enjoy diversified and multi-level as well as 'one-stop' services without having to go out of their neighbourhoods.



2.2 High Starting Point, Forward-looking Social Construction Service Model - The Mature Senior Living Community Model in the US

Retirement communities in the United States are generally divided into five categories: Active Adult Retirement Communities, Self-Care Communities, Assisted Living Communities, Special Care Communities, and Mixed Continuing Care Retirement Communities. Active Adult Retirement Communities are primarily for active, healthy seniors between the ages of 55-70 years old. This type of retirement community basically eliminates the need for medical care, but does allow for the use of third-party-provided services such as housekeeping, sanitation, and health care. The amenities that go along with them are more dynamic and include gyms, swimming pools, and golf courses. Self-care communities are for seniors aged 65-80 who do not need assistance with daily living, but do require medical care. The services required are mainly catering, housekeeping and cleaning services, with supporting facilities such as gyms, swimming pools and libraries. The occupants of assisted living communities are mainly elderly people aged 75 and above who need help. The level of medical care required is higher, requir-

ing three meals, bathing, toileting, medication reminders, physical rehabilitation training, etc. Activity rooms, libraries, exercise and rehabilitation centres are required. Special care communities provide the highest level of medical care, including medically prescribed professional rehab, and 24-hour emergency care. Supporting facilities are primarily recreational facilities, exercise and rehabilitation centres, and physical therapy rooms. Hybrid Continuing Care Retirement Communities are a combination of the previous types of retirement communities.

Elderly communities in the United States are already very mature, with different types of elderly communities for different ages and different self-care abilities of the elderly, as well as different modes of management and profitability. This model of community care for the elderly, which is truly considered from the perspective of different needs, is worth learning from.

A schematic diagram of a Continuing Care Retirement Community in the US
source from Research: Learning from the middle class pension model in the United States

2.3 Shared and transparent mechanisms for the management of socially constructed space

2.3.1 Anhui Wuhu 'Tree of Life' social service management innovation road

Wuhu City, Anhui Province, has proposed the creation of a 'tree of life' information management system, that is, the integration of information resources required in social activities during the different life cycles of human beings, through the establishment of basic databases co-ordinated by various departments, and the initial construction of three-level convenient service enquiry systems for districts, neighbourhoods and communities, with several functions such as household registration management and address management, and at the same time At the same time, information on house ownership, social security, civil affairs, etc. is gradually integrated into the basic database, and several application sub-systems are established, so that all community work is integrated into information management. Information-sharing platforms for all urban and rural communities in the city are gradually being established and covered.

This innovative management model for social services establishes an information platform whereby all sectors of society can more easily grasp information on all types of social services, and government administrations can provide public services more effectively.

2.3.2 Operation of Public Properties by the Government Property Agency of the Hong Kong Government

The Government Property Agency (GPA), a department under the Financial Services and the Treasury Bureau of the Hong Kong Government, was set up in 1990 to consolidate the management of government properties, which at that time were scattered in the Chief Secretary's Office, the Lands Department and the Rating and Valuation Department, into a single department. Its core objective is to manage government properties efficiently and cost-effectively. Its main activities include the construction, acquisition or leasing of public properties to optimise the use of government, agency and community land through the reservation of land, the release of under-utilised government land where appropriate, and the vetting of bureaux and departments' office and

accommodation requirements.

As the government's industrial coordination and management department, it participates in the supply, planning, construction, operation, supervision and management of the city's public welfare properties, and coordinates the management of the city's public welfare properties in an all-around way. For private organisations in need of acquiring and leasing properties, it provides more convenient and favourable application conditions that are open and transparent.

3.Strengthening spatial integration to build a people-centred social construction system

The successful exploration of advanced cities at home and abroad in the field of social construction embodies humanistic care everywhere. Their spirit and philosophy of focusing on human development and putting people first, as well as their successful practical experience, have brought valuable lessons to Shenzhen. Given the existing situation in Shenzhen and some of the problems in social construction, we propose six spatial strategies to cope with social construction, taking space as the entry point:

3.1 Activate the stock of space and encourage the mixing of functions and flexible transformation within the social service space

Ensure the efficient recycling of facilities by converting them to the most needed use of the moment when appropriate. Maximise the value of socially constructed space by adapting, optimising and overlaying internal functions over time. Based on the functional access guidelines, the land use of buildings or public spaces at different times of the day can also be used for different purposes, to achieve the purpose of realising as many uses as possible on the smallest possible plot of land. For example, sports and recreational facilities in primary and secondary schools can be conditionally opened to the community during holidays. Surplus office and conference space in the public sector can be opened up to the community when it is not in use, so that it can be converted into a venue for the activities that the community needs most.

Existing public welfare facilities are encouraged to renew and renovate themselves and increase their floor area ratios in order to expand the space available for use. As the level of urban construction and quality of life continue to improve, when the original public welfare facilities in terms of quality and quantity have gradually failed to meet the needs of residents, in the case of the surrounding land can not be further expanded, can be guided by the planning premise, by applying for the use of the government property maintenance fund or the public-private partnership model, undertake demolition and reconstruction or addition of the existing public welfare facilities in order to expand the use of space, so that they can independently complete the renewal and revitalisation. In this regard, the Government will continue to assist these facilities to enable them to complete their renewal and revitalisation on their own.

3.2 Enlarge the incremental space and release more space for social services in multiple ways

By focusing on internal potential, the government can encourage the reuse of idle or abandoned land or non-construction land for social service facilities. Guiding public participation in the supervision and management of idle or abandoned land suitable for development, and formulating preferential policies to encourage its reformation and utilisation as places or facilities needed by society. In urban landscape zones, green areas and other urban green open spaces under certain conditions, the government takes the lead in designing public facilities and public open spaces that are easily accessible and usable by the public. Encourage the construction of temporary outdoor activity facilities such as tennis courts and football pitches, and revitalise existing non-construction land resources.

Encourage owned buildings to provide public space after the renewal of the building, as well as the surrounding environment through policy instruments such as floor area ratio (FAR) incentives. Further increase efforts to support the transformation of old factory buildings, encourage urban renewal to provide public space, and encourage old factory buildings and other buildings to contribute more public facilities through such means as the distribution of land proceeds, land-price adjustments, and the transfer of plot ratios.

3.3 Focus on the community level and promote social service facilities at the community and grassroots levels

Optimising the scope of community management and services. Explore the establishment of basic community statistical units, and set up a system of basic community statistical units linking professional departments such as planning, land, property, statistics, public security, education and health. Change the statistical system in which each unit works separately and does not interfere with each other, integrate information on spatial and social management resources such as healthcare, culture and sports, education, population and public services, and implement a comprehensive and all-encompassing community statistical system. Integrate various types of statistical units, including those of planning, public security, education and other departments. Allocate social service facilities according to the actual population size. Break down the traditional community boundaries based on administrative boundaries, and determine the scale and type of various types of facilities according to the size of the actual population living in the local area, and establish a service-oriented mechanism for the allocation of community spatial resources. Under a market-based mechanism, the scale and structure of community service personnel of all types are configured around the needs of the community in accordance with factors such as the size of the population served and the carrying capacity of the community, and community boundaries are dynamically adjusted to form a scientifically reasonable physical community boundary for community management services.

Strengthening the provision of grass-roots facilities such as community-level sports and cultural facilities and medical facilities. For example, in response to the shortage of sports venues, increase the construction of community-level simple basketball courts, simple fitness facilities and other grounded, fast-acting and inexpensive cultural and sports facilities. Ensuring the availability of community-level service facilities. Appropriate policy preferences will be given in terms of supporting land for community service facilities outside the original Special Administrative Region or in short supply. Open a 'green channel' for the approval of land for community-level facilities, and simplify the content and procedures for the approval of land for community facilities, so that they can be put into use within the shortest possible time. A multi-sectoral acceptance system has been established to ensure that community facilities meet the normative requirements and practical needs of various sectors.

3.4 Care for the disadvantaged and provide diversified spaces and services for different people in the city

Through differentiated spatial strategies, different groups of people in the city can have their own place and enjoy themselves. Improving the living space for low- and middle-income groups in urban villages and other cities. To address the housing problems of low-income groups, broaden the supply of secure housing by actively promoting urban renewal modes such as conversion of industrial buildings into residential buildings and renewal of allotments, and make good use of the self-renewal mechanism of urban villages. In such a densely populated place as Haisha Village, where water cannot be splashed in, a new underground car park of several thousand square metres has been built, and the decoration of shops on the ground floor of the streets of Shuiwei Village is becoming more and more fashionable. Give some time and policies to allow urban villages to gradually renew themselves; extract some of the buildings to create public activity spaces in urban villages. Perhaps more important than old age reform is to make urban villages more livable. Compared with uprooting, acupuncture-type therapy is more effective.

Real scene of 1368 block in Shuiwei Village (Photo by the author)

To open up space for entrepreneurship among low- and middle-income people, such as the Civic Centre Square as a flea market, and regulating its management by fixing its opening time, location and types of commodities, and so on. The Civic Centre Plaza is grand and empty, with no facilities for public recreation, and not well divided and designed, with a large scale and a lack of vitality. The elevated plaza on its north side and the car park on its south side are very underutilised. We can make the Civic Centre Plaza an ideal place for various urban activities and festivals, so that the Civic Centre Plaza can really become a 'citizens' plaza'. At the same time, an appropriate fee reduction and exemption policy can be implemented, the level of social security for the informally employed can be gradually raised, and the training of the informally employed can be strengthened and improved.

Enhancing accessible design. Tailor humane spaces for women, children and the elderly to enhance the inclusiveness of cities. Improve people-centred barrier-free urban design, provide rehabilitation services or facilities for people with disabilities, adopt universal design, and implement a system of accessibility co-ordination managers and accessibility directors. To address the mobility problems of the elderly, barrier-free facilities such

as handrails have been placed in public activity areas, walkways and even the interior of housing in neighbourhoods, and attention has been paid to the elderly in the smallest detail through refined design.

According to the differences in the self-care abilities of the elderly, various types of retirement communities, such as active adult retirement communities, assisted living communities and special care communities, will be fostered. In response to the trend of aging in Shenzhen, we will focus on cultivating 'residential area + retirement' type of elderly communities in the future, with architectural designs specially designed for the elderly, giving full consideration to the dual needs of the elderly both physically and mentally, and targeting the planning of recreation, arts and culture as well as the main body of recreational living space, to create an image of a rich and personalised residential area, and to respond to the diversified needs of elderly groups in a flexible and changeable way, and to comprehensively promote the community elderly social community. Flexible and changeable ways to respond to the diversified needs of the elderly groups, and comprehensively promote the socialised service mode of community elderly care. There are different types of retirement communities for different age groups, with different management and profit models.

3.5 Enhance citizens' sense of well-being and shape the characteristics of a city of mountains and seas and a diversified city

Create a strong subtropical coastal city character and improve the quality of life of citizens. Insist on creating high-quality ecological space, and create urban clusters with suitable scales, complete support facilities and balanced jobs and housing; accelerate the establishment of the city's ecological protection and compensation system, and explore a variety of ways, such as eco-community planning, government leasing, and transferring the right to development in ecological areas, so as to realise the protection of resources with the mindset of development; and accelerate the adjustment of the function of the shoreline to increase the proportion of public shoreline. In Shenzhen's 260.5 kilometres of coastal zone co-ordination planning, increase the proportion of the original living shoreline of 25% to 35%; enhance the permeability of the coastal space to the service hinterland, so that the public in their daily activities are more close to the coastal space; cultivate more waterfront space, so that the public can see the mountains, look at the water, get close to the sea, forming an open, pleasant mountain and sea city cityscape; in the streetscapes, park landscapes, architectural styles and sculptural vignettes to reflect the characteristics of the coastal city everywhere.

Shenzhen Coastal Corridor (Photo by the author)

Strengthening the 'diversified and inclusive' urban culture and spirit of the city, enhancing the citizens' sense of belonging and happiness in their city, and improving the city's cultural competitiveness. On the basis of the diversified cultures of Lingnan culture, marine culture, reform and opening-up culture and immigrant culture that have already been formed in Shenzhen, learn and absorb the cultural development strategies of world-class cities, and, according to Shenzhen's strategic concept of 'establishing the city with culture', reflect the diversity of the city's cultures in the organisation of urban space, layout of facilities, and architectural design, so as to enhance the inclusiveness and cohesion of urban development. To enhance the inclusiveness and cohesion of urban development. Actively promote the protection of ancient villages and the transformation of historic districts. Different protection and utilisation methods will be adopted for different types of ancient villages, so as to achieve 'original protection' and 'functional regeneration', and to ensure that ancient villages regain their vitality and vigour while retaining urban memory. Regulations on the management, protection and repair of ancient villages should be formulated, and adequate compensation and incentives should be offered in terms of renewal and upgrading, as well as investment in the renovation of municipal facilities. Shape humane and characteristic urban public spaces. Use acupuncture to create a vibrant and interesting Shenzhen, starting from the 'point'. Use different buildings, places, facilities and vignettes to fully express the spirit of innovation and design. Advocating the small-scale transformation of urban villages, creating public courtyard spaces by removing part of the building; taking into account Shenzhen's climatic conditions, creating all-weather promenades, urban bridges, etc.; and proposing the combination of urban locations and urban activities, such as the Binhai Avenue Bicycle Race and the Civic Centre Festivals.

"original appearance protection" + "function regeneration" of Shenzhen Dapeng Fortress source from sznews.com

3.6 Innovative institutional mechanisms and the gradual establishment of a working mechanism for sharing resources across sectors

The Shenzhen Public Property Management Agency was created as the government's industry co-ordination and management department to participate in the supply, planning, construction, operation, supervision and management of public property throughout the city. The Public Property Management Agency is mainly responsible for the operation and management of government and other public welfare properties in the city, and coordinates the supply of land, planning and construction of new development programmes in response to the demands of various functional departments for land for public facilities. Through conversion or renovation, purchase or lease, it flexibly provides housing for social construction services and, where appropriate, vacates underutilised government properties to ensure that the city's public property land use efficiency is maximised.

Developing a 'one account' information network platform at the municipal, district and community levels. Integrate information on healthcare, culture and sports, education, population, and public service space and social management resources, and unify and publish them on the livelihood facilities supply information platform, which will be dynamically updated and maintained according to the use of the facilities, and gradually promote the sharing of public resources managed by different departments. All sectors of society can more conveniently grasp the latest information on the use of social construction space, and apply to public property management organisations on the platform to rent space, as well as apply for the construction or acquisition of certain properties for specific projects.

Open up channels to guide individuals, enterprises and charitable organisations to contribute facilities and services to society. Gradually relax the restrictions on social organisations entering the field of social construction, study and formulate a variety of incentives such as relevant land prices, plot ratios, taxes, etc. to support the entry of private capital into the social sector, and encourage social capital to participate in the construction of

livelihood-type facilities through various modes such as BT and BOT. Encourage individuals to contribute to society by transforming land or buildings in their hands into public facilities and open spaces such as parks, squares and promenades for charitable purposes. A professional operation mechanism of contribution-assessment-distribution-management has been established to respond quickly to current public needs.

Improving mechanisms for the participation of all of society in social construction. Reinforcing the participation of relevant authorities in civil affairs, education, health and human rights, culture and sports in the entire process of social construction projects, including the entire process of planning, approval, acceptance and management, will make it easier for the competent authorities to improve their own sectoral plans promptly and to promote the construction of relevant facilities in due course. Gradually establish a mechanism for teachers, doctors, lawyers, planners and other professionals and technicians related to social construction to share their professional knowledge and serve in social construction. In conjunction with the community planner system, a counselling and service platform for professional and technical personnel has been established in the community to provide a full range of services to community residents regularly.

Abstract
The earthquakes that struck southeastern Türkiye on February 6, 2023, caused massive destruction and displaced thousands to temporary shelters. This study examines the applicability of the UN Women Turkey Gender-Responsive Settlement Model (GRSM) in the cities of Adıyaman and Malatya. Using a GRSM-based checklist, the research evaluates temporary shelter areas and identifies the need for modifying the criteria to allow for more nuanced, scalable assessments. Data were collected through online surveys, field observations, unstructured interviews, and an expert workshop. Content analysis of the findings supports the development of locally adaptable, gender-sensitive settlement design principles. Addressing safety, accessibility, services, participation, and economic opportunity, the GRSM aims to guide local authorities in sustainable, inclusive post-disaster planning.

Key Words: Gender; Temporary Settlement; Post-disaster; Türkiye.

In a world of increasing uncertainty and complexity, enhancing urban resilience is becoming increasingly complex but critical. In particular, global impacts such as climate change, natural disasters, and large migration movements affect vulnerable groups more profoundly, making addressing their needs in a local context imperative. However, in the existing literature and urban policy practices, resilience mainly focuses on physical infrastructure. It does not adequately address the needs of vulnerable groups and their role in post-disaster recovery processes (Vale & Campanella, 2005). Urban planning practices, while central to post-disaster reconstruction and resilience-building, also often fail to integrate the socio-spatial needs of vulnerable populations, particularly women.

This narrow focus on physical infrastructure overlooks how inequalities are embedded in space and reproduced through standard planning responses to crises. As Moser (1993) highlights, women and girls, among the most fragile and disadvantaged groups, face compounded challenges during and after disasters stemming from socially constructed gender roles. These dynamics shape not only how risks are experienced but also how recovery unfolds across different social groups. Therefore, the authors hypothesize that localizing gender-responsive design criteria in temporary post-disaster settlements, where women and girls face intersecting vulnerabilities, can enhance not only social resilience but also the long-term adaptive capacities of communities.

Based on the "Gender Responsive Settlement Model" guidance manual prepared for UN Women Turkey, this paper analyzes local contexts with different social, geographical, and cultural characteristics via the cases of Malatya and Adıyaman. These provinces were selected not only because they were among the most affected by the earthquake, but also because these regions have multi-layered social, economic, and cultural backgrounds due to their strong historical structures.

The existing guide must be tailored to adapt to different geographical and cultural local contexts rather than providing a generic design approach. Thus, the findings of the research in Malatya and Adıyaman are expected to lead to a discussion to point out that considering local characteristics in the design of temporary settlements

will both increase pre-disaster urban and social resilience and strengthen the adaptation capabilities of people in post-disaster recovery and reconstruction processes. This contribution aims to localize a global and generic model and advance the conceptual integration of gender responsiveness within urban resilience policies.

Literature review

Critiques of Technocratic and Infrastructure-Centric Resilience Models

Resilience is a multi-layered concept defined in different ways in different disciplines. Defined as elastic strength and ability to recover in engineering (Chelleri, 2012), resilience is associated with the ability of an individual to cope with difficulties throughout life in psychology (Rutter, 1987). In this transition from the individual and physical level to the societal scale, Adger (2000) defines social resilience as the ability of communities to adapt to environmental and political stresses. While traditional approaches interpret resilience within the framework of "returning to equilibrium" or "maintaining stability," ecological systems theory (Holling, 1973) and complex systems thinking have explained resilience with the capacity for transformation, multiple equilibrium states, and self-organization principles (Levin et al., 1998). The social-ecological systems approach emphasizes that resilience should be addressed not only with the capacity for recovery but also with the capacity for adaptation and transformation (Berkes & Folke, 2003).

Although the concept of resilience is increasingly present in planning and policy discourses, Davoudi (2012) argues that the technocratic treatment of this concept often reduces it to a managerial discourse of "bounce-back-ability." Davoudi (2012) makes a distinction between engineering resilience (the speed at which the system returns to its former state) and evolutionary resilience (the capacity to adapt and transform). This distinction is crucial in the post-disaster context, as returning to a pre-disaster "normal" state can often mean reproducing the same vulnerabilities. Therefore, the integration of resilience into planning should be rethought not only in terms of efficiency and stability but also in terms of justice, power relations, and inclusiveness. However, this technocratic framing of resilience also overlooks how structural gender inequalities shape access to resources, recovery trajectories, and coping capacities, especially for women, caregivers, and marginalized populations.

In parallel with the concept of resilience being interpreted in different ways in different disciplines and diversifying over time into a complex framework, considering the necessity of addressing urban systems as a whole with their social and economic dimensions, gender equality, the role of vulnerable groups in recovery processes and consideration of local contexts have become integral components of current resilience approaches. However, this multi-layered understanding of resilience remains incomplete unless it includes the different vulnerabilities of social groups. In particular, ignoring social resilience weakens post-disaster adaptation capacity and further deepens social inequalities (Sezgin Hatipoğlu & Ersavaş Kavanoz, 2024).

The evolution of resilience across disciplines and time shows that while early resilience approaches focused more on physical infrastructure and technical capacities, current approaches emphasize the central role of social resilience. Social resilience refers to the capacity of individuals and communities to overcome crises and reorganize, adapt, and transform in response to these crises. Therefore, social resilience includes the capacity to survive and prepare for future risks (Smyth & Sweetman, 2015).

Communities contain many social groups, and these groups have different levels of resilience to crises. Resilience should cover risks that vary according to gender, age, and socioeconomic status (Buckle, Mars & Smale, 2000). Gender constitutes one of these different vulnerability parameters. Traditional engineering-based resilience approaches often ignore structural inequalities and render these vulnerable groups invisible (Meerow, Pajouhesh & Miller, 2019). This situation may cause the concept of resilience to function as a 'status quo protector' that reproduces inequalities (Davoudi, 2012; Chelleri et al., 2015). Ignoring social resilience in planning and post-disaster recovery processes may lead to reproducing or deepening existing social inequalities (Sezgin Hatipoğlu & Ersavaş Kavanoz, 2024). Especially in contexts where gender-based inequalities are intense, the absence of community-based strategies limits an inclusive recovery and transformation process.

Therefore, to understand urban resilience holistically, social resilience needs to be addressed, especially in its relationship with gender, care work, and informal solidarity networks.

Gender as a Dimension of Social Resilience

Traditional resilience discourse often celebrates coping strategies developed at the "community" or "household" level but fails to question the social inequalities upon which these strategies are built. Smyth and Sweetman (2015) argue that to address the concept of resilience effectively and fairly, invisible but determining dynamics such as gender roles, power relations within the household, and care work must be taken into account as well. When these elements are ignored, resilience discourse can become a framework that naturalizes and reproduces the unequal burdens on women and girls.

Theis, Bryan & Ringler (2019) argue that most resilience strategies used in social policy and development programs offer a "one-size-fits-all" solution and therefore homogenize social vulnerabilities. Such approaches render inequalities faced by different social groups, such as women, the elderly, migrants, or caregivers, invisible. This can not only result in the needs of these groups not being met but also in the deepening of their risks. Gender-based resilience strategies should not be limited to post-disaster physical shelter or livelihood opportunities. Increasing women's participation in decision-making processes, socializing care work, and reducing time poverty experienced by women directly impact long-term resilience outcomes (Theis, Bryan & Ringler, 2019). Therefore, women should be positioned as "recipients of assistance" and active agents of resilience.

Building on these critiques, a growing body of research emphasizes the need for resilience frameworks that are not only sensitive to structural inequalities but also transformative. In this context, gender-sensitive planning approaches are not only a corrective tool that aims to compensate for existing deficiencies; they are also a call for a fundamental rethinking of how the concept of resilience is defined, measured and implemented. In the context of post-disaster reconstruction, this approach recognizes that states of vulnerability are socially produced and spatially embodied. These vulnerabilities become particularly evident in disaster contexts, as the design of settlements and the distribution of services either reduce or deepen existing inequalities. Therefore, resilience strategies need to take into account the spatial experiences of women and other marginalized groups, along with dimensions such as access, security, care work and participation.

This growing body of feminist and critical resilience literature underscores the necessity of post-disaster planning frameworks that are both intersectional and sensitive to spatial, social, and institutional inequalities. Together, these insights underscore the necessity of rethinking resilience planning through intersectional and locally grounded frameworks.

As earthquakes of February 6, 2023 caused widespread destruction in the southeast of Turkey, spatial and social problems experienced by vulnerable groups have become more visible. Problems such as basic infrastructure deficiencies, security risks and injustice in access to services became apparent in temporary shelter areas established during the crisis. This situation necessitated the rethinking of post-disaster temporary settlements not only as physical shelters but also as places of social resilience and social recovery.

The Gender Responsive Settlement Model (GRSM) (Oğuz Çevik, 2023), developed for the UN Women Turkey Office, provides a holistic framework for planning and designing post-disaster settlement areas with a gender responsive perspective. This model is based on the integration of the specific needs of women, girls, the elderly, the disabled and other vulnerable groups into settlement design. This is particularly evident in Türkiye, where empirical findings after February 6 Earthquakes further validate the critical need for gender-responsive and locally adaptable frameworks.

In Türkiye, studies conducted after the February 6 Earthquakes show how disasters reveal social vulnerabilities (see Altıok, Arıcı & Özüçelik, 2025; Duruel & Avşar Arık, 2023; Tüzün, 2023). These studies demonstrate that the concept of social resilience should be redefined inclusively by focusing on the experiences of different vulnerable groups, such as children, the elderly, and immigrant women. These studies also emphasize that post-disaster interventions should consider the chronic problems that existed before the disaster and the needs of vulnerable groups. Social resilience is not only an individual's adaptation capacity, but it is also closely related to their social support networks. Duruel and Avşar Arık's (2023) study with elderly individuals in Hatay highlights the protective role of solidarity networks over individual strategies. In other words, disaster fragility

is determined by the social system and power relations rather than the disaster itself. The fact that post-disaster social policies are generally based on "one-dimensional" interventions also deepens gender-based vulnerabilities (Altıok, Arıcı Özüçelik, 2023). For example, the focus of public support on uniform and temporary interventions has ignored the needs of migrant women. Thus, post-disaster social policy practices have increased the vulnerability of these groups by making existing inequalities invisible. These findings not only support the theoretical underpinnings of GRSM but also point to the urgent need for planning frameworks that move beyond standard templates to engage with situated experiences of vulnerability and recovery.

The Gender Responsive Settlement Model (GRSM) emerges as a vital planning tool that both responds to and reshapes the conceptual debates on resilience. Rather than treating gender as a secondary consideration or an add-on, the model places it at the centre of post-disaster recovery processes. By foregrounding lived experiences, local dynamics, and care responsibilities, especially those disproportionately shouldered by women, the model offers a transformative vision of resilience that is deeply embedded in place and social relations. It challenges the default technocratic approaches that focus solely on physical reconstruction and instead calls for a paradigm shift: from infrastructure-led to justice-centred planning. In this regard, GRSM bridges the gap between theory and practice by translating feminist and intersectional insights into spatial design principles and policy interventions.

Moreover, the model's adaptability across different local contexts offers a replicable and flexible approach for other disaster-affected regions. By engaging with the specific socio-cultural characteristics and institutional capacities of each locality, GRSM does not impose a one-size-fits-all template but encourages co-production of knowledge and participatory planning processes. It enables communities not just to recover, but to transform in ways that reduce future vulnerabilities and redistribute social risks more equitably. This localized and inclusive perspective aligns with the evolving understanding of resilience as not merely about 'bouncing back' but about building forward with justice, care, and collective well-being at the core. Therefore, the Gender Responsive Settlement Model contributes to an emerging planning paradigm that reframes resilience through gender justice and spatial equity.

In operationalising this vision, the GRSM includes a Gender Equality Self-Assessment Checklist specifically designed for newly established permanent settlements. This tool guides planners and decision-makers in identifying and addressing potential gender inequalities across various domains, including safety, housing, mobility, education, healthcare, employment, governance, and public space. Far from being a static instrument, the checklist is meant to be context-sensitive and adaptable to the unique social, cultural, and spatial dynamics of each locality. It fosters inclusive and equitable communities by integrating the perspectives of women and marginalised groups throughout planning and implementation processes. In doing so, the checklist not only enhances the responsiveness of recovery efforts but also anchors gender-sensitive social resilience within urban design and policy. As climate-induced and socio-political disasters become more frequent and more complex, planning responses must evolve accordingly. GRSM provides a framework for that evolution, one that resists the normalization of inequality in crisis response and instead reimagines post-disaster recovery as an opportunity for structural transformation.

Data and Methodological Approach

This research investigates the applicability of a model developed for designing and managing gender-responsive temporary settlements in different socio-cultural contexts. It is supported by the Scientific Research Projects Coordination Unit of Gebze Technical University. The main objective is to provide an adaptation framework that localises the Gender-Responsive Settlement Model developed by the United Nations Entity for Gender Equality and the Empowerment of Women (UN Women). The research is conducted in temporary shelter areas established following the earthquakes centred in Kahramanmaraş on 6 February 2023, selecting Malatya, Gaziantep, Kahramanmaraş, and Adıyaman provinces as case study areas. The choice of these cities stems from their direct and profound experience of the disaster's destructive impact as well as their social and cultural diversity, which allows the observation of varied experiences and needs within the context of gender.

This research employs a qualitative research approach through a multiple-case study method, as systematised

by Yin (2018). This method facilitates a comparative analysis of how a particular phenomenon manifests across different contexts. By observing the same phenomenon in diverse social, spatial, and institutional environments, it enhances both the validity and generalisability of the findings. Moreover, this approach enables the examination of the intersection between gender and disaster across different countries and contexts. Complementing the multiple-case study design, this research also employs the Grounded Theory approach to conduct an in-depth analysis of the data and to develop theoretical concepts. Grounded Theory, developed by Glaser and Strauss in the field of sociology, is a method that systematically constructs theoretical models based on qualitative data (Glaser & Strauss, 1967; Charmaz, 2014). This approach particularly facilitates the generation of original theoretical frameworks from field data without relying on predetermined hypotheses, making it suitable for understanding social processes, experiences, and complex human relationships. Given the multifaceted nature of women's experiences, needs, and gender dynamics in post-disaster temporary settlements, the flexible and data-driven analysis offered by Grounded Theory provides an appropriate method to reveal the detailed and authentic realities of the field.

The semi-structured interviews, observations, and field notes collected in the study were analysed using the constant comparative method. Through this process, codes and themes were developed to construct key concepts related to gender-sensitive settlement design. This approach provided a critical foundation for enhancing theoretical sensitivity and questioning the adaptability of existing models within the local context (Strauss & Corbin, 1998; Charmaz, 2014). Moreover, Grounded Theory facilitated the reciprocal development of the core "Gender-Sensitive Settlement Model" with the field data. This method went beyond merely defining a phenomenon; it also contributed to understanding the structural and social challenges women face in post-disaster contexts and supported the development of more inclusive and sensitive policies. Researchers such as Gaillard et al. (2017) and Enarson and Meyreles (2004) also emphasise the importance of supporting gender-based approaches in disaster settings with field-based analyses. Accordingly, the Grounded Theory method enriched the study's theoretical depth while enabling the formulation of robust, locally appropriate recommendations for practical application.

The case studies presented in this paper were conducted within a general framework in the provinces of Malatya and Adıyaman. According to Report of Presidency of Strategy and Budget (2025), the earthquakes centred in Kahramanmaraş on 6 February 2023 affected more than 14 million people across an area of 120,000 square kilometres. A total of 53,737 people lost their lives, 107,213 were injured, and more than three and a half million people had to be evacuated from the region. Following the earthquake, the Ministry of Environment, Urbanisation and Climate Change conducted damage assessment studies, which revealed that 102,825 housing units in Malatya and 64,456 in Adıyaman were classified as moderately or severely damaged. In Malatya city centre, there are 75 container settlements currently housing 112,686 people. In Adıyaman, 55 container settlements have been established, accommodating 118,150 people.

Before the case studies commenced, preliminary meetings were held to establish collaboration with active civil society organisations, local and central government institutions, and research organisations operating in the field. Based on these preliminary meetings and document reviews, initial impressions were gathered regarding the provinces of Malatya and Adıyaman, where the fieldwork would take place. Guided by these insights and the partnerships established, the fieldwork was conducted in temporary shelter sites. These temporary shelter sites were directly observed, and on-site assessments were made through photographs and videos. Additionally, semi-structured interviews were conducted with disaster-affected and/or refugee women, NGO staff, and local officials from public institutions. The scope and content of the semi-structured interviews were designed based on the UN Women's gender-sensitive settlement model and tailored with questions appropriate to each target group. The interviews were recorded via audio and/or detailed note-taking, then transcribed and analysed using thematic analysis.

Following the completion of the Malatya case study, the checklist developed within the framework of the Gender-Sensitive Settlement Model was transformed into an online survey form to ensure broader participation and data collection, informed by insights gathered from the field. The aim of the survey is to collect information on temporary settlement areas that could not be accessed during fieldwork due to time constraints and permission limitations. The survey is disseminated using a snowball sampling method, expanding through the trust and collaborations

established during fieldwork. This approach aimed to capture the experiences and perspectives of different social groups. It was deliberately chosen to facilitate rapid and effective access to the lived realities encountered in the field.

In contrast to the Malatya field study, the Adıyaman fieldwork was conducted in collaboration with Adıyaman University through the organisation of the Expert Consultation Workshop on Gender-Sensitive Temporary Settlements. The workshop was designed both to introduce the model and to collect data through participants. Participants included container city residents, local government employees, representatives of public institutions, women-focused NGOs, and academics. During the workshop, themes such as housing, security, infrastructure, access to social services, and livelihood opportunities were examined in the context of Adıyaman's temporary accommodation sites and the post-disaster process. The scope and adaptability of the Gender-Sensitive Settlement Model were discussed specifically within the Adıyaman context.

All field studies, along with their data collection and analysis methods, aimed to contribute to the effective localisation of the Gender-Sensitive Settlement Model and the development of gender-sensitive policy recommendations for post-disaster temporary settlement design. The collected data not only tested the model's practical applicability but also enabled the identification of the unique needs of diverse gender identities and social gender groups experiencing post-disaster conditions. This integrated approach offers a holistic understanding of how gender-responsive strategies can be more effectively designed, implemented, and institutionalised within disaster recovery frameworks.

Findings

Based on interviews and field visits conducted in the provinces of Malatya and Adıyaman, the findings obtained through the testing of the Gender-Responsive Approaches in Post-Disaster Temporary Settlement Planning model are presented below. The analysis first focuses on province-specific conditions, followed by a comparison of the current state of temporary living environments in both locations, and the identification of shared problems and needs. This comparative assessment is structured around the key components of the model. These components are used to comprehensively examine the spatial, social, and administrative dynamics observed during the fieldwork, and to evaluate the model's applicability and adaptability to local contexts.

Evaluation of Temporary Settlements in Malatya

Fieldwork conducted in Malatya revealed that temporary settlements were not designed in accordance with gender-responsive principles. Observations showed that the specific needs of women, girls, and other vulnerable groups were not adequately considered during the planning processes. Significant deficiencies were identified in core GRSM (Gender-Responsive Settlement Model) areas such as safety, privacy, access to services, and participation.

In the visited settlements, each household was typically allocated a single 21-square-meter container (Fig. 1). However, these units failed to provide an interior layout suitable for the age, gender, and care needs of household members. In most cases, no separation of sleeping spaces for women, men, and children was possible, leading to breaches in privacy. Containers were placed in very close proximity, blurring the boundaries of personal space and disrupting daily routines. The lack of proper lighting and inadequate locking systems on container doors posed particular safety concerns for women, especially at night. The separation of sanitary facilities from living units further hindered access to basic needs.

Figure 1. Container Unit. Rönesans 1 Temporary Settlement Area, Malatya.

Security practices varied significantly between container sites and lacked a consistent implementation model. For instance, while some sites allowed unrestricted entry and exit, others were subject to control by law enforcement. No specific protective mechanisms were in place for cases of harassment or violence against women and girls, and survivors were often forced to remain in the same physical environment. Although legal and psychological support was available through civil society organizations, the lack of enforcement authority limited their effectiveness.

Regarding WASH (Water, Sanitation, and Hygiene) services, there were notable shortcomings in meeting basic hygiene needs. Health services specifically for women — including prenatal care, family planning, and reproductive health — were either limited or entirely absent in many of the areas. Psychosocial support services were also found to be irregular and inadequate. Considering the widespread trauma following the earthquake, these gaps are particularly critical.

Although some temporary solutions were implemented in the education field, significant continuity problems were reported. While certain civil society initiatives aimed to uphold the right to education for both girls and boys, public educational facilities remained spatially inadequate. Some NGOs provided play areas, study rooms, and digital equipment spaces, yet the reach of these services remained limited (Fig. 2).

Figure 2. Social areas for Children. Samanköy Temporary Settlement Area, Malatya.

Overall, there were very few safe and inclusive public spaces where women, men, and children could come together. Existing social infrastructure was not designed with a gender-sensitive perspective, and failed to address the distinct needs of women, the elderly, and children.

Evaluation of Temporary Settlements in Adıyaman

Fieldwork conducted in Adıyaman revealed structural and operational problems similar to those observed in Malatya; however, notable differences emerged in administrative practices and the presence of civil society actors. When assessed through the framework of the Gender-Responsive Settlement Model (GRSM), it becomes evident that gender-sensitive planning principles have only been partially implemented in Adıyaman.

Unlike Malatya, Adıyaman's urban fabric has undergone a different set of spatial transformations in the aftermath of the earthquake. Whereas temporary settlements in Malatya were dispersed throughout the city center, in Adıyaman they are primarily concentrated in the urban periphery. Although this spatial arrangement has facilitated the centralized delivery of services, the scale and isolation of these areas have generated challenges for daily life—particularly for women and girls.

Housing typologies in Adıyaman are more diverse. In addition to container-based settlements, prefabricated structures are also commonly used (Fig. 3). In some areas, hybrid settlements composed of both containers and prefabricated units were observed. While prefabricated units offer larger interior spaces and may benefit larger households, their monolithic construction and internal layouts pose disadvantages in terms of privacy and safety. For families with five or more members, the increased floor area does not necessarily translate into improved privacy per capita. Therefore, while spatial expansion may contribute positively to perceptions of security—particularly among women and girls—it does not fully resolve concerns regarding privacy.

Figure 3. Prefabricated Unit. Vartana Temporary Settlement Area, Adıyaman.

Another distinctive feature of Adıyaman's temporary settlements is the spatial differentiation based on social profiles. For example, settlements near the eastern part of the city, especially around hospitals, were designated for healthcare personnel, while those near the university accommodated academic staff. Larger families were predominantly located in the southern Vartana region, within mixed (container-prefabricated) settlements. Conversely, marginalized groups such as the Dom community were placed in segregated settlements in the northeastern parts of the city. These patterns suggest a partial spatial profiling of temporary accommodation, though such arrangements were not consistently applied across all sites.

In terms of WASH (Water, Sanitation, and Hygiene) infrastructure and lighting, conditions were broadly similar to those in Malatya, yet significant variation was observed between settlements. For instance, in areas supported by private sector actors or charitable organizations, infrastructure was generally more developed, while others faced acute deficiencies. City-wide interruptions in water and electricity supply disproportionately affected those residing in temporary settlements, with women and girls bearing the brunt of these disruptions.

Access to education and social activities also revealed deep inequalities across sites. Earlier-established settlements benefited from a broader range of NGO-provided services, whereas newer settlements had more limited access to such resources (Fig. 4). The absence of a systematic and equitable distribution mechanism further exacerbated these disparities.

Figure 4. NGO-Provided Services Units. K-6 Temporary Settlement Area, Adıyaman.

Over time, the withdrawal of NGOs and the reduction of external support have led to significant gaps in healthcare services. Civil society organizations had played a crucial role in addressing the physical and psychological needs of women, girls, and adolescents. However, their diminished presence in the field has resulted in severe service interruptions, leaving these vulnerable groups increasingly unsupported.

Common Challenges and Needs

Field research conducted in Malatya and Adıyaman revealed that temporary settlement areas in both cities exhibit similar shortcomings in terms of gender-responsive planning principles. Common problem areas were identified at both the physical and administrative levels, particularly in relation to the core pillars of the GRSM model: safety, accessibility, participation, access to services, and resilience.

Shelter, Physical Infrastructure, and Safety

In both cities, women and girls report a low perception of safety in temporary settlement areas. In Malatya, this perception is linked to container material quality, spatial design, and layout. In Adiyaman, the issue stems from the location of settlements in large, isolated areas. While centrally located and small-scale settlements in Malatya, integrated into the urban fabric, positively influence perceptions of privacy and safety through greater social interaction, the prefabricated units in Adiyaman offer improved material quality and larger capacity, mitigating some safety concerns.

Urban Planning, Infrastructure, and Transportation

Differences in water, sanitation, and hygiene (WASH) services between the two cities are rooted in the performance of their infrastructure systems post-disaster. Malatya's infrastructure sustained comparatively less dam-

age, whereas in Adiyaman, water provision has been irregular, with scheduled outages during the week and formerly potable tap water becoming non-drinkable. These disruptions have a more severe impact on vulnerable groups, particularly women and girls, for whom hygiene is essential to daily functioning.

Psychosocial Impacts and Mental Health

Psychosocial and mental health support services in both cities are predominantly provided by civil society organizations. However, these services are not equitably distributed, and some units have withdrawn over time. In Malatya, smaller, more integrated settlements such as those outside Samanköy and Teknokent facilitate normalization and trauma recovery, especially for adolescents and children who have easier access to urban activities. In contrast, the larger-scale settlements in Adiyaman complicate coordination and contribute to fragmented service delivery, slowing psychosocial recovery.

Gender and the Status of Women

Although gender-related issues are similar in both cities, women's everyday roles are impacted differently depending on the shelter typology. In Malatya, standardized container units, regardless of household size, intensify domestic responsibilities for women. In Adiyaman, while container areas face similar challenges, prefabricated units with more flexible and spacious layouts provide relatively better conditions for women. Furthermore, Adiyaman features more visible support for women's labor participation through NGOs and women's cooperatives.

Education and Child Rights

The provision of education in both cities lacks standardization. While some areas offer on-site preschool and primary education, others rely on nearby public facilities. These differences are influenced by the settlement's location and development timeline. Similarly, educational support by NGOs is uneven; older settlements host multiple active organizations, whereas newer ones often lack any support mechanisms. In Malatya, public services provide relatively more comprehensive access to education, unlike in Adiyaman where such access is limited.

Social Fragmentation and Discrimination

Temporary settlements in Malatya and Adiyaman demonstrate distinct manifestations of social fragmentation and discrimination. In Malatya, dispersed settlements within the urban fabric foster greater interaction with the host community, which may support integration but also expose residents to exclusionary practices. In Adiyaman, large, homogeneous settlements located on the urban periphery contribute to spatial segregation and feelings of exclusion. The assignment of marginalized groups, such as the Dom community, to separate areas exemplifies institutionalized spatial discrimination.

Social Capital and Societal Change

In both cities, social capital plays a dual role in fostering resilience and reinforcing limitations. In Malatya, the proximity of settlements to pre-disaster neighborhoods has supported the preservation of social networks. In Adiyaman, earlier-established settlements maintain stronger neighborhood ties, while newer ones show weaker social cohesion. Group homogeneity within settlements enhances internal solidarity but restricts intergroup interaction. While women support one another in caregiving, daily tasks, and information exchange, socio-spatial disconnection threatens the sustainability of these networks. Additionally, newly emergent norms—such as refraining from going out at night or interacting with strangers—reproduce traditional gender roles.

Participation, Institutional Capacity, and NGOs

In both cities, participation in the management of temporary settlements is minimal. Decision-making processes are largely centralized, and women's involvement tends to be symbolic. While some NGOs in Malatya operate in a more systematic and institutionalized manner, those in Adiyaman function on a project-based and often fragmented basis. The weak coordination between local authorities and civil society actors negatively affects the continuity and inclusivity of services.

Rights, Access, and Perceptions of Justice

Women in both Malatya and Adiyaman expressed similar dissatisfaction regarding access to basic rights and perceptions of justice. Inequities in public service provision and spatial organization are key contributors to this sentiment. In Malatya, differences in service quality among container settlements were frequently mentioned.

In Adiyaman, the allocation of certain groups to better-equipped areas reinforced the perception of unequal resource distribution. Limited access to legal aid, psychosocial support, and healthcare has led many women to feel excluded from the system, significantly hindering both individual and collective empowerment.

Conclusion

This study aimed to examine the applicability of the Gender Sensitive Settlement Model (GRSM) in the context of post-disaster reconstruction in southeastern Türkiye, as well as its localization requirements. Preliminary findings based on fieldwork conducted in Malatya and Adıyaman provinces confirmed that GRSM offers an inclusive framework based on gender responsiveness but revealed that this model needs to be reinterpreted in a way that is sensitive to local contexts.

Common problems, including security concerns, limited access to care services, lack of participation in decision-making processes, and the neglect of women's or care workers' needs in spatial planning processes, were observed in both cities. This supports the importance and applicability of the basic principles of GRSM. However, at the same time, local differences, such as the spatially dispersed structure of services in Malatya and the stronger informal community networks observed in Adıyaman, indicate that the model cannot be applied uniformly in every context and needs to be adapted according to local socio-spatial dynamics.

Since the research is not yet complete and a fully localized version of GRSM has not been presented, a final model is not proposed in this study. However, the findings in Malatya and Adıyaman provide strong indications of how the model may evolve in the future. In this context, the need to develop participatory, flexible, and process-sensitive adaptation mechanisms, rather than fixed and centralized models, is emphasized for the planning of post-disaster settlements.

In conclusion, this study once again demonstrates the critical importance of integrating gender sensitivity and principles sensitive to social vulnerabilities in the design and governance of post-disaster settlements. Planning frameworks, such as GRSM, should be considered as non-static tools shaped by local realities, power relations, and daily life practices.

The Role of Spatial Alienation in the Journey of Existence as an Actor in Contested Urban Areas: The Case of Kasımpaşa, Istanbul

Abstract
Although alienation represents the arche of Marxist theory, it has also key role in the field of urbanism. In parallel with people's labour, their own life and alienation of human to human, the aggressive policies of production-oriented relationships in cities trigger the alienation of people from the city. This research investigates the levels and types of alienation produced by neoliberal urban policies in Kasımpaşa, one of the most chaotic neighbourhoods of Istanbul. A questionnaire survey was conducted with employees of Istanbul Metropolitan Municipality's located in Kasımpaşa, a group chosen due to their institutional responsibility in urban policies. The findings reveal the levels and processes of alienation experienced by this group within the context of Kasımpaşa while also analysing the urban interventions contributing to spatial alienation.

Keywords: Alienation, Gentrification, Being Actor, Borders, Neoliberal Urbanisation

1. Introduction

Alienation comes to the forefront as one of the main issues discussed in philosophy, sociology, psychology, political science and perhaps most importantly in urbanism. It is inevitable that this concept should be defined by various disciplines, and that this concept should be the product of an interdisciplinary discussion, as there can be a physical alienation with the built environment as well as socio-cultural layers of alienation (Sahan, 2021). What separates people from the environment they live in is the loss of their sense of belonging to that environment; The disappearance of memories of that environment with physical, social and cultural impositions creates a great story of disconnection from space. One of the crucial reasons for this break is that capital's own interests are produced through urban space, and moreover, space becomes a part of the production process. In that case, it is important to analyse the policies of capital on space and to discuss the views of Marxist and post-Marxist theory on alienation in order to understand the processes of breaking up from urban space.

Although the definition of Marx's concept of alienation as alienation from one's own labour continued for many years, it began to take a different form with Lefebvre. The French school and Lefebvre tried to create a synthesis of the concept of city and alienation, which Marxist literature ignored for a long time. Lefebvre (1991) speaks alienation was defined as the separation of human from life blessed with primitive fragility, joy and wisdom: "The human, stripped bare and projected outside of itself, was and remains at the mercy of forces which in fact come from the human and are nothing but human—but torn apart and dehumanized" (Lefebvre 1991, p.276). And it points to the relations of production as the basis of this alienation. Monetary policies have formed the basis of class and social divisions and these policies have revealed a deep alienation. Such a transformation stemming from the internal dynamics of the relations of production denied the existence of the urban dweller as an actor on the street (Lefebvre 2003), redefined it as a commodity and transformed it into individuals who only pass by, do not wait, and do not have a deep relationship with the space.

With the destructive interventions created by neoliberal economic policies on urban space, the increase in crime rates, irregular urbanisation, increase in urban violence and, in parallel, the increase in the control of neoliberalism in the city triggers urban rupture and alienation (Geis&Ross 1998). Alienation is the product of a set of neoliberal policies and gentrification efforts in the areas of cities that are subject to conflicts, causing the deep

relationship between the city and the urbanite to be damaged. In developing or unconsciously developed cities like Istanbul, where alienation is felt at such an aggressive level, the attitude of the local government is at the centre of the problem in the parameters that cause alienation. Therefore, it is necessary to emphasize the importance of local governments and, moreover, the planning departments in local governments in understanding the trends and policies underlying the problems that cause alienation and in solving the problems that arise. Thus, understanding the alienation process of Kasımpaşa from the perspective of the employees of the Istanbul Metropolitan Municipality, which has an aggressive construction area in the region, constitutes the key point of this study. The process and degree of alienation of local administrators provides deep and meaningful conclusions about the spatial alienation of residents. Therefore, this study aims to understand the level of alienation of municipal employees from the environment they live in and the types of alienation they are exposed to and seeks answers to the following questions: To what extent do the commodification processes of neoliberalism affect the physical, cultural and social alienation between urban dwellers and space? Which type of alienation has a deeper relationship with wrong urban policies and chaotic urban space? To what extent does alienation affect the ontological existence of the individual in urban space?

2. Anatomy of Alienation

Marx(1844/2016) says that alienation has many layers, and the first stage of it begins with economic alienation due to the inability to access what one's own labour produces. The object produced by labour appears to man as a foreign substance that does not belong to her/him. In the end, the worker relates to the product of her/his own labour as if she/he was communicating with a foreign object. Therefore, the more labour the worker exerts, the more alien her/his attitude towards the product she/he produces. In addition to the alienation of the worker from the object produced by her/his labour power, Marx also speaks of the alienation of the process of production, that is, the process of activity. The production process is a process in which the workers are active, in which their body, mind, abilities work. The workers' alienation from this process of activity ultimately leads to their alienation from own self. According to Marx (1844/2016), human beings, as a species, turn the activity of their lives into an object of their own consciousness. The human being's life is a conscious activity, and this is the most significant feature that distinguishes it from other animals. The human beings are a conscious being and therefore their life is also their purpose. However, with alienation, man's own life activity ceases to be a goal and becomes a means of her/his essence. The detachment of human beings from their species-being and purpose of life leads to their alienation from others—ultimately, from fellow human beings (Marx 1844/2016). Healy explains the process as follows: "When we are denied control and use over the product of our labour, when it becomes alienated from us, appearing to have power over us, we are in effect alienated from our own species-being; alienated from our own humanity and from the world we inhabit (Healy 2020, p.15)."

In Marxist theory, the process of alienation (Marx 1844/2016) is fundamentally rooted in the worker's labour power (Figure 1). Labour power constitutes the foundation of capitalist production and serves as the primary determinant of the production process. Within this system, the worker is compelled to sell her/his labour to the capitalist in exchange for a wage. The capitalist class, holding private ownership of the means of production, maintains control over the productive assets necessary for labour. Although the worker engages with and activates these means through her/his labour, she/he remains perpetually excluded from ownership, regardless of the intensity of her/his work — a dynamic that generates surplus value (Marx 1867/1990). Consequently, the worker becomes alienated from the product of his labour, as her/his wages are insufficient to purchase the very commodities she/he produces. While the products circulate globally as part of international trade, they largely remain inaccessible to the worker, symbolising his profound alienation from the outcomes of her/his own productive activity. As a result of alienated labour man actually alienates her/his essence. Creativity is inherent in man, and man is essentially a practical being. With the alienation of these creative activities from himself/herself, man loses self-worth. The human being who maintains the purely individual existence of the generic self-worth by working continuously and continuously ceases to be a human. Man's alienation from own essence leads to a direct result: man's alienation from other people (Figure 1). Every relationship that a person establishes with herself/himself finds expression in her/his relationship with other people. In that case, the person who is alienated from herself/

himself becomes alienated from other people and the person who is social by nature turns into an asocial being (Petrović, 1963).

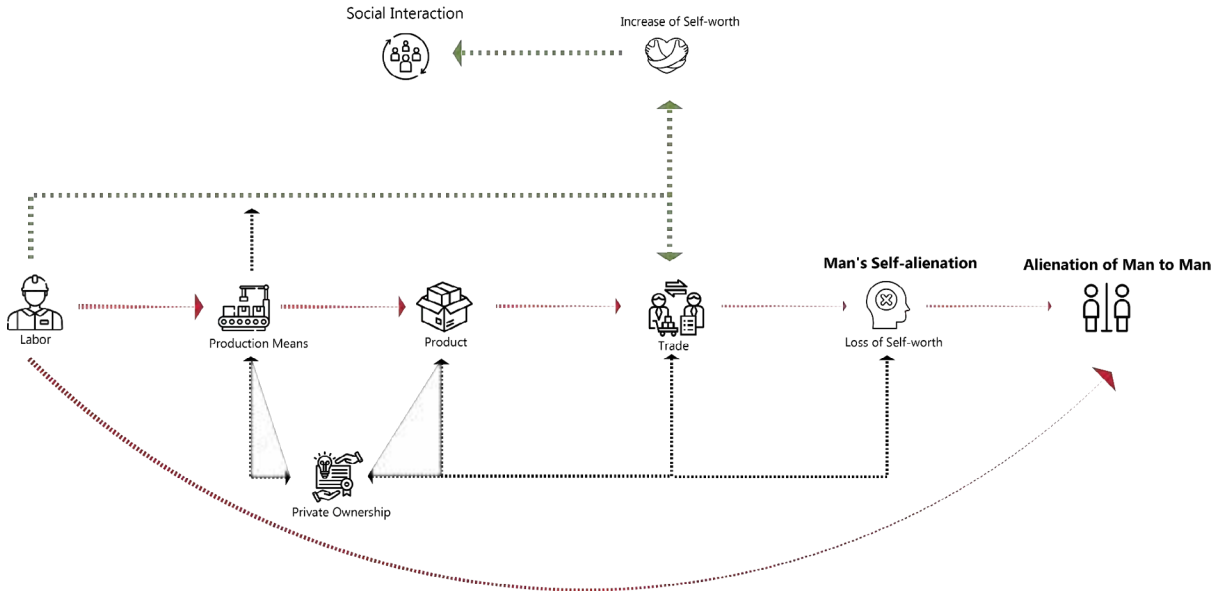

Figure 1: Alienation Process in Marxist Theory (Marx, 1844/2007; Petrović, 1963).

Marx's concept of alienation can be defined as a social and economic process that starts with the alienation of objects as a product of labour, alienates from one's own essence, and ultimately results in alienation from human to human. The main subject of this research is to analyse the alienation of social and physical space to human and human to social and physical space. In this context, analysing an intellectual synthesis of the concept of urban alienation and Marx's concept of alienation will form the basic theoretical framework of this study. Based on Marx's theory of alienation of labour, we first see the integration of space into alienation. Starting from the alienation of objects as products of labour, Lefebvre extends the concept of alienation to the dimension created by capitalism in the production of space and social relations. That is to say, capitalism has transformed cities into centres of production; moreover, it has commodified space itself, eliminating the classifications based on the historical, social, cultural, and natural values that space holds, and replacing them with classifications based on use value. Just as the private ownership of the means of production leaves the labour with the product it produces, the private ownership of the urban land alienates the city dweller from the city both subjectively and objectively (Diaz-Parra and Jover 2021). Right to the city (Lefebvre 1971), one of the most important concepts written by Lefebvre, claims that spatial alienation must be eliminated in order to people for claiming their environment. Ownership also includes the residents taking an active role in the construction of the city. Residents create the city, transform it on a conscious level, transfer their own culture and lifestyle to the city and subsequently shape their own personalities (Lefebvre 1971).

Although the policy of the citizen to build the city directly was common for the pre-capitalist cities, which transformed into places where capital only produced as a commodity tool and moreover, the centre of production. Capitalist institutions, private property, and the expansion of the land market have obliterated the pre-capitalist form of the city. The commodified product (including the space itself) replaces urban structures, the living space replaces the settlement, and alienation is imposed. Thus, while the inhabitants of the city are alienated from the city they have produced and transformed, they are actually expelled from the centres of the city. As city centres

are centres of production, only the working population begins to concentrate in the centre of the city. The commodification, displacement and gentrification processes of historic city centres are at the root of modern urban alienation. For instance, Lefebvre defines the profound interventions and changes that Haussmann created in Paris as the product of these alienation processes. Haussman's intervention is clearly a series of projects that undermine the organizing power of the proletariat, displacing them and further alienating them from the environment in which they live. For this reason, Lefebvre refers to the re-enactment of workers in urban centres as an important part of the right to the city. (Diaz-Parra and Jover 2021).

While capitalism commodifies the city itself and subject it to a deep and concrete change, it tries to abstract all its policies in order to prevent the perception of these concrete changes. Lefebvre expresses this fact that capitalism has tended to transform the space into an abstract space by removing the diversity, vitality and life-recognizing structure of the space, placing it in an abstract context. Capitalism is in an effort to separate space from the real thing and isolate it in order to cover up the urban reality, the struggle for life in the urban slums, the class war and its contradictions. The space of capitalism is an abstract space. As for capitalism, the exchange value is important, not the concrete use of space. For this reason, neither the historical production and use of space nor the social values it represents have a value in itself for capitalism. They are only important to the extent that they contribute to the exchange value of the space in question. What makes one of the two different historical places more valuable than the other - for the capitalists - is the high trade-off value (Lefebvre 2003). Due to the that fact, capitalism wants to commodify the vitality of the space, the life that continues in the space, and the common values, and to ensure that the masses are alienated from these values. With modernist urbanism urban space has become commodified, and standardization has become the basic principle instead of diversity that constitutes the spirit of that space. Lefebvre's criticisms of Le Corbusier's street imagination as the pioneer of modernism are actually based on this basis. According to Lefebvre, street is not only a place where people pass by and move without stopping. The street is the place where people meet, socially exist and interact with each other, connecting places such as cafes, theatres, reading clubs, and moreover providing a continuous relationship amongst these places. The street is a spontaneous theatre, and sometimes a person who was just a spectator suddenly becomes an actor, occupies the street, and turns the street into a battle for her/his unheard voice to be heard. For this reason, the street is a place where people, who tend to be one as a species, are together and establish meaningful relationships with the other (Lefebvre 2003, p.22).

The lack of control over the production process itself exposes the individual to alienation and ultimately leads to alienation from the workplace/street where the individual spends the majority of her/his daily time. The individual's inability to control or predict the consequences of her/his own behaviour ultimately undermines her/his relationship with space. While the behaviours of the individual find themselves in the relationship with the other, the inhibition of these behavioural patterns by alienation detaches them from social life itself. The fact that the rules of the society and social environment she/he lives in are based on the morality of commodities disrupts the semantic integrity of the individual's relationship with others and space. Moreover, when the social norms determined by the world of commodities clash with the individual's value judgments, a social isolation may result. The class culture of the bourgeoisie, such as consumer culture, individualization, globalization, gentrification, elitism, and more importantly, the individual's rebellion against these cultural norms, which are necessary for the uninterrupted continuation of the capitalist production system, also pushes her/him into alienation. In the end, the individual is not only alienated from the society and social environment, but also from the space itself where all these processes take place and continue.

As a catalyst of urban alienation, rapid, unconscious and aggressive urbanisation policies, vandalism, drug use, lack of safety regarding criminal issues have profound effects on the individual's relationship with space. In contemporary urban landscapes shaped by neoliberal capitalism, aggressive urbanisation policies not only exacerbate economic inequalities but also produce conditions of social abandonment, where marginalised groups are increasingly pushed towards acts of vandalism, drug dependency, and violent resistance against the alienating environment (Madden and Marcuse 2016; Rolnik 2019; Watt 2021).Vandalism contributes to the deterioration of shared urban spaces, eroding residents' emotional attachments to their environment and fostering a sense of alienation

(Taylor 2011). Similarly, the prevalence of drug use in urban areas accelerates social fragmentation and generates an atmosphere of distrust, undermining individuals' sense of belonging within the city (Sampson 2012). An increase in criminal activities further compromises residents' feelings of safety, leading to a withdrawal from public spaces and intensifying experiences of urban alienation (Jacobs 1961). Collectively, these dynamics expedite the process of detachment from urban life and weaken the identity bonds individuals form with their cities (Wacquant 2008).

Wirth (1938) argues that increasing urbanisation weakens the connection with place and this triggers spatial alienation. One of the most important reasons triggering urban alienation is the destruction of local ties and neighbourhood relations as a result of complex urban living. Aggressive urbanisation, moreover, the transformation of space into a commodity that is produced and consumed, pushes the limits of control over the environment in which the urban dweller lives. The urban dweller's loss of control over the environment leads to a loss of a sense of belonging and as a result, social isolation emerges (Massey 1996; Geis and Ross 1998). According to Simmel, the chaotic sights and sounds of the city, crowds and noise are the main factors in the deterioration of social control (Simmel 1969). Increasing negative stimuli in cities create an uncontrollable perception of physical environment on citizens. As a result, people living in the city learn that they cannot control the social and physical environment in which they live. This whole experience results in helplessness, that is, the loss of their sense of belonging. Massey argues that spatial alienation is mostly a result of economic relations. He concludes that poverty, especially concentrated at the scale of neighbourhoods, is effective in the deterioration of public order, which in turn triggers the process of alienation. Contrary to many other urban sociologists, he states that this alienation starts at the neighbourhood scale, not at the city level, and that the physical and social environment has a direct impact on people. He claims that the demographic structure of the people living in the neighbourhood; ethnicity, gender, income status shape social life and have a profound impact on alienation (Massey 1996). In line with Massey's view, the necessity of a neighbourhood-scale analysis to understand urban alienation is among the conclusions reached through the literature research. In this context, Kasımpaşa, as one of the most controversial neighbourhoods of Istanbul, has been the focus of this study.

6. The Study Area: Kasımpaşa Neighbourhood

The historic neighbourhood of Kasımpaşa is located in Istanbul's Beyoğlu district. It was an important hub for naval operations throughout the Ottoman era, especially in the 18th and 19th centuries. The neighbourhood had a commercial and military organization throughout this time. The population of Kasımpaşa increased significantly throughout the Industrial Revolution, making it one of Istanbul's most significant residential areas (Çelik 2019). As the economic structure changed in the 20th century, problems including poverty and rapid urbanisation started to appear.

Kasımpaşa has had a swift urban transformation and gentrification trend in recent years. Although the historic fabric of the neighbourhood is at risk, this process has also attracted significant investments and the development of high-end homes and offices (Taşan 2020). Real estate prices have significantly increased due to its close proximity to Galata and Beyoğlu which have high land values. The original residents of the neighbourhood, especially those from lower-income groups, have been displaced as a result of the significant socioeconomic divide brought about by urban transformation (Karaman 2017).

Throughout this process, civil society organizations (CSOs) like Beyoğlu Kent Savunması (Beyoğlu City Defense) and İstanbul Kent Savunması (Istanbul City Defense) have vigorously campaigned against the detrimental impacts of urban transformation while promoting the rights of the locals. These organizations have called for a more equitable transition process and have opposed displacement and the loss of cultural identity (Yılmaz and Kaya 2018). The Union of Chambers of Turkish Engineers and Architects, or TMMOB, has contributed knowledge and oversight to Kasımpaşa's urban transformation initiatives, guaranteeing that urbanisation is executed in a safe and healthy way.

Considering the current situation of Kasımpaşa, the relationship of these new projects with the urban identity and context should be expressed. Istanbul Metropolitan Municipality Kasımpaşa Additional Service Building is

one of the urban interventions in Kasımpaşa (Figure 2). Among the notable uses in the area are Istanbul Bilgi University and Arter Art Gallery, representing the significant educational and socio-cultural interventions in Kasımpaşa. In addition, the first phase of the Piyalepaşa Mass Housing projects created a deep physical boundary between the neighbourhood and the other part of the city. The urban policies of the neoliberal economy try to isolate the city of space by breaking the city out of its real and concrete context, evaluating it as a commodity according to its use value and breaking the solid bond with the city dweller. In this respect, the real relationship between the concrete space and the human being is taken out of its context and it eliminates the possibility of the urban dweller to live as a social being in the space, to be an actor. The removal of many ethnic groups like Romani citizens from their homes for the second phase of the Piyalepaşa Mass Housing project is also the product of such policies. At the same time, the construction of new hotels and office buildings that are disconnected from the identity of the city are similar activities of these policies. The main reason why Kasımpaşa was chosen as the study area was that the ruptures, social isolation, cultural clusters, differences and various urban functions frequently mentioned in the literature were experienced. Although the gradual decrease in the presence of open and wide green areas as a product of aggressive urbanisation is seen in Kasımpaşa, it is still possible to talk about the existence of some large parks. Sururi Park and Hacı Ahmet Cinderesi Park are the two largest neighbourhood parks of Kasımpaşa. (Figure2).

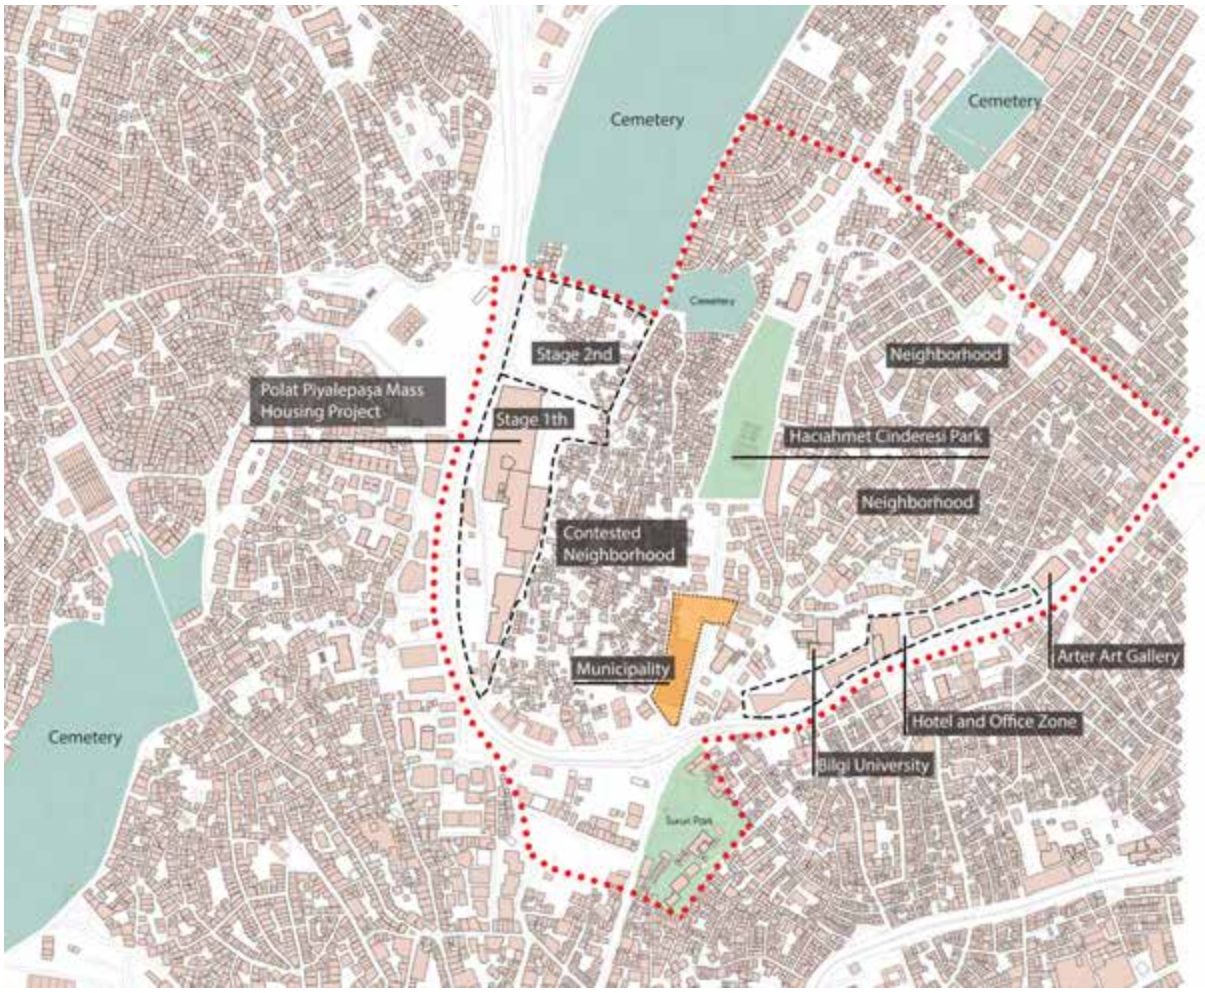

Figure 2: Existing Functional Urban Areas in Kasımpaşa

The first photo seen in Figure 3 and 4 depict the modern exterior façade of the municipal building. The photo on the right, taken from the roof of the municipal building, reveals the chaotic structure of the neighbourhood. On one hand, neglected wooden and concrete buildings stand out, while on the other, high-rise apartment blocks illustrate the picture of unplanned urbanization.

Figure 3: Municipality Building and overhead view of the neighbourhood

Figure 4: An overhead view of the neighbourhood

The photos in Figure 5 illustrate a typical scene of gentrification. The newly completed housing area has been constructed with a façade style that reflects a highly parametric design approach, creating an evident contrast with the surrounding buildings. While it would be inaccurate to describe the existing building stock as structurally sound, it can still be stated that the new developments are incompatible with the existing architectural identity (Figure 5). The photos in Figure 6 reveal the gentrification process at a deeper level. Along Kurtuluş Deresi Street, one side features wealthy, well-maintained, and ornate hotel and office façades, while directly across from them stand small workshops and old buildings with neglected façades—exposing a striking paradox (Figure 6). Figure 7, once again, presents a striking image of Kasımpaşa, featuring small auto repair workshops and commercial units set against a backdrop that is both historical and chaotic (Figure 7).

Figure 5: An overhead view of the neighborhood

Figure 6: On one side, gentrification; on the other, the old urban texture

Figure 7: An image reflecting the chaotic urbanization of Kasımpaşa

"The Arter Art Gallery continues to exist in Kasımpaşa as part of the gentrification process. A pool, constructed as a decorative element at the gallery's entrance, acts as a physical and symbolic barrier between the gallery and the city (Figure 8). On one side of the pool lies art; on the other, Kasımpaşa in all its raw reality. Photographs taken from within the gallery reveal the historic and chaotic urban fabric of the neighbourhood just behind it—historic façades, bay windows, and wooden and brick buildings. Another striking photograph depicts Kasımpaşa as a grim reality behind an abstract work of art (Figure 9).

Figure 8: A photo from in front of Arter Art Gallery

Figure 9: A view of the city from the inside of Arter Art Gallery

6.1. Methodology

The aim of this study is to understand the process of alienation in Kasımpaşa from the perspective of the residents living in the area. One of the dominant subjects of the region is undoubtedly the employees of Istanbul Metropolitan Municipality (IMM). The social and spatial relationships, sense of belonging, and alienation processes of IMM employees with their surroundings were analysed using a questionnaire survey. Due to the ongoing security problems in the neighbourhood, the existence of introverted groups, and the security problems experienced at the entrances and exits to the all part of the neighbourhood, this study could not address the other dwellers of the neighbourhood as a sample group. However, municipality employees are a useful sample group in many contexts to measure alienation. This group both experiences the urban space due to their long working hours

and carries out direct works on public spaces. In this context, municipality employees are considered to have opportunities in terms of measuring alienation. The concepts that emerged as a result of the literature review have been a guide in the preparation of the survey questions. In the table below, we can see the relationship between the concepts that are part, cause, and result of the alienation process and the survey questions (Figure 10).

The literature states that security, vandalism, aggressive urbanisation, gentrification, loss of physical and social control established with the urban environment due to various reasons are the indicators that trigger alienation. As a result of alienation, urban dwellers turn into individuals who cannot socialize in their environment and others with poor communication and put them in social isolation. In that case, the questions trying to understand the relationship between the citizen and the environment he lived in and being an actor were also the subject of the survey. The survey results were subjected to Principal Component Analysis, and mean values (see appendix for the descriptive statistics) were presented to illustrate the overall evaluation of the relevant components grouped under each extracted factor across the sample.

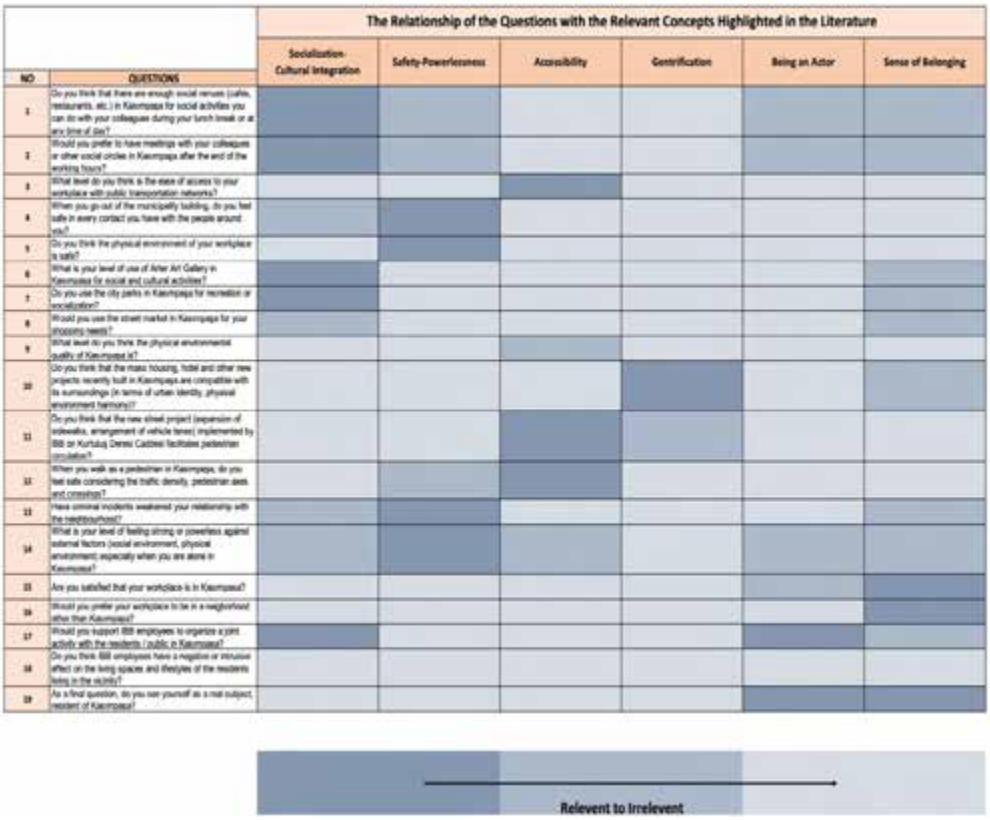

Figure 10: Relation level of the survey questions to some parameters triggered the alienation.

6.1. Interpretation of Results

The level of participation in the survey consists of 156 people. The first four questions aim to obtain information about the demographic structure of the participants. It is seen that the majority of the participants are female (Figure 11), but there is not a deep difference between the proportion of female and male participants. The majority of the participants have at least a bachelor's degree, although there are a few participants with primary and high school education (Figure 11). Although there are participants from almost every age group, the results show that the most intense age group is 31-40 (Figure 11). When we look at the occupational distribution of the participants, we encounter a very cosmopolitan view. Although it is seen that the participants belonging to professions such as Architecture, Landscape Architecture and Urban and Regional Planning, which are prominent in the field of urbanism, are dense, there are also participants from Civil Engineering and other engineering branches and professions with a wide variety of perspectives such as art historian, archaeologist, film director, restorer, cinema writer (Figure 12).

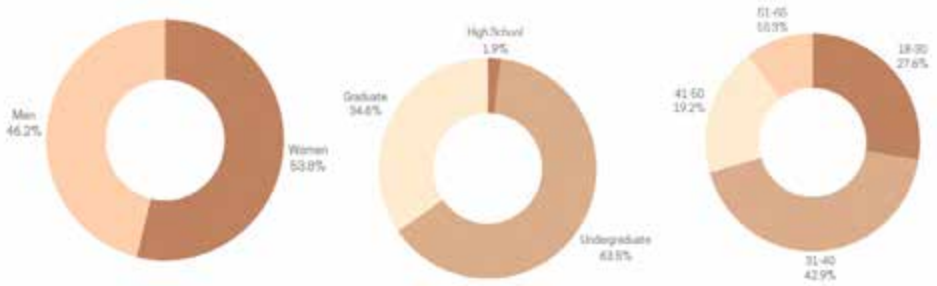

Figure 11: Gender, Education Level and Age Group of Participants

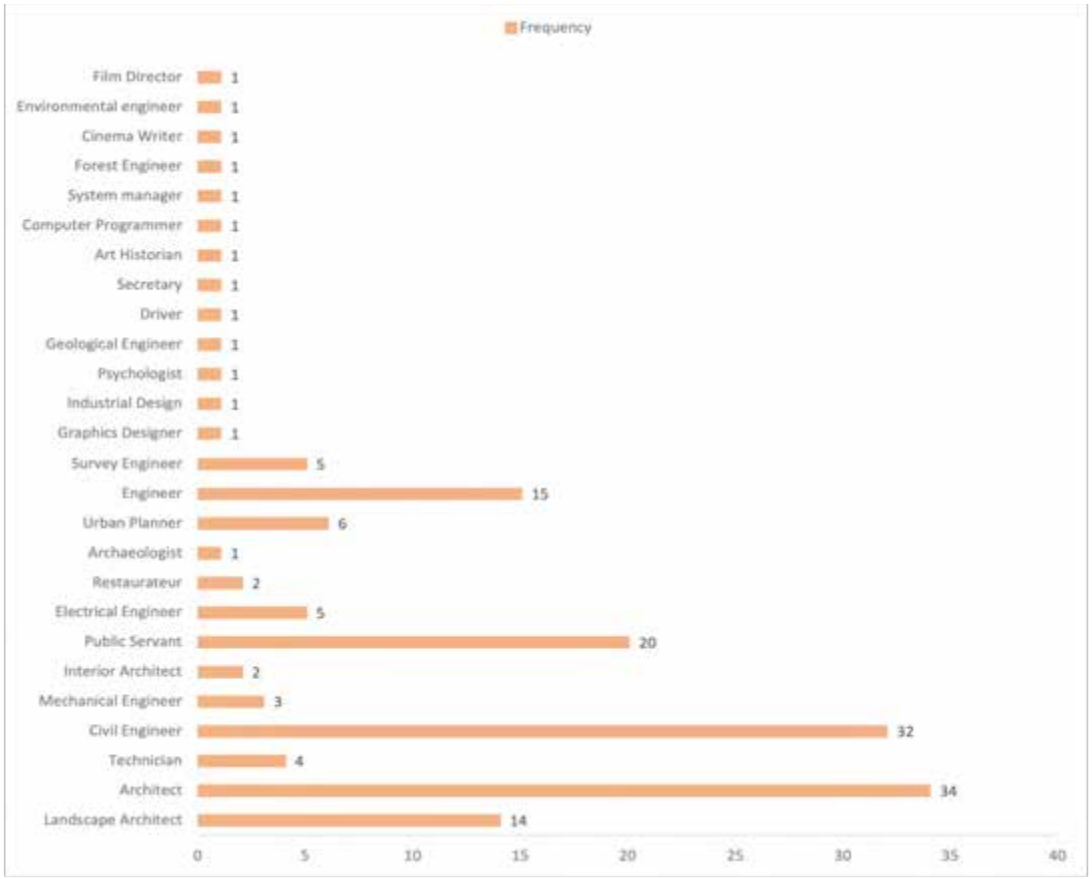

Figure 12: Occupations of Participants

The survey questions were evaluated in two separate sets, and two distinct Principal Component Analyses (PCA) were conducted. The first set of questions aimed to measure respondents' evaluations based on their perceptual evaluations and experiences within the neighbourhood. These questions addressed aspects such as integration into neighbourhood life through use social and cultural facilities, feelings of safety and powerlessness, evaluations of accessibility, and the effects of gentrification processes. The PCA, applied to 14 questions from the first set, revealed five factors that together explain 64,92% of the total variance. These factors reflect urban alienation, related to the use of social and cultural facilities, socialization, sense of safety, environmental quality, accessibility, compatibility of newly developed projects with the urban identity, gentrification, and spatial integration.

Accordingly, the following factors were identified to assess the levels of spatial alienation (Table 1). The first factor is titled "**Inclusion Through the Use of Social Facilities and Infrastructure & Physical Environmental Quality Assessment**" and explains the largest proportion of the variance. This factor consists of includes questions measuring respondents' frequency and tendency to use recreational and social opportunities and shopping facilities in Kasımpaşa after work and during leisure time, as well as their evaluations of physical environment quality and accessibility in the neighbourhood. The average value measuring whether users consider the socialization spaces in the area, such as cafes and restaurants, to be sufficient was recorded as 2.36. When asked whether they use these spaces for socialization outside of work, the average usage level was quite low at 1.75. Similarly, despite the presence of two large parks and green spaces near the municipal building, the results indicate that these parks are rarely used (mean value: 1.69), even though they could be ideal recreational spaces during lunch breaks. There are two large parks close to the town hall. Although one of these parks, Hacıahmet Cinderesi Park, is closer to the municipality and more accessible, when the participants who said that they use the parks were asked which park they use more frequently, Sururi Park, which is less accessible, was predominantly answered as Sururi Park. In parallel, street markets, which are among the most common and fundamental urban functions in Turkey, are set up twice a week in Kasımpaşa. While these markets are considered an essential part of everyday urban life, the responses regarding their usage frequency, although relatively more positive, do not indicate a wholly favourable outcome. In this regard, it can be concluded that the frequency of use of street markets in Kasımpaşa is relatively low. The responses to questions about the accessibility of the municipal building and the overall environmental quality of Kasımpaşa were recorded at 2.35 and 1.71, respectively.

Another factor with a high contribution to the total explained variance has been titled **"Perceived Safety and Powerlessness"** This factor includes questions that assess respondents' feelings of safety both in the immediate vicinity of their workplace and in the broader Kasımpaşa area, as well as the perceived impact of this sense of safety on their relationship with the neighbourhood. The responses to whether municipal employees feel safe in their daily interactions with people in the surrounding area had a low average value of 1.99. Similarly, responses to the direct question of whether Kasımpaşa is perceived as a safe environment yielded a low average score of 1.94. Responses to whether users feel empowered or powerless in relation to environmental factors were relatively more positive, with an average value of 2.62.

The third factor, which has a moderate level of explanatory power, is titled **"Assessments for Pedestrian Experience"** It is composed of two questions: one that evaluates perceived safety during pedestrian movement, and another question that assesses the impact of recent street upgrading projects on pedestrian accessibility. When asked about the effects of the pavement and road lane improvement project on pedestrian accessibility along Kurtuluş Creek Street, one of the main axes of the region, the response of the participants was very positive. However, despite this, responses regarding whether they feel safe as pedestrians when walking or using crosswalks were relatively negative, with an average score of 2.23.

The fourth factor, titled "**Assessment of Spatial Integrity and Inclusiveness of New Urban Interventions**" is based on a single question. It measures respondents' evaluations of whether recently implemented projects in Kasımpaşa — such as mass housing, hotels, and other developments — are compatible with the surrounding area's physical and social characteristics and overall urban identity. When asked about the integration of new urban projects (such as hotels and office buildings that can be considered as part of the gentrification process) with the existing urban identity and built environment, the average of the answers given by the users remained at a low level with 1.94. The fifth factor, titled "**Inclusion Through Use of Cultural Facility**" also consists of a single item and refers to the use of the Arter Art Gallery, which is a prominent cultural and architectural component of the study area. The respondents' level of engagement with this facility represents a distinct dimension of social inclusion (Table 1). The average of the answers given to the question about the frequency of visits to the Arter Art Gallery is below average with 2.25.

Table 1. Principal component analysis results for alienation related to concepts of socialization cultural integration, accessibility, safety powerlessness, gentrification

		1	2	3	4	5
Factor 1: Inclusion Through the Use of Social Facilities and Infrastructure & Physical Environmental Quality Assessment	*Would you prefer to have meetings with your colleagues or other social circles in Kasımpaşa after the end of the working hours?*	0,648				
	What level do you think is the ease of access to your workplace with public transportation networks?	0,63				
	Do you use the city parks in Kasımpaşa for recreation or socialization?	0,71				
	Would you use the street market in Kasımpaşa for your shopping needs?	0,58				
	Do you think that there are enough social venues (cafes, restaurants, etc.) in Kasımpaşa for social activities you can do with your colleagues during your lunch break or at any time of day?	0,499				
	What level do you think the physical environmental quality of Kasımpaşa is?	0,643				
Factor 2: Perceived Safety and Powerlessness	*When you go out of the municipality building, do you feel safe in every contact you have with the people around you?*		0,665			
	Do you think the physical environment of your workplace is safe?		0,721			
	Crime incidents have not weakened my relationship with the environment.		0,723			
	What is your level of feeling strong or powerless against external factors (social environment, physical environment) especially when you are alone in Kasımpaşa?		0,797			
Factor 3: Assessments for Pedestrian Experience	*Do you think that the new street project (expansion of sidewalks, arrangement of vehicle lanes) implemented by IBB on Kurtuluş Deresi Caddesi facilitates pedestrian circulation?*			0,833		
	When you walk as a pedestrian in Kasımpaşa, do you feel safe considering the traffic density, pedestrian axes and crossings?			0,747		
Factor 4: Assessment of Spatial Integrity and Inclusiveness of New Urban Interventions	*Do you think that the mass housing, hotel and other new projects recently built in Kasımpaşa are compatible with its surroundings (in terms of urban identity, physical environment harmony)?*				0,841	
Factor 5: Inclusion Through Use of Cultural Facility	*What is your level of use of Arter Art Gallery in Kasımpaşa for social and cultural activities?*					0,887

Kaiser–Meyer–Olkin measure of sampling adequacy: 0,775 and Bartlett's Test of Sphericity sig.: .000
Each variable comprises an evaluation by the respondent made on a Likert scale where 1 is "completely disagree" and 5 is "completely agree"

In the second set of questions, which included five items, a separate PCA identified three distinct factors explaining 77.9% of the variance. These factors relate to respondents' alienation through dimensions such as workplace preference and satisfaction, intention for social integration and sense of belonging, and perceived intrusiveness

in local life (Table 2). The first factor, **"Workplace Preference and Satisfaction from the Workplace Neighbourhood"** explains 33.18% of the variance individually and consists of questions that assess respondents' satisfaction with working in Kasımpaşa (mean value is 2.62) and their willingness to relocate their workplaces elsewhere (mean value is 3.95).

The second factor, titled **"Intention for Social Integration & Feelings of Belonging"** comprises items that evaluate respondents' willingness to take part in a joint activity with local residents as representatives of Istanbul Metropolitan Municipality (IMM), and the extent to which they perceive themselves as genuine members or residents of Kasımpaşa. Both items capture aspects of alienation in terms of belonging and the perception of oneself as a social actor within the neighbourhood. When the participants were asked about their willingness to participate in a joint activity with the neighbourhood, the average value of the answers given is 2.64, which is a relatively low tendency. The answer to the question about whether the municipality employees consider themselves as a real subject of Kasımpaşa expresses one of the lowest levels with an average value of 1.63.

The final factor, **"Perceived Intrusiveness in Local Life"** includes the question: "Do you think IMM employees have a negative or intrusive effect on the living spaces and lifestyles of the residents living in the vicinity?" This question measures perceived social distance and the potentially disruptive role of institutional actors in everyday neighbourhood life (Table 2). The average value of the answers to the question is 2.25, which is quite neutral.

Table 2: Principal component analysis results for alienation related to concepts of sense of belonging and perception of oneself as an actor

		1	2	3
Factor 1: Workplace Preference and satisfaction from the workplace neighbourhood	*Are you satisfied that your workplace is in Kasımpasa?*	*0,846*		
	Would you prefer your workplace to be in a neigborhood other than Kasımpaşa?	*-0,894*		
Factor 2: Intention for social integration & feelings of belonging	*Would you support IBB employees to organize a joint activity with the residents / public in Kasımpaşa?*		*0,913*	
	As a final question, do you see yourself as a real subject, resident of Kasımpaşa?		*0,577*	
Factor 3: Perceived Intrusiveness in Local Life	*Do you think IBB employees have a negative or intrusive effect on the living spaces and lifestyles of the residents living in the vicinity?*			*0,979*

Kaiser–Meyer–Olkin measure of sampling adequacy: 0,537 and Bartlett's Test of Sphericity sig.: .000
Each variable comprises an evaluation by the respondent made on a Likert scale where 1 is "completely disagree / lowest satisfaction" and 5 is "completely agree / highest satisfaction"

7. Conclusion

Neoliberal urbanisation, where space is considered as a commodity that can be bought and sold, strives to distance space from the concrete realities of society. The concrete reality of everyday life, real problems, emotions, ideas and being a real subject are the most valuable parameters that shape space as human. However, capitalism endeavours to remove the urbanite from real problems and to create masses who can be free only within the confines of their own homes, not on the street. In this respect, spatial alienation can be the product of capitalism's efforts to abstract urban space, as well as its tool.

Kasımpaşa is one of the oldest but also most chaotic neighbourhoods of Istanbul. The scale of the neighbourhood sets an important boundary for understanding and deepening the effects of alienation. This boundary is not only a physical boundary but also a social and emotional one. Kasımpaşa is the living space of various ethnic groups such as Romani people, immigrants, who are the weighty subjects of the neighbourhood. The cosmopolitan character of the neighbourhood has further deepened with the addition of new structures such as the municipal building, art gallery, university campus, large-scale housing complexes, hotel, and commercial facilities.

The cosmopolitan structure of Kasımpaşa acts as a catalyst for spatial alienation in the face of aggressive urban development and transformation. Ultimately, the results of the Principal Component Analysis (PCA) have allowed us to obtain concrete indicators of this alienation. The emergence of five distinct components from the PCA applied to the first set of questions demonstrates that alienation is not a one-dimensional experience; rather, it involves multiple layers such as spatial usage, sense of safety, compatibility of spatial interventions, and cultural integration. This reveals that individuals' relationships with the urban environment—or the lack thereof—should be understood in a multidimensional way.

That the strongest factor relates to the use of recreational, social, and commercial spaces shows how everyday spatial practices shape individuals' feelings of belonging or alienation. If individuals do not engage with these spaces, they may not feel emotionally or socially connected to them, even if they are physically present. This finding aligns with Henri Lefebvre's view that space is produced and experienced through everyday practices. Public space, as a disrupted yet integral part of daily life, becomes a crucial tool in making sense of individuals' existence as social beings in the city. Sometimes a person is an observer; other times, an actor. However, the individual—alienated first from their labour, then themselves, then their ontological existence, and finally from others—also experiences a deep rupture in their relationship with space.

In the case of Kasımpaşa, the predominantly negative responses regarding the frequency, willingness, or motivation to use public spaces indicate a growing spatial alienation. The emergence of "Perceived Safety and Powerlessness" as a distinct and strong dimension highlights how critical the subjective feeling of safety is in fostering a sense of urban belonging. The sense of safety influences how individuals experience the city, how they relate to others, and whether they form emotional connections with their environment. Conversely, the feeling of powerlessness reflects a lack of agency, which is a powerful indicator of alienation—particularly in the context of gentrification or rapid transformation processes.

The factor concerning the compatibility of new spatial interventions—such as mass housing or hotels—with the local urban fabric reflects the tension between development and continuity in the city. That this factor emerges as an independent dimension indicates that participants are highly aware of the spatial identity mismatch and its relation to alienation. Notably, the factor related to the use of a cultural institution like Arter emerges independently, suggesting that cultural participation functions as a bridge that enhances spatial belonging—perhaps even more effectively than physical infrastructure. This provides a meaningful insight into how symbolic spaces (e.g., galleries) affect individuals' feelings of inclusion, visibility, participation, or exclusion.

The second PCA confirms that alienation is not only spatial but also institutional and emotional. The three resulting dimensions—job satisfaction, social integration, and perception of intervention—show that:

- Some individuals may feel alienated despite being satisfied with their jobs;
- Others may feel excluded due to a lack of social or emotional integration;
- A separate group (e.g., municipal employees) may perceive themselves as intervening forces, even if that was not their intention.

Notably, the fact that nearly half the participants acknowledged this intervention as a reality provides significant empirical insight. These findings reflect the multilayered nature of urban space undergoing transformation. Public employees may be physically present in the area, yet their levels of social and symbolic integration vary. Spatial interventions like infrastructure projects or gentrification shape individuals' emotional and perceptual boundaries within the city. Emotions such as safety, participation, and authenticity play a decisive role in whether individuals feel inside or outside the urban system.

To conclusion, this study shows that there is spatial alienation in Kasımpaşa as a result of neoliberal urbanisation. The alienation experienced in Kasımpaşa prevents the physical, social, emotional, artistic and cultural existence of the individual.

Although this study focuses on a significant and well-established sample group — municipal employees — the inability to reach the Romani community, who have been the historical subjects of the neighbourhood for centuries but are now marginalized, due to various safety concerns, constitutes a major limitation of the research. A further, long-term study involving a separate survey with the Romani residents, employees in nearby commercial areas, and staff from art gallery would be necessary for a comparative analysis of the levels of urban alienation among all neighbourhood stakeholders.

Acknowledgment
This study was developed based on the works carried out within the scope of the course 'Reading on Public Space,' led by Associate Professor Dr. Elif Kısar Koramaz as part of the Landscape Architecture PhD program at Istanbul Technical University.

Abstract:
Migration is an urban reality closely tied to multiculturalism, an evolving set of political strategies requiring rethinking immigrants' social and spatial integration. In Portugal, over 9% of the population are foreign nationals, reaching 11% in Lisbon, where inclusion poses unique challenges. Lisbon, with its rich multicultural history, aims to become an inclusive city, ranking first in the European Council's Intercultural Cities Index in 2014 and 2018. Its 2023–2027 strategy emphasizes citizen participation through budgeting and councils, yet spatial integration policies need deeper analysis. While traditional integration focuses on employment, housing, and rights, spatial justice for less-privileged migrants remains under-addressed. This study examines participatory urban projects like Martim Moniz and Almirante Reis to assess who is included in these processes. Findings highlight a design focus and overrepresentation of Portuguese voices, urging reflection on urbanists' role in fostering inclusive spaces.

Keywords: multiculturality; public space; participatory process; migration; spatial integration

1.Introduction: Rethinking Multiculturalism in Urban Contexts

Despite its widespread use, the concept of the multicultural city remains ambiguous. It has been described as a term that encompasses a range of overlapping yet distinct meanings, such as demographic trends, political agendas, institutional frameworks, and ideological commitments (Vertovec, 2010). In most interpretations, the presence of racially, ethnically, and culturally diverse groups is often taken as the defining indicator of multiculturalism in cities (Qadeer, 2014). However, this presence alone does not guarantee inclusion. As Wise and Velayutham (2009) argue, multiculturalism is not just about demographic diversity but about how such diversity is negotiated, recognized, and lived through everyday interactions. When talking about multiculturality, the right to difference must be actively acknowledged and supported through urban life and spatial practices (Sandercock, 2003).

Urban planning has increasingly been shaped by these dynamics. Since the mid-20th century, multiculturalism has influenced both national and local policy agendas (Fleras & Elliott, 2002) and has become central to planning discourses across Western contexts (Sandercock, 1998; Vertovec, 1998; Amin, 2002; Beebeejaun, 2012; Burayidi, 2015; Fincher et al., 2014; Barbarino & Seydel, 2024). In the 21st century, multiculturalism has taken on a more dynamic character, emphasizing intercultural dialogue, the right to the city, and active citizenship within a shared public sphere (Sandercock, 2003). Cities such as Barcelona (with its Intercultural Plan) or Berlin (through inclusive neighborhood planning initiatives) offer examples of ongoing intentional approaches to discuss an intercultural urbanism.

While multicultural planning has evolved from early assimilationist models to more participatory and pluralist approaches (Burayidi, 2015), critiques persist regarding its limitations. Scholars argue that even contemporary planning often fails to accommodate the real diversity of urban life, prioritizing abstract notions of the public good over the specific needs of marginalized groups (Amin, 2013; Sennett, 1992). This can lead to what Ahmed (2000) terms repressive tolerance, a scenario in which difference is celebrated symbolically but controlled or excluded in practice. Moreover, despite calls for inclusive frameworks such as communicative planning, just city theory, and new urbanism (Harper & Stein, 2015), urban policy has at times commodified diversity, using multiculturalism as a marketing tool rather than a means of empowerment (Moghadam, 2024; Torino, 2021). Such instru-

mentalization reduces ethnic and cultural diversity to aesthetic or economic assets, contributing to what some scholars describe as the urban governmentality of multiculturalism, where multicultural rhetoric masks deeper exclusions and inequalities (Moghadam, 2024). In this context, the description of an urban space as "multicultural" can obscure its fragmentations and contradictions, reinforcing its inherently incomplete and contested nature (Sandercock, 2003).

In Portugal, particularly Lisbon, this issue is pressing. Lisbon provides a compelling case for examining how multiculturalism plays out in spatial terms. The city's multicultural character is shaped primarily by recent waves of migration, driven in part by Portugal's aging population and demographic decline. In 2023, the country recorded the highest number of permanent immigrants in a decade, 189,367 people, according to data from the National Statistical Institute of Portugal (INE, 2024). The Lisbon Metropolitan Area absorbed nearly half of this increase, hosting around one-third of Portugal's entire migrant population. With over 9% of the national population and 11% of Lisbon's residents being foreign nationals (with an increasing trend over the past five years), the city is a significant site for exploring inclusion. Although Lisbon has a rich multicultural history and has been recognized for its innovative inclusion practices, such as topping the European Council's Intercultural City Index in 2014 and 2018, it still faces challenges in translating these efforts into spatial realities. The participatory urban policy tool BIP/ZIP[1] that launched in 2011 by Lisbon City council and the policies such as participatory budgeting and local citizen councils are steps forward, yet a deeper analysis is needed to assess their impact on urban space and everyday life.

Migration is a defining feature of contemporary urban life, making multiculturalism an unavoidable political and spatial issue in many cities. However, multiculturalism is not a fixed policy framework; it consists of dynamic, often incomplete strategies that differ by context and evolve over time. For urban planners and designers, this demands a rethinking of how immigrants are socially and spatially integrated into cities and how cities can become shared spaces for diverse populations. As Lisbon's experience shows, the translation of the integration ideals into spatial strategies and inclusive urban design is not always straightforward. Lisbon's migrant communities are far from homogeneous. The term "migrant" spans a spectrum of socio-economic positions, from elite professionals and middle-class expatriates to precarious and marginalized groups. Certain central neighborhoods, which attract more affluent foreigners, project a sanitized image of multiculturalism, while other districts, often inhabited by less-privileged migrant groups, experience increasing exclusionary narrative, surveillance, and social tension.

Therefore, this paper specifically centers on the experiences of less-privileged migrant communities, whose spatial and social integration remains most at risk of being overlooked in mainstream urban policies and multicultural narratives. For instance, in a recent urban regeneration program in the historical Mouraria neighborhood at the city center, the multiculturality of the area is advertised with the slogan "visiting the world without leaving Lisbon" and followed by several urban interventions from public space regenerations to city-scale events. Despite contributing to the area's touristic attractions, these methods neither precisely address nor solve the socio-spatial needs of the foreign populations living there. Today, there are several examples of participatory design activities for public space requalifications. Still, not all the dimensions of spatial justice such as distributive, recognitional and procedural aspects are met. Moreover, as xenophobic policies persist, public spaces predominantly used by migrants have increasingly become the targets of hostile actions and police controls sparking significant public backlash and highlighting the growing urgency of this issue.

2. Policy vs. Practice: Gaps in Spatial Integration

Integration is a central theme in global migration policy, aligned with the 2030 Agenda's goal to "leave no one behind." While definitions vary by context, integration is broadly understood as the process by which migrants become part of society (IOM, 2011). Ager and Strang (2008) outline four key dimensions of integration: access to services (employment, housing, education, health), legal and civic rights, social connections, and barriers such as language or cultural differences. Integration is closely linked to social inclusion (active participation in all aspects

1 https://bipzip.cm-lisboa.pt/

of society) and social cohesion (anti-discrimination and mutual understanding) (IOM, 2017). Portugal has taken notable steps in this area. It was the first UN member to adopt a National Plan for the Global Compact on Migration. Earlier, its 2007 ministerial resolution emphasized integration through improved access to culture, language training, housing, health, and education. Spatially, this has included measures like cultural exchange spaces in libraries, expanded social housing, and public internet access. The 2015 Strategic Plan for Migration aimed to align migration governance with national development and EU priorities, reflecting an evolving approach to a more diverse society.

Portugal performs above the European average on migrant integration indicators, ranking among the top ten in the 2020 MIPEX index. However, gaps remain in labor market access, family reunification, and anti-discrimination efforts (Tsagkroni, 2024; Citron & Gowan, 2004; Niessen et al., 2007). Lopes (2014) views Portugal's integration model ,focused on labor mobility, education, citizenship, and anti-discrimination, as relatively successful, even amid economic strain. Lisbon has played a leading role in integration policy by being the was the first Portuguese city to formally recognize ethnic minority issues, establishing the Municipal Council of Migrant Communities in 1993, which evolved into the Municipal Council for Interculturalism and Citizenship (CMIC) in 2007. Successive National Plans for Immigrant Integration, starting in 2007 and extending through 2022, have guided municipal actions. These efforts are shaped by both national agendas and international expectations and are supported by Lisbon's institutional infrastructure (Juzwiak, 2014).

Despite a generally positive policy climate, recent shifts raise concerns. In June 2024, the government introduced a new immigration law aimed at curbing "excessive abuse" and signaling a "new beginning," as stated by Prime Minister Luís Montenegro. Against this backdrop, the integration policy document analysis show how integration is framed in policy documents and strategies especially in relation to urban space. Traditional integration policies, focusing on employment, housing, health, education, and citizenship, form the backbone of national and municipal strategies. Lisbon has adopted a range of these measures, employing both policy tools and digital technologies to ease bureaucratic integration. However, when it comes to spatial integration, particularly for marginalized or underprivileged migrant groups, the picture becomes less clear. Public spaces play a key role in daily social interaction and identity formation, but many integration efforts fail to fully address the social and spatial justice principles necessary for inclusive urban everyday life and space.

Integration, understood as the strengthening of social ties and institutions (Heckmann, 2004), is a complex and dynamic process shaped by interdependent relationships between people and activities (Asselin et al., 2006). This complexity raises a key question for urban planning: how can "spatial integration" be conceptualized and implemented when migrants are not merely recipients of urban policies, but active agents in shaping the city? Participatory planning and design processes offer valuable insights into this question, particularly in contexts where there is an effort to shift away from top-down governance models. These participatory initiatives provide important grounds for observing how underrepresented groups are included, or excluded, in urban decision-making. They also reveal how cities respond to these groups and how, in turn, the groups engage with participatory opportunities. As such processes aim to promote cities made both for and with people, they are essential for understanding spatial integration not only as a matter of infrastructure and planning, but also in terms of everyday life, social interactions, and the lived experience of urban space.

3. Case Studies: Who is included in participatory design processes?

The area stretching from Martim Moniz northward along Avenida Almirante Reis is widely recognized for its multicultural character (Figure 1 and 2), shaped by diverse commercial activities, services, and products associated with ethnic consumption (Mendes, 2012 in Felix, 2017) Martim Moniz and Almirante Reis have long attracted immigrant populations due to the availability of affordable commercial spaces. Shopping centers built in the 1980s, although not originally intended for such use, gradually became hubs for wholesale businesses operated predominantly by immigrants from former Portuguese colonies, many of whom arrived in the 1970s. This commercial dynamic expanded further with the arrival of Chinese, Indian, and other South Asian communities, which have since become integral to the area's identity. In the parish of Arroios, where much of Almirante Reis is locat-

ed, foreign residents make up approximately 23% of the 33,302 inhabitants, with the largest groups originating from Nepal and Bangladesh. As early as 2004, around 200 shops in the area were identified as being operated by immigrant entrepreneurs (Bastos in Mendes, 2012).

2. Martim Moniz Square: Personal Archive, 2024)

Despite this well-documented socio-cultural diversity along the Almirante Reis axis, it was not meaningfully reflected in the participatory urban design processes conducted by the municipality in 2023. Two recent participatory planning initiatives, Martim Moniz Square and Avenida Almirante Reis, serve as case studies in this research. While both aimed to revitalize public spaces through community engagement, critical questions remain regarding the actual impact of these processes and the extent to which they reflect the area's demographic and cultural diversity. This study investigates how such participatory approaches to public space planning in Lisbon engage or overlook different community groups, with particular attention to patterns of inclusion and exclusion.

"The future of Martim Moniz"

Martim Moniz Square, situated at the intersection of multiple social and ethnic flows in central Lisbon, has long been associated with the city's multicultural identity. Historically, the area has been home to various immigrant communities. Martim Moniz, a historic figure from the 1147 Siege of Lisbon, is remembered for his legendary sacrifice, holding the castle doors to enable the Christian conquest of the city from the Moors (Arabs). After this conquest, Lisbon's Moors were resettled in Mouraria, initially a segregated suburb that evolved into a multicultural enclave where Moors, Jews, and Christians lived side by side. Today, Martim Moniz Square is both a symbolic and functional landmark at the junction of Lisbon's historic center and Almirante Reis Boulevard, a key urban artery. However, Lisbon's ongoing housing crisis and precarious labor market create significant barriers for newly arrived migrants, especially those without stable resources. The square reveals these realities, functioning less as a celebrated "outdoor living room" and more as a collective refuge where marginalized groups adapt public space to meet survival needs, from informal shelters during cold months to social gathering spots and makeshift street markets. This fragmented use underscores the limits of symbolic multiculturalism and calls for participatory planning that addresses structural inequalities.

In recent years, the square became the focus of a participatory urban regeneration project launched by Lisbon Municipality (Figure 3), intended to reimagine the space through inclusive public input. The participatory planning process for Martim Moniz Square, launched in 2021 by Lisbon City Council, followed a structured, multi-phase approach aimed at community involvement and transparent decision-making. It began with a public consultation and exhibition (Jan 2021), followed by the publication of a participatory report outlining key inputs. In May 2021, the report and its proposed intervention principles were unanimously approved by the council. A co-design phase in June 2021 further engaged residents in shaping the project vision. The process continued with the approval of terms for a public design competition (Oct 2022), officially launched in March 2023. A clarification period (April-May 2023) allowed for open communication with applicants, leading to the submission of proposals in June. The final evaluation and selection took place between July and October 2023, concluding with a public exhibition and announcement of the winning design in November 2023, followed by the commissioning of the selected

team for execution planning. Although "multiculturality" emerged as a defining concept among 920 surveyed participants, the process failed to equitably represent the area's diverse user base. Only 11% of the 1,009 total participants were non-Portuguese, and participation from key migrant communities around the site such as Bangladeshi, Nepali, and Pakistani residents was minimal, often limited to a single respondent per group.

This imbalance reflects deeper issues in Lisbon's participatory frameworks. While participatory urban initiatives promote inclusivity on paper, they seem to fall short in engaging marginalized communities meaningfully and participation is frequently instrumentalized. The disconnect became more evident in the design competition's jury process. Despite an inclusive participatory phase in 2021, the 2023 jury included only professionals, architects, engineers, and municipal officials, without representatives from the earlier community engagement phase (Câmara Municipal de Lisboa, 2023). This exclusion reflects what Falanga describes as the "institutional limits of participation," In a space like Martim Moniz, characterized by its ethnic and cultural diversity, such shortcomings risk reinforcing the very inequalities participatory design is meant to address[2].

"The New Avenue Almirante Reis"

The participatory process for Almirante Reis Boulevard[3]was notably comprehensive and multi-faceted (Figure 4), engaging Lisbon's population through various methods. An online survey open to the entire city attracted 2,252 responses, reflecting broad public interest. Additionally, 74 contributions were collected through physical participation boxes placed at key local points such as neighborhood councils and markets, ensuring input from residents who may prefer offline engagement.The process also involved targeted focus groups with 67 invited stakeholders representing security forces, public transport workers, local associations, schools, health professionals, and merchants, fostering dialogue with key community actors. Four "World Cafés," open to all and requiring prior registration, engaged 51 participants in informal yet structured discussions. Lastly, recognizing the importance of including youth voices, the initiative ran four "Urbanist for a Day" session, a marathon of ideas conducted with schoolchildren, where 90 children from 4th and 6th grades contributed their perspectives during guided walks.

Despite the scale and diversity of participation, questions remain about who was truly included and how the input from marginalized groups, particularly migrant communities, shaped the outcomes. Similar to the Martim Moniz case, it is essential to critically assess whether this participatory approach goes beyond city branding or image-making, to genuinely address the socio-spatial needs of all users of Almirante Reis Boulevard. The Lisbon Municipality presented the process as the most participatory ever for a public space in the city. This is correct in terms of final number od particioants. Yet, 93% of respondents were of Portuguese nationality, and only marginal participation came from other nationalities such as Brazilian, Italian, Spanish, or French. The call for the participatory process stated "Almirante Reis with people for people" and the resulting announcement similarly states: Almirante Reis: Made with everyone[4].

4 https://informacao.lisboa.pt/en/dossies-tematicos/eixo-almirante-reis/entry

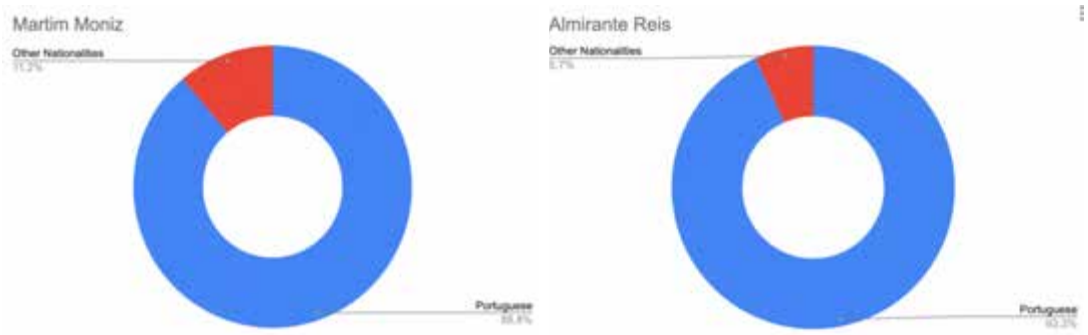

Figure 5. The ratio of participation according to portuguese and other nationalities in both processes

While the process focused on themes like mobility, safety, and the environment with proposals centering on public transport, bike lanes, and green infrastructure, it seems to overlook the area's cultural dimension and the lived experiences of its diverse populations. Given that public space is shaped by all who use it, the area's diverse population represents a missed opportunity to foster a more inclusive and meaningful participatory process. As Félix (2018) argues, understanding public space demands attention to how different cultures perceive and appropriate the urban environment: "Two individuals from different cultures, when placed in the same space, will not extract the same information or feel the same, because they inhabit different sensory worlds" (Hall, 1966). A truly inclusive approach in Martim Moniz and Almirante Reis (Figure 5) would require integrating these layered cultural perceptions into both participatory methods and design outcomes.

4. Discussion and Conclusion

The Lisbon case reveals both the promises and limitations of multicultural urban planning. Despite being recognized for progressive policies and participatory mechanisms such as participatory budgeting, citizen councils, and urban regeneration projects, the translation of these initiatives into spatial equity remains uneven. As this study shows, the celebratory language of diversity often masks the lack of genuine socio-spatial inclusion. In practice, public space design tends to prioritize aesthetics and formal outputs over inclusive processes, leading to a gap between representational success and lived experience. This disconnect is especially evident in the Martim Moniz and Almirante Reis areas, where migrant communities remain underrepresented in participatory processes despite their demographic and cultural presence. While initiatives like the BIP/ZIP program and the redesign of Martim Moniz Square demonstrate some efforts to engage diverse populations, these mechanisms often fall short in meaningfully involving marginalized voices.

The Martim Moniz case illustrates how participation can be instrumentalized more as a symbolic gesture than as a transformative tool for spatial justice. Although steps were taken to include diverse groups, the process ultimately highlighted the difficulty of sustaining procedural inclusion. As Falanga (2023) notes, participatory processes have the potential to open new dialogues in policymaking, but only if deliberate efforts are made to include the most excluded.This study argues for a clearer distinction and stronger connection between spatial integration and social inclusion in urban planning. Urban space must not only be accessible and culturally recognizable but must also support everyday participation and democratic involvement. For this, urban governance must move beyond one-off consultations and invest in long-term, justice-oriented planning models. Planners, urbanists, and researchers play a key role in shaping inclusive cities, not by designing for communities, but by designing with them through these framing recommendations:

- Prioritize process over form: Urban planning must move beyond aesthetic representations of diversity to prioritize inclusive and transparent processes that meaningfully involve marginalized communities.

- Institutionalize inclusive participation: Develop frameworks that embed co-creation and long-term community engagement at all stages of planning and design, not just during consultation phases.
- Recognize migrants as active (city-making) agents: Inclusion should not be symbolic, migrants must be recognized as co-authors of urban space, with real influence over decisions that affect their lives.
- Design for adaptability: Public spaces should be flexible, allowing for cultural appropriations and evolving uses that reflect the shifting dynamics of urban life.
- Embrace interdisciplinary methods: Integrating urban design with social research can better capture the complex socio-spatial realities of diverse populations and inform more responsive planning.

This research presents the critical role of public space in fostering urban justice and inclusion, particularly for immigrant communities. It highlights the need for culturally visible, accessible, and inclusive urban environments that reflect the diversity of their users. To achieve this, urban planning must adopt participatory design processes that actively involve local voices, especially in multicultural neighborhoods Ultimately, achieving spatial integration as a lived reality requires more than policy, it demands a rethinking of how cities are made, for whom, and with whom. Lisbon's experience offers valuable lessons not only about the limitations of current practices but also about the possibilities of building genuinely inclusive urban futures.

Inclusive Renovation Strategies for Aging Residential Communities — A Case Study of Daguan Subdistrict in Hangzhou

Kaixuan Wu
Affiliation: Chongqing University
Email: calebwu0618@gmail.com

Abstract
With rapid urbanisation, many aging communities in China face deteriorating infrastructure and limited spatial functionality, impacting vulnerable groups such as the elderly, disabled, and children. This study argues that renewal efforts must go beyond physical upgrades to include multifunctional spaces, barrier-free design, and community cultural integration. Focusing on Daguan Subdistrict in Hangzhou, the paper analyses issues such as spatial deficiency, fragmented environments, and inadequate services. It proposes inclusive renovation strategies to enhance living quality, address diverse user needs, and support sustainable development. The study offers a systematic framework for inclusive community renewal, serving as a reference for similar urban regeneration projects. As urbanisation advances, continual refinement of design approaches is vital to building more inclusive, equitable, and resilient neighbourhoods.

Keywords: Aging Residential Communities, Inclusive Design, Urban Renewal; Sustainable Development, Hangzhou

1. Introduction

As China's reform and opening-up policy deepened in the late 20th century, the country entered an unprecedented phase of rapid urbanisation and socio-economic transformation. Particularly since the late 1980s, urban development has been driven by market-oriented reforms and an explosive expansion of the real estate sector. During this period, large numbers of residential communities were built to accommodate a growing urban population. However, many of these early developments, especially those constructed prior to the 2000s, now suffer from aging infrastructure, inefficient spatial layouts, and single-function designs that no longer align with contemporary urban lifestyles and demands. These aging residential communities, once considered vital assets during earlier stages of urban growth, are now becoming spatial and social liabilities. They often lack modern amenities, barrier-free accessibility, and adequate public services, creating significant challenges for vulnerable groups such as the elderly, persons with disabilities, and children (Gehl, 2011). According to national statistics, there are nearly 160,000 aging residential communities across China, affecting over 42 million households and covering an estimated total built area of approximately 4 billion square metres. These figures highlight not only the sheer scale of the issue but also its profound implications for urban governance, equity, and sustainability.

Improving the living standards and environmental quality of these communities has thus become a priority in China's urban agenda. In recent years, both central and local governments have issued a series of top-down policy initiatives to address this challenge. A major milestone occurred in December 2019, when the Central Economic Work Conference formally launched nationwide pilot programmes for the regeneration of aging residential communities. This move signified a strategic shift in urban policy—from growth-driven expansion to inward-looking regeneration. In 2020, the General Office of the State Council released the Guidelines on Advancing the Comprehensive Renovation of Aging Urban Communities, setting forth clear goals, tasks, and principles for such efforts. The guidelines emphasised the need for improving infrastructure, enhancing community functionality, and promoting resident participation. These directions were reaffirmed and expanded upon in the 14th Five-Year Plan (2021–2025), which explicitly calls for accelerating urban renewal as a means of improving quality of life, reducing inequality, and fostering resilient cities.

Within this policy and planning framework, inclusive design has emerged as a key conceptual and practical approach. Rooted in the values of social equity, human-centred development, and universal accessibility, inclusive design seeks to create environments that meet the needs of all population groups, regardless of age, ability, or socio-economic background (Imrie, 2012). In the context of aging residential communities, inclusive design implies more than technical retrofitting or cosmetic improvements—it calls for the transformation of public spaces, housing layouts, and community facilities to support interaction, dignity, and autonomy for diverse residents

(Carmona, 2019). Particularly important is the focus on populations that are often underserved in conventional urban development—elderly individuals navigating mobility decline, people with disabilities who face barriers in everyday life, and children who require safe, accessible play environments. Inclusive design provides a framework to not only accommodate these needs but also promote intergenerational interaction, mental wellbeing, and social cohesion (Dempsey, Brown & Bramley, 2012). It supports the vision of a more humane and democratic urbanism.

This paper takes the aging communities of Daguan Subdistrict in Hangzhou as a representative case for exploring how inclusive design principles can guide community renewal. Located in the city's urban core, Daguan comprises multiple residential compounds built in the late 20th century, many of which exhibit typical problems of spatial disconnection, infrastructure decay, and social fragmentation. Through a combination of field surveys, demographic analysis, and comparative case studies, this research identifies the core barriers to inclusivity in these neighborhoods and offers targeted design and policy strategies to enhance spatial functionality, community resilience, and urban equity. By rooting the analysis in real-world conditions and integrating international design principles with local socio-cultural contexts, the study aims to contribute both theoretically and practically to the broader discourse on inclusive urban regeneration. In doing so, it also responds to the national call for innovation in community governance, sustainable urban development, and people-oriented planning.

2. Core Concepts

2.1 Inclusive Design

Inclusive design is an evolving design philosophy and methodology that aims to create products, services, and environments accessible and usable by the widest possible range of users, regardless of age, ability, socioeconomic status, or cultural background (Mace, Hardie & Place, 1991). Its foundational premise is that exclusion often results not from personal limitations, but from environmental, institutional, and attitudinal barriers embedded within the built and social environments. Historically, inclusive design has been closely aligned with the needs of individuals with disabilities (Mitrović, 2024). This association has led to significant advancements in accessibility, such as barrier-free entrances, tactile wayfinding, and universal signage. However, the scope of inclusive design has significantly expanded over the years. Today, it addresses a much broader spectrum of human diversity—including cognitive differences, language proficiency, cultural practices, gender identities, and generational experiences. These factors profoundly influence how individuals perceive and interact with physical spaces and social systems.

Inclusive design is not a stylistic feature or a one-time technical fix; it is a holistic, life-cycle-oriented approach. It encompasses all stages of the design process—from user research and conceptual development to prototyping, implementation, and post-occupancy evaluation. The goal is not to design for the "average" user, but to embrace variability as a norm and embed flexibility, adaptability, and equity into the core of design solutions (Ma'rof, Noor & Xiang, 2023). In architectural and urban contexts, inclusive design manifests through a variety of spatial strategies: adaptable floor plans, step-free circulation paths, age-friendly landscapes, multilingual wayfinding, and participatory design processes. It encourages designers and policymakers to question default assumptions and to centre marginalised voices during planning and implementation.

Importantly, inclusive design also intersects with broader social values such as human rights, public health, and environmental justice. In the face of aging populations, climate change, and widening inequality, inclusive design offers a framework for creating resilient, dignified, and equitable living environments. In the context of aging residential communities, it enables the transformation of outdated, exclusionary urban spaces into welcoming, multi-generational places that foster wellbeing and belonging for all residents.

2.2 Renovation of Aging Residential Communities

The renovation of aging residential communities refers to a systematic and multidisciplinary process aimed at upgrading the physical, social, and environmental quality of residential areas that were built during earlier stages of urban development. These neighbourhoods, typically constructed in the 1980s and 1990s—or even earlier—now face growing issues of obsolescence, functional inadequacy, and social disintegration. As such, their renewal is not only an infrastructural concern, but a key urban policy imperative tied to broader goals of livability,

inclusiveness, and sustainability.

The core aims of such renovation efforts include: upgrading deteriorated infrastructure (e.g., water, electricity, waste systems), improving building safety and energy performance, enhancing the availability and quality of public services and amenities, and integrating smart technologies and digital governance tools to modernise community operations. Importantly, these interventions must be carefully tailored to preserve local identity, architectural heritage, and cultural memory. Blind demolition and reconstruction—common in earlier waves of urban renewal—are increasingly replaced by organic, incremental, and participatory models that value history and local context.

However, the renovation of aging communities presents substantial challenges. Many of these areas were built with minimal regulatory oversight, and suffer from outdated design standards, cramped spatial configurations, and poor environmental performance. Property ownership is often fragmented among residents, government units, and enterprises, leading to legal ambiguity and coordination difficulties. Moreover, many communities lack formal property management structures, and financial mechanisms for long-term maintenance are either weak or entirely absent (Obermuller, 2024). These institutional and governance gaps often result in neglect, where aging communities fall into states of disrepair, characterised by crumbling infrastructure, inadequate waste management, and a decline in social capital. Residents may experience not only physical discomfort but also social exclusion, particularly those who are economically disadvantaged or mobility-impaired.

Thus, the renovation of aging communities must be understood as a complex socio-spatial process, involving not only physical upgrades but also legal reform, financial innovation, stakeholder collaboration, and capacity-building. It requires a shift from top-down, engineering-driven interventions to integrated and inclusive renewal strategies that centre the needs of residents, promote social equity, and align with broader urban development frameworks.

3. The Evolution of Aging Community Renewal in Hangzhou

3.1 Initial Exploration Phase (2000–2012)

Between 2000 and 2012, Hangzhou entered the initial phase of aging community renewal, characterised by government-led pilot projects aimed at improving basic infrastructure. At the time, the primary goal was to address the most visible and urgent physical problems faced by aging neighbourhoods (Gong et al., 2025). These included outdated roads, inadequate drainage systems, poor lighting, and unsafe building conditions. Renovation efforts focused on functional upgrades to restore basic services and improve residents' immediate living environments.

During this period, the Hangzhou municipal government launched a series of targeted interventions. Notably, 2,721 back alleys (urban lanes known for congestion and poor sanitation) were refurbished, and comprehensive infrastructure upgrades were carried out in 1,048 communities. These projects addressed critical urban utilities—such as water supply, sewage systems, electricity, and gas pipelines—and helped stabilise physical conditions in densely populated urban areas.

However, these efforts were primarily engineering-oriented and reactive in nature, focusing on technical fixes rather than long-term transformation. Funding was sourced mainly from municipal and district-level government budgets, with little involvement from residents or external stakeholders. Strategic urban planning integration was minimal, and interventions were often fragmented, conducted on a case-by-case basis without a unified vision. As a result, while physical conditions improved in many communities, issues of social fragmentation, spatial disconnection, and ageing governance systems remained largely unresolved.

3.2 Deepening Reform Phase (2013–2016)

After 2013, Hangzhou's approach to community renewal began to shift from isolated infrastructural fixes toward more holistic, resident-oriented renovation strategies. This transformation was largely influenced by national policy signals advocating for more inclusive and sustainable urban development. During this phase, renovation efforts started to incorporate not only physical improvements but also the wellbeing, cultural life, and participatory rights of residents (Irawati et al., 2025). A key development was the diversification of funding sources. The city began experimenting with public-private partnerships (PPPs), social capital investment, and resident

co-financing models to reduce dependency on government funds and increase financial sustainability. Property management services were reformed to promote standardisation and professionalisation, and new models of community governance were tested, emphasising shared responsibility among stakeholders.

Physically, the renovation scope expanded to include public space enhancement, community landscaping, and the construction of small-scale amenities such as senior activity rooms, fitness areas, and children's play zones. The integration of landscape architecture, community art, and cultural heritage protection emerged as new thematic pillars. The city also began to recognise the role of green infrastructure in improving microclimates and fostering public life. This phase marked the transition from technical repair to spatial and social regeneration. Community renewal initiatives began to align more closely with residents' lived experiences and aspirations. Projects were guided by the principle of "improving quality of life," with more emphasis placed on user feedback, community engagement, and local identity. Importantly, the renewal process began to be seen not just as a government task, but as a collaborative process requiring the co-creation of value by government, market, and society.

3.3 Systematic Renovation Phase (2017–2020)

Beginning in 2017, Hangzhou entered a new stage of systematic and comprehensive urban renewal. With the national implementation of the 13th and 14th Five-Year Plans, cities across China were called upon to accelerate the transformation of aging urban spaces, prioritising human-centred planning, environmental sustainability, and efficient governance. In this context, Hangzhou developed a series of strategic, measurable action plans to complete the transformation of all residential communities built before 2000 by the end of the planning cycle.

During this phase, renovation moved beyond surface-level fixes to embrace urban design, integrated infrastructure planning, and digital transformation. Upgrades included expanded public spaces and pocket parks, new underground utilities, fire safety improvements, universal accessibility features such as ramps and elevators, and traffic reconfiguration to separate pedestrian and vehicular flows.

Crucially, this stage saw a strong emphasis on cultural and historical preservation. Hangzhou, with its rich architectural and cultural heritage, began to take a more nuanced approach to balancing development with conservation. Where possible, historic buildings, architectural features, and vernacular styles were preserved or restored, transforming communities into living archives of the city's evolution. Additionally, the "Smart Community" concept gained traction (Camellato, 2024). Pilot programmes introduced digital platforms for community management, real-time monitoring of energy usage, intelligent lighting, and online resident feedback systems. These technologies aimed to modernise the governance and service delivery mechanisms, making them more responsive, efficient, and transparent.

This phase also featured cross-departmental collaboration between planning bureaus, transportation agencies, environmental departments, and community associations, signalling the maturation of inter-agency coordination and urban governance in Hangzhou.

3.4 Future Community and Organic Renewal Phase (2021–Present)

Since 2021, Hangzhou has embraced a new frontier in urban renewal, defined by the concept of the "Future Community" (Weilai Shequ). This model promotes organic, context-sensitive regeneration over wholesale demolition and reconstruction. It calls for "micro-renewal", whereby each community is assessed based on its unique history, demographics, and spatial potential, and then renovated using flexible, tailored interventions.

This phase reflects a significant philosophical shift: from top-down planning to bottom-up participation, from infrastructure-led growth to people-oriented design, and from hardware improvements to emotional belonging and lifestyle enhancement (Zhou, 2024). The Future Community model incorporates nine core elements—health, education, employment, elderly care, childcare, mobility, architecture, community governance, and smart services—aiming to construct a comprehensive and adaptive ecosystem for urban life. In the wake of the COVID-19 pandemic, this model was further reinforced by the notion of "community as the basic unit of life." Hangzhou invested heavily in improving public health infrastructure, epidemic response systems, and digital integration. Communities became more self-sufficient, data-driven, and resilient.

Sustainability and inclusivity are also key themes (Triggiano, 2024). Green building standards, low-carbon design strategies, shared mobility systems, and intergenerational public spaces have been integrated into new renovation projects. Moreover, the city is emphasising spatial continuity and ecological connectivity, ensuring that revitalised communities are not isolated nodes but part of a larger, cohesive urban ecosystem.

This latest phase has also pioneered new financial and legal frameworks. Incentives were created to attract private capital, banks were encouraged to offer low-interest community redevelopment loans, and regulatory tools were adapted to allow incremental land use changes (Leite, Reis & Correia, 2024). Meanwhile, community participation was institutionalised through resident councils, participatory budgeting, and digital consultation platforms.

In summary, Hangzhou's evolution in aging community renewal reflects a progressive, multi-dimensional, and adaptive transformation. What began as simple infrastructure repairs has evolved into an integrated urban regeneration strategy grounded in inclusivity, sustainability, and innovation. Through diversified funding, policy experimentation, and the application of inclusive design principles, the city has created a model that balances heritage and modernity, growth and equity, government leadership and civic participation. Hangzhou's experience demonstrates how aging community renewal can serve as a strategic entry point for broader urban transformation—not only revitalising neighbourhoods physically, but also reimagining urban governance, strengthening community identity, and enhancing the quality of life for diverse populations.

4. Current Conditions of Daguan Subdistrict

4.1 Location and Historical Context

Daguan Subdistrict, located in the northern part of Hangzhou, represents one of the city's most concentrated clusters of aging residential communities. It occupies a strategically significant urban zone, bounded by Daguan Road to the north, the historic Shangtang River to the east, Shangtang Road to the west, and Shihuiba to the south. The area's name—"Daguan"—derives from the ancient Beixin Customs Gate ("Beixin Guan"), reflecting the district's longstanding role as a key point of commerce and trade during imperial times.

Covering approximately 1.6 square kilometres, Daguan Subdistrict encompasses eight administrative communities—Dongyi, Dong'er, Xiyi, Xi'er, Desheng, Cuiyu, Nanyuan, and Xiangji—and consists of 30 residential neighbourhoods, 29 of which are classified as aging or under-serviced communities, with only one built as modern commodity housing. The concentration of older developments makes Daguan an archetypal case for studying community decline and regeneration in the context of rapid urbanisation in China.

With the progression of urban modernisation in the 21st century, Hangzhou has experienced extensive transformations in land use, transportation systems, and urban design. Daguan Subdistrict, once peripheral, has now become a semi-central area integrating residential, commercial, and service functions. Yet this evolution has exposed the limits of its outdated residential infrastructure. Many buildings constructed during the 1980s and 1990s lack the spatial and technical capacity to meet current demands for comfort, accessibility, and resilience. The consequences include deteriorated environments, weak service provision, and rising dissatisfaction among long-term residents—making urban regeneration an urgent priority for local authorities and planners.

Figure 1. Location of Daguan Subdistrict – Source: Drawn by author

4.2 Demographic Structure and Needs Analysis

The demographic structure of Daguan Subdistrict reveals both stability and tension. According to the 2020 Seventh National Census, the subdistrict's permanent population stands at 42,036. Among these, 5,488 are children aged 0–14, 29,060 are working-age residents (15–64), and 11,059 are aged 60 or above, with 7,488 of them over 65 years old. This means that approximately 26% of the total population is elderly, exceeding the national average and confirming the district's ageing profile.

This demographic structure reflects two simultaneous trends. On one hand, Daguan is home to a stable base of long-term residents who have lived in these communities for decades. Many of them are retired workers or elderly citizens with deep social ties to the area. On the other hand, the subdistrict's strategic location and strong transport connectivity have attracted a substantial floating population, including young professionals, migrant workers, and university students who rent temporary accommodations.

The coexistence of ageing residents and a transient, youthful demographic creates complex service demands and urban management challenges. While older residents require enhanced accessibility, healthcare facilities, and public resting areas, younger residents seek flexible spaces for leisure, study, and socialising. Community planning must therefore address intergenerational coexistence, catering to both long-term attachment and short-term dynamism.

Notably, infrastructure in many aging communities is mismatched with the evolving demographic needs. For example, elevator access is scarce in walk-up buildings, posing barriers to elderly mobility. There is a shortage of daycare and rehabilitation services, and recreational spaces for seniors often double as storage or parking areas. Without targeted upgrades, these mismatches may continue to erode the wellbeing and autonomy of vulnerable groups.

4.3 Land Use Analysis

Land use in Daguan Subdistrict is dominated by residential zoning, with limited functional diversity and fragmented spatial organisation. Although the subdistrict is urban in character, it lacks the land-use efficiency seen in more contemporary mixed-use districts. Green space, in particular, is in short supply and poorly distributed, primarily confined to narrow riverbanks or dispersed in disconnected green strips between buildings.

Much of the public open space is residual—formed as by-products of outdated planning rather than intentional urban design. These spaces often suffer from poor maintenance, single-use layouts, and minimal ecological or social function. Their low quality undermines opportunities for physical activity, community interaction, and visual relief in a dense urban setting. The functional disconnect between land parcels further compounds the issue. Residential blocks are often physically and perceptually isolated from nearby amenities, schools, and transit nodes. The absence of clear spatial hierarchies (e.g., between private, semi-public, and public zones) diminishes legibility and weakens residents' spatial belonging.

Given the high population density and limited expansion potential, internal spatial optimisation is crucial. Renovation efforts should focus on: reclaiming underused plots for community gardens or seating areas, integrating greenery into pedestrian corridors, and reshaping residual lands into multifunctional, climate-responsive micro-environments. When reimagined thoughtfully, internal green spaces can serve not only as lungs of the community but as anchors for social resilience and environmental health.

4.4 Summary of Inclusivity Challenges in Aging Communities

Despite incremental improvements, aging communities in Daguan continue to face a host of barriers to inclusive living. These are structural, spatial, and institutional in nature, and can be grouped into three key domains:

(1) Lack of Functional Public Space

The aging residential compounds in Daguan were largely constructed during the 1980s and 1990s—before the concept of inclusive design was widely adopted in China. Consequently, many public spaces are limited in function, physically degraded, and socially underutilised. For example: 1) Most buildings lack elevators, making upper floors inaccessible to elderly or disabled residents. 2) Entrances typically have steps without ramps, and corridors are too narrow for wheelchairs or walkers. 3) Shared courtyards, when present, are often used for car parking or storage, leaving little room for social gathering or play. These physical limitations isolate vulnerable populations and restrict informal interactions that are vital for mental health and community cohesion. Moreover, women, children, and disabled individuals often experience the most acute forms of spatial exclusion, given the lack of flexible, safe, and accessible environments.

Figure 3. Problems of Functional Deficiency – Source: Drawn by author

(2) Fragmented Spatial Environment

Another critical challenge lies in spatial disconnection and poor environmental integration. Many internal road networks in Daguan's communities are incoherent, with dead-end lanes, non-continuous sidewalks, and inadequate signage. These conditions undermine walkability and deter residents from engaging in outdoor activities. Green infrastructure is similarly fragmented. Landscaped zones, if present, are often isolated patches with minimal ecological layering. Tree species are few, shrubs are scarce, and flowerbeds are replaced by concrete or tiles. This lack of biodiversity and spatial continuity reduces environmental benefits such as shade, air purification, and stormwater absorption. Furthermore, fragmented spaces impair social legibility—residents have no clear sense of where communal life should occur, and visual monotony diminishes aesthetic engagement. Addressing this issue requires a deliberate design strategy that reconnects circulation routes, consolidates fragmented green areas, and creates coherent spatial hierarchies that support everyday life.

Figure 4. Spatial Fragmentation Problems – Source: Drawn by author

(3) Inadequate Community Services
Community services in Daguan are insufficient in both quantity and quality. Most aging communities were developed as open-access neighbourhoods without enclosed management or comprehensive service provision. Although some property management companies have since been introduced, many operate with limited capacity, resulting in: inconsistent sanitation, poor facility maintenance, and unreliable security services. Specialised services such as elderly care centres, daycare for children, rehabilitation clinics, or community kitchens are scarce or entirely absent. Services that do exist are often difficult to access or operate with restricted hours and staffing. Governance mechanisms also remain weak. Communication between government agencies, property managers, and residents is often sporadic or unidirectional. Resident engagement in decision-making is minimal, and co-governance structures are still in a formative stage. This limits the community's capacity for self-management and constrains the long-term success of renovation efforts. In sum, the lack of coordinated services and participatory governance undermines the inclusiveness and resilience of Daguan's aging communities.

Figure 5. Deficiencies in Community Services – Source: Drawn by author

5. Inclusive Renewal Strategies for Aging Communities in Daguan Subdistrict

5.1 Multifunctional Integration and Barrier-Free Design

One of the most pressing spatial challenges in Daguan's aging communities is the lack of multifunctional and inclusive public space. Many of these communities were built during an era when design focused primarily on basic shelter and infrastructure, neglecting the broader social and behavioural dimensions of urban life. As a result, public spaces today are often narrowly functional, underutilised, and devoid of flexibility.

Addressing this issue requires a paradigm shift in design thinking—from static and single-purpose environments to dynamic, adaptable, and multi-use spaces that support a broad range of activities across different age groups and daily time cycles (Ferraro, D'Andria & Fiore, 2024). Designers should adopt an integrated, systems-level approach that reimagines courtyards, alleyways, and transitional spaces as opportunities for interaction and activation. For example, vacant lots or underused corners of the community could be retrofitted with: intergenerational playgrounds that combine fitness equipment for the elderly with safe zones for children, modular seating areas that can be rearranged for gatherings or quiet reading, or seasonal installations that support community events, cultural exhibitions, or pop-up markets.

Such interventions must go beyond decorative beautification. True multifunctionality is achieved through responsive programming, modular infrastructure, and participatory planning processes that reflect actual resident needs and habits (Douka, Mazzoli & Benedetti, 2024). By aligning spatial function with behavioural rhythms, public areas become not just "spaces" but catalysts of community vitality.

Additionally, inclusive spaces should foster social equity, ensuring accessibility for all, particularly for those historically excluded from public life. This includes elderly residents, persons with mobility impairments, visually impaired individuals, and caregivers with strollers. Spatial configurations must therefore anticipate diverse mobility and sensory experiences. Barrier-free design is central to this vision. Renovation plans should include the retrofitting of: step-free entries, standard-compliant ramps and handrails, lift installations in multi-storey walk-up buildings, tactile paving and auditory signals for wayfinding. These elements are not "special" features but essential components of universal usability. Importantly, they must be integrated aesthetically into the urban fabric—not as appendages, but as intentional design choices that dignify rather than stigmatise users. Inclusive environments enable all residents to navigate their neighbourhoods confidently and independently, thus enhancing community cohesion and emotional security.

Ultimately, by reconfiguring spatial hierarchies, enriching functional layers, and embedding accessibility into the design DNA, aging communities can transform shared spaces into "second living rooms"—warm, inclusive, vibrant domains where everyday life unfolds with dignity and joy.

Figure 6. Renovation Vision: Multifunctional Integration and Accessibility – Source: Internet

5.2 Spatial Connectivity and Green Environment Reconstruction

The fragmented spatial structure of Daguan's aging communities poses significant obstacles to everyday mobility, social interaction, and environmental performance. Decades-old planning models prioritised car access or isolated block layouts, resulting in poor connectivity, disjointed pathways, and underperforming green zones.

To restore spatial logic and ecological coherence, community renewal must begin with the reconstruction of internal circulation networks. This includes improving pedestrian flow, eliminating "dead-end" roads, and creating continuous, legible pathways that prioritise walkability (Pang & He, 2025). Such networks should include permeable pavement materials for sustainability, be shaded by vegetation for climate comfort, and include resting

spots, lighting, and signage to support safe and intuitive use, especially for seniors and children.

Small but impactful changes—like converting former fire lanes into green corridors or opening gated barriers between blocks—can substantially improve spatial integration. While large-scale road reengineering may be constrained by high density and ownership issues, tactical urbanism (small-scale, low-cost interventions) offers a pragmatic way forward. Temporary pilot projects and community feedback loops can gradually build consensus for more permanent restructuring.

Equally critical is the reimagining of green infrastructure. Presently, most greenery in Daguan is fragmented and ornamental. Green zones are either leftover marginal lands or mono-functional lawns with minimal social or ecological value.

Future-oriented design should treat green spaces as multifunctional ecological-social infrastructure. Proposals may include biodiverse gardens with medicinal herbs and native species, community farming plots to promote food literacy and intergenerational engagement, stormwater-absorbing rain gardens that reduce urban heat and flooding risk (Harde, 2025). Vertical greening on façades, rooftop gardens, and tree-lined boulevards can expand the green footprint without competing for scarce horizontal space. Vegetation layering is especially important: low shrubs and grasses enhance ground-level visibility and microclimate regulation, while avoiding excessive shading of lower residential units.

Moreover, green environments must be inclusive and programmable. Spaces should cater to diverse rhythms—quiet reflection, physical activity, group celebration—and offer physical, visual, and symbolic relief from urban density. This shift from fragmented green patches to connected green systems will not only improve environmental performance but also anchor communities in a renewed relationship with nature and place.

Figure 7. Renovation Vision: Connectivity and Green Environment Reconstruction – Source: Internet

5.3 Improved Service Facilities and Co-Governance

High-quality service infrastructure is foundational to inclusive communities. In aging neighbourhoods like Daguan, many public services—such as elderly care, health clinics, childcare, and cultural venues—are either outdated or entirely absent. To ensure long-term sustainability, community service systems must be adaptive, modular, and co-created with users.

Facilities should be designed for transformation: e.g., a classroom can function as a community cinema in the evening; a medical outpost can host wellness workshops; a vacant commercial storefront can become a shared tool library or repair station. This multifunctionality extends the lifecycle of limited resources while adapting to evolving demographic needs.

In response to the growing proportion of elderly residents, planners should incorporate ageing-in-place strategies. This includes establishing satellite elderly care centres, installing telehealth kiosks, expanding access to barrier-free toilets and rest areas, and integrating volunteer support networks into the formal service system

(Correia, Leite & Reis, 2024). At the same time, services should support young families and mobile workers through flexible coworking areas, parent-child activity rooms, and after-school tutoring spaces. This inclusive mix not only meets diverse demands but encourages cross-generational solidarity.

On the governance side, community renewal must shift from service delivery to co-production. Rigid top-down management systems must give way to collaborative governance models where government departments, property managers, and residents act as joint stakeholders (Antona, 2024). Practical strategies include: resident assemblies or participatory budgeting platforms, mobile apps for reporting maintenance issues and providing feedback, and rotating volunteer boards that help oversee public facilities. Such approaches democratise planning, increase transparency, and foster a sense of ownership. Empowered residents are more likely to maintain public assets, resolve disputes constructively, and cultivate a resilient social fabric.

Finally, capacity-building programmes for both residents and community managers—covering topics such as digital literacy, participatory planning, and conflict resolution—can enhance administrative professionalism and inclusivity. Over time, these models contribute to a governance culture rooted in trust, shared responsibility, and mutual support.

6. Conclusion

This study has examined the Daguan Subdistrict of Hangzhou as a representative case for understanding how inclusive design principles can guide the renewal of aging residential communities. Against the backdrop of accelerating urbanisation, the demand for human-centred, equitable, and sustainable living environments has become more urgent. Many older communities, particularly those built in the late 20th century, now face multifaceted challenges stemming from deteriorating infrastructure, outdated planning paradigms, and fragmented service systems. These conditions compromise not only the quality of life for residents but also the social cohesion and ecological resilience of the broader urban fabric.

Through a comprehensive assessment of Daguan's spatial structure, demographic composition, land use, and service provision, this study identified a series of structural problems that hinder inclusivity. These include a lack of functional and flexible public spaces, insufficient barrier-free infrastructure for elderly and disabled residents, fragmented pedestrian and ecological networks, and limited or underperforming community services. These issues are further compounded by institutional and governance constraints, such as limited resident participation and weak coordination among stakeholders. Together, they paint a picture of communities that, while rich in historical value and social memory, are increasingly mismatched with the needs and expectations of contemporary urban life.

In response to these challenges, the study proposed a set of context-sensitive and adaptable design strategies grounded in the principles of inclusive urbanism. These include: restructuring and activating public spaces for multi-generational use, implementing barrier-free design standards to promote mobility and autonomy, en-

hancing green space continuity and ecological performance, and strengthening community services through co-governance models and flexible facility programming. These interventions are not isolated technical solutions but form part of a holistic renewal framework that views aging communities as living systems—embedded within complex social, environmental, and governance networks. As such, inclusive design must be understood not merely as an aesthetic or functional upgrade, but as a strategic and ethical commitment to creating urban environments where all individuals—regardless of age, ability, or socioeconomic background—can participate fully and equally in public life.

Importantly, the strategies developed for Daguan are scalable and replicable, offering practical insights for other urban districts across China and beyond that face similar challenges. By rooting the design process in empirical research, local specificity, and participatory dialogue, the framework balances universal accessibility principles with place-based adaptations, thus enhancing its transferability and long-term impact. Looking ahead, the success of inclusive community renewal efforts will depend on cross-sector collaboration, integrating the knowledge and resources of government institutions, urban planners, architects, community leaders, and residents themselves. Policy support must be coupled with design innovation, financial tools must support long-term maintenance, and participatory mechanisms must be institutionalised rather than ad hoc.

Moreover, future research should explore the development of quantitative metrics for evaluating inclusivity in community renovation projects, as well as post-occupancy studies to track the lived impacts of design interventions. Expanding the analytical lens to include digital inclusion, environmental justice, and care infrastructure will also be vital in adapting to emerging urban challenges—especially in the context of climate change, demographic ageing, and post-pandemic urban life.

In conclusion, the inclusive regeneration of aging residential communities is not only a spatial or technical project but also a moral imperative for equitable and sustainable urban development. Through targeted design strategies, institutional reforms, and a culture of shared responsibility, it is possible to reimagine older urban areas not as sites of decline, but as resilient and inclusive neighbourhoods that reflect the values and aspirations of a just and future-ready city. Only through such shared vision and multi-stakeholder commitment can we ensure that the urban environments we build today remain welcoming and liveable for generations to come.

Abstract
This study assesses the livelihoods of Syrian refugees in Konak District, İzmir, exploring their livelihoods and their context based on a capital framework, and vulnerability dimensions determined by the Intergovernmental Panel on Climate Change (IPCC). It employs household surveys, the Livelihood Vulnerability Index (LVI), and qualitative analyses with Syrian refugees and non-governmental organisations. The research questions seek the most effective capitals and dimensions for the LVI and the LVI-IPCC, and strategies affecting capital distribution and reproduction in refugee-dense areas. The study reveals a high-level LVI for Syrian refugees, especially due to financial capital. The LVI-IPCC indicates moderate vulnerability, with exposure as the main contributing factor. Specific capitals are vulnerable to varying extents. Urban planning should develop supportive strategies to reproduce capital and regulate distribution.

Keywords: Vulnerable Syrian Population, Refugee Crisis, Livelihood Capital.

1. Introduction

The livelihoods of refugees have recently attracted attention, as they are increasingly affected by and related to major global transitions in climatic, economic and social systems. In particular, the examination of the livelihood vulnerability of refugees is necessitated by human-made disasters and mass migrations. The United Nations' 2030 Sustainable Development Goals adopt a livelihoods approach to emphasise capital assets that reflect people's adaptive capabilities and sensitivities. The ability to sustain a livelihood in a manner that is both sustainable and viable is predicated upon the maintenance of resources and the reproduction of capital assets, thus ensuring resilience in the face of adversity and stress. According to United Nations reports, the Syrian Civil War is one of the largest refugee crises in the world, causing the forced displacement of approximately 10 million people (Izmir Mülteci Çalışmaları Ağı, 2021). This migration from Syria defined by the Syrian Crisis by the United Nations High Commissioner for Refugees (UNHCR) due to its rapidity and scale. According to the United Nations High Commissioner for Refugees (UNHCR), Türkiye has approximately 3 million Syrian refugees, making it the world's largest host country for Syrian refugees (UNHCR, 2025). The scale and rapidity of the mass migration also defines a crisis for Türkiye, the host country. The consequence of such actions is an imbalance in the distribution and reproduction of livelihood capitals, as well as a deterioration in interrelationships between capitals. Consequently, threats to livelihood sustainability result in livelihood vulnerability.

This study contributes to the extant literature by addressing a gap in research on livelihood vulnerability assessments at the household level for Syrian refugees in Türkiye. This study adopts a livelihood capital approach to improve Syrian refugees' ability to adapt to hazards, increase risk awareness, and develop urban policies for both host communities and refugees. It draws attention on livelihood vulnerability rather than only social vulnerability, which includes a social capital dimension (Quandt, 2018), because a livelihood vulnerability analysis provides a more comprehensive assessment of all types of livelihood capital. The aim of this study is to assess the vulnerability of Syrian refugees' livelihoods based on a capital framework and vulnerability dimensions (exposure, vulnerability and adaptive capacity) determined by the Intergovernmental Panel on Climate Change (IPCC) definition of vulnerability. Syrian refugees have been identified as a particularly vulnerable group in light of the Syrian Civil War and the subsequent forced displacement of their population. The challenges faced by this group are numerous and significant. In this study, the variables specific to the vulnerable group will be identified according to the extant literature and preliminary interviews. The variables will then be analysed with a multidimensional approach by grouping them according to capital types and dimensions that contribute to vulnerability, and livelihood vulnerability will be evaluated by creating a Livelihood Vulnerability Index (LVI) to capture socio-economic problems, the presence or absence of diverse forms of capitals, and problems of organisation or balance among these capital types. For a comprehensive evaluation of the sensitivities and adaptive capacities of the Syrian refugees, interviews with both Syrian refugees and non-governmental organisations (NGOs) will be conducted, encompassing a wide range of perspectives on social, human, financial, physical, and natural capital

types. Thus, both place-specific and community-specific disadvantages, advantages, needs and potentials for sustainable development through a livelihood vulnerability assessment of Syrian refugees. This study seeks to answers these research questions are as following:

- What is the level of LVI of Syrian refugees, and what type of capitals make it more or less vulnerable?
- What dimension of vulnerability is more effective on vulnerability?
- How should planning strategies regulate the distribution and reproduction of capitals in refugee-dense areas?

2. Literature Review

Chambers and Conway (1992) define livelihood as the process of accumulating assets and resources, encompassing both material and social capital, in addition to capabilities. The Sustainable Livelihoods Approach is centred on five categories of household assets, referred to as "livelihood capitals," which encompass natural, social, financial, physical (infrastructural), and human capital assets (Chambers and Conway, 1992). Livelihood capital assets, as an essential component of the livelihood system, have the capacity to effect change in structures and processes that are subject to 'disturbances'. However, these assets may be constrained by structural transformation and social processes within the system (Quandt, 2018; Glavovic et al., 2003). The livelihood approach has been demonstrated to be particularly efficacious at the community level (Hahn et al., 2009; United Nations General Assembly, 1997). Scoones (1998) also defined natural, physical, financial, human and social capital as livelihood resources. It is hypothesised that maintaining a balance of these five capitals is essential for the sustainability of adaptive capacity and well-being (Quandt, 2018; Jacobs et al., 2015).

According to Bourdieu (1986), capital is defined as a self-sustaining force with the capacity to generate profit and the ability to reproduce itself. The structure of the distribution of capital into different types reflects the social world at a given time, revealing constraints, opportunities and the success of practices (Bourdieu, 1986). As Gkartzios et al. (2022) emphasised, the interaction between the forms of planning and forms of capital is of paramount importance. Planning has been demonstrated to play a pivotal role in both the reproduction and the deterioration of capital. In accordance with the aforementioned framework, capitals are to be classified into different categories. However, the forms of capital do not explicitly differentiate between these categories, as they are interrelated. Gkartzios et al. (2022) further draw upon the concept of spatial energy, which is predicated on the interaction of capitals.

Human Capital

Human capital refers to conditions such as good health, good nutritional conditions, ability to work, knowledge and skills. It is similar to Bourdieu's definition of cultural capital. Due to insufficient income in crowded families, the division of parental attention with children, and too many responsibilities, household size and the age of the head of the household, who is the decision-maker, are determinant in the development of human capital of generations (Rahman et al., 2018). Zhang and Fang (2020) used occupational diversity to assess human capital as formal or informal skills provide diversity in livelihood capital assets. It also has a strong relationship with economic capital by expressing the socio-economic status of individuals.

Physical Capital

Physical capital relates to the conditions of built-up areas and urban infrastructures. This type of capital refers to the proportion of built-up area, safe shelter and buildings, affordable housing and transport, energy access to information, distance to areas offering education, health and market opportunities (Rahman et al., 2018). Gkartzios et al. (2022) considered physical capital as built capital. Rahman et al. (2018) used the term manufactured to refer to physical capital.

Financial Capital

Financial capital includes savings, loans, remittances, wages, pensions, salaries, other government transfers, subsidies and monthly expenditures (Rahman et al., 2018). Economically, it refers to livelihood goals, assets and regular income (Zhang and Fang, 2020).

Natural Capital

Natural capital includes natural resources such as land services, water, soil quality, crop diversity and air. Although natural capital was not defined by Bourdieu, Gkartzios et al. (2022) used the term land-based capital to refer to stocks of natural resources. Natural capital refers to the extraction of social and economic value from natural resources and the effects of natural capital on social structure. Urban areas suffer from a lack of natural ventilation and intensive industrial activities (Aygün Oğur, 2023). This shows that land uses and their location choices, which are physical capital, can have detrimental effects on natural capital.

Social Capital

Social capital is the resources derived from institutionalised or non-institutionalised networks of relationships, connections, group memberships such as family, class, workplace or neighbourhood (Bourdieu, 1986). These connections, trust and exchange in relationships can be used to facilitate access to resources and increase resources, support and opportunities (Bourdieu, 1986). The volume of social capital depends on the size of the social network. It represents solidarity and collective action. It is the establishment of communication paths and social relations that facilitate the acquisition of power and access to capital.

As a result, there are trade-offs between types of livelihood capitals (Quandt, 2018; Obrist et al., 2010). Moreover, the trade-off between capital assets has been demonstrated to generate income, enhance capacity and promote adaptability (Rahman et al., 2018; Chambers, 1989; Scoones, 1998). The capital-based approach facilitates the incorporation of context-specific and community-specific variables associated with Syrian refugees, in addition to variables commonly utilised in vulnerability assessments.

Urban planning is concerned with the field as a social space in which people interact and compete for capital. In both theoretical and practical contexts, the concepts of planning and capital are mutually reinforcing. In circumstances where capital is distributed unequally across a given field, said field becomes a source of specific capital-related effects. The aforementioned effects include power and profit as dominant forces within the field, with the result that laws are imposed which regulate the most effective mechanisms for the reproduction of capital (Bourdieu, 1986). This statement underscores the significance of not only the presence or absence of capital, but also the equilibrium between distinct forms of capital, in determining the reproduction of capital. Planning develops convenient practices and strategies to reproduce capital and regulate its distribution. However, in doing so, planning also functions as a transformative factor by supporting the spatial energy arising from the relations between types of capital (Gkartzios et al., 2022). It is also observed that different types of capitals frequently function in coordination with one another. It is therefore vital to understand the balance or relationship between these capitals in order to develop effective planning strategies (Gkartzios et al., 2022).

Dimensions of Vulnerability

Vulnerability is a concept which can be conceptualised as comprising three dimensions or contributing factors. These are exposure, adaptive capacity, and sensitivity. These are determined by the Intergovernmental Panel on Climate Change (IPCC).

Exposure results from environmental, social and economic uncertainties or rapid changes. It is also based on governmental causes, such as civil conflicts and extreme economic fluctuations. Geographical location poses risks but reflects population density and types of habitat in an area. Duration and degree of hazards and disasters refer to climate variations including high temperatures and precipitation (Lottering et al., 2021, Feyissa et al., 2018). Human density and conflict can also result in exposure to hazards.

Sensitivity is a risk factor. It is the responsiveness of a system to changes in social, economic and climate change. It is more closely related to inadequacy and lack of resources. Groups vulnerable to change are highly sensitive or responsive to rapid changes. Sensitivity and adaptive capacity vary according to circumstances including country, society and time (Aygün and Baycan, 2018).

Adaptive capacity is the ability of a system to deal with sudden social and economic changes and the impacts of natural changes, like climate change. It depends on access to resources. Literature on climate adaptation highlights the adaptive role of capital assets (Rahman et al., 2018). A system with more adaptive capacity is less

vulnerable. Reduced adaptive capacity due to poverty, education, social norms, health-economic policies and governance can cause increased sensitivity and exposure.

Roles of Non-Governmental Organisations and Intergovernmental Agencies in Livelihood Vulnerability Reduction
In consideration of the increasing number of refugees, the role of NGOs and intergovernmental agencies in fostering bridging social capital through inter-community activities is of crucial importance. It is asserted that these activities have the potential to foster social cohesion and facilitate refugees' integration into the national system and relations with the host community (Zihnioğlu and Dalkıran, 2022). The establishment of social ties within each particular community is imperative in order to decrease livelihood vulnerability and improve social capital (Zhang and Fang, 2020). The establishment of contact is of paramount importance in the process of deconstructing prejudices and fostering a culture of coexistence. According to United Nations statistics from previous refugee crises, the perception of foreignness or otherness should be eliminated in the integration of refugees (İzmirde Suriyeli Mültecilerle Dayanışma Derneği, 2020). The social concept of inclusion is proposed in lieu of integration (İzmirde Suriyeli Mültecilerle Dayanışma Derneği, 2020). The underlying rationale for this approach is to underscore the reciprocal relationship between the host nation's citizens and the refugee population. However, significant constraints exist with regard to the integration and sustainability of relationships between refugees and host communities, including language barriers (Zihnioğlu and Dalkıran, 2022).

A bottom-up approach is imperative in advocating for the rights of vulnerable groups, including refugees, children and women. A concerted effort by local governments, academics, non-governmental organisations, and private sectors is necessary to develop strategies and policies to reduce the vulnerability of refugees (İzmirde Suriyeli Mültecilerle Dayanışma Derneği, 2020). The government, as the primary policy maker, has a significant influence in reducing the vulnerability experienced by refugees. The government is responsible for the equitable distribution of aid to both the host and refugee communities. However, the collaboration between the government and non-governmental organisations is also crucial in order to achieve this objective.

All NGOs and official intergovernmental agencies, such as the UN, play vital roles in supporting populations worldwide. They work in many areas, including development, population planning, access to human rights, poverty reduction, health, education and crisis response, to address the refugee crisis and reduce the vulnerability of vulnerable groups. In particular this study, the UNHCR states that the Konak district of Izmir works with 10 implementing partners and 10 supporting agencies for Syrian refugees.

3. Based on Community and Context Scope of the Study

3.1. Vulnerable Group

This study aims to evaluate the effects of the refugee crisis based on livelihoods of Syrian refugees in the Konak district. Since 2011, Türkiye has hosted around 7 million Syrians, including returnees and those settled in third countries (UNHCR, 2024). According to data from the General Directorate of Migration Management (n.d.), with the end of the Syrian civil war and the start of returns, the number of Syrians under temporary protection is approximately 2.8 million in Türkiye and 111,374 in Izmir as of 10 April 2025. Izmir is the ninth city in Türkiye with the largest Syrian population and is defined as an ancient city of migration, having been a transit or destination city for migrants throughout history (Kurtarır et al., 2023). In this study, Syrians will be referred to as refugees due to their mass forced displacement and social circumstances. Historically, civil wars and tensions following the Second World War led to a refugee crisis in Europe.

Subsequently, Türkiye signed the 1951 Geneva Convention, the first international legal instrument to define refugee status and the obligations of states. However, Türkiye only granted refugee status to those coming from Europe (Al Munajed and Ekren, 2020; Chatty, 2016). Syrians do not fit the geographical definition of refugee. Therefore, they are granted temporary protection status. This status is a practical, complementary solution developed to provide urgent responses to mass migration events. It is applied within the framework of states' obligations to prevent individuals from being returned to situations of risk, thereby avoiding delays to the individual assessment of their international protection status (General Directorate of Migration Management, n.d.). Although Syrians in Türkiye are not legally recognised as refugees, they experience the social conditions associated with refugee status without being subject to geographical restrictions. However, since social recognition does not

include legal recognition, they do not have the same legal rights as refugees (Yükseker, Kurtuluş, Tekin and Kaya Erdoğan, 2023). Syrian refugees are a powerless group due to their lack of capital. They develop spatial strategies to increase their capital and maintain their presence in the city. Consequently, the role of immigrant communities in producing space, and the way they express the social logic of space, are important factors in spatial development.

3.2. Study Area

The geographical area selected for the study is the most commonly known as Basmane, Agora and Kadifekale neighbourhoods of Konak District, which is one of the districts with the highest refugee density in Izmir (Figure 1). Actually, the study area covers 22 neighbourhoods in Basmane Region in Konak: Alireis, Süvari, Faikpaşa, Yeni, Tuzcu, Ülkü, Altay, Kadifekale, Etiler, Ballıkuyu, Akarcalı, Kocakapı, Mirali, Kubilay, Pazaryeri, Sakarya, Kurtuluş, Altınordu, Yenigün, Hurşidiye, Akıncı and Namazgah. With the exception of Tuzcu, Ülkü, Ballıkuyu, Kurtuluş, Yenigün, Hurşidiye and Akıncı, all other neighbourhoods in the study area are closed to foreigners under temporary protection or international protection due to the high proportion of foreigners (Presidency of Migration Management, 2022). Due to its geographical location, the study area functions as a transit city or a destination city for numerous refugees, beyond those fleeing Syria. However, the fact that Izmir is a transit point to Europe for many refugees is one of the important factors for them to come here. In this study, spatial analyses will be conducted throughout Konak district, while qualitative analyses will focus on Basmane district, where a high concentration of Syrian refugees has been recorded. Konak district has an ageing population, with a persistent decline in population and an increase in the average age. It is important to note that, whilst all other districts in Izmir have experienced population growth, Konak district has undergone a decline. This highlights the need for a review.

According to the Avcan study (2024), the biggest population loss in the period 2009-2023 is -40.75% in the region called Kadifekale and -36.80% in the region called Basmane. These regions include neighbourhoods covered by the study. It is also emphasised that these neighbourhoods are the most socio-economically undeveloped and have a high population of migrants, refugees and asylum seekers.

The Basmane district is one of the most deprived areas in the city centre, characterised by poor physical conditions, inadequate infrastructure and social insecurity. Consequently, it provides affordable housing and facilitates access for a significant number of economically disadvantaged migrants and refugees, thereby enabling them to establish themselves in the community and cultivate social networks. In addition to the aforementioned points, it is important to note that employment opportunities are also available in and around Basmane in a variety of sectors. These sectors include, but are not limited to, the textile industry, the wedding and fashion industries, and the leather industry. The Kemeraltı Historical Bazaar, archaeological sites such as Agora and Kadifekale, hotels, restaurants and other shopping venues also serve tourism, bringing vitality and mobility to the study area (Oner et al., 2020).

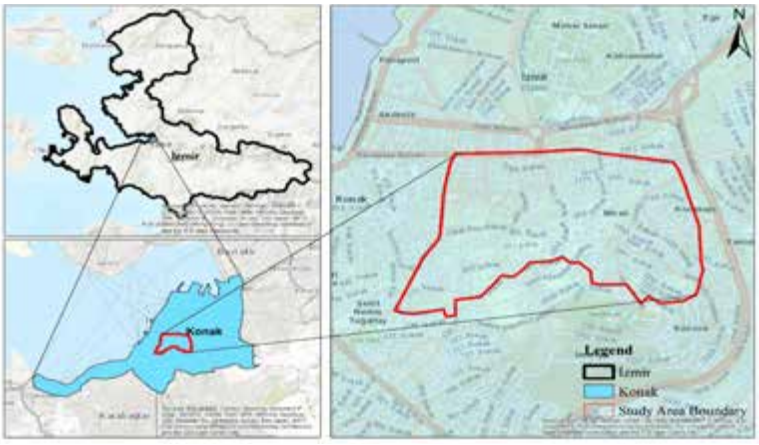

Figure 1: Study Area

4. Data and Method

A mixed method was employed by including both qualitative and quantitative analyses to maximise the reliability of the research. The capital-based livelihood approach is based on five types of capital: human, social, financial, physical and natural. Syrian refugees were selected as a vulnerable group due to the difficulties they face as a result of the Syrian Civil War and forced displacement. The literature review, field visits, discussions with vulnerable Syrian refugees, and in-depth interviews with non-governmental organisations, and household surveys were employed in order to grasp their needs, perspectives, and experiences. The study primarily relied on data derived from household surveys exploring or gaining a more nuanced understanding of complex issues related to livelihood vulnerability.

The employment of a mixed-method approach in the present study will facilitate a more nuanced interpretation of the quantitative and qualitative analyses, thereby enhancing the study's validity and its ability to discern similarities and differences in terms of the vulnerability of livelihood capitals. The determination of vulnerability variables was informed by a comprehensive literature review and insights from civil society organisations engaged in work with Syrian refugees.

First of all, based on previous studies of vulnerability indices such as refugee vulnerability, social vulnerability, and livelihood vulnerability, seventeen indicators and seventy-two variables have been selected. The seventeen indicators, which include the following variables, are: family structure; age; gender; education; employment; occupation; socio-economic status; housing tenure (ownership); livelihood strategies; minority/language; health; food; settlement/infrastructure; social safety; population growth; climatic variability; and hazards (natural and human). The table below shows the indicators and relevant variables used, how these variables affect vulnerability, and the relevant references (Table 1).

Table 1: Selection and Rationales for LVI Indicators of Syrian Refugees for Basmane Region

Indicators	Variables	Effect on Vulnerability	Justification
Family Structure	percentage of large families (more than 6 members)	increases	Arab Water Council and World Food Programme (2022), Mukherjee and Siddique (2020), Rahman et al. (2018), Frigerio et al. (2018)
	percentage of single parent households	increases	Arab Water Council and World Food Programme (2022), Lottering et al. (2021), Berchouxa and Hutton (2019)
	percentage of households with orphans	increases	Hahn et al. (2009)
	percentage of households with positive change in women's role/position in family after arrival in Türkiye	decreases	developed within the scope of research
Age	percentage of age 65+ in a household percentage of age ≤ 5 in a household number of children in a household	increases	Gerçek and Güven (2023), Mitra and Kumar Mandal (2023), Arab Water Council and World Food Programme (2022), Lottering et al. (2021), Fucile-Sanchez and Davlasheridze (2020), Zhang and Fang (2020), Frigerio et al. (2018), Duman Yuksel (2014)
	percentage of age of household head < 18 or > 65	increases	Arab Water Council and World Food Programme (2022), Rahman et al. (2018)

Gender	percentage of women in a household	increases	Gerçek and Güven (2023), Mitra and Kumar Mandal (2023), Fucile-Sanchez and Davlasheridze (2020)
	percentage of female-headed households	increases	Gerçek and Güven (2023), Mitra and Kumar Mandal (2023), Arab Water Council and World Food Programme (2022), Lottering et al. (2021), Fucile-Sanchez and Davlasheridze (2020), Mukherjee and Siddique (2020), Hahn et al. (2009)
Education	percentage of households with less than high school education	increases	Mitra and Kumar Mandal (2023), Arab Water Council and World Food Programme (2022), Lottering et al. (2021), Fucile-Sanchez and Davlasheridze (2020), Zhang and Fang (2020), Quandt (2018), Frigerio et al. (2018)
	percentage of households who participate in vocational training	decreases	Zhang and Fang (2020)
	percentage of households who can not afford education expenses	increases	developed within the scope of research
Employment	percentage of unemployed family members	increases	Arab Water Council and World Food Programme (2022), Fucile-Sanchez and Davlasheridze (2020), Frigerio et al. (2018)
	percentage of employed women	decreases	Berchouxa and Hutton (2019), Frigerio et al. (2018)
	percentage of employed children (age < 15)	increases	developed within the scope of research
	percentage of households who have a work permit	decreases	developed within the scope of research
Occupation	percentage of households with weather-exposed workers (agriculture, forestry, fishing, and hunting; mining; construction; manufacturing; and transportation and utilities)	increases	EPA (2021), Graff Ziven and Neidell (2014)
Socio-economic Status	percentage of households where members had any formal or informal skill	high decreases; low increases	Mitra and Kumar Mandal (2023), Arab Water Council and World Food Programme (2022)
	per household income monthly	high decreases; low increases	Arab Water Council and World Food Programme (2022), Rahman et al. (2018)
	percentage of households owning private or permanent land in any location that is usually used as a dwelling	decreases	Rahman et al. (2018)
	percentage of households with no vehicle	increases	Fucile-Sanchez and Davlasheridze (2020)
	percentage of households using technological devices (fridge, electric heater, fan, washing machine, computer)	decreases	developed within the scope of research
	housing quality (comfortable living conditions (e.g. indoor plumbing, and hot showers) (scale of good to bad)	**good** decreases; bad increases	Zhang and Fang (2020)
Housing Tenure (ownership)	percentage of renter households	increases	Arab Water Council and World Food Programme (2022), Fucile-Sanchez and Davlasheridze (2020), Quandt (2018)

Livelihood Strategies	percentage of earning member in a household	high decreases; low increases	developed within the scope of research
	percentage of households with members working for the government	decreases	Zhang and Fang (2020)
	percentage of households who took loan in the past 5 years	increases	Mitra and Kumar Mandal (2023), Zhang and Fang (2020)
	percentage of households that reported at least one family member worked outside the community to earn a wage	decreases	Mitra and Kumar Mandal (2023), Mukherjee and Siddique (2020), Hahn et al. (2009)
Minority/Language	language proficiency	**good** decreases; bad increases	developed within the scope of research
	percentage of households who participate in language course	decreases	developed within the scope of research
	percentage of households who have language problems with their children	increases	developed within the scope of research
	years when refugees are in Türkiye	high decreases; low increases	developed within the scope of research
	percentage of households who have a residence permit	decreases	developed within the scope of research
Health	percentage of households registered another province (in this case, they do not benefit from health services)	increases	developed within the scope of research
	percentage of households with chronically health difficulties	increases	Mitra and Kumar Mandal (2023), Mukherjee and Siddique (2020), Hahn et al. (2009)
	percentage of households with disabled people	increases	Mitra and Kumar Mandal (2023)
	percentage of households who not visiting doctors during illness	increases	Mukherjee and Siddique (2020)
	percentage of households who cannot afford medical expenses	increases	Zhang and Fang (2020)
Food	average number of months households struggle to obtain food for their family	increases	Mitra and Kumar Mandal (2023), Hahn et al. (2009)
	distance to market	high increases; low decreases	Zhang and Fang (2020)

Settlement/ Infrastructure	access to evacuation routes and/or assembly areas	decreases	Gerçek and Güven (2023)
	normal and rainy season road conditions (scale of good to bad)	**good** decreases; bad increases	Quandt (2018)
	percentage of households using the Internet	decreases	Mukherjee and Siddique (2020)
	percentage of households using unsafe water for drinking, cooking, bathing and washing	increases	Zhang and Fang (2020), Mukherjee and Siddique (2020)
	percentage of households who do not have toilet facilities	increases	Mitra and Kumar Mandal (2023), Mukherjee and Siddique (2020)
	distance to medical establishments and services	high increases; low decreases	Mitra and Kumar Mandal (2023), Arab Water Council and World Food Programme (2022), Mukherjee and Siddique (2020), Quandt (2018), Hahn et al. (2009)
	distance to schools	high increases; low decreases	Quandt (2018)
	percentage of households who cannot afford transportation expenses	increases	developed within the scope of research
	built-up area rate	increases	Frigerio et al. (2018)
	the amount of open and green areas per capita	decreases	Aygün and Baycan (2018)
Social Safety	percentage of households without access to information on health systems (getting disability report, appointment system, or language assistance)	increases	developed within the scope of research
	percentage of households who participate in adaptation events	decreases	Quandt (2018)
	percentage of households aware of vulnerabilities of the becoming refugee (e.g. social exclusion)	decreases	developed within the scope of research
	relationship with Turkish neighbours (scale of strength to weak)	**strength** decreases; weak increases	Quandt (2018)
	percentage of households with difficulty accessing daily information	increases	Zhang and Fang (2020)
	percentage of households who do not get awareness of hazards	increases	Mitra and Kumar Mandal (2023), Mukherjee and Siddique (2020)
	percentage of households who have opportunities to work outside the community using personal networks	high decreases; low increases	Rahman et al. (2018)
	percentage of households who receive assistance from a social network and other sources (NGOs) in the last 5 years	decreases	Mitra and Kumar Mandal (2023), Zhang and Fang (2020), Mukherjee and Siddique (2020), Hahn et al. (2009)
	percentage of households who do not receive assistance from the Government in the last 5 years	increases	Mitra and Kumar Mandal (2023), Fucile-Sanchez and Davlasheridze (2020), Zhang and Fang (2020), Mukherjee and Siddique (2020), Hahn et al. (2009)
Population Growth	average annual growth rate of refugee population	high increases; low decreases	Arab Water Council and World Food Programme (2022), Duman Yuksel (2014)

Climatic Variability	percentage of households reporting changes in livelihood due to climate change	increases	Mitra and Kumar Mandal (2023)
	both summer and winter temperature change (%) in the last 10 years	increases	Mitra and Kumar Mandal (2023), Duman Yuksel (2014)
	both summer and winter precipitation change (%) in the last 10 years	increases	Mitra and Kumar Mandal (2023), Duman Yuksel (2014)
Hazards	percentage of households exposed to increased frequency and intensity of natural hazards (inland floods or heat waves) in the last 10 years	increases	Mitra and Kumar Mandal (2023), Mukherjee and Siddique (2020), Hahn et al. (2009)
	percentage of households who have members injured or died as a result from human-induced hazards in the last 10 years	increases	developed within the scope of research
	percentage of households who have members injured or died as a result from natural hazards in the last 10 years	increases	Zhang and Fang (2020), Mukherjee and Siddique (2020), Hahn et al. (2009)
	percentage of households that have experienced damage to their property	increases	Mukherjee and Siddique (2020)
	percentage of households that have experienced a loss of their property	increases	Zhang and Fang (2020), Mukherjee and Siddique (2020)
	percentage of households that did not receive a warning about the pending natural disasters	increases	Mitra and Kumar Mandal (2023), Lottering et al. (2021), Mukherjee and Siddique (2020) Hahn et al. (2009)
	percentage of households who know how to turn off the installations in your home after any disaster	decreases	Demirci (2021)
	average air quality values of PM_{10}, $PM_{2.5}$, SO_2, NO_2 in the last 5 years	high increases; low decreases	Duman Yuksel (2014)

The following table illustrates the indicators according to the vulnerability dimensions (Table 2).

Table 2: Indicators by IPCC contributing factors to vulnerability

IPCC contributing factors to vulnerability	**Indicators**
Exposure	Occupation
	Population Growth

	Social Safety

A livelihood assessment matrix was created by placing the relevant variables in the matrix with vulnerability dimensions on the horizontal and livelihood capitals on the vertical (Table 3). The variables were categorised under five types of livelihood capital (human, physical, financial, social, natural), and under three contributing factors to vulnerability.

Table 3: Variables by Livelihood Capitals and Vulnerability Dimension

Livelihood Capitals Dimensions of Vulnerability	Exposure	Sensitivity	Adaptive Capacity
Human Capital	**12.** percentage of households with weather-exposed workers (agriculture, forestry, fishing, and hunting; mining; construction; manufacturing; and transportation and utilities)	**1.** percentage of large families (more than 6 members)	**10.** percentage of households with less than high school education
	25. percentage of households who have members injured or died as a result from human-induced hazards in the last 10 years	**2.** percentage of age 65+ in a household	**11.** percentage of households where members had any formal or informal skill
	26. percentage of households who have members injured or died as a result from natural hazards in the last 10 years	**3.** percentage of age ≤ 5 in a household	**13.** percentage of unemployed family members
		4. number of children in a household	**14.** percentage of employed women
		5. percentage of women in a household	**15.** percentage of employed children (age < 15)
		6. percentage of female-headed households	**16.** percentage of households who have a work permit
		7. percentage of age of household head < 18 or > 65	**17.** language proficiency

Human Capital		**8.** percentage of single parent households	**18.** percentage of households who participate in language course
		9. percentage of households with orphans	**19.** percentage of households who participate in vocational training
		20. percentage of households registered another province (in this case, they do not benefit from health services)	**24.** percentage of households who do not get awareness of hazards
		21. percentage of households with chronically health difficulties	**27.** percentage of households who know how to turn off the installations in your home after any disaster
		22. percentage of households with disabled people	
		23. percentage of households who not visiting doctors during illness	
Physical Capital	**4.** housing quality (comfortable living conditions (e.g. indoor plumbing, and hot showers) (scale of good to bad)	**2.** percentage of households using unsafe water for drinking, cooking, bathing and washing	**1.** percentage of households using the Internet
	10. percentage of households that did not receive a warning about the pending natural disasters	**3.** percentage of households who do not have toilet facilities	**5.** distance to medical establishments and services
	11. built-up area rate	**9.** normal and rainy season road conditions (scale of good to bad)	**6.** distance to schools
			7. distance to market
			8. access to evacuation routes and/or assembly areas
Financial Capital	**13.** percentage of households reporting changes in livelihood due to climate change	**2.** per household income monthly	**1.** percentage of earning member in a household
	14. percentage of households that have experienced damage to their property	**5.** percentage of households who cannot afford medical expenses	**3.** percentage of households who took loan in the past 5 years
	15. percentage of households that have experienced a loss of their property	**6.** percentage of households who cannot afford education expenses	**4.** percentage of households that reported at least one family member worked outside the community to earn a wage
		7. percentage of households who cannot afford transportation expenses	**8.** percentage of renter households
		12. average number of months households struggle to obtain food for their family	**9.** percentage of households owning private or permanent land in any location that is usually used as a dwelling
			10. percentage of households with no vehicle
			11. percentage of households using technological devices (fridge, electric heater, fan, washing machine, computer)
			16. percentage of households who receive assistance from a social network and other sources (NGOs) in the last 5 years
			17. percentage of households who do not receive assistance from the Government in the last 5 years

Social Capital	**12.** average annual growth rate of refugee population		**1.** years when refugees are in Türkiye
			2. percentage of households with members working for the government
			3. percentage of households who have opportunities to work outside the community using personal networks
			4. percentage of households who have language problems with their children
			5. percentage of households who participate in adaptation events
			6. percentage of households who have a residence permit
			7. percentage of households without access to information on health systems (getting disability report, appointment system, or language assistance)
			8. percentage of households aware of vulnerabilities of the becoming refugee (e.g. social exclusion)
			9. percentage of households with positive change in women's role/position in family after arrival in Türkiye
			10. relationship with Turkish neighbours (scale of strength to weak)
			11. percentage of households with difficulty accessing daily information
Natural Capital	**1.** percentage of households exposed to increased frequency and intensity of natural hazards (inland floods or heat waves) in the last 10 years		**5.** the amount of open and green areas per capita
	2. both summer and winter temperature change (%) in the last 10 years		
	3. both summer and winter precipitation change (%) in the last 10 years **4.** average air quality values of PM_{10}, $PM_{2.5}$, SO_2, NO_2 in the last 5 years		

Household survey comprising 63 questions used to obtain primary data on Syrian refugees. The survey was conducted in Turkish and Arabic with 250 Syrian household representatives. Snowball method was used to identify participant households. In some regions, a household survey was conducted through random selection and then continued with the snowballing technique.

Secondly, in the qualitative method, livelihood vulnerability was explored through in-depth interviews with both Syrian refugees and NGOs. In the collection of data from Syrian interviewees, snowball method was used to facilitate the identification of the interviewees. The interviews averaged about 10-20 minutes in length. In order to explore the role of NGOs and intergovernmental organisations in reducing livelihood vulnerability, in-depth interviews were conducted with relevant parties. A series of semi-structured in-depth interviews were conducted with eight representatives or managers of organisations or associations related to refugees.

The interviews, comprising a total of 14 questions, were conducted in the workplace of non-governmental organisations. The duration of each interview was between 20 and 50 minutes. The fact that the majority of these organisations working with refugees are in close contact with refugees, as most of them are located in the field of work, provides direction to the study. The interviewed NGOs provided information about their activities and

their perspectives on the problems, needs and potential of refugees. The assessment of why Syrians choose the Basmane, Kadifekale, Agora and around and their social and economic relations, which will inform the spatial structure, is based on the results of interviews with Syrian refugees. Representatives or leaders of associations and networks on refugees were interviewed to assess social inclusion and integration policies from the perspective of the host country and refugee beneficiaries.

4.1. Creating Livelihood Vulnerability Index

The maximum and minimum values for these variables, based on community characteristics, were determined using the dataset resulting from a survey of 250 households. The normalisation of values measured on different scales is necessary to resolve incompatibility and imbalanced weighing (Gerçek and Güven, 2023). The min-max method was employed for data normalisation of all values, which provides dimensionless range between 0 and 1 (Ajtai et al., 2023) (please see Table A1). The normalization is conducted using Equation (1) for variables positively related to vulnerability, and Equation (2) for variables negatively related to vulnerability.

$$index\ V_{(positively)} = \frac{v - vmin}{vmax - vmin} \quad (1)$$

$$index\ V_{(negatively)} = \frac{vmax - v}{vmax - vmin} \quad (2)$$

where V is the normalized value of the variable, v is the original (raw) value of the variable, vmin and vmax are the minimum and maximum values, respectively, for each variable, and V [0, 1].

The related variables were averaged using Equation (3) in order to calculate the value of each indicator (please see Table A2).

$$Indicator = \frac{\sum_{i=1}^{n} index\ V_i}{n} \quad (3)$$

The calculation of livelihood capital specific vulnerability value will be adapted above formula with capital related variables. The same process was followed to calculate the capital-based values (4).

$$Livelihood\ Capital = \frac{\sum_{i=1}^{n} index\ V_i}{n} \quad (4)$$

Equation (5) demonstrates overall LVI calculation. The weights are included that all variables contribute equally to the overall LVI (Hahn et al., 2009; Sullivan et al., 2002). In this study, LVI is scaled from 0 (least vulnerable) to 0.60 (most vulnerable).

$$LVI = \frac{\sum_{i=1}^{5} w_{livelihoodcapital\ i}\ Livelihoodcapital_i}{\sum_{i=1}^{5} w_{livelihoodcapital\ i}} \quad (5)$$

To find LVI-IPCC, firstly values are calculated through Equation (6) for each vulnerability dimension or contribution factor to vulnerability. Then, Equation (7) presents LVI-IPCC.

$$CF = \frac{\sum_{i=1}^{n} w_{livelihoodcapital\ i}\ Livelihoodcapital_i}{\sum_{i=1}^{n} w_{livelihoodcapital\ i}} \quad (6)$$

where CF is an IPCC-defined contributing factor to vulnerability (exposure, sensitivity, or adaptive capacity), Livelihoodcapitali are the five types of the livelihood capital indexed by i, wlivelihoodcapital i the weights of each livelihood capital, and n is the number of livelihood capitals in each contributing factor.

$$LVI - IPCC = (e - a) * s \quad (7)$$

where LVI-IPCC represents LVI based on IPCC vulnerability framework, e represents computed score of exposure, a represents computed score of adaptive capacity, and s represents computed score of sensitivity. The LVI-IPCC scale varies between - 1 (least vulnerable) to 1 (most vulnerable) (Table 4).

Table 4: Levels of Livelihood Vulnerability for This Study arranged from (Islam and Ghosh, 2024) based on the IPCC (2007) and Hahn et al. (2009)

LVI	Range	LVI-IPCC	Range
Not vulnerable	0 - 0.20	Very less	(-1) - (-0.61)
Vulnerable	0.21 - 0.40	Less	(-0.60) - (-0.20)
Highly vulnerable	0.41 - 0.60	Moderate	(-0.19) - 0.20
		High	0.21 - 0.60
		Very high	0.61 - 1

5. Results

A total of 250 household surveys were carried out. The resulting data set comprised 1,373 Syrian refugees, with an average stay of 10 years in Türkiye. 49% of Syrian refugees are women. The average family size is 5.5, with the largest family consisting of 15 individuals. Family size refers to the number of people who sleep and eat in a household. 51% of Syrian refugees are under 18, while the family with the most children has 9 children. Language is a barrier for Syrian refugees, which is assessed by language proficiency. While 30% of Syrian refugees stated that their language proficiency is good, 60% chose intermediate proficiency. Among those who chose this level, some cited the presence of Turkish and non-Turkish speakers. Another variable is Syrian refugees' occupations or the sectors they work in. According to the household survey, the top 5 occupations (Figure) are textile manufacturer (33%), construction worker (19%), recycling employee (10%), tailor (5%) and repairman (5%), respectively. It is clear that Syrian refugees work most in textiles. 4% of the Syrian households stated that they were not registered in Izmir, although they had difficulty answering due to their hesitation.

As illustrated in Table 5, the table demonstrated the contribution value of each indicator to livelihood vulnerability. The indicator indices range from 0, representing no contribution to vulnerability, to 1, representing the maximum contribution to vulnerability. In the exposure factor, the highest value is attributed to both occupation and hazards.

In relation to sensitivity dimension of vulnerability, it has been demonstrated that food is the principal factor in the enhancement of livelihood vulnerability.

It is evident that the factor of adaptive capacity, which is a contributing element to vulnerability, is a highly effective measure in the context of livelihood vulnerability.

Table 5: Indices of IPCC contributing factors to vulnerability

IPCC contributing factors to vulnerability	Indicators	Indices of Indicators
Exposure	Occupation	**0.47**
	Hazards	**0.47**
	Climatic Variability	**0.41**
	Population Growth	**0.23**
Sensitivity	Food	**0.54**
	Gender	**0.33**
	Family Structure	**0.32**
	Health	**0.28**
	Age	**0.15**
Adaptive Capacity	Housing Tenure (ownership)	**1.00**
	Education	**0.78**
	Livelihood Strategies	**0.68**
	Socio-economic Status	**0.59**
	Minority/Language	**0.58**
	Settlement/Infrastructure	**0.51**
	Social Safety	**0.49**
	Employment	**0.46**

Human Capital of Syrian Refugees

The present study examines human capital through indicators of gender, age, family structure, health, education, socio-economic status, minority/language, occupation, employment, and awareness of hazards, losses related to hazards, and social safety. The importance of human capital lies in its role in the reproduction of social and financial capital, as well as the acquisition of advantages. This highlights that Syrian household have a large family and increasing demands for livelihoods, children are forced to work and are falling behind in their education. Also, Association of Konak Refugee - Konak Refugee Centre said that:

> "Most Syrians have completed primary school and there is a problem with enrolment in education. There are working children."

Furthermore, the lower socioeconomic status that characteristically typifies single-parent households renders them particularly susceptible to disaster. This is due to the fact that the responsibility for daily care and education of children is shouldered exclusively by the parent. In response to the question regarding the most vulnerable demographic, a Syrian woman whose husband had emigrated abroad provided the following answer:

> "People without a spouse, fatherless children and disabled people are in dire need."

Human capital has 0.44 exposure value, whereas 0.21 sensitivity value. Adaptive capacity with value of 0.41 helps to decrease livelihood vulnerability.

Physical Capital of Syrian Refugees

Physical capital refers to tangible infrastructure and urban services. The Syrian refugee

Considering the physical structure of the Basmane Region where Syrian refugees live, the study area has a high rate of built-up area, poor infrastructure, a lack of open and green spaces, which may allow to residents' physical, psychological and social amenities to the residents, and in some places, an excessive distance to school. These are interpreted as a lack of human and social capital due to capital relations, indicating that the study area is facing the challenge of being a deprived place that lacks the means and capacity to cope with economic struggles.

An Anonymous Nongovernmental Organization in Basmane District explained circumstances of the study area as follow:

> "There are many people of both Syrian and African nationalities. The number of roads that can be accessed by vehicle is fewer, surveillance and control are limited and low, and they can hide easily. There are many irregular migrants in this area. There are illegal workers, sex workers and laboured children. ***The vulnerability caused makes them more vulnerable.*** For example, it is difficult for a disabled Syrian living in there..."

Association for Monitoring Equal Rights expressed their insights about municipal services in the study area:

> "If there is a building stock in a region, it should be within the framework of the municipal services, there should be planning including transport, playgrounds, public spaces should be for women and children. The municipality withdraws itself to avoid being close to the Syrians. The growing hatred towards them has led to the withdrawal of the services provided by the municipality."

Lack of physical capital increases their exposure level to disasters. Therefore, natural hazards can cause disaster for people due to lack of physical capital. Syrian respondents mentioned the most common disasters they have experienced in the household survey. These include flooding, leaking toilets, water leaking from the roof and no electricity. This is due to building conditions and infrastructure deficiencies in the Basmane Region. Most Syrian households live in poor physical conditions. Many share a single dwelling, which may adversely affect the progress and consequences of a possible disaster.

According to index results, the exposure, sensitivity and adaptive capacity values of physical capital are 0.65, 0.32 and 0.48, respectively.

Financial Capital of Syrian Refugees
Households in Syria have suffered financial losses as a result of the ongoing conflict. During the course of the household survey, 73% of respondents indicated that they had been dispossessed of their houses, workplaces and vehicles. The provision of financial assistance to refugees is typically facilitated by government entities or family members. Syrian households have reported the provision of material and social support from relatives, neighbours and NGOs.

Additionally, they receive assistance from non-governmental organisations in the form of rights, such as education and healthcare. Moreover, access to employment opportunities is facilitated through language and vocational courses provided by NGOs. The Konak Refugee Centre has asserted that the absence of financial capital exacerbates the vulnerability of Syrian refugees, as articulated in the following statements:

> "Economic conditions are the most decisive factor, the most influential factor on everything. If there is a regular flow of money, you will feel comfortable both psychologically and in terms of access to your needs."

In the context of the dimensions under consideration, the value of exposure is identified as the highest, with a value of 0.58. It is evident that the value of adaptive capacity is 0.39, which has the effect of reducing livelihood vulnerability.

The variable pertaining to the percentage of households that have experienced damage to their property has a value of 0.77. The variables that contributed most significantly to enhancing adaptive capacity were as follows: the percentage of households that had previously taken out a loan within the last five years, and the percentage

of households that used technological devices. The value of the contribution was 0.95.

Social Capital of Syrian Refugees
Social capital is defined as connections with both internal and external parties at local and global levels. Furthermore, it was related to the social environment, which shapes the cognitive capacities of communities.

The subject, a 25-year-old female, articulated her experiences and challenges in her social environment and in her daily life as follows:

> "Sometimes I'm afraid for my children. I want to go out. If I were Turkish, I would not have to go through this. The salary is not enough. My landlord behaves very badly. I cannot answer. I keep quiet so that my children will not be harmed. The thing I want most is to get out of this house."

Moreover, Association of Konak Refugee - Konak Refugee Centre stated power of thinking of Syrian refugees in this way:

> "Their power of thinking is shaped by social environment. In the process, they spontaneously learn culture and education. In addition, the social environment has a great influence on behaviour. For example, tensions between both foreigner and domestic people in need rise when the person in need cannot get what they need."

Besides to social challenges, Syrian refugees have strong relationship with Turkish neighbours, and (Man, 18) stated this as follows:

> "I have no problem with the Turks. I am sincere with my Turkish customers, there is no discrimination."

(Man, 60) emphasised a different dimension for the relations between refugees and host communities:

> "Solidarity among Syrians may hinder their integration with Turks."

The percentage of households with positive change in women's role/position in family after arrival in Türkiye measures human agency and the power of thinking of Syrian refugees. This reveals the consequences of their habitus. Association of Solidarity with Syrian Refugees in Izmir highlighted the positive change in roles or position of Syrian women in the family after coming to Türkiye.

> "There has been a notable shift in their understanding, thoughts, attitudes, and roles. Women have changed in a positive way; they do not stay closed. Especially, 80 % of women in Halep do not go out of the house. Women can now go out alone because of the difficulties and needs of life. They help their families by carrying out tasks such as shopping, paying bills and going to hospital."

In addition to above statement, Syrian interviewee (Woman, 29) expressed the changing and developing structure of thought in terms of women after coming to Türkiye as follows:

> "Women in Syria are very limited. We cannot even go to the shops because of the shame. Former Syrians are very restrictive. We get married at a very young age. But you need to go to school, you need to learn a profession, I learned these things in Türkiye."

In the Basmane region, Çorakkapı Mosque, Hatuniye Mosque and Hatuniye Square, Anafartalar Street and Agora Park are areas where Syrian refugees socialise and engage with members of the local community. These spaces offer them the opportunity to rest, meet and shop, and communicate with the host community, but this contact is limited due to the density of refugees.

The exposure level is low with a value of 0.23 and the adaptive capacity of social capital is high with a value of 0.51.

Natural Capital of Syrian Refugees
Natural and physical capital affect each other. The study area, in Konak District of Izmir, is one of the oldest settle-

ments in the region. It is characterised by a high concentration of built-up area and urban infrastructure that is both old and poor-maintained. The primary challenges faced by the district include high population density, the presence of an unregistered population resulting in an uncertain demographic profile, and a severe lack of green and open spaces. High population density triggers human-induced air pollution. These issues have a detrimental effect on air quality. Furthermore, The findings indicate that the extent of open and green space per capita exerts an increasing influence on vulnerability, as evidenced by its negligible effect on the development of adaptive capacity, with a value of 0.22. The exposure level, as determined by 0.48 in terms of natural capital, is influenced by increased frequency and intensity of natural disasters, temperature and precipitation variation, and air quality values. Lastly, 47% of Syrian households have workers exposed to the weather, with temperature and precipitation variation having a significant impact. 32% of households have experienced increased natural hazards in the last 10 years. During surveys, respondents provided information on disaster experiences.

Finally, as demonstrated in Table 6, exposure is the most significant contributing factor to livelihood vulnerability, with a value of 0.50. Conversely, sensitivity is the least significant contributing factor, with a value of 0.31. Nevertheless, it is crucial to acknowledge the sensitivity multiplier effect on LVI-IPCC identification, as this value has the potential to exacerbate livelihood vulnerability. The Syrian refugee population has been found to demonstrate an adaptive capacity of 0.44. Moreover, findings indicate that physical, financial and natural capitals are the most effective in increasing livelihood vulnerability. Conversely, the possession of social capital has been demonstrated to contribute to the reduction of livelihood vulnerability through the enhancement of adaptive capacity. The study emphasised that Syrian refugees demonstrated notable social resilience and adaptability to change.

Table 6: Capital Specific and Overall Values of Vulnerability Dimensions

Livelihood Capitals	Exposure	Sensitivity	Adaptive Capacity
Human Capital	0.44	0.21	0.41
Physical Capital	0.65	0.32	0.48
Financial Capital	0.58	0.55	0.39
Social Capital	0.23		0.51
Natural Capital	0.48		0.22
Overall	**0.50**	**0.31**	**0.44**

The table compares LVI and LVI-IPCC values of each capital (Table 7). Human capital is found to be in a vulnerable position, whereas other capitals have high vulnerability level of livelihood vulnerability.

LVI is 0.48, indicating high livelihood vulnerability. Social capital is less vulnerable, while human, physical and financial capitals are moderately vulnerable, and natural capital is highly vulnerable. Overall LVI-IPCC is 0.02, indicating moderate livelihood vulnerability.

Table 7: Comparing Capital Specific and Overall Values of LVI and LVI-IPCC

Livelihood Capitals	LVI-Capital based*	LVI-IPCC
Human Capital	0.39	0.01
Physical Capital	0.50	0.06
Financial Capital	0.59	0.10
Social Capital	0.46	-0.29
Natural Capital	0.51	0.26
Overall	**0.48**	**0.02**
Reference range*	0 < LVI < 0.60	
Reference range	-1 < LVI-IPCC < 1	

6. Discussion

The concept of livelihood capitals encompasses the physical, natural, social, human and financial dimensions of communities. It introduces strategies and policies that address the absence, deficiencies and assets of these capitals within the context of urban planning. Despite the existence of numerous international literature studies on LVI, no studies have been found in Türkiye. The present study draws chiefly upon the research conducted by Pandey et al. (2017) and Zhang and Fang (2020) with regard to capital-based implementation. In this study, the assessment of livelihood vulnerability was conducted through the utilisation of a multifaceted approach, encompassing five distinct types of capital. An investigation was conducted into each type of capital, with particular reference to exposure, sensitivity and adaptive capacity. In addition to calculating overall livelihood vulnerability values, this study calculates both capital-specific LVI and LVI-IPCC based on capital-specific vulnerability dimensions. This approach facilitates the formulation of strategies and policies that are tailored to the specific livelihood vulnerabilities of each capital and each dimension of vulnerability. This study is therefore useful in reducing the increasing divergence in favour of vulnerability in dimensions of vulnerability, such as high levels of exposure or sensitivity and low adaptive capacity, and imbalances among types of capital and the distribution and reproduction of capital assets. In a similar vein, Rahman et al. (2018) employed varied methodologies for the organisation and combination of livelihood capital assets. This study uses more indicators (17) and variables (72) than other LVI studies. Also, compared to both similar and different studies in terms of different contexts, vulnerable groups and disasters, the study's level of livelihood vulnerability is higher than others.

Furthermore, if variables in adaptive capacity increase vulnerability, these should be inversely normalised to calculate the LVI-IPCC, since the value of adaptive capacity is included in the LVI-IPCC calculation. This causes errors in the LVI and LVI-IPCC calculations. This study used a different approach to calculate adaptive capacity to get more accurate LVI-IPCC results. Other studies have ignored this. Some studies use different methods for adaptive capacity (Pandey et al., 2017; Zhang and Fang, 2020).

Zihnioğlu and Dalkıran (2022) highlighted gaps in the literature regarding refugee-related topics such as NGOs, integration and human rights, and the lack of empirical studies with NGOs. NGOs, intergovernmental agencies and the media may help to reduce discrimination and hate towards refugees. This study is different from previous research because it includes in-depth interviews with relevant NGOs, including refugee-led organisations working with Syrians, foreigners, citizens and people with other statuses. Interviewed NGOs have provided information

about their activities and their perspectives on the problems, needs and potential of refugees.

7. Conclusion

The mass displacement of Syrians due to man-made disasters is the largest displacement on record and shows how shocked Syrians and host communities are about the loss and alienation of livelihoods, the reproduction and distribution of livelihood capital, and protracted displacement. This study focuses on the livelihood vulnerability of Syrian refugees in the Konak District's Basmane and around region of Izmir. İzmir is a transit point to Europe, which is an important incentive for many refugees. The Basmane region is one of Izmir's neglected areas, characterised by poor physical conditions and inadequate infrastructure and social insecurity, but providing cheap housing and easy access to many poor migrants or refugees, allowing them to settle and develop social networks. Syrian refugees face many challenges, including forced displacement, and lack of access to human and labour rights.

Syrian refugees are highly vulnerable in terms of physical, financial, social and natural capitals, and moderately vulnerable in terms of human, physical and financial capital, but less vulnerable in terms of social capital. Syrian refugees are the most exposed in terms of physical capital with a value of 0.65, financial capital is the most sensitive with a value of 0.55 and natural capital has the lowest adaptive capacity with a value of 0.22. Syrian refugees have the highest adaptive capacity value in social capital with 0.51.

NGOs contact refugees one to one and they have chance to observe due to their locations. The most effective capitals on livelihood vulnerability are financial and social capital according to NGOs. Syrian refugees believe that orphaned children, women and people with disabilities are the most vulnerable groups besides the refugees themselves. NGOs also state that social capital has a positive effect on the development of Syrian refugees' capacity and ability. Poverty is a common factor affecting both parties, host community and refugees. This commonality unites them. Examining the dynamics of the local economy, economic circulation and diversity of livelihoods in the study area through the income-earning activities of Syrian refugees can develop and sustain their livelihoods.

Livelihood vulnerability in areas heavily populated by refugees can be reduced and/or eliminated through a sustainable livelihoods approach. This study allows for the identification of capital-specific, context-specific and vulnerability dimension-specific problems, revealing the potential and making planning decisions to reduce livelihood vulnerability of both the vulnerable group and the host community to stressors and hazards. It provides sustainable livelihood opportunities for future generations.

Appendices

Table A1: Raw Values of Variables and Data Ranges

Indicators	Types of Livelihood Capitals	Variables	Units	Raw Values	Max Values	Min Values
Family Structure	HC	**1.** percentage of large families (more than 6 members)	Percent	**23**	100	0
	HC	**8.** percentage of single parent households	Percent	**22**	100	0
	HC	**9.** percentage of households with orphans	Percent	**6**	100	0
	SC	**9.** percentage of households with positive change in women's role/position in family after arrival in Türkiye	Percent	**24**	100	0
Age	HC	**2.** percentage of age 65+ in a household	Percent	**0.01**	0.5	0
	HC	**3.** percentage of age ≤ 5 in a household	Percent	**0.14**	0.6	0
	HC	**4.** number of children in a household	Percent	**2.82**	9	0
	HC	**7.** percentage of age of household head < 18 or > 65	Percent	**2**	100	0
Gender	HC	**5.** percentage of women in a household	Percent	**0.48**	1	0
	HC	**6.** percentage of female-headed households	Percent	**19**	100	0
Education	HC	**10.** percentage of households with less than high school education	Percent	**78**	100	0
	HC	**19.** percentage of households who participate in vocational training	Percent	**9**	100	0
	FC	**6.** percentage of households who can not afford education expenses	Percent	**66**	100	0
Employment	HC	**13.** percentage of unemployed family members	Percent	**2**	100	0
	HC	**14.** percentage of employed women	Percent	**4**	100	0
	HC	**15.** percentage of employed children (age < 15)	Percent	**1**	100	0
	HC	**16.** percentage of households who have a work permit	Percent	**15**	100	0
Occupation	HC	**12.** percentage of households with weather-exposed workers (agriculture, forestry, fishing, and hunting; mining; construction; manufacturing; and transportation and utilities)	Percent	**47**	100	0

Socio-economic Status	**HC**	**11.** percentage of households where members had any formal or informal skill	Percent	**58**	100	0
	FC	**2.** per household income monthly	Turkish Lira (thousand)	**20.81**	120	0
	FC	**9.** percentage of households owning private or permanent land in any location that is usually used as a dwelling	Percent	**49**	100	0
	FC	**10.** percentage of households with no vehicle	Percent	**89**	100	0
	FC	**11.** percentage of households using technological devices (fridge, electric heater, fan, washing machine, computer)	Percent	**95**	100	0
	PC	**4.** housing quality (comfortable living conditions (e.g. indoor plumbing, and hot showers) (scale of good to bad)	Percent	**17**	100	0
Housing Tenure (ownership)	**FC**	**8.** percentage of renter households	Percent	**100**	100	0
Livelihood Strategies	**FC**	**1.** percentage of earning member in a household	Percent	**0.25**	1	0
	SC	**2.** percentage of households with members working for the government	Percent	**1**	100	0
	FC	**3.** percentage of households who took loan in the past 5 years	Percent	**5**	100	0
	FC	**4.** percentage of households that reported at least one family member worked outside the community to earn a wage	Percent	**7**	100	0
Minority/Language	**HC**	**17.** language proficiency	Percent	**30**	100	0
	HC	**18.** percentage of households who participate in language course	Percent	**20**	100	0
	SC	**4.** percentage of households who have language problems with their children	Percent	**16**	100	0
	SC	**1.** years when refugees are in Türkiye	Years	**9.55**	15	1
	SC	**6.** percentage of households who have a residence permit	Percent	**15**	100	0

Health	**HC**	**20.** percentage of households registered another province (in this case, they do not benefit from health services)	Percent	**4**	100	0
	HC	**21.** percentage of households with chronically health difficulties	Percent	**37**	100	0
	HC	**22.** percentage of households with disabled people	Percent	**23**	100	0
	HC	**23.** percentage of households who not visiting doctors during illness	Percent	**32**	100	0
	FC	**5.** percentage of households who cannot afford medical expenses	Percent	**44**	100	0

Exploring Environmental Perception, Cognition, and NIMBY Sentiments Toward Psychiatric Hospitals: A Spatial Planning Perspective

Abstract
This study through the Semantic Differential scales explores how spatial planning and design influence perceptions of psychiatric hospitals in Taiwan. Preliminary findings of the study show that hospitals situated within vibrant urban environments and possessing indistinct spatial boundaries are perceived as less 'lifeless' or 'dark'. Moreover, if the residents near the hospital with accurate knowledge of hospital departments and the patient the hospital services report lower levels of negativity. These results underscore the significance of environmental stimuli and cognitive familiarity in shaping public attitudes, suggesting that integrated spatial planning and enhanced transparency may mitigate stigma and facilitate community acceptance of psychiatric facilities.

Keywords: psychiatric hospital; psychiatric institution; NIMBY; perception

1. Introduction

The term 'deinstitutionalisation' first appeared in the 1950s in Europe and the United States, in the hope of removing the closed and institutionalised management of institutions and attempting to transform them into part of the community, with the right of patients in stable condition to live independently and be included in the community (UN Committee on the Rights of Persons with Disabilities, UN CRPD, 2021). In 2017, an international expert review of the Committee on the Rights of Persons with Disabilities (CRPD) also recommended the closure of large organisations in Taiwan.

However, in the process of promoting deinstitutionalisation in Taiwan in recent years, the emergence of community psychiatric rehabilitation, psychiatric nursing homes, and other places for the integration of people with mental disorders into community life has often led to a backlash from residents in the surrounding areas. For example, in 2019, residents of Zhoumei objected to a local group home for people with mental disorders due to concerns about safety and the impact on the quality of life, demonstrating that psychiatric facilities are still regarded as 'NIMBY facilities'.

The concept of mental healthcare has been introduced in Taiwan since the Japanese colonial period (1895-1945), but initially the psychiatric hospitals were still based on surveillance and management, and they were mostly located in the urban periphery. After the end of World War II, Taiwan's government attitude towards mental healthcare institutions changed from 'confinement and shelter' to 'therapy and care', but some urban planning land-use zoning regulations still kept psychiatric hospitals separate from medical institutions, restricting them from appearing in urban areas or new towns. Under the influence of historical context and spatial planning, the location of psychiatric hospitals has long been regarded as a space that 'should be located in remote areas.' This study explores whether spatial characteristics contribute to public perceptions, NIMBY sentiments, and the reinforcement of psychiatric stigma and spatial exclusion.

Therefore, this study aims to understand how the spatial planning of psychiatric hospitals affects people's attitudes, perceptions, and feelings about psychiatric hospitals by comparing the surroundings of psychiatric hospitals respectively in the 'urban frontier' and 'urban centre' regions. By understanding the exclusionary nature of spatial location for specific groups and its impact on facility perceptions and NIMBY sentiments, we propose recommendations for inclusive planning for disadvantaged groups, in the hope that spatial planning can help prevent the reproduction and deepening of stigma against disadvantaged groups.

2. Literature Review

2.1 Psychiatry hospitals (psychiatric institutions) in Taiwan

Mental health resources for mental disorders, as classified by Taiwan's Ministry of Health and Welfare, are broadly divided into three categories: 'psychiatric hospitals', 'psychiatric rehabilitation institutions', and 'psychiatric nursing homes', and established regulatory standards. This study focuses on 'psychiatric hospitals' that have been certified by the Ministry of Health and Welfare's Department of Mental Health through the 'psychiatric hospital accreditation' or 'psychiatric teaching hospital accreditation' and remain valid before the year 2027. However, the term 'psychiatric hospitals' only emerged in modern times, making it challenging to distinctly classify 'psychiatric hospitals', 'psychiatric rehabilitation institutions', and 'psychiatric nursing homes' in historical contexts. Therefore, the term 'psychiatric institutions' is used hereafter to refer to the aforementioned facilities in this study.

2.1.1 The Development of Psychiatric Institutions in Taiwan

'Yōkōdō', which was founded in 1929 by Professor Nakamura Yuzuru, is the earliest psychiatric institution in Taiwan, established from a medical treatment perspective. However, in 1930, the Taiwan Daily News reported incidents such as a patient smuggling firewood into a ward and setting a mosquito net ablaze, causing the second and third floors of the building to burn down, and another patient killing a nurse with a hammer in July. These events led the Governor-General's Office to take the social issues caused by mental disorders seriously, resulting in the establishment of the first public psychiatric hospital, 'Yōshin-in', in 1934 (Ko Yi-Ching, 2021).

During the Japanese colonial period, psychiatric institutions built in Taiwan included the 'Aigoryō' in Tainan (1929), 'Yōkōdō' in Taipei (1929), 'Xikou Yōshin-in' (1934), and 'Jōwa Hospital' in Taichung (1936). These institutions, regardless of their capacity, were mostly located on the outskirts of cities or in rural areas. Shen Xiancheng (2003) speculated on two possible reasons: first, in the 19th century, rural environments away from cities were considered ideal for patient recuperation, a common planning approach in Western countries at the time; second, influenced by the repeated relocations of Matsuzawa Psychiatric Hospital in Japan due to urban neighborhood rejection, the selection of remote hospital sites aimed to achieve isolation.

After World War II, U.S. aid became the main source for medical projects. In 1958, the Xikou Sanatorium (formerly 'Yōshin-in') added 200 beds, and the establishment of the Provincial Kaohsiung Sanatorium was also related to U.S. aid. Subsequently, with the World Health Organization's mental health programs, the invention of new medications, and the promotion of therapeutic environments, psychiatric hospitals gradually shifted from 'custodial' to 'therapeutic' models (Lin Xian, 1987, cited in Shen Xiancheng, 2003). However, when the Yuli Veterans Hospital was established in 1957, the concept of 'deinstitutionalsation' in Western psychiatry was emerging, but due to Taiwan's political and economic context at the time, psychiatric hospitals development still leaned towards 'institutionalisation' and geographical 'marginalisation'. To prevent patient escapes, hospitals and nursing homes were often enclosed by walls and situated on isolated blocks. During this period, stigmatisation still heavily influenced society. It wasn't until the lifting of martial law in 1987 that more opportunities were given to disadvantaged groups, indirectly leading to the legislation of the 'Mental Health Act' in 1990.

In the 1980s, the government successively completed facilities such as the Bali Psychiatric Center, Tsaotun Psychiatric Center, and the Daliao Branch of Kaohsiung Kai-Syuan Psychiatric Hospital. These facilities were mostly located in suburban areas with large land areas and included 'community-based' rehabilitation institutions within the hospitals. However, unlike the large sanatoriums in early Western countries, they still provided 'rehabilitation environments based on hospitals'. Hospitals like the Bali Psychiatric Center and the Daliao Branch of Kaohsiung Kai-Syuan Psychiatric Hospital were located in sparsely populated neighborhoods, even near some NIMBY facilities like landfills; indicating their peripheral positioning. Due to the strong negative connotations associated with psychiatric institutions, they are not considered desirable elements of a community's image. After 1990, 90% of institution operators indicated that communities still had low acceptance of these facilities (Shen, 2003).

Since 2000, the Executive Yuan has passed a series of mental health system restructuring plans, including strengthening social psychiatric rehabilitation resources and referral mechanisms after discharge, along with multiple amendments to the 'Mental Health Act', aiming to promote patients' integration into community life

after treatment. However, despite policies advocating for community-based and deinstitutionalised approaches, in practice, there is still strong opposition from residents to the establishment of psychiatric institutions in residential areas, such as 'community psychiatric rehabilitation' and 'psychiatric nursing homes.' For example, in 2000, the Recovery Friends Association's attempt to establish a full-day care institution faced protests from nearby residents, and in 2019, the Wenlin Home faced opposition from residents of the Zhoumei community, indicating that integrating psychiatric institutions into communities remains challenging even today.

2.1.2 Environmental Planning and Design for Mental Healthcare Institutions

Psychiatric institutions are often associated with 'isolation' and 'exclusion' (Gawlak et al., 2025), a perception that can be traced back to the historical perspective of psychiatry. Early psychiatric hospitals, as institutions for 'managing' patients, often featured physical barriers from the outside world, such as gates, high walls, fences, forests, or wilderness. Goffman (2012) referred to these as 'total institutions', categorising psychiatric hospitals as one such type. Due to the unique spatial requirements of psychiatric hospitals, they were designed to treat or care for patients while preventing their unpredictability from affecting external groups. However, overemphasis on management and surveillance functions in hospital planning and design, while neglecting actual users, can lead to cold and unwelcoming spaces. This sense of confinement is a significant reason why the public generally finds psychiatric medical institutions unapproachable (Ko Yi-Ching, 2021).

Over the past 30 years, numerous case studies on hospital environments have led to an increasing emphasis on 'evidence-based design (EBD)'. EBD involves using scientific evidence as a foundation for design, assessing the impact of the built environment on users' physical and mental health, and considering their experiences within the environment. The introduction of EBD concepts can enhance patient well-being during treatment and reduce stress for healthcare workers (Elisa et al., 2018; Szymańska et al., 2025). For instance, research by Mohamed and Roslinda (2010) indicated that diverse colours, natural elements (such as the sound of flowing water, plants, and vibrant gardens), and factors like homely, bright, and well-ventilated environments can effectively promote the caregiving environment for both healthcare workers and patients.

In terms of hospital locations, urban and rural hospitals can offer different therapeutic characteristics. According to a systematic literature review by Szymańska et al. (2025), urban hospitals can provide inpatients with more social stimulation, reducing feelings of social isolation. However, potential risks include safety concerns regarding interactions between patients and external individuals, necessitating environmental planning to ensure hospital security and alleviate nearby residents' fears of patient escapes. Rural hospitals, with generally larger spaces, allow for more flexible planning of suitable landscapes and buildings, meeting patients' needs for interaction with nature during treatment. However, transportation convenience becomes a barrier for patients without private vehicles. The study concluded that architectural planning and design can help improve public perceptions of psychiatric hospitals, summarising two influencing factors: 'locating hospitals in urban areas to promote shared green spaces with nearby residents' and 'using gentle materials and designs in hospital spaces to significantly impact spatial perception and cognition' (Szymańska et al., 2025).

However, as reviewed in the previous section, early psychiatric institutions in Taiwan were mostly located on the outskirts of cities or in rural areas. Even today, certain urban planning land-use zoning regulations continue to reflect this tendency. For example, the amended 2021 Taipei City Land Use Zoning District conditions allow for the use of psychiatric hospitals with more stringent standards than general hospitals, and the Tainan City Central and Western District Plan (Chinatown and Canal Diamond Area), which was released and implemented in 2016, avoids locating psychiatric institutions in the urban core area.

From the above literature, it is evident that past research on the environmental planning and design of psychiatric hospitals has primarily focused on 'patient treatment', 'patient safety', 'external personnel safety', and 'staff management', with few studies exploring how spatial planning indirectly affects residents' perceptions of psychiatric hospitals; early establishments on urban outskirts and current restrictions on setting up mental health care facilities in urban centers may stem from early construction habits or planners' perceptions of psychiatric institutions' environments, leading to the reconstruction of environmental perceptions through urban planning controls.

2.2 Not In My Back Yard

Not In My Back Yard (NIMBY) refers to facilities that are socially necessary but elicit negative emotions among local residents when sited nearby. NIMBY facilities can generally be categorised based on the nature of the rejection into three types: pollution-related, risk-clustering, and psychological dismay. Pollution-related facilities include sewage treatment plants and highways, which are opposed due to their direct environmental impacts; risk-clustering facilities are high-risk but low-probability facilities such as nuclear power plants; psychological dismay facilities include psychiatric hospitals, funeral parlours, and cemeteries—facilities that do not directly affect physical health but evoke long-term psychological rejection (Zhang et al., 2022). The psychiatric institutions explored in this study tend to fall under the category of psychological dismay NIMBY facilities.

When NIMBY facilities are constructed involuntarily by the surrounding residents, when they are beyond their control, provide no benefits to them, and are associated with fearful, adverse, or irreversible outcomes, a heightened perception of risk is often triggered. This may give rise to strong emotions such as worry, anger, anxiety, fear, and hostility, affecting individual attitudes and behaviours (Covello et al., 2001). These emotions are usually rooted in concerns over property values, personal safety, and quality of life (Dear, 1992). Chiu and Lo (2011), through interviews with key personnel from institutions serving people with intellectual and psychiatric disabilities, found that, unlike pollution-related NIMBY facilities, the resistance towards disability institutions is mainly linked to the 'facility users' themselves. Reasons for protest include damage to the landscape and feng shui, impact on air and water quality, concerns over child development (fear of imitation), personal safety concerns (fear of being frightened or of crimes committed by persons with disabilities), traffic safety or congestion, and declining property prices. These findings broadly align with Dear's (1992) summary of public concerns towards NIMBY facilities.

Regarding the formation mechanism of psychological dismay-type NIMBY emotions, Yu et al. (2022), in their literature review, cited Xu and Jing (2020), who found through qualitative research that community conflict over an elderly care centre in Wuhan in 2015 originated from 'psychological resistance', which gradually developed into heightened 'risk perception', eventually evolving into 'behavioural resistance.' Through an online questionnaire, they found that superstition, NIMBY attitudes, and perceived risk had a positive correlation with opposition to elderly care facilities in the community, while perceived knowledge and perceived benefits were positively correlated. These results indicate that NIMBY attitudes and risk perception greatly influence public support for elderly care facilities. In terms of attitude, Moon (1984) believed that aside from attitudes and beliefs, personal positive or negative experiences with psychiatric patients or care facilities also affect acceptance. However, to explore the entire community's NIMBY sentiment towards psychiatric institutions, broader structural factors such as social, economic, and political elements must be included, revealing differences between individual and community perspectives in understanding the formation of NIMBY sentiment.

3. Materials and Methods

3.1 Research Framework

Through literature review, it was found that psychiatric institutions in Taiwan have long been located in rural or urban fringe areas throughout their historical development. Therefore, this study uses questionnaires to investigate, within equal residential distances, whether residents of urban fringe areas and city centre areas differ in spatial familiarity with psychiatric hospitals, and whether the overall spatial locations and environmental planning create different spatial perceptions. Furthermore, the study seeks to identify the causes of these differences to understand how the spatial characteristics and surrounding environments of psychiatric hospitals influence the emotional perceptions of the public. The variable relationships in this study are shown in Figure 1.

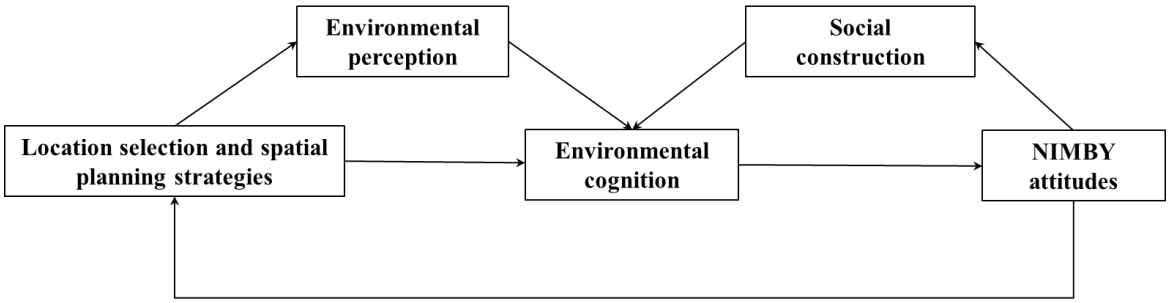

Figure 1 Relationship diagram of research variables

In terms of research locations, the study selected the two largest psychiatric hospitals in Tainan and Kaohsiung—Jianan Psychiatric Center in Tainan and Kai-Syuan Psychiatric Hospital in Kaohsiung. Jianan Psychiatric Center is situated on the border between East District and Rende District of Tainan City and has long been in an urban fringe area, with only recent developments in the past 30 years due to the Huwuiliao readjustment area (Figure 2). Kai-Syuan Psychiatric Hospital is located in the city centre of Lingya District, Kaohsiung, near the Kaohsiung Cultural Centre and National Kaohsiung Normal University, with relatively dense residential and commercial development in its surroundings (Figure 3).

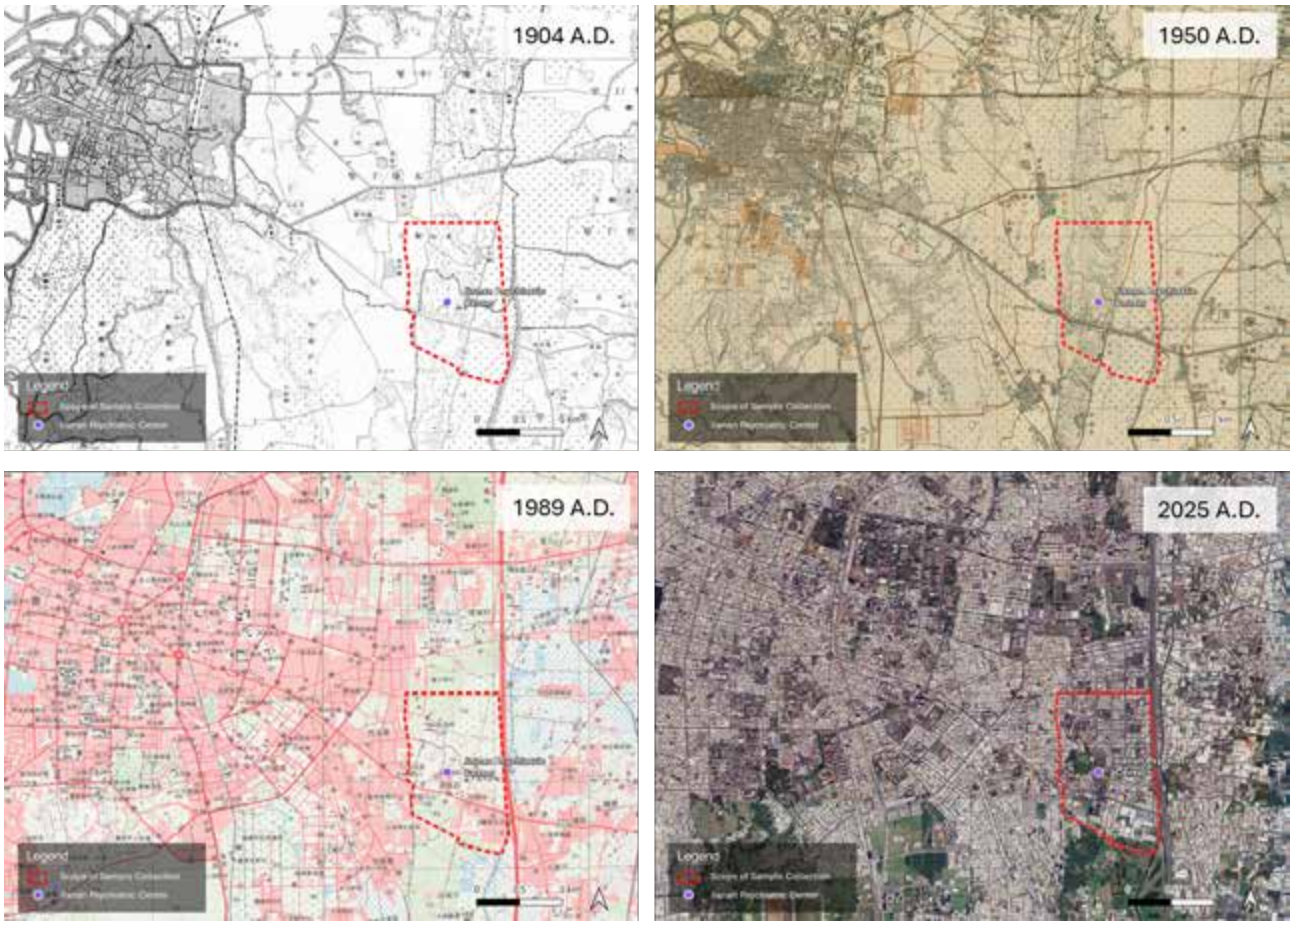

Figure 2 Urban development in Tainan City and around Jianan Psychiatric Centre

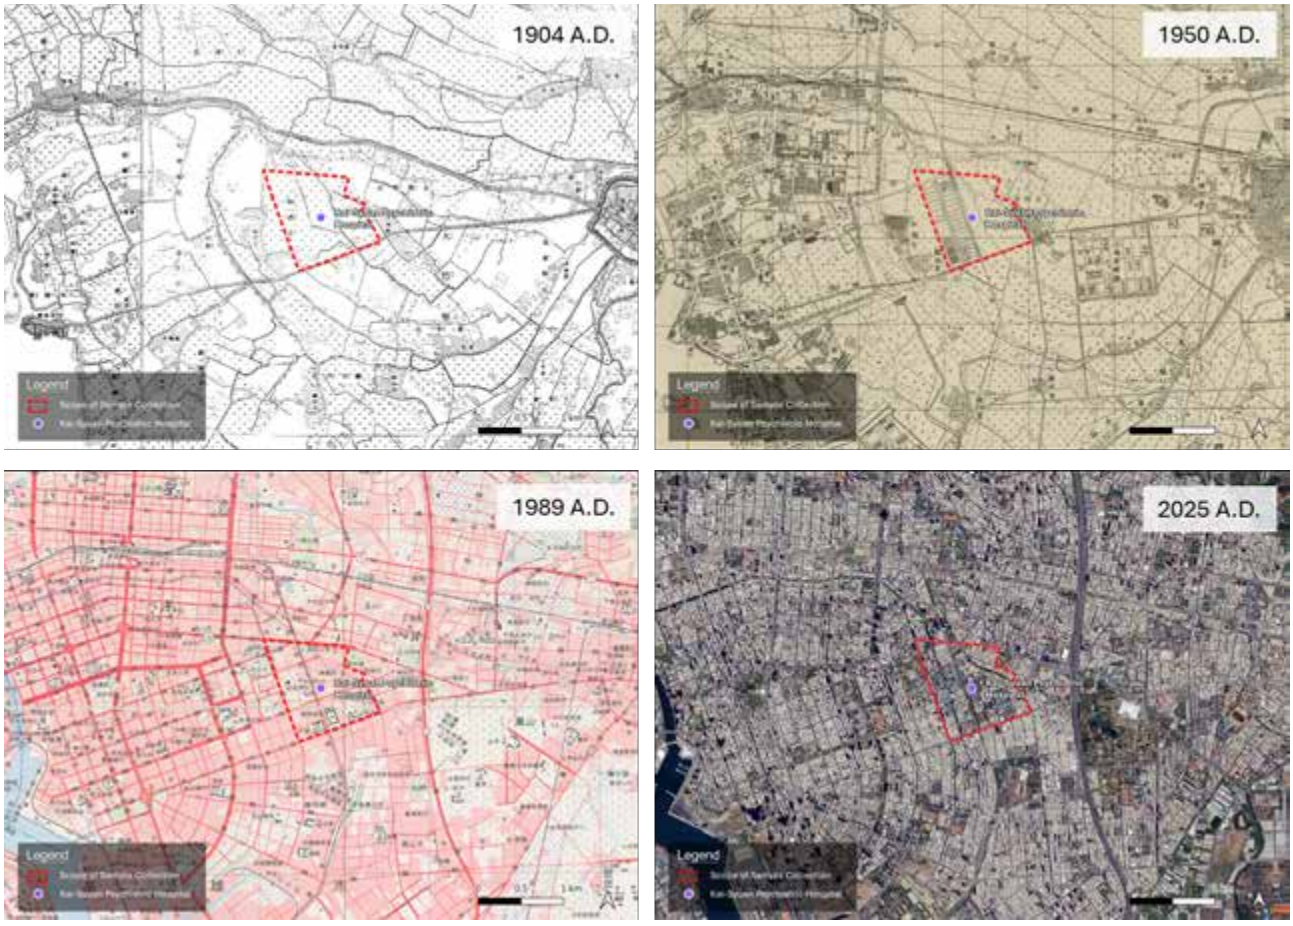

Figure 3 Urban development in Kaohsiung City and around Kai-Syuan Psychiatric Hospital

3.2 Research Methods

The purpose of this study is to use a questionnaire survey to understand the actual emotional perceptions of the public towards psychiatric hospitals and to compare whether NIMBY sentiments differ under different surrounding environmental conditions. To avoid over-focusing on the hospitals and thus losing authenticity, the questionnaire is divided into three parts:

The first part investigates the spatial images within about 500 metres of Jianan Psychiatric Center and Kai-Syuan Psychiatric Hospital, from the perspective of local community residents, to gain preliminary insight into impressions and perceptions of psychiatric hospitals in comparison to other spaces within the community.

The second part applies the Semantic Differential (SD) Scale to examine residents' emotional responses towards the hospitals within their block areas, and their perceptions of how the hospital environment reflects characteristics of its users (primarily the patients).

The third part is based on the premise that residents fully understand that both hospitals are psychiatric institutions and asks residents about their views on the relationship between psychiatric hospitals and the community and whether they consider them NIMBY facilities.

Through these three parts of the questionnaire, this study compares differences in overall spatial perceptions shaped by hospitals located in different communities and further explores whether spatial planning influences the public's NIMBY perceptions of psychiatric facilities.

4. Results

4.1 Current Conditions of the Research Sites

4.1.1 Kai-Syuan Psychiatric Hospital

Kai-Syuan Psychiatric Hospital is located in Lingya District, Kaohsiung City, in the city centre. The hospital site covers approximately 2.65 hectares and includes the main hospital, a psychiatric nursing home, and a community rehabilitation centre.

To the north of the site lies Fucheng Street, with the Kaohsiung City Department of Health located across the road. To the west is Kai-Syuan 2nd Road, a 20-metre-wide road with a light rail transit (LRT) line. The hospital entrance directly faces the Department of Health Station. To the south is Lane 189, Fude 3rd Road, lined with approximately 50-year-old residential townhouses. To the east is Zoujie Art Park, a neighbourhood park. The surrounding area is predominantly residential, with a large elderly population and relatively low traffic on the northern and southern roads. As a result, many residents take walks or engage in recreational activities in Zoujie Art Park, as well as along Fucheng and Fushou Streets in the evening.

Figure 4 Kai-Syuan Psychiatric Hospital Surrounding Environment

4.1.2 Jianan Psychiatric Center

Jianan Psychiatric Center is located in Rende District, Tainan City, on the urban fringe of the metropolitan area, adjacent to the southeastern side of the East District. The site covers approximately 5.3 hectares and includes the Chest Hospital under the Ministry of Health and Welfare, which is the only psychiatric teaching hospital in the Yunlin-Chiayi-Tainan area.

To the north of the site are wooded, unused lands and hospital car parks. To the west is Yuzhong Road, along which about ten new townhouses have been constructed over the past five years. Current land use in this area includes industrial, storage, and residential functions. To the south is the Chest Hospital, and to the east is Gong-Er-3 Park, which is adjacent to the hospital's rear entrance.

Figure 5 Jianan Psychiatric Center Surrounding Environment

4.2 Public Perceptions of the Community Environment Surrounding the Hospitals

As this stage involved pilot testing of the questionnaire, the sample size collected was insufficient for statistical analysis. Therefore, the following paragraphs will provide descriptive statistics to summarise the public's views on the areas surrounding the hospitals.

4.2.1 Kai-Syuan Psychiatric Hospital

A total of 5 questionnaires were collected in the area around Kai-Syuan Psychiatric Hospital. All respondents were former students who had attended senior high school or university in this area. Consequently, the 'most familiar place' was consistently identified as the surroundings of National Kaohsiung Normal University; the 'least familiar places' were typically Fudong Elementary School and Linjing Park, which are further away from the school. Two respondents mentioned Kaixuan Road and the hospital itself as places they were least familiar with. The 'least safe areas' were described as the dim alleyways and tree-lined boulevards.

According to the questionnaire's content, respondents did not express significantly more negative emotions towards Kai-Syuan Psychiatric Hospital compared to other areas. They did not spontaneously describe the area around the hospital using terms such as 'dangerous' or 'frightening', which are typical of NIMBY sentiments. Moreover, the field observations revealed that the layout of the roads, the proximity of the hospital to the park, and the absence of clear boundary walls encouraged many nearby residents to walk or engage in recreational activities in the park and along Fucheng Street. They did not deliberately avoid the hospital. Some shop owners even mentioned that the hospital and nearby medical facilities are important sources of business.

4.2.2 Jianan Psychiatric Center

A total of 9 questionnaires were collected in the area around Jianan Psychiatric Center, with all respondents having lived there for over ten years. 'Most familiar places' included major community parks such as Wensheng Park and areas surrounding primary schools. Three respondents identified the area around the Chest Hospital and Jianan Psychiatric Center as the 'least familiar', while four mentioned areas south of Zhongshan Road. Areas perceived as the 'least safe' were predominantly around the Chest Hospital and Jianan Psychiatric Center, mainly

due to lower pedestrian activity. One respondent mentioned that although they live near the hospital, their daily activities are centred in the east-side Huwuiliao readjustment area. The hospital's surroundings, being largely undeveloped, have little connection to their everyday life.

4.3 Public Perceptions of the Hospital Environment

This stage mainly sought to understand 'people's feelings when passing by the hospital' and 'the perceived atmosphere of the hospital itself'. Residents near Jianan Psychiatric Center generally described their feelings when passing the hospital as 'serious', without experiencing significant emotional burden or threat. However, the hospital atmosphere was perceived as 'quiet', 'gloomy', and 'lifeless'. Similarly, residents near Kai-Syuan Psychiatric Hospital also expressed a 'serious' and somewhat 'heavy' feeling when passing the hospital. The atmosphere was similarly seen as 'gloomy' and 'lifeless', but described as noticeably more 'dark' than that of Jianan Psychiatric Center.

4.4 Public Cognition of the Hospital

In this analysis, none of the five respondents near Kai-Syuan Psychiatric Hospital did not understand the hospital's departments or the patients they serve, making it difficult to assess how the hospital's presence influenced their understanding of psychiatric institutions. In contrast, five out of nine respondents near Jianan Psychiatric Center did understand the hospital's departments and the patients they serve.

During this stage, five respondents near Jianan Psychiatric Center were invited to 'recall the appearance and environment of the hospital, and describe their imagined image of the patients it serves. All five associated the patients with adjectives such as 'depressed' and 'controlled'. However, when asked whether they were concerned about being affected by the hospital's service users or whether they rejected psychiatric outpatient services, all respondents expressed little concern or rejection.

Comparing residents who 'understood' versus those who 'did not understand' the hospital's departments and the patients the hospital serves, it was found that those who lacked such understanding were more likely to perceive the hospital as 'threatening', 'dark', 'lifeless', and 'cold.' This suggests that the physical appearance and surrounding environment of a hospital can provide informational cues to the public, particularly for those unfamiliar with the hospital's function. Residents who understood the hospital showed fewer negative descriptions of the atmosphere, which may also reflect a lower level of stigma towards psychiatric hospitals.

5. Conclusion

Through the review of the literature, we can find that psychiatric hospitals were often initially sited on the urban periphery, and that conflicts arose during deinstitutionalisation between psychiatric facilities and surrounding residential areas. This study used semantic differential scales to explore how community residents perceive and accept psychiatric hospitals, aiming to test whether such peripheral siting influences public cognition and acceptance.

Preliminary results indicate that in terms of the physical environment, Jianan Psychiatric Center is located in a relatively remote area with fewer residential neighbourhoods, limited pedestrian activity, and primarily through traffic. Residents rarely pass by the hospital unless they have medical needs. They often described the area as 'unsafe', 'dark', and 'gloomy' due to its 'low flow of people' and abundance of 'vacant land'. In contrast, the area surrounding Kai-Syuan Psychiatric Hospital benefits from proximity to parks and daily amenities. The hospital has no boundary walls or clear separation from nearby residences, leading to perceptions of the hospital as 'gloomy' but not necessarily 'threatening'. Residents are more likely to engage in activities nearby. A comparison of the interface between each hospital and its surrounding residential areas shows that Jianan Psychiatric Center's layout and functions are more spatially separated from the community, resembling the spatial planning of 'total institutions' (Goffman, 2012), characterised by physical isolation, which gives rise to stronger feelings of 'darkness', 'insecurity', and 'threat', making the hospital less approachable. This suggests that the physical interface between psychiatric facilities and their surrounding neighbourhoods significantly influences public perception.

In terms of the residents' cognition about the hospital, long-term residents near Jianan Psychiatric Center had

a higher understanding of the hospital's function and the types of patients it serves, and demonstrated greater acceptance. Compared with those who did not understand the hospital's attributes, informed residents gave more neutral descriptions of the hospital and rated it lower in terms of 'coldness', 'darkness', and 'lifelessness.' On the other hand, although Kai-Syuan Psychiatric Hospital is located within the city and forms part of a medical cluster alongside the Kaohsiung City Department of Health and other institutions, it remains functionally detached from residents' daily routines. The medical area's circulation routes are separated from the community, which has not notably enhanced public familiarity or acceptance. Public understanding of the hospital remains limited. This phenomenon may reflect the findings of the research of Xu and Jing (2020), which found that perception knowledge significantly influences support for psychologically stigmatised NIMBY facilities.

Moreover, most respondents near Jianan Psychiatric Center were from small households living in newly developed residential areas from the past 30 years. In contrast, respondents near Kai-Syuan Hospital were mostly university students from the National Kaohsiung Normal University. A comprehensive comparison of community-wide NIMBY sentiments towards medical institutions requires consideration of broader structural factors such as social and economic status (Moon, 1984). This presents a future direction for refining questions and analyses.

Therefore, future research will further explore spatial layout and residents' daily interactions, focusing on the challenges and potential of integrating small-scale psychiatric care facilities (e.g., community psychiatric rehabilitation) into neighbourhoods amid the shift towards deinstitutionalisation. Key questions include: why do these community-based facilities, despite their proximity to residents' lives, still face psychological rejection or suspicion? Are these reactions linked to unfamiliarity with people with mental illness and limited spatial interaction? By comparing perceptions and attitudes under different facility and spatial conditions, future research will examine how urban planning might act as a mediator, designing spaces that foster understanding and inclusion—making it more natural for the public to engage with psychiatric service users and enabling patients to live more comfortably within the community.

Abstract
During the transformation of cities, the concept of sustainability has been incorporated into political discourse. Due to the emphasis on environmental and economic aspects of sustainability in urban interventions, issues of social inequality, insufficiency, insecurity, social exclusion, and a lack of social unity have been highlighted. Since the primary purpose of urban interventions is to improve the spatial structure, enhancing and maintaining social structure is essential in ensuring spatial sustainability. This paper focuses on measuring and assessing social sustainability before and after urban interventions. This paper presents a model that defines the key issues and criteria of social sustainability, the objectives and sub-objectives for achieving social sustainability, and the indicators to measure and evaluate them. The universal model is based on a holistic approach that can be applied to all urban areas and scales.

1. Introduction
In the ongoing process of urban transformation, the concept of sustainability has increasingly been integrated across various disciplines, primarily due to the widespread impact of human activity on all systems, including cities. As sustainability emerges as a key framework for addressing global challenges, it has gained prominence in both theoretical discourse and practical applications. Although the need to evaluate the three fundamental components of a sustainable society—environmental, economic, and social—became more widely acknowledged after the 1980s, urban renewal efforts have primarily focused on the physical and economic revitalization of existing urban areas to meet evolving urban demands (Colantonio and Dixon, 2009).

This focus has often led to the neglect of the social dimension of sustainability, resulting in increased inequality, inadequacy, and insecurity within urban spaces. As cities face limitations imposed by their physical and economic structures, a holistic approach that simultaneously considers environmental, economic, and social aspects becomes essential. Such an approach is necessary not only to achieve social sustainability but also to lay the groundwork for building resilient and sustainable cities in the face of changing conditions.

From this perspective, this research focuses on measuring and assessing social sustainability before and after urban interventions. This paper presents a model that defines the key issues and criteria of social sustainability, the objectives and sub-objectives for achieving social sustainability, and the indicators to measure and evaluate them. The universal model is based on a holistic approach that can be applied to all urban areas and scales. Ankara Dikmen Valley has been selected as a case study for implementing the model. The Dikmen Valley Housing and Environmental Development Project is the first multi-purpose urban development project in Turkey; in other words, it is an urban regeneration project for slum areas and squatter settlements. Dikmen Valley was chosen as the implementation area as it has been inhabited for more than 5 years.

2. Concept of Social Sustainability
Although there is no universally accepted definition of social sustainability, its theoretical framework varies depending on factors such as scale, spatial characteristics, subject matter, and the disciplinary perspectives of

researchers. Compared to the environmental and economic dimensions, the development of social sustainability has been relatively slow, mainly because it has historically received less attention and interest (Woodcraft, 2015). Early definitions of social sustainability primarily aimed to clarify and legitimize the concept within broader sustainability discourse. However, since the 2010s, more comprehensive explanations and in-depth analyses have emerged, reflecting a growing recognition of the importance of the social dimension in achieving truly sustainable urban development.

The fundamental key of social sustainability is described as the equitable access to resources for all residents of a region and the provision of fair opportunities for well-being (Murphy, 2012). Social sustainability is most broadly defined as the maintenance and enhancement of the well-being of current and future generations (Chiu, 2003) and the fulfilment of the fundamental social needs of all communities (Eizenberg and Jabareen, 2017). From an urban living perspective, the process of creating sustainable and prosperous places that enhance well-being involves understanding what people need from the spaces in which they live and work. Social sustainability 'integrates the design of physical space with the design of the social world' (Woodcraft, 2015).

More detailed definitions of social sustainability emphasize its nature as an integrated relationship between the physical environment, individuals, and the broader social structure.

In addition to approaches that examine the concept of social sustainability from different perspectives, there are also holistic and multi-layered approaches. The concept of social sustainability can be further expanded when considering basic needs, culture, well-being, and the continuation of the human species (Littig and Griessler, 2005). In this context, according to Cuthill (2010), social sustainability is shaped by principles such as well-being and quality of life, incorporating concepts including health, participation, needs, social capital, economy, ecology, and, more recently, happiness—all grounded in the core values of equity and democracy.

Colantonio and Dixon (2009), who argue that urban regeneration efforts can yield potential outcomes across various dimensions of social sustainability in cities, define these dimensions as follows: demographic change (ageing, migration, and mobility), education and skills, employment, health and safety, housing and environmental health, sense of belonging, place identity and culture, participation, empowerment and achievement, social capital, social mixing and cohesion, well-being, happiness, and quality of life. Underpinning all these concepts—including social exclusion, social inclusion, and social capital—is the premise that individuals in society must interact and collaborate to ensure social Sustainability (Bramley and Power, 2009).

In its broadest sense, social sustainability refers to the existence of equal, fair, and equitable living conditions in the built environment and its components for all segments of society. While equity and justice are at the heart of the concept, they must be considered in conjunction with other key issues, including population, accessibility, education and skills, health, housing, safety, belonging, participation, social capital, social cohesion, diversity, and satisfaction. Social sustainability can thus be defined as systems in which equity and justice are central values, where population distribution and economic welfare are balanced, equal access to basic services is ensured, opportunities necessary for individual and societal development are available, fundamental needs such as health, housing, and security are met, individuals feel a sense of belonging to their community and environment, public participation in governance is realized, and where social capital, cohesion, and satisfaction with quality of life are achieved (Atalay, 2023).

3. Definition of The Model For Measuring And Assessing Social Sustainability

In developing countries, particularly within urban contexts, there appears to be a lack of a comprehensive system or model capable of assessing and evaluating the extent to which the sustainability of the social structure is ensured as a component of achieving spatial sustainability. Based on this premise, the present study proposes a model specifically tailored to the Turkish context, designed to facilitate the assessment and evaluation of social sustainability within the field of urban planning. The proposed model constitutes an integrated measurement and evaluation framework that identifies the mechanisms through which the social fabric may be sustained in urban environments. The primary objective of the model is to identify the key dimensions and criteria of social sustainability, articulate the corresponding objectives necessary to ensure its realization and establish a set of

measurable indicators for evaluating these objectives. Designed to be universally applicable, the model adopts a holistic perspective and is intended for implementation across diverse urban settings and at varying spatial scales.

As part of the literature review conducted for this study, a comprehensive analysis was undertaken of publications by international organizations, academic books, peer-reviewed articles, and project reports, with a specific emphasis on methodologies and frameworks related to the measurement and evaluation of sustainability, particularly social sustainability. Each study reviewed in the literature has been systematically analyzed based on its respective criteria, and a comprehensive matrix encompassing all identified criteria and indicators has been constructed through synthesis. This matrix served as a methodological tool for selecting relevant social sustainability criteria and indicators based on their recurrence and frequency across the literature while also taking into account the spatial planning framework.

Utilizing this approach, ten principal criteria have been defined to constitute the thematic framework of the indicator system designed to assess social sustainability. These include demography and employment, accessibility, education and skills, health, housing, safety, sense of belonging, participation, social capital and social cohesion, and urban life quality, satisfaction, and adequacy of services (Figure 1).

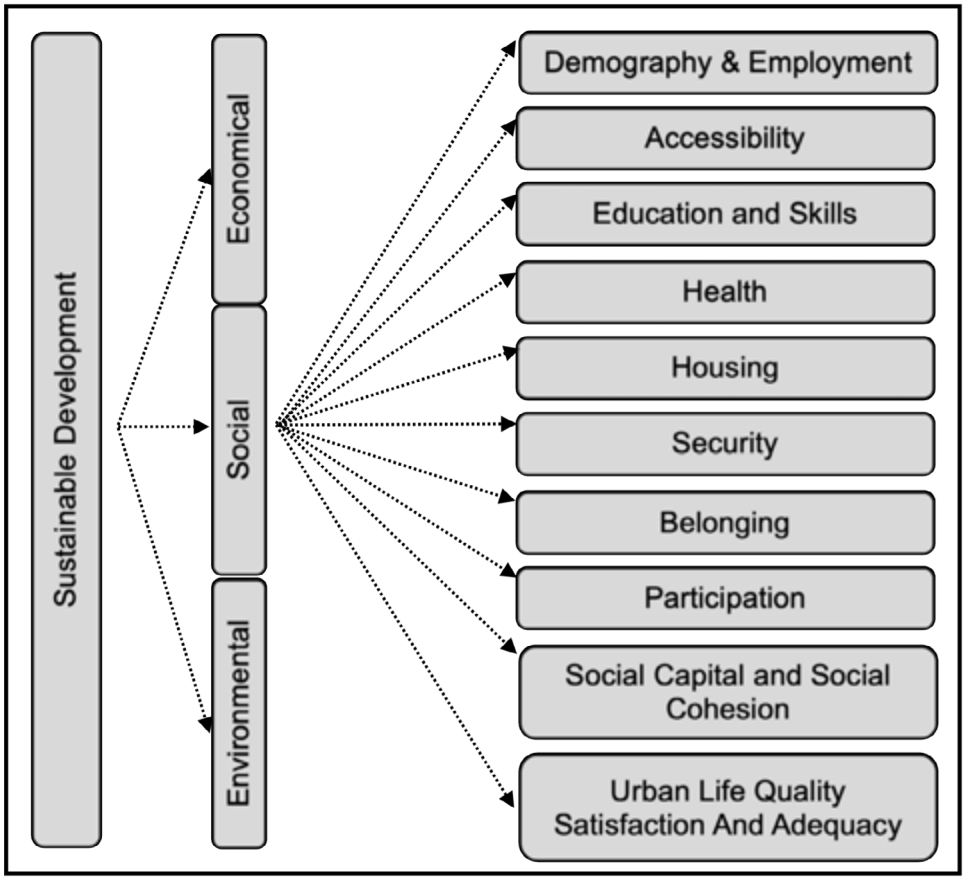

Figure 1. Criteria of the measuring and assessing social sustainability model

Within the scope of the social sustainability measurement and evaluation model, a total of 12 strategic objectives and 24 subordinate targets have been formulated concerning the ten core criteria (Table 1).

Table1. Targets and sub-targets of the social sustainability model

Criteria's	Targets	Sub-Targets
A.Demography & Employment	TA(1) Ensuring a Balanced Distribution of the Population	TA(1.1) Ensuring a Balanced Distribution of the Population by Birthplace
	TA(2) Ensuring the Balance of the Economic Well-Being of the Population	TA(2.1) Poverty Prevention
		TA(2.2) Provision of Employment Opportunities
		TA(2.3) Ensuring Productivity in Employment
		TA(2.4) Ensuring Gender Equality in Employment Opportunities
B.Accessibility	TB(1) Ensuring Equality of Access to Basic Urban Services	TB(1.1) Ensuring Equality of Access to Social Infrastructure, Open Green and Urban Working
C. Education and Skills	TC(1) Individual and Social Education, Raising and Promoting The Level of Development	TC(1.1) Raising literacy and education level
		TC(1.2) Promoting Participation in Vocational Education
		TC(1.3) Promoting Participation in Talent Development Education
D. Health	TD(1) Ensuring the Adequacy of Health Services	TD(1.1) Ensuring the Adequacy of Health Services
E. Housing	TE(1) Ensuring Housing Conditions for All	TE(1.1) Ensuring Increasing Housing Capacity
		TE(1.2) Improving the Physical Condition of Housing
F. Security	TF(1) Ensuring Individual Safety	TF(1.1) Ensuring Security in Public Spaces and Private Areas
G. Belonging	TG(1) Ensuring the Acquisition of Social, Spatial Belonging, Urban Image, and Heritage Values	TG(1.1) Ensuring Social and Spatial Belonging
		TG(1.2) Creation of Urban Image Awareness
		TG(1.3) Creating Awareness of Conservation of Heritage Values
H. Participation	TH(1) Promoting Public Participation in Management, Planning Processes, and Works Related to Municipal Services	TH(1.1) Ensuring Participation in Country and Local Government
		TH(1.2) Ensuring Public Participation in the Planning Process
		TH(1.3) Ensuring Transparency in Works Related to Municipal Services
I. Social capital and social cohesion	TI(1) Ensuring The Level of Social Development and Social Interaction	TI(1.1) Increasing Social Development
		TI(1.2) Level of Social Interaction
	TI(2) Ensuring Diversity and Cultural Integration	TI(2.1) Ensuring Cultural Diversity and Cultural Integration
L. Urban Life Quality Satisfaction And Adequacy Of Services	TL(1) Ensuring Local Residents' Satisfaction with Their Living Environment and the Adequacy of Provided Services	TL(1.1) Ensuring Satisfaction with Urban Quality of Life
		HL(1.2) Ensuring the Adequacy of Urban Services

4. Applying the Measuring And Assessing Social Sustainability Model: A Case Study of Dikmen Valley

4.1 General Overview of Dikmen Valley and Its Urban Development Project

Since the 1950s, internal migration from rural to urban areas in Turkey has led to a substantial increase in urban populations, particularly within metropolitan centres. This demographic shift has led to the proliferation of informal and unauthorized housing areas—commonly referred to as gecekondu settlements—across many cities (Gülersoy Zeren, 2003). One such area is the Dikmen Valley, located in Ankara, which was previously characterized by unregulated and illegal residential structures.

Dikmen Valley is situated within the Çankaya district of Ankara and encompasses the neighbourhoods of Ayrancı, İlkadım, Güzeltepe, Metin Akkuş, and İlker (Figure 2).

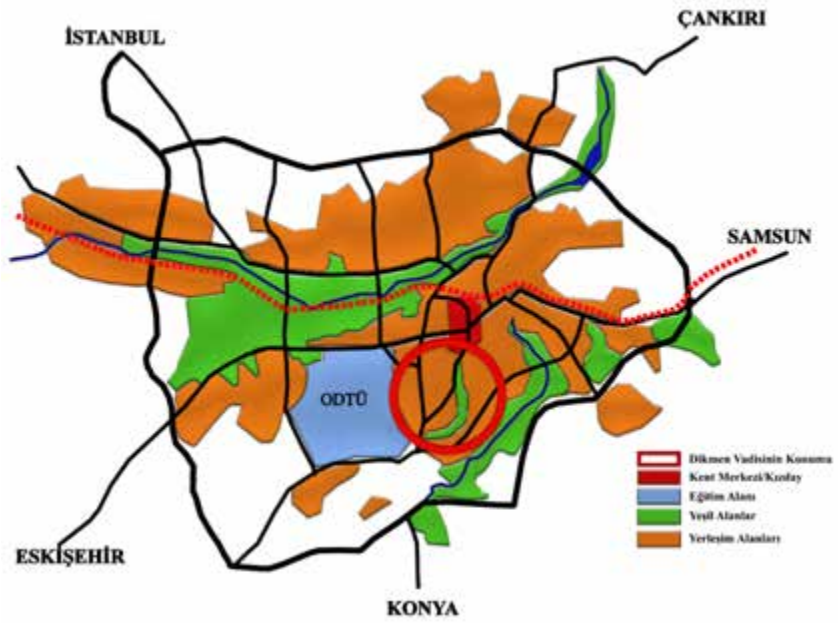

Figure 2: The Location of Dikmen Valley within Ankara (Adapted from Ankara Metropolitan Municipality et al., 1999).

In the aftermath of the 1989 local elections, the Ankara Dikmen Valley Housing and Environmental Development Project was initiated as a comprehensive intervention aimed at addressing this informal settlement. The project constitutes Turkey's first multi-functional urban development initiative, specifically an urban transformation project designed to regenerate informal housing areas. Its overarching aim was to enhance the living environment and improve the quality of life for the resident population and rightful stakeholders within the valley.

Crucially, the planning and preparatory stages of the project deviated from conventional top-down urban planning practices. Instead, a participatory planning approach was adopted, actively involving property owners and other stakeholders in the decision-making process. This inclusive and context-sensitive methodology renders the project a particularly salient case study in the field of urban regeneration.

Accordingly, the implementation of the proposed social sustainability assessment model has been spatially confined to the geographical boundaries encompassing Phases I, II, and III of the Dikmen Valley Housing and Environmental Development Project, as illustrated in Figure 3.

Figure 3: Boundaries of the Study Area

4.2. Scope and Limitations of the Study

For the implementation of the proposed model, the study area was defined as the spatial extent encompassing Phases I, II, and III of the Dikmen Valley Housing and Environmental Development Project. To conduct face-to-face household surveys within this area, separate verbal and written communications were initiated with apartment managers, site administrators, and security personnel.

Despite providing comprehensive information regarding the aim, scope, methodology, and disciplinary relevance of the study, several site and apartment administrations—particularly in Phases I and II—responded unfavourably to the survey request. However, following repeated efforts, access was granted by the management of Çankaya Evleri in Phase I, as well as Çankaya Park Evleri and select homeowner units in Phase II.

Although a formal written request was submitted following an in-person meeting with Phase III management, permission to administer the survey was ultimately denied.

The research sample is composed exclusively of homeowners and tenants residing within the defined study area. No data was collected from individuals outside the project boundary. The survey was administered in four sub-areas: Çankaya Park Evleri, Çankaya Evleri, Yeşil Vadi Street, and Zone 4, which are indicated in Table 2 and Figure 4.

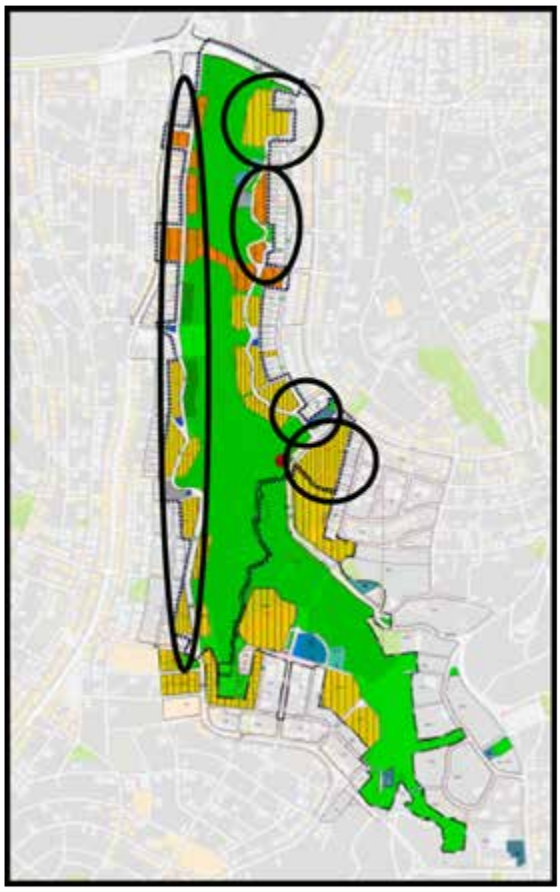

Figure 4: Distribution of Surveys by Area

Table 2: Distribution of Surveys by Area

Area	Number	Percentage
Çankaya Evleri	23	26,7%
Çankaya Park Evleri	32	19,2%
Yeşil Vadi Sokak	41	34,2%
4. Bölge	24	20,0%
Total	120	100,0%

4.3. Methodology

Method for Measuring Social Sustainability in Dikmen Valley

Within the framework of the Social Sustainability Measurement and Evaluation Model, both quantitative and qualitative research methods were employed to assess the indicators developed to achieve the defined criteria, objectives, and sub-objectives of social sustainability. The data used to measure social Sustainability in Dikmen Valley primarily consists of primary sources. These include spatial data, responses collected through household surveys, and insights obtained from in-depth interviews. A mixed-method data collection approach was adopted in the study.

Secondary data were also utilized to contextualize the findings. These include general household statistics from the Turkish Statistical Institute (TURKSTAT) about Ankara Province and Çankaya District, where Dikmen Valley is located, as well as data extracted from existing literature and prior studies conducted on Dikmen Valley.

The face-to-face survey was conducted between May 2018 and October 2018. During this period, 870 individuals were contacted. Of the completed questionnaires, 120 survey forms that were fully and accurately filled out were included in the final evaluation.

Evaluation Method for Measuring Social Sustainability in Dikmen Valley

To determine the demographic characteristics of survey respondents, a nominal scale was utilized, while a five-point Likert scale was applied to assess perceptions of adequacy regarding various social sustainability indicators. The survey forms included both closed-ended and open-ended questions. Where more detailed insights were needed, open-ended questions were used to support responses to closed-ended items.

During the data collection phase, a Computer-Assisted Personal Interviewing (CAPI) technique was employed. In this approach, the questionnaire was digitized and deployed via tablet devices using specialized software to facilitate real-time data entry and minimize errors. The data obtained through the surveys were processed and analyzed using SPSS version 22.0.

All quantitative and qualitative data derived from spatial assessments and face-to-face interviews were quantified on a five-point Likert scale, assigning scores ranging from 1 to 5. These data were then incorporated into the indicator tables developed for each criterion defined in the proposed model. For each criterion, the average scores of the corresponding objectives and sub-objectives were calculated to determine the level of achievement.

The achievement levels were categorized as follows based on average scores:

- 1.00–1.49: Very Poor
- 1.50–2.49: Poor
- 2.50–2.99: Below Average
- 3.00–3.49: Average
- 3.50–3.99: Above Average
- 4.00–4.49: Good
- 4.50–5.00: Very Good

In the final stage of the model's implementation, a comprehensive synthesis was conducted. This included spatial analysis results, survey data, and findings from in-depth interviews with various stakeholders: professionals involved in the project implementation process, current residents who remained in the area following the completion of the Dikmen Valley Housing and Environmental Development Project (DVHEDP), former residents who were relocated after the project, and community activists.

The assessment of social sustainability across the application area—which encompasses Phases I, II, and III of the DVHEDP—was conducted by evaluating the extent to which the objectives and sub-objectives outlined in the Social Sustainability Measurement and Evaluation Model were achieved.

4.4. Implementation of the Social Sustainability Indicator System in the Context of Dikmen Valley

The measurement and evaluation of social sustainability within the implementation area, encompassing Phases I, II, and III of the Dikmen Valley Housing and Environmental Development Project, are conducted by assessing the extent to which the objectives and sub-objectives defined in the Social Sustainability Measurement and Evaluation Model have been achieved. Within this framework, the indicator system criteria are as follows:

A. Demographics and Employment

B. Accessibility

C. Education and Skills

D. Health

E. Housing

F. Safety

G. Belonging

H.Participation

I. Social Capital and Social Cohesion

L. Urban Life Quality, Satisfaction And Adequacy Of Services

4.4.1. Demographics and Employment

In addition to revealing the general population profile of Dikmen Valley, the Demographics and Employment criterion is significant in relation to other model criteria, particularly regarding population dynamics, demographic change, development trends, and employment conditions. The objectives defined for this criterion are as follows (Table 3):

- TA(1.1) Ensuring a Balanced Distribution of the Population
- TA(1.2) TA(2) Ensuring the Balance of the Economic Well-Being of the Population

Table 3: Performance Scoring Table: Demographics and Employment

TA(1.1)) Ensuring a Balanced Distribution of the Population by Birthplace			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I(1) The level of distribution of the population by birthplace	The level of distance from the birthplace of the population to the ageing area	4.4	4.4
		TA (1) Mean	**4.4**
TA(2) Ensuring the Balance of the Economic Well-Being of the Population			
TA(2.1) Poverty Prevention			
I(2) Income level distribution of the population	The proportion of the population living below the poverty line	2.0	3.4
	The proportion of the population with a monthly income below the minimum wage	4.7	
TA(2.2) Provision of Employment Opportunities			
I(3) The level of employment of the population	I(4) The level of employment of the population	4.9	4.6
	The proportion of the working population	4	
	The proportion of the working population over 65	5	
TA(2.3) Ensuring Productivity in Employment			
I(4) The level of productivity of employment	Duration of Employment within the Same Organization	2.3	3.2
	Professional Skill Level	4	
TA(2.4) Ensuring Gender Equality in Employment Opportunities			

I(5) Gender equality level in employment opportunities	The ratio of the number of female employees to the number of male employees	1.9	3.6
	The ratio of average women's wages to male wages	4	
	The ratio of the number of unemployed women to the number of unemployed men	5	
		TA (2) Mean	**3.7**
		General Mean	**4.1**

Within the social sustainability indicator system, the achievement level of these two objectives is assessed based on five sub-targets, five indicators, and one indicator definition (Table 3).

According to the research findings, the sub-objective TA(1.1): Ensuring a Balanced Distribution of the Population by Birthplace was fulfilled at a score of 4.4, indicating a good level of achievement. Although the sub-objective TA(2.1): Poverty Prevention received an average score of 3.4 (moderate level), the specific indicator measuring the proportion of the population living below the poverty line was scored at 2.0, indicating a poor and inadequate level of performance. The sub-objective TA(2.2): Provision of Employment Opportunities was found to be fulfilled at a perfect level with a score of 4.6. While the sub-objective TA(2.3): Ensuring Productivity in Employment received an average score of 3.2, the indicator for Level of Tenure at the Same Workplace was rated at 2.3, which falls within the poor level. The sub-objective TA(2.4): Ensuring Gender Equality in Employment Opportunities was scored at 3.6, indicating a good level of achievement; however, the ratio of female to male employees was rated 1.9, corresponding to an upper-moderate level of achievement. Overall, objective TA(1), Ensuring a Balanced Distribution of the Population, was achieved at a reasonable level with a score of 4.4, while objective TA(2), Ensuring the Balance of the Economic Well-Being of the Population, was rated at 3.7, corresponding to an upper-moderate level (Table 3)

4.4.2. Accessibility

The second criterion of the Social Sustainability Measurement and Evaluation Model—Accessibility—serves not only to assess access to basic services but also to evaluate individuals' ability to meet essential needs and access relevant information. Accessibility is a crucial factor in enhancing social interaction and promoting positive social change and development. The objective defined for the Accessibility criterion is as follows:

- TB(1) Ensuring Equality of Access to Basic Urban Services

Within the social sustainability indicator system, the achievement of this objective is assessed through one sub-objective, one indicator, and five indicator definitions.

According to the research findings, the sub-objective TB(1.1) Ensuring Equality of Access to Social Infrastructure, Open Green and Urban Working, under the Accessibility criterion, was achieved with a score of 4.3, indicating a good level of fulfilment. Although the overall objective and sub-objective of the Accessibility criterion were met at a perfect level, the specific accessibility to healthcare facilities was found to be at a poor and insufficient level, with a score of 2.3 (Table 4).

Table 4: Performance Scoring Table: Accessibility

TB(1) Ensuring Equality of Access to Basic Urban Services		
TB(1.1) Ensuring Equality of Access to Social Infrastructure, Open Green and Urban Working		
Indicators	**Indicator Definitions**	**Score**
I(6) Access level to social infrastructure areas	Level of access to educational facilities	4.6
	Level of access to health facilities	2.3
	Level of access to cultural facilities	4.5
	Level of access to religious centres	4.9
	Level of access to green spaces	5
	General Mean	**4.3**

4.4.3. Education and Skills

The third criterion of the Social Sustainability Measurement and Evaluation Model—Education and Skills—is a key factor in enhancing societal capacity by improving the overall level of education, developing knowledge and competencies, and increasing employability. The objective defined for the Education and Skills criterion is as follows:

- TC(1) Individual and Social Education, Raising and Promoting The Level of Development

Within the social sustainability indicator system, the achievement of this objective is evaluated through three sub-objectives, five indicators, and five indicator definitions (Table 5).

Table 5: Performance Scoring Table: Education and Skills

TC(1) Individual and Social Education, Raising and Promoting The Level of Development			
TC(1.1) Raising literacy and education levels			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I(7) Literacy level	Adult literacy levels	5	4.5
I (8) Level of education	Latest graduated school levels	3.4	
I (9) Spatial adequacy level of educational facilities	The level of competence of the current situation is according to the standards of educational facilities that should be according to the population	5	
TC(1.2) Promoting Participation in Vocational Education			
I (10) Level of participation in vocational courses	Level of participation in existing vocational courses	1.0	1.0
TC(1.3) Promoting Participation in Talent Development Education			
I (11) Level of participation in talent development courses	Level of participation in existing talent development courses	1.0	1.0
		General Mean	**2.2**

According to the research findings, the sub-objective TC (1.1)- Raising literacy and education levels, under the Education and Skills criterion - was found to be at an outstanding level, with an average score of 4.5. However, the sub-objectives HC(1.2): TC(1.2) Promoting Participation in Vocational Education and HC(1.3): Promoting Participation in Skills Development Programs were both scored at 1.0, indicating an inferior level of achievement. Accordingly, the overall objective HC(1): TC(1.3) Promoting Participation in Talent Development Educations was

found to be at a poor level, with an average score of 2.2, indicating that the objective was not achieved (Table 5).

4.4.4. Health

The fourth criterion of the Social Sustainability Measurement and Evaluation Model—Health—is a critical component for maintaining both individual and societal quality of life, as well as the continuity of community-level activities. The objective defined for the Health criterion is:

- TD(1) Ensuring the Adequacy of Health Services

Within the social sustainability indicator system, the achievement level of this objective is assessed through one sub-objective, two indicators, and three indicator definitions (Table 6).

According to the research findings, the objective TD (1), Ensuring the Adequacy of Health Services, was found to be at a poor and insufficient level, with an average score of 2.05 (Table 6).

Table 6: Performance Scoring Table: Health

TD(1) Ensuring the Adequacy of Health Services			
TD(1.1) Ensuring the Adequacy of Health Services			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I(13) Spatial adequacy level of health facilities	The level of adequacy of the current situation is according to the standards of health facilities should be according to the population	1.3	1.3
I(14) Level of access to healthcare	The level of access of local people to health services	3.8	2.8
	The distance level of the health institution to the area that the local people access when they have health problems	1.8	
		General Mean	**2.05**

4.4.5. Housing

The fifth criterion of the Social Sustainability Measurement and Evaluation Model—Housing—is a vital component for sustaining individual and collective daily life activities, as well as for ensuring the continuity of social capacity.

The objective defined for the Housing criterion is:

- TE(1): Ensuring Adequate Housing Conditions for All

Within the social sustainability indicator system, the achievement of this objective is assessed through two sub-objectives, three indicators, and three indicator definitions (Table 7).

According to the research findings, the sub-objective TE(1.1): Increasing Housing Capacity was rated at 3.75, indicating an upper-moderate level of fulfilment.

Similarly, the sub-objective TE(1.2): Improving the Physical Condition of Housing Units received a score of 3.95, also reflecting an upper-moderate level. Accordingly, the main objective TE(1), Ensuring Adequate Housing Conditions for All, was fulfilled at an upper-moderate level with a score of 3.85, indicating that the objective was successfully achieved (Table 7).

Table 7: Performance Scoring Table: Housing

TE(1) Ensuring Housing Conditions for All			
TE(1.1) Ensuring Increasing Housing Capacity			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I (15) Property status of the houses	The ratio of homeownership to tenancy	5	3.75
I (16) The level of affordability of rents with household income	The ratio of average housing rent to average household income	2.5	
HE(1.2) Improving the Physical Condition of Housing			
I (17) Physical condition of the houses	Building status levels of houses	3.95	3.95
		General Mean	**3.85**

4.4.6. Safety

The sixth criterion of the Social Sustainability Measurement and Evaluation Model—Safety—is a crucial component for maintaining both individual and societal life activities, as well as for the continued and safe use of urban space.

The objective defined for the Safety criterion is:

- TF(1): Ensuring Individual Safety

Within the social sustainability indicator system, the achievement level of this objective is evaluated through one sub-objective, three indicators, and seven indicator definitions (Table 7).According to the research findings, the sub-objective TF (1.1): Ensuring Safety in Public and Private Areas was found to be fulfilled at a satisfactory level, with an average score of 4.1. Consequently, the main objective, TF(1): Ensuring Individual Safety, was determined to have been successfully achieved (Table 8).

Table 8: Performance Scoring Table: Safety

TF(1) Ensuring Individual Safety			
TF(1.1) Ensuring Security in Public Spaces and Private Areas			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I (18) Level of security in housing	Level of feeling safe in residences during the day	4.45	4.4
	Level of feeling safe in residences at night	4.3	
I (19) Level of security in public spaces	Level of feeling safe walking on the road during the day	4.25	4.0
	Level of feeling safe walking on the road at night	3.7	
	Level of feeling safe in public spaces during the day	4.05	
	Level of feeling safe in public spaces at night	3.85	
I (20) Level of trust in neighbourly relationships	Level of trust in neighbours	4.1	4.1
		General Mean	**4.1**

4.4.7. Belonging

The seventh criterion of the Social Sustainability Measurement and Evaluation Model—Belonging—is a key component that strengthens individual, spatial, and societal responsibility. It plays a crucial role in establishing and reinforcing connections between people and the places and communities they inhabit, thereby supporting social sustainability. The objective defined for the Belonging criterion is:

- TG(1): Ensuring the Acquisition of Social and Spatial Belonging, Urban Image Awareness, and Cultural Heritage Values

Within the social sustainability indicator system, the achievement of this objective is evaluated through three sub-objectives, four indicators, and six indicator definitions.

According to the research findings, the sub-objective TG(1.1): Ensuring Social and Spatial Belonging was rated at 3.5, reflecting an upper-moderate level of achievement.

The sub-objective TG(1.2): Creation Urban Image Awareness scored 3.95, also indicating an upper-moderate level. In contrast, the sub-objective TG(1.3): Creating Awareness of Conservation of Heritage Values was rated at 1.7, which reflects an inferior and insufficient level. As a result, the main objective, Ensuring the Acquisition of Social and Spatial Belonging, Urban Image Awareness, and Cultural Heritage Values (HG (1)), was found to be achieved at a moderate level, with an average score of 3.05 (Table 9).

Table 9: Performance Scoring Table: Belonging

TG(1) Ensuring the Acquisition of Social, Spatial Belonging, Urban Image, and Heritage Values			
TG(1.1) Ensuring Social and Spatial Belonging			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I (21) The level of belonging of local people to the society they live in	The level of local people's feeling like part of society	4.0	3.5
I(22) The level of the local people's sense of belonging to the area where they live	The level of life expectancy in the area	2.4	
	The level of feeling of belonging to the place they live	4.0	
TG(1.2) Creation of Urban Image Awareness			
I (23) Awareness level of local people about the changing conditions of the area	The level of desire for the area to improve its urban image	3.9	3.95
	The level of thinking that the urban image of the area has improved with the project	4	
TG(1.3) Creating Awareness of Conservation of Heritage Values			
I (24) Level of activities that contribute to the conservation of heritage values	Level of awareness of activities related to the protection of natural heritage in the area of living	1.7	1.7
		General Mean	**3.05**

4.4.8. Participation

The eighth criterion of the Social Sustainability Measurement and Evaluation Model—Participation—is a vital component of social sustainability, as it enhances individual, spatial, and societal responsibility and supports the establishment and integration of relationships between people and their living environments. The objective defined for the Participation criterion is:

- TH(1) Promoting Public Participation in Management, Planning Processes, and Works Related to Municipal Services

Within the social sustainability indicator system, the achievement of this objective is assessed through three sub-objectives, six indicators, and seven indicator definitions.

According to the research findings, the sub-objective TH(1.1) Ensuring Participation in Country and Local Government received a score of 4.8, indicating a very high level of achievement. However, the sub-objective TH(1.2) Ensuring Public Participation in the Planning Process was rated 1.0, and the sub-objective TH(1.3) Ensuring Transparency in Works Related to Municipal Services was rated 1.1, both reflecting an inferior level of performance. Consequently, the overall objective TH(1) Promoting Public Participation in Management, Planning Processes, and Works Related to Municipal Services was found to be not achieved, with an average score of 2.3, corresponding to a poor level of fulfilment (Table 10).

Table 10: Performance Scoring Table: Belonging

TH(1) Promoting Public Participation in Management, Planning Processes, and Works Related to Municipal Services			
TH(1.1) Ensuring Participation in Country and Local Government			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I (25) Level of participation in the country's administration	Level of participation of local people in general elections	4.8	4.8
I (26) Level of participation in local government	Level of participation of local people in local elections	4.8	
TH(1.2) Ensuring Public Participation in the Planning Process			
I (27) Level of public participation in the project design process	Level of participation of local people in the project design process	1	1
I (28) Level of public participation in the completion of the final project	Level of participation of local people in the completion of projects	1	
I (29) Level of public participation in the monitoring process of the project	Level of participation of local people in monitoring of projects	1	
	The level of ability of local people to influence the decisions made in the area where they live	1	
TH(1.3) Ensuring Transparency in Works Related to Municipal Services			
I (30) Level of knowledge of local people about municipal works	Level of informing the local people about the municipal work	1.1	1.1
		General Mean	**2.3**

4.4.9. Social capital and social cohesion

The ninth criterion of the Social Sustainability Measurement and Evaluation Model—Social Capital and Social Cohesion—is a key element of social sustainability. It reflects individuals' sense of belonging to their community, their involvement in local initiatives, participation in collective social efforts, and engagement with others in their environment. The objectives defined for the Social Capital and Social Cohesion criterion are:

- TI(1) Ensuring The Level of Social Development and Social Interaction
- TI(2) Ensuring Diversity and Cultural Integration

Within the social sustainability indicator system, the achievement of these objectives is evaluated through three

sub-objectives, five indicators, and eight indicator definitions.

According to the research findings, the sub-objective TI(1.1) Increasing Social Development was found to be at an inferior level, with an average score of 1.0. The sub-objective TI(1.2) Level of Social Interaction received a score of 2.8, indicating a lower-moderate level. Consequently, the main objective, TI(1) Ensuring the Level of Social Development and Social Interaction, was not achieved, with an overall average of 1.9, corresponding to a poor level.

Additionally, the sub-objective TI(2.1) Ensuring Cultural Diversity and Cultural Integration was rated at 1.4, indicating a very poor level, and the main objective TI(2) Ensuring Diversity and Cultural Integration was also found not to be achieved (Table 11).

Table 11: Social capital and social cohesion

TI(1) Ensuring The Level of Social Development and Social Interaction			
TI(1.1) Increasing Social Development			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I(31) Level of participation in information studies	Level of participation in the information studies organized about the area of living	1	1
I (32) Level of participation in social awareness studies	Level of participation in social awareness studies	1	1
	Level of voluntary involvement in any association/non-governmental organization (NGO)	1.1

4.4.10. Urban life quality satisfaction and adequacy of services

The tenth criterion of the Social Sustainability Measurement and Evaluation Model— Urban life quality satisfaction and adequacy of services—is a critical element of social sustainability, as it contributes to individual and societal well-being, happiness, equity, and a sense of sufficiency.

Table 12: Social capital and social cohesion

TL(1) Ensuring the Satisfaction of the Local People in the area they live in and the Adequacy of the Services Provided			
TL(1.1) Ensuring Satisfaction with the Quality of Urban Life			
Indicators	**Indicator Definitions**	**Score**	**Mean**
I(36) Level of satisfaction with environmental quality	Level of satisfaction with the quality of the natural environment	3.8	3.8
	Level of satisfaction with the quality of the built environment	3.8	
I(37) Level of satisfaction with housing and living conditions	Level of satisfaction with the standard of housing	4.3	4.2
	Level of satisfaction with the residence	4.2	
	Level of satisfaction with living conditions	4.2	
I(38) Level of satisfaction with social areas	Level of satisfaction with open and green areas	4.1	4.0
	Level of satisfaction in sports areas	3.7	
	Level of satisfaction in the religious areas	4.0	
I(39) Level of satisfaction with economic opportunities	Level of satisfaction with employment opportunities	3.6	3.6
I(40) Level of satisfaction with safety conditions	Level of satisfaction with personal security	4.0	4.0
I(41) Satisfaction level of participation in decision-making processes related to the area of living	Level of participation in decision-making processes and planning related to the area of living	3.3	3.3
		TL(1.1) Mean	**3.8**
TL(1.2) Ensuring the Adequacy of Urban Services			
I(42) Adequacy level of educational services	Adequacy level of educational services	3.5	3.3
	Adequacy level of cultural facilities	3.4	
	Adequacy level of library services	3.0	
I(43) Adequacy level of recreation areas	Adequacy level of entertainment areas and areas for spending time	3.6	3.6
I(44) Adequacy level of economic opportunities	Adequacy level of employment opportunities	3.4	3.4
I(45) Adequacy level of social services	Adequacy level of social services	3.5	3.5
		TL(1.2) Mean	**3.5**
		General Mean	**3.6**

The objective defined for this criterion is:

- TL(1) Ensuring the Satisfaction of the Local People in the area they live in and the Adequacy of the Services Provided

Within the social sustainability indicator system, the achievement of this objective is evaluated through two sub-objectives, ten indicators, and seventeen indicator definitions.

According to the research findings, the sub-objective TL(1.1), Ensuring Satisfaction with the Quality of Urban Life,

was scored 3.8, and the sub-objective TL(1.2), Ensuring the Adequacy of Urban Services, was scored 3.5, both corresponding to an upper-moderate level of achievement. Consequently, the main objective TL(1), Ensuring the Satisfaction of the Local People in the area they live in and the Adequacy of the Services Provided, was determined to be achieved, with an average score of 3.6, indicating an upper-moderate level of fulfilment (Table 12).

4.4.10. Result and Discussion

According to the research findings, within the implementation area of the Dikmen Valley Housing and Environmental Development Project (DVHEDP), the criteria of the social sustainability indicator system were evaluated based on their average scores. The criteria of Demographics and Employment (4.1 points), Accessibility (4.3 points), and Safety (4.1 points) were found to be at a reasonable level, with average scores exceeding 4.

The criteria of housing (3.85 points) and urban life quality satisfaction and adequacy of services (3.6 points) were determined to be at an upper-moderate level.

The Belonging criterion scored 3.05, corresponding to a moderate level. In contrast, the criteria of Education and Skills (2.2 points), Health (2.05 points), Participation (2.3 points), and Social Capital and Social Cohesion (1.7 points) were identified as being at a poor level of achievement (Figure 5).

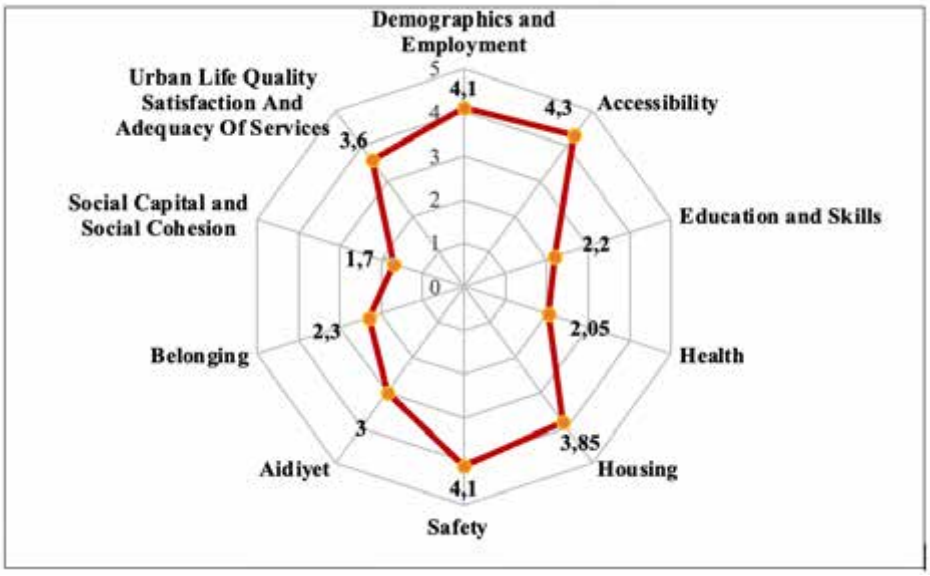

Figure 5: Assessment Scores of the Social Sustainability Indicator Framework

According to the research findings, within the implementation area of the Dikmen Valley Housing and Environmental Development Project (DVHEDP), the criteria of Demographics and Employment, Accessibility, and Safety achieved high average scores. They were determined to be at a reasonable level, indicating that the corresponding objectives and sub-objectives were successfully met.

In terms of Demographics and Employment, it was found that before the implementation of DVHEDP, the area was an informal settlement. Following the project, the original right holders began residing in planned housing, which resulted in a homogeneous population structure in terms of population balance and economic welfare, with limited heterogeneity.

For the Accessibility criterion, the integration of social infrastructure within the project's planning boundaries and surrounding areas ensured that the population's needs were met within walking distance.

The Safety criterion was also met, mainly due to the presence of security personnel in building complexes and gated areas developed under DVHEDP, as well as the restriction of unauthorized access to these zones.

Regarding Housing and Urban life quality satisfaction and adequacy of services, the criteria were found to be at an upper-moderate level. All buildings in the area were newly constructed as part of the DVHEDP, leading to an improvement in their physical condition. High homeownership rates contributed to achieving housing capacity objectives. The findings for Urban Quality of Life and Services reflect satisfaction with environmental quality, housing and living conditions, recreational areas, and safety—demonstrating the spatial benefits of the DVHEDP.

Although the Sense of Belonging criterion met its objectives and sub-objectives at a moderate level, the lack of awareness regarding the preservation of heritage values within the area was identified as a shortcoming. Given the valley's natural and ecological significance, it is necessary to increase residents' awareness and engagement in preserving the area.

The criteria that failed to achieve the defined objectives and sub-objectives in terms of social sustainability include Education and Skills, Health, Participation, and Social Capital and Social Cohesion, each scoring poorly.

For Education and Skills, despite the relatively low number of employed women in the area, participation in vocational and skill development programs was almost non-existent. This harmed the overall level of personal and community development. Promoting participation in such programs is essential to improving this criterion.

In the Health criterion, the lack of sufficient health facilities within the effective service radius and the distant location of existing health institutions from the population were the primary reasons for failing to meet health-related objectives. Although new facilities were proposed in the DVHEDP master plan, they were not implemented. Ensuring the construction of appropriately scaled facilities is essential for fulfilling the criteria's goals.

Under the Participation criterion, while residents were found to engage in national and local governance, they did not actively participate in neighbourhood-related planning processes. Therefore, the sub-objectives related to citizen involvement in planning and transparency in municipal services were not achieved. Encouraging and enabling participation in these processes is a key requirement for social sustainability.

Lastly, Social Capital and Social Cohesion were the weakest-performing criteria, with none of its sub-objectives being met. Actions aimed at enhancing social development interaction and promoting cultural diversity and integration are urgently required to strengthen this dimension.

Rethinking Social Inclusivity. The Case of Urban Villages in Delhi

Pranavi Kasula
Affiliation: Griffith University, Gold Coast, Australia
Email: pranavi.kasula@griffithuni.edu.au

Abstract
This study analyses the socio-spatial inclusion and exclusion of Delhi's urban villages under the framework of inclusive and safe urban development. Unlike slums, urban villages receive limited policy attention, despite their important role in housing rural migrants and supporting local economies. Their exclusion from official planning makes them vulnerable to marginalisation or gentrification. Using a qualitative technique, the study combines policy analysis with comparative case studies of Hauz Khas and Zamrudpur. Findings reveal a gap between policy intent and implementation, facilitated by fragmented governance, dated planning regulations, and inadequate finance. The two cases illustrate distinct outcomes driven by selective planning, political influence, and administrative neglect. The paper recommends for a context-sensitive, participatory planning acknowledging unique characteristics of urban villages, along with inclusive, localised policy reform.

Keywords: Socio-Spatial Inclusion; Urban Village; Gentrification; Marginalisation; Inclusive Planning Policies; Participatory Planning

Introduction

Urban Village Exclusion: A Global Issue

In the recent years, urban villages—former rural villages now encroached by cities, have garnered increased attention in urban studies, notably in cities in global South (Wang, 2022). Found predominantly in India, China and other Southeast Asian countries, urban villages are often viewed as informal settlements, arising from rapid urbanisation (Banerjee, 2021, Chen et al., 2023, Kochan, 2015, Tong et al., 2021, Wang, 2021) and large scale rural-to-urban migration (Al, 2023, Zhang, 2021, Tan et al., 2019). These settlements exist at the intersection of rural and urban systems and are typified by dense mixed-use development (Banerjee, 2021, Islam, 2023, Lin and de Meulder, 2011) with dark and narrow streets (Al, 2023, Qu, 2020, Zhang, 2021), inadequate infrastructure, and substandard rental housing (Wang, 2022, Tong et al., 2021, Spreeuwers, 2014). Given these physical characteristics, urban villages and their residents often face socio-spatial segregation within broader urban fabric.

In addition to their physical characteristics, urban villages experience socio-economic marginalisation. Many urban villagers, particularly rural migrants, lack recognition as "citizens," limiting their access to economic, social, political, and cultural spheres, making their integration into cities difficult (Cappo, 2002). This is further aggravated by internal stratification among urban villagers, which increases existing social disparities. According to He et al. (2010), rural migrants who make up for a significant portion of the urban village population are at the bottom of the social structure, while indigenous villagers who own land assume the role of petty landlords, benefitting from rental income. Furthermore, existing research have documented socio-economic exclusion of urban villagers, particularly rural migrants, who incur structural barriers across multiple domains. Their access to legal housing is limited (Lin et al., 2015) due to the lack of formal employment opportunities as a consequence of low education levels (Yu and Wu, 2021, Zhang, 2021). Furthermore, their political representation is overlooked, often hampered by discriminatory institutional systems (Li and Sun, 2021, Ren, 2018, Wong et al., 2018).

While socio-economic exclusion is well-documented, the spatial exclusion of urban villages remains an equally pressing issue. Despite being an important part in the local economy and offering affordable housing (Islam, 2023, Liu et al., 2018, Chen et al., 2023, Spreeuwers, 2014), urban villages are systematically excluded from formal urban planning frameworks (Banerjee, 2021). This exclusion is perpetuated by urban governance structures that either neglect these areas or impose restrictive planning controls. Bureaucratic inefficiencies, such as time-con-

suming land title registration (Tong et al., 2021), further hamper their integration. Discriminatory practices like China's hukou or household registration system limits rural migrants' access to formal housing and services, aggravating urban villages' marginalisation (Chen et al., 2023, Zhang, 2021). Wu et al. (2020) underscore that despite urban villages falling within the city or the officially designated urban growth boundary (UGB) they are excluded from the urban service boundary (USB), which defines the extent of municipal service provision. This deliberate exclusion reinforces a cycle of informality, socio-spatial inequality and constant marginalisation. Market-driven urban redevelopment strategies further compound the problem, prioritising financial benefits over social inclusion and often resulting in the displacement of vulnerable populations (Liu et al., 2018). Gentrification processes, spurred by urban renewal projects, frequently transform urban villages to attract wealthier demographics while alienating lower-income residents (Davidson and Lees, 2005, Song et al., 2008). This phenomenon underscores the increasing overlap between social and spatial exclusion, emphasising the need for integrative planning approaches to mitigating urban inequalities.

Role of Planning in Exclusion

In many Global South cities, urban planning frameworks fail to integrate urban villages into formal urban development strategies. Strategic planning measures for their inclusion are either poorly articulated or entirely absent from master plans (Thinh et al., 2024). Zoning and planning regulations play a pivotal role in shaping urban villages (Wu et al., 2022), often determining whether they are integrated or excluded from the broader urban fabric. As a top-down regulatory framework, zoning governs land use through bureaucratic controls such as restrictive land-use conditions, complex planning permissions, and rigid development bylaws. These mechanisms are embedded in urban governance instruments, including development plans, building codes, deed restrictions, and transferable development rights (Geyer, 2024). However, in many Global South nations, zoning laws have been inherited from colonial-era planning systems with minimal adaptation to contemporary socio-economic contexts. Many African and Asian countries, including India, continue to rely on outdated master planning and zoning frameworks introduced during colonial rule (Watson, 2009). These rigid regulatory structures fail to accommodate the needs of marginalised urban populations, limiting their access to tenure security and formal economic opportunities (Devas, 2001).

Instead of promoting inclusion, zoning and planning rules often displace vulnerable groups, prompting them to informal settlements such as Brazil's favelas, Bogota's barrios, India's jhoppad-pattis, functioning beyond the regulations (Mangin, 2014, Nel, 2016). Once zoning regulations are enforced in these areas, residents face costly and impractical regularization measures that further deepen socio-economic inequalities (Geyer, 2024, Pennington, 2000). The exclusionary nature of these policies necessitates a critical reassessment of how zoning and planning mechanisms impact urban village development. Policymaking plays a decisive role in determining whether urban villages are included or excluded from formal urban systems. When zoning laws and planning regulations are designed with inclusion in mind, however, they can facilitate tenure security, improve infrastructure provision, and support social mobility for marginalised communities. Conversely, exclusionary policies reinforce urban iequalities by limiting access to public services, employment hubs, and civic participation. Addressing these systemic challenges requires a paradigm shift in urban governance—one that prioritises inclusion over market-driven imperatives (Lens, 2022).

In the light of the above challenges, this study aims to bridge the identified gaps by examining the central research inquiry: How do existing regulatory tools and planning policies influence the socio-spatial inclusion and exclusion of urban villages within the broader urban fabric? The specific objectives addressed include: (1) analysing policy gaps in existing regulatory tools and planning policies governing urban villages; (2) identifying key stakeholders and their role in shaping urban villages; (3) assessing policy outcomes that contribute to socio-spatial exclusion of urban villages; and (4) proposing policy recommendations for fostering integration of urban villages through inclusive zoning, planning and urban governance mechanisms. To achieve these objectives, this study employed a systematic policy review and comparative case study approach to inform inclusive policy reforms that enhance urban governance and integrate urban villages.

Methodology

This study used a two-phase method that combined a policy review with comparative case study approach (Yin, 2009) to analyse the planning policies and regulatory tools that impact urban village's socio-spatial inclusion. In India, urban villages, often occur in grey areas of urban planning systems, experiencing exclusionary planning practices that impede their inclusion into formal city frameworks. The study aimed at understanding how urban planning instruments, such as master plans and zoning regulations affect these communities. The first phase included a thorough analysis of 'pre-textual sources' (Morgan, 2022), like land-use policies, government documents, and planning policies pertaining to urban villages in Delhi NCT. A systematic search method was utilised to collect policy papers from official government websites, with an emphasis on policies that have historically and now governed urban villages. The second phase included a comparative case study (Bartlett and Vavrus, 2017, Yin, 2009), concentrating on two urban villages in Delhi: Hauz Khas Village (HKV), a gentrified neighbourhood, and Zamrudpur, a marginalised village. The case study sites were chosen for their distinct socio-spatial, economic, and cultural qualities, which provide insights into how similar regulatory frameworks result in disparate outcomes in urban integration. This comparative analysis sought to emphasise the influence of planning strategies in either reinforcing or alleviating urban inequality.

The study employed the Institutional Analysis and Development (IAD) framework (Kiser and Ostrom, 1982, Polski and Ostrom, 1999) an analytical tool for data analysis (Figure 1). This paradigm is intended to help researchers better understand the interplay between governance, actors, and the external factors that influence policy outcomes. It focuses on the "action arena," where policy decisions are made and influenced by three external variables: biophysical conditions, community characteristics, and rules in use. For this study, the bio-physical conditions refer to characteristics of urban villages, rules-in-use are formal planning policies and regulations governing urban villages. The action arena is the urban village policymaking, where policies are formulated, and decisions are made by key actors or decision-makers. The pattern of interactions has been revised to stakeholder interactions, to understand the relationships and differences between key actors, which can aid in identifying management gaps. Finally, the outcomes of these policies were assessed through comparative case study approach, by analysing baseline reports, and other grey sources discussing the implications and effectiveness of these regulatory tools. Based on the assessment, policy reforms were recommended aimed at modifying the exogenous factors like rules-in-use, to reshape the action area i.e., policymaking landscape to enable inclusive and effective policy enforcement for Delhi NCT's urban villages. In conclusion, the adoption of IAD framework helped in identification of policy gaps, stakeholder interactions and interests hindering inclusion of urban villages. The IAD framework was used during both the policy review and comparative case study phases. The study followed a qualitative thematic analysis using NVivo software for data coding. The study revealed reoccurring themes, sub-themes, and gaps in policy implementation. Thematic analysis was carried out using Braun and Clarke (2006) six-phase approach: data familiarisation, code creation, theme search, theme review, theme definition, and reporting findings. This method enabled a thorough understanding of how policies reinforced exclusion or promoted inclusion in urban villages.

(Source: Adapted from Ostrom (2005); grey square added by Author).

Findings

India's urban planning system is structured as a hierarchy of statutory and non-statutory plans that are developed in response to evolving planning needs, legal mandates, and traditions (TCPO, 2015). These include the Perspective Plan, Regional Plan (RP), Development Plan (e.g., Master Plan, City Development Plan), and Local Area Plan (LAP), which operate at various spatial levels and increase in detailing with descending hierarchy (Kundu et al., 2019), as illustrated in Figure 2. Perspective Plans establish long-term objectives at the national, state or regional level, whereas Regional Plans combine state and national resources at the metropolitan or district level. Development Plans address city-wide policies, while Zonal Plans and LAPs govern zones and neighbourhood-level planning. Furthermore, Special Area or Purpose Plans address context-specific issues, while Annual Plans developed by local bodies assist in project implementation and budget allocations (TCPO, 2015). In accordance with this hierarchy, this study reviewed important regulatory instruments influencing Delhi's urban villages. These were the NCR Regional Plans, the Delhi Sub-Regional Plan, the Delhi Master Plan, and the Zonal Development Plans, as highlighted in blue in Figure 2. Special Area Plans and frameworks tailored to each urban village were also considered. This multi-tiered policy research sought to identify policy flaws, operational gaps, and socio-spatial impacts affecting the inclusion or exclusion of urban villages in Delhi's overall planning framework.

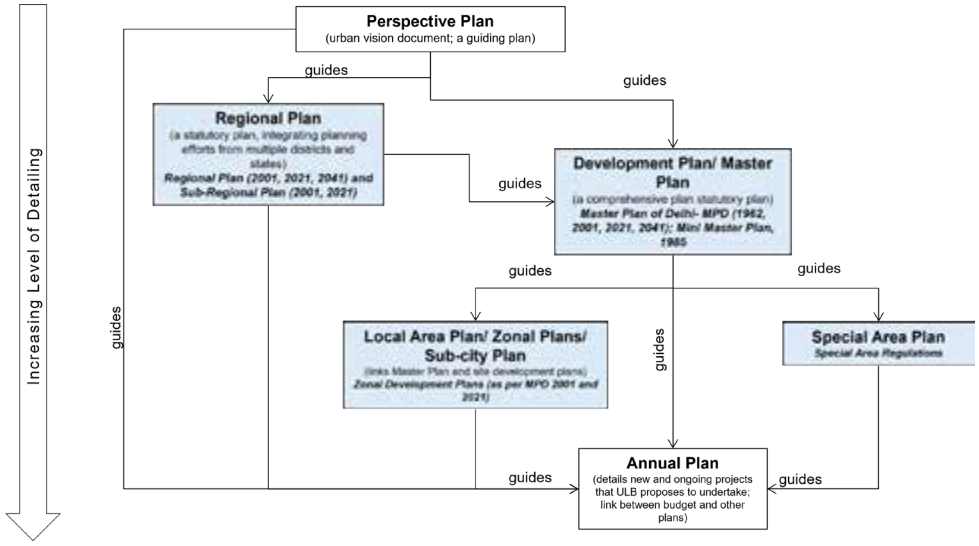

Figure 2 Types of plans and their inter-relationships in India (Source: Author's compilation).

Variable I: How are Urban Villages Discussed within the Existing Rules-in-Use?

Within the existing rules-in-use, Delhi's urban villages are often classified as unplanned settlements in legal documents like the MPDs and ZDPs, suffering from inadequate infrastructure, low housing quality, and a lack of regulatory control (DDA, 2021b, DDA, 2007a, DDA, 2011). These settlements have emerged from the British-era Lal Dora notification, which exempted them from building regulations with the intention of preserving rural identity, in unregulated development and spatial separation from adjacent urban areas (MoUD, 2007). Today, 135 urban villages in Delhi are centres for affordable housing, predominantly housing labour migrants. They also serve as hub for small-scale businesses, yet these villages are politically ignored and excluded from mainstream urban development (MoUD, 2007, GNCTD, 2024).

Variable II: The Rules-in-Use: Key Planning Instruments and Policies

The Foundational Planning Frameworks: Regional, and Sun-Regional Plans

The examination of Delhi's planning tools found several policy gaps, particularly in terms of socio-spatial integration. The NCR Regional Plans, which serve as the foundation for urban planning in the National Capital Region (NCR), only briefly address urban villages. The Regional Plan-2001 focused on regional development but disregarded urban villages, classifying them as rural (NCRPB, 1988). The following RP-2021 made minor attempts to incorporate urban villages by focusing on infrastructure improvements through public-private partnerships (PPP) modes but without planning strategies for their development or integration (NCRPB, 2005). The latest plan, RP-2041, explicitly acknowledged the existence of urban villages , and suggested redevelopment and conservation measures tailored to their distinct needs and characteristics, such as heritage preservation and environmental considerations for communities in sensitive locations like riverbed (NCRPB, 2021). However, these plans did not effectively address these communities' socio-spatial, and cultural dynamics, limiting the potential for significant urban transformation.

At the sub-state level, the Sub-Regional Plans (SRPs), developed under the NCRPB Act, 1985, serve as an intermediate plan translating the objectives of Regional Plans (RPs) into feasible proposals. The NCR Planning Board mandates all participating states to develop SRPs to integrate planning efforts with the larger objective of balanced regional development (DDA, 1994a). In Delhi NCT, the SRPs were prepared by DDA (NCR Planning Cell), aligned with the objectives of the Regional Plans 2001, and 2021, respectively. The SRP-2001 aimed to relieve the capital's urbanisation pressures by projecting its demands into the larger Regional Plan, consequently influencing the Master Plans and SRPs of neighbouring NCR states (DDA, 1994a). Like RP-2001, SRP-2001 did not acknowledge urban

villages' existence. The plan had primarily concentrated on the urban and rural areas, ignoring the transitional and informal characteristics of urban villages, thereby excluding them from formal planning document (DDA, 1994a).

In contrast, the SRP-2021 conformed with the aim of RP-2021, acknowledged the urban villages, particularly in the context of demographic shifts. Between 1991 and 2011, Delhi experienced decline in rural population from 11% to 2%, this can be attributed to reclassification rural villages as urban as per Master Plan-2021. Also, with land pooling scheme in pipeline, the plan anticipates all existing villages will become urban villages (DDA, 2021a). Despite their official recognition in SRP-2021, substantial policy and data gaps persists. The plan did not provide population data or socio-economic profiles for urban villages, unlike its detailed treatment of slums and unauthorised colonies[1]Furthermore, the plan stereotyped urban villages as one of the sources for encroachment, and unplanned development near heritage precincts like Shahjahanabad, Mehrauli, and Tughlaqabad, highlighting negative perceptions and lack of inclusion DDA (2021a). Overall, while SRP-2021 marked a change toward acknowledging urban villages in planning debate, it fell short of providing a viable framework for their growth. Both Regional and Sub-Regional Plans lacked a comprehensive knowledge of how urban villages fit into Delhi's urban framework. Their continuing marginalisation, whether through omission or unfavourable portrayal, highlighted a persistent gap between planning strategy and ground realities.

Provisions under Master Plans: Evolution of Urban Village Policies

The Master Plan Delhi (MPD) have gradually addressed urban villages, with each update reflecting changes in administration, urbanisation, and policy objectives. These urban villages, which are frequently viewed as marginalised pockets, have undergone substantial transformations in both policy discourse and urban planning practice, but in inconsistent ways. The following describes the evolution of provisions for urban villages in several Master Plans, aligning with broader Regional and Sub-Regional Plans, highlighting key issues and developments.

The First Master Plan for Delhi formulated in 1962 (or MPD 1962) was designed to control the city's expansion in response to the population influx post-partition. The goal was to guide urban expansion using land use zoning and spatial consolidation for an estimated population of 5 million by 1981 (DDA, 1962). The plan divided Delhi into eight planning zones, with an additional zone for rural areas in Outer Delhi. It emphasised on large-scale land acquisitions, structured zoning, and infrastructure development to meet projected population growth. However, the MPD 1962 overlooked urban villages, regarding them as rural areas, and sites for non-polluting industries and rural trades like dairy and cow farming (DDA, 1962). In the following year 1963, an exemption notification by the MCD, permitted urban village residents to develop structures without legal authorisation from governing agencies. This resulted in unchecked growth, congestion, and increased migration, altering the socio-economic and spatial landscape of urban villages (MoUD, 2007).

In 1985, the Government of National Capital Territory of Delhi (GNCTD), drafted a Mini Master Plan for the planned development of rural areas, including 135 urban villages. The strategy aimed to prevent unregulated expansion and promote the orderly development of urban villages by abolishing the Lal Dora system and requiring the adoption of municipal regulations for construction activities (GNCTD, 1985). It advocated incorporating urban villages into the Delhi Development Authority's (DDA) development limits, as well as the introduction of land use policies to regulate the villages' increasing industrial activity. Furthermore, the plan also proposed a gradual redevelopment strategy for urban villages, with a focus on infrastructure upgrades, integration with adjacent planned areas, and the implementation of village-specific building codes (GNCTD, 1985). However, a lack of regulatory clarity and a failure to apply the suggested building regulations resulted in the prolonged neglect and marginalisation of urban villages. The intended policy framework was left in uncertainty, and urban villages were excluded from the larger urban transformation effort.

1 Unauthorised colonies refer to residential areas in Delhi that have developed in violation of the city's master plan regulations.

MPD 2001: A Shift in Acknowledgment of Urban Villages

The Second Master Plan-2001 (MPD 2001) identified urban villages in a more structured way, including them into the larger framework of the Delhi Metropolitan Area (DMA) (DDA, 1990). The MPD attempted to address the housing needs of informal settlements, including urban villages, and encompassed a variety of planning zones, such as heritage zones and periphery rural areas. The plan focused on physical infrastructure, health, and education services in certain regions, while also acknowledging the need for transforming urban communities and preserving their traditional lifestyles (DDA, 1990). However, the rules for urban villages in the MPD 2001 were ambiguous and lacked clear planning guidance. The plan advocated for 'sensitive treatment' and the provision of new amenities while retaining cultural identity, but it did not offer tangible solutions for integration. Urban villages were left with few alternatives for planning, particularly in places with inconsistent land ownership, dense built form, and insufficient infrastructure.

MPD 2021: A Progress Toward Integration

The Third Master Plan (MPD 2021) aimed to transform Delhi into a global metropolis and a world-class city. This version of the plan identified urban villages as crucial components of Delhi's urban fabric, highlighting their distinct socio-economic and spatial qualities. It permitted small-scale businesses within villages, encouraged mixed-use regulations, and relaxed group housing standards to accommodate the compact, organic structure of urban villages. Furthermore, the plan established requirements for public facilities, enabling the efficient supply of services in limited spaces (DDA, 2007a). The plan designated the urban villages and its extension areas under residential zones, even though they did not fall under the standard land-use classification. Furthermore, it identified pedestrian-friendly commercial streets, and mixed-use corridors, highlighting the vital role of urban villages in supporting local economies (DDA, 2007a). The plan additionally recommended the Land Pooling Model for land assembly and infrastructure development, highlighting a move towards more inclusive and adaptive urban planning. However, MPD-2021 had certain implementation flaws. While the master plan developed foundations for integrating cities, their implementation remained aspirational, slowed by policy formation delays and regulatory uncertainty. The plan indicated a trend toward acknowledging the urbanity of Delhi's urban villages, but it failed to transform these objectives.

MPD 2041: Shift towards Sustainable Development and Heritage Integration

The MPD 2041, which was implemented in 2021, sought to make Delhi a sustainable, liveable, and vibrant city. Several elements of previous plan MPD 2021 were maintained in this plan, notably the residential character of the urban villages. It also highlighted the regeneration of urban villages, particularly those with heritage significance, and regarded them as sites for high-end retail and cultural activities (DDA, 2021b). The plan aimed to improve physical infrastructure, safety standards, and overall quality of life in these villages, and solve the issues of integrating urban villages into the city. Still, MPD 2041 failed to explicitly state regeneration implementation methods, and a lack of specificity about important stakeholders and regeneration techniques left many anticipated actions unresolved. Despite acknowledging the socio-economic potential of urban villages, MPD 2041's policy shortcomings underscored the persistent issue of bridging the gap between planning and execution.

Zonal Development Plans: The Micro-Level Plans (2001 to 2021)

Zonal Development Plans (ZDPs), which bridges Master Plans and neighbourhood or layout plans, have addressed urban villages haphazardly across planning periods. Urban villages received divided attention in the ZDPs under MPD-2001. For example, zones A, B, and C ignored urban villages (DDA, 1994b, DDA, 1994c, DDA, 1994d), while Zones D and F identified urban villages primarily due to presence of heritage monuments, recommending 'conservative surgery' approach for heritage villages like Nizamuddin (DDA, 1988). Whereas zone F emphasised unsuccessful redevelopment attempts and allowed restricted mixed-use until formalisation (DDA, 1998). Other zones, like zone K highlighted infrastructural deficiencies, indicating ongoing planning negligence (DDA, 1992).

Under the framework of MPD-2021, ZDPs experienced a partial policy shift with the Village Redevelopment

Schemes, promoting infrastructural upgrades, mixed-use zoning, and re-densification. Villages in Zones A, C, and F were classified as 'Special Areas' to foster context-sensitive development (DDA, 2007b, DDA, 2010f, DDA, 2010c). Some were also permitted to develop small-unit housing opposing planned developments (DDA, 2010b, DDA, 2010e, DDA, 2010f). Zones K-II and O (DDA, 2010a, DDA, 2010d) indicated a rising but limited sensitivity to heritage and the ecological environment, with Zone K-II mandating heritage protection, emergency access, and social services. Despite these improvements, implementation remained patchy. Formal integration was hampered by regulatory constraints.

ZDPs under MPD-2041 are still pending, indicating a procedural gap between strategic vision and local planning. This delay denies urban communities timely development recommendations, maintaining their socio-spatial marginalization (DDA). Overall, a review of Delhi's planning instruments demonstrates a recurring gap between strategic objective and execution, resulting in the socio-spatial exclusion of urban villages. Although regional and sub-regional plans eventually acknowledged urban villages, they were presented as unfavourable pockets of the city with few integration approaches. While Master Plans progressed from neglect in MPD-1962, to gradual recognition in MPD-2001 and MPD-2021, and regenerative goals in MPD-2041, implementation delayed due to legal ambiguity and a lack of stakeholder transparency. Zonal Development Plans reflected this inconsistency, with selective attention and delayed modifications. In conclusions, urban villages continue to be neglected by inclusive urban development because of fragmented, and inconsistent planning strategies.

Actors in the Urban Village Policymaking: Their Interests, Goals, and Conflicts

Ostrom (2005) describes the action situation as a 'conceptual space' or setting where actors interact on a particular issue—in this context urban village policymaking resulting in a shared outcome. It is structured by institutions or rules-in-use and is also influenced by exogenous variables. Also, during the interaction process, the actors respond in a certain way that enable them to achieve goals, preferably based on their interests, goals, mandates, and benefits. For this study, the key actors and their interactions in the urban village policymaking (action situation) were identified through the assessment of urban planning policies and regulations (rules-in-use).

Delhi's urban village governance is influenced by a multi-scalar, fragmented structure including multiple institutional players with overlapping mandates and frequently competing interests (Figure 3). Although urban development is theoretically a state responsibility, Delhi's governance is divided between the central and state governments, which adds to administrative ambiguity (GNCTD, 2024, NIUA, 2020a, NITI Aayog, 2021).

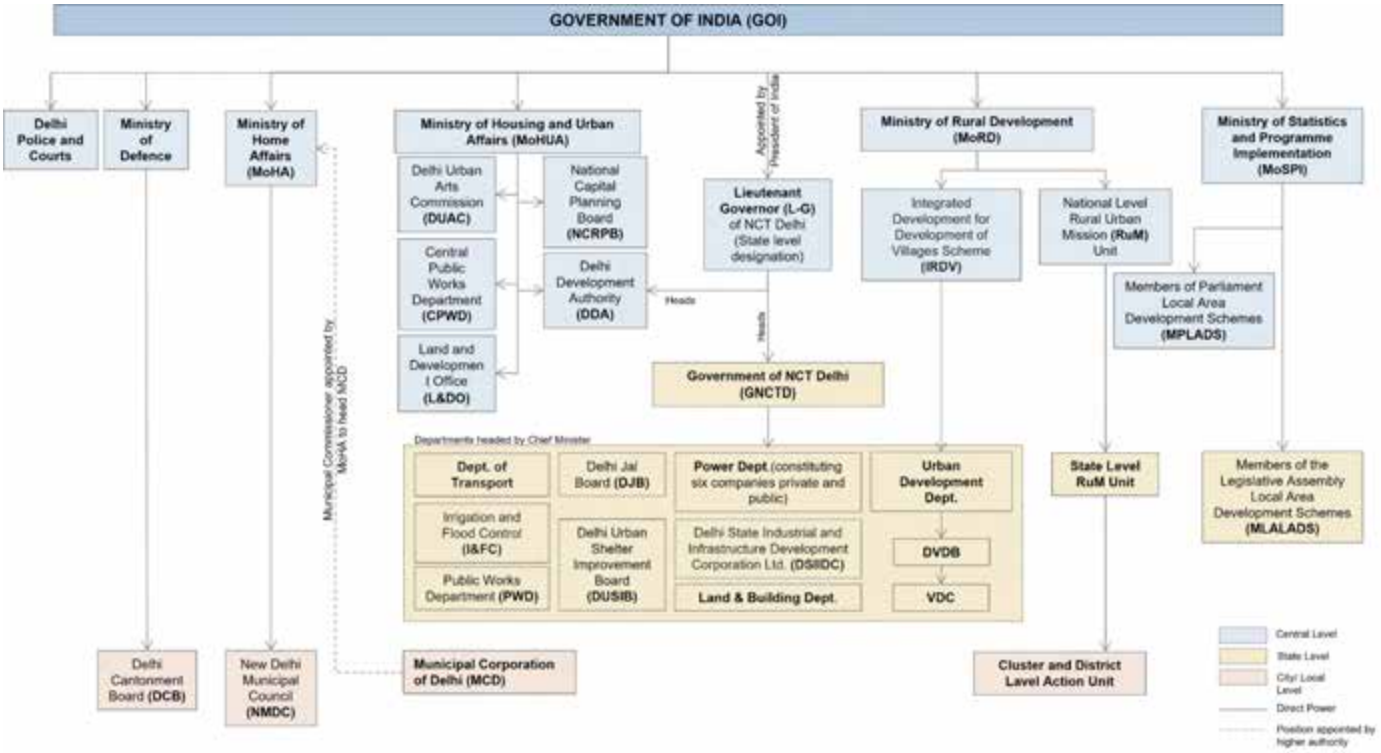

Figure 3 Key actors and their interactions in urban village planning and governance. Solid lines show administrative hierarchy; dashed lines indicate appointments by higher authorities (Source: Author's compilation).

Statutory planning is driven by key central institutions such as the Delhi Development Authority (DDA) and the National Capital Region Planning Board (NCRPB), which use regional and master plans. However, early NCRPB plans lacked specific solutions for urban villages, instead focusing on infrastructure through public-private partnerships that ignored socio-spatial issues (NCRPB, 2005). Only RP-2041 proposed mechanisms such as TDRs, higher FAR, and GIS-based land titling, but implementation remained limited (NCRPB, 2021). At the subregional level, SRP-2001 failed to identify urban settlements at all, whereas SRP-2021 recognised them but supported their integration but lacked socioeconomic data (DDA, 2021a). On the implementation front, institutions like DDA, MCD (Urban Local Body), and state departments like DJB, PWD, and DVDB have been pursuing infrastructure targets with little coordination (GNCTD, 2024, GNCTD, 1985). This institutional distribution has resulted in service gaps and unfulfilled growth in urban communities.

Meanwhile, informal actors such as private developers, NGOs, heritage organisations, and local leaders add to the complexity of governance. While commercial developers profit from high-density redevelopment, NGOs and historic organisations such as ASI and INTACH frequently have contradictory missions and lack a single heritage database (NIUA, 2020b). Residents of urban villages seeking tenure security, service access, and cultural preservation continue to be caught between regulatory complexity and policy neglect because of outdated rules and inaccurate land records. These competing interests and fragmented responsibilities have exacerbated socio-spatial exclusion, highlighting the importance of coordinated, context-sensitive governance anchored in local reality.

Assessing Policy Outcomes through Comparative Case Study Analysis

This study assessed the local, case-specific outcomes by conducting a desktop-based comparative case studies of HKV and Zamrudpur villages, situated in Zone F. The zonal level proposals and regulations specific to urban villages were compared to current state of identified sites. Doing so, enabled identification of effectiveness of

these rules-in-use, and addressing local-level gaps, particularly how policies are planned, governed, and implemented. Utilisation of the IAD framework encouraged this assessment of effectiveness of urban planning policies and regulations (Heikkila and Andersson, 2018), and how these rules hinder or foster socio-spatial inclusion of urban villages in Delhi. Data for the analysis was gathered from zonal plans, policy documents, official government websites, grey literature, blogs, and media sources, resulting in thorough, case-specific insights into these villages. Before conducting the comparative studies, the review first identified key provisions for urban village provisions in zone F (Table 1). These key themes where then assessed against the existing conditions of the two urban villages under investigation.

Table 1 Urban Village Zonal Development Plan Provisions for Villages in Zone F.

Zonal Plan Provisions	As per MPD-1962 (DDA, 1962)	As per MPD-2001 (DDA, 1998)	As per MPD-2021 (DDA, 2007b)
Land Use Classification and Zoning	Classified as rural use with agricultural activities	Acknowledged urban villages; permitted residential use and potential for mixed-use under Urban Renewal Scheme	Identified as 'Special Areas' with special regulations; compatible mixed-use permitted provided it is compatible with the surrounding residential areas
Mixed-Use and Commercial Development	Not specified	Mixed use was conditionally permitted under conditions	Identified mixed-use zones and pedestrian commercial streets in village
Building Regulations and Development Control Norms	No village specific provisions; bylaws relaxed to allow sub-standard housing	No provisions; highlighted weak enforcement of bylaws leading to substandard growth	Village Redevelopment Schemes proposed with stricter controls aligned with Special Area Regulations
Infrastructural Improvement and Provisions	Encouraged basic improvements to support village economies	Recognised need for upgrades; implementation remained inconsistent	Infrastructure improvement prioritised with redevelopment, mixed-use and conservation
Urban Village Planning and Integration Approaches	Proposed village-specific master plans for conservation, rehabilitation, and redevelopment	No provisions; some redevelopment plans were prepared but poorly implemented	Mandated Village Redevelopment Schemes with infrastructure upgradation to foster integration
Heritage Management	Heritage not addressed	Prioritised conservation of ASI protected monuments; mandated conservation measures under the Ancient Monuments and Archaeological Sites and Remains Act, 1958, and special building controls ; proposed landscaping strategies near monuments and improvement of basic services recommended	Emphasised on heritage conservation; HKV monuments (10) under ASI and five tombs under state government (GNCTD) ; highlighted conservation schemes through local authorities or designated organisations

Institutional Mechanisms	Not specified	No clear enforcement or monitoring highlighted	Role of local authorities and designated agencies for implementation of redevelopment and conservation initiatives

Case Study I: Hauz Khas- The Gentrified Enclave

Hauz Khas Village (Figure 4), formerly a rural settlement mainly inhabited by the Jat[2] community, exhibits the gentrification trajectory of Delhi's urban villages. The DDA designated it an 'urban village' in 1962, and large land acquisitions in the 1960s provided the groundwork for future change. HKV's transformation began in the late 1980s, when a well-known designer built a shop, attracting Delhi's elite and sparking its transformation into a cultural and commercial hub (Negi and Taraporevala, 2018, S, 2019, Ramesh et al., 2023). Low rents, closeness to heritage monuments, and important roadways all encouraged this transition. By the 2000s, HKV had surpassed markets such as Defence Colony and Khan Market, becoming a thriving hub of cafés, galleries, and boutiques (Gupta, 2024, Bernroider, 2015). However, rising property values, speculative development, and commercialisation have displaced many original residents, and exacerbated socio-spatial disparities, drawing uneven policy attention.

Figure 4 Location of Hauz Khas Village (Source: OpenStreetMap).

Case Study II: Zamrudpur- The Marginalised Village

Unlike the highly commercialised Hauz Khas Village, Zamrudpur (Figure 5) in South Delhi is an urban village that has received little policy attention or urban integration. Zamrudpur, located near the affluent neighbourhoods of Greater Kailash-I and Kailash Colony, has typical urban village features such as congested, haphazard development, narrow streets, and deteriorating infrastructure (Prakash and Sharma, 2021, Memories, 2016, Justtripping, 2021). Despite its rich cultural legacy, the village has been continually neglected in Delhi's planning narratives, with little investment from both the government and market actors. Zamrudpur, which is predominantly inhabited by migrants and service workers who support neighbouring affluent areas, demonstrates the systematic marginalisation that many urban villages in Delhi NCT face when governance frameworks fail to address their developmental demands (Prakash and Sharma, 2021, O'Leary, 2014). While both HKV and Zamrudpur fall within Zone F (South Delhi) of Delhi's Master Plan, their divergent outcomes reveal deep-rooted inequalities in planning implementation across the city.

2 Jat (also Jaat or Jatt) are traditional agrarian community found in Northern India and Pakistan. Today, they are prominent landowning farmers and key contributors to India's food grain production.

Figure 5 Location of Zamrudpur Village (Source: OpenStreetMap).

Evaluating Policy Implementation to Outcomes

The systematic comparison of policy outcomes is structured across six key themes: (1) land use, zoning, and mixed-use development, (2) building regulations and development control failures, (3) urban village planning and governance, (5) heritage management and commercialisation, and (6) planning and institutional gaps (Table 2).

Land use, Zoning, and Mixed-Use Development

HKV, which was previously a rural community, has evolved into a premium business and residential hub mostly through informal and market-driven mechanisms (Gupta, Negi and Taraporevala, 2018). Initially designated as an "urban village" by the Delhi Development Authority in 1962, it was not subject to conventional zoning regulations, allowing for substantial commercialisation (Ramesh et al., 2023). This regulatory loophole, which was reinforced by the NCTD Amendment Act of 2017, encouraged the expansion of unlicensed cafes, boutiques, and bars that violated land-use restrictions (Darji, 2018, Jeelani, 2018)Gulam</author></authors></contributors><titles><title>How Delhi's urban villages turned into 'no plan land'</title></titles><dates><year>2018</year></dates><publisher>Hindustan Times</publisher><urls><related-urls><url>https://www.hindustantimes.com/delhi-news/how-delhi-s-urban-villages-turned-into-no-plan-land/story-wI6PqbrcETuM3eqnZ59xWP.html</url></related-urls></urls></record></Cite></EndNote>.The outcome has been the fast commercialisation of residential plots with no formal planning control, displacing long-term residents and accelerating gentrification (Bernroider, 2015, Gupta, 2024, Verma and Modi, 2024). Property values in HKV have skyrocketed, with 3-4 BHK flats ranging from 1600 to 2000 sq. ft. costing more than INR 5 crores and renting for INR 50,000 to INR 110,000 per (Grovy India Limited, Royale Realtors India, 2025). Market-driven growth has transformed HKV into a high-value enclave that combines heritage and modernity, aided by its green surroundings, cultural activities, and central location (Ramesh et al., 2023).

Zamrudpur, in contrast, operates as an informal low-income rental zone surrounded by affluent neighbourhoods while remaining outside of official land-use plans and policy frameworks (Menon and Varma, 2019). Despite housing five neglected Lodi-era tombs, the region is not included in formal urban documentation, resulting in spatial fragmentation and unregulated development (Prakash and Sharma, 2021). According to limited real estate data, Zamrudpur's rental market mostly caters to hostels and paying guests, with monthly fees ranging from INR 6000

to 10,000, depending on occupancy and access to amenities (Magicbricks). Financial institutions continue to market urban villages like Zamrudpur as affordable home zones, using exemptions from building codes that allow for unregulated construction without municipal approval (Bajaj Finserv, Godrej Properties Limited, 2023).

Unlike HKV, which has been integrated into Delhi's economic framework through informal commercialisation, Zamrudpur is still institutionally excluded and functionally invisible in the planning regime.

Building Regulations and Development Control Failures

Failures in building regulation are obvious in both villages but emerge in different ways. HKV business facilities frequently operate often without license, fire safety clearances, or other legal permissions (Gupta et al., 2022, Darji, 2018). Height violations, insufficient setbacks, and small, narrow streets endanger emergency access and fire safety (Betigeri, 2013, Press Trust of India, 2020). Political intervention, particularly during elections, frequently undermines regulatory enforcement (Singh, 2013) . Multistorey rental structures flourish in Zamrudpur without permits, and congested layouts with exposed electrical wire demonstrate a lack of commitment to development rules (Justtripping, 2021, Memories, 2016). In all cases, planning officials failed to enforce or monitor building codes, exposing residents to long-term risks.

These inequities are also evident in infrastructure development. HKV's physical infrastructure has not kept up with its commercial growth (Darji, 2018). Sewer lines, solid waste management, and streets are still inadequate, resulting in frequent water logging and poor sanitation (Bernroider, 2015, Ramesh et al., 2023). Despite requests for modifications in redevelopment plans, execution remains inconsistent and disjointed (Guerrieri, 2017). Zamrudpur, in contrast, lacks even basic amenities: open drains, inconsistent water supply, mismanaged garbage, and dangerous electrical systems are frequent (Prakash and Sharma, 2021). Streets as narrow as three meters limit access for municipal or emergency vehicles. Despite its strategic location near metro lines and educational institutions, the town is excluded from most urban service plans, furthering its marginalisation.

Urban Village Planning and Governance

Furthermore, the governance structures in both villages are fragmented and ineffective, but the impacts differ significantly. Villages such as HKV and Zamrudpur were historically excluded from Delhi's formal planning processes. HKV benefited due to location, while others remain marginalised (Negi and Taraporevala, 2018). HKV's transformation proceeded in the absence of a coordinated planning framework, facilitated by political inertia and inadequate administrative control (Gupta, Jeelani, 2018, Negi and Taraporevala, 2018). Initial efforts to exempt such villages from planning laws have backfired, resulting in ad hoc urbanisation (Ramesh et al., 2023). Although strategies like Local Area Plans (LAPs) attempted to fill this gap, entrenched landownership and resource scarcity have slowed implementation (Bernroider, 2015). HKV benefits from its accessibility to key metro routes and universities, but the community's institutional capacity to manage change remains low (Betigeri, 2013). However, participatory planning procedures, such as consultations between local organisations and stakeholders, are theoretically possible and can aid in the balance between development and cultural protection (Guerrieri, 2017).

In contrast, Zamrudpur exemplifies institutional neglect. It lacks a single agency responsible for development or heritage preservation. Outdated land records and a lack of socio-economic databases lead residents to perform their own surveys (Menon and Varma, 2019, Prakash and Sharma, 2021). This fragmented governance has resulted in extended exclusion from planned urban structures. Despite its proximity to major metro line and educational institutions, Zamrudpur remains absent from formal master plans and socio-economic databases (Prakash and Sharma, 2021). This neglect from formal planning and census documents perpetuates exclusion from municipal infrastructure services and larger redevelopment initiatives, leaving basic service provision ad hoc and unplanned.

Heritage Management and Commercialisation

The treatment of heritage further reflects contrasting forms of policy failure. HKV's architectural legacy, particularly the Hauz Khas Complex, is integral to its identity, although it has been commercialised to some extent (Beyondbombay, 2021, Madan, 2015). The built heritage serves as a visual background to cafes, and pubs (Bernroider, 2015, Gupta et al., 2022). Despite tourism-related conservation measures, the shift toward aesthetic consumption threatens the area's historical integrity (Guerrieri, 2017). In comparison, Zamrudpur is home to five Lodi-era tombs of archaeological significance, the sites are not on the ASI's protected list in Zone F, and relevant agencies have allowed them to decay (Menon and Varma, 2019). Today, they serve as temporary shelters and dumping places. The lack of conservation plans, or heritage-zoning restrictions has made these structures vulnerable to encroachment and irrevocable heritage loss.

Planning and Institutional Gaps

Both villages have revealed how institutional gaps in planning, regulation, and enforcement can produce radically different yet equally problematic urban outcomes. The HKV's current state demonstrates institutional fragmentation and ineffective enforcement. Weak oversight has enabled illegal operations to thrive while lawmakers struggle with coordination and regulatory clarity (Ramesh et al., 2023). Political challenges, particularly from strong real estate and corporate interests, restricts implementation of building and zoning rules (Jeelani, 2018). Although participatory planning frameworks exist, their implementation is sparse (Guerrieri, 2017). Zamrudpur represents this inefficient through a severe governance gap. With no official planning agency or protected status, the village operates informally. The lack of institutional engagement has resulted in it being excluded from municipal records, diminishing responsibility and capability for integrated development (Prakash and Sharma, 2021). As a result, both settlements represent distinct manifestations of institutional failure: one of laissez-faire overdevelopment, the other of continued neglect. For the assessment of Zamrudpur village, limited data was available online, with most focusing on existing conditions of heritage tombs rather than overall urban village. Based on the data analysed from media sources, blogs, and a few articles, the analysis reveals that there is a lack of effective land use planning, heritage conservation, infrastructure development, and governance mechanisms in Zamrudpur.

Table 2 Overview of Policy Intent versus Outcomes.

Category	Hauz Khas Village	Zamrudpur
Land Use and Zoning	Uncontrolled commercialisation due to exemptions and unclear zoning regulations (Gupta, Negi and Taraporevala, 2018, Ramesh et al., 2023)	Primarily residential; neglected from all sources (Menon and Varma, 2019, Prakash and Sharma, 2021)
Building Regulations and Development Controls	Widespread violations of building controls; unauthorised vertical growth; no fire NOCs (Darji, 2018, Gupta et al., 2022, Press Trust of India, 2020)	Unregulated constructions; unsafe development; no building permits (Justtripping, 2021, Memories, 2016)
Urban Village Planning and Integration	Some efforts like LAP were attempted buy inconsistently implemented (Gupta, Negi and Taraporevala, 2018, Ramesh et al., 2023, Jeelani, 2018)	No efforts made towards village integration, excluding from city and local planning initiatives (Prakash and Sharma, 2021)
Heritage Management	Heritage driven development, due to presence of ASI protected monuments, but largely commodified; tourism focused (Beyondbombay, 2021, Gupta et al., 2022, Madan, 2015)	Existing heritage monuments neglected by state government; lack of conservation efforts (Menon and Varma, 2019)

Mixed-Use and Commercial Development	Unregulated commercialisation: cafes, pubs, and boutiques dominate (Bernroider, 2015, Guerrieri, 2017, Gupta et al., 2022)	No commercial development, remains as a low-income residential enclave (Prakash and Sharma, 2021)
Infrastructural Development	Strained infrastructure due to commercialisation (Bernroider, 2015, Guerrieri, 2017, Gupta et al., 2022, Ramesh et al., 2023)	Lack of basic services (Prakash and Sharma, 2021)
Institutional Mechanisms	Fragmented governance; political influence; market-driven inclusion (Betigeri, 2013, Guerrieri, 2017, Jeelani, 2018, Ramesh et al., 2023)	Institutional neglect; total policy neglect (Prakash and Sharma, 2021)

Discussion

The analysis of policies through IAD framework, provided a comprehensive overview of the urban village policy planning, implementation and its outcomes. The primary goal of this research was to examine existing policy gaps and their impact on socio-spatial inclusion and exclusion of urban villages. Based on the coding, the review identified five inter-related themes perpetuating socio-spatial exclusion of urban villages at city level: (1) political influence and erosion of community rights, (2) institutional fragmentation and regulatory ambiguity, (3) neglect of informal economies and socio-cultural transitions, (4) spatial exclusion and built environment neglect, and (5) transparency and administrative accountability.

Political Influence and Lack of Community Rights

Land reform and development policies, particularly the Delhi Land Reforms Act, fragmented land acquisition processes, and land pooling mechanisms, have adversely impacted rural livelihoods while providing little or no compensation to displaced populations (Datta, 2004, Mehra, 2005, MoUD, 2007). These efforts have disproportionately benefited corporate investors and politically associated actors, directing urban village development toward political gain rather than community need (Sheth, 2017, MoUD, 2006, MoUD, 2007). The adoption of public-private partnerships (PPPs) and selective regularisation procedures has resulted in uneven infrastructure provision and increased land commodification, marginalising original landowners and reducing local governance capacity (MoUD, 2006, Tyagi and Vats, 2020). Absorbed by neighbouring wealthy neighbourhoods, urban villages have not benefited from integrated development (GNCTD, 1985), leading to a system of spatial outcomes. The extension areas of urban villages have often been misused due to speculative development under the guide of community development (GNCTD, 1985). These practices have therefore resulted in scepticism towards planning and administrative organisations by the urban village residents.

Institutional Fragmentation and Regulatory Ambiguity

Institutionally, urban villages function within a fragmented structure characterised by overlapping mandates, inefficient inter-agency coordination, and lax enforcement. The lack of co-ordination among key planning and managing authorities—such as the DDA, MCD, GNCTD—has led to significant administrative and policy gaps (MoUD, 2006, Singh, 2024, GNCTD, 1985). These fragmented duties, coupled with the lack of a dedicated planning and management cell for urban villages, have hindered the urban village integration. Furthermore, the incomplete implementation of previous redevelopment plans, demonstrate administrative stagnation (GNCTD, 1985). A regulatory void has existed between the formal declaration of urbanisation and the execution of applicable regulations under the Delhi Municipal Corporation (DMC) Act, allowing unregulated building to spread unabated (GNCTD, 1985). Additionally, the breakup of village council (gram sabhas) and the failure to apply land mutation standards have increased legal uncertainty, limiting access to municipal services, credit systems, and secure tenure (Tyagi and Vats, 2020). These institutional flaws not only push informality but also limit meaningful community participation in planning processes (Singh, 2020, Singh et al., 2024). The overall administrative system of Delhi is widely viewed as overly fragmented (MoUD, 2006), preventing the integration of

urban villages into larger city frameworks. Furthermore, statutory planning documents such as Master Plans and Zonal Development Plans have consistently failed to account for the tangible and intangible qualities of urban villages, making them almost invisible in official spatial development strategies (Rewal, 2014, Sheth, 2017)

Neglect of Local Informal Economies and Socio-Cultural Transitions

Urban villages have been transformed into essential hubs of affordable housing and informal economic activity, but changes to laws have not kept pace. Existing regulatory frameworks do not provide for inclusive zoning, livelihood integration, or acknowledgment of informal rental and commercial networks (Mehra, 2005, DDA, 2007a). As a result, populations, particularly marginalised, landless, and migrants, continue to be excluded from social services, inheritance rights, and financial services (Tyagi and Vats, 2020). The lack of property documentation perpetuates informality, exacerbating inter-class disparities, and undermining community cohesion. Informal businesses face a constant danger of penalties, while regulatory neglect undermines social mobility, gender fairness, and long-term socioeconomic resilience (Singh et al., 2024, Govinda, 2013).

Spatial Exclusion and Built Environment Neglect

Despite their 'urban' status, many villages experience chronic infrastructural neglect and spatial exclusion. Inadequate building regulatory implementation, redundant land record systems (e.g., single-khasra or plot no.), and prolonged sanctioning processes enabled for unregulated growth and unplanned mixed-use development (Harikrishanan, 2021, GNCTD, 1985). Aggressive enforcement measures, such as sealing and demolition, focus on the tangible signs of informality rather than the underlying socio-economic conditions (Singh, 2020). Redevelopment projects continue to be elite-driven, with little participatory processes or context-sensitive design, alienating residents further (Tyagi and Vats, 2020). The lack of planned public infrastructure, municipal services, and open space perpetuates slum-like conditions (Bernroider, 2015, Prakash and Sharma, 2021, Ramesh et al., 2023) . These findings suggest that urban villages are symbolically included through over-regulation but functionally excluded by inadequate funding, prolonging cycles of socio-spatial injustice (Sheth, 2017, Datta, 2004)

Transparency and Administrative Accountability

Administrative transparency has exacerbated these inefficiencies. Residents are usually unaware of the documents required for permits, and critical information—such as sanctioned layouts, ownership records, and building codes—is neither accessible nor proactively supplied (Prakash and Sharma, 2021). The lack of digitised and publicly available information reinforced reliance on informal brokers and brokers, delaying legal recognition, and exacerbating animosity between communities and institutions (GNCTD, 1985, NCRPB, 2005).

What Approaches Can Integrate Urban Villages and Promote Socio-Spatial Inclusion?

Existing studies presents several alternative planning and policy approaches that challenge traditional top-down urban planning frameworks for urban villages. Prakash and Sharma (2021) have highlighted on Bottom-up Jugaad [3]based placemaking approach, which promotes community ownership and tangible outcomes. Furthermore, they also argue for moving away from the traditional PPP model to more inclusive People-Public-Private Partnership (PPPP) model. This new framework empowers locals to identify local needs, choose experts, and contribute to resource mobilisation, while public and commercial stakeholders assist with implementation (Prakash and Sharma, 2021). WRI India (2020) provided actionable recommendations like the Urban Village Development Plan (UVDP), a gradual planning framework for phased, local-level planning. The UVDP prioritises eight principles, including stakeholder engagement, transparency, and accountability, context-sensitive design, and linkage with larger urban planning policies and zoning regulations (WRI India, 2020). This framework assures that village development is both locally relevant and institutionally consistent.

3 Jugaad in Hindi language refers to an innovative, and creative idea offering a quick, alternative way—often cost-effective—of solving problems using readily available materials and resources.

Harikrishanan (2021) established the Shared Responsibility Model, which bridges the gap between top-down and bottom-up approaches by encouraging residents and the state to collaborate. This concept brings together adaptive reuse of built heritage, catalytic pilot interventions, and conservation incentives. It is built on enabling reforms including flexible master planning, digitised land records, and incentive-based land pooling to promote long-term spatial and socioeconomic integration. Gupta (2025) suggested for the integration of urban villages through neighbourhood-level planning frameworks, stating that their exclusion causes spatial disintegration, land misuse, and speculation. He further advocated for equitable distribution of surplus land value, infrastructural provisions, participatory methods, and employment-oriented planning. By addressing residents' lived realities, such initiatives can help to promote inclusive urban government, reduce socio-spatial disparities, and improve the incorporation of urban villages into metropolitan growth processes.

Conclusion and Future Suggestions

This study analyses the persisting policy gaps affecting urban villages in Delhi, India, using the IAD framework to investigate the drivers and consequences of socio-spatial exclusion. A comparative case study of Zamrudpur and Hauz Khas Village reveals a gap between planning discourse and implementation. Urban villages, while symbolically mentioned in policy documents, are functionally excluded from formal development due to political influence, institutional fragmentation, disregard of informal economy, spatial marginalisation, and inadequate administrative transparency. This selective integration exacerbates urban inequality and maintains socio-spatial imbalances. In theory, the study strengthens our understanding of how planning tools and governance institutions lead to urban exclusion. In practice, it provides guidance to urban planners and lawmakers by advocating for collaborative, integrated, and context-sensitive strategies. Recommendations include updating outdated land and zoning regulations, promoting bottom-up governance, recognising informal economies, ensuring transparency, and integrating urban villages into larger planning frameworks. Future study should investigate comparative case studies across Indian cities, socio-cultural dynamics within urban villages, the effectiveness of participatory planning, and novel finance mechanisms and public-private partnerships for urban village redevelopment. Such research will help to advance inclusive urban policies that address exclusionary actions and empower communities at large. Overall, the study adds to the greater issue of urban inclusion by providing a structured socio-spatial policy analysis. It highlights the necessity of hybrid governance models in which inhabitants collaborate to build development visions that are supported by public and commercial institutions, ultimately achieving the objective of equitable, inclusive cities.

Abstract
Urban-rural integration is essential for China's modernization, aiming to bridge the urban-rural divide and promote common prosperity. The Chengdu Plain Economic Zone, accounting for 63.2% of Sichuan's GDP, faces challenges such as a 39.3 percentage point urbanization gap and industrial homogenization. This study assesses integration from 2012 to 2021 across economic, social, spatial, and demographic dimensions, using the entropy method and geographical detector model. Results reveal an 8.65% annual growth in integration, with a spatial pattern of "high in the center, low in the southwest." Chengdu leads consistently, while De yang and Mian yang progress via industrial upgrades; Ya an and Leshan lag due to geographical constraints. Key drivers include urbanization rate (q=0.62), per capita GDP (q=0.58), and income gap (q=0.45). The proposed policy framework advocates multi-center collaboration, industrial complementarity, infrastructure connectivity, and talent sharing to achieve "value symbiosis," providing a model for less-developed regions in Western China.

Keywords: urban-rural integration; spatio-temporal patterns; geographical detector; multi-center collaboration

1. Introduction
Urban-rural integration is a central issue in China's modernization process, aiming to dismantle the urban-rural dual structure, promote bidirectional factor flows, and achieve balanced and coordinated socio-economic development between urban and rural areas. As a key growth pole for high-quality development in Western China, the Chengdu Plain Economic Zone encompasses eight prefecture-level cities, including Chengdu, Deyang, and Mianyang. In 2021, it accounted for 63.2% of Sichuan Province's GDP, with an urbanization rate of 56.16%, making it one of the most densely populated and economically vibrant regions in Western China. However, significant regional imbalances persist: Chengdu, the core city, boasts an urbanization rate of 79.5% and an urban-rural income ratio reduced to 2.01, while peripheral areas such as Ya'an and Ziyang face challenges including widening urban-rural income gaps (Ya'an's urban-rural income ratio was 2.35 in 2021), pronounced industrial homogenization, and inadequate infrastructure connectivity. Against this backdrop, studying the spatio-temporal evolution patterns and driving mechanisms of urban-rural integration in the Chengdu Plain Economic Zone not only responds to the policy demands of China's 14th Five-Year Plan for Urban-Rural Integration but also addresses the practical need to optimize regional resource allocation and promote coordinated development across the region.

Theoretically, current research on urban-rural integration predominantly focuses on developed eastern regions such as the Yangtze River Delta and Pearl River Delta, with relatively limited dynamic analyses of Western economic zones. Moreover, existing evaluation systems often overemphasize singular economic dimensions, neglecting multifaceted aspects such as social equity and spatial balance. This study constructs a four-dimensional indicator system encompassing economic efficiency, social equity, spatial coordination, and population mobility. By integrating the entropy method and the geographical detector model, it seeks to address the paucity of empirical studies in Western China and provide methodological advancements to urban-rural integration theory. Practically, the findings offer scientific evidence to support differentiated policymaking and cross-regional resource collaboration in the Chengdu Plain Economic Zone. For instance, a "core city radiation–secondary center absorption" model could mitigate Chengdu's "siphon effect," while optimizing transportation networks could narrow the development gap in the southwestern peripheral areas.

Focusing on the Chengdu Plain Economic Zone and utilizing statistical data from 2012 to 2021, this study addresses two key questions: (1) how to scientifically quantify the level of urban-rural integration, and (2) the spatio-temporal patterns and core driving factors of regional disparities. Methodologically, the entropy method is employed to construct a comprehensive evaluation model to analyze the temporal evolution characteristics of urban-rural integration. ArcGIS spatial analysis techniques are used to delineate the "high in the center, low in the southwest" spatial differentiation pattern. The geographical detector model identifies key influencing factors such as urbanization rate and per capita GDP. The innovation of this study lies in proposing a composite framework of "static indicator weight allocation + dynamic spatial attribution analysis," which overcomes the limitations of traditional studies confined to a single spatio-temporal dimension.

2. Theoretical Foundation and Literature Review

The theoretical evolution of urban-rural integration has consistently paralleled deepening understandings of urban-rural relationships. Early scholars often analyzed urban-rural dynamics from an "opposition-coordination" perspective. For instance, Ebenezer Howard's "Garden City" theory, proposed in 1898, advocated for planned integration of urban economic vitality and rural ecological value to achieve functional complementarity [1], laying a cornerstone for subsequent urban-rural integration studies. In the mid-20th century, Arthur Lewis's "dual economy structure theory" elucidated the economic roots of urban-rural segmentation in developing countries [2], emphasizing that the transfer of surplus agricultural labor to industrial sectors is essential for resolving urban-rural divides. However, its "urban-biased" perspective was critiqued by scholars like Michael Lipton, who argued that overly urban-centric policies lead to rural resource depletion and exacerbate urban-rural inequality. Lipton's concept of "balanced urban-rural development" marked a significant shift in the field [3].

Since the 21st century, with the acceleration of globalization and informatization, urban-rural integration theories have expanded to encompass multidimensional interactions across spatial, social, and ecological domains. John Friedmann's "core-periphery" theory highlighted the radiating influence of central cities on surrounding areas [4], while Michael Storper's "new regionalism" advocated for institutional innovation and local governance to facilitate the free flow of urban-rural factors [5]. Chinese scholars, building on Western theories and adapting to national conditions, have proposed localized interpretations. For example, Liu Yansui introduced the concept of "urban-rural equivalence," advocating for equalized public services and industrial linkages to narrow the quality-of-life gap between urban and rural areas [6]. Lu Dadao, from the perspective of "human-land relationships," emphasized the need to balance resource and environmental carrying capacity with socio-economic development demands in urban-rural integration [7]. These theories provide critical support for constructing the "economic-social-spatial-demographic" four-dimensional analytical framework in this study.

Empirical research on urban-rural integration, both domestically and internationally, exhibits a pattern of "eastern focus and methodological diversity." Early international studies were predominantly qualitative, such as T.G. McGee's exploration of the "Desakota" (urban-rural transition zone) model in Southeast Asia, which revealed the unique role of informal economies in transitional areas [8]. In recent years, quantitative modeling has gained prominence; for instance, J. Van den Bergh used spatial econometric methods to verify the role of infrastructure connectivity in promoting urban-rural income convergence [9]. In China, early studies focused on policy interpretation and case descriptions. After 2010, with improved statistical data, scholars began developing comprehensive evaluation systems. Liu Rongrong's team constructed an indicator system based on economic, social, and environmental integration, finding that urban-rural integration levels in the Yangtze River Delta urban agglomeration followed a "center-periphery" declining pattern [10,11]. Che Bingqing's study on the Huaihai Economic Zone identified topographic complexity and policy implementation capacity as key factors influencing urban-rural integration [12,13]. However, existing indicator systems often prioritize economic dimensions, with insufficient quantification of social equity (e.g., accessibility to public services) and spatial justice (e.g., ecological resource allocation). Moreover, dynamic spatio-temporal analyses targeting less-developed economic zones in Western China remain scarce.

Existing studies provide important insights for this research but exhibit three main limitations. First, at the theoretical level, most studies reduce urban-rural integration to "gap narrowing," overlooking the deeper logic of functional complementarity and value symbiosis between urban and rural areas. Second, at the methodolog-

ical level, static cross-sectional analyses predominate, with insufficient tracking of the dynamic evolutionary pathways of urban-rural integration. Third, at the regional level, there is inadequate attention to the unique and complex characteristics of Western China, particularly the influence of factors such as topographic barriers and ethnic diversity, which have not been fully incorporated into analytical frameworks. This study seeks to advance the field in the following ways: (1) constructing a composite indicator system encompassing economic efficiency, social equity, spatial coordination, and population mobility to address the multidimensional nature of urban-rural integration; (2) utilizing a decade-long time-series dataset to reveal the staged characteristics of the integration process in the Chengdu Plain Economic Zone; and (3) employing the geographical detector model to identify the interactive effects of natural conditions and institutional factors on the spatial differentiation of urban-rural integration, thereby providing a basis for differentiated policy design in less-developed regions of Western China.

3. Study Area Overview and Data Methods

3.1 Study Area Overview

The Chengdu Plain Economic Zone is located in the western Sichuan Basin, spanning a geographical range between 28°28'–33°02'N and 101°56'–106°59'E. It encompasses eight prefecture-level cities: Chengdu, Deyang, Mianyang, Leshan, Meishan, Ziyang, Suining, and Ya'an, covering a total area of 86,400 square kilometers. As a core component of the Chengdu-Chongqing Economic Circle, the region had a permanent population of 42.141 million in 2021, accounting for 50.3% of Sichuan Province's total population, and a GDP of 3.29 trillion yuan, contributing 63.2% of the province's economic output. This makes it one of the most densely populated and economically dynamic regions in Western China. However, internal development disparities are pronounced: Chengdu, with less than 20% of the region's land area, contributes 46.7% of the economic zone's GDP, and its urbanization rate (79.5%) is nearly double that of Ya'an (40.2%). Although the urban-rural income gap has gradually narrowed (from an urban-rural income ratio of 2.57 in 2012 to 2.01 in 2021), challenges such as insufficient rural public service provision and lagging infrastructure connectivity remain prominent in peripheral areas.

3.2 Data and Methods

The research data primarily come from the Sichuan Statistical Yearbook (2012–2021), the China City Statistical Yearbook, and statistical bulletins on national economic and social development from the respective prefecture-level cities. For missing data (e.g., county-level fiscal expenditures in certain years), linear interpolation was applied, and raw data were standardized to eliminate dimensional differences. The indicator system was constructed based on principles of "systematicity, operability, and policy orientation," selecting 16 indicators across four dimensions: economic integration, social integration, spatial integration, and population integration (Table 3-1). Economic integration focuses on urban-rural production efficiency and income equity (e.g., per capita GDP, non-agricultural industry share). Social integration emphasizes public service accessibility and consumption equity (e.g., medical insurance coverage, urban-rural consumption expenditure ratio). Spatial integration measures infrastructure and ecological coordination (e.g., highway density, green coverage rate in built-up areas). Population integration reflects labor structure and mobility (e.g., urbanization rate, non-agricultural employment ratio). Indicators are classified as positive or negative: for example, a smaller urban-rural income ratio (negative) indicates higher integration, while a larger per capita GDP (positive) reflects superior development levels.

Table 3-1 Evaluation Index System for the Level of Urban-Rural Integration in the Chengdu Plain Economic Zone

Dimension	Indicator	Indicator Calculation or Description	Attribute
Economic Integration	Per Capita Regional GDP	Per capita regional GDP (Yuan/person)	Positive
	Proportion of Non-Agricultural Industries in GDP	Proportion of secondary and tertiary industry added value in GDP * 100 (%)	Positive
	Proportion of Agricultural Expenditure in Total Expenditure	Agricultural fiscal expenditure / total fiscal expenditure * 100 (%)	Positive
	Urban-Rural Per Capita Disposable Income Ratio	Urban per capita disposable income / rural per capita disposable income	Negative
	Dual Production Efficiency Ratio	(Primary industry added value / primary industry employees) / (secondary and tertiary industry added value / secondary and tertiary industry employees)	Positive
Social Integration	Education Expenditure as a Proportion of GDP	Education expenditure / GDP * 100 (%)	Positive
	Basic Medical Insurance Coverage Rate	Insured population / total population * 100 (%)	Positive
	Hospital Beds per 10,000 People	Number of hospital beds in medical institutions per 10,000 people (beds/10,000 people)	Positive
	Urban-Rural Per Capita Consumption Expenditure Ratio	Urban per capita consumption / rural per capita consumption	Negative
	Urban-Rural Engel Coefficient Ratio	Urban Engel coefficient / rural Engel coefficient	Negative
Spatial Integration	Regional Urban Greening Rate	Green space area / construction land area * 100 (%)	Positive
	Highway Network Density	Highway operating mileage / total land area (km/km²)	Positive
	Proportion of Built-Up Area	Built-up area / total land area * 100 (%)	Positive
Population Integration	Population Urbanization Rate	Permanent urban population / total population * 100 (%)	Positive
	Proportion of Non-Agricultural Employed Population	Number of employees in secondary and tertiary industries / total employees * 100 (%)	Positive
	Urban-Rural Population Interaction Degree	Total urban-rural population migration rate (‰)	Positive

The entropy method was employed to determine indicator weights, avoiding biases from subjective weighting. First, raw data were standardized using the range method, and the information entropy and redundancy of each indicator were calculated to derive weight values. Next, a weighted sum formula was applied to compute the comprehensive urban-rural integration score, with values ranging from [0, 1]; higher scores indicate superior integration levels. Spatial analysis was conducted using the ArcGIS 10.2 platform, employing the natural breaks method to classify integration levels into five categories (low, medium-low, medium, medium-high, high). Standard deviational ellipse and hotspot analysis were used to reveal spatial differentiation patterns. The geographical detector model was utilized to identify key driving factors by calculating the explanatory power (q-value) of each factor, with q-values ranging from [0, 1]; higher q-values indicate greater contributions to spatial differentiation.

4. Spatio-Temporal Patterns and Evolution of Urban-Rural Integration in the Chengdu Plain Economic Zone

4.1 Measurement and Classification of Integration Levels

To evaluate the urban-rural integration levels in the Chengdu Plain Economic Zone from 2012 to 2021, this study applied the entropy method to measure the weights of each indicator. Subsequently, a specific computational formula was used to derive the comprehensive urban-rural integration score for the economic zone, serving as the benchmark for assessing the degree of integration. These comprehensive scores are detailed in Table 4-1, providing a foundation for subsequent in-depth analysis.

Table 4-1 Comprehensive Score for Urban-Rural Integration Level in the Chengdu Plain Economic Zone, 2012–2021

Region	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	Average for each city
Chengdu City	0.502	0.537	0.570	0.594	0.626	0.716	0.742	0.731	0.719	0.782	0.652
Deyang City	0.275	0.295	0.294	0.333	0.321	0.331	0.368	0.376	0.423	0.443	0.346
Mianyang City	0.234	0.262	0.330	0.351	0.351	0.365	0.412	0.403	0.449	0.497	0.365
Meishan City	0.210	0.236	0.251	0.305	0.286	0.316	0.320	0.325	0.366	0.408	0.302
Leshan City	0.225	0.224	0.258	0.308	0.301	0.295	0.331	0.339	0.366	0.406	0.305
Ziyang City	0.215	0.228	0.247	0.277	0.328	0.334	0.341	0.364	0.390	0.414	0.314
Suining City	0.347	0.302	0.302	0.370	0.351	0.358	0.390	0.395	0.469	0.517	0.380
Ya'an City	0.186	0.191	0.185	0.226	0.235	0.224	0.280	0.307	0.367	0.389	0.259
Average	0.274	0.284	0.305	0.346	0.350	0.367	0.398	0.405	0.444	0.482	
Average growth rate %		3.692	7.121	13.418	1.266	5.002	8.336	1.759	9.537	8.650	

Building on the practical context of urban-rural integration in the Chengdu Plain Economic Zone, combined with national policy orientations, Sichuan Province's urban-rural development plans, and various comprehensive factors, this study thoroughly analyzes the spatio-temporal evolution characteristics of urban-rural integration levels in the region. The analysis reveals not only temporal progression but also significant spatial differentiation and variation. To comprehensively and accurately assess urban-rural integration levels, ArcGIS 10.2 software was utilized to conduct detailed hierarchical processing of the comprehensive urban-rural integration scores for the eight prefecture-level cities in the Chengdu Plain Economic Zone.

Adhering to the concept of high-quality urban-rural integration development, this study employed the natural breaks method to classify the comprehensive scores into five levels, sequentially named "high-level integration zone," "medium-high-level integration zone," "medium-level integration zone," "medium-low-level integration zone," and "low-level integration zone." Table 4-2 provides a detailed breakdown of the number of prefecture-level cities included in each level, offering valuable reference for in-depth research and strategy formulation for urban-rural integration in the Chengdu Plain Economic Zone.

Through this comprehensive analysis, the evolutionary trends of urban-rural integration levels can be more fully understood, providing robust data support and strategic guidance for future sustainable development strategies.

Table 4-2 Statistics on the Number of Prefecture-Level Cities at Various Levels in the Chengdu Plain Economic Zone by Urban-Rural Integration Level, 2012–2021

Year	Relatively high level	Relatively medium high level	Relatively medium level	Relatively medium low level	Relatively low level
2012	1	1	1	4	1
2013	1	2	1	3	1
2014	1	3	1	2	1
2015	1	2	3	1	1
2016	1	2	2	2	1
2017	1	2	3	1	1
2018	1	2	1	3	1
2019	1	2	2	2	1
2020	1	2	3	1	1
2021	1	3	2	1	1

4.2 Temporal Evolution of Urban-Rural Integration Levels

4.2.1 Overall Characteristics of Temporal Evolution

As shown in Table 4-1 and Figure 4-1, from 2012 to 2021, the urban-rural integration levels in the Chengdu Plain Economic Zone generally exhibited an upward trend. Chengdu City maintained a relatively high urban-rural integration score throughout the period, displaying steady growth, while the integration scores of other cities showed varying degrees of increase.

(1) The overall urban-rural integration level in the Chengdu Plain Economic Zone shows a fluctuating upward trend.

The comprehensive urban-rural integration score increased from 0.274 in 2012 to 0.482 in 2021, reflecting an overall increase of 0.208 over the decade. This indicates significant improvement in urban-rural integration levels during this period. Data on annual growth rates reveal fluctuations in the pace of growth. The growth rate was relatively high between 2014 and 2015, reaching 13.418%, but it slightly declined between 2019 and 2020 to 1.759%. Nevertheless, the average annual growth rate remained positive, demonstrating a steady upward trend. Between 2018 and 2019, the annual growth rate was 1.759%, while it increased to 8.65% from 2020 to 2021. This suggests notable progress in urban-rural integration efforts in the later stages, with an accelerated growth rate. Significant disparities in integration levels exist across regions. For instance, Chengdu City consistently achieved high comprehensive scores, whereas Ya'an City recorded relatively low scores. These differences may be influenced by factors such as regional economic development levels and the extent of policy support.

(2) The urban-rural integration level in the Chengdu Plain Economic Zone has risen from relatively medium-low to relatively medium-high levels.

From 2012 to 2021, the number of prefecture-level cities with relatively high integration levels remained stable, with only one city (Chengdu) consistently at this level each year. This indicates that Chengdu has achieved notable success in urban-rural integration and maintained a relatively high level. The number of prefecture-level cities with medium-high integration levels fluctuated but showed an overall increasing trend. From 2014 to 2018, the number of such cities steadily increased, peaking in 2021. This may reflect relatively stable and positive development in urban-rural integration in these areas. The number of cities with medium integration levels also exhibited an overall increase from 2012 to 2021, with significant growth between 2014 and 2017, reaching a peak in 2020. These regions likely made some progress in urban-rural integration, but their development levels still require further improvement. The number of cities with medium-low integration levels showed a fluctuating downward trend, decreasing from four in 2012 to one in 2021. These regions may face challenges in urban-rural integration, necessitating greater policy support and resource investment. The number of cities with low integration levels remained stable from 2012 to 2021, with one city (Ya'an) consistently at this level each year. This suggests that Ya'an is a region with persistently low urban-rural integration levels, requiring intensified reform efforts and policy support to enhance its integration.

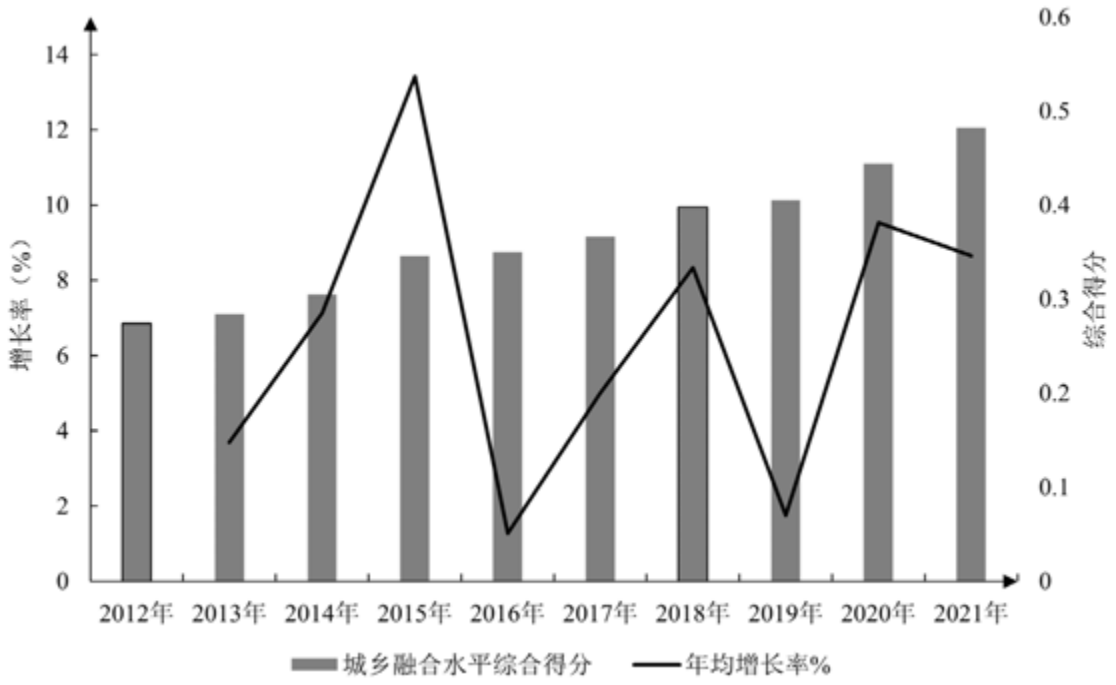

Figure 4-1 Comprehensive Score Trend for Urban-Rural Integration Level in the Chengdu Plain Economic Zone (2012-2021)

4.2.2 Temporal Variation Characteristics of Each Dimension

Based on the urban-rural integration indicator data for the Chengdu Plain Economic Zone from 2012 to 2021, this study employed the entropy method to calculate comprehensive scores for the four key dimensions: economic integration, social integration, spatial integration, and population integration. These scores are presented in detail in Figure 4-2 and Table 4-3, providing a comprehensive and in-depth understanding of the urban-rural integration levels in the Chengdu Plain Economic Zone.

As shown in Figure 4-2, the comprehensive score for urban-rural economic integration exhibited a steady upward trend from 2012 to 2021, increasing from 0.620 in 2012 to 1.106 in 2021, a growth of approximately 78.7%. From 2012 to 2015, the comprehensive score grew relatively slowly, with an increase of 0.181. During this period, constraints such as urban-rural development disparities and industrial structure transitions likely contributed to uneven economic development, slowing the progress of urban-rural integration. From 2016 to 2021, the comprehensive score increased more significantly, by 0.486. This may be attributed to accelerated urbanization, enhanced government policy support, and notable progress in industrial structure optimization and regional economic output growth.

The comprehensive score for urban-rural social integration showed a gradual increasing trend from 2012 to 2021, rising from 0.570 to 1.016, a growth of approximately 78.6%. Based on the magnitude of growth, this period can be divided into two phases: from 2012 to 2015, the comprehensive score grew slowly, with an increase of 0.237. This may have been influenced by issues such as widening urban-rural income gaps and imbalances in access to basic education and healthcare resources. From 2016 to 2021, the comprehensive score increased more noticeably, by 0.446. This is likely due to increased government investment in infrastructure, improvements in social security systems, and enhanced public service levels, which helped narrow the urban-rural social development gap.

The comprehensive score for urban-rural spatial integration demonstrated a steady upward trend from 2012 to 2021, increasing from 0.549 to 0.920, a growth of approximately 67.0%. From 2012 to 2015, the comprehensive score grew slowly, with an increase of 0.036, possibly due to issues such as inadequate transportation and

lagging infrastructure. From 2016 to 2021, the comprehensive score increased more significantly, by 0.371. This may be attributed to improvements in urban planning and transportation network development, which reduced spatial distances between urban and rural areas and strengthened their connectivity.

The comprehensive score for urban-rural population integration exhibited a fluctuating upward trend from 2012 to 2021, rising from 0.455 to 0.813, a growth of approximately 78.7%. From 2012 to 2015, the comprehensive score grew slowly, with an increase of 0.175, likely constrained by factors such as household registration (hukou) restrictions and limited urban-rural population mobility. From 2016 to 2021, the comprehensive score increased more significantly, by 0.358. This may be driven by household registration system reforms and increased absorption of rural populations into urban areas, facilitating greater population mobility and reducing urban-rural population disparities.

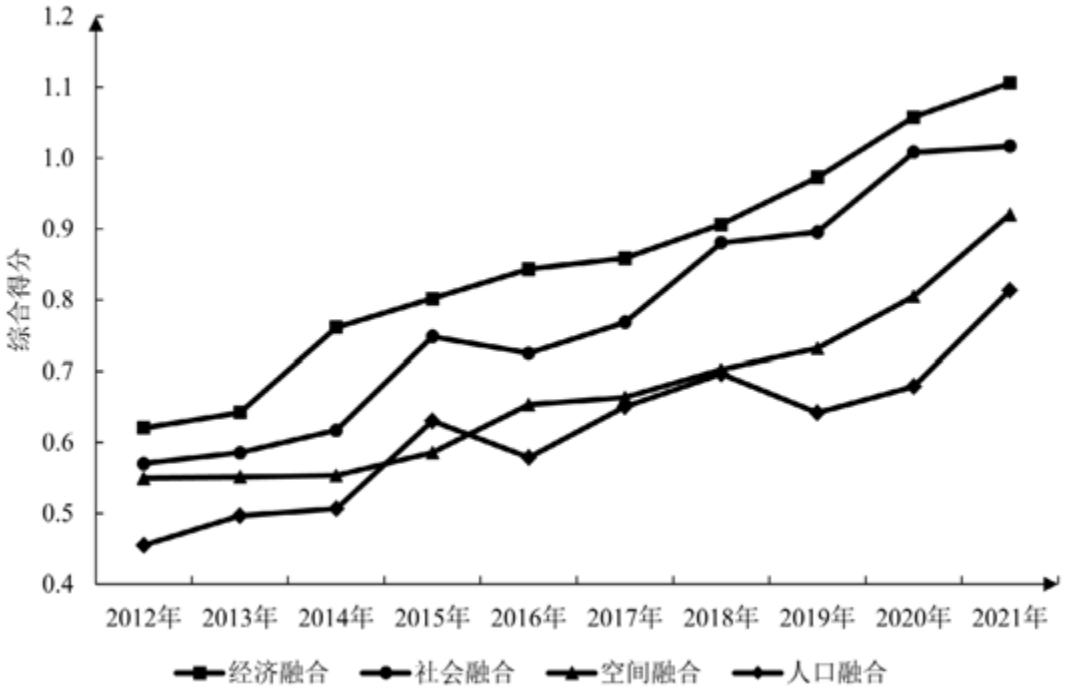

Figure 4-2 Comprehensive score trends for various indicators of urban-rural integration in the Chengdu Plain Economic Zone (2012-2021)

Table 4-3 Comprehensive Scores for Each Indicator Level of Urban-Rural Integration in the Chengdu Plain Economic Zone from 2012 to 2021

Year	Economic integration	Social integration	Spatial integration	Population integration
2012	0.620	0.570	0.549	0.455
2013	0.642	0.585	0.551	0.497
2014	0.761	0.617	0.553	0.506
2015	0.801	0.748	0.585	0.630
2016	0.843	0.724	0.653	0.579
2017	0.858	0.768	0.663	0.650
2018	0.906	0.880	0.702	0.696
2019	0.973	0.895	0.732	0.642
2020	1.058	1.008	0.805	0.679
2021	1.106	1.016	0.920	0.813

4.3 Spatial Patterns and Evolution of Urban-Rural Integration

4.3.1 Overall Characteristics of Spatial Patterns

Using the ArcGIS 10.2 platform, the spatial differentiation patterns of urban-rural integration levels in the Chengdu Plain Economic Zone were examined based on the average annual comprehensive scores of its eight prefecture-level cities from 2012 to 2021. The results (see Appendix Figure 4-3) reveal distinct spatial characteristics in the urban-rural integration levels of the Chengdu Plain Economic Zone: Chengdu City, located in the central region, exhibits the highest development level, followed by the northeastern areas, while the southwestern regions show lower levels of urban-rural integration, with significant internal spatial differentiation overall.

Within the Chengdu Plain Economic Zone, Chengdu, as the central city, plays a pivotal leadership role, exerting substantial influence across the entire region. This area displays a clear pattern of radiating outward from the center, forming a typical core-periphery structure. As a sub-provincial city and one of China's national central cities, Chengdu benefits from unique resource conditions and policy advantages that other cities in the region cannot match. Consequently, Chengdu's socio-economic development level is generally high, resulting in relatively weaker competitive capacity in other areas of the Chengdu Plain Economic Zone.

Regarding the overall spatial differentiation within the study area, Deyang, Mianyang, and Suining exhibit relatively high comprehensive scores for urban-rural integration, classifying them as medium-high-level integration zones. As secondary central cities within the Chengdu Plain Economic Zone, Deyang and Mianyang have slightly lower development levels compared to Chengdu. However, they are actively promoting urban-rural integrated development by improving infrastructure, adjusting industrial structures, enhancing rural living environments, and advancing the equalization of urban-rural public services. These efforts aim to narrow urban-rural development gaps and achieve regional development and shared prosperity. Although Suining may hold a relatively smaller position compared to Deyang and Mianyang, its economic development is more balanced and stable, with relatively high rural economic development levels, contributing to a favorable degree of urban-rural integration.

Meishan and Leshan, located in the mountainous regions of Sichuan Province, are geographically remote with rugged terrain. The mountainous topography results in lagging transportation and infrastructure development. Compared to the main cities in the Chengdu Plain Economic Zone, Meishan and Leshan have relatively lower economic development levels. Weak economic foundations lead to sluggish rural economic growth and significant urban-rural development disparities, resulting in medium-low levels of urban-rural integration.

Ya'an City, situated in northwestern Sichuan Province, is characterized by mountainous terrain and inconvenient transportation, which hinders connectivity between urban and rural areas and restricts the flow of resources

and industries. Ya'an's economy is predominantly agricultural, with relatively weak industrial and service sectors. This leads to uneven urban-rural development, with rural areas suffering from inadequate infrastructure and low levels of public services, resulting in significant urban-rural disparities. Furthermore, Ya'an's infrastructure development lags behind, and population outflow is severe, contributing to its persistently low level of urban-rural integration.

Figure 4-3 Spatial pattern of urban-rural integration in the Chengdu Plain Economic Zone

4.3.2 Spatial Characteristics of Each Dimension

Based on the average annual comprehensive scores for economic integration, social integration, spatial integration, and population integration across the eight prefecture-level cities in the Chengdu Plain Economic Zone from 2012 to 2021, the spatial characteristics of the four dimensions of urban-rural integration were analyzed using the data visualization capabilities of ArcGIS 10.2. The results are presented in Figure 4-4.

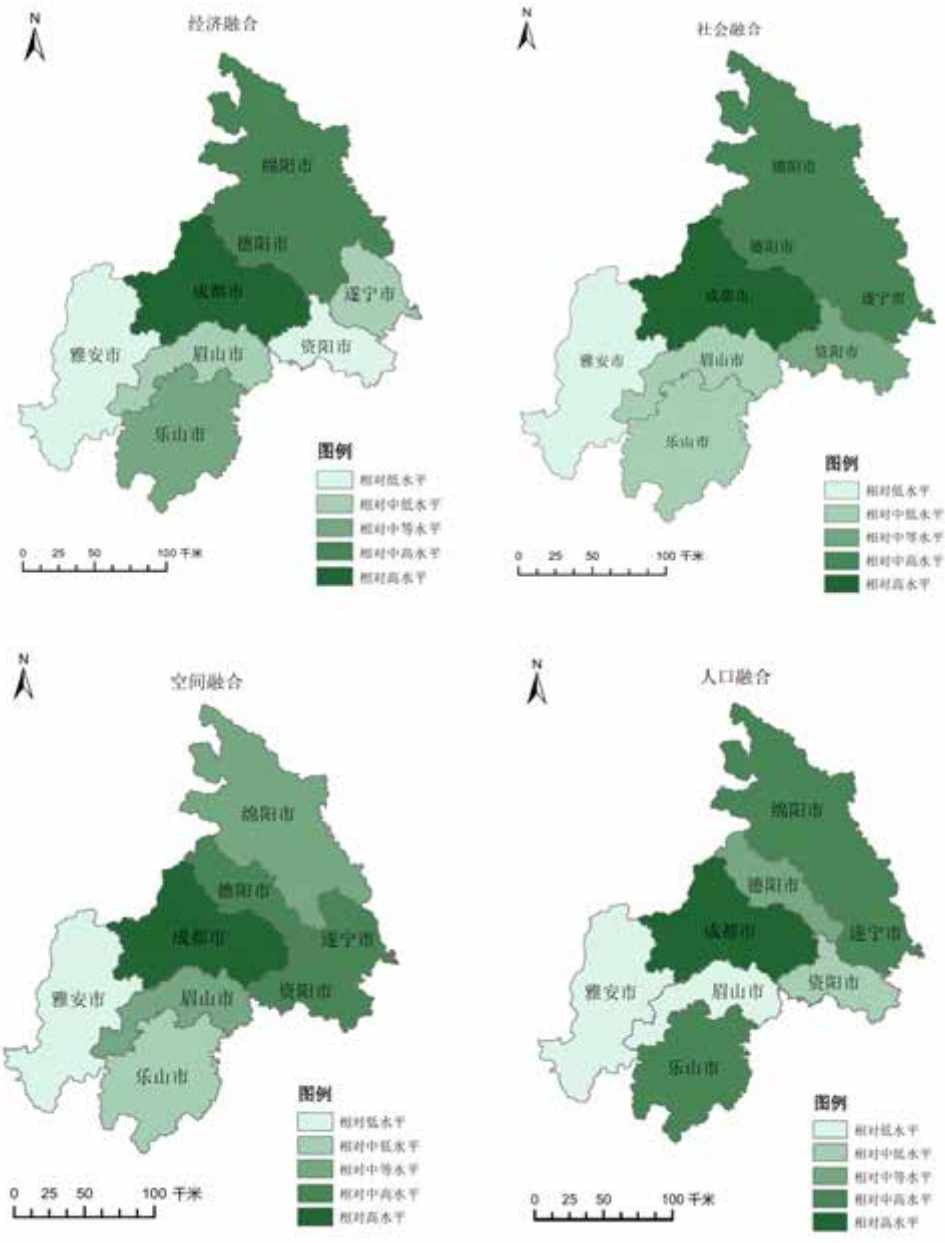

Figure 4-4 Spatial pattern of urban-rural integration levels in various dimensions of the Chengdu Plain Economic Zone

The urban-rural integration in the Chengdu Plain Economic Zone exhibits significant spatial differentiation and dynamic evolution characteristics. In the economic dimension, Chengdu, as the core city, leverages its diversified industrial structure and national strategic positioning to lead regional coordinated development. Deyang and Mianyang, relying on equipment manufacturing and aerospace industries, form secondary growth poles. Leshan depends on tourism resource development but has a lower industrial level, while Ya'an and Ziyang face integration lags due to isolated transportation and singular industrial structures. In the social dimension, Chengdu promotes social equity through high-quality public services and infrastructure. Deyang and Mianyang maintain medium levels through balanced resource allocation, while Meishan and Leshan are constrained by shortcomings in education and healthcare. Ya'an, with significant urban-rural consumption gaps and deficiencies in public services, remains a low-performing area. In the spatial dimension, Chengdu achieves urban-rural spatial inte-

gration through efficient road networks and ecological planning. Deyang and Suining facilitate factor flows via transportation hubs, whereas Leshan and Ya'an are limited by topographic constraints and unplanned expansion, resulting in weaker spatial integration. In the population dimension, Chengdu's high urbanization rate and non-agricultural employment advantages create a strong agglomeration effect. Deyang and Suining optimize labor structures through industrial upgrading, while Leshan attracts population settlement through cultural and tourism resources but with low conversion efficiency. Ya'an and Meishan, hindered by economic lag and transportation barriers, face population outflow and weak urban-rural interactions. The regional pattern overall displays a gradient differentiation of "core polarization–secondary emergence–peripheral decline," necessitating targeted policies to address the dual constraints of natural conditions and institutional barriers in peripheral areas.

4.3.3 Characteristics of Spatial Pattern Evolution

Based on detailed data from 2012 to 2021, this study conducted a comprehensive assessment of urban-rural integration levels in the Chengdu Plain Economic Zone. Using ArcGIS software and the natural breaks method within standard classification techniques, the comprehensive urban-rural integration scores were meticulously categorized. The study specifically focused on the comprehensive scores for the key years of 2012, 2016, and 2021, integrating these with vector maps of the Chengdu Plain Economic Zone to create spatial pattern evolution maps of urban-rural integration levels for these three years.

Building on these results, the study further analyzes and explores the evolutionary characteristics of the overall spatial pattern of urban-rural integration levels in the economic zone, aiming to provide robust data support and theoretical reference for future strategic planning of urban-rural integration.

Analysis of Figure 4-5 (see Appendix) reveals that in 2012, the urban-rural integration levels in the Chengdu Plain Economic Zone exhibited a spatial distribution pattern centered on Chengdu, radiating outward, with lower levels in the southwest and higher levels in the northeast. As the core city of the Chengdu Plain Economic Zone, Chengdu plays a leading and driving role. Its urban-rural integration development is at a relatively high level, characterized by close integration between urban and rural areas. Chengdu's development serves as a "pacesetter," exerting a radiating effect on surrounding areas. Suining City ranks at a relatively medium-high level of urban-rural integration. Although its development level is slightly lower than Chengdu's, it still has a certain radiating and driving effect, contributing to the integration development of neighboring areas. Deyang City's urban-rural integration level is at a relatively medium level. While it ranks at a medium level within the Chengdu Plain Economic Zone, its performance in urban-rural integration remains relatively stable, serving as a bridge connecting Chengdu with other regions. The remaining five cities maintain medium-low to low levels of urban-rural integration, with significant gaps compared to Chengdu. These disparities may be related to factors such as economic development levels, infrastructure development, industrial structures, and policy support in these regions.

Figure 4-5 Spatial pattern of urban-rural integration in the Chengdu Plain Economic Zone in 2012

In 2016, the significant improvement in urban-rural integration levels in the Chengdu Plain Economic Zone reflected the region's positive achievements in advancing urban-rural integrated development. First, Chengdu City, as the core city of the economic zone, continued to play a leading role, maintaining a relatively high level of urban-rural integration and demonstrating its advantages in economic, social, and cultural domains. Second, Mianyang City, an important component of the economic zone, achieved a notable increase in its urban-rural integration level, likely benefiting from the city's sustained efforts in urbanization and rural reform policies. Additionally, Ziyang City's urban-rural integration level advanced from a medium-low to a medium level, reflecting progress in infrastructure development and public service provision. These positive changes indicate that various regions within the Chengdu Plain Economic Zone have made significant strides in urban-rural integration, gradually narrowing urban-rural disparities and laying a solid foundation for comprehensive regional socio-economic development. (See Appendix Figure 4-6)

Figure 4-6 Spatial pattern of urban-rural integration in the Chengdu Plain Economic Zone in 2016

In 2021, the urban-rural integration level in the Chengdu Plain Economic Zone further improved, demonstrating a positive and upward development trend. However, the spatial distribution pattern of "low in the southwest, high in the northeast, and highest in the center" persisted. Within this pattern, Chengdu City remained the only region with a relatively high integration level, continuing to lead in urban-rural integration performance. Additionally, Deyang City saw a significant improvement in its urban-rural integration level, emerging as a new force in the medium-high-level integration zone. Meishan City progressed from a relatively low level to a medium level, indicating a positive trend in the development of its urban-rural integration. Overall, the urban-rural integration level in the Chengdu Plain Economic Zone exhibited a strong development trajectory in 2021, with all regions actively working to address urban-rural development imbalances and advance urban-rural integration to higher levels. (See Appendix Figure 4-7)

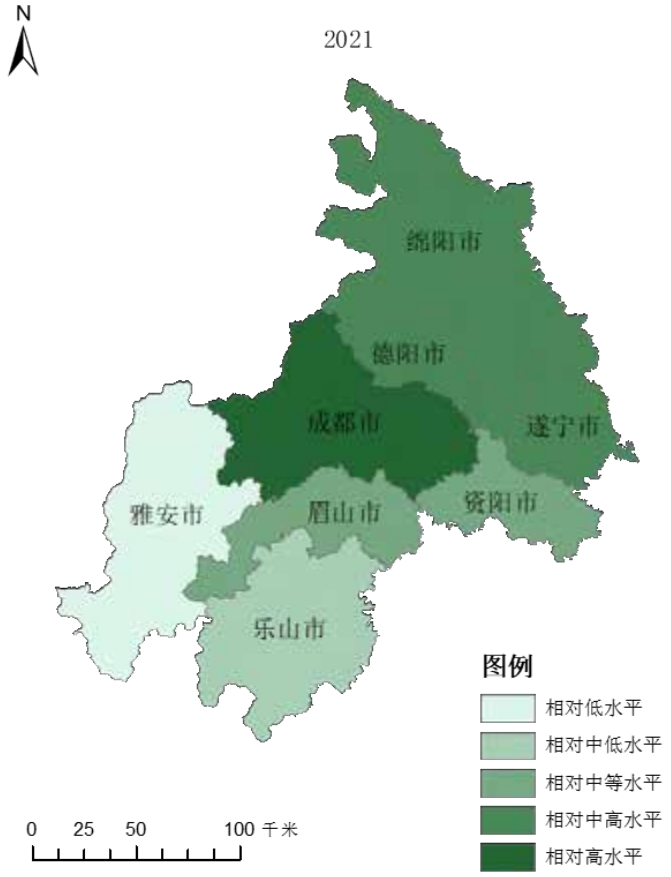

Figure 4-7 Spatial pattern of urban-rural integration in the Chengdu Plain Economic Zone in 2021

5. Influencing Factors of Urban-Rural Integration Levels in the Chengdu Plain Economic Zone

5.1 Variable Selection and Data Sources

5.1.1 Variable Selection

To explore the comprehensive influencing factors of urban-rural integration development levels, this study conducted a thorough review of relevant literature and studies, identifying six key dimensions: economic development level, population structure, policy investment, natural conditions, social conditions, and information development level. Subsequently, eight representative variables were carefully selected under these dimensions to comprehensively analyze how these variables influence and constrain the overall level of urban-rural integration. The selection of these variables not only enriches the dimensions of the study but also enhances the accuracy and comprehensiveness of the analysis.

5.1.2 Data Sources

The dependent variable data used in this chapter are derived from the comprehensive evaluation scores for the four dimensions of urban-rural integration—economic, social, spatial, and population—calculated using the entropy method in Chapter 4. The data for the explanatory variables primarily come from multiple sources, including the Sichuan Statistical Yearbook, statistical yearbooks of individual cities, the China City Statistical Yearbook, and the China Regional Economic Statistical Yearbook. This study focuses on the eight prefecture-level cities in the Chengdu Plain Economic Zone, covering the period from 2012 to 2021, to thoroughly examine the dynamics of urban-rural integration development in this region.

5.2 Construction of the Indicator System for Influencing Factors

The spatio-temporal evolution of urban-rural integration levels in the Chengdu Plain Economic Zone results from the combined effects of multiple influencing factors. Drawing on existing research and considering the actual conditions of urban-rural integration development in the economic zone, an indicator system for the influencing

factors of spatial differentiation in urban-rural integration levels was constructed, as shown in Table 5-1.

Table 5-1 Spatio-temporal Evolution of Factors Influencing the Level of Urban-Rural Integration in the Chengdu Plain Economic Zone, 2012–2021: Indicator System

Variable factors	symbol	Specific indicators	Explanation of indicators
Level of economic development	X1	GDP per capita	GDP/total land area (10,000 yuan/km²)
	X2	Ratio of non-agricultural to agricultural workers	Number of people employed in non-agricultural industries/number of people employed in agriculture
Population structure	X3	Urbanization rate	Urban population/total population
Policy investment	X4	Per capita fiscal expenditure	Fiscal expenditure/total population
Natural conditions	X5	Green space ratio	Statistical data
Social conditions	X6	Ratio of disposable income between urban and rural areas	Per capita disposable income in cities/per capita disposable income in rural areas
	X7	Ratio of Engel's coefficient between urban and rural areas	Engel's coefficient in cities/Engel's coefficient in rural areas
Level of information development	X8	Limited radio and television penetration rate	Number of cable TV users/total population*100

Building on the previous discussion of the spatio-temporal evolution characteristics of urban-rural integration patterns in the Chengdu Plain Economic Zone, this study selected the years 2012, 2016, and 2021, and comprehensively compiled data on relevant influencing factor indicators for these years. Subsequently, the geographical detector model was employed to analyze the influencing factors of urban-rural integration levels in the economic zone, aiming to explain its spatial distribution characteristics.

5.3 Analysis of Influencing Factors

5.3.1 Main Influencing Factors

According to the detection results presented in Table 5-2, the urban-rural integration levels in the Chengdu Plain Economic Zone across the eight single factors varied in 2012, 2016, and 2021. Based on the average q-values over multiple years, the main influencing factors can be categorized into different tiers. Urbanization rate, per capita GDP, urban-rural disposable income ratio, and the ratio of non-agricultural to agricultural employment rank at the top in terms of average q-value influence, with mean q-values of 0.927, 0.925, 0.922, and 0.907, respectively. The second tier includes the urban-rural Engel coefficient ratio and per capita fiscal expenditure, with mean q-values of 0.643 and 0.521, respectively. The third tier comprises the penetration rate of cable television and the green coverage rate, which have relatively smaller q-values. Overall, the q-values of the second and third tiers are relatively low, indicating their weaker influence on the spatial differentiation of urban-rural integration in the Chengdu Plain Economic Zone.

Observing the changes in the q-values of the influencing factors, the spatial differentiation influence of per capita GDP, the ratio of non-agricultural to agricultural employment, the urban-rural disposable income ratio, and the urban-rural Engel coefficient ratio on urban-rural integration levels in the economic zone shows an increasing trend. This suggests that the differences in these factors across different years have a progressively stronger impact on urban-rural integration levels. Conversely, the influence of green coverage rate and cable television penetration rate on the spatial differentiation of urban-rural integration levels exhibits a decreasing trend. This implies that the impact of changes in these two factors across different years on urban-rural integration levels is gradually weakening, or that the influence of other factors is increasingly dominant.

Table 5-2 Detection results of influencing factors of urban-rural integration in Chengdu Plain Economic Zone

Factor Index	2012		2016		2021		Average	
	q	p	q	p	q	p	q	Average q Value Ranking
Land GDP per Unit Area	0.858	0.414	0.965	0.096	0.951	0.224	0.925	2
Ratio of Non - Agricultural to Agricultural Personnel	0.816	0.578	0.972	0.073	0.934	0.221	0.907	4
Urbanization Rate	0.888	0.33	0.974	0.071	0.919	0.308	0.927	1
Per Capita Fiscal Expenditure	0.234	0.935	0.97	0.07	0.36	0.881	0.521	6
Greening Rate	0.655	0.652	0.451	0.825	0.35	0.911	0.485	8
Ratio of Urban - Rural Disposable Income	0.848	0.458	0.977	0.055	0.94	0.215	0.922	3
Ratio of Urban - Rural Engel Coefficients	0.414	0.83	0.569	0.694	0.945	0.196	0.643	5
Cable TV Penetration Rate	0.84	0.484	0.492	0.77	0.192	0.975	0.508	-

5.3.2 Temporal Variation Characteristics of Main Influencing Factors

Based on the multi-year average values of the eight detection factors, the top four factors were selected as the primary determinants of spatial variation in urban-rural integration levels within the Chengdu Plain Economic Zone for temporal change analysis. The results show:

The multi-year average q-value for urbanization rate in the Chengdu Plain Economic Zone is 0.927, indicating that it is the most significant factor influencing the spatial differentiation of urban-rural integration levels. From 2012 to 2021, the q-value for urbanization rate increased from 0.888 to 0.919, while the p-value approached 0, indicating a significant enhancement in its influence. This change in the degree of influence reflects adjustments in the region's urban-rural development strategies and shifts in its economic structure. On the one hand, the government has implemented a series of policy measures during the urbanization process, such as increasing investment in urban infrastructure, optimizing urban planning and layout, and improving the level of urban public services, to accelerate the urbanization process. These measures have attracted a large number of rural residents to migrate to cities, thereby driving the growth of the urbanization rate. On the other hand, as the urbanization process has advanced, the economic structure of the Chengdu Plain Economic Zone has also undergone changes, shifting toward sectors such as services and high-tech industries. Meanwhile, rural areas have also transitioned toward diversified industrial development, prompting more people to migrate from rural areas to cities, further increasing the urbanization rate. Therefore, the influence of the urbanization rate on the spatial differentiation of urban-rural integration in the Chengdu Plain Economic Zone has gradually strengthened.

The second major factor influencing the spatial differentiation of urban-rural integration levels in the economic zone is GDP per unit of land area. Its multi-year average q-value is 0.925. Between 2012 and 2021, the q-value

of GDP per unit of land area rose from 0.858 to 0.925, while the p-value approached 0, indicating a significant increase in its influence. In the Chengdu Plain Economic Zone, the influence of GDP per unit of land area as a key factor in the spatial differentiation of urban-rural integration has gradually increased for multiple reasons. First, the regional economy has continued to grow. Through measures such as technological innovation, industrial upgrading, and optimized resource allocation, the Chengdu Plain Economic Zone has continuously improved production efficiency and economic benefits, thereby driving the growth of GDP per unit of land area. Second, the government has implemented proactive urban-rural integration policies, strengthened infrastructure construction, promoted industrial structure optimization, and accelerated urbanization, further fostering balanced regional economic development and elevating the level of GDP per unit of land area. Additionally, strengthened urban-rural exchanges and accelerated talent mobility have injected new momentum into regional economic development, further enhancing the influence of GDP per unit area. Therefore, the growing influence of GDP per unit area in the Chengdu Plain Economic Zone reflects the combined effects of sustained regional economic development, proactive government policies, and strengthened urban-rural exchanges.

Over the years, the multi-year average q-value of the urban-rural disposable income ratio has been 0.922, making it one of the key factors influencing the spatial differentiation of urban-rural integration levels within the economic zone. Between 2012 and 2021, this indicator rose from 0.848 to 0.940, while its p-value continued to decline, indicating that the significance of spatial differentiation is increasing. In the process of urban-rural integration, the influence of the urban-rural disposable income ratio as a key factor has gradually increased, for various reasons. First, the optimization of the economic structure has driven this trend. By promoting industrial upgrading, strengthening rural economic development, and providing more employment training, economic ties between urban and rural areas have become closer. Second, the government has implemented proactive urban-rural integration policies, including more in-depth infrastructure development, improved public service levels, and the formulation of more comprehensive urban-rural integration plans. The implementation of these policies helps to further narrow the urban-rural income gap, reflecting greater fairness and balance in economic and social development, enhancing overall social stability and sustainable development, and thereby strengthening the influence of the urban-rural disposable income ratio. Additionally, the widespread adoption of information technology and improvements in transportation networks have provided urban and rural residents with broader employment and income opportunities, further driving the increase in the urban-rural disposable income ratio. Overall, the gradual increase in the influence of the urban-rural disposable income ratio reflects the adjustment and optimization of the economic structure, the comprehensive implementation of government policies, and the combined effects of multiple factors such as information technology.

The average Q-value for the ratio of non-agricultural to agricultural workers over the years is 0.907. From 2012 to 2021, the Q-value increased from 0.816 to 0.934, with the P-value continuously decreasing, indicating a significant increase in the influence of spatial differentiation. As urban-rural integration progresses, the more balanced allocation of social resources has brought about multiple impacts. First, the balanced development of education, healthcare, and science and technology has enhanced the overall quality and skill levels of urban and rural residents, making them more capable and competitive in non-agricultural industries. Second, fairer distribution of social resources has promoted talent cultivation and attraction in rural areas, reducing cities' reliance on migrant labor and thereby increasing non-agricultural employment opportunities and income levels. These factors collectively contribute to the rise in the ratio of non-agricultural to agricultural workers. Urban-rural exchanges facilitate the cross-regional dissemination of technology and management experience, enabling rural laborers to access more advanced technical knowledge and management expertise, thereby enhancing their capabilities and proficiency in non-agricultural industries. Additionally, rural talent also has the opportunity to enter urban areas through urban-rural exchange and participate in urban economic activities, thereby increasing the number of non-agricultural workers. This flow of technology and talent promotes complementary development between urban and rural economies, driving the growth of the ratio of non-agricultural to agricultural workers. These factors collectively enhance the influence of the ratio of non-agricultural to agricultural workers on urban-rural integration.

6. Research Conclusions and Policy Recommendations

6.1 Research Conclusions

The integrated urban-rural development of the Chengdu Plain Economic Zone exhibited significant regional differentiation and dynamic evolution from 2012 to 2021. From a temporal perspective, the comprehensive score for integrated urban-rural development in the region increased from 0.274 to 0.482, with an average annual growth rate of 8.65%, but internal gradient differences persisted. Chengdu, as the core city, has consistently remained in the high-level integration zone, with its economic agglomeration effects and policy advantages driving efficient allocation of urban-rural resources; cities in the northeastern region such as Deyang and Mianyang have gradually risen to the medium-high level through industrial upgrading and population aggregation; while cities in the southwestern peripheral regions such as Ya'an and Leshan have long remained at the medium-low level due to geographical barriers and lagging infrastructure. A dimensional analysis indicates that economic integration and population integration are the fastest-growing areas, with the increase in the proportion of non-agricultural industries and the growth in urbanization rates contributing the core driving forces. However, spatial integration is constrained by insufficient expansion of transportation networks, resulting in relatively slow growth. Geographic detector results show that urbanization rates (q=0.62) and GDP per unit of land area (q=0.58) are the primary factors driving spatial differentiation in urban-rural integration, followed by urban-rural income gaps (q=0.45) and non-agricultural employment structures (q=0.38), confirming the dual logic of "economic efficiency-driven" and "population aggregation-driven" development.

6.2 Policy Recommendations

Based on the above conclusions, policy design should focus on three key directions: regional coordination, factor mobility, and functional complementarity. First, a "core-secondary-peripheral" coordinated development network should be established to enhance the industrial reception capacity of secondary central cities such as Deyang and Mianyang. This would guide the outward expansion of Chengdu's high-tech industries to Deyang's high-end equipment manufacturing base and Mianyang's science and technology Transfer Pilot Zone, while providing targeted support for peripheral regions such as Ya'an and Leshan. Infrastructure projects such as the Chengdu-Ya'an high-speed rail double track and the Leshan-Xichang expressway should be implemented to reduce spatial-temporal distances, and the ecological compensation mechanism should be leveraged to explore a "green industry + rural tourism" integration model. Second, reforms to facilitate the two-way flow of urban and rural resources should be deepened. Pilot programs for the entry of collectively-owned operational construction land into the market should be launched in Chengdu's suburban areas to activate the value of rural land assets. In peripheral regions, the "rural homestead land swap for urban housing" policy should be implemented to promote the urbanization of agricultural populations. Concurrently, a cross-regional talent sharing network should be established to encourage flexible talent mobility through the "weekend engineer" model, and mechanisms for cross-regional social security coordination should be improved to lower barriers for non-resident populations to access public services. Finally, efforts should be made to promote complementary urban-rural functions and shared value creation. The metropolitan area should focus on developing high-end industries such as research and design, and financial services, while peripheral counties should take on labor-intensive industries such as agricultural product processing and logistics warehousing, forming a "research in the city, production in the countryside" industrial chain. At the same time, local cultural resources such as the Sichuan Western Forest Villages and Qiang-Tibetan villages should be explored to create a "intangible cultural heritage workshops + digital tourism" brand, using cultural identity to promote spiritual integration between urban and rural areas, to achieve a profound transformation from "spatial integration" to "value integration."

Transformation of Consumption Space in Urban Regeneration: Spatial Characteristics and Influencing Factors of Youth Subcultural Consumption Space

Shuyan Guo, Shijie Sun
Affiliation: School of Architecture, Southeast University
Email:guoshuyan0402@163.com

Abstract:
Multicultural demands and spatial transformations have fostered emerging consumption spaces, particularly youth subcultural venues in Chinese cities. Focusing on Nanjing's historic urban core, this study utilizes Dianping POI data to examine the spatial distribution patterns of youth subcultural spaces and their influencing factors within a multicultural context. GIS analysis reveals a "single-core with three subcentres" spatial configuration and point-axis development structure. SLM spatial lag models identify key agglomeration determinants: commercial density, catering density, cultural facility density, landmark density, and residential density. These spaces facilitate autonomous renewal of traditional commercial areas while creating inclusive social environments for youth, representing a transformative trend in urban consumption space evolution.

Keywords: multiculturalism; youth subculture; consumption space; inclusiveness; Nanjing

0. Introduction

Driven by the rapid development of the cultural economy, China is transitioning from the industrial era to the information era, from the mechanical age to the creative age, and from growth-oriented development to sustainable development. Urban development is gradually shifting from functional cities to cultural cities [1]. However, certain urban challenges have emerged, including the disconnection between cultural consumption spaces and consumption values, an emphasis on construction over operation, and the separation of production, living, and consumption—collectively termed as new urban maladies. In historical districts, the encroachment of commercialised spaces has triggered a cultural crisis in urban spaces[2]. Excessive commercialisation has eroded the original cultural identity, historical memory, authentic architecture, and folk customs, replacing them with homogenised dining streets, Yiwu commodity markets, tourist souvenirs, and globalised fast-consumption symbols.Cultural consumption plays an increasingly vital role in urban economic life. Cities, functioning as entertainment machines, continuously create diverse spaces to meet the growing demand for cultural consumption. A key challenge for many cities is how to cultivate vibrant cultural consumption spaces.

The evolution of urban spatial demands and qualitative upgrading of consumption patterns have expanded cultural consumption beyond material acquisitions (e.g., purchasing audiovisual products and printed materials) to encompass experiential dimensions (e.g., exhibition visits and cinema attendance), while subcultural groups increasingly engage in identity-driven consumption (e.g., live music venues, Pop Mart collectibles, and tattoo culture) for emotional value and social recognition.This diversification further stimulates the upgrading of cultural consumption and revitalises underutilised spaces. Nanjing, a renowned historical and cultural city in China, has witnessed a surge in youth-oriented subcultural consumption spaces amid the new consumption wave[3]. Against this backdrop, examining the spatial distribution patterns and influencing factors of youth subcultural consumption spaces holds significant implications for systematic research on consumption spaces and their transformation in urban renewal.

1. Research Context

The acceleration of globalization has intensified the flow and collision of cultural elements within urban spaces, transforming cities into dynamic carriers of multicultural coexistence, stratification, and evolution. Existing studies have adopted interdisciplinary approaches to analyze the plurality of urban cultural landscapes, systematically deconstructing their spatial characteristics through layered frameworks. For instance, research on Southeast Asian cities has employed macro-, meso-, and micro-scale analysis to examine the temporal evolution of urban morphology, street networks, and iconic architectural features[4], establishing an analytical model for understanding multicultural urban landscapes in coastal cities[5].Scholars have also applied the Historic Urban Landscape (HUL) approach to investigate how cultural diversity influences the development of urban historical spaces and heritage[6]. A notable example includes studies on the port city of Qingdao, where the organic integration of

maritime culture, foreign influences, and indigenous traditions has played a sustainable role in shaping the city's unique identity. During the urban regeneration phase focused on enhancing quality and efficiency, the inclusive capacity of public open spaces to accommodate multicultural interactions has emerged as a critical factor in improving spatial vitality. Empirical research in Macao—a multicultural hub—has examined the congregation patterns of migrant domestic workers in public spaces, analyzing their spatial distribution, underlying factors, and formation mechanisms[7]. Preserving the authenticity and continuity of multicultural expressions not only fosters social well-being but also unlocks economic potential. Multicultural neighborhoods, with their inherent complexity and diversity, contribute significantly to urban vitality and economic resilience[8]. This body of research underscores the need for integrated approaches that balance cultural preservation with sustainable urban development[4].

The rise of youth subcultural consumption spaces has occurred within the broader context of experiential consumption and the transformation of consumption spaces. Within Chinese academic discourse, the concept of 'youth subculture' is generally understood to represent cultural paradigms and typologies that diverge from dominant social culture while gaining popularity among youth demographics. The post-Birmingham School interpretation of subcultural circles has effectively deconstructed the traditional binary opposition between subculture and mainstream culture[9].

Core characteristics manifest in three dimensions:

(1)Identity Attributes: Exclusivity and Social Enclaving

Centreed on youth cohorts, these spaces coalesce around distinct subcultural interests and identity formations. Through curated symbols, behaviors, vernaculars, sartorial codes, and musical practices, subcultural groups demarcate collective identities, forging insulated social enclaves that consciously diverge from mainstream culture. This interactive boundary-making enhances spatial stickiness, transforming locales into physically demarcated territories with high identifiability.

(2)Functional Attributes: Placemaking and Symbolic Consumption

These spaces manifest a cyberspace-to-physical transition—exemplified by offline venues like trendy collectible stores—where "cool" and "edgy" elements materialize digital tribal cultures into tangible environments saturated with subcultural ethos. Functioning as urban cultural strongholds, they typically anchor commercial hubs, creative districts, or neighborhood nuclei, evolving into symbolic urban landmarks. For instance, subcultural malls in metropolitan trend zones form distinctive cultural circuits that become integral to city identity. Beyond commercial venues, they serve as epicentres for cultural praxis and collective identification.

(3)Cultural Attributes: Commodification-Culture Hybridity

Defined narrowly, these spaces inherently possess dual characteristics: commercial viability through sales of subcultural merchandise/services/experiences, and cultural authenticity as vessels of youth expression. Crucially, subcultural meaning remains contingent on relational frameworks—absent referential systems, subculture defies definition.

Based on these attributes, youth subcultural consumption spaces are identified through a tripartite lens:①Youth-dominant participation;②Cultural consumption orientation;③Provision of goods/experiences bearing subcultural symbolic value. Here, consumption extends beyond products/services to encompass spatial embodiment itself—patrons engage with tangible/intangible subcultural commodities while inhabiting meaning-charged environments. Through spatial praxis, participants experience multilayered subcultural immersion, forge social networks, and enact identity construction. This transcends mere transactional fulfillment, constituting instead deep cultural performance, social ritual, and identity-forming agency.

Accordingly, this study defines youth subcultural consumption spaces as purpose-built physical venues in urban environments that cater specifically to distinct youth subcultural groups. These spaces fulfill consumers' demands for identity affirmation, cultural experience, and community engagement through the commercialisation of subculture-specific merchandise and the creation of immersive spatial experiences.

International scholarship addressing youth subcultural consumption spaces remains fragmented, with most research confined to theoretical examinations of youth subculture from an urban sociological perspective, focusing primarily on associated social phenomena and issues[10-12]. Chinese academic inquiries into subculture have predominantly engaged with concepts including micro-media youth, cultural capital, ACG (animation, comics, and games) culture, and stereotype formation, with particular emphasis on the social impacts of subculture on youth development and detailed analyses of specific subcultural groups' behavioral characteristics across both online and offline platforms[13-16].

The current academic landscape reveals significant gaps in research from urban planning and human geographical perspectives, particularly regarding the interaction mechanisms between youth subcultural groups and physical environments, as well as detailed case studies focusing on specific demographic groups. Existing studies, such as those investigating urban and community influences on youth culture formation[16], comparative analyses of international youth fashion districts from cultural perspectives[17], and examinations of the 'Smarti' phenomenon's spatial distribution patterns within urbanisation processes[18], generally lack comprehensive analytical frameworks. While subsequent empirical research has explored the evolutionary processes of culturally hybrid consumption spaces exhibiting transnational subcultural characteristics[19], substantial research opportunities remain concerning the comparative spatial distribution relationships between youth subculture and mainstream culture in urban consumption landscapes, the spatial translation mechanisms of youth subculture within urban consumption space transformations, and the spatial distribution patterns and influencing factors of youth subcultural spaces.

2. Research Data and Methodology

2.1 Data Sources and Processing

2.1.1 Youth Subcultural Consumption Spaces

As one of China's first cohort of National Famous Historical and Cultural Cities and a UNESCO Creative City of Literature, Nanjing possesses profound historical heritage and abundant cultural resources. In recent years, the city has facilitated the unleashing of cultural consumption momentum through advancements in culture, tourism, and MICE sectors. Consequently, the typology of youth subcultural consumption spaces within Nanjing's Old City has been continually enriched. [20].

This study focuses on youth subcultural consumption spaces within Nanjing's Old City as its primary research object. The foundational research data comprise Point of Interest (POI) data and spatial vector datasets sourced from the Amap (Gaode) and Dianping platforms. Specifically, POI data pertaining to youth subcultural consumption spaces were extracted from the Dianping platform during April 2024. Following comprehensive data cleaning and filtering procedures, a refined dataset of 1,333 valid entries was obtained. Through rigorous random sampling validation, the processed data achieved an accuracy rate of 95%.

Currently, the academic community lacks a consensus regarding the precise definition of youth subcultural consumption spaces. Fundamentally, these spaces do not constitute a specific category of space per se, but rather represent consumption venues intentionally designed for specific youth subcultural groups and their associated cultural practices. Consequently, this research adopts a systematic classification framework grounded in the "National Economic Industry Classification (GB/T 4754-2017)" standard and the POI categorization coding system of the Dianping platform. Youth subcultural consumption spaces are thereby defined and classified into three mutually exclusive categories: 1) Artistic Creation Spaces, 2) Creative Retail Spaces, and 3) Leisure & Socialization Spaces(Table 1).

Table 1 Typology and Specific Formats of Youth Subcultural Consumption Spaces

Category	Content Description	Sub-category	Quantity (count)
Artistic Production	Renting studios or compact venues for subcultural art production	Street Dance Studios, DIY Workshops, Tattoo Parlors, Independent Recording Studios	226
Creative Retail	Providing commodities associated with specific subcultures	Designer toy boutiques, anime derivative merchandise stores, alternative fashion boutiques, vintage clothing shops, import goods specialty stores, record and music merchandise retailers, and skateboard specialty shops	227
Leisure Socialisation	Preferred Social Venues of Subcultural Groups	Punk bars, live music venues, comedy clubs, internet cafés, arcades, VR experience centres, escape rooms, murder mystery parlors, and alternative markets	880

2.1.2 Influencing Factors

The spatial distribution pattern of youth subcultural consumption spaces emerges as a complex outcome shaped by multiple interacting factors. A comprehensive review of literature examining determinants of consumption space distribution reveals that transportation factors, commercial factors, and socioeconomic factors consistently constitute common quantitative variables in empirical research[21-24]. Given the distinctive cultural attributes characterizing youth subcultural consumption spaces central to this investigation, cultural factors were deliberately integrated into the analytical framework. Guided by data availability constraints, this study operationalized variable selection by employing bus stop density, metro station accessibility, and road network density to represent transportation factors; shopping mall density and catering facility density to characterize commercial factors; school accessibility, cultural facility density, and scenic spot density to quantify cultural factors; and residential density alongside housing price levels to capture socioeconomic dimensions. This multi-factorial approach facilitated systematic analysis of influences governing the spatial distribution of youth subcultural consumption spaces within Nanjing's Old City, ultimately yielding four overarching influence categories—Transportation, Commercial, Cultural, and Socioeconomic—comprising ten explanatory variables (Table 2). To model spatial heterogeneity, a grid-based analytical approach was implemented wherein comparative model fitting analyses evaluated grid sizes standardized at 100-meter, 500-meter, and 1000-meter resolutions, accounting for both the physical extent of the Old City and the characteristic service radius of consumption spaces. Model performance metrics substantiated the optimality of the 500 × 500 meter grid resolution, consequently delineating 238 standardized analytical units across the study area. Prior to spatial econometric analysis, comprehensive data preprocessing was conducted, including multicollinearity diagnostics performed through multiple linear regression analysis using IBM SPSS Statistics 27 software. The computed Variance Inflation Factor (VIF) values for all independent variables remained consistently below the critical threshold of 3, confirming the absence of significant multicollinearity and thereby validating the mutual independence of explanatory variables for subsequent integration into spatial regression equations.

Table 2 Determinants of Youth Subcultural Consumption Space Distribution

Category	Factor	Variable Description	Data Source
Transportation	Bus stops	Number of bus stops per research unit (count)	Amap POI data
	Metro stations	Distance to nearest metro station (m)	Amap POI data
	Road network	Road length per unit area (km/km²)	Nanjing road vector data
Commercial	Shopping malls	Number of shopping malls per unit (count)	Amap POI data
	Restaurants	Number of catering establishments per unit (count)	Amap POI data
Cultural	Schools	Distance to nearest school (m)	Amap POI data
	Cultural facilities	Number of cultural venues per unit (count)	Amap POI data
	Tourist attractions	Number of scenic spots per unit (count)	Amap POI data
Socioeconomic	Residential areas	Number of residential communities per unit (count)	Amap POI data
	Housing prices	Average housing price per unit (¥/m²)	Beike second-hand housing data

2.2 Research Methods

This study employs a systematic suite of spatial correlation analysis models to comprehensively investigate the determinants and operational mechanisms governing the distribution of youth subcultural consumption spaces. The analytical framework progresses from global patterns to local variations, capturing both overarching trends and spatial heterogeneity, thereby providing an empirical grounding for evidence-informed urban spatial planning and youth cultural policy formulation. Prior to regression modelling, spatial autocorrelation diagnostics were conducted using Global Moran's I and Local Moran's I indices applied to youth subcultural consumption space distribution data. The Global Moran's I ascertains whether the data exhibit clustering or dispersion tendencies across the entire spatial domain, whilst the Local Moran's I identifies specific regional agglomeration characteristics. This dual-index approach determines the presence of spatial autocorrelation and informs subsequent model selection. Should significant spatial autocorrelation be observed, spatial econometric models become methodologically requisite.

Predominant methodologies for spatial correlation analysis encompass Ordinary Least Squares regression (OLS), spatial regression models (Spatial Lag Model/Spatial Error Model, SLM/SEM), and Geographically Weighted Regression (GWR). The OLS approach proves suitable under idealised scenarios devoid of significant spatial autocorrelation, whilst SLM/SEM models—contingent upon spatial weight matrices—are routinely employed in investigations of complex spatial mechanisms. GWR is particularly apt for examining localised spatial variations in influencing factors. An initial OLS model was constructed to provisionally estimate determinants of youth subcultural consumption space distribution. Rigorous diagnostic testing for multicollinearity, heteroscedasticity, and residual normality was undertaken to evaluate model suitability and robustness. Where substantial multicollinearity, heteroscedasticity, or non-normal residual distributions were detected, variable transformations or corrective methodologies were applied to ensure estimative validity.Subsequent to confirming spatial autocorrelation presence, both SLM and SEM specifications were implemented to discern whether spatial dependence operated predominantly through lagged-dependent or error-correction mechanisms. These three modelling frameworks—OLS, SLM, and SEM—were systematically deployed to analyse influencing factors, with comparative evaluation identifying the optimally fitted specification. Within this analytical architecture, youth subcultural consumption space density served as the dependent variable, whilst ten independent variables representing transportation, commercial, and cultural dimensions were operationalised[25]. Model selection adhered to established econometric criteria: higher R^2 and Log-Likelihood (Log L) values denote superior statistical significance,

whilst diminished Akaike Information Criterion (AIC) and Schwarz Criterion (SC) values indicate enhanced explanatory power. Following comprehensive assessment, the Spatial Lag Model (SLM) was retained for primary inference due to its demonstrable explanatory coherence and empirical verifiability.

Following the identification of the optimal global spatial econometric specification, the Geographically Weighted Regression (GWR) model was employed to interrogate the locally varying effects of individual determinants on the morphological configurations of youth subcultural consumption spaces. Through calibrated bandwidth parameterisation and kernel function selection, locally adaptive regression equations were formulated, facilitating the derivation of spatially distributed coefficient estimates for each influencing factor. Subsequent analysis examined inter-regional disparities in coefficient magnitude, directional effects, and statistical significance—thereby elucidating spatially heterogeneous patterns governing the distributional dynamics of youth subcultural consumption spaces.

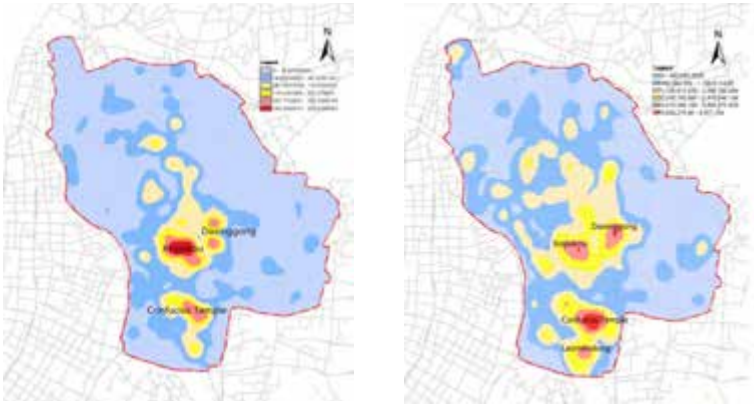
3. Macroscopic Distribution Characteristics of Youth Subcultural Consumption Spaces

Initially, the spatial autocorrelation analysis tool (Global Moran's I) within ArcGIS was employed to examine whether statistically significant spatial clustering exists in the distribution of youth subcultural consumption spaces within Nanjing's Old City. The results yielded a Moran's I index of 0.57, with a p-value < 0.001 and a Z-score of 15.51, strongly indicating the presence of significant positive spatial autocorrelation—demonstrating pronounced clustering effects among youth subcultural consumption spaces across the Old City.

Youth subcultural consumption spaces within Nanjing's Old City manifest a distinct polycentric agglomeration pattern, characterised by a primary central nucleus and three secondary clusters radiating through the urban fabric(Figure 1-a). This spatial configuration demonstrates pronounced concentration within both the historic commercial core and southern cultural districts, where high-density commercial-cultural hybrids have coalesced into identifiable subcultural quarters through complex socio-spatial processes.The central nucleus, anchored by the Xinjiekou-Daxinggong corridor, constitutes the traditional commercial heart of Nanjing. Here, premium retail complexes such as Deji Plaza and Central Mall have transcended conventional consumption functions through strategic cultural programming, including avant-garde art exhibitions and limited-edition brand activations specifically designed to attract fashion-conscious youth demographics. Adjacent to this, the 1912 precinct exemplifies successful heritage commodification, where Republican-era architecture has been adaptively reused to house concentrated subcultural venues - from craft cocktail bars to designer pop-up stores - creating a distinctive nocturnal economy. This area's exceptional accessibility, deriving from its pivotal position at the intersection of Metro Lines 1 and 2 supplemented by extensive bus networks, ensures sustained pedestrian flows that underpin the commercial viability of these specialised retail ecosystems.Among the secondary clusters, the Confucius Temple (Fuzimiao) district has leveraged its deep historical capital to cultivate immersive traditional cultural experiences. Specialist operators offer hanfu costume rentals for photogenic heritage exploration along the Qinhuai riverscape, complemented by hands-on workshops demonstrating Nanjing brocade weaving and other intangible cultural heritage techniques. This synthesis of tradition and youth culture has been further enhanced through deliberate urban interventions, particularly the Mendong Historic Quarter redevelopment, where carefully curated independent retailers - ranging from avant-garde bookshops to micro-roasteries - have established a culturally-anchored consumption node. These spaces simultaneously preserve architectural heritage while fostering contemporary creative expression, creating a palimpsest of historical and modern cultural layers.

Nanjing's Old City exhibits a pronounced polarisation in its cultural consumption landscape, with Xinjiekou emerging as a dominant central 'polar core' while peripheral areas demonstrate negligible agglomeration effects. This spatial configuration indicates an advanced stage of centralisation that warrants caution regarding potential regional development imbalances stemming from excessive resource concentration(Figure 1-b). Xinjiekou's longstanding status as Nanjing's civic centre has afforded it unparalleled advantages in cultural infrastructure development. The district boasts an integrated cultural ecosystem encompassing premium cinemas within major retail complexes such as Nanjing New Century and Central Mall, complemented by specialised venues including the People's Assembly Hall and Cultural Arts Centre. Together these facilities create a comprehensive cultural consumption spectrum ranging from popular entertainment to highbrow artistic experiences.

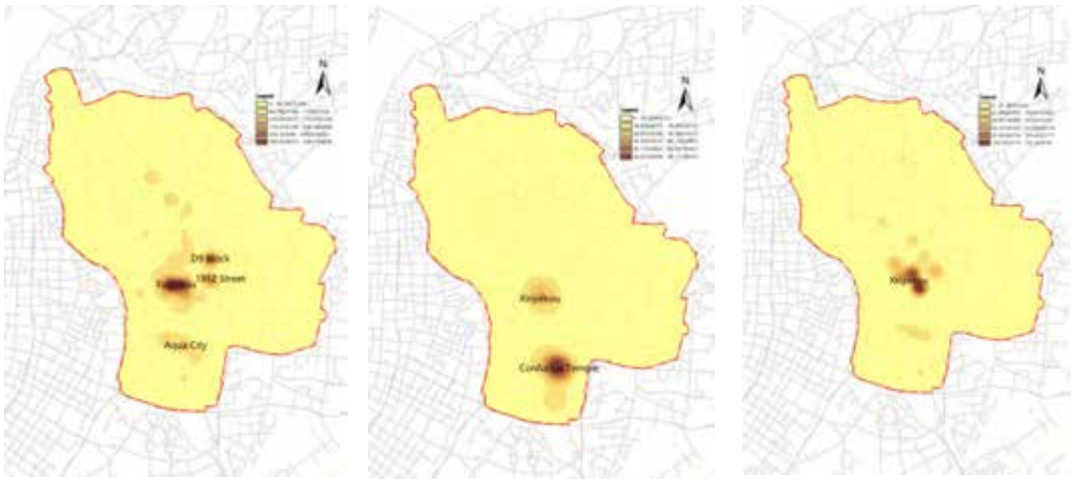
This concentration has been systematically reinforced through targeted policy interventions, including preferential funding for cultural infrastructure and the strategic allocation of major cultural events, thereby cementing Xinjiekou's position as the city's undisputed cultural nucleus.Conversely, peripheral zones within the Old City manifest significantly underdeveloped cultural consumption provision. The western districts exemplify this disparity, where historical planning priorities emphasised residential functions while neglecting cultural infrastructure. Limited commercial development has further compounded this imbalance, creating an environment inhospitable to major cultural enterprises and resulting in sparse, monotonous cultural offerings that fail to generate meaningful agglomeration effects.This polarised spatial structure presents dual challenges: Xinjiekou contends with the negative externalities of over-concentration, including chronic traffic congestion and market saturation, while peripheral residents face constrained access to diverse cultural consumption opportunities. Such asymmetrical development threatens the balanced growth of Nanjing's cultural economy and may engender self-reinforcing cycles of central accumulation and peripheral deprivation.



1-aYouth Subcultural Consumption Spaces

1-bCultural Consumption Spaces

Figure 1 Typology of Cultural Consumption Spaces



2-a Artistic Production

2-b Creative Retail

2-c Leisure Socialisation

Figure 2 Typology of Youth Subcultural Consumption Spaces

The kernel density analysis reveals that all three types of youth subcultural consumption spaces exhibit clustered distribution patterns, forming preliminary complementary spatial development clusters in both the central and southern parts of the historic urban core. Leisure and social spaces account for the largest proportion (approximately 66%), primarily comprising bars, live music venues, comedy clubs, internet cafés, and gaming arcades, with main concentrations in central areas including Xinjiekou, 1912 Pedestrian Street, and D9 Block (Figure 2-a). Creative retail and artistic production spaces constitute 16% and 17% respectively, where creative retail spaces (dominated by designer toy stores and anime derivative shops) mainly cluster around the Fuzimiao historic cultural district (Figure 2-b), while artistic production spaces (primarily street dance studios, DIY workshops, and tattoo parlors) predominantly concentrate in the Xinjiekou central area (Figure 2-c).

The leisure-socialisation youth subcultural consumption spaces (Figure 2-a) exhibit pronounced clustering within Nanjing's historic city centre, a spatial pattern fundamentally shaped by the area's vibrant commercial ecosystem, exceptional transport connectivity, and concentrated youth demographics. Xinjiekou, as the city's premier commercial district, accommodates upscale retail complexes including Deji Plaza and Central Mall, which have strategically diversified their offerings by incorporating bars, live music venues, and comedy clubs alongside conventional retail establishments. Deji Plaza exemplifies this trend through its sophisticated cocktail bars and regular musical performances that consistently attract fashion-conscious young patrons. Adjacent to this, the 1912 pedestrian precinct capitalises on its distinctive Republican-era architectural heritage to cultivate a thriving nocturnal economy, where atmospheric bars and cafés create compelling social destinations after dusk. Meanwhile, the D9 Block has emerged as a creative entertainment hub, integrating gaming arcades and internet cafés within its mixed-use development. This agglomeration is further facilitated by Xinjiekou's unparalleled accessibility as the interchange station for Metro Lines 1 and 2, supported by an extensive bus network that ensures sustained visitor flows essential for these leisure-socialisation businesses.

Creative retail subcultural spaces (Figure 2-b) demonstrate a distinct spatial logic, with approximately 16% concentration around the Confucius Temple historic district. These specialist retailers, including designer toy stores and anime merchandise shops, leverage the area's cultural capital and substantial tourist footfall to develop niche product lines that incorporate local heritage motifs. Innovative examples include collectible items featuring artistic interpretations of Qinhuai River scenery and Nanjing landmarks, which simultaneously cater to youth preferences for distinctive goods while promoting regional cultural narratives.

The precinct's mature tourism infrastructure, characterised by pedestrianised streets and public squares that regularly host creative markets, provides an ideal ecosystem for these ventures to flourish. Artistic-production spaces (Figure 2-c) display a 17% concentration in Xinjiekou, benefiting from the district's unique confluence of educational institutions and commercial vitality. Street dance studios, tattoo parlours, and DIY workshops thrive in this environment by drawing upon the abundant student populations from nearby Nanjing University and Southeast University, who serve as both primary consumers and potential practitioners. The district's robust commercial ecosystem enables innovative hybrid business models, exemplified by craft workshops that collaborate with consumer brands to produce customised merchandise. Furthermore, Xinjiekou's status as an information hub facilitates continuous exposure to emerging trends, fostering an environment of constant innovation that reinforces its agglomeration advantages.

This tripartite spatial configuration emerges from several interconnected urban processes: the strategic co-location of complementary subcultural businesses that create critical mass; high-capacity transport infrastructure enabling metropolitan-scale accessibility; synergistic relationships between cultural heritage and contemporary youth practices; and concentrated demographics with disposable income and cultural capital. The case offers valuable insights for urban planners seeking to cultivate vibrant youth cultural ecosystems while preserving historic urban character, demonstrating how careful spatial policy can mediate between commercial development and cultural sustainability in post-industrial cities. The organic formation of these specialised clusters illustrates the potential for creating dynamic interfaces between traditional urban forms and emergent youth cultures, suggesting pathways for other historic cities undergoing cultural-economic transitions.

4. Influencing Factors of Youth Subcultural Consumption Space Distribution

4.1 Analysis of Influencing Factors

The results of the three spatial econometric models are presented(Table 3). Regarding goodness-of-fit, the spatial lag model (SLM) (R^2=0.79601; Log L=-757.445706; AIC=1536.89; SC=1575.09) and the spatial error model (SEM) (R^2=0.794118; Log L=-756.318; AIC=1536.64; SC=1578.3) demonstrate comparable explanatory power for the distribution mechanisms of youth subcultural consumption spaces, with both outperforming the ordinary least squares (OLS) regression model. However, the SLM exhibits superior significance levels in its independent variables and, while having identical AIC values, shows slightly higher SC values than SEM, making it more suitable for subsequent mechanistic analysis of influencing factors. In conclusion, the SLM results prove more verifiable and interpretable, and thus this model is selected for the regression analysis of influencing factors.

Table 3 Comparative Results of Global Regression Models with Youth Subcultural Consumption Space Density as the Dependent Variable

Variable	OLS			SLM			SEM

Table 4 Influence Levels of Determinants on Youth Subcultural Consumption Spaces

Category	Factors	Directionality	Significance Level
Commercial	Shopping malls	Positive effect	***
	Restaurants	Positive effect	***
Cultural	Cultural facilities	Positive effect	**
	Tourist attrac-tions	Positive effect	**
Socioeconomic	Residential areas	Negative effect	**

Note: *,**and***indicate significance at the 5%, 1%, and 0.1% levels, respectively.

The SLM model results indicate that the primary factors influencing the agglomeration of youth subcultural consumption spaces are shopping mall density, restaurant density, cultural facility density, tourist attraction density, and residential area density. Among these, shopping malls, restaurants, cultural facilities, and tourist attractions exert positive effects, whereas residential areas demonstrate negative effects (Table 4).

First, commercial service facilities such as shopping mall density and restaurant density exert positive effects on the spatial distribution patterns of youth subcultural consumption spaces. The supply of commercial facilities like shopping malls and restaurants attracts consumers, expands consumer scale, and consequently promotes the agglomeration of consumption spaces to a certain extent, broadening customer acquisition channels for youth subcultural consumption spaces. The high-density human flow in these commercial spaces creates public spatial fields that provide low-cost venues for youth-dominated subcultural consumer groups, thereby facilitating rational spatial planning that maintains an elastic balance between commerce and diverse cultural formats.

Second, cultural facility density and tourist attraction density also demonstrate significantly positive effects on the distribution of youth subcultural consumption spaces. As spatial anchors for urban cultural tourism development, these facilities attract large numbers of non-local visitors and traveling youth, whose diverse demands present new spatial requirements and challenges to mainstream cultural facilities. On one hand, cultural facilities utilise media like books and exhibitions to serve as spatial platforms for disseminating youth subcultures within diverse cultural systems. On the other hand, through spatial translation of culture, independent artists are commissioned to create wall paintings and graffiti at tourist sites, creating inclusive spaces that facilitate equal dialogue between mainstream culture and subcultures. This collision and exchange of diverse cultures generates positive feedback effects for the composite development of cultural spaces.

Finally, residential density exhibits a significantly negative effect on the distribution of youth subcultural consumption spaces. Residential clusters are typically located in urban land price peak zones, where priority is given to mainstream cultural facilities such as libraries and sports stadiums. According to Alonso's bid rent theory, the payment capacity of youth subcultural businesses cannot compete with high-value-added industries like finance, upscale retail, and mainstream cultural media, leading to spatial squeeze effects on youth subcultural venues. Additionally, residential areas impose specific safety requirements for living environments, and some residents exhibit resistant attitudes due to stereotypical perceptions of youth subcultures. This negative influence reveals inherent conflicts between residential efficiency priorities and cultural diversity values in urban renewal processes.

4.2 Spatial Distribution Characteristics of Influencing Factors

A Geographically Weighted Regression (GWR) analysis was applied to the factors influencing youth subcultural consumption spaces previously identified through the Spatial Lag Model (SLM), enabling further exploration of how these five categories of factors shape such spaces. Visualization of the GWR regression coefficients effectivly captures the spatial heterogeneity of each factor's influence (Figure 3). The results reveal that, overall, the five influencing factors exhibit highly differentiated spatial clustering patterns. Their magnitude and direction

of influence display varying degrees of dispersion and equilibrium across different spatial extents within Nanjing's Old City, forming distinct clustered zones. This reflects significant spatial variations in the intensity of each factor's impact across urban districts.The influence of shopping mall density and catering density on youth subcultural consumption space distribution progressively diminishes from the central Old City toward its periphery. This pattern correlates with the Ming Palace area and its surroundings, where high concentrations of cultural heritage protection units and military zones result in lower commercial density and consequently reduced vitality of commercial services. Furthermore, large shopping malls and distinctive commercial streets are primarily distributed along Zhongshan South Road, Zhongshan North Road, and within the Confucius Temple (Fuzimiao) and Laomendong (Old East Gate) districts. In contrast, peripheral areas of the Old City feature fewer shopping malls and generally underdeveloped commercial and catering sectors.The influence of cultural facility density and scenic spot density decreases gradually from the southern Old City toward the north. The spatial extent of scenic spot influence corresponds directly to their distribution within the Old City. The southern districts possess abundant cultural facilities and densely concentrated scenic spots; this high saturation of historical and cultural resources contributes positively to increased density of youth subcultural consumption spaces. The influence of residential density diminishes from the northeastern periphery toward the northern Old City. Residential population density is lower in the northeastern periphery compared to the southern Old City. Areas with lower population density exhibit a stronger influence of this factor on youth subcultural consumption space distribution, consistent with the identified negative correlation associated with residential density.

Development priorities and trajectories diverge significantly across different regions of Nanjing's Old City. Historically dominated by factories and dense urban villages, the northern Old City has undergone large-scale regeneration in recent years, aiming to establish a model zone for industry-city integration within a megacity context. Conversely, the southern district of Qinhuai focuses on historical preservation and cultural-tourism integration. These differing historical paths and functional orientations have fostered pronounced north-south disparities in cultural diversity. The southern Old City exhibits vibrant cultural consumption, with cultural tourism driving district development. Over the past two years, youth subcultural consumption spaces have integrated with numerous traditional commercial spaces in the south, undergoing spatial renewal and business diversification, thereby infusing new vitality into the area's cultural consumption landscape. Meanwhile, regeneration efforts in the north prioritize the revitalization of traditional cultural corridors along the Yangtze River waterfront. The variation in regeneration priorities and levels of cultural inclusivity across these districts inevitably influences the locational attractiveness for youth subcultural consumption spaces. Effectively integrating urban multiculturalism with cultural consumption spaces thus constitutes a critical focus for contemporary urban regeneration strategies.

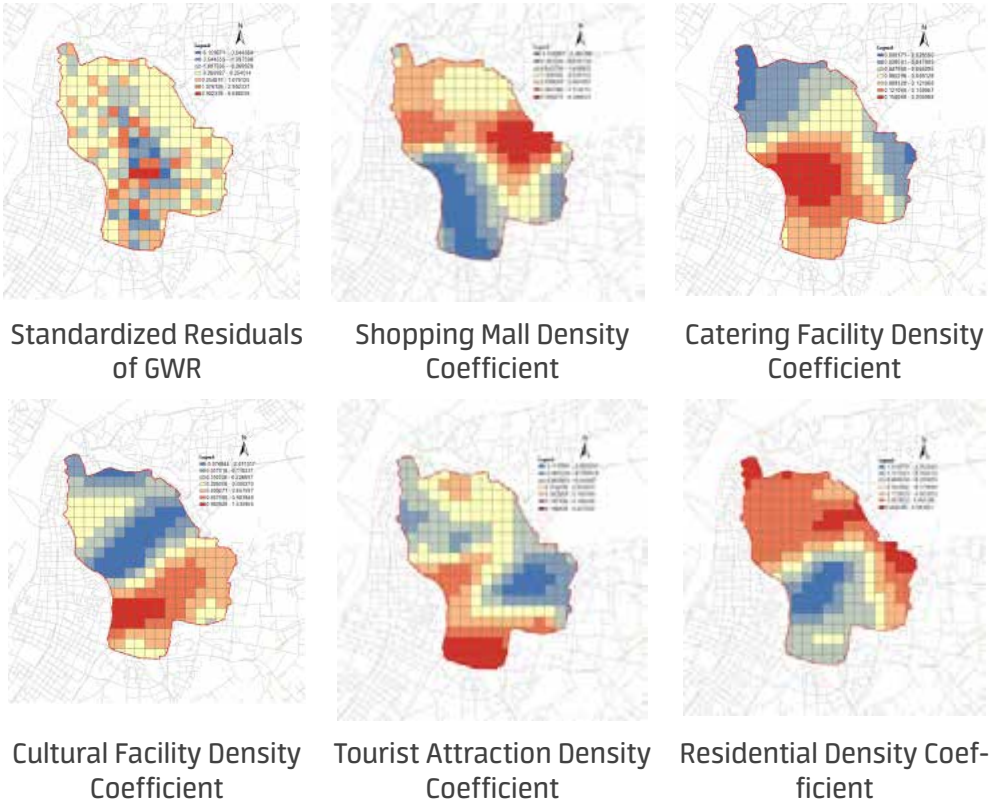

Figure 3 Spatial Heterogeneity of Influencing Factors for Youth Subcultural Consumption Spaces: A Geographically Weighted Regression (GWR) Analysis

5 Conclusions and Prospects

5.1 Key Findings

This study focuses on the macroscopic distribution characteristics and influencing factors of youth subcultural consumption spaces within Nanjing's historic urban core, with key findings as follows:

(1) At the interdisciplinary level of multiculturalism and urban consumption space research, this study constructs a youth subcultural consumption space framework at the macroscopic scale. Differing from previous studies that categorised these spaces into artistic creation spaces, creative retail spaces, and leisure-social spaces, youth subcultural consumption spaces represent an emerging typology within the urban cultural consumption system, constituting a critical subject for investigating consumption space transformation during urban renewal.

(2) Building upon the systematic framework of youth subcultural consumption spaces, this study focuses on analyzing their distribution patterns and influencing factors at the macroscopic scale, establishing an indicator system across four dimensions: transportation, commercial, cultural, and socioeconomic factors. The results demonstrate that youth subcultural activities in Nanjing's historic urban core exhibit vibrant spatial concentration, primarily clustering in the central and southern districts with high-density distributions centreed around modern commercial and cultural hubs. Specifically, shopping malls, restaurants, cultural facilities, and tourist attractions exert positive effects, while residential density shows negative impacts.

(3)The agglomeration of youth subcultural consumption spaces exhibits pronounced spatial heterogeneity in its driving factors across Nanjing's Old City. The clustering dynamics manifest distinct spatial dependencies wherein cultural facilities and tourist attractions exert stronger agglomerative forces in the southern districts, residential density emerges as the dominant driver in northern sectors, and commercial determinants—particularly concentrations of shopping malls and catering establishments—predominate in the central core area. This

centre-periphery differentiation further reveals that proximity to Xinjiekou, the metropolitan commercial nucleus, renders spatial aggregation predominantly responsive to commercial variables, whereas peripheral zones demonstrate heightened sensitivity to non-commercial influences including cultural facilities, scenic sites, and residential density. Such documented spatial divergence in formative mechanisms fundamentally illuminates the disparate logics governing cultural consumption space distribution, thereby providing an empirical foundation for designing spatially-targeted interventions to rectify developmental imbalances while simultaneously addressing a critical theoretical gap in consumption geography research through its context-sensitive explanatory framework.

5.2 Discussion and Prospects

This study systematically examines the role of youth subcultural consumption spaces in Nanjing's urban regeneration process, revealing their multifaceted value and operational mechanisms. Through empirical investigation and theoretical analysis, the research identifies four key functions these spaces perform in facilitating urban transformation, collectively constituting an integrated urban renewal promotion system.

(1) Cultural Agency as Spatial Catalyst: Activating Transformations in Existing Urban Fabric

Youth subcultural consumption spaces provide sustained cultural momentum for urban regeneration through unique cultural translation and spatial reconfiguration mechanisms. The study identifies two predominant transformation models: complete spatial renewal (e.g., the comprehensive conversion of Haishanghai Department Store into an anime-themed youth space) and partial functional adaptation (e.g., the introduction of trendy youth-oriented retail in Fashion Lady, Xinjiekou). These models demonstrate successful implantation of subcultural semiotics into physical spaces, facilitating cultural capital reproduction while reshaping place identity and spatial justice. Notably, this cultural transformation process often involves intergenerational cultural dialogue, preserving urban historical memory while infusing contemporary cultural significance. This study empirically validates the positive impact of shopping malls on the agglomeration of youth subcultural consumption spaces, providing theoretical underpinnings for the redevelopment of underutilized commercial assets in urban contexts. From a spatial economics perspective, malls generate synergistic agglomeration effects through intensive physical clustering, thereby reducing spatial fragmentation of subcultural consumption scenes and achieving a "1+1>2" multiplier effect that aligns with youth demands for diversified experiential consumption. Practically, renovating aging retail infrastructure not only revitalizes inefficient commercial properties but also facilitates cultural value reproduction within urban public spaces. Exemplary cases such as Shanghai's TX Huaihai and Chengdu's ACG Plaza demonstrate how integrating subcultural formats—including collectible art toys, ACG (Anime-Comics-Games) culture, and guochao (national trend) elements—significantly enhances their appeal to Generation Z demographics, catalyzing the transformation of commercial spaces from monofunctional retail venues into integrated cultural-social complexes. However, current revitalization initiatives face persistent challenges including homogenized competition and insufficient cultural depth, where some projects merely engage in superficial stacking of trendy formats without excavating subcultural essences, consequently resulting in consumption scenes with ephemeral appeal.

(2) Cultivating Cultural Habitats: Multicultural Inclusivity and Human-Centreed Urbanism

The construction of "cultural habitats" through multicultural inclusivity constitutes a profound practice of reshaping urban humanistic values via spatial empowerment. Youth subcultural consumption spaces serve as convergence fields integrating diverse cultures, populations, spatial configurations, and behavioral patterns, wherein leisure-socialization spaces embody principles of egalitarian interaction, creative-retail environments manifest self-expressive freedoms, and artistic-creation zones signify cultural pluralism. This symbiotic relationship between youth subcultural spaces and broader urban consumption landscapes intrinsically reflects the core values of human-centreed cultural habitats. Urban regeneration initiatives must therefore strategically leverage the catalytic capacity of these spaces to advance urban consumption ecosystems, delivering inclusive spatial provisions and functional services responsive to diverse cultural needs.As polycultural aggregators, youth subcultural spaces and their synergistic coexistence with mainstream consumption arenas epitomize the humanistic logic underpinning cultural habitat development: leisure-socialization spaces dissolve social hierarchies through equitable encounters; creative-retail venues empower individual agency through personalized

expression; artistic-creation domains embrace cultural heterogeneity through radical openness—collectively forming a microcosm of urban multicultural inclusivity. Nevertheless, persistent value disjunctures in integrating these spaces within mainstream urban fabrics reveal significant challenges: certain redevelopment projects prioritize commercial imperatives to the extent of commodifying subcultural spaces into mere traffic-generating instruments, thereby neglecting their essential cultural articulation and community-building functions; simultaneously, spatial planning frequently fails to accommodate differentiated group needs, creating disconnects between subcultural consumption scenes and residents' quotidian realities. These contradictions fundamentally manifest the tension between humanistic values and economic logics in urban spatial production, necessitating urgent recalibration through integrated institutional frameworks and transformative spatial praxis to achieve sustainable equilibrium.

(3) Negotiating Institutional-Spatial Dialectics: Elastic Coordination in Urban Regeneration
The interplay between institutional frameworks and spatial production manifests pronounced regional differentiation within Nanjing's Old City renewal initiatives. In the northern sectors, the industry policy-driven spatial production paradigm—while facilitating technology-oriented subcultural consumption scenarios through developments like data industrial parks—suffers from functional mismatches stemming from rigid industrial land conversion mechanisms and lagging commercial infrastructure planning. Conversely, the southern districts leverage culturally-grounded governance policies to cultivate flexible institutional environments. Through instruments such as intangible cultural heritage protection ordinances and adaptive reuse of culturally protected buildings, these frameworks enable symbiotic integration between subcultural expressions and historical settings.This institutional design achieves dual objectives: preserving spatial cultural memory while fostering structured growth of subcultural consumption scenes through regulatory control over business typologies. Such configurations empirically validate how institutional elasticity positively correlates with spatial diversity and inclusivity. However, both northern and southern practices reveal an inherent tension: the contradiction between institutional inertia and spatial innovation demands. The north's excessive reliance on industrial policies constrains spatial vitality, while the south's stringent cultural governance potentially inhibits subcultural experimentation and boundary-pushing innovation.

Research on youth subcultural consumption spaces constitutes a strategic implementation of national cultural industry development policies. This study elucidates macro-scale spatial distribution patterns and their determinants within Nanjing's Old City, while acknowledging that meso-micro level empirical investigations remain underdeveloped. Future scholarship should prioritize strengthening theoretical-empirical integration through quantitative analysis of spatial agglomeration dynamics across diverse subcultural business formats, thereby establishing standardized revitalization assessment frameworks for aging retail infrastructure. Concurrently, research must explore synergistic pathways between subcultural spaces and urban cultural ecosystems by facilitating their convergence with localized intangible heritage and collective memory—achieving equilibrium between cultural continuity and commercial innovation. The transformative potential of emerging technologies warrants rigorous examination, particularly regarding blended reality environments leveraging metaverse platforms and AI-driven immersion to reconfigure consumption experiences. Policy formulation requires enhanced regulatory frameworks addressing copyright protection, safety protocols, and operational standards to ensure sustainable sectoral development. Crucially, the integration of underutilized commercial assets with youth subcultural elements may catalyze urban transformation and consumption upgrading—a phenomenon demanding sustained scholarly attention given its profound socioeconomic implications for urban futures.

The Demand-Supply Measurement of Youth Development-Oriented Cities Based on the Characteristics of Generation Z: A Case Study of Shanghai, Nanjing, and Hangzhou

Sun Keyi, Wang Xingping
Affiliation:School of Architecture, Southeast University
Email:Sunkeyi2000@outlook.com

Abstract
This study examines Generation Z's (born 1997-2012) demand patterns and urban development alignment in Shanghai, Hangzhou, and Nanjing. As key drivers of urban innovation and economic growth, Gen Z exhibits atomized lifestyles and self-actualization tendencies. A demand-supply evaluation framework is developed across three tiers: basic growth, relational cohesion, and developmental leap. Empirical analysis reveals supply-demand mismatches: Shanghai and Hangzhou excel in employment ecosystems and recreational infrastructure, while Nanjing achieves higher youth satisfaction despite weaker supply capacities. Findings highlight Shanghai's lag in leisure services, Hangzhou's deficiency in cultural amenities, and Nanjing's need for entrepreneurship support. The study advocates policy optimization to bridge gaps in youth-oriented urban development, emphasizing tailored strategies to enhance productivity and social integration for this generation.

Keywords: Youth Development-Oriented Cities,Demand-supply matching,Generation Z,development evaluation

Introduction

As China's demographic dividend begins to wane, major cities across the country are increasingly recognizing the vital role that young people play in driving high-quality development across economic, social, and urban domains. In response, national and local governments have introduced a range of youth-oriented policy initiatives—ranging from improving talent attraction mechanisms to enhancing urban appeal for young residents. In April 2017, China released its first national-level plan dedicated to youth development: the Medium and Long-Term Youth Development Plan (2016–2025) (hereafter referred to as the Youth Development Plan), which provided clear guidance on education, employment, and entrepreneurship for young people (China, 2017). Later, in April 2022, the National Development and Reform Commission, along with 16 other ministries, jointly issued the Opinions on the Pilot Construction of Youth Development-Oriented Cities, advocating for the creation of cities that meet young people's needs in housing, employment, health, and education (NDRC et al., 2022).

Amid the growing trend of youth migration to urban areas, cities in economically advanced regions such as the Pearl River Delta and the Yangtze River Delta have seen increasingly concentrated youth populations. First-tier cities like Beijing, Shanghai, and Guangzhou, along with emerging cities such as Hangzhou, Nanjing, and Chengdu, have become the primary destinations for young people, offering abundant employment opportunities, high-quality healthcare and education services, and appealing living environments (Dou et al., 2023). In line with national strategies to build youth-friendly cities, many regions have prioritized creating high-quality spaces for youth production, living, and ecological wellbeing. Cities such as Shanghai, Hangzhou, and Nanjing have actively undertaken various youth development-oriented city-building initiatives.

However, despite the richness of these policy practices, a corresponding theoretical framework for youth-friendly urban spatial development remains underdeveloped in the academic realm. At the macro level, some scholars have proposed evaluative frameworks for youth development-oriented cities. For instance, Zheng et al. (2022) developed a four-dimensional assessment model—"livability, employment, vibrancy, and potential"—based on the characteristics of Generation Z. Xu et al. (2020) utilized multi-source big data to build digital profiles of youth groups, supporting evaluation efforts with empirical tools. Liu et al. (2021) constructed an assessment framework for youth-friendly cities using Zhuhai as a case study and offered policy suggestions accordingly. Other studies have focused on policy evaluations, assessing the effectiveness of housing support, spatial inclusivity, employment protection, and administrative services in pilot cities (Zhu, 2018; Wu and Zhou, 2023), or using methods such as fuzzy-set Qualitative Comparative Analysis (fsQCA) and the PMC index model to evaluate talent policy (Li and Zhang, 2023).

Scholars have also examined spatial needs, identifying the typologies and characteristics of youth-friendly spaces (Li, 2023), and proposing spatial configurations based on youth demand (Wang et al., 2023; Yin et al., 2021). Internationally, research has mainly focused on the relationship between cities and youth employment, often incorporating negative externalities brought by rapid urbanization (Zhu et al., 2019). In countries such as the United States, Canada, Poland, and Germany, cities have developed youth-friendly public policies and urban strategies centering on employment and community life. For example, the American Institute for Economic Research (2016) released a ranking of the best U.S. college destinations, evaluating cities' appeal to youth through demographic features, quality of life, and economic development. Similarly, Youthful Cities, a Canadian strategy consulting firm, identified key characteristics of youth cities—connectivity, dynamism, growth, novelty, and creativity—and developed an urban youth index accordingly (Youthful Cities, 2023). Some scholars have also addressed youth vulnerability, highlighting socio-economic and spatial inequalities faced by marginalized urban youth (Sriskandarajah, 2021).

In sum, current academic research either focuses on the interaction between youth populations and urban development—exploring evaluation systems and development pathways—or investigates spatial configuration through an analysis of youth behavior and needs. Yet, within the discipline of urban planning, such studies remain exploratory. There is a lack of attention to the dynamic coupling between evolving youth needs and urban spatial responses. Quantifying the multidimensional development needs of Generation Z youth and constructing a precise "demand-supply" matching mechanism has become a critical breakthrough for implementing national strategies and invigorating urban youth. This calls for deeper theoretical inquiry to support the development of urban spaces conducive to youth innovation and entrepreneurship.

1. Research Foundation for Youth Development-Oriented Cities

1.1. Homo-Urbanicus Theory

The Homo-Urbanicus Theory is a human-centered planning framework proposed by Liang Heren, which emphasizes that urban residents make rational choices regarding their settlement locations to balance their material needs with spatial interaction needs. Liang (2012; 2019) defines Homo Urbanicus as a composite identity, wherein an individual may simultaneously possess multiple urban roles. In the context of this study, the Homo Urbanicus identity of youth in industrial communities is shaped by life stage, age, gender, occupation, job position, and family roles.

Building upon the humanistic logic of "self-sufficiency and co-existence balance" embedded in the Homo-Urbanicus Theory, domestic scholars have begun to construct planning evaluation methodologies that reflect Chinese characteristics. For example, Wei Wei of Wuhan University has attempted to develop an assessment framework for urban public service facilities based on this theory. He positions public facilities as carriers of spatial interaction opportunities and argues that their spatial distribution should strive to fulfill both individual and collective needs—emphasizing full coverage, equalization, and equitable access to opportunities within regions. This forms the basis for a planning evaluation model from the perspective of Homo Urbanicus (Wei et al., 2018; 2020; 2022).

1.2 Constructing a Demand–Supply Evaluation Framework

According to the Homo-Urbanicus Theory, planners aim to achieve an optimal match between "typical urban residents" and "typical habitats" by analyzing both ends of the urban experience. The attributes of "typical urban residents" are defined by demographic characteristics (such as age and gender) as well as contextual elements like life stage, socio-economic status, and cultural background. Meanwhile, typical habitats refer to urban spatial units that provide opportunities for spatial contact.

In this study, youth residing in industrial communities are identified as the demand side—"typical urban residents" in search of spatial interaction—while the industrial community, as an integrated unit of production and living, serves as the supply side, i.e., the "typical habitat." Based on this logic, the study proposes an evaluation pathway for industrial communities by assessing the demand characteristics of Homo Urbanicus and the spatial supply capacity of the habitat. The aim is to enable optimal matching between human needs and spatial opportunities, thereby fostering youth development (Fig 1).

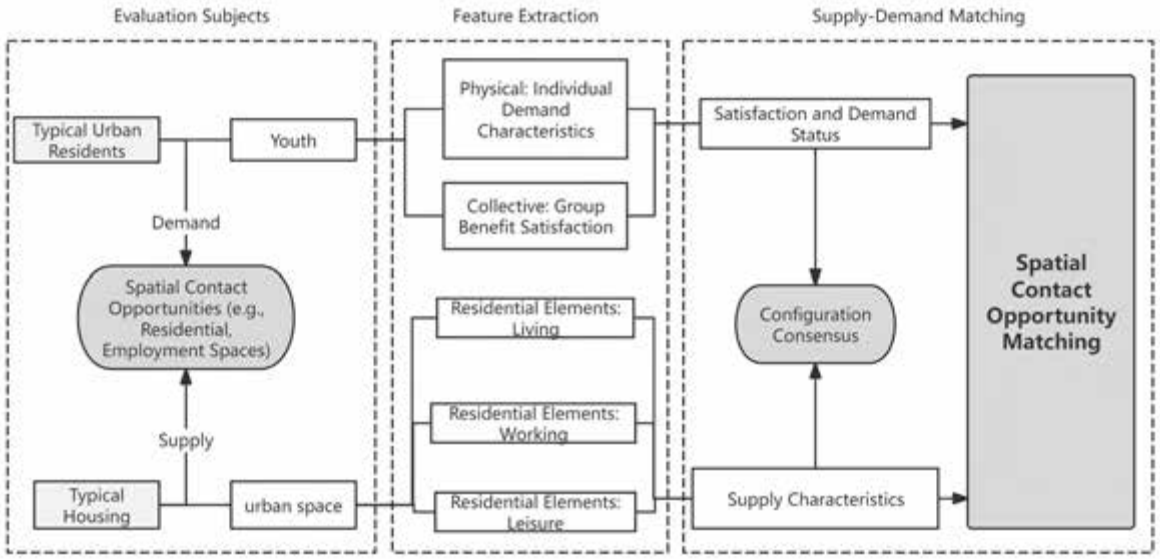

Fig 1 Construction of evaluation pathways for youth development-oriented cities

2.Construction of the Demand–Supply Evaluation Indicator System for Youth-Oriented Cities

Establishing an evaluation system for youth-oriented cities provides a scientific tool to promote their construction and sustainable development. The assessment of youth-oriented cities must adhere to a human-centered approach, using quantitative methods to measure the comprehensive effectiveness of science and technology innovation (STI) industrial communities in meeting the multidimensional needs of contemporary youth, stimulating regional innovation vitality, and optimizing spatial efficiency. This study evaluates the effective demand–supply matching of spatial resource allocation in youth-oriented STI industrial communities from both demand and supply perspectives.

2.1 Analysis of Generation Z Youth Demand Characteristics

Based on the 2021 China Social Status Comprehensive Survey (CSS) data, this study selects urban youth born between 1994 and 2003 who have entered the workforce. [Given that most industrial communities are located in areas with high urbanization rates, rural populations were excluded for research purposes.] The intergenerational characteristics of this cohort are analyzed to summarize youth group traits and development demand preferences, providing the "demand-side" direction for selecting evaluation indicators for youth-oriented industrial communities.

1) High Educational Attainment

According to the CSS data, urban youth generally possess high educational backgrounds(Fig 2), with approximately 68.2% having attained college education or above, including 34.8% with a bachelor's degree and 4.6% with a postgraduate degree. A comparison across generations reveals that, due to increased emphasis on higher education and demand for highly skilled talents, Generation Z exhibits a significant educational advantage over previous generations. This high educational attainment not only broadens employment options for Generation Z but also facilitates access to higher-paying jobs and promotion opportunities.

	Not enrolled in primary school	Primary school	Junior high school	High school	Technical secondary school	Vocational high technical school	Junior college	Undergraduate	Graduate student
1974-1983	1.18%	8.43%	28.99%	11.69%	9.47%	1.92%	15.53%	19.67%	3.11%
1984-1993	0.16%	2.66%	18.91%	10.78%	6.09%	2.19%	24.53%	28.59%	6.09%
1994-2003	0.00%	0.00%	11.48%	8.20%	8.85%	3.28%	28.85%	34.75%	4.59%

Fig 2 Statistical analysis of educational attainment across intergenerational cohorts

2) High Degree of Atomization
Influenced by the one-child policy and the fast-paced modern era, Generation Z youth display a marked degree of atomization. Compared with cohorts born between 1974–1983 and 1984–1993, the proportion of only children among Generation Z is higher by 26.5 and 9.7 percentage points, respectively, with a rate of 43.6%. Regarding marriage and fertility, 2021 data indicate nearly 75% of Generation Z youth are unmarried and childless, with only 11.8% having children.

3) Virtual and Fragmented Socialization
With rapid advances in information technology and the popularization of social media, Generation Z exhibits virtual and fragmented socialization characteristics. They prefer online platforms for information acquisition, business/work communication, and social relationship building, rather than traditional face-to-face interaction. Over 80% of Generation Z maintain diverse virtual social circles, including family groups, friend/classmate groups, workplace colleague groups, community groups, hometown groups, and interest groups. While this facilitates the formation of virtual networks, it weakens their real-life social connections. Due to fast work rhythms and life pressures, they often struggle to participate in community activities or develop deep interpersonal ties, which further intensifies atomization and fragmentation.

4) Coexistence of Enjoying Life and Self-Actualization
In terms of consumption, Generation Z emphasizes personalized life experiences and enjoys traveling, artistic creation, fitness, or novel consumption experiences such as immersive theater and escape rooms. They also exhibit strong self-actualization awareness, valuing not only material needs but also spiritual satisfaction and growth. They tend to seek positions and enterprises that are challenging, innovative, and development-oriented. Additionally, they focus on personal growth and learning, willingly investing time and effort in training and educational activities to enhance their overall quality and competitiveness, and enjoy engaging in culturally enriching activities such as visiting museums and art galleries.

2.1.1 Demand Hierarchy Characteristics of the Youth Group

In 1943, American psychologist Abraham Maslow proposed a hierarchy of needs theory based on motivation theory, which includes five basic needs: physiological needs, safety needs, love needs, esteem needs, and self-actualization needs, as well as cognitive needs related to knowledge and understanding, totaling six main domains of needs (Maslow, 1943). The priority of these needs differs between levels; higher-level needs only emerge after the more fundamental needs are adequately satisfied. In further discussions, Maslow suggested that for dif-

ferent personality types, there are variations in the hierarchy of needs, showing different tendencies. In 1954, Maslow elaborated this theory in his work Motivation and Personality, dividing the hierarchy into seven levels (Fig 3), where aesthetic and cognitive needs represent higher levels (Maslow, 2021).

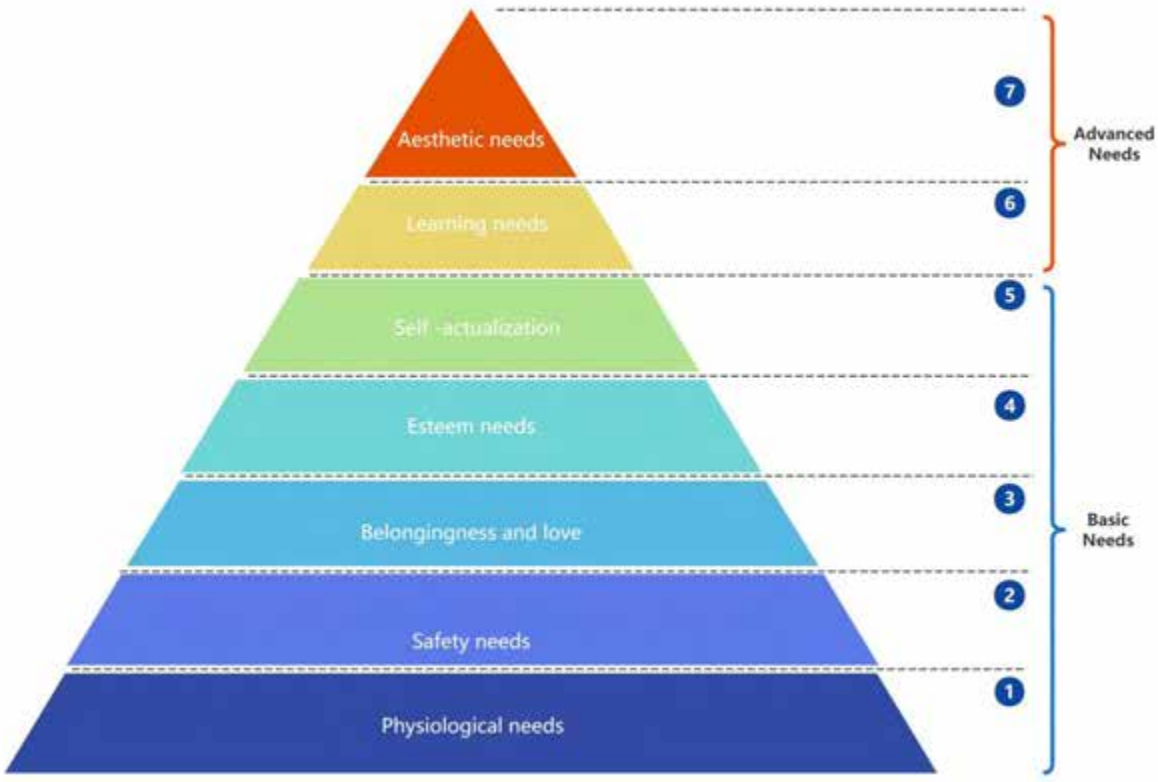

Fig 3 Seven-stage hierarchical model of Maslow's needs theory

Following the introduction of Maslow's hierarchy of needs theory, it has been widely applied and further developed. Clayton Alderfer, a scholar at Yale University, conducted extensive empirical research and revised the traditional hierarchy, proposing the ERG theory of needs (Alderfer, 1969). In his paper An Empirical Test of a New Theory of Human Needs, Alderfer argued that Maslow's five needs did not show clear distinctions and that there was overlap between love, esteem, and self-actualization needs. Therefore, he condensed the five needs into three types: Existence needs, Relatedness needs, and Growth needs. Existence needs include material and physiological desires such as food, salary, and physical working conditions. Relatedness needs reflect the human desire for interaction with others, including positive and negative emotions. Growth needs refer to the desire to influence oneself and the surrounding environment. This categorization avoids internal overlap among different need types. The ERG theory retains the concept of need hierarchies but emphasizes that the levels are not strictly sequential and highlights the reality of individual differences in needs (Shen, 2010).

This study divides the youth group's needs into three main levels: existence needs, relatedness needs, and growth needs, with existence needs further divided into three key areas: housing, employment, and living. As shown by the treemap analysis (Fig 4), employment is the area of highest concern for youth, followed by housing and living, while attention to self-improvement is greater than to consumption and social interaction. Employment is the core focus of young people because it directly relates to their economic independence, social status, and future career prospects. Therefore, youth who have just entered society tend to prioritize local employment opportunities and work environments. Housing conditions are closely linked to quality of life; choices such as renting or purchasing, housing location, and transport accessibility directly impact life quality, making it an important concern. After satisfying basic needs, youth tend to pursue personal growth and self-improvement rather than

invest excessive energy in consumption and socializing. Limited resources lead them to prioritize activities that enhance competitiveness by balancing time, money, and effort, emphasizing long-term self-investment. Meanwhile, consumption and social activities remain important ways for youth to regulate life pace and enhance satisfaction, though they receive slightly less overall attention than self-improvement.

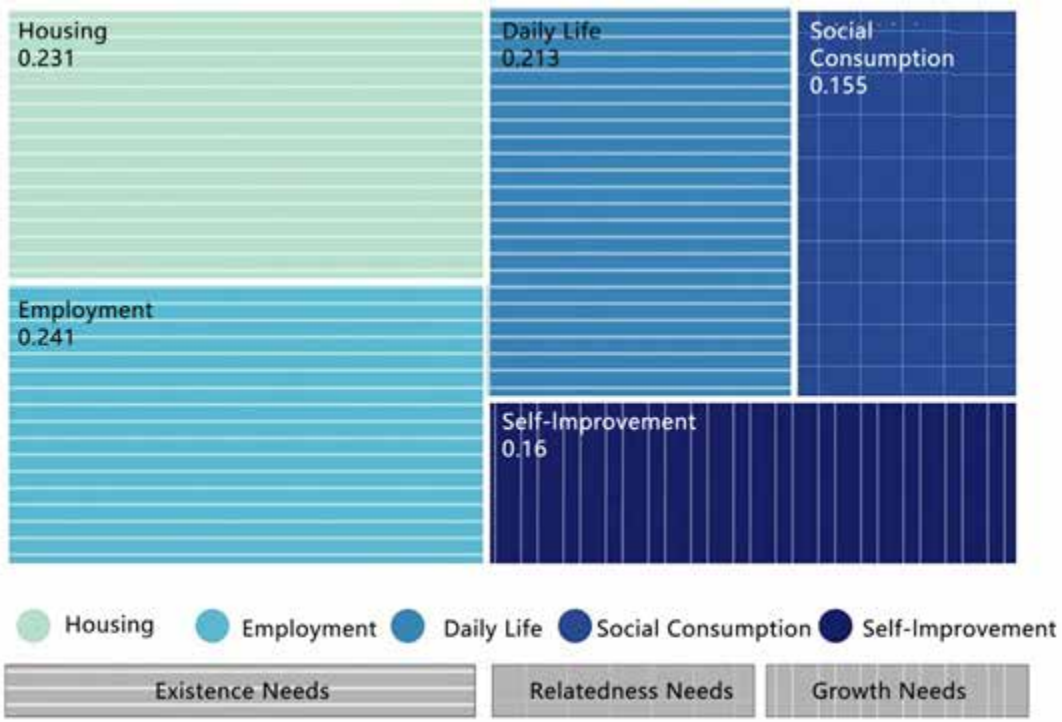

Fig 4 Hierarchical Treemap Analysis of Youth Needs

The division of these five levels and their relative attention can be further explained by ERG theory. These levels interact dynamically: on one hand, after satisfying lower-level needs such as existence and relatedness, youth tend to pursue higher-level needs; on the other hand, unmet higher-level needs can cause individuals to focus more on lower-level needs as a compensatory mechanism, resulting in a frustration-regression effect. For self-improvement needs, increasing satisfaction does not weaken demand but rather enhances it, showing a satisfaction-enhancement effect. This also explains why youth in industrial communities pay more attention to self-improvement needs than to relatedness needs (Fig 5).

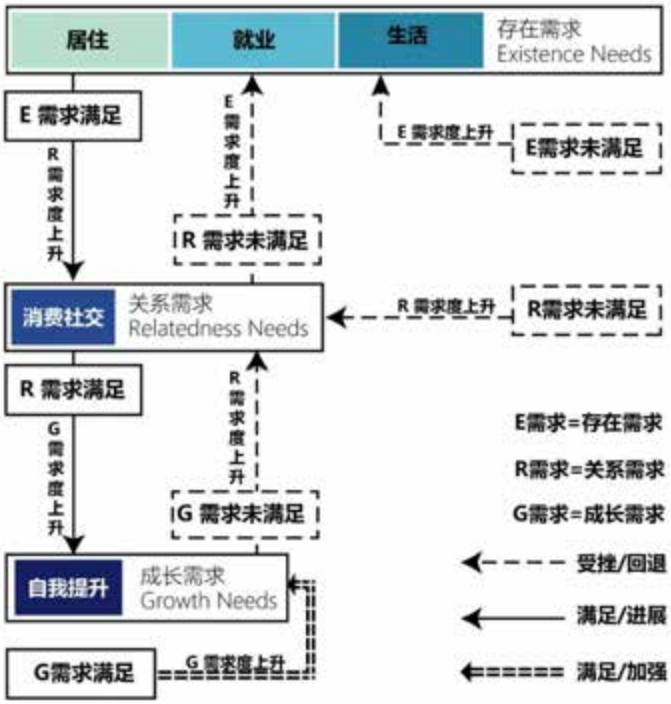

Fig 5 Interactive Mechanisms of Gen Z's Need Hierarchies

2.1.2 Analysis of Youth Development Needs

Based on the characteristics and hierarchical needs of youth, this section summarizes the development needs of the youth group:

Existence needs include housing, employment, and basic living needs related to material security, serving as the foundation for personal development. Regarding housing, the "high atomization" characteristic of Generation Z youth leads to greater attention to rental housing and employer-provided talent housing, with a strong demand for affordable and flexible rental models. In terms of employment, Generation Z youth typically have higher educational attainment and thus exhibit a stronger desire for economic independence and financial freedom. They seek income and career prospects that match their educational qualifications and tend to pursue meaningful and fulfilling work, placing emphasis on opportunities for innovation, entrepreneurship, and career development pathways (Fig 6). For daily basic living, Generation Z has a high demand for online consumption; ordering takeout and purchasing daily necessities or medicines online have become integral parts of their everyday life.

Fig 6 Occupational Value Systems of Generation Z
Data Source: TTI Gen Z Workplace Expectations Report 2024

Relatedness needs reflect the importance of socialization for Generation Z youth, who satisfy their sense of belonging and interaction needs through social activities and community participation. Growing up in the internet era, Generation Z is adept at using digital media platforms for communication, yet they also have a strong desire for offline interactions, especially deep social connections based on shared interests and values. They tend to join communities aligned with their interests and beliefs, emphasizing individual uniqueness and contributions within groups. By providing creative social spaces, multicultural interaction platforms, and supporting interest-based clubs and public welfare activities, industrial communities can foster richer social participation and cultural exchanges among youth.

Self-growth needs refer to individuals' demands for potential development, value realization, and long-term growth, representing advanced needs for Generation Z youth. Influenced by fast-paced lifestyles and social competition, they place high importance on mental and physical health, investing significantly in fitness, body shaping, and wellness. Moreover, Generation Z values personalized development and unique cultural expression, favoring art, design, and new media forms for self-expression. They pursue continuous knowledge updating and skill enhancement, aiming to access educational resources at any time to adapt to the rapidly changing society.

2.2 Composition of Supply Subject Elements

The city is analyzed as an integrated system (Fig 7). According to human settlement environment theory, it can be considered a system unit at the "community" level within the five hierarchical levels of human settlement environments: global – regional – city – community – building. This system contains five subsystems: population (man), society, shell, support network, and nature. These five subsystems collectively form the supply elements of youth development-oriented science and technology innovation industrial communities and correspond respectively to three types of capital in overall system analysis: human capital = population system + social system; structural capital = shell + support network; natural capital = various environments and resources. The specific interpretation of each subsystem in youth development-oriented science and technology innovation industrial communities is as follows:

Population Subsystem: This subsystem mainly targets the user populations within the industrial community, including employment groups, residential groups, and community managers.

Social Subsystem: This subsystem includes economic, socio-cultural, and government management aspects. Economically, it focuses on labor and employment, market trade, production, and consumption. In terms of socio-cultural and government management, it encompasses social medical and educational security, cultural activities organization, community management, and party-building activities.

Shell Subsystem: This includes spatial support systems such as housing, shops and malls, administrative offices, industrial facilities, and cultural and entertainment facilities, providing venues for human activities.

Network Subsystem: This refers to infrastructure networks such as water and electricity supply systems and transportation networks, linking various independent shells and forming the basic spatial organizational framework of the science and technology innovation industrial community.

Natural Subsystem: Serving as the "foundation" for the other subsystems, this includes natural resources such as land, water bodies, and vegetation. It should be noted that natural resources like water bodies and vegetation may be artificially modified and optimized through human activity, for example, by constructing artificial lakes and green parks.

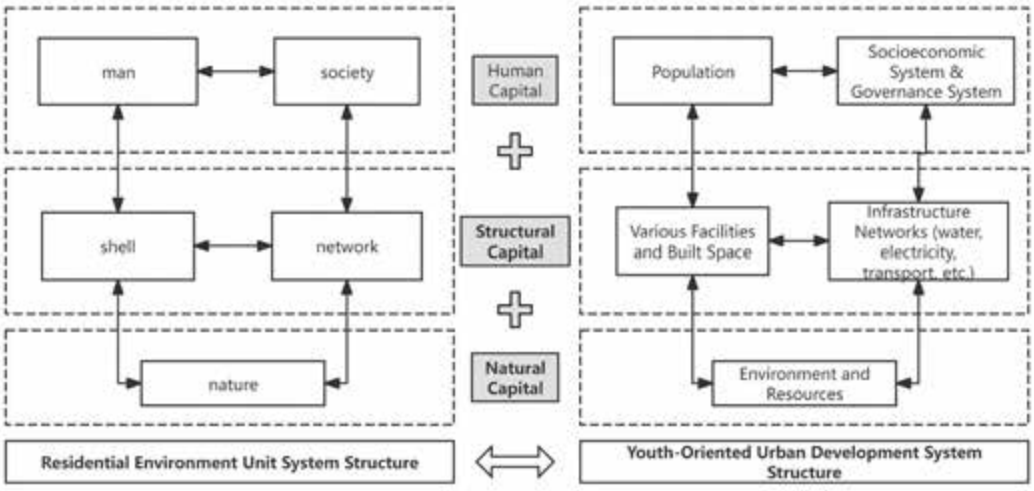

Fig 7 Schematic Diagram of Youth Development-Oriented City System Framework

2.3 Construction of the Evaluation System

The evaluation indicators are divided into three hierarchical levels: the goal layer, the criterion layer, and the implementation layer. The goal layer includes two main dimensions: the demand side and the supply side, referring respectively to youth's demand satisfaction and the urban supply level from the perspective of youth development. The criterion layer is classified in accordance with Maslow's hierarchy of needs theory, divided into five aspects: housing, employment, living, entertainment and consumption, and self-improvement. The criterion layer indicators on the demand side correspond one-to-one with those on the supply side. The selection of evaluation indicators at the implementation layer is based on the characteristics of youth development-oriented cities, youth demand preferences, and relevant academic studies on youth development city evaluation indicators, integrating these factors to construct a comprehensive indicator system (Table 1)

Table 1 Integrated Evaluation Index System

Goal Layer	Criterion Layer	Implementation Layer Indicator	Indicator Evaluation Standard
Supply Side	Work-Living Level	Commuting Convenience	Average Commute Time
		Housing Affordability and Friendliness	Average Income-to-Housing Price Ratio
		Career Development Level	Average Graduate Salary
	Daily Life Level	Medical Supply Level	Number of Tertiary Hospitals
		External Traffic Convenience	Cities Covered in 1-Hour High-Speed Rail Circle
		Online Shopping Supply Level	Coverage Rate of Express Stations / Food Delivery
		Daily Dining Supply Level	Convenience Store Coverage Rate
	Social Vitality Level	Shopping and Consumption Facility Supply Level	Commercial Area Foot Traffic
		Public Social Space Supply Level	Coverage Rate of Coffee / Milk Tea Shops
		Leisure and Entertainment Facilities Supply Level	Coverage Rate of Cinemas, KTVs
		Youth Activity Organization Supply Level	Frequency of Various Cultural and Entertainment Events
	Self-Improvement Level	Sports and Fitness Facilities Supply Level	Number of Sports Venues
		Cultural and Artistic Venue Supply Level	Coverage Rate of Specialty Bookstores
		Park and Green Space Development Level	Quality of Green Spaces
Demand Side	Work-Living Level	Commuting Satisfaction	Satisfaction Survey Results
		Housing Cost Satisfaction	
		Career Development Satisfaction	
	Daily Life Level	Medical Support Satisfaction	
		Traffic and Travel Satisfaction	
		Online Shopping Satisfaction	
		Dining Facility Satisfaction	
	Social Vitality Level	Shopping and Consumption Satisfaction	
		Public Social Space Satisfaction	
		Leisure and Entertainment Satisfaction	
		Youth Activity Organization Satisfaction	
	Self-Improvement Level	Sports and Fitness Satisfaction	
		Cultural and Artistic Venue Satisfaction	
		Park and Green Space Satisfaction	

2.4 Weights of Evaluation Indicators

To scientifically determine the relative importance of indicators at each level in the youth development-oriented city evaluation system, this study employs an interactive weighting method. Using a digital questionnaire platform, a multi-dimensional weight allocation was implemented, with a dynamic matrix slider weighting mechanism designed to allow respondents to systematically allocate weights within a bounded rationality framework. The weight results of each indicator are shown in Table 2. The weights for the demand side and supply side indicators correspond to each other, each accounting for 50% of the total.

Table 2 Comprehensive Evaluation Indicator System Weight Results

Goal Level Indicator	Weight	Criterion Level Indicator	Weight	Implementation Level Indicator	Weight
Supply Side / Demand Side	0.5	Employment & Residence Level	0.173	Commuting Convenience / Commuting Satisfaction	0.048
				Housing Affordability / Housing Cost Satisfaction	0.071
				Career Development Level / Career Development Satisfaction	0.053
		Daily Life Level	0.128	Medical Service Availability / Medical Service Satisfaction	0.027
				External Transportation Convenience / Transportation Satisfaction	0.033
				Online Shopping Availability / Online Shopping Satisfaction	0.04
				Daily Dining Availability / Dining Facilities Satisfaction	0.027
		Social Vitality Level	0.111	Shopping Facilities Availability / Shopping Satisfaction	0.031
				Public Social Space Availability / Public Social Space Satisfaction	0.033
				Leisure & Entertainment Facilities Availability / Leisure & Entertainment Satisfaction	0.031
				Youth Activity Organization Availability / Youth Activity Organization Satisfaction	0.017
		Self-Improvement Level	0.089	Sports & Fitness Facilities Availability / Sports & Fitness Satisfaction	0.028
				Cultural & Artistic Venue Availability / Cultural & Artistic Venue Satisfaction	0.029
				Park & Green Space Development Level / Park & Green Space Satisfaction	0.032

3. Empirical Evaluation: Taking Shanghai, Hangzhou, and Nanjing as Examples

3.1 Research Scope and Basic Situation

This study selects Shanghai, Hangzhou, and Nanjing as empirical evaluation targets. As core cities of the Yangtze River Delta, these three cities exhibit significant and typical structural characteristics in their youth populations. Shanghai, as a mega-city, had youth aged 14–35 accounting for 29% of its population in 2022, concentrating 19% of the nation's innovation and entrepreneurship enterprises, thus forming a "high-level employment – high-density agglomeration" characteristic. Hangzhou, relying on its digital economy ecosystem, had a youth population aged 14–35 reaching 5.13 million by the end of 2022, accounting for 34.6% of the city's total population, showing a resonance of "industrial youthfulness – population youthfulness." Nanjing, known for its strong higher education advantages with over 900,000 university students, also has a youth population proportion exceeding the national average in all three cities.

3.2 Evaluation Results

3.2.1 Supply Side Evaluation Results

Through an in-depth analysis of supply-side implementation-level indicators in Shanghai, Hangzhou, and Nanjing, differentiated characteristics and optimization pathways of urban youth development efficiency are revealed(-Fig 8). The comprehensive evaluation results show Hangzhou ranked first with a score of 11.88, followed closely by Nanjing (11.60) and Shanghai (11.51), with less than a 3% difference among the three cities, reflecting a trend of homogenized youth service supply in the Yangtze River Delta urban cluster. Specifically, Hangzhou leverages the deep penetration of the digital economy, leading in seven indicators including shopping and consumption facilities supply, daily dining density, cultural and artistic venue availability, and leisure and entertainment facilities. Nanjing excels in livelihood services, with comprehensive advantages in housing affordability and online shopping supply, but its youth activity organization supply (0.430) is only 43% of Shanghai's, revealing weaknesses in community operation capacity. Shanghai maintains the lead in hard resources such as career development level, medical resource supply, and external transportation convenience, but the housing cost pressure far exceeds that of Nanjing and Hangzhou, urgently needing to resolve the "high-level resource – high-cost" development paradox.

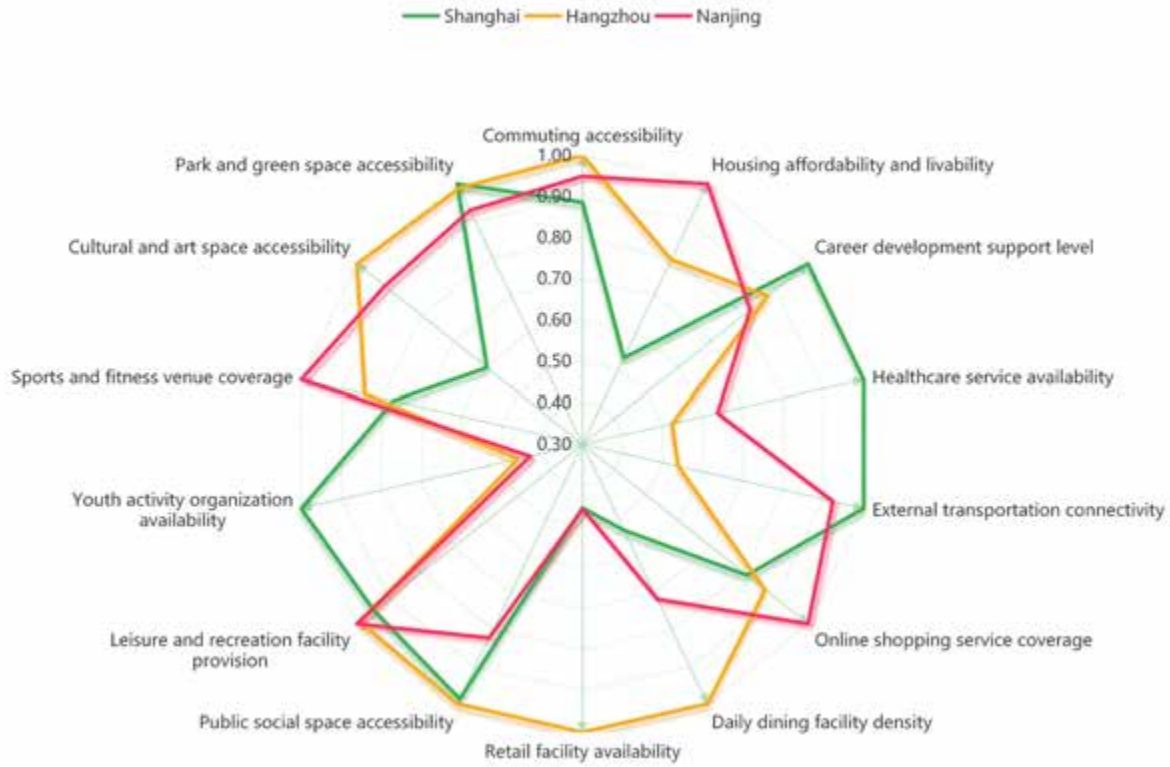

Fig 8 Shanghai-Nanjing-Hangzhou Tri-City Supply-Side Evaluation Results

3.2.2 Demand Side Evaluation Results

Based on empirical data analysis of youth development satisfaction in Shanghai, Hangzhou, and Nanjing, the study finds differentiated characteristics in youth development quality across the Yangtze River Delta urban cluster(Fig 9). From the overall average score, Nanjing ranks first with 3.258, followed by Hangzhou (3.200), and Shanghai lags behind at 3.001, reflecting the transformation pressures faced by mega-cities in youth development.

In the dimension of basic survival quality, housing cost and commuting efficiency are critical constraints. Housing cost satisfaction in all three cities is below the 3.0 benchmark, showing a "Yangtze River Delta youth housing anxiety belt" phenomenon, with Shanghai experiencing the most severe housing pressure (2.52), 8.3% lower than Nanjing. Relying on innovative affordable housing policies, Nanjing achieves a significant advantage with a survival quality score of 3.07. Shanghai faces the diminishing marginal benefits of its mega-city commuting network, with a transportation satisfaction of 3.12, significantly lower than Hangzhou (3.44) and Nanjing (3.43), exposing risks of service quality degradation due to rail transit over-saturation.

Public service supply shows gradient differentiation. Benefiting from its rich cultural capital, Nanjing leads in cultural and artistic venue satisfaction (3.64) and park green space (3.33), verifying the spatial empowerment effect of historic heritage revitalization. Driven by digital technology innovation in public services, Hangzhou's youth activity organization satisfaction reaches 3.71, forming an advantage in social vitality, with leisure and entertainment indicators 41.6% higher than Shanghai, highlighting the spillover benefits of the digital entertainment industry cluster. Although Shanghai maintains its traditional advantage in career development potential (2.88), its fragmented public social spaces (3.24) reveal community alienation issues during modernization.

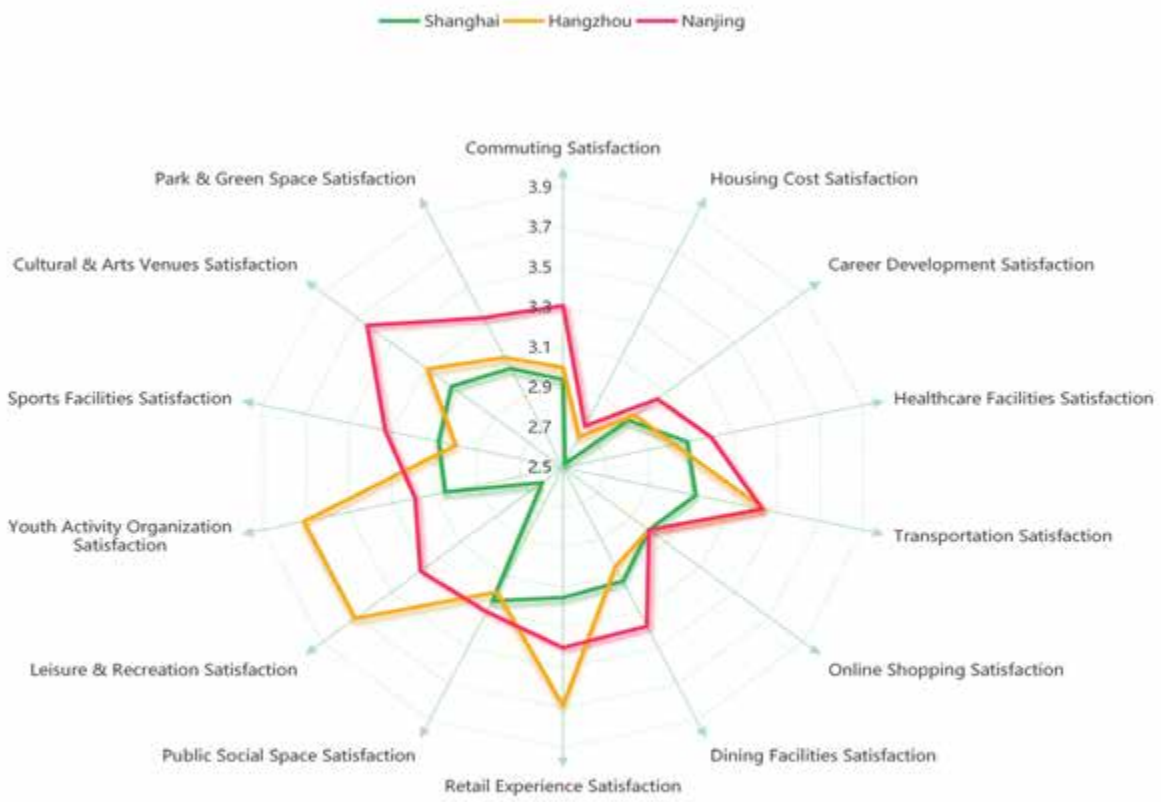

Fig 9 Shanghai-Nanjing-Hangzhou Tri-City Demand-Side Evaluation Results

3.2.3 Comprehensive Supply-Demand Analysis Results

The evaluation indicates varying degrees of supply-demand mismatch across Shanghai, Nanjing, and Hangzhou-Fig 10 A deeper analysis of youth development dynamics in these three Yangtze River Delta cities reveals differentiated characteristics. Hangzhou demonstrates the strongest alignment with Generation Z demands, achieving the highest congruence between urban resource supply and youth needs through optimized spatial planning

and resource allocation. In contrast, Shanghai exhibits relatively abundant supply-side resources but lower demand-side satisfaction among youth, indicating deficiencies in the targeting and precision of spatial elements and service provision. This necessitates enhanced supply orientation and adaptability to better accommodate the diversified needs of young populations. Nanjing presents a reverse pattern, with higher demand-side satisfaction but insufficient supply-side capacity, reflecting proactive attention to youth demands yet persistent shortages in critical supply elements such as housing, employment, and public services.

Fig 10 Supply-Demand Alignment Assessment in the Shanghai-Nanjing-Hangzhou Tri-City Region

The core cities of the Yangtze River Delta exhibit distinct youth attraction profiles shaped by their functional positioning and developmental trajectories. As a global metropolis, Shanghai holds clear advantages in public service provision and transportation infrastructure. Its tertiary hospital system and international healthcare networks form a robust health security framework, while high-speed rail hubs enable a two-hour connectivity circle within the Yangtze River Delta, facilitating cross-regional mobility for young populations. However, urban expansion has intensified spatial contradictions, with escalating housing costs and prolonged commutes in central areas creating compound pressures that undermine residential stability for youth.

Hangzhou leverages its digital economy-driven innovation ecosystem to foster unique advantages in youth social network development. Internet industry-enabled diversified social platforms and innovative professional communities provide nontraditional pathways for self-improvement. The integration of natural landscapes with digital economic features creates hybrid work-life spatial models. Yet, industrial structure homogeneity reduces labor market inclusivity, where technical thresholds may constrain career development opportunities for certain youth groups.

Nanjing demonstrates multidimensional equilibrium in its youth support system. The geographic integration of higher education resources and industrial parks establishes an industry-education-research collaboration model. Coordinated spatial planning between rail transit networks and employment centers maintains reasonable commuting durations. The synergistic evolution of historical cultural heritage and modern industrial systems cultivates an urban environment balancing cultural identity and professional growth. However, limited capacity in aggregating international high-end resources due to city-tier constraints may affect long-term retention of high-caliber young talent.

Conclusion

This study constructs an evaluation system for youth development-oriented cities based on spatial supply and demand theory, aiming to provide relevant authorities with scientific and reasonable criteria to accurately assess the progress of youth development city construction. The empirical analysis results of Shanghai, Nanjing, and Hangzhou reveal certain mismatches between supply and demand in the construction process of youth development-oriented cities. In future development, it is necessary to further integrate the characteristics and needs of the youth population to explore and form a sustainable and targeted model for building youth development-oriented cities.

Just smart?
A Preliminary Study on the correlation of Smart City Infrastructure and Gentrification

Sin Yu Wang & Tzuyuan Stessa Chao

Abstract
This study uses Kaohsiung City as an example to explore whether smart city infrastructure leads to gentrification. Smart cities aim to improve quality of life and competitiveness, but they may attract high-income groups and force low-income residents to relocate. The study categorizes types of smart city infrastructure and employs Hedonic Price Method to analyze the relationship between the benefits of smart infrastructure and gentrification indicators, aiming to understand the impact of smart cities on spatial equity and propose policy recommendations for achieving inclusive and sustainable development.

Keyword: smart city; gentrification; sustainability

Introduction

In recent years, global urbanization has been on the rise, and urban issues are often inextricably linked to economic, social, environmental and governance issues. Smart cities are seen as one of the solutions that can address these issues (Micozzi and Yigitcanlar, 2022). However, as smart city policy advances and develops, there is no international consensus on its definition, which varies according to the target audience and influences policy making, except for the consensus on information and communication technology (ICT) as a core component of the infrastructure (Micozzi and Yigitcanlar, 2022). There is also no international consensus on how to define a smart city and what conditions a smart city should fulfill, but smart cities can be broken down as a combination of human capital, social capital and ICT infrastructure(Chang and Smith, 2023).

While past smart city research has focused less on quality of life and resident-centered issues, issues and challenges are beginning to emerge as smart cities are used as a means of solving all aspects of development. Infrastructure provision should be oriented towards improving the quality of life of the residents and moving towards sustainable development(Chang and Smith, 2023). Smart city infrastructure development emphasizes the need to balance the efficiency of urban infrastructure with the quality of urban life, and to identify priority areas for development, understand smart city needs, and integrate economic, social, environmental, and spatial domains(Grochulska-Salak and Wężyk, 2021).

With urban development, gentrification has begun to occur in a variety of contexts and areas. Gentrification, first used by Ruth Glass in 1964, describes a process of socio-economic change in urban areas caused by multiple factors (Johnson-Schlee, 2024), which is intuitively manifested by the loss of local residents' homes and the rise in real estate prices, with the middle and upper classes replacing the local residents in the community(Johnson-Schlee, 2024). The state of gentrification can be correlated with the amount of investment and infrastructure upgrading (Lees, Slater and Wyly, 2013).

Therefore, the construction of smart city infrastructures changes the local infrastructure pattern, improves the overall efficiency, and increases the local investment. Currently, there are fewer academic and practical studies on whether the upgrading of smart city infrastructures results in local gentrification. In this study, we will select a region as a site to discuss the changes in the various facets of a smart city as a result of the local government's policy and resource inputs.

In recent years, there has been growing discussion about the impact of investments in various smart city facilities on residents' quality of life and well-being. To provide better infrastructure, smart cities are increasingly intervening in data collection and utilization, integrating data into spatial applications. However, the collection of data that is private, widespread, and long-term has posed challenges to the autonomy of individuals and groups, blurring the boundaries between public and private domains, and gradually leading to the emergence of digital gentrification(Gstrein, 2024). In fact, when smart city projects are officially launched, signs of this phenomenon have already begun to emerge. The acceptance of smart infrastructure, from the overall residential area to the

individual level, should be incorporated into smart city governance.

The types of smart city infrastructures will cover four forms, namely technical and road infrastructure, social and service infrastructure, communication and data management infrastructure, and ecosystem infrastructure (Grochulska-Salak and Wężyk, 2021). It can be generalized into hard and soft infrastructure, where hard infrastructure refers to all types of buildings, equipment, space, facilities, etc., and soft infrastructure refers to education, applications, cloud systems, local norms, etc. Because most of the enhancements to the gentrification infrastructure are hard facilities, and that it is difficult to assess the impact of soft facilities on the price of housing and the local community when they are applied to the physical space, the study will focus on the hard infrastructure.

The study will focus on the following issues:

(a) Does smart city infrastructure cause changes in local housing prices?

(b) Is there a gentrification effect of the smart city infrastructure?

Study area

Kaohsiung City is in the southern region of Taiwan, with a large hinterland with an international commercial port and an international airport, is the political, cultural and industrial core of the south, and is one of the six Special Municipality in Taiwan, with 38 administrative districts, and is also the promotion area of the Asia New Bay Area 2.0 Intelligent Technology and Innovation Park.

The urban development policy has brought great changes to Kaohsiung's space and industries. Since the 1960s, Kaohsiung has been a major industrial center for Taiwan's heavy industry and light industry for processing and exporting, with rapid industrial development. 1980s, the major industries gradually dominated the city, shifting to low energy consumption, low pollution, and high value-addedness; in 1990s, Industrial Park and science park were established, and the townships possessed very high industrial intensity, with the industrialization level reaching its peak; it was not until 2000 that the type of industries changed and industries upgraded, with tertiary service industries gradually replacing some of the industrial industries. Since 2000, the industrial type has changed and the industry has upgraded, and the tertiary service industry has gradually replaced part of the industrial industry, and later joined the WTO(WU, 2011); since 2015, the smart city policy has been gradually implemented; in 2020, the Kaohsiung Smart City Promotion Committee was established, which is a team that combines industry, government, and academia, and combines the use of wisdom to drive the sustainable development of the city and the transformation of industries; and in 2021, the national program Asia's New Bay will be launched. Promote the 5GAIoT New Innovation Park Project in Asia's New Bay Area, a national-level project (Information Industry Council, 2021).

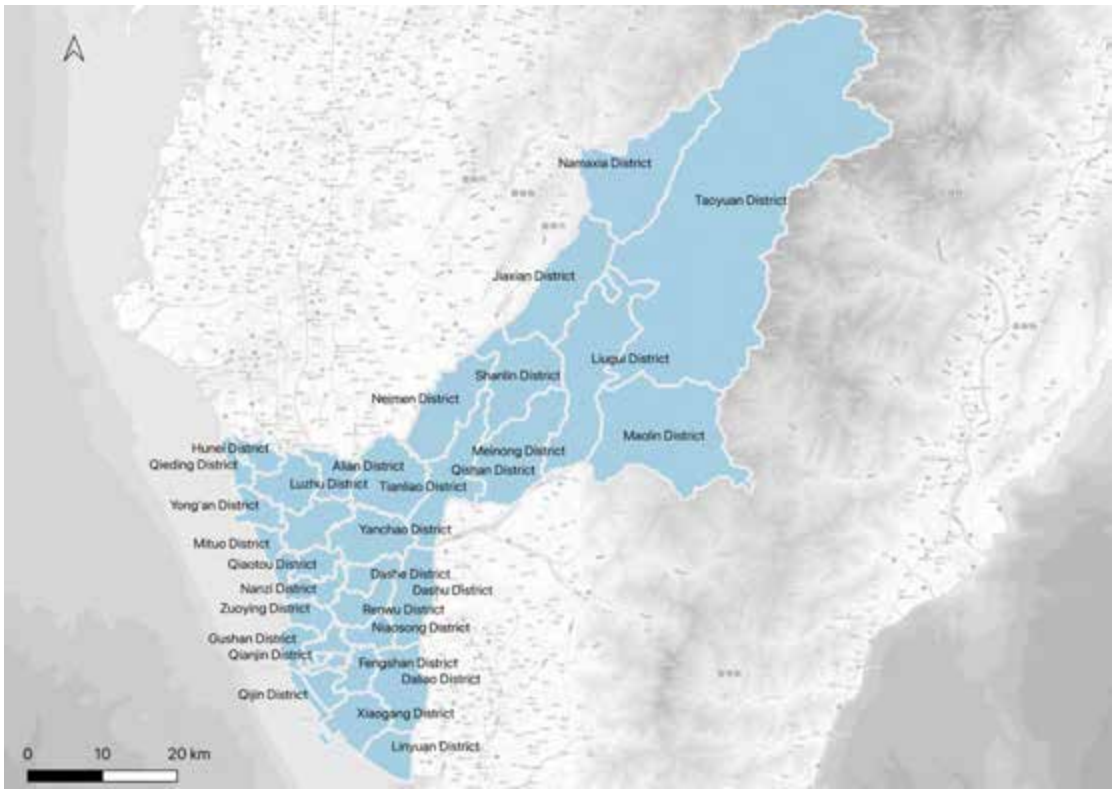

Figure 1 Kaohsiung City

Materials and methods

In this study, the hedonic property value method is used to understand which projects are the main influencing factors. Therefore, it is necessary to first select case areas, collect their smart city infrastructure construction plans or policies, compile infrastructure projects, and then conduct project screening. After eliminating soft infrastructure projects, the remaining hard infrastructure projects will be subject to the next round of screening, and then the facilities that are too small in scale or have a timeliness will be eliminated. Next, the representative year of the case area was selected, and the average price of housing in the area was used as the information of housing price in the area by collecting the price of housing in the area according to the year. After the data collection and processing, the information is analyzed by the hedonic property value method. Figure 2 the filtering process and the analyzing process shows the filtering process and the analyzing process.

Since 2015, smart city-related programs have been gradually implemented in Kaohsiung, and the types of smart city infrastructure are categorized according to nine major categories in the Kaohsiung Smart City Promotion Platform Project Achievement Zone: smart Mobility, smart living, smart healthcare, smart governance, smart security, smart tourism, smart education, smart energy, and smart agriculture. After counting the projects that have been implemented and will be implemented soon, the development of smart mobility, smart security, smart healthcare, and smart governance is the main focus, and the preliminary statistics of the main projects include software level and hardware level, and the 2025 Smart City Exhibition promotes the newest policies with healthcare, transportation, and life as the main axes (Kaohsiung Smart City Promotion Platform, 2025).Table 1 Unifying the Kaohsiung Smart City Infrastructure Buildings Table 1Categories, projects, and program listings (Kaohsiung Smart City, 2025).

Table 1 Kaohsiung City Smart City Infrastructure Project Statistics

Category	major projects	Number of Projects	Description of Projects
Smart Mobility	7	21	Kaohsiung Light Rail Transit (LRT), Kaohsiung Transportation Mobility Service Program (MeNGo), etc.
smart living	10	11	Kaohsiung Net Zero House and Intelligent Building Promotion Program (regional design principles and standards), Smart Public Housing (Smart building system), etc.

smart healthcare	6	7	Physical Medicine Specialized Hospital 5G Intelligent Safe Care System (iSafe, iCure), etc.
smart governance	11	18	Smart Kaohsiung AI Lighthouse Project (city-level sovereign AI platform), 3D pipeline data integration application project, etc.
smart security	12	21	Smart Water Resources Monitoring and Networking Platform, Climate Change Adaptation Promotion Platform (Disaster Alert System, Climate Change Disaster Risk Mapping Platform, Adaptation Enforcement Program Reporting System), etc.
smart tourism	3	3	Kaohsiung Fun Card Intelligent Tour, Seeing Greater Kaohsiung (5G XR Smart Tour System), etc.
smart education	2	2	E-game U generation island learning paradise, Net Zero Academy
smart energy	5	6	Fishery and electricity symbiosis , etc.
smart agriculture	3	3	Kaohsiung Farmer's Newsletter, Kaohsiung Plant Doctor's Help, Livestock Manure and Urine Water Irrigation and Farming Reuse Adopting and selecting from (Kaohsiung Smart City Promotion Platform, 2025)

STEP1

This study conducts the first classification of smart city infrastructure types in Kaohsiung City, Taiwan, distinguishing infrastructure types into soft and hard infrastructure categories. The selection is based on whether the infrastructure exists in a physical space. Considering the characteristics of hard and soft infrastructure, this study focuses on hard infrastructure to examine its impact on surrounding property prices. Infrastructure types, based on the aforementioned characteristics, can be categorized into hard domains, soft domains, and hybrid domains (Albino and and Dangelico, 2015. "Hard" domains include buildings, energy grids, natural resources, water management, waste management, mobility, and logistics, where ICT can play a decisive role in system functionality. "Soft" domains include education, culture, policy innovation, social inclusion, and government, where ICT applications are typically not decisive (Senatore and Sessa, 2023). Hybrid smart city implementation projects are composed of both soft and hard infrastructure, initially classified as hard infrastructure, with subsequent spatial impact assessments conducted.

After screening, preliminary selections were made based on hardware infrastructure, and projects with little relevance to housing or housing prices were excluded based on actual application scenarios. Smart city infrastructure that does not directly impact housing prices, such as facial recognition at daycare centers, physiological monitors in hospitals, and tunnel detection systems, were excluded. Only hardware infrastructure with housing price impacts were presented. The detailed list is shown in Table 2.

Table 2 Step 1: Kaohsiung Smart City Hard Infrastructure

category	Scope of influence	Facility projects	Description of the facility	Sources:
Smart Transportation	Within 800 meters of each station along the light rail line	Light rail transit system	There are no overhead lines on the whole line, 100% low floor of the carriage, vibration and noise suppression track system	(Yu and Hsu, 2025)

Table 2 Step 1: Kaohsiung Smart City Hard Infrastructure

category	Scope of influence	Facility projects	Description of the facility	Sources:
Smart Transportation	Within 300 meters of a highway ramp	Important intersections around national highway ramps within the jurisdiction of the city	Taking national highway ramps and flat roads as the planned scope, 5G and AI image recognition were introduced, and real-time traffic flow detection modules and road network-based instrumentation and control strategies were established	The Impact of Transportation on the Real Estate Prices in Taipei City
Smart living	There is no clear scope	6-year 1.25GW plan	The roof is equipped with a solar photovoltaic system, a ground row and a water surface photoelectric system	-
Smart living	It is usually a single building	Intelligent building systems	Centralized setting of smart water meters, smart electricity meters and microcomputer gas meters, and centralized information management system	Exploring the Future Real Estate Market and Industry Development Trend from the Planning Concept of Smart City (Lai Zongyu|2018)
Smart living	It is usually a single building	Central monitoring system	Intelligent security and disaster prevention, waterproof and anti-theft systems, intelligent public facilities management, renewable energy equipment and monitoring systems	(Bagheri and Shaykh-Baygloo, 2021)
Smart governance	It is usually a single building	Carbon and water footprint monitoring and analysis of buildings	Smart water meters and smart meters are installed in buildings to collect water consumption and electricity consumption, and timely control the peak and off-peak power consumption and water consumption of buildings	(Bagheri and Shaykh-Baygloo, 2021)

Table 2 Step 1: Kaohsiung Smart City Hard Infrastructure

category	Scope of influence	Facility projects	Description of the facility	Sources:
Smart security	There is no clear scope	Charging disaster prevention mechanism	Promote the construction of a friendly charging environment for electric vehicles, promote a four-fold disaster prevention mechanism, including thermal imaging cameras, intelligent automatic notification systems, low-pressure water mist fire-fighting equipment, as well as special fire blankets and fire-fighting measures for electric vehicles, and a total of 738 charging piles have been set up in 121 public parking lots	-

STEP2

From the literature, understand whether the introduction of smart facilities has improved the performance of existing facilities, enhanced quality of life, and attracted highly educated individuals. Collect data on the types of facilities that have had an impact, focusing on changes in room availability between 2023 and 2024, and concentrate on the administrative districts where these facilities are located. Examine the annual changes in property prices registered in the real estate price registration system for these administrative districts. This study utilizes publicly available data from the Real Estate Transaction Case Actual Information System, focusing on residential buildings and facilities in the surrounding areas. After confirmation, the locations of smart city infrastructure are primarily concentrated in seven administrative districts: Qianjin District, Lingya District, Yantian District, Gushan District, Zuoying District, Sanmin District, and Fengshan District.

Result

This study aims to investigate the impact of smart city infrastructure types on housing prices. Taking Kaohsiung City as a case study area, the study takes an inventory of nine major categories and their projects, namely, smart mobility, smart living, smart healthcare, smart governance, smart security, smart tourism, smart education, smart energy, and smart agriculture, which have been promoted in recent years, in order to further explore the changes in the overall housing prices before, during, and after the promotion of the smart city. It is expected that by identifying the types of infrastructures with significant impacts and describing their spatial status, the results of this study can help to address the issues of spatial inequality and social inclusion in smart city infrastructures, and also serve as a reference for subsequent studies across different spatial scales or long-term changes.

Research Limitations

In terms of gentrification and smart cities, it can be seen that the formation factors of gentrification are quite diversified, and housing prices are only one of the forms of presentation, and there is a lack of discussion and exploration of local population migration in the study, so it may only serve as an illustration of the extent of the impact of smart city infrastructures on local housing prices. Secondly, the types of smart city infrastructures constructed do not have the same spatial scale of impact, and although the concept of smart cities has been around for a number of years, the actual time for improvement and construction has not been long, so it is not easy to see the obvious state of affairs in the short term. In addition, as the infrastructure of smart cities is widely oriented, this study only focuses on the hard infrastructure and does not include the soft infrastructure. Ultimately, because the case study area is an administrative district, different facilities, land types, and other influencing factors in each administrative district are neglected; and the average price of housing also leads to a lack of precision, and the price of housing varies with multiple factors such as the facilities of the lot, the land,

the building, and the quality of life. Therefore, as a preliminary study on the impacts of smart city infrastructure and gentrification, this research attempts to explore the relationship between the two.

Abstract
Mobility barriers for people with disabilities remain a critical issue in many cities, especially in developing countries. This study uses metro smart card data from Nanjing, China, to explore the spatiotemporal patterns and network-based community structures of metro travel among disabled individuals. Results show a distinct "dual-peak" travel pattern and a "core-periphery" spatial structure, with higher network centrality during peak hours. Community detection reveals four types of travel clusters—commuting-oriented, residence-dominated, mixed-function, and special-node—each shaped by both travel purpose and urban functions. Spatial regression analysis highlights transit accessibility and land-use mix as key factors influencing travel flow. These findings offer insights for promoting transport equity and optimizing accessible transit planning.

Key words: Spatial-temporal patterns travel communities people with disabilities smart card data

1. Introduction

In recent years, the mobility challenges faced by people with disabilities (PWDs) in urban environments have attracted increasing scholarly and policy attention worldwide, especially in rapidly urbanizing developing countries where infrastructure development and social inclusion often lag behind economic growth (Guo et al., 2022; Liu et al., 2018). According to the latest report from the World Health Organization (WHO), over 1.5 billion people worldwide—nearly 20% of the global population—live with some form of disability. In China alone, official statistics from the China Disabled Persons' Federation (CDPF) indicate that approximately 85 million individuals, accounting for 6% of the national population, are classified as disabled. This sizable demographic represents a critically underserved group whose urban mobility constraints significantly restrict their access to essential services, economic opportunities, and social participation. Consequently, improving transportation equity for PWDs has emerged not only as a matter of human rights and social justice but also as a key indicator of urban sustainability, inclusivity, and resilience (Liu et al., 2018).

Despite substantial efforts and investments in barrier-free infrastructure, including ramps, elevators, tactile paving, and auditory guidance systems, there remains a pronounced disconnect between the provision of accessible facilities and the lived travel experiences of PWDs. Existing research has often emphasized infrastructural availability or static accessibility indices, which inadequately capture the complexity and dynamism of disabled individuals' mobility behaviors (Ma, 2023). Such approaches risk oversimplifying the multifaceted barriers PWDs encounter—ranging from physical environment constraints, psychological apprehensions, to temporal variability in travel demand and purpose. Without a comprehensive understanding of actual travel patterns and their spatial-temporal heterogeneity, urban planners and policymakers face challenges in designing truly inclusive transport systems that accommodate diverse needs effectively.

As a vital backbone of urban public transport systems, metro networks offer inherent advantages of safety, speed, reliability, and weather protection, making them an increasingly preferred mode of travel for many PWDs in dense metropolitan areas (Zheng et al., 2024). The rapid expansion of metro systems in Chinese cities provides a valuable opportunity to leverage detailed smart card transaction data to examine mobility patterns at an unprecedented granularity. However, most extant studies focus primarily on aggregated station-level indicators—such as boarding/alighting volumes or accessibility scores—without delving into the dynamic, directional flows that connect different nodes in the network (Chen et al., 2023; Kolkowski et al., 2023). This station-centric perspective neglects the underlying network topology and the interdependencies among stations, which are essential for revealing the functional structure of travel behavior.

Particularly underexplored is the application of complex network theory and community detection algorithms

to model and interpret the travel flows of PWDs. Considering that PWDs often exhibit more regularized and constrained travel patterns due to physical limitations and environmental barriers, their mobility networks may reveal distinct spatial clusters or "mobility communities" that differ fundamentally from those of the general population (Wei et al., 2024). Identifying these communities and their temporal dynamics is critical for detecting underserved areas, optimizing resource allocation, and tailoring targeted interventions to enhance the equity and efficiency of accessible transport services (Liu et al., 2024). Such an approach transcends traditional accessibility measures by incorporating the relational and flow-based characteristics of urban mobility.

To fill these research gaps, this study employs metro smart card data from Nanjing, China, integrating network analysis with temporal community detection techniques to investigate the spatiotemporal characteristics of metro travel flows among people with disabilities. Specifically, this research aims to answer three key questions: (1) What are the spatiotemporal travel patterns of PWD metro users across different times of day and week? (2) How do the underlying network structures and community configurations evolve temporally, and what does this reveal about the organization of disabled mobility? (3) Which built environment and socio-spatial factors influence travel behaviors within the identified mobility communities? By addressing these questions, this study contributes a novel analytical framework and empirical insights to the growing discourse on urban transport equity, thereby supporting evidence-based policy formulation to promote inclusive, accessible, and resilient urban transport systems.

2. Methodology

2.1 Study area and data

Nanjing, the capital city of Jiangsu Province in eastern China, encompasses a total area of approximately 6,587 square kilometers and had a permanent resident population of about 9.28 million as of 2019. For the purpose of spatial analysis, the study area is delineated into two primary concentric zones (Figure 1): the Central Urban District (CUD) and the Suburban and Urban Distant (SUD) zone. The CUD comprises most parts of Gulou, Qinhuai, Xuanwu, and Jianye districts, alongside sections of Yuhuatai, Qixia, Jiangning, and Pukou districts. This zone represents the city's core urban fabric, characterized by dense residential, commercial, and institutional land uses. In contrast, the SUD zone includes the peripheral districts of Liuhe, Lishui, and Gaochun, which are relatively less urbanized and often represent the city's suburban fringe and outlying rural-urban transition areas. According to the latest Nanjing Statistical Yearbook, the city is home to approximately 595,000 people with disabilities, accounting for 6.4% of its total population, reflecting a substantial demographic group whose mobility needs are critical for inclusive urban development.

In recent years, Nanjing has witnessed rapid expansion and modernization of its urban rail transit system. The metro network now comprises 10 operational lines, servicing a total of 159 stations dispersed across the urban and suburban areas. This expansive metro system has become an increasingly vital mode of transportation for the city's residents, especially for people with disabilities, as a result of continuous improvements in barrier-free infrastructure such as accessible station designs, elevators, tactile guidance paths, and inclusive mobility policies aimed at reducing travel barriers. These efforts have positioned the metro as a backbone of accessible urban mobility, facilitating safer, more reliable, and convenient travel for PWDs within a sprawling metropolitan environment.

This study utilizes smart card data provided by the Nanjing Metro Group Co., Ltd., covering 315,685 metro trip records made by people with disabilities over 20 weekdays and 8 weekend days in 2019. Built environment data were collected from multiple sources: building and land-use data from the Nanjing Planning Bureau, point-of-interest (POI) data from AMap, and transportation facility vector data from OpenStreetMap. Given the average walking speed of people with disabilities (approximately 0.8 m/s), a 15-minute walking distance (equivalent to a 480-meter radius) is adopted as the service buffer threshold around each metro station.

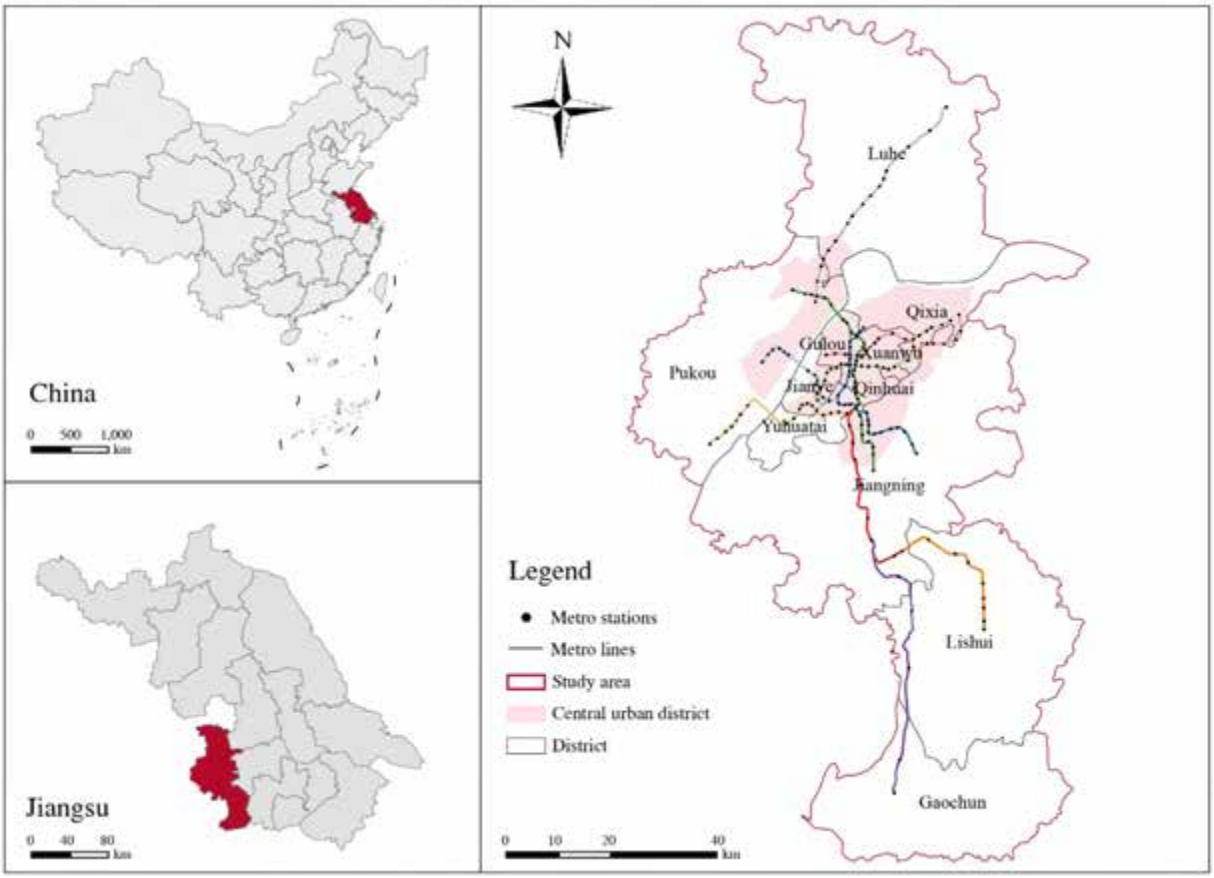

Figure 1 Study area.

2.2 Measurement of Time-Specific Travel Networks

Based on metro smart card data, this study first extracted the daily sequence of entry and exit times for each trip. By analyzing temporal fluctuations in ridership, three representative periods were identified: morning peak, off-peak, and evening peak hours. These periods serve as key time windows for analyzing the commuting-related travel behavior of people with disabilities. For each period, the origin and destination stations of individual trips were extracted. Metro stations were treated as network nodes, and travel flows between stations were represented as directed weighted edges, thereby forming a directed and weighted metro travel network. To characterize the structural properties of these networks, we calculated basic topological metrics such as number of nodes and edges, node degree, and weighted centrality (J. Liu et al., 2023), revealing the spatial structure and connectivity patterns of disabled individuals' metro travel.

2.3 Community Detection Based on Travel Flows

To uncover latent structures within the travel network, we adopted the Leiden community detection algorithm, which has been shown to outperform traditional methods in terms of computational efficiency and partition quality (Chang et al., 2023). This approach enables the identification of functional "mobility communities" by maximizing modularity, a measure that captures the strength of within-group connections. Unlike conventional methods based on administrative boundaries or individual station attributes, community detection allows for a more behaviorally grounded analysis, capturing actual spatial associations and functional regions formed through disabled travelers' movement patterns. By analyzing the size, spatial distribution, and internal flow characteristics of these communities, the study further identifies inter-community differences and group-specific mobility preferences.

2.4 Exploring the Determinants of Travel Flows: Regression Modeling

To examine the factors influencing metro travel flows across different communities, we constructed spatial regression models using average hourly metro ridership of people with disabilities (during weekdays) as the dependent variable. Independent variables included a set of built environment indicators surrounding each metro station, such as land-use mix, road network density, facility accessibility, and the number of disability-specific service facilities .Given the over-dispersion observed in the dependent variable, Poisson regression models were employed. Data subsets were constructed for three key weekday periods—morning peak, midday, and evening peak—and further stratified by mobility community for group-wise modeling. This approach accounts for both temporal variation and spatial heterogeneity in travel behavior across different community types. The modeling outputs include regression summaries and coefficient tables for each group, allowing for comparative analysis of the determinants shaping travel flow intensity across spatiotemporal units.

3. Result

3.1 Spatial-temporal characteristics of metro ridership of people with disabilities

Figure 2 illustrates the temporal distribution of metro trips made by people with disabilities on weekdays and weekends. On weekdays, the travel pattern exhibits a clear "dual-peak with off-peak differentiation" structure, with distinct morning (7:00–9:00) and evening (16:00–18:00) peaks. Travel volumes during off-peak hours are considerably lower. In contrast, weekends show a smoother dual-peak curve, reflecting non-commuting, leisure-driven travel behavior. In addition, notable differences are observed in the average hourly ridership across metro stations in central urban districts and suburban areas, indicating that the metro trips of people with disabilities are primarily concentrated in the urban core. Given the significant reduction in average trip volumes during weekends, this study focuses on weekday travel patterns, and classifies daily metro flows into three periods for further analysis: morning peak (7:00–9:00), noon off-peak (9:00–16:00), and evening peak (16:00–18:00). This classification enables a detailed comparison of travel flows and network structures across different time windows.

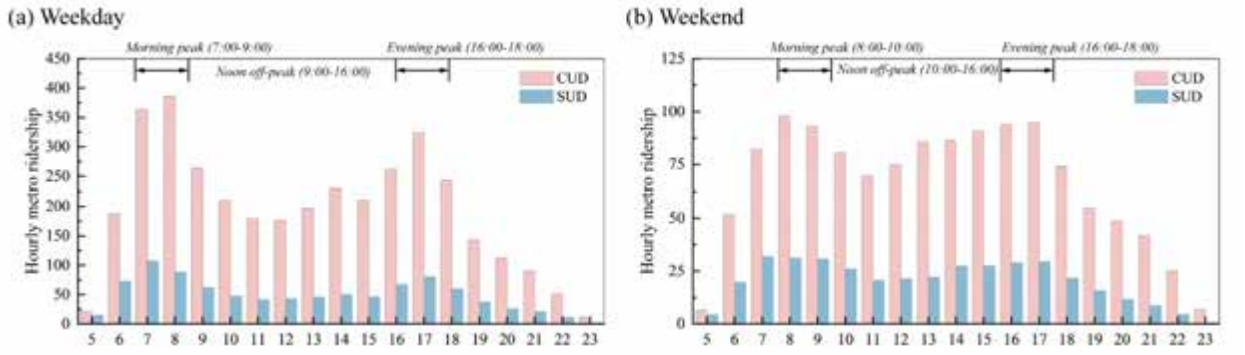

Figure 2 Temporal distributions of hourly metro ridership during weekdays and weekends.

Figure 3 illustrates the spatial and temporal differentiation of metro travel flows and station-level ridership of people with disabilities during weekdays. In the morning peak period, the OD flow pattern shows a strong centripetal tendency, with the highest observed hourly flow reaching 526 trips from Maigaoqiao to Gulou. Notably, 70% of the top 10 OD pairs represent commuting flows from suburban areas to the urban core. During the noon off-peak period, travel flows become more bidirectionally balanced, exemplified by the Maigaoqiao-Gulou link, where flows in both directions remain around 400 trips per hour. In the evening peak (T3), a clear centrifugal pattern emerges, with flows shifting from central areas to the periphery. The flow from Xinjiekou to Maigaoqiao reaches a peak of 421 trips per hour, marking a 22.3% increase over the same direction during the morning peak. Furthermore, aggregated station-level ridership across all time periods highlights a consistent core–periphery disparity. Metro stations in central urban districts exhibit significantly higher passenger volumes than those in suburban areas. In particular, Xinjiekou and Gulou serve as peak flow nodes during rush hours, a pattern closely

associated with the high density of employment centers, public services, and superior metro accessibility in these areas.

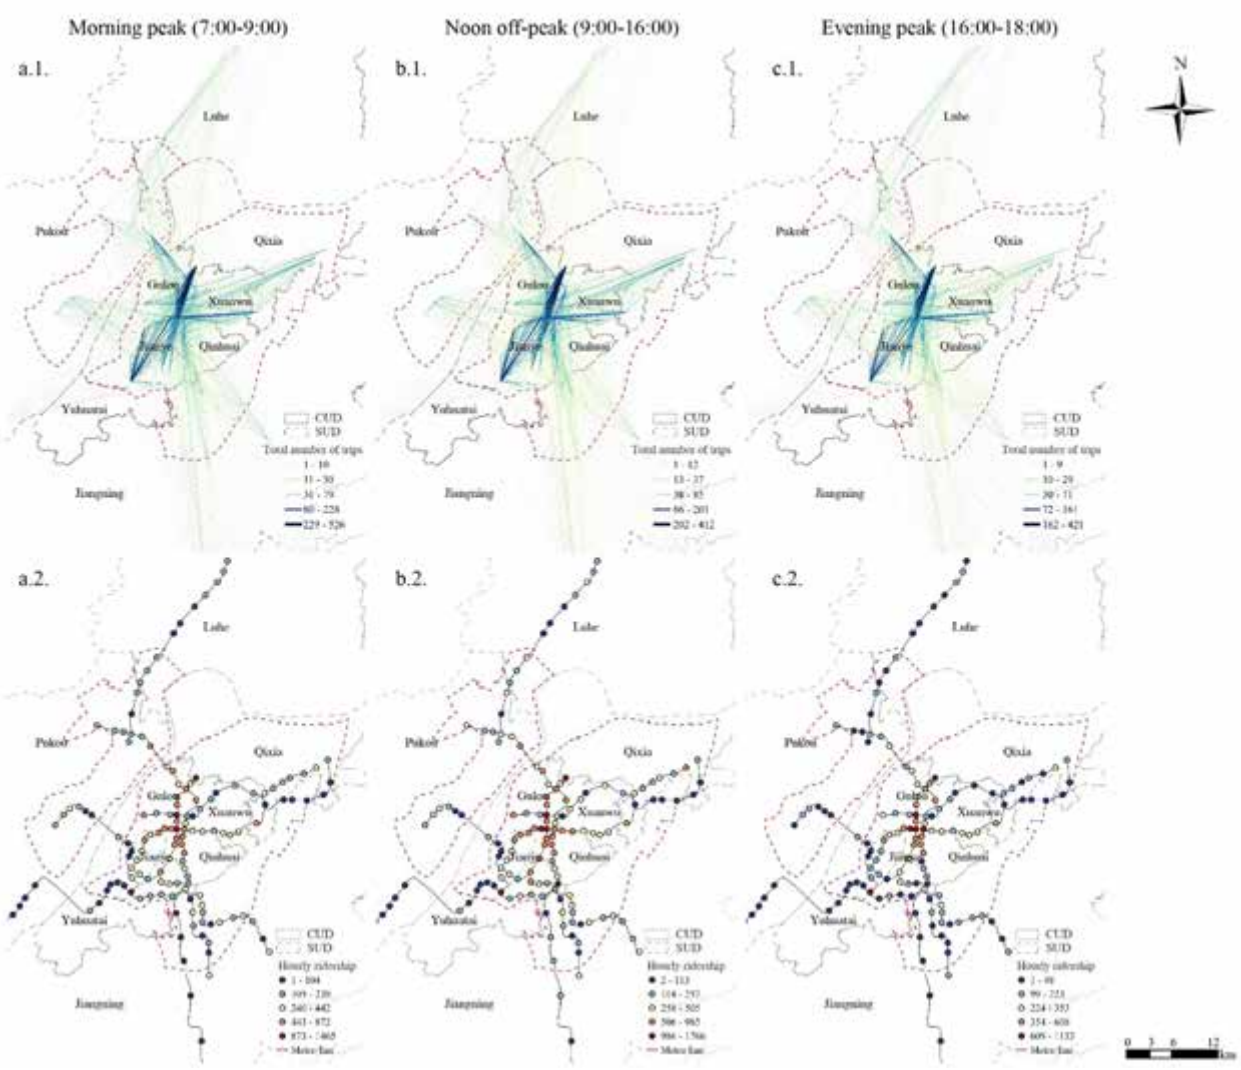

Figure 3 Spatial temporal variations of metro ridership on weekdays.

3.2 Network characteristics analysis

This study conducted a time-segmented analysis of node importance in the metro travel network of people with disabilities using the weighted degree centrality metric. The results reveal significant temporal variations in network structure. During the morning peak, stations such as Maigaoqiao, Difangqiao, and Gulou serve as critical hubs within the disabled passengers' travel network. In the noon off-peak period (T2), the overall network centrality decreases slightly (ranging from 0.003 to 0.041). However, the relative dominance of high-centrality nodes becomes more pronounced, with the maximum centrality increasing by 5.1% compared to the morning peak. For instance, Xinjiekou Station's centrality rises sharply to 0.0410, surpassing Maigaoqiao as the most important node. Meanwhile, Shanghai Road and Gulou stations maintain high centrality scores, highlighting the growing importance of commercial centers during non-commuting hours. In the evening peak, the network centrality strengthens markedly, with the distribution shifting upward (range: 0.004 to 0.047). Xinjiekou Station reaches a daily peak centrality of 0.0466, while Maigaoqiao Station, located at the urban fringe, regains its status as a secondary core node. Together with Difangqiao, these stations form a dual-core structure in the evening peak travel network. Overall, these spatiotemporal dynamics further illustrate the "core–periphery" structure of the metro

travel network for people with disabilities, with higher network concentration observed during peak hours. The most central stations are predominantly located in the historic urban core, whereas peripheral stations exhibit significantly lower importance in the daily travel network of disabled passengers.

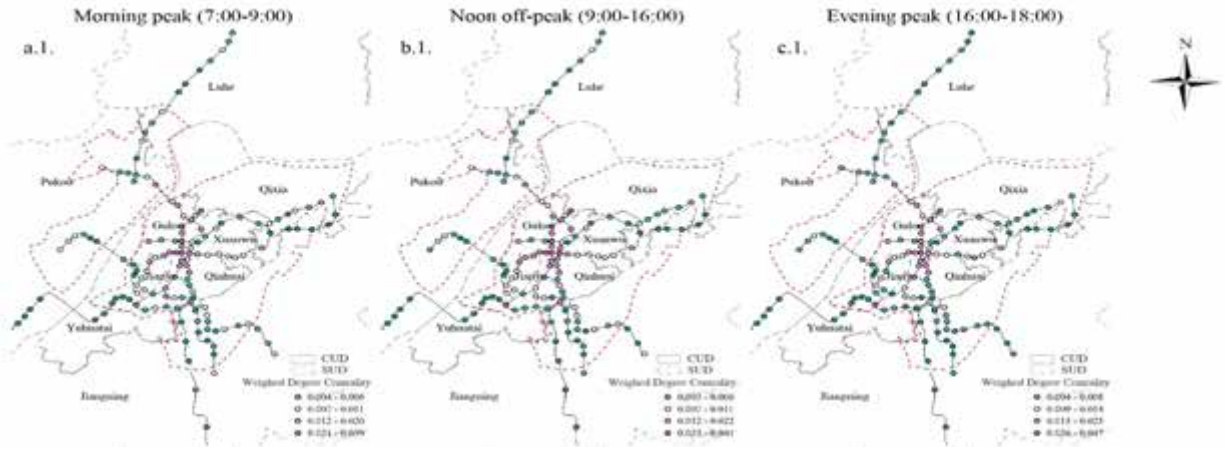

Figure 4 Spatial distribution of weighed degree centrality during the different period

3.3 Community detection analysis

Using a complex network community detection algorithm, this study analyzed the community structure of the metro travel network for people with disabilities across different time periods (Figure 5). The results reveal a high similarity between the morning and evening peak travel networks, whereas distinct differences emerge when comparing peak periods with the noon off-peak period. During peak hours, four prominent communities (C1–C4) are identified, each showing a significant alignment with the metro lines' spatial layout. Specifically, Community 1 (C1) is primarily concentrated along Metro Lines 2, 10, and the S3 line, exhibiting clear line homogeneity. Community 2 (C2) is mainly distributed along the north–south oriented Lines 3 and S8. Community 3 (C3) covers the interchange section between Lines 1 and part of Line 4. In contrast, Community 4 (C4) centers on the Yuhuatai and Jiangning districts, encompassing the S1 line and reflecting the suburban commuting network's relative independence, likely corresponding to a residentially oriented, single-function area. During the noon off-peak period, community structure shows stronger line intermixing with the number of communities reduced to three. Stations from different lines increasingly cluster within the same communities, indicating that the diversified travel purposes during non-commuting hours weaken spatial differentiation.

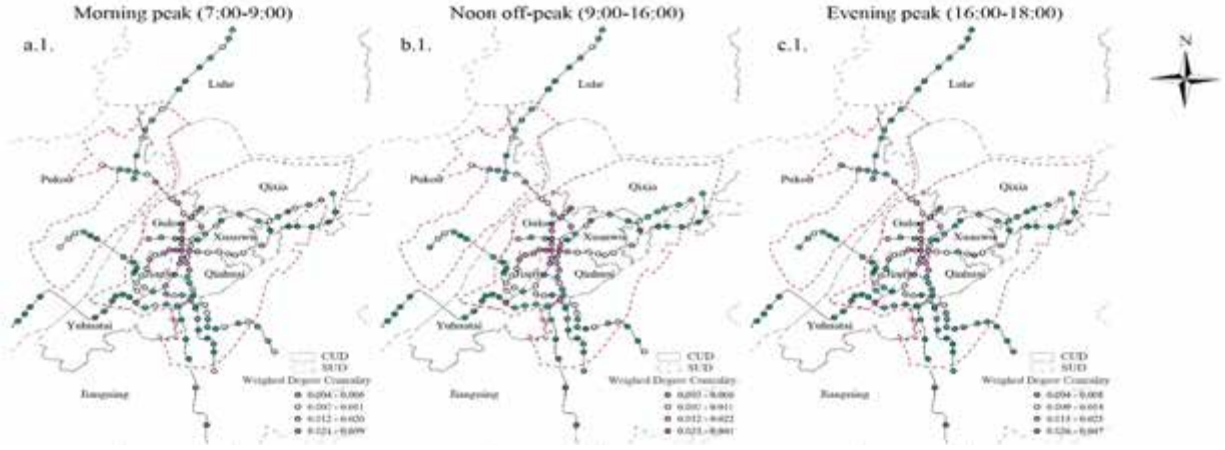

Figure 5 Detected communities for people with disabilities during different period

3.4 Potential Factors Influencing Community Formation

To better understand the formation of these community structures and the differences in travel activity patterns among communities, this study focuses on the morning peak travel network on weekdays, where community differentiation is most pronounced. We statistically analyzed the built environment characteristics of the four identified communities (Figure 6) and further explored the relationships between travel flows and urban built environment features within each community (Table 1).

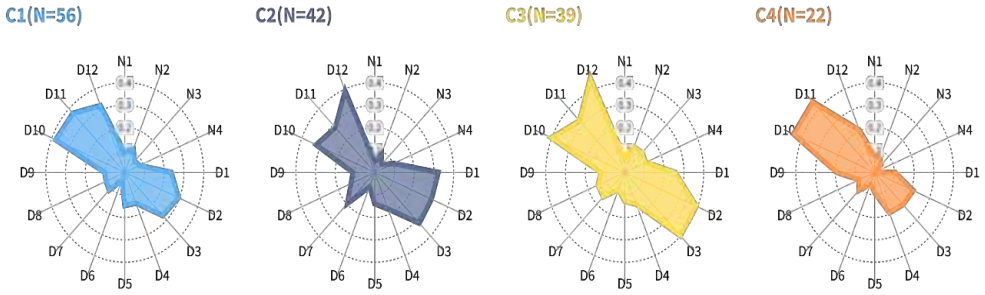

Figure 6 Indicator visualization results for each community during morning peak hours.

The study identified four distinct community types with differing built environment influences on disabled individuals' metro travel flows. Cluster 1, the commuting-oriented community (35% of total), exhibited a significant transportation-commercial synergy, where metro connectivity (β = 0.666*) and bus accessibility (β = 1.812*) combined with commercial facilities (β = 0.811*) to drive travel volume. Travel demand decreased by 1.576 units per kilometer from the CBD ($p < 0.01$), confirming the effectiveness of the traditional TOD model. Cluster 2, the residence-dominated community (26%), displayed typical "bedroom city" characteristics, with leisure facilities (β = 2.398*) and medical resources (β = 0.641*) as main attractors, while enterprise presence (β = -2.002*) and functional mix (β = -2.239*) exerted significant inhibitory effects, indicating spatial job-housing imbalance. Cluster 3, the mixed-use community (25%), reflected balanced development, with medical services (β = 1.792*) and bus coverage (β = 1.351*) as core drivers and minimal impact from distance variables, highlighting the effectiveness of the "15-minute city" concept. Cluster 4, the special-node community (14%), showed pronounced monopolar characteristics, where metro connectivity (β = 264.413*) and medical resources (β = 60.169*) had extraordinary impacts, but road network density (β = -6.840*) strongly suppressed travel, revealing its role as a specialized regional hub. Overall, transportation accessibility consistently underpinned all communities (all D12 coefficients $p < 0.01$), while differences in functional composition constituted the key dimension of community differentiation.

4. Discussion and conclusion

4.1 Key findings

This study reveals the community structure within the metro travel network of people with disabilities and systematically explores the potential factors influencing travel volumes within each community across different time periods. The findings highlight significant temporal and spatial variations in travel patterns, network characteristics, community structures, and their driving factors between peak and off-peak periods. Methodologically, this research integrates transit card data analysis, complex network modeling, and community detection algorithms, establishing a replicable analytical framework that contributes to urban transport equity research and offers valuable insights for meeting the daily travel needs of people with disabilities, optimizing accessible infrastructure, and promoting transport fairness.

From a temporal perspective, metro travel on weekdays exhibits a typical "double-peak" commuting pattern, with passenger volumes significantly higher during morning and evening peaks compared to off-peak periods, reflecting the rigid travel demands associated with employment or scheduled services for some people with disabilities. Weekend travel patterns are comparatively flatter, indicating that leisure-oriented trips dominate while commuting demands sharply decline. Spatially, travel activities of people with disabilities are highly concentrated in central urban areas, especially in employment-dense and service-rich zones. This concentration correlates closely with the accessibility level of the urban built environment, suggesting that despite rapid expansion of the metro network, people with disabilities tend to favor activity in resource-intensive core areas.

Topological analysis of the travel network shows a typical "core-periphery" structure. Network centralization significantly increases during peak hours, with a few core stations such as Xinjiekou, Maigaoqiao, and Gulou serving as critical hubs. This reflects the concentration of travel destinations during commuting periods and reveals spatial imbalance in metro system service capacity, with peripheral stations showing relatively weaker connectivity and attractiveness. During off-peak hours, the network structure is more dispersed, and the centrality of certain nodes increases, indicating that travel during service- or medical-oriented periods relies more on individual preferences and functional orientation rather than large-scale commuting flows.

Further community detection results identify distinct differences among the metro travel communities of people with disabilities during peak hours and their association with the built environment. The four identified commu-

nity clusters show pronounced heterogeneity in spatial structure, metro line orientation, and functional attributes. The commuting-oriented community (Cluster 1) is closely linked to the urban core and main metro lines, demonstrating the spatial influence of TOD patterns; the residential-dominated community (Cluster 2) is mainly distributed in urban peripheries, reflecting spatial contradictions of job-housing imbalance and mono-functionality; the mixed-function community (Cluster 3) embodies the phased achievements of the "15-minute living circle" planning, where balanced layouts of transportation and service facilities reduce sensitivity to distance; and the special-node community (Cluster 4) shows extreme hub characteristics, revealing the strong attraction of certain medical and special facilities to people with disabilities. These findings indicate that community structures are shaped not only by commuting behaviors but also by the interplay of diverse travel purposes and the functional spatial organization of the city.

4.2 Limitations

Due to data availability constraints, this study has several limitations. First, the smart card data used only cover metro travel, which may overlook trips made by other modes of transportation. Future research should consider incorporating multi-source travel data to provide a more comprehensive understanding of the daily travel behaviors and spatiotemporal network characteristics of people with disabilities. Second, although this study explored built environment factors influencing intra-community travel flows, it lacks causal inference and does not examine other potential longitudinal factors such as weather conditions or policy changes. Future studies could further investigate these key determinants affecting public transit use by people with disabilities to offer stronger insights for urban planning interventions (Kim, 2018).

What kind of shrinkage differences do urban agglomerations at different stages of development lead to in the era of negative population growth?

Abstract
Currently, the phenomenon of localized urban contraction has brought challenges to the high-quality development of the region. Based on the study of urban contraction in the Chinese context, we explore the phenomenon and characteristics of contraction in the city clusters of the Yangtze River Delta and the middle reaches of the Yangtze River, comparatively analyse the contraction patterns, temporal and spatial patterns and other changes presented by city clusters with different development processes. It also explores what kind of contraction differences mature and developing city clusters show in their respective development stages, taking the Yangtze River Delta city cluster and the city cluster in the middle reaches of the Yangtze River as examples.

Keywords: negative population growth, urban shrinkage, urban agglomeration, development process, regional differences

0 Introduction

The phenomenon of urban contraction first appeared in Western countries and gradually became a worldwide socio-economic problem (Fernandez C, Audirac I and Fol S, et al., 2012; Döringer S, Uchiyama Y and Penker M, et al., 2020). Currently, in the process of China's rapid urbanization, urban contraction is a phenomenon emerging from urban development mainly characterized by population loss, accompanied by negative externalities such as inefficient use of land resources, housing vacancy, and economic downturn (Guo, Li, 2019), which brings impacts and challenges to the traditional paradigm of growth-oriented thinking (Sun, 2022). China is in the parallel stage of rapid urbanization and urban contraction (Sun, 2022), and in 2019, the National Development and Reform Commission (NDRC) issued the "Key Tasks of New Urbanization Construction in 2019", which mentioned "shrinking cities" for the first time, and explicitly required shrinking small and medium-sized cities to slim down and strengthen their bodies, strictly control incremental growth, and revitalize the stock, which was mentioned in the "New Urbanization Construction and Urban Integration Development in 2020". In the "Key Tasks of New Urbanization Construction and Urban-Rural Integration Development in 2020", the development demands of shrinking cities are also emphasized. The phenomenon of urban contraction has become a key topic of concern at the current stage of emphasizing high-quality development.

Based on the research of foreign scholars, relevant domestic studies start from the introduction of foreign experience to carry out the "China Shrinking Cities Research Network", which researches the connotation (Sun, 2022), identification (Zhang, Shan and Zheng et al., 2019), development path (Zhou, Qian, 2015), and influence mechanism (Sun, Zhang and He, 2022) of shrinking cities. From the perspective of the object, northeastern cities, third-tier cities, resource-based cities are the main ones, and the phenomenon of local contraction within the metropolitan area and city clusters has gradually attracted the attention of scholars. Current research mostly considers the identification of cities with population contraction and the analysis of influencing factors, with less consideration of social and economic factors, and insufficient research on the differences in urban development brought about by contraction. In this paper, we adopt the population census data from the fifth to the seventh census to reflect the population loss of cities in a more comprehensive and real-time manner; at the same time, we select two city clusters of the Yangtze River Delta and the middle reaches of the Yangtze River, and conduct a comparative research on different types of city clusters to better reflect the characteristics and differences in the occurrence of the phenomenon of urban contraction; and based on the different directions and degrees of urban contraction, we will further put forward optimization suggestions.

1 Research Methods

1.1 Research object and data

The study selects the Yangtze River Delta city cluster and the city cluster in the middle reaches of the Yangtze River, considering that both of them have certain types of characteristics in the development of city clusters (Table 1), are located along the Yangtze River Economic Belt, adjacent to each other, the Yangtze River Delta city cluster is in a relatively mature stage of development, and the city cluster in the middle reaches of the Yangtze River is more inclined to be a cultivation period and a developmental type of city cluster, and its comparative study is a reference for the city clusters in different stages of development. Considering the administrative factor of zoning, the phenomenon of city contraction and its causes are analyzed from the prefecture-level city level.

Table 1 Comparison of city clusters in the Yangtze River Delta and the middle reaches of the Yangtze River

Research target	Yangtze river delta city cluster	Mid-Yangtze river city cluster
Geographical position	Yangtze river economic belt (east end)	Yangtze river economic belt (central)
Distributional characteristics	Coastal, open to the outside world	Inland, central hub
Developmental stage	Mature city cluster	Developmental city clusters
Development goal	High-quality integration	Cooperative development

The GIS analysis and visualisation were carried out using the Chinese standard map with review number GS(2020)4619, with the geographic coordinate system GCS_Beijing_1954 and the projected coordinate system China_Lambert_Conformal_Conic. demographic data were the data of the fifth, sixth and seventh censuses from 2000 to 2020, and the resident population of selected prefectural cities was selected for the change trend study; economic data were the GDP data of each city from the statistical yearbook of the local statistical bureau; spatial data were obtained by integrating DMSP-OLS and SNPP-VIIRS data after correction. The population data are the 2000-2020 VP, VIP and VIIP data, and the resident population of prefecture-level cities is selected to study the trend of change; the economic data are the GDP data of each city from the statistical yearbooks of local statistical bureaus; and the spatial data are corrected nighttime lighting data from 2000 to 2020 obtained by integrating the data of DMSP-OLS and SNPP-VIIRS (Chen, Yu and Yang et al., 2021).

1.2 Technical route of research

Starting from the three dimensions of 'population-economy-space', we select the indicators of urban agglomerations in the past years to conduct uni-dimensional, bi-dimensional and multi-dimensional contraction research and judgement, and at the same time analyse the paths and characteristics of urban contraction, discuss the spatial and temporal dynamics of the contraction of different urban agglomerations, and then put forward the corresponding suggestions and optimization strategies for different types of contracting cities, see Figure 1.

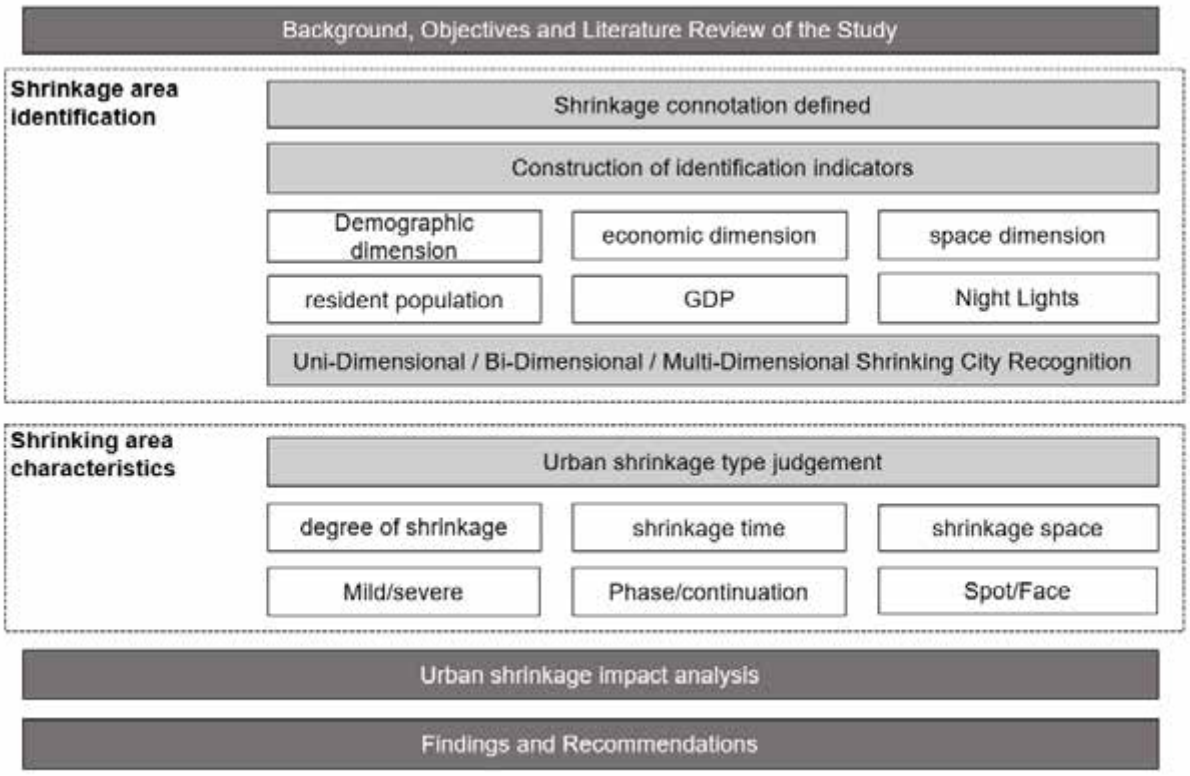

Figure 1 Research pathway framework

2 Shrinkage identification from multi-dimensional perspective

Shrinkage city identification is carried out using prefecture-level cities in city clusters as the division scale; the Yangtze River Delta city cluster includes Shanghai, Jiangsu, Zhejiang and Anhui provinces, totalling 41 cities, and the city cluster in the middle reaches of the Yangtze River includes Hubei, Hunan and Jiangxi provinces, totalling 31 cities. See Table 2 and Table 3 for details.

Table 2 Composition of the Yangtze River Delta Urban Agglomeration

The Yangtze River Delta city cluster contains prefecture-level cities (41)	
Shanghai	Shanghai
Jiangsu Province	Suzhou, Nanjing, Wuxi, Nantong, Changzhou, Xuzhou, Yancheng, Yangzhou, Taizhou, Zhenjiang, Huai'an, Lianyungang, Suqian
Zhejiang Province	Hangzhou, Ningbo, Wenzhou, Shaoxing, Taizhou, Jiaxing, Jinhua, Huzhou, Quzhou, Lishui, Zhoushan
Anhui Province	Hefei, Wuhu, Ma'anshan, Anqing, Chuzhou, Fuyang, Bengbu, Suzhou, Xuancheng, Lu'an, Bozhou, Tongling, Huainan, Huaibei, Chizhou and Huangshan.

Table 3 Composition of urban agglomerations in the middle reaches of the Yangtze River

City cluster in the middle reaches of the Yangtze River including prefecture-level cities (31)	
Hubei Province	Wuhan, Huangshi, Ezhou, Huanggang, Xiaogan, Xianning, Xiantao, Qianjiang, Tianmen, Xiangyang, Yichang, Jingzhou, Jingmen
Hunan Province	Changsha, Zhuzhou, Xiangtan, Yueyang, Yiyang, Changde, Hengyang, Loudi

Jiangxi Province	Nanchang, Jiujiang, Jingdezhen, Yingtan, Xinyu, Yichun, Pingxiang, Shangrao, and some counties (districts) in Fuzhou and Ji'an (Fuzhou and Ji'an were all delineated at the time of the study)

The term 'urban contraction' is used to emphasise the fact that this social problem exists in multiple economic, demographic, geographic, social and physical dimensions, rather than a simple linear process. Therefore, the study starts from a multi-dimensional perspective, taking demographic, economic and spatial indicators into account, and draws on the concept of 'one body, two wings and three dimensions' put forward by Zhang Wei and others (Zhang, Shan and Zheng et al., 2019). Drawing on the concept of 'one, two wings and three dimensions' of shrinking cities proposed by Zhang Wei and others (Figure 2), the study considers the dominant factors of city shrinkage under different scenarios from a multi-perspective perspective. Through three-dimensional identification and judgement, we can more accurately define the type, degree and status of urban contraction, and provide strategic benchmarks for urban regulation and development response.

Fig. 2 One body, two wings and three dimensions of shrinking city concept

2.1 Population contraction

Population contraction, as the main feature of urban contraction, is a key indicator for defining urban contraction. Classifying the data from the three censuses and calculating the rate of change in the resident population of each region from 2000 to 2010 and from 2010 to 2020 respectively, cities with a rate of change in population of less than -3% are identified as shrinking cities (Sun, Wang, 2021; Zhang, Liu and Lv, 2016; Gong, Zhang and Wang, 2022).

Table 4 shows that in 2000-2010, the Yangtze River Delta urban agglomeration mainly faced light to medium contraction, and the city agglomeration in the middle reaches of the Yangtze River existed in light to heavy contraction; in 2010-2020, the contracting cities of the Yangtze River Delta urban agglomeration decreased but the degree of contraction further deepened, with heavy and medium contraction predominating, and the contracting cities of the city agglomeration in the middle reaches of the Yangtze River increased but shifted to medium contraction more often.

Table 4 Identification of cities with shrinking populations

	2000-2010		2010-2020	
shrinkage strength	Yangtze River Delta (12)	Middle reaches of the Yangtze River (8)	Yangtze River Delta (6)	Middle reaches of the Yangtze River(15)
>20% (severe shrinkage)	——	Xiantao (1)	Anqing, Lu'an (2)	——

10%-20% (general severe shrinkage)	——	Tianmen, Huanggang (2)	——	Tianmen, Yiyang, Xiaogan (3)
5%-10% (moderate shrinkage)	Fuyang, Lu'an, Yancheng, Suqian (4)	Jingzhou, Xianning (2)	Huaibei, Yancheng, Huaian (3)	Qianjiang, Changde, Jingzhou, Jingmen, Yueyang, Hengyang, Fuzhou, Ji'an, Yichun (9)
3%-5% (mild shrinkage)	Bengbu, Bozhou, Xuancheng, Taizhou, Nantong, Huaian, Xuzhou, Lianyungang (8)	Qianjiang, Jingmen, Xiaogan (3)	Chizhou (1)	Xiantao, Xiangyang, Huanggang (3)

In terms of the number of cities with different degrees of contraction (Figure 3), between 2000 and 2020, the number of cities in the YRD with mild contraction is decreasing, moderate contraction is decreasing, and severe contraction is increasing; and in the middle reaches of the Yangtze River, there are no change in the number of cities with mild contraction, moderate contraction is increasing, more severe contraction is increasing, and severe contraction is decreasing.

Overall, the YRD has more contracting cities during 2000-2010, decreasing but further intensifying during 2010-2020; the middle reaches of the Yangtze River have fewer contracting cities during 2000-2010 and more during 2010-2020, but to a relatively slower extent.

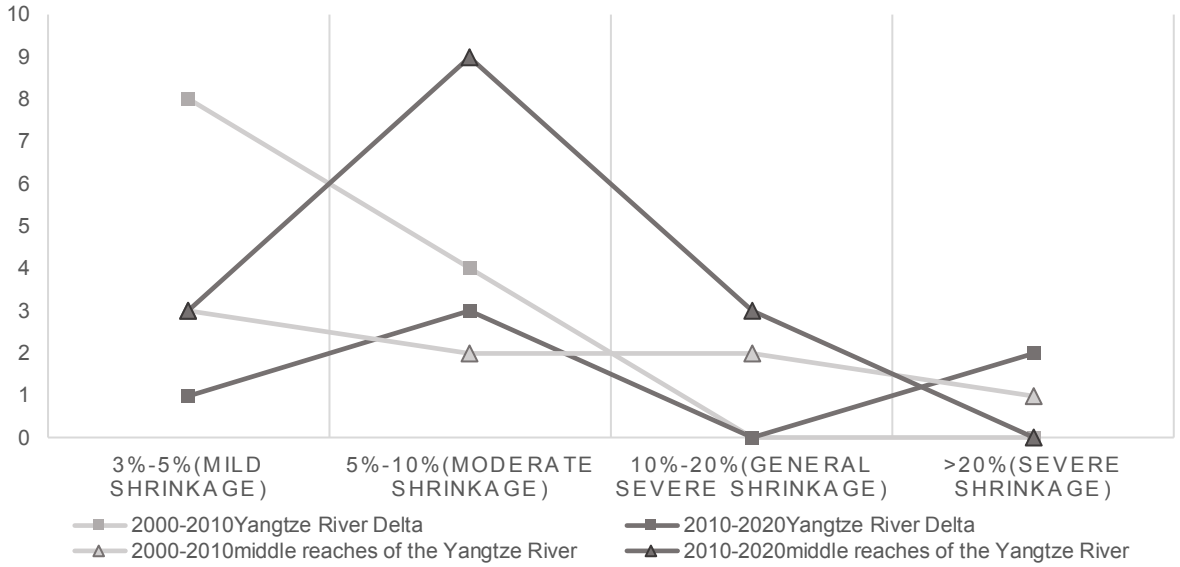

Figure 3 Comparison of cities with shrinking populations

2.2 Economic Contraction

Economic contraction mainly analyses the rate of change of GDP of regional gross domestic product of each city from 2000 to 2020, according to the data of statistical yearbook of each region (Table 5), the Yangtze River Delta has 4 cities with economic contraction phenomenon in the period of 2000-2010, and there are 3 cities in the period of 2010-2020, of which, Huainan is the only city with economic contraction phenomenon in two consecutive years; the middle reaches of the Yangtze River have 5 cities with economic contraction phenomenon in the period of 2000- 2010 period there were five cities that experienced economic contraction, and 2010-2020

excluding the impact of the 2020 epidemic, three cities were considered to have economic decline.

Table 5 Identification of economically contracting cities

Yangtze River Delta		Middle reaches of the Yangtze River	
2000-2010(4)	2010-2020(3)	2000-2010(5)	2010-2020(3)
Fuyang, Ma'anshan (2001) Wuhu (2001, 2006) Chuzhou (2005)	Lu'an (2010) Huainan (2014-2015) Tongling (2019)	Jingzhou, Jingmen, Xianning, Huanggang, Xiaogan (2005)	Pingxiang, Xinyu and Jingdezhen (2018)

2.3 Spatial contraction

Using night lighting data to reflect the spatial vitality of the city, taking into account China's unique 'population loss - land expansion' characteristics and did not choose the built-up area to identify the contraction of the land area, take the city in 2000, 2005, 2010, 2015, 2020 night lighting data to carry out the study in the gis to show the table partition. Statistics, when the average intensity change rate is less than 0, the city will be identified as a spatial contraction city.

The average nighttime light intensity in the Yangtze River Delta region is in a growing trend and basically has no contraction; the cities with contraction in the city cluster in the middle reaches of the Yangtze River are mainly Xiantao, Pingxiang, Yichang, Yiyang, Loudi, Changde, Yueyang, Changsha, Xiangtan, Zhuzhou, Yichun, Huanggang and Xiaogan.

2.4 Multi-dimensional contraction

By integrating the trends of the cities in the city cluster in terms of population, economy, and space, the analysis leads to the shrinking cities under the multi-dimensional perspective. In the Yangtze River Delta city cluster, Fuyang City and Lu'an City belong to the population-economy contraction, because the Yangtze River Delta region basically shows an upward trend in the spatial dimension, and the contraction phenomenon is more in a certain degree of shrinkage in population and economy. In the city cluster in the middle reaches of the Yangtze River, Xiangyang , Jingzhou , Jingmen , Xianning , Huanggang , Xiaogan belong to the population-economic contraction, Xiantao , Yiyang , Changde , Yueyang , Yichun , Huanggang , Xiaogan belong to the demographic-spatial contraction, and comprehensively Huanggang , Xiaogan belongs to the 3D contraction city, and the phenomena of contraction such as a certain degree of population reduction and economic decline exist to a certain extent in many aspects.

3 Evolutionary characteristics of population contraction

From the results of urban contraction research, population contraction is relatively more reflective of the real state of urban contraction, subject to relatively few external uncontrollable factors, based on the population contraction data to analyse the spatial and temporal characteristics of the two major urban agglomerations in the local contraction, and to discuss the contraction of the urban agglomerations in the degree and time of the trend of change.

3.1 Degree of contraction

The contraction of the Yangtze River Delta urban agglomeration in 2000-2010 mainly occurred in the north, Jiangsu and Anhui periphery, presenting a band form; to 2010-2020, the contraction mainly occurred in the east of Jiangsu and the west of Anhui, presenting a relative distribution of points, relatively speaking, the contraction of the city there is a significant reduction, but the degree of contraction from the previous general light to moderate to Medium-heavy. Analysis in the Yangtze River Delta integration to promote more coordinated and balanced development of cities in the urban agglomeration, their own city economy to drive employment growth, reducing

the phenomenon of urban contraction. However, there are also local areas that are relatively lagging behind in development, and neighbouring cities have more attractive resources, leading to a polarisation effect in the degree of contraction and increased wastage.

The city cluster in the middle reaches of the Yangtze River contracted mainly in the centre of Hubei Province in 2000-2010, and in 2010-2020, the phenomenon of piecemeal contraction will occur in the western and southern parts of the entire city cluster, with an increase in the number of contracting cities and a relative slowdown in the degree of contraction. Considering the uneven development of Hubei Province in the early stage, the development of neighbouring cities is relatively lagging behind, the capital city of Wuhan is too high to attract the population of neighbouring cities to gather here, resulting in a high degree of population loss in several neighbouring cities; then, with the gradual development of the neighbouring cities, a number of polarization centres appear in the city cluster in the middle reaches of the Yangtze River, and the economic development of Wuhan, Changsha, and Nanchang, etc., is faster than that of the neighbouring cities, and the resources of these cities are more superior, resulting in the emergence of neighbouring areas. The more superiority of the city leads to a greater range of population movement phenomenon in the peripheral areas, and the contraction further expands at the city level.

3.2 Time of contraction

By considering the overall contraction in 2000-2020, the time characteristics of the contraction of the city cluster are defined, if there is no population loss in both time stages judged as no contraction; if there is a contraction in Stage 1 and none in Stage 2, it is judged as a stage contraction; if there is no contraction in Stage 1 and there is a contraction in Stage 2, it is judged as a potential contraction; and if there is a contraction in both stages, it is judged as a sustained contraction.

Accordingly, comparing the Yangtze River Delta city cluster and the city cluster in the middle reaches of the Yangtze River in terms of contraction time con, it can be seen that from 2000 to 2020, 22% of the cities in the Yangtze River Delta city cluster are in stage contraction, 7% are in potential contraction, and 7% are in sustained contraction; and in the middle reaches of the Yangtze River city cluster, 3% of the cities are in stage contraction, 26% of the cities are in potential contraction, and 23% of the cities are in continuous contraction.

The Yangtze River Delta city cluster has a better advantage in regional integration and coordination, overall the development of each region is relatively balanced, in the face of the problem of urban contraction there is a better basis for coping with the problem, more is to seize the development of local areas to drive, higher quality to achieve regional integration; the middle reaches of the Yangtze River city cluster is still in the stage of cultivation and development, the polarity between the cities is relatively serious, and the differences in regional development are obvious, resulting in the emergence of a large proportion of cities or there is a risk of contraction, and more cities are in the stage of potential contraction. Or there is a risk of contraction, more to regional synergistic development to promote the promotion of the central city to drive the employment and economic development of the surrounding areas, to reduce the phenomenon of underdeveloped areas of the outflow of population.

4 Shrinkage causes and countermeasures analysis

4.1 Causes of contraction

From the current city contraction structure, the Yangtze River Delta city cluster and the city cluster in the middle reaches of the Yangtze River belong to the ‘core expansion - peripheral contraction’ type of contraction mechanism, in which the core city or the central city of the city cluster is attracted by the international co-operation and policies, and the introduction of resources is constantly growing, and the city governance ability

is relatively high and the advantage of innovation-driven development is obvious, attracting the population and industries of the surrounding small and medium-sized cities to gather in the centre. In the city cluster, the core city or the central city is attracted by international cooperation and policies, and continues to grow and bring in resources, from transportation, industry, facilities and social security, and has relatively high urban governance capacity and obvious advantages in innovation-driven development, which attracts the population and industry of the surrounding small and medium-sized cities to the centre, and all kinds of factors gradually tend to develop in the central region, leading to the contraction of the peripheral cities of the city cluster.

The Yangtze River Delta city cluster is a typical case of integrated development with the metropolis of Shanghai as the core, and the development strength of several leading central cities is very considerable, with more people flocking to the several central cities for further development and livelihood, which brings about a lack of sufficient innovative attraction and industry to retain the population in the surrounding small and medium-sized cities, leading to local contraction problems.

The city cluster in the middle reaches of the Yangtze River has a relatively low degree of integration and development, and is still the central city of several provinces in the driving force, the flow of factors between the region tends to converge to a few central nodes, and the nodes around the urban areas are also prone to the proximity of resources leading to the flow of factors, the essence of the spatial resources to the region of the higher level of energy and more promising areas of the development of the tilt brought about by the demographic tendency to be from the economic tendency to the contraction of the phenomenon as the phenomenon of contraction, as an unavoidable aspect of rapid urban development in the process of urbanisation, and the growth of cities present a situation of mutual pull, and the cities in the region are constantly pulling between 'contraction-growth', and the factors are constantly redistributed in space under the perspective of factor flow, which brings about the dynamic evolution and development of the region.

4.2 Planning Countermeasures

For the Yangtze River Delta and the city cluster in the middle reaches of the Yangtze River, the city contraction is dominated by population contraction, accompanied by economic contraction and slowing down of spatial vitality.

As a mature urban agglomeration, the Yangtze River Delta is now mainly characterised by population contraction, with more cities contracting in the northern region and a high degree of contraction in the western region, and contraction in recent years has mainly focused on some cities in the peripheral regions. The overall development of the Yangtze River Delta city cluster is more powerful and mature, and the contraction is mainly due to the loss of population from the peripheral cities to the core, and the contraction should be considered as the main mitigation, relying on the development of the power to transform the regional competitive relationship into the centre, and improve the configuration of the regional economic factors through the policy and planning (Peng, Luo and Liu et al., 2023), and effectively ease the transfer of the functions of the central urban areas to the periphery.

The city cluster in the middle reaches of the Yangtze River as a developmental city cluster, from uni-dimensional to multi-dimensional contraction type is more diverse, the contraction shows the trend of expansion and spreading, and is dominated by potential contraction and continuous contraction. Compared with the Yangtze River Delta City Cluster, which has a stronger development drive, most of the cities in the Middle Reaches of the Yangtze River cluster are contracting because of the disordered development caused by the loss of labour force and the depletion of resources, the limited role of the central city in radiating and driving the small and medium-

sized cities in the vicinity, and the lack of a regional network hierarchy due to the unbalanced development of the cities, which makes it difficult to form an effective linkage and collaboration. Based on economic activities, it is considered to cultivate secondary cities that are closely connected to each other to buttress the metropolitan area and radiate and drive the population flow and economic development of the contracting cities (Yu, 2024).

In terms of the type of contraction, for the phenomenon of population contraction in the city cluster, it is necessary to resist population loss in the early stage, improve urban development, promote the division of labour and cooperation in order to integrate into the regional development system, and drive its own development with developed cities. When the contraction continues to be severe, we should consider appropriately reducing the size of the city and promoting the development of a leaner and stronger city. For the phenomenon of 'population-economy' double contraction, the development positioning and effective development scale of cities in the urban agglomeration should be clarified, and the support of major industries should be appropriately increased to promote the economic development of the cities, and at the same time, the adjustment and optimisation of the industrial structure should be considered, as well as the comprehensive coordination of the spatial distribution of industries and the development of the population. Facing the phenomenon of 'population-space' double contraction, which mainly lies in the reduction of spatial vitality brought about by population exodus, we should control the scale of cities, optimise the land use structure, and adapt to the needs of urban development. For the multi-dimensional contraction phenomenon of 'population-economy-space', the adaptation contraction strategy is the main one, and the 'small and beautiful' development of the city should be realised through spatial resource integration and redistribution within the limited resources and space. Planning should take into account the type and degree of urban contraction and time, and make differentiated decisions on the response strategies to urban contraction.

From the perspective of urban agglomeration, the analysis of urban contraction strategy suggests that it is necessary to grasp the key points of regional integration and development, strengthen the internal integration and flow of factors such as labour, technology, capital and information within the region, enhance the synergy of regional development, and buttress the external cycle of the region. Taking 'population' as the root, we should guide the matching of population increase and employment, pay attention to changes in population size and age structure, encourage births moderately, and increase the introduction of talents to promote the inflow of young and strong people into the cities. With 'economy' as the driving force, we will optimise the regional industrial division of labour, adjust the industrial structure, introduce high and new technologies to upgrade traditional industries, promote the extension and integration of closely-connected industries, and create competitive alternative industrial clusters. On the basis of 'spatial vitality', the construction of regional spatial networks should be strengthened, and an attractive urban environment should be created to support the coordinated development of the region (Yu, 2024).

5 Summary

This paper identifies the contraction of the two major urban agglomerations of the Yangtze River Delta and the middle reaches of the Yangtze River from 2000 to 2020 through the multi-dimensional perspective of 'population flow - economic output - spatial vitality', and further analyses the spatial and temporal dynamics of urban contraction based on the main population contraction, and explores the spatial characteristics of the two types of urban agglomerations under the background of contraction, with the following main conclusions. The main conclusions are as follows:

Firstly, from the multi-dimensional identification of population-economy-space, it can be seen that the shrinking cities of the Yangtze River Delta urban agglomeration show the spatial characteristics of 'more in the north and less in the south, higher in the west and lower in the east', while the shrinking cities of the city agglomeration in

the middle reaches of the Yangtze River show the characteristics of 'more in the west and less in the east, higher in the north and lower in the south'. In terms of the distribution of bi-dimensional or multi-dimensional shrinkage cities, the Yangtze River Delta region is mainly located in the periphery, while the middle reaches of the Yangtze River tends to be distributed in the vicinity of the regional centre cities.

Secondly, analysing the time dimension, the contraction trends of the YRD urban agglomeration and the city agglomeration in the middle reaches of the Yangtze River show an opposite trend. In the time periods of 2000-2010 and 2010-2020, the number of shrinking cities in the YRD urban agglomeration decreases and intensifies, while the number of city agglomerations in the middle reaches of the Yangtze River increases and decreases, which is related to the fact that the two urban agglomerations are at different stages of development.

Thirdly, in terms of the type of contraction, the Yangtze River Delta Urban Agglomeration shows a 'periphery-core' structure, with population loss from the peripheral areas to the central cities occurring within the scope of the urban agglomeration, which mostly belongs to the type of phased contraction. The city cluster in the middle reaches of the Yangtze River shows a 'point-circle' structure, with the provinces as the scope of the phenomenon of circle contraction around the regional central city, and the population loss from the peripheral areas to a number of node cities, which is more of a potential contraction type.

For the two major city clusters in the context of contraction of different performance, targeted optimisation proposals: the Yangtze River Delta city cluster has basically entered the stage of integrated development, regional synergy is better, the future more consideration for the relative backwardness of the peripheral areas to further pull and boost, tendency to innovation, the introduction of talent and other policy guidance. The city cluster in the middle reaches of the Yangtze River is still in the stage of their own development, the three provinces have not yet reached the regional synergy drive, consider the core city of each province to make joint efforts, from independent development to the regional joint, to strengthen the competitiveness of the differences between the various regions of the city, and promote the balanced allocation of resources. As for the contraction of small cities caused by the overdevelopment of large cities, the governance means are more inclined to optimise the spatial layout of small cities, promote the fine development and smart contraction of small cities, cultivate their own characteristic industries and localisation, improve basic public service facilities, and promote the 'slimming and strengthening' of urban development.

The urban growth model is no longer applicable to the sustainable development of all cities and regions, and the planning discipline needs to reconsider the multidimensional impacts of urban contraction and urban regeneration strategies in practice, as well as the need to expand the current research paradigm of urban planning from 'growth' to 'growth and decline', as interconnected and interrelated. The current research paradigm of urban planning needs to be expanded from 'growth' to 'growth and decline' as interrelated urban development processes (Fernandez C, Audirac I and Fol S, et al., 2012). The phenomenon of city contraction in urban agglomerations brings more thoughts on regional synergy and integrated high-quality development: based on the metropolitan area to control over-concentration of population and inhibit the spread of contraction; shifting from factor accumulation to improving economic efficiency and promoting the implementation of bottom-up security policies; and different cities exploring location advantages and core competitiveness to promote balanced regional development. Urban contraction is a process of continuous change and adjustment, and dynamic assessment of the effectiveness of shrinking cities and the implementation of improvement measures to promote the refined development of cities is the focus of further research on the realisation of urban slimming and strengthening.

Equity of pediatric diagnosis and treatment hospital allocation from the perspective of supply and demand: a case study from Shanghai, China

Chen Ge, Wang Yuchen, Huang Jianzhong
Tongji University
Email: 1670865568@qq.com

Abstract
It has become a consensus to promote a balanced and equitable distribution of regional medical and health facilities, and hospitals that provide paediatric care are an important place and the last line of defence in safeguarding children's health. However, problems such as uneven distribution of medical resources and poor accessibility to nearby services are common. In order to understand whether there is equity in the allocation of paediatric hospitals, from the perspective of 'supply and demand', taking into account the spatial distribution and supply of hospitals, as well as the distribution of children and their demand, to explores whether there is an imbalance between the supply and demand for resources in different regions.

Keywords: Supply and demand balance, social justice, vulnerable groups, pediatric hospitals

1 Introduction

There is currently widespread concern about social issues related to children's health, and ensuring that the need to safeguard children's healthy development is not overlooked has become an important consideration in facility planning. Hospitals, as key venues for safeguarding children's health, serve as the last line of defence for their physical and mental well-being. This study examines the distribution of children's healthcare facilities from a supply-demand perspective to investigate how hospital layout impacts children's access to nearby services and the balance between supply and demand, thereby providing planning recommendations for the allocation of medical resources.

The urban-rural dichotomy has led to issues such as uneven distribution of medical facilities between urban and rural areas (Ni et al., 2025). Therefore, many scholars have conducted research on the distribution and accessibility of medical facilities. Existing studies have used various research units, including counties (Cheng et al., 2016) and townships/subdistricts (Zhong, Yang and Chen et al., 2016), and common measurement methods include the proportional model method (Kong, Li, and Zhang et al., 2008), the minimum distance model (Fan et al., 2017), the two-step moving search method (Deng et al., 2015), and the potential model (Wu et al., 2017). This study comprehensively considers the spatial distribution of the research subjects, as well as supply and demand factors, to analyse the differences in the supply and demand of children's healthcare resources across different regions.

2 Data and Methods

2.1 Research area and subjects

Shanghai Municipality was selected as the study area. Chongming Island was temporarily excluded from consideration due to its geographical isolation. The study scale was based on the administrative divisions of towns and sub-districts in Shanghai (Fig. 1). The population aged 0–14 years in each sub-district was considered the demand side, while hospitals providing paediatric care were considered the supply side. The study analysed the proximity of paediatric healthcare services, supply-demand balance, and facility competition, and proposed an evaluation of the layout of paediatric care hospitals in the city.

Fig. 1. Administrative divisions of Shanghai municipalities (excluding Chongming Island).

2.2 Data Sources and Processing

(1) Child Population Data.

The number of children aged 0–14 in each subdistrict of Shanghai was extracted from the seventh national census to serve as the demand volume for healthcare services. The centroid of each subdistrict was used as the location for healthcare service demand, with a total of 202 subdistrict demand points.

(2) Paediatric Hospital Data.

Referring to the Shanghai Municipal Government's 'List of Major Medical Institutions Providing Paediatric Medical Services in Shanghai,' paediatric care-providing hospitals were selected from Shanghai's medical POI data, including both general and specialised hospitals, as the locations of healthcare providers. The actual number of available beds at each hospital was queried as the supply volume of healthcare providers. Due to the inclusion of branch hospitals under the main hospital, a total of 84 hospital supply points were extracted.

2.3 Research Methods

Considering that medical institutions are public welfare facilities, the study first employs service area analysis to examine their proximity service capacity. It then uses the moving search method and two-step moving search method to analyse their supply-demand relationships. Finally, the Huff model is applied to analyse the influence ranges of each hospital, reflecting a certain degree of facility competition, thereby proposing evaluations and recommendations for the current distribution of paediatric hospitals.

3 Results and Analysis

3.1 Distribution of the Child Population and Paediatric Healthcare Facilities

First, the data was visually analysed using graded symbols to indicate the number of people aged 0–14, divided into ten categories based on natural breaks. As shown in Fig. 2 (a), children and adolescents are primarily distributed in suburban areas, with significant concentrations in districts such as Baoshan, Minhang, Pudong, and Putuo. In central urban areas, the distribution is densely concentrated, but each neighbourhood has a relatively small population.

From Fig. 2 (b), which shows the distribution of paediatric hospitals and the number of beds, it can be seen that hospitals in the central urban areas are generally larger in scale. This is likely because comprehensive hospitals are typically headquartered in the central urban areas, resulting in a higher number of beds. For example, Huangpu and Jing'an districts have several large medical institutions offering paediatric care. In peripheral areas, each district generally has one or two large medical institutions, with some smaller affiliated hospitals distributed around the periphery to meet local healthcare needs.

(a) Population aged 0–14 each subdistrict. (b) paediatric hospitals and number of beds.

Fig. 2. Spatial distribution of research subjects in Shanghai.

3.2 Proximity Service Analysis

Proximity services primarily consider the spatial relationship between supply points and demand points. Starting from a customer-oriented perspective, the nearest supply point for each demand point is determined. Due to the large spatial scale, Euclidean distance is used for calculation. Through GIS nearest neighbour analysis, the hospitals closest to each subdistrict demand point are identified. Figure 3 shows the number of times each hospital is the nearest facility. It can be seen that some hospitals are the nearest hospitals for five surrounding subdistricts demand points, while others are not the nearest hospitals for any demand point, indicating an uneven spatial distribution.

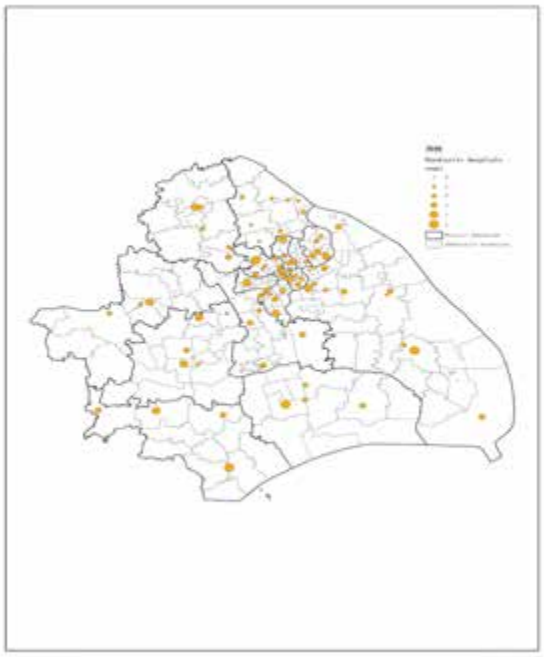

Fig. 3. Number of paediatric diagnostic and treatment hospitals in Shanghai as the nearest facility.

Secondly, from a facility-oriented perspective, buffer zone analysis (Fig. 4) shows that within a 5 km service radius of the hospital, i.e. a 15-minute commute, the central urban area is basically fully covered, but there are still a large number of demand points in the suburbs of Shanghai that are not covered. Within a 10 km service radius, i.e., a 30-minute commute, only a few demand points remain unaccounted for, and within a 15 km radius, all townships are within the service area. From a facility-oriented perspective, the central urban area is highly concentrated, making medical travel very convenient, while medical travel for children in suburban areas generally requires a longer time.

(a) 5km buffer (b) 10km buffer (c) 15km buffer

Fig. 4. Coverage of 5km, 10km and 15km service radius of Shanghai paediatric diagnostic and treatment hospitals.

3.3 Supply-Demand Balance Analysis

Supply-demand balance analysis primarily considers the capacity limits of facilities. The mobile search method is employed to simultaneously account for proximity-based service provision and supply-demand balance. As hospitals are public welfare facilities, the mobile search method is suitable for calculating the maximum service capacity available at each demand point. Given that paediatric healthcare facilities must achieve full coverage, and based on the '1560' healthcare circle planning in Shanghai, which stipulates that a tertiary hospital must be reachable within 60 minutes, a distance threshold of 15 km was selected for this study.

Figure 5 shows the maximum likelihood of obtaining services at each demand point, visualised using geometrical intervals. The supply-demand ratios in the central urban areas are relatively high, with supply fully meeting children's needs. Some townships in Baoshan District, Songjiang District, Minhang District, and Pudong New Area are also close to hospitals, with relatively high supply-demand ratios. However, some townships in the outer suburban areas have very low supply-demand ratios, with significant supply-demand imbalances observed in the northwestern and southeastern suburban areas.

Fig. 5. Ratio of supply and demand of hospitals for children in subdistrict of Shanghai.

Furthermore, the two-step moving search method is employed to consider scenarios where supply points serve multiple demand points simultaneously. The two-step moving search method analyses the accessibility of facilities through supply-demand relationships, ensuring that the supply-demand ratio within the search threshold range adequately accounts for both supply and demand (Zong et al., 2021).

As shown in Fig. 6, when considering the simultaneous provision of services at supply points, the central urban area has the highest service accessibility, while the southern suburban area has relatively improved medical accessibility, mainly because there are fewer demand points sharing the same hospital in the surrounding areas, allowing hospital resources to better serve local children. However, the current suburban areas of Qingpu and Jiading still face issues of poor accessibility. Spatial connectivity better reflects the supply-demand balance of paediatric healthcare facilities, with better conditions in the central urban area and southwestern suburban areas, and poorer conditions in the northwestern and eastern peripheral regions of Shanghai.

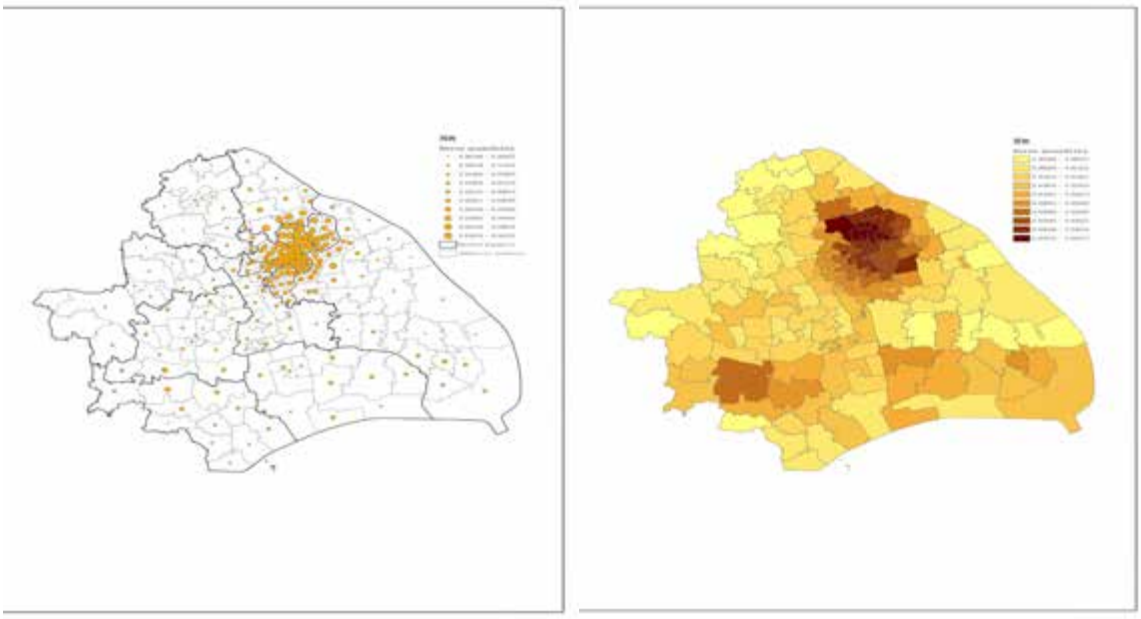

Fig. 6. Accessibility of children's medical services each subdistrict in Shanghai.

3.4 Facility Competition Analysis

There is also an issue of patient preference for hospitals. Although hospitals are public service facilities, it is necessary to consider competition between different hospitals. The aforementioned supply-demand relationship reflects the opportunities for children to choose hospitals, while facility competition reflects their preferences. The Huff model from the interaction model is selected, with hospital grading (Grade A > Grade B, Grade 3 > Grade 2) as the basis for determining attractiveness. with attraction increasing sequentially from Grade 2 Grade B to Grade 3 Grade A, and the power function distance decaying with a coefficient of 2. The maximum potential of each demand point is calculated (Fig. 7). Hospitals in suburban areas generally have greater potential in district centres, as medical institutions tend to be located in district centres to better serve the surrounding areas.

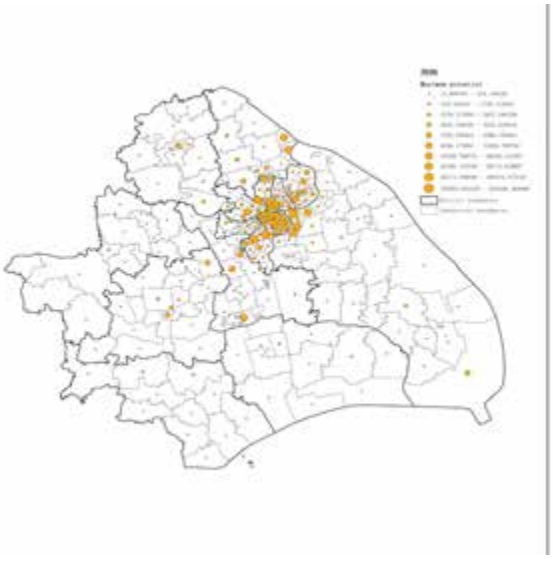

Fig. 7. Maximum potential of children's medical treatment in Shanghai.

From the sphere of influence (Fig. 8), it can be seen that under certain attraction settings, paediatric hospitals have their own main service areas. Competition is fierce in the central urban areas, with each hospital basically occupying one subdistrict. The suburbs are relatively loose. Based on attraction and distance, some hospitals need to serve the medical needs of children in a larger area. Overall, the further out the hospital is, the more subdistricts and townships it serves, but it is also relatively balanced, with each hospital serving several areas.

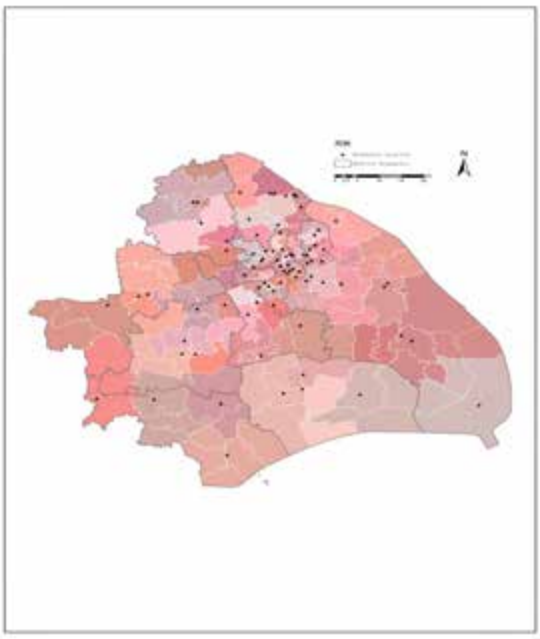

Fig. 8. Areas of influence of paediatric hospitals in Shanghai.

4 Summary

4.1 Conclusions

(1) From the perspective of spatial distribution characteristics, children and adolescents are primarily concentrated in the northern part of Shanghai, with a higher concentration in districts such as Baoshan, Jiading, and Pudong. Hospitals providing paediatric healthcare services are predominantly located in urban centres, with relatively balanced distribution in outlying areas, and each district has its own leading hospital.

(2) From the perspective of spatial proximity, hospitals located in district centres provide more services and are the nearest facilities to a higher number of demand points.

(3) From the perspective of spatial supply and demand, the central area has significantly higher supply and demand, while the central parts of Pudong, the southern part of Jinshan, and the central parts of Qingpu and Songjiang have relatively lower supply and demand. Considering the constraints on simultaneous supply capacity, the northwestern and eastern parts of Shanghai have poorer supply and demand, as these areas have a large number of children but fewer hospitals.

(4) From the perspective of hospital quality appeal and distance, the central urban area, Baoshan District, and Minhang District all have significant medical potential. From the perspective of influence distribution, hospitals in the outer suburbs serve the paediatric healthcare needs of more sub-districts, with relatively balanced distribution across corresponding sub-districts and towns.

4.2 Recommendations

Based on the above conclusions, the study proposes the following recommendations: (1) Overall, from a supply and demand perspective, Pudong, Qingpu, and Jiading districts have relatively insufficient paediatric hospitals. It is necessary to further supplement local medical resources and establish more hospitals specialising in paediatric care. (2) In terms of quality, Pudong has a higher concentration of attractive hospitals, while Qingpu and Jinshan districts lack sufficient hospital appeal. The penetration of tertiary hospitals, including service quality, lags behind other regions. It is necessary to further decentralise high-quality resources to local areas and build higher-quality paediatric hospitals.

Hospitals providing paediatric care serve as a crucial line of defence for ensuring children's healthy development. They should achieve full coverage within the region and maximise accessibility for children seeking medical care, thereby reducing the time required to reach a hospital. From the current layout of paediatric care hospitals, the supply-demand balance and accessibility in Shanghai's central urban areas are at a relatively high level, while suburban areas exhibit varying degrees of disparity in supply-demand balance and accessibility. In the future, it is recommended to adopt medical consortiums and resource sharing to drive the development of local paediatric hospitals. For example, medical consortiums can be used to integrate and reorganise the talent, technology, and information resources of medical institutions at all levels (Chen, Li and Zeng et al., 2018), optimise their supply and demand structure, promote the downward flow of high-quality medical resources, and provide more high-level hospitals for the treatment of children's diseases in a wider area, thereby driving the high-quality coverage of medical resources across the entire region.

Grassroots Organization and Informal Economy: Learnings from Hawker Sangram Committee

Binita Mahato

Arindam Roy
Affiliation: University of Cincinnati
Email: roya2@mail.uc.edu

Abstract:
The informal sector, characterized by unregulated economic activities, dominates the contemporary global economy and supports about 80% of all employed individuals in India. Grassroots Organizations (GROs) play a crucial role in legitimizing and supporting the informal sector, particularly when formal means are unavailable. The GRO, Hawker Sangram Committee (HSC) in Kolkata, India, has united hawkers' unions across the city, state, and country, formed the National Hawker Federation, and passed the 2014 Street Vendors Act, legalizing street hawking and vending in the country. This study presents the roles and practices of such GROs in legitimizing informal workers through interviews with HSC members and union leaders, focus group discussions with street hawkers, and photo documentation. As the informal sector is expected to grow with global urbanization, recognizing GROs' roles in supporting marginalized individuals can provide useful policy insights to governments, practitioners, and scholars across nations.

1. Introduction

1.1. Street Vending: A Quintessential Form of Informal Economy

The informal economy, more popularly known as the informal sector (Bhowmik, 2010), comprises a wide range of unregulated economic activities and provides jobs for almost two billion (61%) of the world's workers today (ILO, 2019). The informal sector refers to unincorporated enterprises not affiliated with government authorities or managed by legal entities but owned by individuals (ILO, 2019). In informal employment, workers are typically self-employed individuals, unpaid family workers, and wage workers with no written contract, social insurance, or protection (World Bank, 2015). The absence of strict adherence to national legislation, income taxation, social security, and employment benefits makes this economy prone to injustice, violation of human rights, and straying away from labor moralities.

In India, almost two-thirds of the workers are in the informal sector; 88.2% of such workers reside below the poverty level, and 79% live in cities (ILO, 2019). While the informal sector dominates the world's employment and the nature of urbanization, it also creates challenges to comprehend and control informality, especially in developing countries. As these nations continue to urbanize, informal economies like street vending[1], also often referred to as hawking, question their legitimacy and future sustainability. Due to a dearth of initiatives by formal regimes, informal grassroots organizations (GROs) have taken the lead in formalizing the informal. This paper investigates the roles of GROs in the informal economy by scrutinizing the actions of the Hawker Sangram Committee (HSC) in legalizing street vending and hawking in India. The goal is to understand when, why, and how GROs like HSC operates and facilitate grassroots actions. The paper argues that GROs, like HSC, play crucial roles in both the macro- and micro-levels of government structures and civic bodies, blurring the conventional boundaries of formal and informal.

1 The 2014 Street Vendors Act of India defines street vendor as "a person engaged in vending of articles, goods, wares, food items or merchandise of everyday use or offering services to the general public, in a street, lane, sidewalk, footpath, pavement, public park or any other public place or private area, from a temporary built up structure or by moving from place to place and includes hawker, peddler, squatter and all other synonymous terms which may be local or region specific."

Street vending is one of India's most popular forms of informal self-employment, especially in urban areas (Bose and Mishra, 2013). It is a crucial source of income for many as the organized sector cannot employ all of the working population, leaving a significant part still reliant on the unorganized sector (Banerjee and Ghosh, 2019). Many street vendors are migrant workers who immigrate from neighboring countries like Nepal, Bhutan, and Bangladesh or rural areas of the country, owing to the poor economic conditions of their native places. Most of these migrants are unskilled, have low literacy, and struggle to secure jobs in the formal economy (Anjaria, 2006). Some may have had work experience in the formal sector, such as factories, but had turned to street vending due to the decline of industries in India (Bhowmik, 2005). Despite the low income and uncertainty, street vending is a viable option as it requires low investment and a bare minimum skillset (Morales, 2000; Bhowmik, 2007; 2010; Tucker & Devlin, 2019). In India, it is estimated that street vendors share 2.5% of the urban population, but the actual number exceeds 10 million (Bose and Mishra, 2013). The average daily income of a street vendor is estimated at 65 rupees. Street vendors can earn up to 150 rupees, which is higher than the income of daily wage laborers (Anjaria, 2006; Shah, Joshi, & Gopinathan, 2023). Street vending generates hundreds of thousands of jobs in major metro areas, wherein each area, street vendors and hawkers contribute approximately 12,000 million rupees annual turnover (Bose and Mishra, 2013, pg. 167). However, in most cases, these incomes go undocumented and untaxed due to a lack of government initiatives to manage street vending.

The growing number of street vendors poses a challenge to urban development, especially in urban governance (Rafieian & Kianfar, 2023). Street vending creates spatial conflicts over the use of sidewalks and other vital public spaces in the dense cities of India. The Indian government has only been recently active in addressing the issue. However, the laws passed by the state and local governments have mostly been against the welfare of these vendors and hawkers. Moreover, due to the lack of government interventions, mobile and stationary vendors and hawkers have used unregulated make-shift stalls, thus creating visual pollution and leading to the common notion of being eyesores to the middle and upper classes in the city. Street vendors mostly support the urban poor by providing food, clothing, utensils, and other necessities at affordable prices. They also provide the middle classes with the convenience of shopping at the door front. However, the constant struggle of a city to maintain its "image" as a brand in the milieu of globalization and development has rendered informality undesirable (Kamalipour and Dovey, 2019). The undesirability of the street vendors by the upper cohorts and the government has led to attempts to evict them from the country's urban landscape, also known as spatial purification movements. As a reaction to these movements, the formalization of informal vendors began at the grassroots level with the formation of the HSC, a GRO in Kolkata. Their relentless efforts to legitimize street vending and hawking in India brought about the passing of the 2014 Street Vendors Act, which legalized street vending in the country.

Figure 1: *Street Vendors and Hawkers in Kolkata*

1.2. Kolkata and its Street Hawkers:

Kolkata is the capital of the state of West Bengal and was founded in 1686 with the conglomeration of three villages – Sutanuti, Govindopur, and Kalikata, by the East India Company as the colonial capital for the expansion of the British Raj. Today, the city houses a population of around 4.5 million, and the Kolkata Metropolitan Area has a population of around 14 million (Census 2011). The city has a population growth rate of 4%, owing to the migrants from neighboring states and countries like Bangladesh, Nepal, and Bhutan. Almost 23% of the city's population resides in informal settlements, such as slums, 19% of the population is below the poverty level, and more than 20% are unemployed. Of the total workers in the city, around 52% are migrant workers. Almost 65% of such migrant workers stay in the city for more than ten years, residing in slums or other informal settlements and earning livelihood through informal commercial activities, like street vending. In India, approximately 2.5% of the urban population is engaged in street hawking and vending, contributing to around 10 million street hawkers and vendors. Being India's third largest metropolitan city post-independence, especially following the huge migration from Bangladesh in the 1970s, Kolkata observed an influx of street vendors who opted for this mode of income as their only way of survival. Today, the streets of Kolkata are filled with hawkers and vendors who occupy portions of the sidewalks and vehicular roads to sell a wide range of fresh and prepared food items, stationeries, clothes, shoes, books, furniture, and whatnot. Most vendors sell from temporary stalls, shades, or even mobile carts. Their vending areas are typically fixed, except for mobile hawkers who roam around different parts of the city. A recent survey conducted by the Kolkata Metropolitan Corporation (KMC) identified 59,085 street hawkers in various hawking zones of all 144 wards of the city (Kolkata Municipal Corporation, 2024). However, these numbers only represent the "genuine" hawkers who have a valid vending license with the KMC and do not account for "ghost" ones who sell illegally (Ray, 2024). Regardless of their genuineness, hawkers pay around Rs. 265 crore (31.6 million USD) a year, almost 3% of their annual turnover, as bribes to various agencies, signifying a lack of management

and the prevalence of corruption in the hawking business in Kolkata (Ganguly, 2006). Figure 1 shows a variety of street vendors and hawkers in Kolkata and their vending styles.

1.3. Spatial Purification Movements:

In the mid-1990s, major metropolitan cities in India witnessed "spatial purification" movements to eliminate street dwellers, vendors, and hawkers – mostly immigrants from rural areas and neighboring countries (Sibley, 1995). These movements were led by the city governments orchestrating brutal approaches of excluding unwanted cohorts of society from its public spaces. Several such instances include "Operation Pushback" in New Delhi in the 1990s, designed to force illegal immigrants from Bangladesh out of the city who were mostly residing as slum dwellers (Ramachandran, 2002). Around the same time, in Mumbai (formerly known as Bombay), various neighborhoods undertook grassroots social and spatial purification movements by deploying cleanup projects to purge the poor and homeless out of their neighborhoods. Most of these initiatives were patronized by the local governments and law enforcement. For example, "the former Sheriff of Bombay had a vision of tree-lined boulevards, fountains, and playgrounds. There will be no slums. The streets will be clean, with wide pavements unencumbered by hawkers. People will stroll through pedestrian plazas. The night will be brilliant with majestic buildings and fountains" (Seabrook, 1996, pg. 48). The Brihanmumbai (Greater Mumbai) Municipal Corporation (BMC) employed several regimes to prohibit vending and begging on the beaches and gardens of the posh areas of the city, limiting the use of quality public spaces by the urban elites (Fernandes, 2004). This instigated the relocation of the hawkers and beggars to other parts of the city, creating further revolts among several middle-class residents and citizens' organizations challenging the BMC's legal zoning plans to prevent these relocations to their neighborhoods (Devidayal, 1998). Civic organizations, such as the Citizens for the Protection of Public Space, are examples of the rising conflicts between the bourgeoisie and the proletarians in many cities of India attempting to keep the 'ugly' occupants off 'their beautiful urban spaces.' Kolkata experienced similar forms of spatial purification movements in the 1970s and 1990s. In 1975, Kolkata saw an extreme rise in street hawkers due to the influx of immigrants from rural parts of West Bengal and neighboring countries like Bangladesh, Nepal, and Bhutan. The congestion and inconvenience caused by these informal workers to the public life of the streets motivated the city government to undertake active eviction actions. "Operation Hawkers" in 1977 and "Operation Sunshine Drive" in 1996 were two mass-scale eviction projects executed in Kolkata. "Operation Sunshine Drive" recruited around 10,000 policemen who forcefully demolished around 7,000 street vending stalls from major informal commercial corridors of the city (Dell and Ghose, 2009).

1.4. The Hawker Sangram Committee in Kolkata:

HSC was founded in August 1996 as a reactionary measure to the spatial purification actions witnessed in Kolkata. The organization became renowned and most vocal after Operation Sunshine (OS) Drive on November 24th, 1996, led by the Kolkata Metropolitan Corporation (KMC) and the Kolkata Police. The committee was formed by a coalition of 36 street hawkers' unions. Before OS, a smaller committee of four unions was in place in reaction to the 1981 Sealdah Flyover hawkers' eviction project, the first documented case of eviction and political protest. HSC works towards the welfare of street hawkers and protects the "pavement economy" and human rights from the pressures of global growth and development (HSC Constitution, 2022). HSC acts as a 'collective resistance' against the eviction of street hawkers post-OS (Bandhopadhay, 2016). The committee's mission is to unionize, organize, and unite street hawkers and existing hawker unions to protect and legitimize street hawking in West Bengal and India. They can be conceptualized as an umbrella organization of the hawker unions and categorized as "a voluntary, non-sectarian, non-profit making organization" (HSC Constitution, 2022). HSC also facilitated the formation of the National Hawkers Federation (NHF) in May 2001 – an association of Street Vendors across 28 States, with 1,188 Unions, including 11 Central Trade Unions and over 20 International Trade unions abroad. The committee operates under the leadership of Saktiman Ghosh, the HSC and NHF general secretary, and manages 132 hawker unions of KMC and neighboring Bidhannagar and New Town areas. The current members are a group of leaders of the unions affiliated with HSC. The HSC members represent unions registered under the United Trade Union Congress, the Indian Federation of Trade Unions, the All India Central Council of Trade Unions, the All India Trade Union Congress, the Indian National Trade Union Council, the Trade Union Coordination Committee, unions with the Socialist Unity Centre of India, and few other unregistered unions (Lahiri, 2022).

The main source of funding for HSC is from membership fees and donations. The organization collects around 50,000 INR (around 600 USD) annually through member union subscriptions and donations. These funds are used for expenses incurred towards prints and stationery items, meetings, travel, festivities, office electricity charges, rallies and processions, audits and renewals, newspapers and magazines, social welfare programs, disaster reliefs, and other miscellaneous expenditures. The list below shows the operations HSC run on a regular basis:

- issuance of identity cards to new hawkers; creating new unions based on need and interest
- monitoring affiliation and legitimacy of existing member unions
- organizing monthly meetings with member unions to address concerns and issues
- communicating with KMC's Mayor in Council of Hawkers Rehabilitation Plans, State Government, Central Government, and other government bodies for policy implementation and validation
- organizing annual rallies and processions, such as the International Hawkers' Day on May 26 and Operation Sunshine Day on November 24
- facilitating protests against pressing government policies and actions against hawkers' welfare
- representing and communicating hawkers rights to local, state, regional, national, and international conferences
- connecting national and international stakeholders, such as United Nation bodies and Ministries of Development and Poverty Alleviation in India and in Southeast Asia
- engaging in intellectual and scholarly discussions through workshops and seminars
- developing policies, design guidelines, and acts for hawkers' welfare
- organizing periodic workshops to train and educate hawkers on hawking rules and practices
- staying vigilant about illegal hawking in HSC affiliate member union areas and in the city in general

1.5. What roles does GRO play in the Informal Economy?

A few studies, like Lahiri, 2022; Bandyopadhyay, 2009, 2011, 2014, and 2016, have researched HSC's actions in passing the 2014 Street Vendors Act, but their role as a GRO is yet to be analyzed. This study aims to understand how GROs work and their roles in legitimizing the informal when formal means are unavailable by analyzing the case of HSC. While it is widely accepted that GROs play crucial roles in solving local-level issues (Uphoff, 1993; Brown & Ashman, 1996; Ostrom, 2004; Hilmi, 2012; Recio, 2015), their approach to solving such issues is not scrutinized enough, especially from the perspective of their contribution to the informal economy. GROs like HSC have often been observed to organize themselves in a scenario that emerges as an immediate response to the cause, in this case, to stop the evictions of the hawkers. However, very little is known about how they organize themselves without any training or assistance from a formal organization. This research attempts to investigate such modes of operation by understanding HSC's roles in formalizing and managing the informal street hawkers and vendors. The study emphasizes the importance of GROs in the sustainability of informal street hawkers and vendors in India (and the Global South). The study also highlights possible coalitions between GROs and formal organizations, such as city corporations and planning departments, that can foster better ways to manage urban informality.

2. GROs and Informal Economy:

2.1. Defining GROs:

Organizations are typically associated with the sector of society they belong to or represent. For example, public agencies represent the state sector and corporations belong to the market sector ((Brown & Ashman, 1996). In such categorization, GROs are considered the basic local building blocks of society and are typically recognized as organizations serving at the local, communal, and group levels of decision-making and activity for development (Uphoff, 1993). Although there are many ways to understand grassroots, most scholars consider them as local organizations that are comprised of and benefit local people (Uphoff, 1993; Brown & Ashman, 1996; Ostrom, 2004; Hilmi, 2012; Recio, 2015). They are clearly distinguished from national or regional organizations that remain distant from the local community for whom they work and provide benefits. GROs are also considered different

from Non-Governmental Organizations or NGOs. NGOs represent the civil society sector but may or may not comprise or work for the grassroots (Brown & Ashman, 1996). Grassroots are characterized by the purpose they serve in society. For example, in defining grassroots innovation, Hilmi considers that GROs are formed "at the bottom of the pyramid, usually due to necessity, hardship, and challenges" (Hilmi, 2012, p.g. 2). GROs solve local problems often overlooked or ignored by formal organizations or due to the absence of relevant formal institutions (Bhaduri and Kumar, 2011). GROs can also be defined as the byproducts of collective actions exercising human agency that requires more than one individual to contribute to an effort to achieve a certain outcome (Ostrom, 2004; Recio, 2015). GROs are associated with the "ungovernable" cohorts of the population (Recio 2015) and are referred to as the fringe stakeholders of urban development and processes (Chowdhury, Kourula, & Siltaoja, 2018). With these notions, HSC qualifies as a GRO created at the grassroots level by informal street hawkers and vendors to prevent their eviction representing the grassroots agency.

2.2. Urban Informality:

Urban informality is an idiom of urbanization and a logic through which differential spatial value is produced and managed (Roy and AlSayyad, 2004). Informality is "a sphere of unregulated activities that exist outside the formal order of urbanization" (Roy, 2010, pg. 98). It is a "mode of production of space, expression of class power and have the ability to command infrastructure, services, and legitimacy" (Roy, 2011, pg. 233). In planning terms, informality represents "a state of deregulation" (Roy, 2009, pg. 80), as public land management, use, and ownership cannot be controlled by established or "formal" laws and regulations and exists due to open and multiple interpretations of laws and regulations in the Global South (Berry, 1993; Holston, 2008). Urban informality exists due to inadequate formal infrastructure, but the complexity of urbanism in Indian societies and the Global South lies in the diffused boundaries between formal and informal. As Mehta (2019, pg. 239) points out, "by viewing informality as the "other' and through the lens of the formal, we cannot fathom and appreciate these processes and the benefits they entail." Therefore, urban informality can be understood as the coexistence of the formal and the informal in terms of activities, legitimacy, regulation, institutionalization, and production/ reproduction of space and interaction between the formal and the informal by means of everyday resistance, survival strategy, conflict and resolution, and expression of class power (Mahato, 2020). In the societies of the Global South, including India, urban informality contributes in two ways. Firstly, increasing differences between the two extremes of society give rise to structural adjustments favoring the elites and middle classes – forcing the marginalized population to seek refuge in informal means of living and occupation. Informality as a process of providing shelter to the undesirables of society is preferred because of its nature of negotiation between legality and illegality, legitimacy and illegitimacy, and authorized and unauthorized, and acts as a "logic of resource allocation, accumulation, and authority" (Roy, 2009, pg. 83). Secondly, informal institutions and relations provide power and existential purpose to the grassroots – an alternative means of solving urban issues. Informality challenges the conventional socio-spatial structure of developing societies and is increasingly being institutionalized out of necessity.

2.3. Role of GROs in Urban Informality:

GROs are increasingly being associated with the informal sector, especially in establishing agencies for the informal population (Lindell, 2010; JumaAgaya, Ungaya, & Okuto, 2021). In recent years, we have seen the "institutionalizing informality" in India and other countries of the Global South through the standardization of labor relations and commodity chains within the informal economy and affiliation of informality through unionization (Ustyuzhantseva, 2015; Bandyopadhyay, 2016; Schoenecker, 2023). GROs play important roles in such institutionalization. With the absence of formal means of managing and controlling informal activities and population, urban informality has sought refuge to self-help through grassroots in many instances. It is widely assumed that informality exists because the poor are politically passive groups – therefore, marginalized or informalized (Bayat, 2000). However, the notion of the passive poor is being challenged to become increasingly active and powerful. They are becoming mainstream, giving rise to a new social class – the "precariat" who, as informal and marginalized populations, continuously reclaim their place in society through grassroots initiatives (Schierup et al. 2015). Informality is the survival strategy where marginalized groups opt for informal ways to counter unemployment or inflation and demonstrate everyday resistance or micropolitics through protests among subaltern groups due

to the dearth of collective action (Bayat, 2000; Butcher, 2021). Organized political practices are often seen to herd and feed such survival politics of the poor (Chatterjee, 2004). GROs contribute not only to the survival strategies of the poor but are also an involuntary part of the formal political structure and advocates of the marginalized (Mitlin, 2001; Roy, 2009). Castells (1983) defines these forms of grassroots insurgency as "urban populism," which occurs in day-to-day activities. GROs instigate the urban territorial movement by supporting urban informality's claim over urban space (Chatterjee, 2004) and advocate to mark informality not to be marginalized but integrated into the urban society (Bayat, 2000). The spatial purification movements are such urban territorial movements and their counter-movements by the informal sectors that showcase the advancement of the informal into formalized society through grassroots. A grassroots social movement is a group-level phenomenon initiated and maintained by an umbrella organization that unites fragmented groups for collective action (Bettencourt, 1996). GROs maintain coalitions and leadership between groups and provide basic resources and technology.

2.4. Conceptualizing HSC as a GRO:

The case of HSC presents the tension between the governed and the government, showcasing the complex urban dynamics of subaltern urbanism. These dynamics of civil society have been studied and conceptualized in various ways in the discourse concerning subaltern urbanism witnessed in Indian cities. Chatterjee (2004) discusses a unique aspect of politics known as "political society," which involves the entanglement between the elite and subaltern politics in rights, security, and welfare issues. Political society provides the space for negotiation and contestation with the governmental agencies for population groups that organizations like HSC represent (Chatterjee, 2004). The efforts of HSC also resonate with what Appadurai (2019) calls "deep democracy." Deep democracy reframes the movements of the urban poor to the rights of citizenship that signify new modes of mediation for reclaiming urban space from the urban elites. Non-governmental actors, like the hawkers in this case, are ubiquitous parts of global governance and local democracy, and hence, they give rise to a new form of democracy that connects similar actors across the globe (Appadurai, 2009, p. 31).

Scholars bring forth many non-traditional aspects of HSC's success in the hawkers' movement of Kolkata. The hawkers forced themselves to be archived as a legitimate part of society, a tactic for marginalized groups that Bandyopadhyay (2011) calls the "politics of archiving" to establish themselves as a visible category of the public. HSC's actions in Kolkata and its larger impacts on India's hawking culture also negate the traditional ways of understanding cities as motions of urban infrastructure. Bandyopadhyay (2017; 2022) reimagines the hawkers' movement in Kolkata as the politics of "'durable obstruction' that 'spatialized motion' or distributed motion across spaces" through the "organized encroachment of the sidewalks by hawkers" (2022, p. 206). HSC's movements can also be understood through the lens of the "politics of inclusion," coined by Roy (2009), to explain the ways GROs "seek to construct and manage a civic realm" (p. 160). The efforts to be included in civil society by the marginal groups represent "civic governmentality," "a spatialized regime" that uses tools of mediation, knowledge production, and self-norms by the marginalized population (Roy, 2009, p. 160).

This paper positions itself around these critical discourses on the processes of the subaltern to gain rights in civil society by conceptualizing HSC as a GRO for various reasons. Firstly, HSC is constituted by grassroots actors for grassroots needs and acts at the grassroots level. This character distinguishes HSC from other union groups in Kolkata and India, which historically have been affiliated with political parties in contrast to HSC's non-political aspirations. Secondly, the formation of HSC was a departure from the traditional protest against the hawker evictions by individual hawkers and unions to a more organized protest that involved the community for human rights beyond just hawkers' interests. Thirdly, HSC acts more as an umbrella organization of hawkers and hawker's unions than a union or association itself. This calls for an understanding of the workings of HSC as a grassroots agency rather than a union body. Finally, the expansion of HSC's efforts to local, regional, national, and international levels resonates with the concept of deep democracy and calls for understanding how grassroots actions connect global grassroots actors in the neoliberal globalization processes. This characterization of HSC leans more towards the qualities of GROs than traditional union bodies whose realms typically remain localized. This paper, thus, presents the case of HSC as a success story of a GRO that has multi-level roles addressing issues of informal and marginalized economic actors beyond the scope of unions or associations.

3. Methods:
The study uses a multi-method approach to understand the role of HSC in formalizing the informal street hawkers and vendors in India. This includes an archival study of old newspaper articles and working documents of HSC, interviewing HSC board members and selected union leaders, focus group sessions with their member hawkers, and observation and photo documentation of HSC and hawkers' daily operations, protests and rallies, and their hawking and vending practices.

3.1. Archival Study
Due to the unavailability of online or published materials, the study relied on the archives of the HSC office located in Central Kolkata. The office has a collection of historical documents, including past newspaper articles on the eviction of hawkers across India, court cases fought by HSC, their meeting agendas and minutes, action plans, budget and spending calculations, documents on past workshops and events, action plans, proposals for vending and hawking space and stall designs, HSC strategic planning reports, and their constitution. The archives relevant to the study were scanned and converted to PDF for analysis. An archival study was conducted, and conversations with the HSC general secretary helped in understanding the history of the HSC and its roles, along with the dialogues it engages in with the government and the hawkers. Additionally, some published materials on rights and regulations about street hawkers in India were found on the website of the National Association of Street Vendors of India.

3.2. Interviews
The study organized a total of 36 semi-structured interviews in October 2022. These interviews included meetings with the HSC General Secretary, Vice President, and union leaders. The research also interviewed the Kolkata Corporation Mayor in Council and conducted a focus-group meeting of fifty hawkers representing the eight studied hawkers' unions. The interviews aimed to listen to the past, current, and future initiatives of the HSC governing board members who have been involved with the organization since its inception and the hawkers' and their union leaders' current challenges and future needs.

3.3. Observations and Photo Documentation
Following the interviews, the research conducted field visits to the vending locations of the interviewed hawkers' unions to capture their actions and behavior. The aim was to observe the hawkers' use of public spaces, understand the types of goods they sell, learn about their interactions with customers, and deal with authority personnel like the police. Short videos were recorded while walking through the streets where hawkers were present, and relevant still images were extracted from these videos. The research also photo-documented the annual Operation Sunshine Day procession of 2022, attended by thousands of hawkers' in the city, and the speeches offered by HSC leaders and other union leaders. The speeches were especially useful in gauging current issues of hawking and vending, ongoing actions, and future aspirations.

3.4. Data Analysis
The interviews, originally in Bengali, are first translated and transcribed into English. Personal information found in the recorded audio is not included in the transcriptions. All the transcriptions are then imported into NVivo, a software used for qualitative analysis. Content analysis is done for the transcriptions using codes. The transcriptions are carefully read line by line, and each small idea is coded as one code. A total of approximately 270 different open codes are identified, followed by selective coding by unifying ideas. A set of selective codes is further grouped into themes to understand the roles of HSC at macro and micro levels, as described in the findings. Figure 1 shows an example of the coding process, depicting how raw interview data were used to generate themes that helped identify HSC's macro- and micro-level roles, such as its role as an arbitrator.

RAW DATA	OPEN CODING	SELECTIVE CODING	THEME
Yes, the Hawkers in Kolkata know about the union. When they face any issues they contact us and we go there so solve it.	Hawkers can address local concerns to Unions	Conflict resolution at local level	Role of an Arbitrator
We sort out that to allocate hawkers can where they can sit, what to say to the police.	Unions addressing conflicts with police		
Now they (police) have realized no one can remove them if they (the hawkers) are under any hawker's committee.			
We have to go out and look for instances of illegal hawking.	Unions looking out for illegal hawking		
Now, maybe there is political help, but we don't want to take that help because, in that case, we need to do a lot of favors for them.	No need for doing favors for any party	Non-political affiliation	
The plus point was that it was non-political platform, no personal need shall be there, so that there could be proper fight for the welfare of the society.	Welfare of hawkers is the main priority		
	No personal gains		
As far as I know what the central government is thinking or doing for the hawkers is done by the hands of this HSC. In this way, we do not have to rely on any political party	No reliance on any local political party		

Figure 2: Sample Coding Process

4. Findings:

HSC's efforts to formalize and legitimize informal street hawkers in Kolkata and India have been unique, unprecedented, and revolutionary. Their struggle for equal rights was ultimately rewarded by the central government's passing of the 2014 Street Vendors Act. Although the actual implementation of the Act is still underway, HSC's journey since its inception tells the story of how GROs operate to address grassroots social issues, in this case, to stop the eviction of the hawkers (Figure 3). Adapting Lahiri's (2022) interpretation of HSC's political strategies, this paper classifies HSC's role in formalizing the informal hawkers into macro and micro levels (Figure 4). The macro and micro level roles position HSC in the spectrum of the two extremes of the political society – the formal or established institutions versus the informal or marginalized groups. The study finds that GROs like HSC stand in between the formal and informal dichotomy and, in many ways, blur the boundaries between the state and civic. As Roy (2009) talks about the informality of India's planning regime characterized by deregulation, ambiguity, and exception, HSC's macro and micro-level roles give a perspective of ways GROs can take advantage of an informalized government structure to solve grassroots issues.

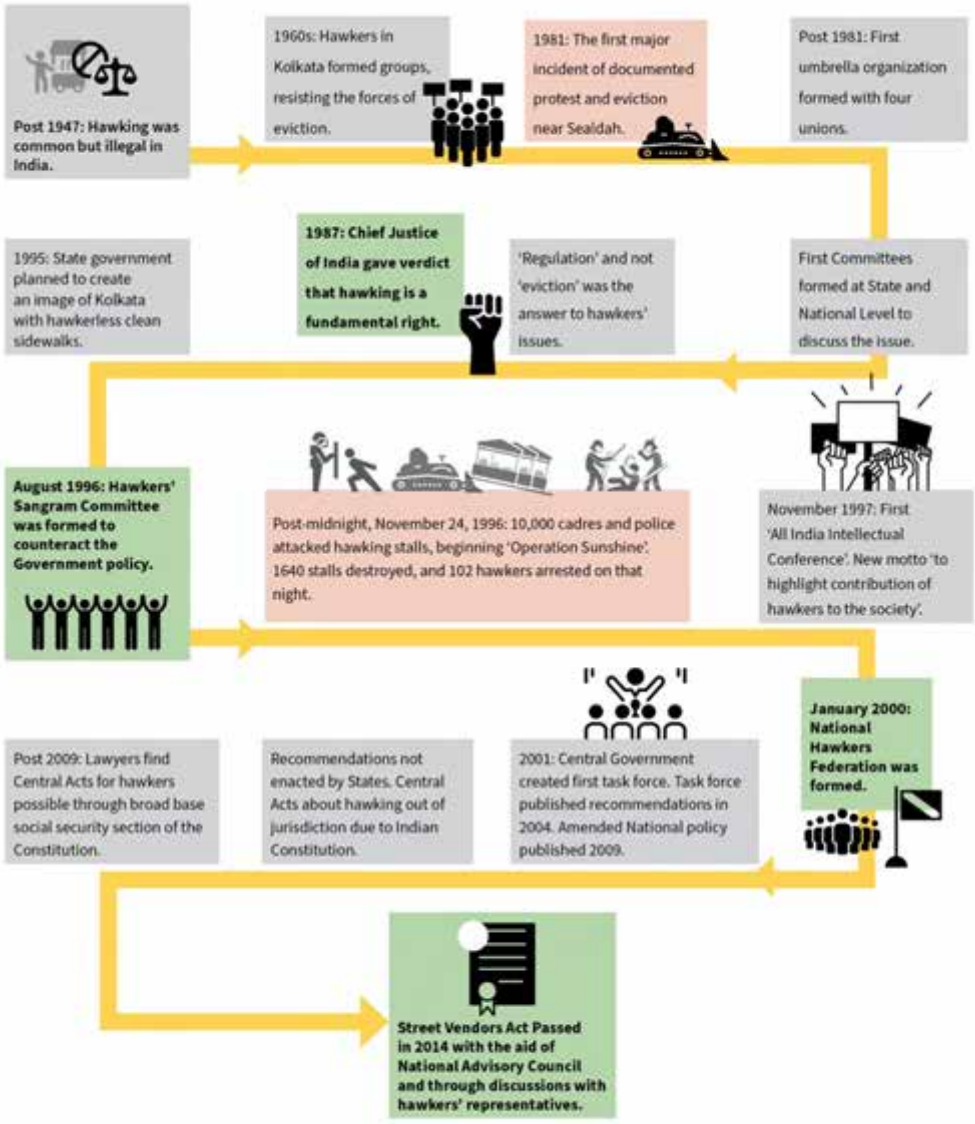

Figure 3: The Hawker Sangram Committee's Actions to Legalize Street Vendors in India

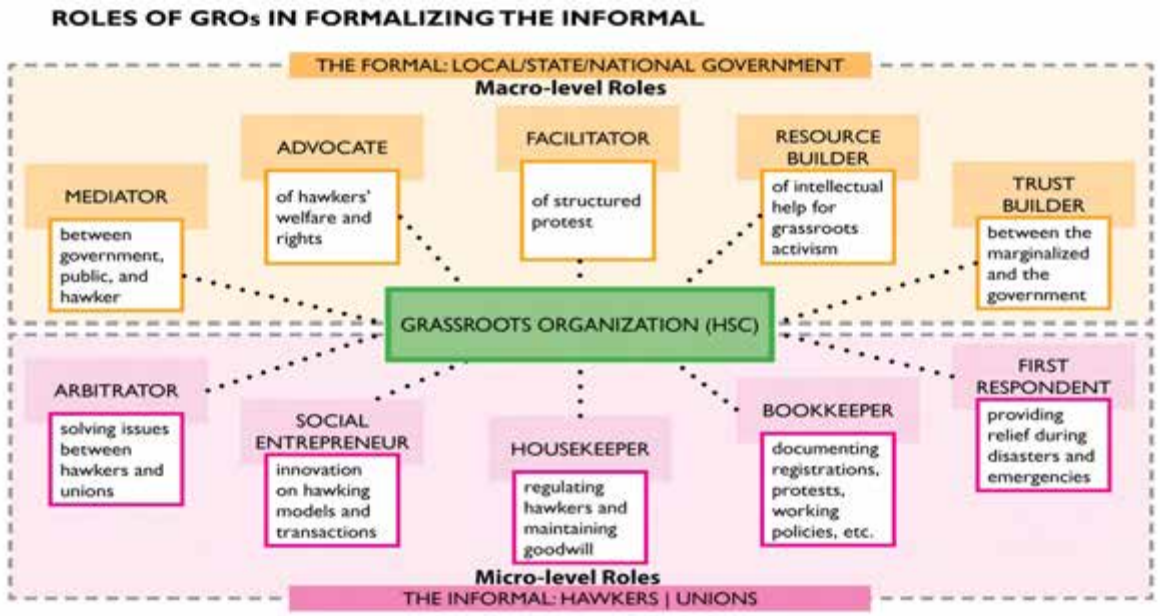

Figure 4: The Macro- and Micro-level Roles of GROs in Formalizing the Informal

4.1. Macro-level Roles:

Macro-level roles of HSC are carried out through its relationship with the formal sector at the municipal, state, and national scales. HSC takes crucial initiatives to present local grassroots issues to higher authorities that can provide more permanent and universal solutions. While the HSC was initially formulated to protest an eviction issue in central Kolkata, over the years, HSC has facilitated the formation of state and national-level GROs that eventually resulted in the passing of the 2014 National Vendors Act. The multifarious roles played by the HSC at the macro level can be defined as that of a mediator, an advocate, a facilitator, a resource builder, and a trust builder.

4.1.1. Mediator

HSC acts as a mediator between the government, the public, and the hawkers when hawkers' needs are beyond the scope of HSC or the unions and, therefore, require government interventions. Vending zones create conflicts among pedestrian users and hawkers as the Vendors' Act allows only 1/3 of the sidewalk width for vending, which is difficult to enforce in narrow sidewalks of older parts of the city. HSC works on finding alternate vending designs/plans and better vending zones that will resolve such conflicts. HSC also mediates conflicts over the relocation of vendors, which often affects customer access to hawkers. In many such relocations, major thoroughfares create barriers because of the lack of adequate pedestrian infrastructure like crosswalks, pedestrian signals, subways, or foot overbridges. Other needs for mediation include creating parking spaces near big natural markets and involving hawkers in the relocation plans to identify suitable locations for hawkers in case displacement is necessary for valid development purposes. HSC's major act of mediation has been the inclusion of a Town Vending Committee (TVC) in each city in the 2014 Act to increase grassroots representation in the government. TVC is to be composed of 40% hawkers, 10% NGOs, and the rest members of the city council with an aim to keep a directory of hawkers, issue hawking licenses controlling their numbers up to 2.5% of the total population, and demarcate vending and non-vending zones to avoid encroachment issues of street vending. TVC works for the welfare of the hawkers and the city government or the public and has been the first-ever attempt to create a formal and informal coalition. Organizing annual rallies and protests also form an important role of the HSC in reminding the government of their presence and solidarity among the associations, as pointed out by the Secretary of the Ballygunge Hawkers Association: "I think they are very important. To have the organization working and keep it strong, these gatherings are vital. These are the 'tactics.'"

4.1.2. Advocate

HSC advocates for the welfare and rights of hawkers. Although TVCs are responsible for the facilities and benefits of hawkers, the committee is not yet fully functional. In its absence, HSC advocates for the needs and demands of its member unions and hawkers to the KMC. HSC presents proposals to alleviate hawkers' working conditions, including access to basic infrastructure, healthcare, financial benefits, and better vending zones and structures. Basic infrastructure, such as access to drinking water, electricity, and toilets, especially for women hawkers, is a dire need for many hawkers. "There is no problem with water, but the toilet is a problem. This problem is very common here." (Secretary of the Kalighat Vivekananda Hawker committee). The Calcutta Electric Supply Corporation (CESC) is reluctant to provide electricity to the shops for fire risks due to the use of combustible materials like plastic in the shops. The inability to afford electricity forces some hawkers to run businesses only in daylight or to borrow electricity connections from nearby big shops and residential homes at higher prices. HSC also urges KMC to provide durable, sustainable, safe, and aesthetically pleasing shops and stalls for the hawkers to diminish environmental and fire hazards and elevate the city's beauty and has provided concept designs of stalls by partnering with a food service equipment company (Congas). Other issues HSC advocates for are government-led awareness workshops and health camps for hawkers, access to existing social benefits like health insurance cards and student credit cards, newer policies for bank loans for hawkers, and office spaces for the unions like other government employees.

4.1.3. Facilitator

Without formal initiatives to legalize hawking and vending, the HSC acted as the facilitator of the legalization of street hawkers in India. Hawkers' unions existed before the formation of HSC but operated in fragments in their respective geographic areas. The unions hardly interacted or worked together due to the absence of a unifying body. HSC provided a structure for hawkers' fight against displacement by uniting the fragmented hawkers' unions of the city under one umbrella, facilitating a common platform for expression. "This platform had given right to the hawkers and also gave the place so that they can be united. Many people who cannot share their problems got a platform to share and raise their voice against all the odds," explained the General Secretary of HSC. With the help of HSC, the unions and their hawkers could stand in solidarity to fight against the government and be more powerful than remaining siloed in their respective unions. HSC also structured the revolution by conducting organized protests and processions, slowly gaining momentum from the local level to the state level and then to the national level. HSC also facilitated the creation of a hierarchical structure for organizing the street vendors and hawkers by forming the NHF. NHF worked for the unification of hawkers from other states and spearheaded the hawkers' protests of eviction at state and national levels. The 2014 Act was possible owing to the unified nature of the protest and the systematic way grassroots actions were taken to the national level. Currently, NHF is led by the Central Secretariat, and state leaderships represent hawkers' unions across the states.

4.1.4. Resource Builder

Hawkers need intellectual help in their fight for equal rights. The hawkers, union leaders, and HSC leaders did not have the capacity in terms of education, skill, or power to materialize their strategies to prevent the eviction of hawkers. They seek help from the "face of the society" to support their cause, gain public attention, and contribute through their expertise. HSC held an intellectual conference where they brought together big personalities like film stars, singers, poets, social activists, lawyers, scholars, teachers, and even ministers. "In 1997 we organized an 'intellectual conference'. There was no intellectual in West Bengal who did not attend" (HSC General Secretary). These pioneers of the society brainstormed strategies, slogans, and action plans to modify the perception of hawkers. The intellectuals' involvement helped them modify their "motto of the revolution from fighting against eviction to studying the contribution of hawkers in society," stated the HSC General Secretary. It is also important to note that initially, the Spatial Purification Movements, like OS, were glorified by poets and singers to uplift the aesthetics of the city. Hence, it was even more important to include prominent personalities who could be insistent against such glorifications and make a case for the hawkers on humanitarian grounds. Intellectuals like lawyers were an integral part of their success as they helped them win court cases against the government, helped formulate policies into laws, and laws into acts. The current president of the NHF is a veteran

lawyer who assists in passing hawking and vending laws nationwide. HSC also collaborated with local scholars to find national and international research articles and case studies about the rights of informal hawkers and their legitimization process to legitimize their claims for hawking and vending rights in the country.

4.1.5. Trust Builder

The past eviction events made hawkers distrust the government's willingness to help the marginalized. HSC was crucial in reinstating that trust between the hawkers and the city officials. This was achieved through efforts on multiple fronts. HSC maintains a non-political status by operating on neutral grounds, avoiding political patronage, and attaining its objectives through systematic and democratic means. Historically, hawkers and unions were affiliated with political parties and used for political agendas as vote banks. However, during the spatial purification movement, the political parties supported the evictions regardless of their connection with the unions. Historically, informal hawkers have earned their livelihood by paying bribes to the police and being exploited by political leaders to find ways into the workforce. Periods of despair and ignorance instigated a sense of distrust toward authority and government. An organization concerned for its true welfare seemed surreal to them. HSC gained this trust by employing hawkers as union members and leaders. Similarly, HSC leaders belong to the working class and lead a lifestyle similar to the hawkers. This was unlike previous instances of politically patronaged hawkers' unions where union leaders were often political party members, aspiring to become ministers and leading a fancier lifestyle than their member hawkers. Being apolitical helped the HSC, as stated by a union representative from Kalikapur Hawkers' Association, "The plus point was that it was a non-political platform, no personal need shall be there so that there could be a proper fight for the welfare of the society. Gaining public trust by highlighting hawkers' contribution to society is another major achievement of HSC. As many residents, especially the middle and upper cohorts, deemed hawkers as eyesores of cities, a way to gain their support was to take human rights ground and showcase the contribution of the hawkers to society. Hawkers run a parallel economy that alleviates poverty, helps with unemployment, creates a huge economic turnover, and provides shopping convenience at the doorstep. HSC encourages its member unions to maintain goodwill with the residents of the neighborhoods where they vend and hawk, ask reasonable prices for their goods, provide services like product return options and home delivery opportunities when needed, and have "eyes on the street" for the area's safety.

4.2. Micro-level Roles

GROs like HSC are vital community support for the grassroots population. In addition to communicating the grassroots' needs to local, state, and national authorities, HSC has taken several steps to address the micro-level needs of the unions and the hawkers. These are local needs that can be resolved by HSC and do not always need to be brought to the government. At the micro-level, HSC performs the roles of an arbitrator, a social entrepreneur, a local problem solver, a housekeeper, and a bookkeeper.

4.2.1. Arbitrator

Issues with informal hawking exist at multiple levels and on multiple scales. While some issues need interventions from higher authorities, such as dealing with court cases, stopping evictions, or formulating acts, other trivial issues are left under the unions' jurisdiction. Unions deal with minor hawker-related issues, such as managing vending and hawking zones, illegal hawking, police interference, or other local issues. The president of the All-India Women's Hawkers Federation stated, "We sort out that to decide where the hawkers can sit... what we can tell the police, all these things." The individual unions are responsible for employing rules and policies and regulating hawking in their respective geographic areas. If a conflict or an issue arises locally, the area's union leader is first to be approached. The union leaders make the first attempt to resolve the conflict. If the issue cannot be solved at the union level or is beyond the union's scope, the union leaders present the issue to HSC during their monthly meetings. HSC here acts as a body for arbitration. It is important to maintain the hierarchy and mode of operation to address grassroots issues. HSC holds neutral ground for being non-political and not having any vested interest in individual hawking and vending areas. The hawkers always respect HSC decisions as they appreciate the organization's and its leadership's benevolence, which has been fighting for hawkers' rights. Also, as most union

leaders are vendors or hawkers, their opinions may sometimes create conflicts of interest. HSC possesses no such conflicts. The issues mostly brought to HSC concern new hawkers' registration or spatial conflicts between two street vendors. Since the number of hawkers in existing vending zones is limited, HSC typically sends the new vendors and hawkers to a new market area that can accommodate newcomers. Union leaders do not have the authority to assign a hawker to a zone and, therefore, resort to HSC for such arbitration needs.

4.2.2. Social Entrepreneur

The modes of commerce are constantly changing in the contemporary world. As grassroots individuals like street hawkers and vendors do not have the resources to adapt to that change, GROs like HSC must act as social entrepreneurs to help them with new and innovative ways of vending and hawking to keep up with other shops and retailers. Many hawkers reside below the poverty level and have limited access to modern technology for economic transactions, such as smartphones, online banking, or mobile banking. This limits their ability to cater to younger generations and middle and higher economic groups of customers who often prefer to use such transaction modes for convenience over cash transactions. Hawkers' livelihoods are also threatened by online shopping giants like Amazon, Flipkart, Swiggy, Zomato, and others, which steal their customers, especially the tech-savvy young population. While addressing such shortcomings needs more formal initiatives, hawkers and union leaders rely on HSC for innovative ways to compete with the changing economic environment. One of the ways HSC tackles the situation is to encourage hawkers to match or sell at lower prices than online vendors with options for return and refund. Alongside this, HSC has been organizing workshops to train hawkers to use Paytm and other forms of cashless transactions. These transactions require hawkers and vendors to have bank accounts, online access, and smartphones, which many of them, especially those from rural areas, do not have. HSC has created a working relationship with local banks as guarantors for creating bank accounts and online banking options for their hawkers. In addition, HSC planned to establish an online association with hawkers as suggested by a union representative, "We once decided to take an initiative to open a website named hawkerbajaar.com - where the hawkers themselves would deliver the things and essentials at the doorsteps." However, this initiative was affected by the advent of the COVID-19 pandemic.

4.2.3. Housekeeper

With the lack of government initiatives, HSC continues to perform housekeeping tasks to regulate in-house hawkers and maintain their goodwill to society. In the absence of the TVC, the HSC manages new union formations, existing union affiliations, and new hawker registrations with the KMC. When a group of hawkers is interested in forming a union under the affiliation of HSC, the committee hears their appeal and sends them the constitution to be adopted and followed. The HSC General Secretary stated, "We identify a set of leadership positions among them like a president, a secretary, a working president, a treasurer, and working committee members." HSC then sets a fee structure and defines norms, such as having meeting minutes, taking decisions unanimously, and, when required, taking decisions through voting. Any new union under HSC is reported to the NHF and included in a national list of unions. HSC requires the union leaders and their hawkers to attend HSC meetings, conferences, and other assemblies, pay dues and comply with the HSC-defined constitution to maintain their affiliations. HSC and individual union leaders look after preventing illegal hawking in their respective jurisdictions. Another major housekeeping task for HSC is ensuring its member unions maintain goodwill in the community.

4.2.4. Bookkeeper

Without the TVC, the HSC performs the bookkeeping tasks for all its member unions and hawkers. Even before passing the 2014 ACT, HSC strategized to document the protest process systematically so that it could be used to present an authentic claim locally, regionally, nationally, and even internationally. HSC archived and kept records of each meeting, conference, rally, procession, eviction action, court case, and notable event, including news articles on hawkers' evictions. Since there was no official log of the street vendors and hawkers in the city, an important aim of bookkeeping was to survey hawkers and keep records. HSC kept a count of the number of hawkers in the city, the types of items they sell, hawking and vending modes, and vending zones. This was important to manage and organize the hawkers during protest rallies. Bookkeeping also helps HSC oversee where hawkers need to be unionized or reach out to unions not affiliated with HSC. In addition to keeping records, HSC surveyed

the conditions of their member hawkers and vendors and published regular reports on their socio-economic profiles. They also published conference and academic papers, newspaper articles, proformas, and memorandums and kept minutes of meetings to organize their efforts. Since its inception in 1996, HSC has maintained and archived files in its small office in Central Kolkata. Due to space limitations, they have been working since 2018 on digitizing the documents and making them available to the public through the NHF website. As TVC is not active yet, HSC oversees managing vending licenses and hawker registrations. HSC bookkeeping also maintains a dossier of member unions, leadership, and hawker information. Earlier, the hawkers did not have identity cards. "That time, we didn't have cards. We used to give pictures and signatures according to our post (Secretary of the Ballygunge Hawkers Association). The HSC issues hawkers' identity cards, collects membership dues, and maintains funds to run regular activities. Since 2020, they have been able to computerize and expedite the registration process. This has been an important achievement for the HSC. Since the number of hawkers in the city is increasing, it has been difficult to maintain physical records. Nonetheless, HSC hopes that TVC will take over this job soon, as HSC operates with limited staff, most of whom are hawkers and can only participate in HSC activities part-time.

4.2.5. First Responders

Unlike formal shopkeepers or business owners, informal street hawkers and vendors are more vulnerable to natural calamities and other disasters. As government reliefs in such events do not reach these informal cohorts, HSC performs as first responders on such occasions. Both before and after the passing of the 2014 Act, HSC has been the "go-to" place for local hawkers and vendors. The street vendors and hawkers mostly use temporary and cheap building materials like plastics, tin shades, and bamboo structures, which are prone to destruction during storms, cyclones, heavy rain during the monsoon season, and fire. These disasters have economic consequences since they do not have business insurance, often leading to total business loss. Street vendors and hawkers have relied on HSC's help to recover from such downfalls without any other means of revival. During many such disasters, including the recent COVID-19 pandemic, HSC collected donations, food and sanitation items, clothing, and stationeries and provided them to the hawkers whose livelihoods were affected. On the occasion of the unfortunate deaths of hawkers, HSC offers their vending rights to immediate family members to support them in times of turbulence.

5. Conclusion:

Even though the 2014 Act legitimized hawking in India, a full formalization of street vending and hawking is yet to be accomplished. A decade after the Act was passed, the formation of a TVC in Kolkata and many other cities is still in process. Formal authorities tend to be reluctant to meet the needs of the informal population (Bhowmik, 2000; Joshi, 2018), as is apparent in the case of street vending in India. The demands for equal rights, permanent shops, and basic facilities are deemed unnecessary or are not prioritized by the authorities. The demand for permanent and durable vending stalls is ignored, with the perception that "hawkers should remain hawkers and not try to be shop owners," as expressed by the mayor of the Council of KMC when interviewed. The Act also requires KMC to survey the current hawkers in the city to monitor their numbers, vending zones, and items they sell. The survey was recently finished but created immense unrest among the hawkers due to several aspects of illegality and associated corruption. Interviews with the hawkers revealed that the Act has not fully gained their trust and reliance on the government. They consider the HSC, especially their general secretary Shaktiman Ghosh, their "savior" and sole means to deal with the government. The police and political leaders are the "opportunists" who help the hawkers for their own benefit. The decade-long hiatus of the actual implementation of the Act, especially the skepticism of TVC's workings, has rekindled the long-held distrust and hatred against the government among the informal street hawkers.

It is apparent that the major issue of street hawking is encroachment, which is allowed by politicians and the police in exchange for bribes from hawkers. In some recent "anti-encroachment" and "hawker pushback" drives by KMC to clear off city streets from hawkers, clashes occurred between the law enforcement officers and the hawkers who demanded that they were allowed to sell in those locations by the authorities (Zeeshan, 2024). The current chief minister of the state criticized these actions, supporting hawkers' claim, saying, "I do not believe in first allowing encroachers and then using bulldozers. I want restrictions to be imposed from the beginning,"

and warned the authorities, declaring, "Politicians who incite hawkers will be arrested, regardless of their party affiliation, and police officers supporting them will either be arrested by their superiors or removed from their positions" (Ghosh & Banerjee, 2024). In the interviews, many hawkers revealed the chief minister's party's endorsement of their welfare. They also expressed their distrust of the previous government, which initiated the spatial purification movements in the 1970s and 1990s. Similar issues of hawking politics can be observed in other Indian cities, such as Mumbai, where a similar eviction drive has invoked the questions of hawkers' rights and legality (Pinto, 2024). Nevertheless, marginalized populations like street vendors are significant voting assets for politicians and are often manipulated for political gain (Bandyopadhyay, 2024).

GROs like the HSC are the backbone of the informal population and economy, with or without the brace of formal institutions. Street vendors and hawkers would not have thrived or survived without their support, let alone been legalized. GROs are the missing link in the overlapping, often conflicting spheres of the formal and the informal. In polarized societies like India, the formal and the informal lie at the extreme ends of the population cohort. Their interdependency and interrelationship are full of friction, which, perhaps, can only be lessened by means of GROs. The HSC was formed to stop eviction, but its role and importance did not stop after inhuman evictions were stopped and hawkers became legal in India. It continued to exist even more actively because of the limitation of formal institutions in effectively attending to the needs and demands of the marginalized.

In a country where the neoliberal economy is channeled by the pressure of development forces to create neoliberalizing middle classes and the new rich (Fernandes, 2004), the informal economy supports the urban poor. With patterns of political and climate migrations around the world, the informal economy has been and will remain the lifeline of immigrants (Mingione, 1999; Rodgers, Shahid, & Williams, 2019). Since formal institutions do not have any vested interest or benefit from the informal economy (Huang, Xue, & Wang, 2019), GROs like HSC will continue to be the lifeline of the informal population. Street vending and vendors have thrived, not just in India but worldwide, through the changing epochs of society and the economy (Morales, 2007). The challenges that vendors encounter in India may be unique. However, issues such as bribery, harassment, lack of licensing, confiscation of goods, and eviction drives are problems that vendors face in almost every city worldwide. As political, social, and economic variables change, hawkers and vendors innovate and improvise to adapt. This research sheds light on one of the many such ways the actors of the informal economy perform. A universal generalization of the informal economy is unreasonable (Williams & Round, 2007), and therefore, the case of HSC may be unique and not the only way grassroots continue to exist and excel. Perhaps a comparative analysis of other cases around the world will provide a holistic insight into the ubiquitous relationship between the GROs and the informal economy

Floating Population Structure in Shrinking Area of Shanghai Metropolitan Area: An Urban-Rural Mobility Network Analysis

Ge Wan[1], Jianzhong Huang[1,*]

Abstract
With the advancement of urbanization in China, urban and rural areas are experiencing different trends and structural changes in population mobility. In particular, some shrinking areas exhibit diverse and complex migration patterns. However, few studies have examined these areas from the perspective of spatial mobility networks. This paper employs an urban-rural population mobility network analysis to explore the structural characteristics and movement patterns of the floating population in the shrinking areas of the Shanghai metropolitan area. It identifies the key factors influencing population structure and provides new insights for local governments to promote regional and urban-rural integration and to formulate effective policies for managing shrinking areas.

Keywords: Population structure; Floating population; Shrinking area; Network analysis; Shanghai metropolitan area

1. Introduction

China's long-standing planning practices have been dominated by a growth-oriented development paradigm, leading to the neglect of urban shrinkage. However, with the intensification of low fertility and population aging, the country is entering a stage of overall population decline. As policies promoting regional integration and urban-rural fusion take effect, the siphoning effects of central cities have led to varying degrees and types of shrinkage across many urban agglomerations and metropolitan areas. While Chinese scholars have mainly focused on urban shrinkage in the Northeast due to long-term reliance on resource-based industries, less attention has been paid to shrinkage in economically developed regions such as the Yangtze River Delta and Pearl River Delta. Yet, research has already identified signs of shrinkage in parts of cities like Shanghai and in certain counties and small towns within cities like Taizhou, Yancheng, Nantong, Jiaxing, and Wuxi. As a result, China's traditional growth-driven urbanization model may no longer be applicable, marking the arrival of a post-growth era in urban development.

Current research on shrinking areas primarily focuses on cities, with relatively little attention given to shrinking towns. However, towns are often typical areas experiencing population loss, aging, and hollowing out during China's urbanization process, facing the dual challenges of natural population decline and out-migration. Population structure has profound implications for regional economic development and long-term competitiveness, which in turn determines whether regional shrinkage is temporary or long-term. Martinez-Fernandez (2013, p. 303-308) suggested that from the perspective of global urban networks and spatial mobility networks, shrinking cities may experience a weakening or even severing of their connections to global flows. However, empirical studies testing this hypothesis remain limited. Compared to research on urban networks, studies focusing on urban-rural network characteristics are scarce. Therefore, this study aims to explore the characteristics of shrinking areas within metropolitan regions from the perspective of spatial network linkages, emphasizing the population agglomeration capacity of towns. Unlike Western countries, China's ongoing urbanization has made population loss less pronounced in cities. Urban shrinkage in China is not only a result of internal urban factors but also of regional and spatial interactions. Thus, examining shrinking areas through the lens of factor flows provides a more effective way to assess their future development trajectories.

This study focuses on all towns within the Shanghai metropolitan area, an area characterized by frequent economic interactions and distinct network connectivity. First, traditional demographic data are used to calculate population changes in each town, providing a preliminary identification of shrinking towns. Next, massive mobile phone mobility data are utilized to construct urban-rural and rural-rural population flow networks within the metropolitan area. By analyzing population travel profiles—including flow volumes and demographic attributes

such as age and gender—this study examines the population mobility and structural characteristics of shrinking towns. It identifies key influencing factors, ultimately proposing optimization strategies. By adopting the novel perspective of population mobility networks, this study offers a new analytical framework for understanding shrinking areas in metropolitan area and provides valuable insights for promoting regional coordination, urban-rural integration, and the development of targeted policies for managing shrinking areas in China.

2. literature review

At present, the definition of shrinking areas is primarily based on population change and involves multiple dimensions such as demographics, economy, and time. However, due to differences in national development contexts and statistical standards, there is no unified measurement criterion. Moreover, the phenomenon of shrinkage in China's urbanization process has unique characteristics, and changes in population size alone may not objectively reflect regional shrinkage.

Existing studies on shrinking cities tend to focus on descriptive analysis. However, with the ongoing processes of economic globalization and regional integration, the traditional "place-based economy" rooted in comparative advantages of resource endowments is gradually being replaced by a "flow-based economy" centered on capital, technology, markets, and innovation, with flow space becoming the mainstream paradigm. In economics, some scholars have begun using total factor productivity combined with econometric methods as criteria to determine regional shrinkage or growth (Yang, 2022). Wu (2021) utilized a unique dataset on intercity investment flows in mainland China to demonstrate a significant positive correlation between network centrality of investment and population change, revealing a link between urban shrinkage and the loss of external investment. Sun (2022) proposed that urban shrinkage reflects a relative or absolute decline in a city's "regional capacity to agglomerate development factors" within regional linkages, leading to the "relocation" of population and other key development factors—a market-driven behavior, with population outflow being merely a manifestation. With the emergence of flow space theory, research on spatial networks has deepened, and advances in information technology have enabled the use of mobile signaling data and Internet app-generated big data to track various flows. These data, supported by increasingly mature algorithms, are widely applied in studies of urban agglomeration and metropolitan spatial structures, thus making it increasingly feasible to analyze shrinking areas from the perspective of element flows.

The identification of shrinking cities has primarily relied on static data analysis, lacking dynamic analysis from the perspective of network connectivity and an essential understanding based on the outflow of development factors. Overall, current methods for identifying shrinking cities are mostly population-centered, using statistical and spatial data to construct multi-dimensional indicator systems. With technological advancement, simulation-based models have also begun to emerge (Liu, 2016). While prefecture-level cities remain the main unit of measurement, studies identifying shrinkage at the district, county, and township levels are increasing.Some scholars have proposed that, from the perspective of global urban networks and spatial flow networks, shrinking cities may also exhibit a weakening or even severance of their connections to global flow spaces—particularly in terms of knowledge and information flows (Martinez-Fernandez, 2014). The inequality between cities and regions integrated into global networks and those excluded from them is intensifying. Cities connected to global networks are the "winners," while others struggle to maintain ties and survive in global economic competition. Cities bypassed by global networks may fall into what Castells termed the "black holes" of globalization—isolated from or disconnected from global growth engines. Therefore, shrinking cities can also be analyzed through their association with urban factor networks. By constructing regional factor networks based on factor flows, areas with weak or disrupted connections to other parts of the region can be identified, thereby detecting cities with shrinkage tendencies.

Research on population structure has mostly relied on static statistical analysis, with limited focus on how population structures evolve in shrinking cities. Demographic structure is often only used as an indicator for identifying shrinkage, rather than as a subject of study in itself. There is a lack of systematic investigation into how population structures change in shrinking cities and how these changes in turn affect urban population,

economic, and social development. Yet demographic shifts can profoundly influence regional economic growth. Therefore, integrating the study of mobile populations with population structure is crucial for understanding the socioeconomic impacts of population decline (Chen, 2025).

3. Methodology and data

3.1 Research area and data source

The Shanghai Metropolitan Area, located in eastern China, is a key component of the Yangtze River Delta. In 2022, the governments of Shanghai, Jiangsu Province, and Zhejiang Province jointly released the "Shanghai Metropolitan Region Spatial Coordination Plan", which aims to advance the national strategy of integrated development in the Yangtze River Delta. The planned area includes the administrative regions of nine cities: Shanghai, Wuxi, Changzhou, Suzhou, Nantong, Ningbo, Huzhou, Jiaxing, and Zhoushan—referred to as the "1+8" city cluster. The Metropolitan Area features diverse patterns of population agglomeration and, as the most functionally concentrated and economically advanced area within the Yangtze River Delta, it is characterized by a high degree of economic clustering and rapid development. With multiple interconnected centers and a strong need for close collaboration, the region plays a pivotal role in driving coordinated regional development. Therefore, integrated urban-rural development holds particular importance for the Shanghai Metropolitan Region.

This study takes the Shanghai Metropolitan Area as the research area, dividing the nine cities into 913 sub-city administrative units at the street (township) level. Based on the "Statistical Compilation Rules for Administrative Division Codes and Urban-Rural Division Codes" (index no. 410A03-1201-201708-0006) issued by the National Bureau of Statistics, each administrative unit was classified by its urban-rural attribute using the first digit of its urban-rural classification code: 1 for urban areas and 2 for rural areas. In total, 404 urban streets and 495 townships were identified.

This study primarily uses statistical data and mobile signaling data. Population statistics are derived from China's Sixth Population Census (2010) and Seventh Population Census (2020), both providing resident population data at the street and town levels. The mobile signaling data consist of weekday origin-destination (OD) travel data from October 2022. Users' movements were located using cell tower grids, and their residence and workplace locations were identified by the longest stay during nighttime and daytime, respectively. The population flow analysis in this study focuses mainly on work-related commuting based on residential origins.

3.2 Research approach and methodology

Compared with traditional studies that explore the characteristics of shrinking areas using static statistical data, this research aims to examine the features of shrinking regions within metropolitan areas from the perspective of regional spatial network linkages, focusing on the population agglomeration capacity of towns. Therefore, this study first adopts the conventional but crucial indicator of population change by calculating population growth rates to identify areas with significant population decline. Next, based on large-scale population mobility data, a population flow network is constructed for the Shanghai Metropolitan Area. This network is analyzed at two levels: urban–rural and rural–rural population flows. These levels respectively represent the connections between shrinking towns and both urban subdistricts and neighboring towns, and can reflect, to some extent and in a timely manner, the ability of shrinking towns to attract and retain population development factors. Based on the constructed networks, the structural characteristics of mobile populations in shrinking towns are statistically analyzed in both urban–rural and rural–rural networks. This analysis is of great significance to promoting urban-rural integration and coordinated development in the Shanghai Metropolitan Area.

The first step involves identifying shrinking towns. Although there is no consensus in academia on how to define shrinking areas, negative population growth remains a key criterion. Given the continued urbanization in China and its significant impact on rural populations, this study follows relevant methodologies (Wang and Xue, 2016; Cheng, Zhang and Liu, 2021) by first selecting towns with negative population growth between 2010 and 2020. Then, the average population change rate is calculated for all townships in Jiangsu Province, Zhejiang Province, and Shanghai. By computing the relative population change rates that exclude the impact of urbanization,

townships within the metropolitan area that still exhibit negative relative growth are defined as shrinking towns.

The second step focuses on analyzing the population mobility network. Using mobile signaling data, the subdistricts and towns are treated as network nodes, and the total bidirectional commuting trips between them are used as the measure of network connection strength. This enables the construction of an urban–rural and rural–rural commuting population network within the metropolitan region. Commuting flows reflect labor force mobility and indicate the degree of productive economic collaboration between regions. Based on this, statistical analyses are conducted on the gender, age, and other characteristics of the mobile population in shrinking towns.

4. Results and discussion

4.1 Distribution characteristics of shrinking towns

Based on the calculation of town-level relative population change rates after excluding the impact of urbanization, a total of 135 shrinking townships were identified in the Shanghai Metropolitan Region. In terms of quantity, Shanghai and Nantong have the highest number of shrinking townships, with 31 and 33 respectively, mainly concentrated in Chongming District (Shanghai) and Rudong County (Nantong). Suzhou, Wuxi, and Changzhou have fewer shrinking townships, each in the single digits, while Zhoushan, Ningbo, Jiaxing, and Huzhou each have around 15.

In terms of spatial distribution, the shrinking townships in the Shanghai Metropolitan Region show a combination of localized clustering and a perforated pattern, mainly concentrated in peripheral areas of the metropolitan region and the border zones between cities. Overall, although current research using cities or districts as the statistical unit does not indicate significant population decline within cities in the Shanghai Metropolitan Region, a more detailed analysis at the township level reveals varying degrees of shrinkage within cities. This better reflects the unique development characteristics of different areas. For example, towns in the Suzhou-Wuxi-Changzhou area maintain stable population levels due to a solid industrial base and balanced internal economic development. In contrast, the areas surrounding Shanghai are affected by the strong siphoning effect of the central urban core and related policies, leading to frequent population mobility in towns. (Figure 1)

Given the limitations of traditional population statistics, shrinking towns in different regions should be further categorized and analyzed. Big data sources such as population mobility data can dynamically reflect the current development status of towns.

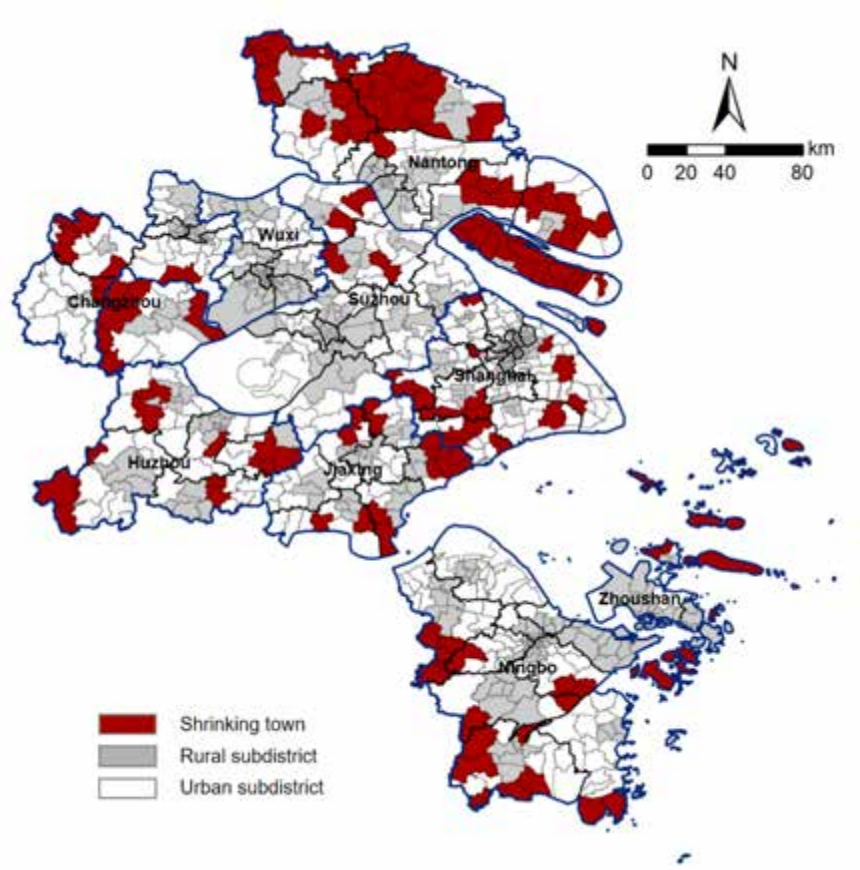

Figure 1. Location, urban-rural classification and shrinking towns layouts of Shanghai metropolitan area

4.2 Connection characteristics of shrinking towns

The travel connections of shrinking townships were filtered and visualized . In both the urban–rural and rural–rural networks, shrinking townships show stronger internal connectivity within their respective districts or counties, indicating the significant constraint imposed by administrative boundaries. However, cross-boundary connections are more prominent in the rural–rural network, suggesting that inter-township interactions are less influenced by administrative borders.

Among the 2 types of networks, shrinking townships in Shanghai, Suzhou, and Jiaxing exhibit higher overall connection volumes, while those in Ningbo, Zhoushan, and Huzhou generally show lower levels of external connectivity. This may be due to topographical constraints such as the Siming Mountains and Tianmu Mountains. In the urban–rural network, shrinking townships are not only closely linked to urban subdistricts within their counties but also maintain functional connections with central urban areas. In the rural–rural network, the connections between shrinking townships and other rural areas appear more evenly distributed.**(Figure 2)**

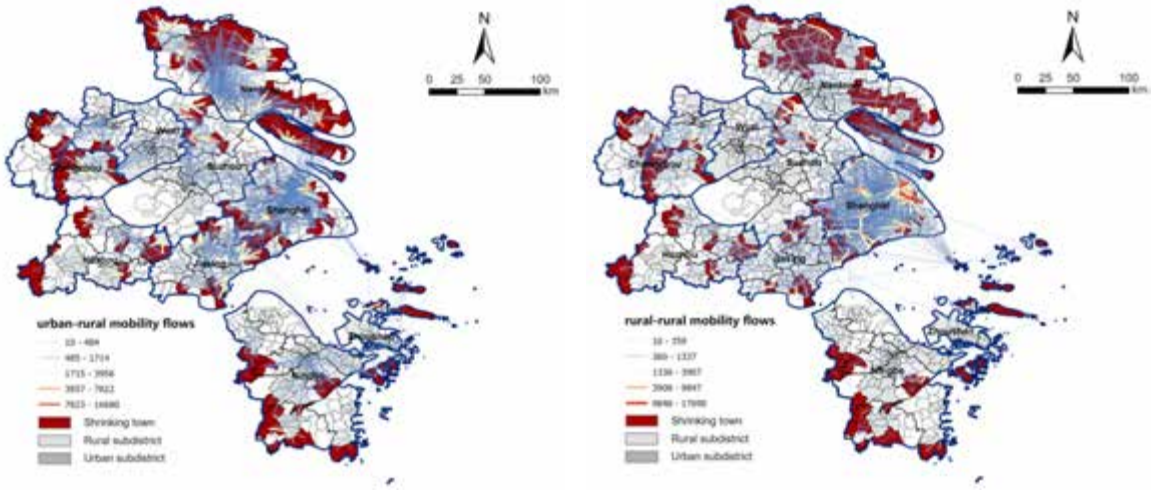

Figure 2. Characteristics of urban - rural population flow network in shrinking towns of Shanghai metropolitan area

4.3 Structural characteristics of the floating population in shrinking towns

The structural characteristics of the floating population in shrinking towns are analyzed from five key aspects: gender, age, education level, income, and consumption level. By comparing the characteristics and differences of the floating population between rural–rural and urban–rural flows, this study conducts a comparative analysis of the overall development trends and internal disparities within the shrinking towns.

4.3.1 Gender characteristics

In both rural–rural and urban–rural population mobility networks, the proportion of males is higher than that of females, which is closely related to the development characteristics of townships. As the main labor force, men are typically the primary source of household income in these areas. In the rural–rural mobility network, the gender imbalance is more pronounced, with a male-to-female ratio of approximately 1.4:1. This indicates that in township labor distribution, men are mainly engaged in labor-intensive industries such as construction and logistics, while women are more likely to migrate through marriage or work in the service sector.

In the urban–rural mobility network, the gender ratio is more balanced at 1.1:1. This suggests that urban–rural labor flows are more likely to involve couples working together or seeking nearby employment opportunities, reflecting a trend of "family-based migration." **(Figure 3)**

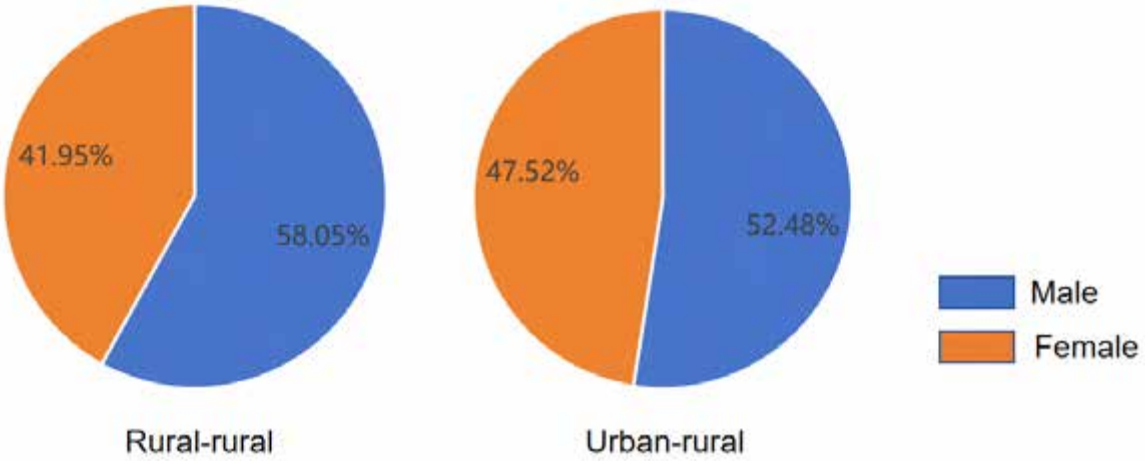

Figure 3. Gender characteristics of floating population in Shanghai metropolitan area

4.3.2 Age characteristics

Among the mobile labor population in shrinking townships, young and middle-aged individuals aged 16–35 remain the main force. In the urban–rural mobility network, this age group accounts for a higher proportion—up to 70.19%—reflecting the strong demand for young labor in urban labor-intensive industries and physically demanding jobs, which attracts more people to engage with urban areas.

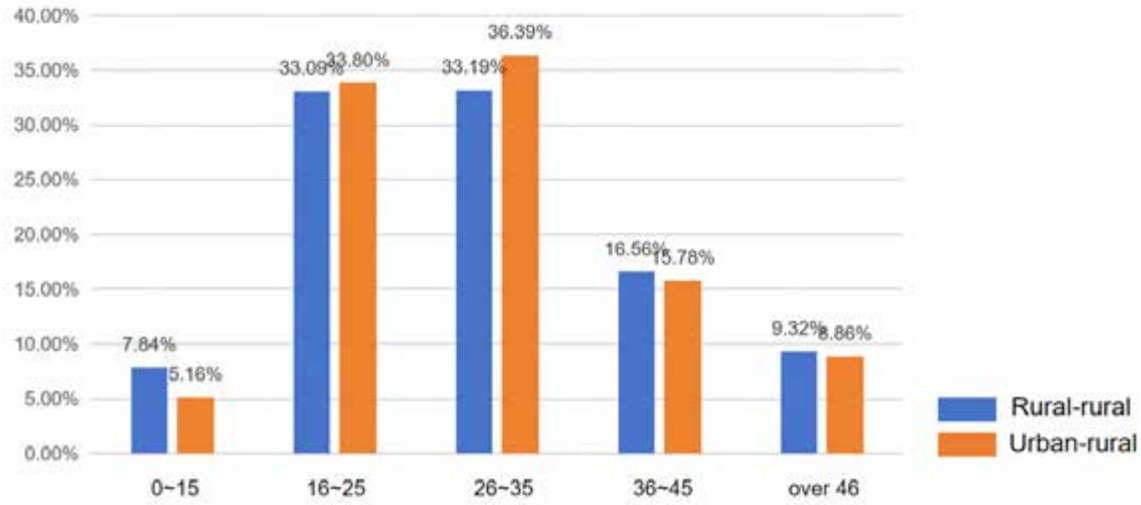

Figure 4. Age characteristics of floating population in Shanghai metropolitan area

In contrast, the proportions of elderly and youth within the mobile population are relatively low, showing a polarized distribution. In the rural–rural mobility network, the proportions of youth and middle-aged or elderly individuals are slightly higher, indicating that these groups tend to move over shorter distances between townships **(Figure 4)**.

4.3.3 Educational attainment

The education level of the mobile labor population in shrinking townships is categorized into three types: high (associate degree and above), middle (high school or vocational school), and low (junior high school and below). The educational attainment of this population shows a polarized pattern, with a predominance of individuals with higher education levels. This differs from internal rural–rural mobility and suggests that those leaving the townships tend to be more highly educated, which is often associated with skill advantages and higher income levels.

Among the urban-rural mobile population, the proportion of individuals with higher education is significantly greater. This indicates that, in addition to some medium- and low-educated laborers, there is also a group of well-educated and skilled professionals. This trend aligns with the industrial structure of the Shanghai metropolitan area, where the secondary and tertiary sectors dominate, and agriculture holds less competitive advantage-resulting in a labor force with relatively higher education levels.

In contrast, the rural-rural mobile population has a higher proportion of individuals with lower education levels. This group is likely engaged in agricultural work, basic manufacturing, or service-sector jobs that require minimal skills.**(Figure 5)**

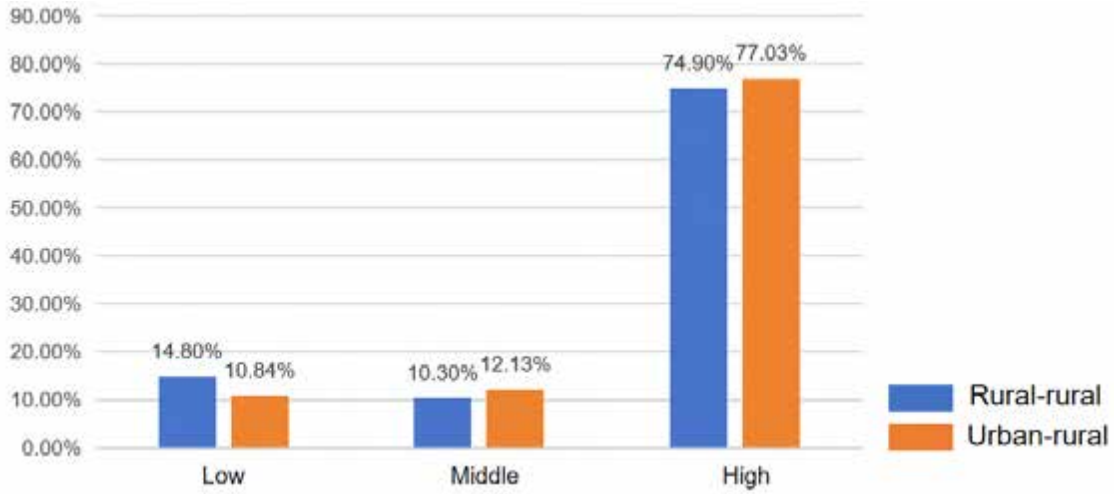

Figure 5. Educational attainment characteristics of floating population in Shanghai metropolitan area

4.3.4 Income and consumption level

In terms of income and consumption levels, both types of mobile populations-urban-rural and rural-rural-are primarily characterized by low income and low consumption, which is closely related to the overall level of development in townships. For township residents, incomes tend to be unstable and grow slowly. Consumption is generally low, focused on basic needs such as food and clothing, with relatively limited spending on housing, education, healthcare, and other areas.

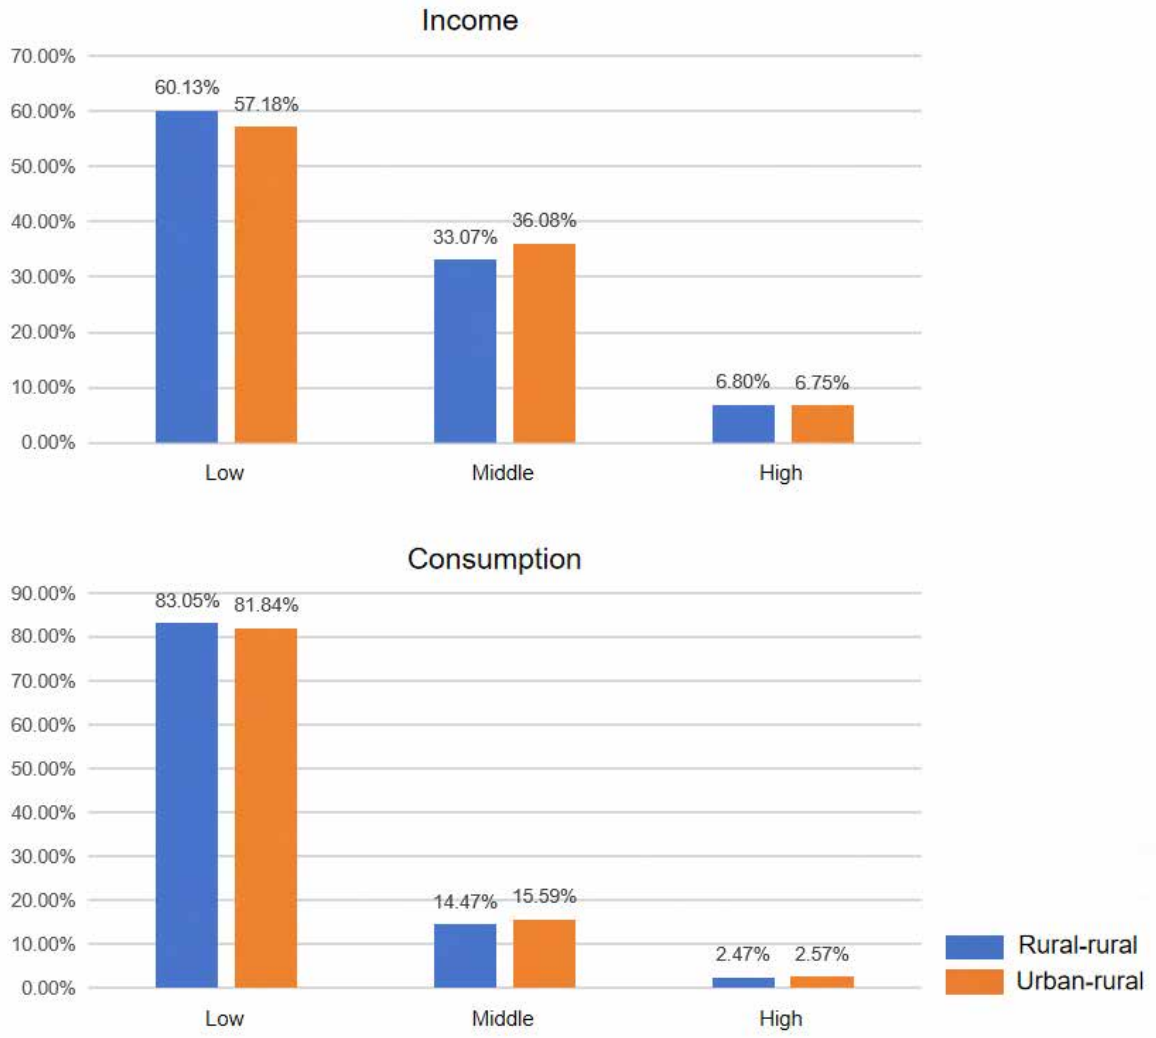

Figure6. Income and consumption characteristics of floating population in Shanghai metropolitan area

However, among the urban-rural mobile population, the proportion of individuals with medium income and consumption levels is higher than that of the rural-rural group. This suggests that urban-rural migrants may have additional sources of income, such as urban savings or investment returns. Consequently, their consumption in townships tends to be at a higher level-not only meeting basic living needs, but also including expenditures on housing improvement, children's education, and cultural or recreational activities.

Overall, for shrinking townships, both urban-rural and rural-rural mobile populations exhibit similar structural characteristics, but also reveal internal heterogeneity. This heterogeneity brings diverse development dynamics and demands, but may also lead to social conflicts and challenges, such as interest coordination among different groups and the differentiated provision of public services. Therefore, it is essential to propose targeted strategies based on these influencing factors.**(Figure 6)**

4.4 Influencing factors of floating population structure in shrinking towns

Based on the distribution, connectivity characteristics, and migrant population structure of shrinking townships in the Shanghai metropolitan area—and in light of current development conditions—the formation of their population structure is primarily influenced by a combination of economic development, geographic location, policy and institutional frameworks, and sociocultural factors.

Firstly, the impact of economic and industrial development: The Shanghai metropolitan area is dominated by the secondary and tertiary sectors, with agriculture playing a less prominent role. As a result, workers in agriculture-related industries tend to have relatively higher educational attainment. Among urban–rural migrants, there is a higher proportion of well-educated and skilled individuals who are more likely to migrate to cities or peri-urban townships to engage in jobs associated with the secondary and tertiary industries. The overall economic development level of the townships is relatively low, with unstable and slow-growing incomes, resulting in a predominantly low-income and low-consumption mobile population. Among urban-rural migrants, some individuals accumulate significant wealth through employment in cities, resulting in relatively higher income and consumption levels. In contrast, rural-rural migrants tend to have lower income and consumption levels overall.

Secondly, the influence of geography and spatial conditions: Shrinking towns are mostly located in the outer regions of the metropolitan area or in intercity border zones (such as Chongming in Shanghai and Rudong in Nantong), where the radiation effect of the central city is weak. In areas like Ningbo, Zhoushan, and Huzhou, geographical barriers such as the Siming and Tianmu Mountains limit external connectivity. Rural–rural mobility networks exhibit more cross-boundary connections due to geographic proximity, while urban–rural networks are more constrained by administrative boundaries. The convenience of transportation also influences the direction and frequency of population mobility—areas with better transportation tend to attract more inflows, whereas poorly connected regions see less movement. These spatial differences also lead to variations in the structure of the mobile population.

Thirdly, the role of policies and institutions: Shrinking towns generally maintain strong internal connections within their respective districts and counties, with administrative barriers exerting significant influence. However, cross-boundary connections are more apparent in rural–rural networks, indicating that township-level interactions are less constrained by administrative borders. Policy plays a crucial role in shaping population flows. The siphoning effect of central urban areas and associated policies can draw population toward cities or peri-urban townships. Under the hukou and land systems, rural–rural migrants are often limited by land transfer regulations, leading them to engage primarily in seasonal or temporary work. By contrast, urban–rural migrants benefit from urbanization policies, which often grant them more stable living conditions.

Lastly, sociocultural influences: Men, as the primary labor force and income earners in households, have higher mobility rates. In urban-rural migration, “family-based migration” is common, with couples working together or choosing jobs nearby, leading to a more balanced gender ratio. Women are more likely to migrate into townships through marriage and are typically employed in services or household-related work-a trend more prominent in rural–rural migration. Public services in town-s-particularly in education and healthcare-are relatively underdeveloped, which contributes to higher internal mobility among lower-educated populations. Conversely, individuals with higher education and specialized skills are more inclined to migrate to cities or peri-urban townships in search of better educational and healthcare resources.

In summary, the population structure of shrinking townships in the Shanghai metropolitan area is shaped by the combined effects of economic positioning, policy guidance, geographic conditions, and sociocultural factors. The internal heterogeneity of these townships calls for policies that can accurately identify the needs of different groups. Through industrial restructuring, optimization of public services, and institutional innovation, shrinking townships can be guided to shift from passive decline toward a model of “smart shrinkage.”

5. Conclusions

This study analyzes the characteristics of two types of mobile populations: urban-rural and rural-rural migrants, in shrinking townships within the Shanghai metropolitan area. It summarizes key structural features including gender, age, educational attainment, income, and consumption levels, and identifies their primary influencing factors. Based on the current development status of these shrinking townships, the following development recommendations are proposed:

First, to address regional development imbalances, the siphoning effect of central urban areas and industrial hollowing in peripheral townships should be mitigated through **"differentiated county-level economic positioning." For example, peripheral townships in Shanghai could focus on health and wellness services or cultural and tourism functions, while Suzhou, Wuxi, and Changzhou could strengthen support for manufacturing industries.

Second, to resolve disparities in public service provision, mechanisms for the sharing of education and healthcare resources within counties should be improved to serve rural-rural migrants, while urbanization-related support services should be enhanced for urban-rural migrants.

Third, to address mismatches between skills and industrial needs, a "dual-track training system combining education and vocational skills" should be established to align with the demands of industrial upgrading in townships.

Lastly, population management should be stratified: entrepreneurial support should be provided to highly skilled urban–rural migrants, while employment security and the formalization of informal economies should be strengthened for low-skilled rural-rural migrants.

By employing a population mobility network analysis approach, this study explores the characteristics and patterns of migrant populations in shrinking areas from spatial, mobility, and structural perspectives. The findings provide valuable insights for local governments to formulate targeted population policies, optimize resource allocation, and enhance regional development potential.

Transformative Planning for Sustainable Futures: Bridging Global Goals and Local Actions through Adaptive Frameworks

YI ZHONG
Affiliation: Università IUAV di Venezia
Email:y.zhong@stud.iuav.it

Abstract

Planning plays a transformative role in addressing global crises such as climate change, biodiversity loss and inequality. This study emphasizes the integration of environmental considerations into urban and regional planning, rather than prioritizing economic benefits alone. It explores how planning can bridge the gap between global sustainable development goals and local implementation, especially in rapidly urbanizing areas. Using an interdisciplinary approach including case studies, spatial analysis and participatory workshops, this study examines governance innovation, community empowerment and adaptive infrastructure. The findings suggest that transformative planning can foster collaboration, integrate sustainability into decision-making, and support equitable development. The proposed adaptive planning framework promotes flexibility, inclusiveness and systems thinking and provides guidance for addressing complex global challenges and advancing the sustainable development goals.

Key words: Transformative Planning; Adaptive Framework Sustainable Development Goals

1.Introduction

Contemporary societies face a variety of global crises, including climate change, biodiversity degradation, socioeconomic inequalities, forced migration, demographic change, and political instability. These challenges are unevenly distributed, disproportionately affecting marginalized populations, exacerbating existing inequalities, and placing increasing pressure on urban systems around the world. With the acceleration of urbanization and the increase in the frequency and intensity of climate-related shocks, traditional planning approaches are no longer adequate.

Mainstream urban and regional planning paradigms are often centered on technology and growth and are not well suited to complex socio-ecological transformations.These approaches tend to marginalize the voices of the most affected groups - migrants, women, people with disabilities, and low-income groups - while exacerbating spatial inequities through top-down interventions and a narrow view of public goods.

In this context, transformation planning has emerged as a compelling alternative. It aims to combine global sustainable development agendas such as the United Nations Sustainable Development Goals (SDGs) with locally based, socially inclusive and practical planning approaches.Change-making shifts the focus from largely technical solutions to critical shifts, democratic participation, and distributive justice. The importance of incorporating a variety of ideologies and traditional knowledge is highlighted in establishing versatile frameworks.

How are the social, cultural, and economic factors that cause disillusionment and action addressed effectively in transformative planning? This research draws on the lived experience of vulnerable features and the co-production of gathering information to create a theory and practice that are both resilient and future-oriented, fair and interactive.

2. Theoretical Framework: Adaptive and Inclusive Planning

The theoretical framework developed in this assessment incorporates findings from adaptive planning, various urbanisation, and significant management plans. According to the idea behind adaptive planning, confusion and modification are natural characteristics of social-ecological items. It prioritises scenario-based techniques, adaptive feedback loops, and continuous decision-making (Walker et al., 2004; Wilkinson, 2011)[1]. This perspective is required to address social change, population movement, and climate change issues.

Various studies also highlight the essential responsibility marginalised groups play in developing technologyudies. It examines well-known power relationships and politicians for spatial justice using deliberative democracy, feminist planning, and rights-based frameworks. In this environment, cooperation is seen as both a legal

requirement for formal cooperation and a pressing need for the inclusion of different expertise and lived experience in decision-making strategies.

In favour of context-based, historically integrated approaches, the framework draws on postcolonial urban theory and Southern epistemologies (Parnell & Pieterse, 2016) [2]. These tenets emphasise range, directness, and understanding how different common systems, civil society, and condition players interact.

This review incorporates transformative planning as a system-thinking, justice-focused training with roots in network thinking and functional resilience. It challenges democratic forms of knowledge and power based on power and prediction, in contrast to supporting co-evolutionary techniques, collective learning, and social forms of knowledge and power. While hard strength and prediction-dominated reasoning emphasise co-evolution, collective learning, and multi-agent talk. The article's factual and analytical components are built on this philosophical base.

3. Methodology

This study utilizes a multi-method qualitative research approach, combining comparative case study analysis, spatial ethnography and participatory action research. Methodologically, the study is based on the understanding that "knowledge is co-produced and contextualized",requiring planners to work with different participants in an iterative and context-sensitive manner.

3.1 Case Selection And Comparative Design

Two urban environments were purposely chosen for this study because of their very different institutional setups and planning cultures - Chengdu, China and Rotterdam, the Netherlands. This comparative design helps to explore how transformative planning manifests itself in different governance systems and socio-political environments.

3.2 Data Collection Methods

Primary data collection methods included in-depth, semi-structured interviews with planners, local government officials, community organizers, and residents (N=28), as well as participant observation during planning workshops and community meetings. We also analyzed spatial data, including GIS-based land use maps, socio-demographic overlay maps, and mobility patterns to support an understanding of context.

3.3 Participatory Planning Tools

Participatory tools include mapping exercises, digital narratives, visioning sessions, and AI-assisted scenario modeling. These tools aim to democratize the planning process by visualizing complex trade-offs and integrating non-expert knowledge (Brown & Kyttä, 2014)[3]. Special attention is paid to power dynamics in participatory settings to ensure equitable inclusion and avoid elite capture .

3.4 Analytical Framework

Analytical Framework Data analysis combined grounded theory and critical discourse analysis, allowing the recognition of repeating designs, changing habits, and core strength relationships that power planning processes and outcomes. To increase the study's resilience, this study used validation from various data sources, including conference transcripts, research notes, and natural materials.

This multi-method approach to survey preparation study uses reflexivity and social consciousness as key components. A critical analysis of transformative planning strategies ' potential and limitations in various social settings also emphasises the value of creative data production.Process event studies undergo a large change.

4. Case Studies: Inclusive Transformation in Practice

4.1 Case 1: Revitalization of Older Neighborhoods in Chengdu, China

Chengdu, one of China's oldest towns, was revitalised. Thee Chengdu Municipal Government in China put forth several neighbourhood regeneration ideas in the early 2010s to handle the state's decaying situations, including the ageing community, daily financial activities, and poor housing conditions. The process employed a phased on-site recovery system based on participatory planning guidelines, in contrast to the conventional method, which focused on large-scale death.

Residents, generally old tenants and remote-to-industrial American families, were properly engaged through participatory mechanisms like gathering workshops, participation monitoring, and discussion forums.(Liqing Yang,2023)[4].These engagements directly affected decisions regarding planning for public spaces and service enhancements.

The development of energetic group services, the improvement of discharge systems, and the addition of cranes to buildings were some of the actions taken by Chengdu, such as placing commissions and other important intermediaries between government entities and society stars. These initiatives prioritised the protection of historical and cultural recollection, social mobility, parent unity, and material development.

By combining standard assembling tools with native knowledge systems, the Chengdu work demonstrates the viability of communicative planning in a hybrid governance framework. Because the court's people actively participated in the healing process while maintaining their regional independence, the occasion strongly connects to the "right to the city" approach. The occasion demonstrates how well-designed, complex interventions can promote equity and develop long-term resilience in rapidly changing business environments.

4.2 Case 2: Climate Migration Planning in Rotterdam, the Netherlands

As a lower-lying close place, Rotterdam, the Netherlands, has excellently positioned itself as a captain in the weather version. In 2010, Rotterdam expanded its speech method to have recruitment- gentle planning in response to the growing problem of climate migration and the potential for population movement in flood-damaged regions. A multi-agency working group was established to organise work on housing, present, social inclusion, and software development.

The Design for Resilience programme, which brought up local partners, foreign companies, and professional designers, was a key component of this method. The project used interactive workshops and cutting-edge model tools to make prototypes for a nature-based problem safety equipment, assess projected action flows, and choose the best locations for affordable housing. The main objectives of the position were to lower the risk of climate gentrification and to ensure that speech investment would benefit both clear refugee groups and already-vulnerable areas.

The Rotterdam method adheres to effective governance principles and engaging route planning reasoning. It further demonstrates how powerful polycentric governance and lateral institutional collaboration are at resolving complex business problems. The event demonstrates using interesting, forward-looking practices and diverse organisational structures to reorient technology-driven resilience planning toward funds and additional resources.

In conclusion, Rotterdam and Chengdu demonstrate the potential of transformative planning by including the global sustainable development approach into socially acceptable, equitable, and flexible methods despite their firmly different political and cultural contexts. Both situations provide valuable insight into how to account for statistical shifts, geographical disparities, and social vulnerability.

Case Comparison: Chengdu vs Rotterdam

Category	Chengdu, China	Rotterdam, Netherlands
Planning Goal	Revitalize old neighborhoods and protect historical culture	Prepare for climate migration and plan for adaptation
Governance Structure	Hybrid: state + community coordination	Multi-center: multi-institutional collaboration
Target Groups	Elderly, migrant families, low-income tenants	Displaced migrants, vulnerable communities
Participatory Tools	Community mapping, workshops, forums	Scenario modeling, digital simulations
Infrastructure Focus	Accessibility upgrades, social spaces	Nature-based flood protection + housing
Equity Strategy	Right to stay, localized inclusion	Avoid climate gentrification
Planning Philosophy	Communicative, heritage-rooted	Anticipatory, resilience-focused

5. Key Findings and Discussion

According to the findings of this study, the effectiveness of move planning depends on how well it integrates many theories, how well it can join many theories, and how effective the current governance structures are. Three main components are necessary for its action: community empowerment, governance innovation, and the production of adaptive infrastructure.

5.1 Governance Innovation:

Governance Innovation: Both functional reports emphasise the value of multi-level coordination and functional skills in implementing innovative preparation. In order to promote shared role in the organising process, China's hybrid governance framework encourages power sharing between state and community organisations. In comparison, Rotterdam adopts a polycentric governance view that favors ahead- looking mix- business engagement. These governance arrangements abandon traditional prepared models and promote institutional resilience and managerial diversity by redistributing energy and broadening the range of reasonable stars, including illegal institutions and civil society organisations. (Ansell & Gash, 2008)[5].

5.2 Community Empowerment:

The independence of marginalised and resilient activities is a prerequisite for a proper plan to improve socially acceptable and appropriate results. Both occasion studies demonstrate how successful real-world creative processes are in promoting regional ownership, strengthening administrative beliefs, and creating local interventions that work better than local needs. Similar plans exist for "rebel organising" and "deep democracy," which promote fairness and support localised, frequently uncertain knowledge systems. Contrary to the frequently used "displacement" discussion of market-oriented expert maintenance, the position in Chengdu, China, illustrates how planning does prevent the "right to help" of low-income people and older occupants.

5.3 Co-creation of Adaptive Infrastructure:

A socio-technical assembly that embraces and reproduces cultural norms, power relationships, and social priorities should not be seen as only material. Technology organising is embodied in both case studies as a co-productive and incremental process that incorporates natural problems, cultural names, and investment goals. Using affordable accommodation and personality-based crisis protection methods in Rotterdam demonstrates how resilience can be redefined to encourage social inclusion. Progressive but carefully targeted therapies like

modifications to open space and convenience demonstrate Chengdu's worth of resident-centred, community-based strategies for promoting long-term industrial resilience.

These problems challenge conventional making types that promote technical rationality and economic productivity over democratic participation and distributive justice. Instead, they provide factual justification for a brand-new, democratic, and energising model that emphasises long-term socio-ecological change (Davoudi et al., 2012)[6]. Additionally, transformative planning gives the potential for conflicting corporate risk (related to age, disability, action place, or anxiety) a lot of thought. Planning is reframed as a political and ethical training in this environment, emphasising officials as agents, officers, and co-learners in social industrial change techniques, rather than being seen as technical specialists or regular managers.

6.Conclusion

In order to solve the interconnected problems of demographic transition, people action, social injustice, and climate change, transformative planning is a required model change, according to this analysis. Cities may move beyond expert treatments to more built-in and tough business prospects by incorporating versatile logics into participatory, equitable, and justice-oriented planning systems.

How diverse management structures and co-created recognition can be used to promote structural change is illustrated by the examples of Chengdu and Rotterdam. As evidenced by China's community-focused approach to revival, the urban renaissance is grounded in social capital, cultural heritage, and standard practice. In comparison, Rotterdam's predicted management model demonstrates how managers can adjust their strategies to address unplanned issues like climate-induced movement while upholding the rights and well-being of underprivileged groups.

The planner's transition from analyst to an educator, arbitrator, and embedded co-learner is at the heart of both situations. This change aligns with popular desire for more meditative, grounded, and understated planning methods. The selection of how to arrange hypotheses is broadened due to the focus on intersectionality and intellectual variety. It underscores the need for equitable urbanisation strategies that embrace a range in companies and ideas and knowledge systems.

Applying this design calls for long-term investments in the account system, official recognition of peaceful and aboriginal information, and the development of open, flexible, and reliable operational frameworks. In addition to regularly fundamental planning goals, distributing resources, and identifying options, it calls for developing geographical characteristics that help marginalised groups.

Abstract
China's urban renewal reveals persistent mismatches between formal public spaces and the heterogeneous behavioural needs of an ageing population. Employing a Multi-Group Huff Three-Step Floating Catchment Area model, this study quantifies age-stratified accessibility in Shanghai's Yinhang community, where elderly residents constitute 48% of the population (n = 1,016). Incorporating subgroup-specific walking distances and visitation frequencies demonstrates that conventional single-group models overestimate accessibility in 70% of residential compounds, disproportionately disadvantaging the oldest-old. Low formal accessibility significantly predicts the emergence of informal gathering nodes, indicating a compensatory bottom-up mechanism. Integrating behavioural heterogeneity and informal spatial practices into urban planning frameworks can thus enhance equity and efficiency in public-space provision for rapidly ageing cities.

Keywords: Two-step floating catchment area; Improved model; Equity; Accessibility

1. Introduction

The global demographic transition towards an ageing society is accelerating, with the proportion of individuals aged 60 and above projected to increase from 12% in 2020 to 22% by 2050 (World Health Organisation, 2024). China exemplifies this trend, with its elderly population expected to reach 39.9% by 2050, including a significant proportion (10.5%) aged 80 and above (Textor, 2023). As ageing progresses, the mobility of elderly residents declines, leading to a growing reliance on proximate public spaces within communities for daily activities (Wang, 2009) Informal public spaces, often spontaneously formed near residential entrances, small shops, and temporary structures, serve as critical everyday venues for elderly residents due to their proximity, familiarity, and ease of access.

Despite this, existing planning studies predominantly focus on formal public spaces, such as community parks and street green spaces, and often neglect the functional significance of informal public spaces. Moreover, current planning frameworks tend to generalise elderly residents as a homogenous group, failing to acknowledge behavioural distinctions across age cohorts. This homogenisation results in a spatial mismatch between standardised public space configurations and the differentiated needs of elderly residents, particularly the oldest-old. This leads to the underutilisation of formal spaces and the growing reliance on informal alternatives.

The Two-Step Floating Catchment Area (2SFCA) method has become a prominent tool for measuring public space accessibility, particularly in health care, green infrastructure, and elderly care (Tao and Cheng, 2016). However, conventional 2SFCA models assume uniform behavioural characteristics, ignoring variations in walking range, activity frequency, and spatial preference across elderly subgroups. This study introduces an enhanced model (Song, Kong and Cheng, 2024), the Multi-Group Huff Three-Step Floating Catchment Area (MGH3SFCA), incorporating age-specific behavioural parameters to overcome the limitations of conventional accessibility measurements. The objectives are threefold:
(1) Quantify behavioural differences in space usage across elderly age groups;
(2) Assess the impact of age-differentiated behaviours on accessibility measurements;

(3) Examine how accessibility deficits contribute to the emergence of informal public spaces.

2. Materials and Methods

2.1 Model Framework

The proposed MGH3SFCA model introduces three principal improvements to the conventional two-step floating catchment area (2SFCA) method. First, it incorporates a Gaussian distance-decay function (Liu, Chen, Xiang et al., 2024) to reflect the declining likelihood of accessing a facility as travel distance increases. Second, it employs the Huff probability model (Luo, 2014) to account for competitive interactions among alternative public spaces. Third, the model integrates age-specific behavioural parameters, including activity frequency and walking distance, and applies differentiated search radii according to the spatial scale of public space supply (Zhang et al., 2019). Larger-scale facilities are assumed to serve multiple residential clusters, whereas smaller spaces primarily cater to the immediate vicinity. The model operates in the following three steps.

(1) Estimating the Probability of Visiting Public Spaces

This step defines public space j and residential compound i as supply and demand nodes. Their geographic centroids are extracted for spatial calculations. The probability that residents in unit i will visit public space j is denoted as $\mathrm{Huff_{ij}}\mathrm{Huff_{ij}}$, calculated using Equation (1). Specifically, S_jS_j denotes the area of public space j, $d_{ij}d_{ij}$ represents the network distance between units i and j, and $G\left(d_{ij},d_0\right)G\left(d_{ij},d_0\right)$corresponds to the Gaussian distance-decay function defined in Equation (2).

$$\mathrm{Huff_{ij}} = \frac{S_j G\left(d_{ij},d_0\right)}{\sum_{k\in\{d_{kj}\le d_0\}} S_k\, G\left(d_{kj},d_0\right)} \quad (1)$$

$$G\left(d_{ij},d_0\right) = \frac{e^{-\frac{1}{2}\times\left(\frac{d_{ij}}{d_0}\right)^2} - e^{-\frac{1}{2}}}{1-e^{-\frac{1}{2}}} \quad \left(d_{ij}<d_0\right) \quad (2)$$

(2) Calculating the Supply-to-Demand Ratios

A first-step search is performed around each public space j within a predefined distance threshold $d_{0*}d_{0*}$. The supply-to-demand ratio R_jR_j is calculated using Equation (3), representing the relationship between the facility's supply capacity and the total weighted demand from elderly residents within its catchment area. Specifically, P_kP_k indicates the older adult population of a given age group in residential compound k, $f_{kj}f_{kj}$ reflects the frequency coefficient for visits from k to j, and $\mathrm{Huff_{kj}}\mathrm{Huff_{kj}}$ denotes the visit probability. These parameters jointly determine the composite demand weight for space j.

$$R_j = \frac{S_j}{\sum_{k\in\{d_{kj}\le d_{0*}\}} \mathrm{Huff_{kj}}\, f_{kj} P_k} \quad (3)$$

(3) Assessing Accessibility by Age Group

A second-step search is conducted around each residential compound i within the same distance threshold d_0d_0. Using the calculated supply-to-demand ratio, the age-specific accessibility (A_iA_i) of elderly residents in unit i to public space j is determined via Equation (4).To capture behavioural heterogeneity, the older adults population P_kP_k in each residential compound is divided into three subgroups: young-old $P_{kM1}P_{kM1}$, middle-old $P_{kM2}P_{kM2}$, and oldest-old $P_{kM3}P_{kM3}$. Group-specific accessibility scores are first computed and then aggregated into a composite multi-group accessibility index ($A_{i(multi-group)}A_{i(multi-group)}$) for each residential compound through weighted integration, as outlined in Equation (5).

$$A_i = \sum_{j \in \{d_{ij} \le d_0\}} Huff_{ij}\, G(d_{ij}, d_0) R_j \quad (4)$$

$$A_{i(multi-group)} = \frac{\sum_{M_1}^{M_n} A_{iM_n} f_{kj(Mn)} P_{kM_n}}{\sum_{M_1}^{M_n} f_{kj(Mn)} P_{kM_n}} \quad (5)$$

2.2 Study Area

Yinhang, located in the northeastern sector of Shanghai's Yangpu District, is the study site. Spanning 7.98 km², the community hosts approximately 194,100 residents, with nearly 47.7% of the population aged 60 or above. Among them, the proportion of elderly residents in poor health reaches 12.6%, compared to the municipal average of 9.7%; similarly, the share of functionally dependent elderly (i.e., unable to care for themselves) exceeds 4.7%, significantly higher than the Shanghai average of 3.2% (National Bureau of Statistics of China, 2021). These figures indicate that Yinhang exhibits a higher-than-average burden of ageing-related health limitations. The community comprises 66 residential compounds and a diverse public space system, including formally planned and spontaneously formed informal public spaces (Figure 1).

Figure 1. Location of Yinhang Community in Shanghai

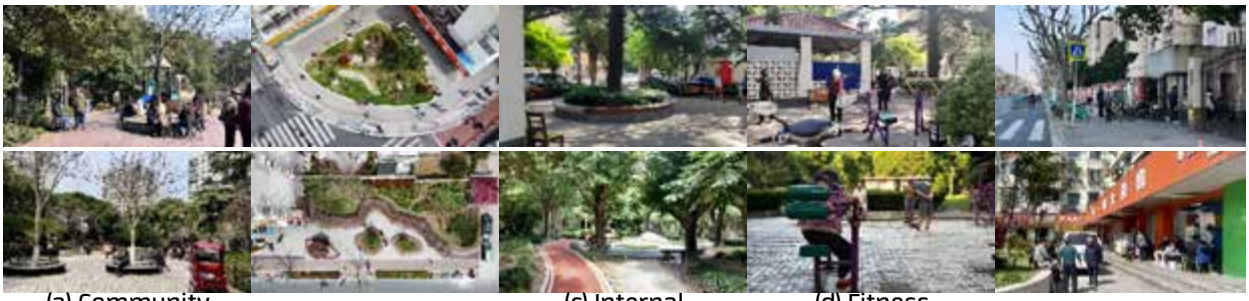
2.3 Data Collection and Processing

(1) Elderly Residents' Demand

Residential population data directly reflect the spatial distribution and quantity of potential public space users, while age structure provides a critical demographic basis for evaluating differentiated deman (Wang, Wu, Gao et al., 2021). The smallest unit of analysis is the "residential compound" ('xiaoqu'), a prevalent housing type in Chinese cities. Population data were derived from the Seventh National Population Census of China (2020–2021) and were classified into three age cohorts: young-old (60–69 years), middle-old (70–79 years), and oldest-old (80 years and above). Walking distances were defined by observed gait speeds: 5-, 10-, and 15-minute walks equate to 180–300 m, 360–600 m, and 540–900 m, respectively. These demographic layers were integrated with spatial data using ArcGIS to support the demand-side component of the model.

(2) Public Space Supply

Public spaces within a 500-m radius of the Yinhang community were identified using a combined approach that included point-of-interest (POI) annotation from online maps and on-site field investigations conducted in March 2024. A total of 95 formal public spaces were delineated and classified into four types according to their functional role and designated service radius: community parks (J1), street green spaces (J2), internal parks (J3), and fitness stations (J4). The assignment of service radii, ranging from 300 to 1000 meters, followed the guidelines outlined in China's Urban Green Space Planning Standards (GB/T 51346–2019). All spatial locations were geocoded in ArcGIS to construct the supply-side spatial database. Additionally, 24 informal public spaces were identified through a structured, week-long behavioural observation period. These locations exhibited consistent patterns of elderly gathering and were equipped with basic amenities such as benches, shade structures, or handrails. Based on these characteristics, they were defined as Spontaneous spaces (J5) and incorporated into the model's supply-side dataset. (Figure 2)



(a) Community Park (b) Street Green Space (c) Internal Park (d) Fitness Point (e) Spontaneous Space

Figure 2. Examples of Public Space Types (J1–J5

(3) Behavioural Data

A structured questionnaire survey targeting residents aged 60 and above was conducted in Yinhang community from March to July 2024. The survey was administered during clear daytime periods (08:00–18:00) across all days of the week to account for variability in behavioural patterns. The questionnaire comprised two parts: personal demographics (age, health status, and mobility condition) and public space usage behaviours (frequency, duration, type of activity, and mode of travel). Only respondents who reported walking directly from home to a public space were included in the modelling. Actual walking distances were computed using the Origin-Destination (OD) matrix function in ArcGIS. The resulting dataset informed the behavioural weights used in the MGH3SFCA model, particularly in estimating frequency coefficients and mobility thresholds across age groups.

3. Results

3.1 Age-Specific Differences in Behavioural Activities

A total of 1,525 questionnaires were distributed, yielding 1,405 valid responses. Walking emerged as the dominant mode of travel among elderly residents (84.9%), followed by non-motorised vehicles (11.5%) and public buses (0.9%). Among respondents, 87.6% reported walking directly from home to their activity destinations, while only 8.3% indicated detouring through other activities. The final sample included 1,049 elderly residents who reported walking directly to a public space. (Table 1)

Table 1. Age Distribution of Elderly Residents by Public Space Type

	Young-old	Middle-old	Oldest-old	Total
Community Park (J1)	136 (37%)	172 (47%)	57 (16%)	365
Street Green Space (J2)	129 (46%)	94 (34%)	56 (20%)	279
Internal Park (J3)	81 (43%)	71 (38%)	37 (20%)	189
Fitness Point (J4)	44 (53%)	20 (24%)	19 (23%)	83
Spontaneous Space (J5)	54 (41%)	52 (39%)	27 (20%)	133
Total	444	409	196	1049

Note: Percentages in parentheses represent the proportion of each age group within the corresponding public space type.

Chi-square tests (Table 2) revealed significant age-related differences in health status and mobility. The proportion of individuals with chronic illness increased from 18% in the young-old group to 36% in the oldest-old group ($p < 0.01$). Meanwhile, the share of residents with unimpaired walking ability dropped from 91% to 53% across the same age ($p < 0.01$). These age-related health and mobility declines significantly influence public space use patterns and walking range.

Table 2. Chi-Square Test Results of Behavioural Characteristics by Age Group

	Young-old	Middle-old	Oldest-old	Total	χ^2	p
Health status						
With chronic disease	18%	33%	36%	27%	35.928	0.000**
Without chronic disease	82%	67%	64%	73%

> 2.00	21%	24%	21%	22%		

Note: * p < 0.05; ** p < 0.01. Significant results are marked accordingly in the respective rows.

(1) Age Differences in Walking Distances

Figures 3 and 4 present the distribution of walking distances and visit frequencies across various types of public spaces, stratified by the three age groups of the elderly. The young-old group exhibits the strongest walking ability, with a broad range of spatial activity across all space types. In particular, the median walking distances to community parks (J1) and street green spaces (J2) range from 400 to 600 metres, with some individuals walking more than 1,000 metres, indicating extensive mobility. In contrast, the middle-old and oldest-old groups show a progressive decline in walking ability. Their median walking distances are generally shorter, especially in internal parks (J3) and fitness stations (J4), where most visits occur within a 300-metre radius. This reduction is most pronounced among the oldest-old, whose median distances fall below 300 metres across all space types, reflecting a high dependence on nearby spaces. Notably, in spontaneous public spaces (J5), the differences among age groups are much smaller. This suggests that informal public spaces are significant for the oldest-old, as their proximity effectively accommodates the mobility limitations of this subgroup.

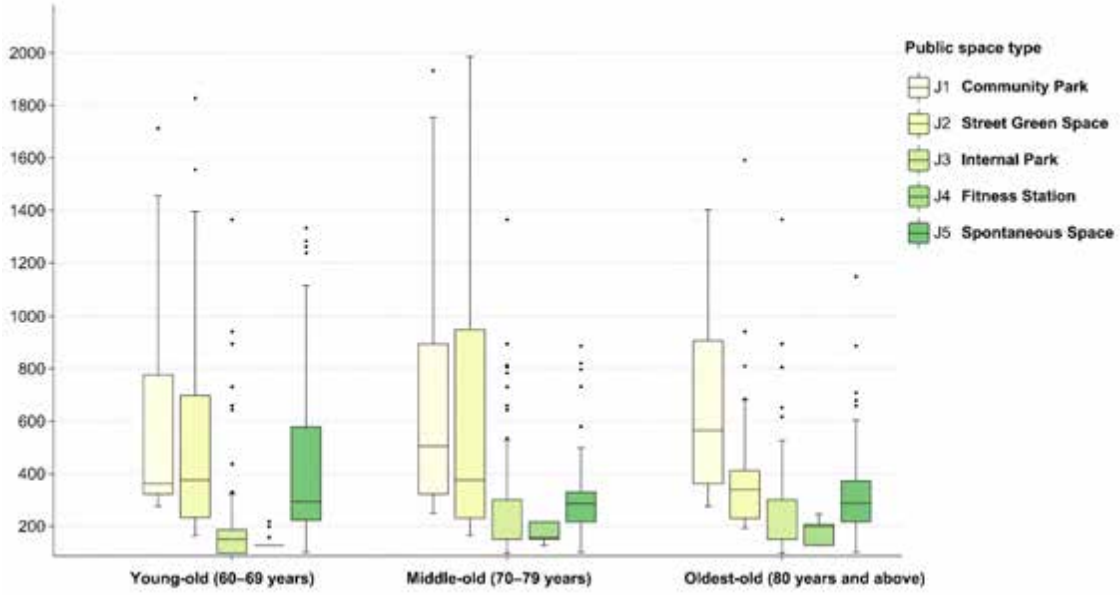

Figure 3. Walking Distance to Public Spaces by Age Group

(2) Age Differences in Visiting Frequency

Regarding visit frequency, community parks (J1) and street green spaces (J2) exhibit relatively stable usage across all age groups, with an average of once per day. Internal parks (J3) and fitness stations (J4) exhibit a moderate decline in visitation among the middle-old and oldest-old groups, possibly due to smaller spatial scale or higher use thresholds. In contrast, spontaneous public spaces (J5) maintain consistently high visitation frequencies

across all age groups. This trend is particularly pronounced among the oldest-old, with a median visit frequency of one to two times per day, and some individuals reporting up to three visits per day. These findings highlight residents' substantial reliance on informal public spaces, particularly among those with mobility constraints. In summary, walking distance and visit frequency demonstrate age-related stratification and marked differences across space types. Formal public spaces (J1–J4) are more likely to attract the young-old for medium- to long-distance, low-frequency use. In contrast, informal public spaces (J5) support high-frequency, short-distance daily activities among the oldest-old due to their proximity, flexibility, and accessibility.

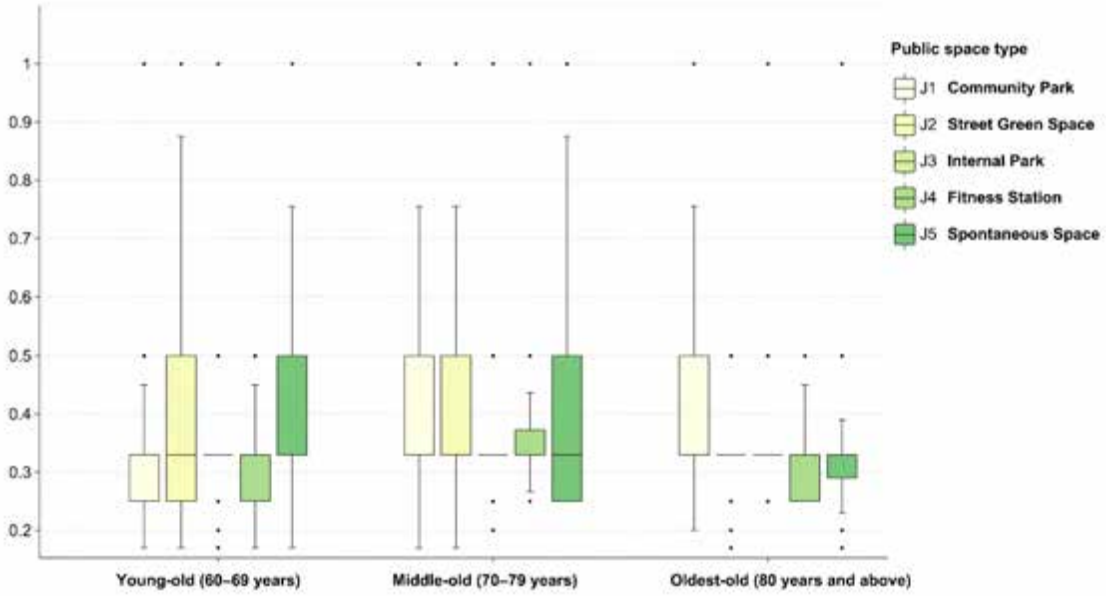

Figure 4. Visit Frequency to Public Space Types by Age Group

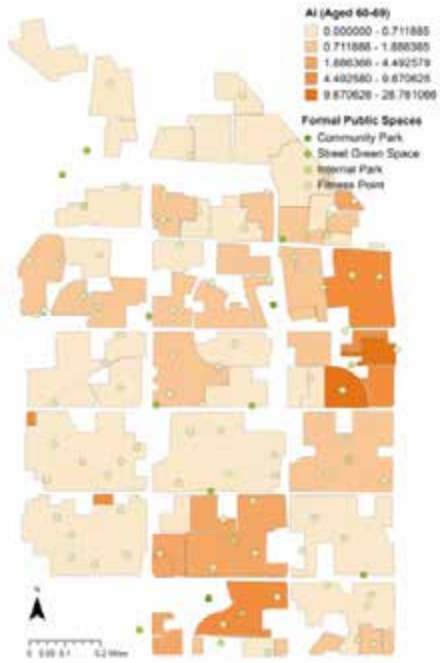
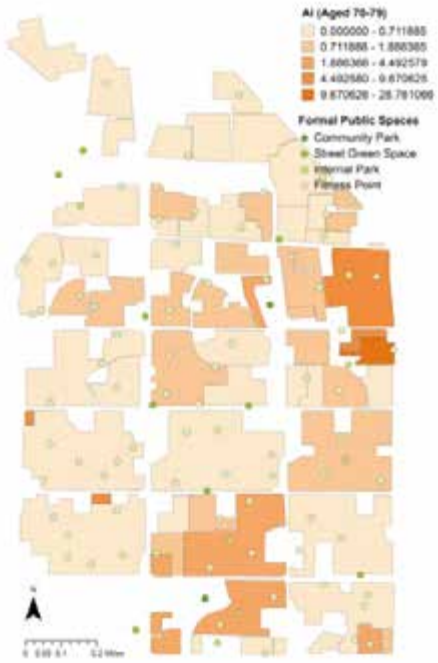
Note: Visit frequency codes: 0.17 = occasional; 0.20 = weekly; 0.25 = several times/week; 0.33 = daily; 0.50 = twice/day; 1.00 = three times/day.

3.2 Accessibility Results of Single vs Multi-Group Models

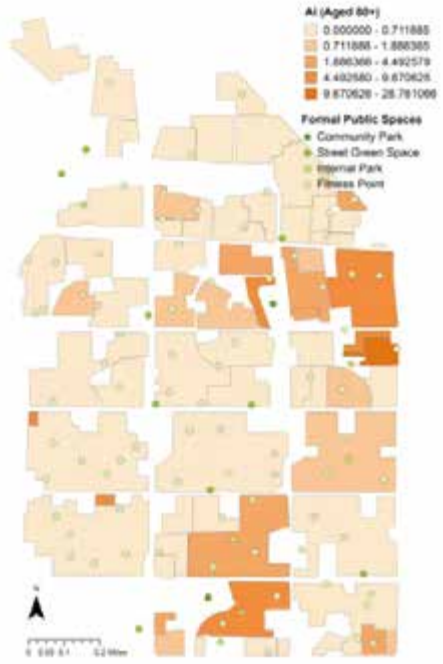
Based on MGH3SFCA model outputs, public space accessibility was calculated for each age group across residential compounds. Values were categorised into five levels using ArcGIS natural breaks: very high, high, medium, low, and very low (Figure 5a–5c). Results show that the single-group model consistently overestimates accessibility compared to the age-specific model. Around 70% of residential compounds exhibited overestimation, with an average margin of 15.9% (Figure 5d). This disparity is most evident in units rated 'very high' by conventional models, where the oldest-old residents still face limited effective access. The findings highlight the importance of incorporating intra-group behavioural variation in accessibility planning.



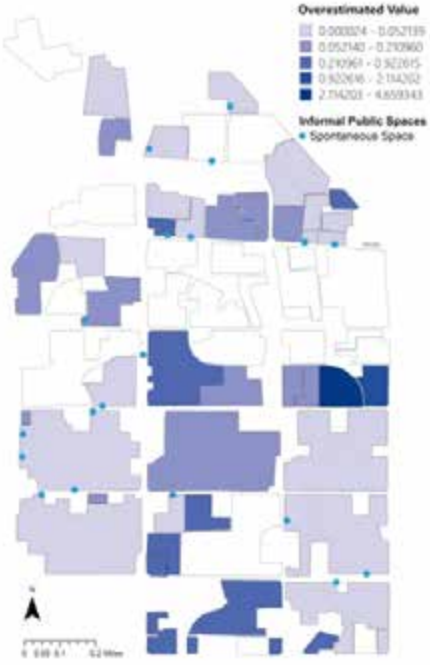
(a) Accessibility for Young-Old Residents



(b) Accessibility for Middle-Old Residents



(c) Accessibility for Oldest-Old Residents



(d) Spatial Distribution of Accessibility Overestimation

Figure 5. Multi-Group Accessibility Modelling Results

3.3 Correlation Analysis of Accessibility and Informal Public Space Distribution

In the Yinhang community, informal public spaces formed through the spontaneous gathering of elderly residents are predominantly located near the entrances of residential compounds, which have zero or low comprehensive accessibility, particularly in communities with a high proportion of residents aged 80 and above. For example, although Guohe No. 2 Community and Shiguang No. 2 Community are relatively limited in spatial scale, they effectively accommodate the needs of elderly residents for nearby social interaction and daily leisure activities. Moreover, even in communities with relatively well-organized formal public spaces, informal gatherings are often observed beneath the eaves of street-facing shops, such as those located at Lane 590 and Lane 296 on Yinhang Road. These spatial patterns indicate that elderly residents, particularly those in the oldest-old group, tend to choose locations with high pedestrian traffic and open visibility, such as traffic intersections or commercial frontages, to engage in social interaction activities, including conversation and chess. This behavioural preference reflects a conscious strategy to increase the likelihood of informal social encounters and to mitigate the sense of isolation often experienced in daily routines.

To further quantify the relationship between comprehensive accessibility and the distribution of informal public spaces, this study employed a binary logistic regression model to examine the correlation between accessibility levels and the presence or absence of informal public spaces, using residential compounds as the unit of analysis. Additionally, a negative binomial regression model was employed to examine the impact of accessibility on the number of informal public spaces. The results indicate a significant negative association between the comprehensive accessibility of elderly residents and the emergence of informal public spaces (Table 3). Specifically, for every 0.1 unit decrease in comprehensive accessibility, the probability of informal public space formation increases by approximately 24.6% (odds ratio = 0.059, p = 0.011), while the number of such spaces increases by roughly 20.4% (incidence rate ratio = 0.102, p = 0.011). These findings suggest that when formal public space provision fails to accommodate the behavioural capabilities of senior residents, they are more likely to create alternative spaces within the community spontaneously. This pattern reflects a spatial equity feedback mechanism, whereby informal public space formation emerges as a compensatory response to deficiencies in formal accessibility.

Table 3. Influence of Accessibility on Informal Public Space Formation

	Model 1: Presence (0/1)	Model 2: Count (Number)
Regression method	Logistic regression	Negative binomial regression
Exp(B)	0.059	0.102
95% CI	[0.007, 0.527]	[0.018, 0.595]
p-value	0.011*	0.011*
Sample size (n)	66	66
Model fit	McFadden R^2 = 0.316	Pearson χ^2/df = 0.570

Note: * p<0.05; ** p<0.01.Model 1 estimates the probability of informal public space presence; Model 2 estimates its quantity.

4. Discussion

4.1 Deficiencies in Conventional Accessibility Planning

With the accelerating ageing process, differences between younger-old and oldest-old residents can surpass those between elderly and non-elderly populations (Neugarten, 1974). Nevertheless, current urban planning often treats older adults as a single group, using average walking capacity to define service radii for public spaces, which fails to address the age-specific needs of this population. In Shanghai, the Beautiful Homes Three-Year Action Plan (2021–2023) was implemented as part of the broader 15-Minute Community Life Circle initiative, aiming to improve community environments through micro-scale renewal (Liu, Qian, Huang and Zhou, 2020). However, many newly built formal public spaces remain underutilised, while informal areas such as residential entrances and street-facing shopfronts attract frequent use by elderly residents.

Empirical findings further demonstrate that the walking distance of the oldest-old group is significantly shorter than that of the young-old. However, current planning practices overlook this disparity, resulting in a systematic overestimation of formal public space accessibility for the senior population. Moreover, formal public spaces often exhibit homogenisation in scale, spatial layout, and functional design, with limited adaptation to the specific needs of senior residents, such as provisions for short-distance resting or enhanced visual safety (Sun et al., 2020). This misalignment between spatial supply and actual behavioural demand drives elderly residents to frequent informal public spaces near residential entrances and street-facing shops. Variations in accessibility among different housing units primarily reflect disparities in the spatial provision of housing. In contrast, disparities among elderly age groups within the same unit reveal deeper issues related to equity in the allocation of public space.

4.2 Informal Public Space as a Behavioural Adaptation

The theory of everyday urbanism emphasises that the production of urban space is shaped not only by top-down planning and design but also by residents' routine behaviours and spatial practices. Informal public spaces emerge spontaneously through micro-scale actions by elderly residents, such as placing chairs or installing pergolas. These spatial practices complement formal spaces and reflect overlooked equity demands of elderly residents (Torres and Cao, 2019). The formation and spatial distribution of informal public spaces exhibit apparent regularities, with concentrations typically observed in highly accessible locations such as entrances of residential compounds and areas beneath the eaves of street-level shops. This spatial pattern is shaped by the combined influence of physiological limitations and psychological needs among elderly residents. Proximity to residential buildings ensures that these locations remain reachable even for individuals with reduced mobility. At the same time, such areas often offer open sightlines and steady pedestrian flows, which enhance the perceived safety of outdoor activities and provide opportunities for social interaction and incidental encounters with acquaintances, fulfilling essential psychological and social needs. In contrast, although physically open, marginal spaces such as street corners, the peripheries of enclosed green areas, or the backs of public facilities, are rarely used by elderly residents. These areas lack sufficient accessibility, visibility, and pedestrian presence, and are often devoid of environmental familiarity. These findings suggest that the formation and utilisation of informal public spaces are not solely determined by physical attributes, but reflect active spatial choices made by elderly individuals within the constraints of their physical capabilities. Such preferences underscore a perceived demand for environments that offer both safety and opportunities for social interaction.

4.3 Strategies for Integrating Informal Public Spaces into Planning Frameworks

Although formal public spaces can theoretically achieve optimal spatial allocation through rational planning and design, their implementation is often constrained by limited land availability and high construction costs. These constraints hinder formal spaces' ability to fully meet the diverse activity needs of senior residents, particularly in communities with high population ageing. In this context, informal public spaces serve an essential compensatory role due to their flexibility, convenience, and proximity to residential areas. With appropriate guidance and moderate planning intervention, these spontaneously formed spaces can be gradually integrated into the formal public space system. Such integration can effectively address the limitations of formal planning and enhance the overall equity and responsiveness of urban public space provision (Sikorska et al., 2020).

The strategic incorporation of small-scale public spaces at spontaneous gathering sites can effectively respond to the diverse needs of elderly residents in ageing communities where spatial resources are limited. First, modest physical improvements at residential entrances and exits, including surface paving, ground levelling, and installing seating, shading structures, and handrails, can transform these locations into formally accessible areas for rest and social interaction. Second, residual spaces beneath shop eaves can be utilised by providing simple benches or small activity platforms, thereby encouraging elderly residents to gather in a safe and orderly manner within the street environment. When immediate physical upgrades are not feasible, community-led services such as regular health consultations, social activities, or chess games can activate these spaces and incorporate them into routine community management. Through the coordinated advancement of physical

micro-renewal and service provision, informal public spaces can be gradually integrated into the broader public space system. This process not only addresses the differentiated needs of elderly residents across age groups but also improves spatial utilisation, promotes resident engagement, and enhances the overall quality of life in ageing communities.

5. Conclusion

This study highlights the importance of behavioural heterogeneity in assessing public space accessibility for elderly residents. The MGH3SFCA model, which integrates age-specific walking distances and activity frequencies, reveals that conventional approaches substantially overestimate accessibility. The spatial emergence of informal public spaces in low-accessibility areas further reflects bottom-up compensatory behaviours driven by unmet needs. Two policy implications can be drawn. First, accessibility models should differentiate between elderly subgroups to avoid systemic misestimations. Second, informal public spaces should be considered essential for ageing-supportive urban systems. Behaviour-sensitive modelling and inclusive spatial design collectively provide promising strategies for achieving more equitable and effective public space provision in ageing societies.

Inclusive Urban Planning Based on Time-Use Analysis: A Markov Chain Approach Across Family Life Cycles

Jing Guo, De Wang[1]

Abstract
As China's urbanization shifts from rapid expansion to quality-oriented development, understanding the dynamics of time use across different stages of the family life cycle is essential for designing more inclusive and targeted urban planning strategies. Time, as a key indicator of quality of life, is profoundly influenced by family structure, social roles, and the living environment. However, existing studies on time pressure and behavioral dynamics lack a systematic life-cycle perspective. Drawing on the 2018 Shanghai time-use survey, this study identifies weekday activity structures and high time-pressure periods across typical life stages and applies a Markov chain model to construct activity-state transition matrices. Through this, we uncover critical spatiotemporal stress points at each stage and propose planning strategies for inclusive cities. Key findings include: (1) Time-use patterns evolve from a "work-oriented" structure to a more complex "care–work–leisure" interplay as families progress through life stages, with the childcare phase showing the most acute time pressure. (2) Entropy-based fragmentation metrics highlight morning and evening peaks as the most stressful periods. (3) Markov models reveal frequent activity transitions within these pressure zones: work-centric paths dominate during the pre-nesting phase; dual cores of employment and family responsibilities emerge during the nesting phase; childcare years exhibit the most complex and fragmented chains; post-child phases shift toward work and leisure; and the dissolution phase focuses on health care and rest. (4) Based on these insights, we propose differentiated spatial strategies aligned with family life cycles, including nighttime leisure facilities, parenting support spaces, and age-friendly infrastructure. This research contributes to a deeper understanding of dynamic time-space behaviors and offers data-driven insights for building age-inclusive and socially equitable cities.

Keywords: Time use; Family life cycle; Markov chain; Time pressure; Inclusive urban planning

0. Introduction

Identifying differences in residents' time use across various life stages is crucial for advancing inclusive urban planning. Time is not only a constraint on daily activity participation but also a central indicator of quality of life and lifestyle (Jiao & Wang, 2021). With the advancement of activity-based approaches, spatiotemporal behavior research has deepened, and concepts such as time-space prisms and potential path areas have provided a theoretical foundation for linking time use with life quality.

The family life cycle offers a critical perspective for understanding the evolving stages of family development, encompassing processes such as marriage, childbearing, child-rearing, children leaving home, and elder care (Wang & Liu, 2024). In recent years, China's family structures have become increasingly diverse, with a rise in aging populations, nuclear families, and empty-nest households, accompanied by a continuous restructuring of internal family roles. In Shanghai, for instance, people aged 60 and above make up 23.4% of the population, and grandparents are responsible for 31.7% of childcare for children aged 0–3 (Ma et al., 2023), highlighting the prevalence of "active aging." At the same time, young adults face challenges such as flexible employment and economic dependence on parents(Wang, 2024), with intensified workloads and parenting responsibilities leading to time poverty and declining life satisfaction (Jiao et al., 2023).

While prior research has addressed the impacts of aging, family transformation, and employment pressures on well-being, systematic time-use studies from a family life cycle perspective remain limited. This gap constrains our understanding of the mechanisms behind quality of life and hinders the formulation of evidence-based urban policies.

This study draws on the 2018 Shanghai residents' time-use survey to classify five stages of the family life cycle and extract twelve major categories of daily activities. It summarizes time-use patterns across life stages, identifies high time-pressure periods using fragmentation entropy, and applies a Markov chain model to extract

typical behavior transition pathways. By uncovering the distinctive time-pressure characteristics and behavioral mechanisms of each life stage, the study offers targeted recommendations for inclusive urban planning.

1. Literature Review

The family life cycle is a theoretical concept that describes the developmental stages a family undergoes from formation to dissolution. First introduced by sociologists Sorokin, Zimmermann, and Galpin in 1931, the framework outlines key life events such as marriage, childbirth, children leaving home, and the death of family members (Sorokin et al., 1931). Building on this foundation, Paul C. Glick (1947) proposed a more systematic classification, dividing the family life cycle into the formation, expansion, stability, contraction, empty-nest, and dissolution stages—each corresponding to critical family milestones like marriage, child-rearing, children becoming independent, and spousal loss (Glick, 1955). This framework has proven valuable for understanding evolving family needs and behavioral shifts across stages, and it has been widely applied in sociology, economics, demography, and urban planning.

In recent years, scholars have localized and refined the family life cycle theory to better reflect China's social realities. For example, Guo Jingjing and Chai Yanwei (2014) examined suburban residents' lifestyles and leisure preferences, emphasizing how leisure activity types and time allocation vary by life stage. Du Xiaojuan et al. (2017) further subdivided the "full nest" phase into distinct stages such as infancy, preschool, school age, and adult children, offering a more nuanced view of parenting-related transitions, particularly in consumption preferences and shopping behavior. Mao Yaqian and Li Jiuquan (2020) focused on the elderly and multigenerational households, identifying diverse living arrangements such as empty-nest single living and co-residence with children. Their work expanded the applicability of the life cycle framework by incorporating the perspective of intergenerational family support.

The family life cycle not only shapes individual behavior but also deeply influences urban spatial practices. Research shows that life stages significantly affect housing decisions (Pan, 2024), spatial settlement preferences among migrant populations (Yang et al., 2024), and willingness to participate in the renewal of aging neighborhoods (Xiao et al., 2022). Thus, detailed segmentation of the life cycle offers critical insights into understanding modern household spatial needs, aligning urban services, and informing policy interventions. In particular, it serves as a guiding framework for inclusive urban planning and housing policy in the face of population aging and increasing multigenerational living arrangements.

Time Use Surveys (TUS) serve as high-resolution tools for recording individuals' daily activities and time allocation. Now conducted in over 100 countries worldwide, TUS data are widely applied across disciplines such as sociology, economics, gender studies, and the built environment (Osman & Ouf, 2021). A time use pattern refers to the structure of activity types, sequences, and time distribution over a given period, encompassing key life dimensions such as work, domestic chores, leisure, and commuting (Song et al., 2023). These behavioral patterns involve both static attributes—such as activity type, location, and social role—and dynamic temporal sequences.

In recent years, growing attention has been paid to the relationship between individual time use and subjective well-being. For instance, Zhao Hong (2023), using China's 2017 national TUS data, estimated that the "optimal work duration" for employees is 6.25 hours per day. Similarly, Jiao Jian et al. (2023) introduced a "time poverty" threshold, defining it as 60% of the median free time, and suggested that workers in Shanghai should have at least 2.72 hours of discretionary time daily.

Amid the twin challenges of population aging and digitalization, researchers have also focused on time-use patterns among specific groups. These include studies on older adults' travel time (Sen et al., 2022), sedentary behavior (Perchoux et al., 2023), and the use of leisure and screen time (Sturm & Cohen, 2019). Such research is increasingly important for identifying disparities in life satisfaction and addressing equity in public service provision, particularly for vulnerable populations.

From the perspective of dynamic behavioral modeling, the Markov Chain has become a widely used tool in studies of life cycle, health, employment, and mobility due to its structural capability to model state transitions (Xia et al., 2023). Its foundational assumption of "memorylessness"—where the probability of transitioning to the next state depends solely on the current state—makes it ideal for modeling evolving behavioral trajectories. In the context of family studies, Han et al. (2020) applied Markov models to explore pathways of family structure evolution, identifying typical transition chains and influencing factors between different life stages. When integrated with time use data, Markov Chain models can be used to construct activity time sequences and capture the structural dynamics of daily behaviors, thereby offering quantitative insight into how families reallocate time and adjust behaviors over the course of the life cycle.

Based on this foundation, the present study adopts the following analytical framework (Figure 1). First, using 2018 Shanghai TUS data, we focus on residents' time use during workdays and summarize time-use patterns across different stages of the family life cycle. Second, we apply entropy-based fragmentation metrics to identify high time-pressure periods for each stage. Third, using these high-pressure intervals as analytical windows, we calculate transition probability matrices via the Markov Chain model to reveal the most frequent activity shifts for each life cycle stage. Finally, we propose differentiated strategies for optimizing time-space resource allocation tailored to the unique spatiotemporal challenges of each stage.

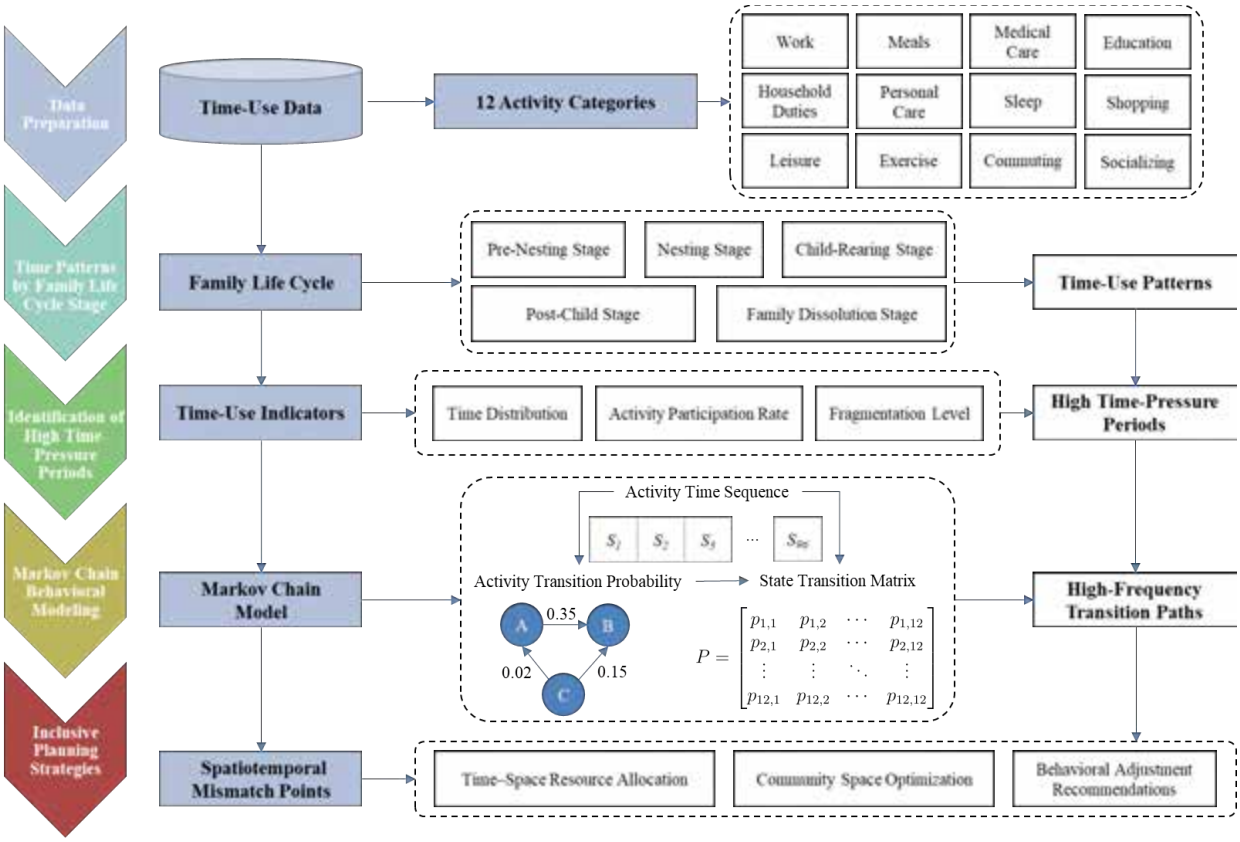

Figure 1. Technical Framework of the Study

2. Research Data and Methods

2.1 Time-Use Data

This study draws on data from the 2018 Shanghai Time Use Survey, which employed a stratified sampling approach and collected responses from 1,351 households, comprising a total of 3,297 individual samples. The survey captured comprehensive information on individual demographics, household composition, and time-use behaviors, documenting specific activities in 15-minute intervals over the course of a single day.

The raw data were cleaned and standardized, with all time entries converted into 96 uniform 15-minute segments per day to form a continuous time series. To simplify the analysis, 48 original detailed activity categories were consolidated into 12 broader activity types (Table 1). These categories represent the individual's activity status at each time point and serve as the basis for constructing the Markov transition model in subsequent stages of the research.

Table 1. Classification of Time-Use Activity Types

Category	Included Activities
Work	Full-Time Work, Part-Time Work, Agricultural Work, Non-Agricultural Business, Job Training, Vocational Training, Job Search
Household Duties	Household Management, Caregiving, Daily Care, Child Pick-Up/Drop-Off, Laundry and Cleaning, Cooking, Pet Care, Playing With Children
Leisure	Tea Drinking, Fishing, Board Games, Cultural and Media Activities, Web Browsing, Arts, Tourism, Smoking
Meals	Breakfast, Lunch, Dinner, Other Eating Activities
Personal Care	Grooming, Washing, Using the Restroom
Exercise	Fitness Training, Health Management
Medical Care	Medical Treatment, Doctor Visits, Accompanying Someone to The Doctor, Beauty Services
Sleep	Night Sleep, Rest Breaks, Naps
Commuting	Personal Transportation
Education	Formal Education, Adult Education, Homework, Tutoring, Waiting for Classes, Internships
Shopping	Buying Goods, Purchasing Services
Socializing	Social Visits, Companionship, Conversations, Volunteer Work

2.2 Classification of Family Life Cycle Stages

To systematically analyze structural differences in time-use patterns across life cycle stages, this study develops a tailored classification framework (Table 2), drawing on demographic and sociological theories of the family life cycle and incorporating the lived realities of Shanghai residents.

The classification is based on both the logical progression of household development and the intergenerational composition of family members. On one hand, five primary stages are defined according to changes in household structure and role transitions: Pre-Nesting, Nesting, Child-Rearing, Post-Child, and Family Dissolution. On the other hand, to reflect generational composition, the Child-Rearing stage is further divided into two subtypes: Nuclear Families (households composed of only parents and their children) and Multigenerational Families (households where three or more generations live together).

Table 2. Family Life Cycle Stage Statistics

Family Life Cycle Stage	Stage Description	Households
Pre-Nesting	Adult individuals who are single, unmarried, and childless, living independently. They have minimal family responsibilities, with daily activities centered around work and personal routines.	N = 105
Nesting	Married or cohabiting couples without children. These households are in stable partnerships, take on limited domestic responsibilities, and are not yet engaged in childrearing.	N = 127
Child-Rearing	Households with children aged 0–18 or grandparents caring for grandchildren in the same age range. Includes both nuclear and multigenerational families. Typically face heavy caregiving and domestic responsibilities.	N = 406
Post-Child	Households where children have reached adulthood or are attending university (18+), but still reside with parents or grandparents. While caregiving burdens are reduced, intergenerational cohabitation requires continued resource and space coordination.	N = 208
Family Dissolution	Households where children have fully left home, or where the family structure has undergone reorganization (e.g., divorce, widowhood, empty nest). These households are typically composed of older adults or grandparents living with adult children. Time autonomy is high, but issues such as health concerns, loneliness, or spatial mismatch may arise.	N = 505

2.3 Markov Chain Model

2.3.1 Time Distribution and State Definition

On the temporal dimension, each 24-hour workday is divided into 96 discrete time intervals, each representing a 15-minute segment. For each interval, the individual's primary activity is recorded and treated as a discrete state, denoted as S_t. This produces a daily activity-state sequence of length 96 for each individual:

$$\{S_1, S_2, \ldots, S_{96}\}$$

According to the classification system outlined in Table 1, all activities are grouped into 12 major categories. Each category is defined as a unique state, forming the complete set of possible activity states:

$$S=\{S_1, S_2, \ldots, S_{12}\}$$

This state set captures the primary behavioral types that make up residents' daily routines and serves as the foundation for the subsequent Markov chain-based behavioral modeling.

2.3.2 Activity Participation Rate

At the aggregate level, to assess the prevalence and temporal patterns of different activity types across family life cycle stages, this study introduces the indicator of activity participation rate. This metric reflects the proportion of individuals engaged in a specific activity during a given time interval, relative to the total sample size at that time. It is used to identify the temporal concentration and peak periods of particular behaviors.

The participation rate is calculated using the following formula:

$$P_{a,t} = \frac{N_{a,t}}{N_t} \times 100\%$$

Where: $P_{a,t}$ represents the participation rate of activity a at time t; $N_{a,t}$ is the number of individuals engaged in activity a during that time interval; and N_t is the total number of individuals in the sample at time t.

2.3.3 Fragmentation Entropy Calculation

During periods characterized by frequent transitions between activity states, individuals are more likely to experience elevated time pressure. To capture the degree of time-use fragmentation, this study employs the Shannon entropy index. Based on each individual's full-day activity sequence, the proportion of time spent on each activity category is calculated, and the corresponding fragmentation entropy is computed as follows:

$$H = -\sum_{i=1}^{n} p_i \log_2 p_i$$

Where: p_i represents the proportion of total daily time spent on activity category i, and $n = 12$ is the total number of activity categories. A higher fragmentation entropy indicates that the individual engages in a greater variety of activities, with more frequent transitions and a more dispersed time distribution throughout the day.

In addition, this study also calculates group-level fragmentation entropy at each time point. Specifically, for a given life cycle stage, the activity distribution $p_i(t)$ across all individuals during a specific time interval is used to compute the Shannon entropy. This value reflects the behavioral diversity of the group at that particular moment in time.

2.3.4 Identification of High Time-Pressure Periods

By plotting the average fragmentation entropy curve across the 96 daily time intervals for each family life cycle stage, this study identifies periods marked by sharp increases in entropy and significant behavioral diversity. These intervals are defined as high time-pressure periods. Such periods often correspond to peak commuting hours or times when multiple household responsibilities converge, characterized by frequent activity switching and heightened time constraints.

2.3.5 Markov Modeling and Transition Matrix Construction

After identifying the high time-pressure periods, the activity-state sequences of individuals within these intervals are extracted for each family life cycle stage. A first-order discrete-time Markov chain model is then constructed, where the state transition is defined as follows:

$$P(S_{t+1} = j \mid S_t = i) = p_{ij}$$

Where: p_{ij} represents the probability that an individual currently in state *i* transitions to state *j* in the next time interval. For each family life cycle stage, all observed transitions during the high time-pressure periods are aggregated and normalized to construct the state transition probability matrix:

$$P = \begin{bmatrix} p_{1,1} & p_{1,2} & \cdots & p_{1,12} \\ p_{2,1} & p_{2,2} & \cdots & p_{2,12} \\ \vdots & \vdots & \ddots & \vdots \\ p_{12,1} & p_{12,2} & \cdots & p_{12,12} \end{bmatrix}$$

This matrix captures the internal structure of behavioral switching within each life cycle stage. It serves as the basis for identifying typical high-frequency behavioral pathways and uncovering structural differences in time allocation and daily rhythms across different family types.

3. Time-Use Patterns Across Family Life Cycle Stages

3.1 Weekday Time Allocation in Representative Family Life Cycle Stages

The time-use survey data clearly illustrate the full-day structure of individual schedules, patterns of household division of labor, and spatial activity chains. Representative households from each family life cycle stage were selected from the sample, and 24-hour weekday activity timelines were constructed for all household members (Figure 2).

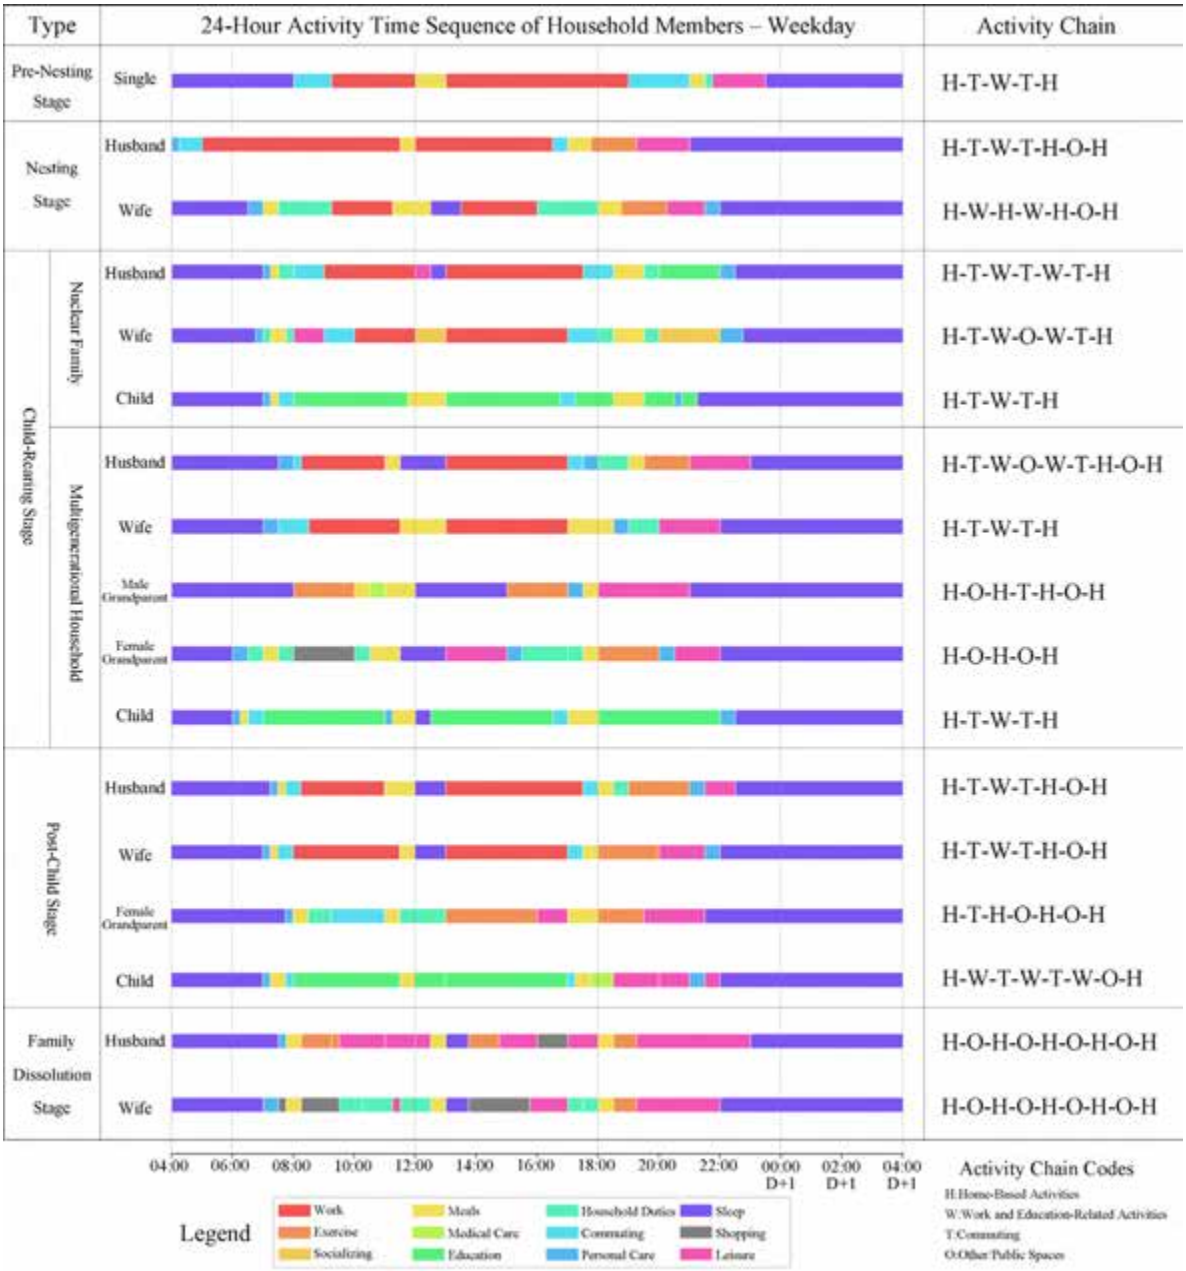

Figure 2. Time-Use Distribution on Workdays Across Typical Family Life Cycle Stages

1. Pre-Nesting Stage: The household consists of a single adult male or female. The daily activity pattern follows a streamlined "Work–Commute–Leisure–Sleep" cycle. The activity chain is highly simplified, with strong personal control over time and no interference from household responsibilities, reflecting a typical pattern of autonomous time use.

2. Nesting Stage: The household is composed of a husband and wife, both primarily engaged in professional work, with generally synchronized daily rhythms. In addition to the basic commute–work loop, their activity chains include connections to non-residential spaces such as commercial areas or fitness facilities, reflecting expanded engagement in leisure and personal services. The wife assumes household responsibilities before and after meals, indicating the early formation of an internal division of labor.

3. Child-Rearing Stage (Nuclear Family): Both the husband and wife maintain work-centered schedules, but with additional responsibilities related to caregiving and education, reflecting the time pressure experienced by dual-earner households balancing employment and parenting. Children follow a "Study–Rest" structure.

Child-Rearing Stage (Multigenerational Family): Compared to nuclear households, some caregiving responsibilities are shared with grandparents. These older family members typically follow short-loop activity chains (e.g., Home–Outside–Home), centered around shopping, caregiving, and meal preparation, thus providing auxiliary parenting support. As a result, both the husband and wife enjoy more leisure time than in nuclear families. Children still follow a study-oriented routine, forming a clear model of intergenerational division of labor and cooperative caregiving.

4. Post-Child Stage: The husband and wife continue to work, while their children are in college. Household caregiving demands are significantly reduced, with noticeable increases in time spent on fitness and leisure activities. Their activity chain shifts from the previously intense "Commute–Work–Caregiving" mode to a more relaxed "Work–Leisure/Fitness" structure.

5. Family Dissolution Stage: Most household members are empty-nest elderly individuals. Daily routines center around non-work activities such as leisure, exercise, and shopping. The activity chain is highly flexible with minimal repetition, and the time structure is loose, indicating a high degree of autonomy and a lifestyle characterized by "non-commuting, non-working" patterns.

3.2 Time-Use Patterns Across Family Life Cycle Stages

Figure 3 presents the average weekday duration of each activity category across the five family life cycle stages, highlighting the overall influence of life stage on time-use patterns—particularly in the allocation of time to work, household duties, and leisure.

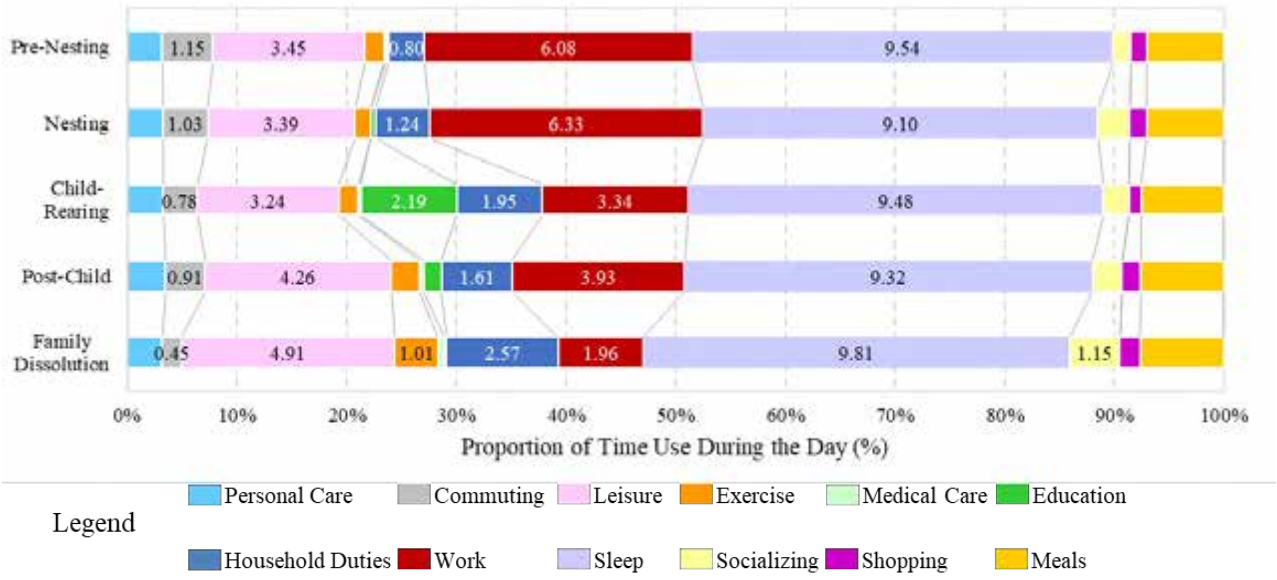

Figure 3. Average Daily Activity Duration by Family Life Cycle Stage

First, work hours exhibit an overall inverted U-shaped pattern. During the career-intensive stages of the Pre-Nesting and Nesting phases, average work durations reach 6.08 and 6.33 hours per day (h/d), respectively. As families enter the Child-Rearing stage, work time becomes compressed due to increased caregiving responsibilities, though both husbands and wives continue to spend substantial time working. In the Post-Child and Family Dissolution stages, work duration gradually declines to 3.93 h/d and 1.96 h/d, respectively—reflecting a restructuring of daily schedules in the context of retirement.

Second, household responsibilities and educational activities peak during the Child-Rearing stage. Individuals in this stage spend an average of 2.19 h/d on education-related tasks and 1.95 h/d on household duties—significantly higher than in any other life stage. This suggests that family members are simultaneously managing both caregiving and educational support, making it one of the most time-pressured phases of the life cycle.

Third, leisure and physical exercise time increases at both ends of the life cycle. Residents in the Pre-Nesting, Post-Child, and Family Dissolution stages each report more than 3.4 h/d of leisure time. In the Family Dissolution stage specifically, individuals also spend about 1 h/d on exercise and socializing, resulting in nearly twice as much discretionary time as those in the Child-Rearing stage. This shift reflects greater time autonomy and a slower, more flexible daily rhythm.

In contrast, sleep duration remains stable across all life stages, with average sleep time exceeding 9 h/d in each category. This consistency underscores sleep as a basic physiological necessity, largely unaffected by changes in life stage.

Finally, commuting time is most prominent during the Pre-Nesting, Nesting, and Child-Rearing stages, indicating that commuting is closely tied to employment. The time squeeze becomes especially acute when individuals must balance full-time work with active parenting responsibilities.

Further, Figure 4 illustrates the full-day activity participation rates on weekdays across the five family life cycle stages, revealing the stage-specific influence of family life progression on individual time rhythms and allocation patterns.

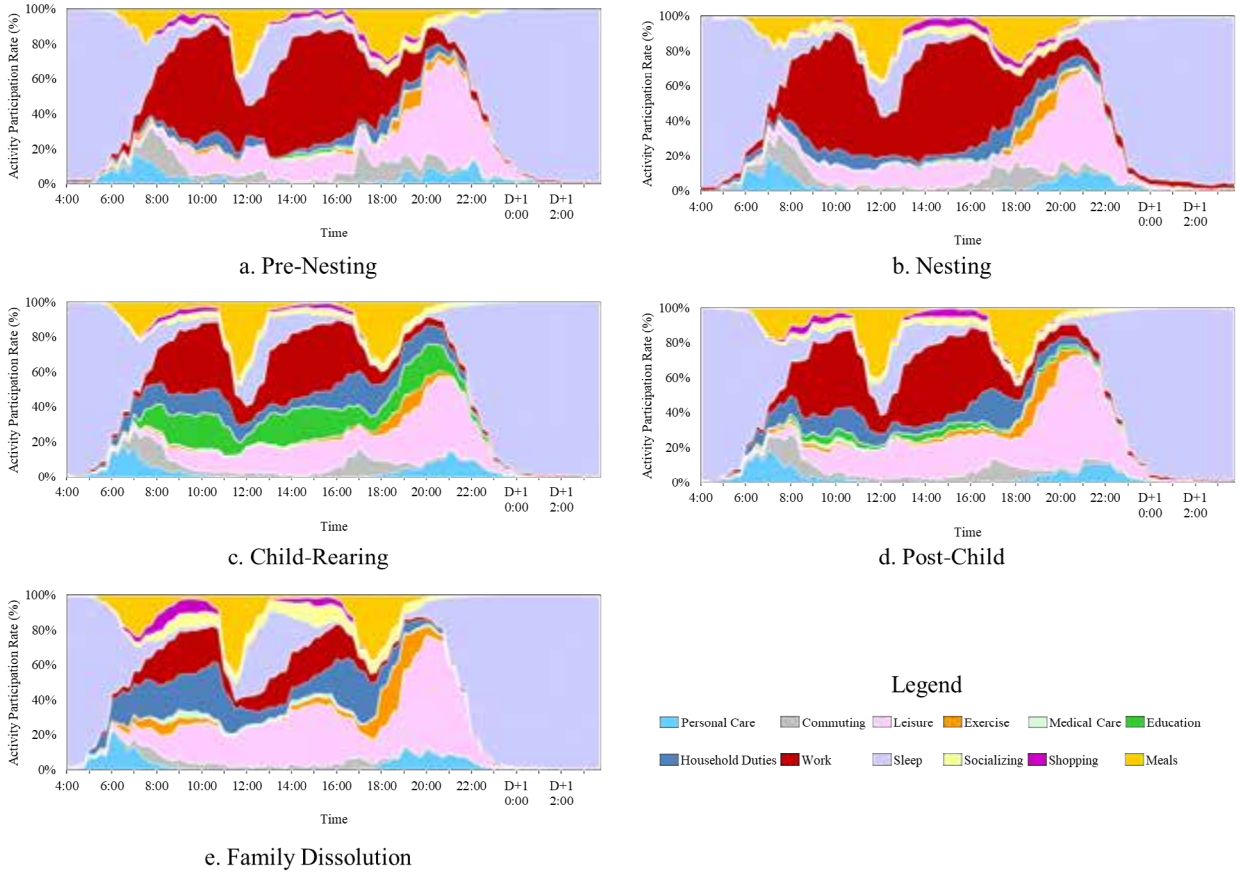

Figure 4. Activity Participation Rates Throughout the Day by Family Life Cycle Stage

1. Pre-Nesting Stage: Time-use rhythms are highly concentrated and autonomous. Work-related activities form a clear double peak between 9:00–12:00 and 14:00–18:00, while commuting peaks appear around 8:00 and 18:00, reflecting an intensive "commute–work" cycle. After 19:00, leisure becomes dominant—particularly virtual forms of leisure—with participation rates approaching 60%, indicating a high level of temporal freedom.

2. Nesting Stage: Daily rhythms are strongly work-centered, exhibiting clear synchronization between partners and emerging patterns of household coordination. Work participation remains high from 9:00 to 17:00, with pronounced commuting peaks that slightly extend earlier and later than in the Pre-Nesting stage. Participation in household duties, shopping, and exercise rises during early morning and evening hours, suggesting the early formation of internal role division and shared domestic routines.

3. Child-Rearing Stage: This stage shows the most complex distribution of activities, with a fragmented time-use pattern driven by the interplay of employment and caregiving. Work and educational activities remain high between 9:00 and 17:00, while commuting peaks occur from 7:00–8:00 and 16:30–17:30. Household duties and meals are concentrated in the morning, midday, and evening, highlighting the pressure of managing multiple roles—work, caregiving, and domestic tasks. In multigenerational households, grandparents also participate in household responsibilities and shopping during morning and afternoon hours. Leisure and exercise are mostly confined to nighttime, often squeezed out by other obligations.

4. Post-Child Stage: Daily activities shift toward leisure and personal development. While employed household members continue to follow standard work routines, work and commuting participation rates decline compared to the Nesting stage. Participation in leisure, exercise, and social activities increases significantly, indicating a growing emphasis on quality of life outside of work. Household responsibilities remain stable and relatively minimal.

5. Family Dissolution Stage: The structure of daily activity participation shifts strongly toward non-work and self-care routines. Participation in work and commuting drops sharply, while leisure, exercise, and socializing become the primary components of the day. Household duties and shopping are distributed across the morning and afternoon hours, and the overall daily rhythm is more relaxed—reflecting the increased time autonomy of older adults.

4. Time Pressure Identification and Markov Chain Behavioral Modeling

4.1 Identifying High Time-Pressure Periods

On weekdays, different family life cycle stages exhibit distinct patterns of time fragmentation. To identify high time-pressure periods across family types, this study uses fragmentation entropy as an indicator of activity-switching frequency and temporal discontinuity. A higher entropy value indicates more frequent activity transitions and greater behavioral dispersion within a given time interval, reflecting heightened tension in time management.

Following the approach of Shi et al. (2022), we adopt a fragmentation entropy threshold of 2.8 to define high time-pressure periods, based on the following rationale: (1) Across all life cycle stages, the value of 2.8 falls within the upper quartile of entropy distributions, indicating relatively intense time fragmentation; (2) As shown in earlier analyses, when entropy exceeds this threshold, behavioral patterns typically involve rapid transitions between work, household duties, and commuting—hallmarks of time fragmentation overload. Therefore, 2.8 is used as the dividing line between routine daily rhythms and high time-pressure conditions.

Figure 5 presents the fragmentation entropy curves for weekdays across different family life cycle stages, along with the identified high time-pressure periods.

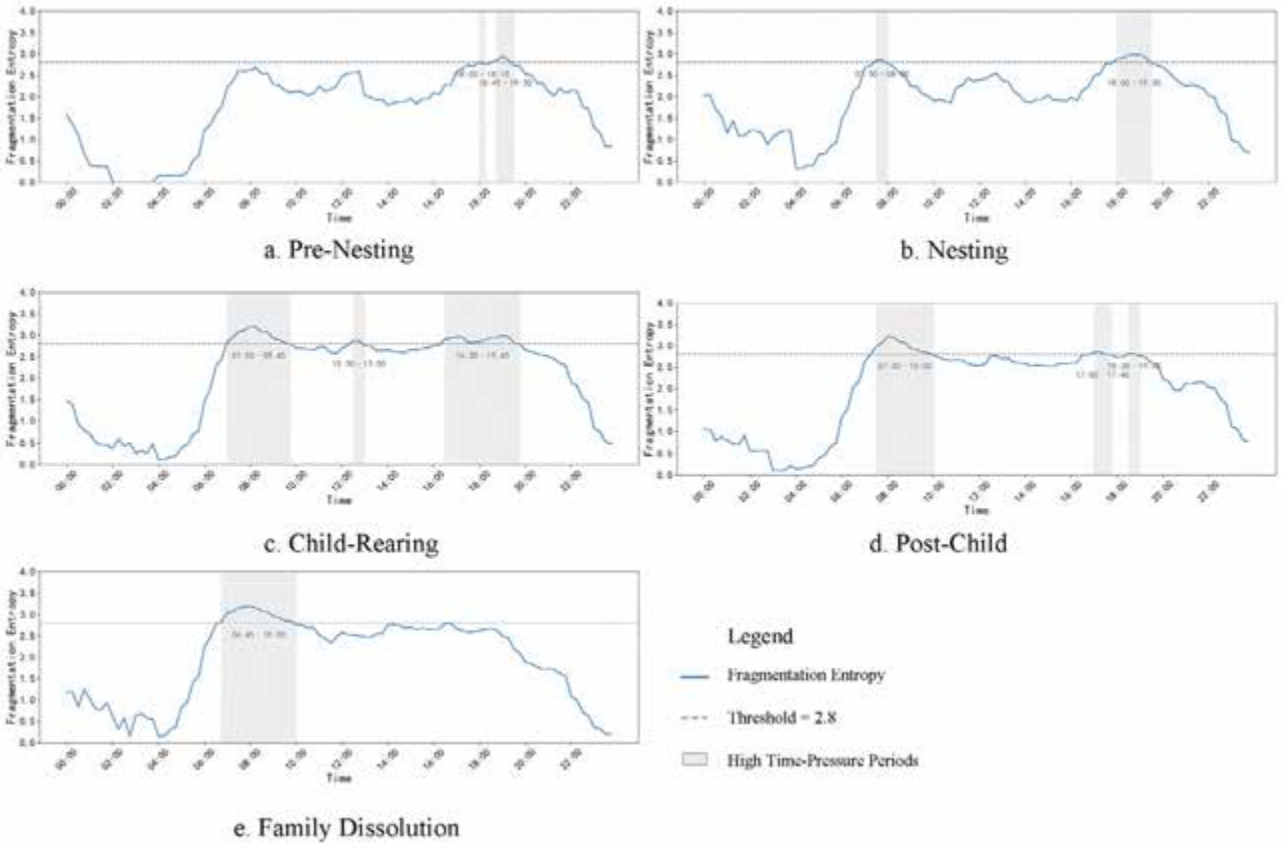

Figure 5. Intraday Variation of Time Fragmentation Entropy Across Life Cycle Stages

1. Pre-Nesting Stage: Entropy levels remain stable throughout the day, briefly exceeding the threshold only between 18:00 and 19:30. This suggests a generally manageable time rhythm with minimal scheduling stress.

2. Nesting Stage: Notable entropy spikes occur during two commuting peaks—7:30–8:00 and 18:00–19:30—highlighting time pressure arising from transitions between commuting, work, and emerging household responsibilities.

3. Child-Rearing Stage: Displays a clear "three-phase" structure of time pressure, with elevated entropy from 7:00–9:45 (morning commute and school drop-off), 12:30–13:00 (midday rest and domestic chores), and 16:30–19:45 (evening caregiving and household tasks). Entropy remains high for extended periods, marking this as the most prolonged and intense stage of time pressure.

4. Post-Child Stage: While the early morning (7:30–10:00) and evening (17:00–19:00) still show noticeable increases in entropy, the overall fluctuation is more moderate, reflecting reduced caregiving burdens and a partial alleviation of time stress.

5. Family Dissolution Stage: Elevated entropy appears only during 6:45–10:00, after which the daily rhythm stabilizes. This reflects a typical post-retirement pattern—high autonomy with concentrated morning activity followed by a slower, more relaxed pace throughout the day.

4.2 Identifying High-Frequency Behavioral Transitions Using Markov Chains

To further uncover behavioral patterns during high time-pressure periods across different family life cycle stages, Markov transition matrices were constructed based on the previously identified high-fragmentation time windows. These matrices model the weekday activity transitions for each of the five life cycle stages under time pressure. The matrices capture the probability of shifting from one activity to another, while the bar charts above each matrix (Figure 6) display the inflow probability of each activity type.

Overall, the structure of activity transitions under time pressure varies significantly across life stages, reflecting two key dimensions: the functional concentration of behavioral pathways and the complexity of transitions.

1. Pre-Nesting Stage (Figure 6a): The transition structure is relatively simple, with work remaining the central activity during pressure periods. The dominant transition pathways include Work - Commuting, Commuting - Meals, and Meals - Leisure, indicating a focused routine with few competing demands.

2. Nesting Stage (Figure 6b): Work and household responsibilities coexist, forming a dual-core transition structure. In addition to the work-centered transitions, notable pathways include Household Duties - Meals (0.34) and Leisure - Household Duties (0.21), suggesting an emerging division of domestic labor between partners.

3. Child-Rearing Stage (Figure 6c): The transition matrix is highly complex and densely connected, reflecting a multi-centered, high-pressure behavioral landscape. Prominent pathways include Education - Meals (0.19), Household Duties - Meals (0.21), Shopping - Household Duties (0.19), and Medical Care - Household Duties (0.21). These transitions form a dual-loop structure of education and caregiving, indicating the need for frequent multitasking. Notably, the inflow probability for Sleep is relatively high, highlighting a strong demand for restorative activities among residents in this stage.

4. Post-Child Stage (Figure 6d): Behavioral transitions shift back toward work and leisure. While work-related pathways remain visible, they appear more compressed. Commuting remains a burden, though household responsibilities begin to ease. Leisure activity sees an increase in inflow probability, suggesting a growing emphasis on personal time.

5. Family Dissolution Stage (Figure 6e): The transition network becomes significantly simplified, centering on a loop between self-care, household duties, meals, and leisure. Core pathways include Medical Care - Leisure (0.21) and Leisure/Exercise - Household Duties (0.23), reflecting a rhythm of health maintenance and relaxed daily living. The inflow probability for work-related activities drops sharply, underscoring a non-productive, high-autonomy time-use structure typical of older adults.

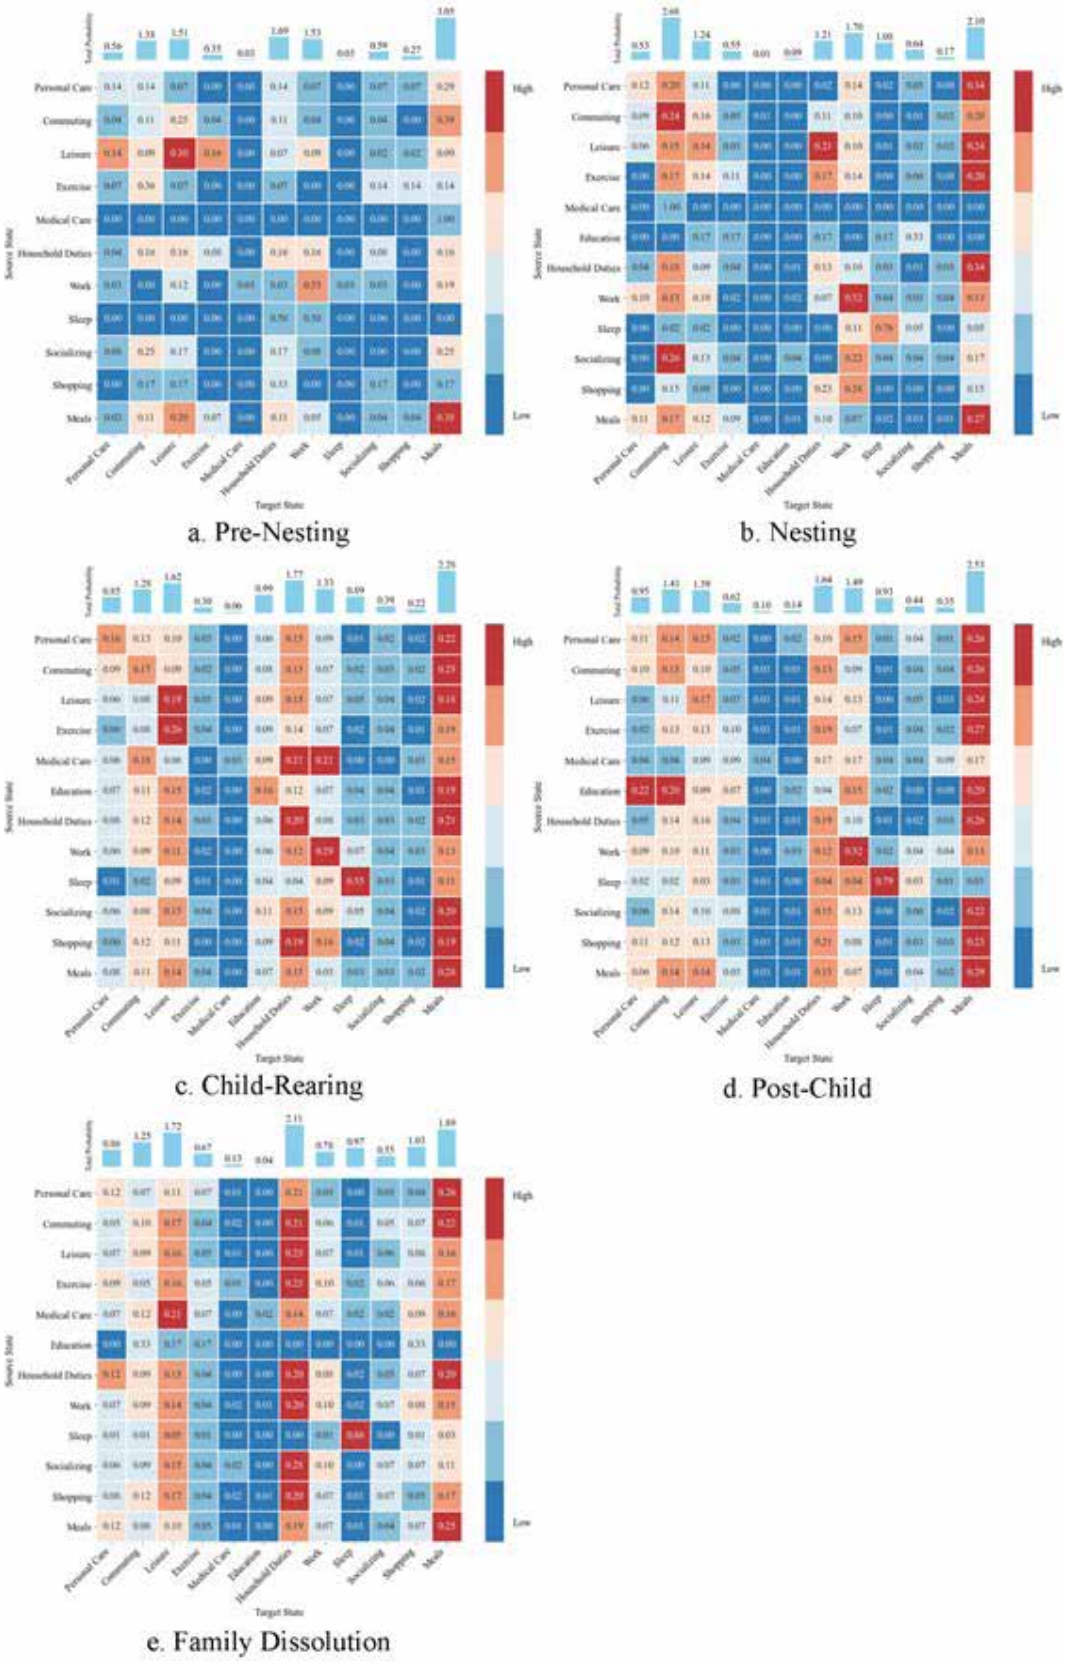

Figure 6. Markov Transition Matrices and Inflow Probabilities by Family Life Cycle Stage

5. Spatiotemporal Needs and Recommendations for Inclusive Urban Planning

5.1 Life Cycle–Oriented Spatiotemporal Matching Needs

With the integration of the family life cycle perspective, residents' time-use behaviors and spatial activity needs exhibit distinct stage-specific differences. Drawing on the earlier identification of high time-pressure periods and Markov-based behavioral transitions, we can pinpoint the unique time constraints, high-frequency activity pathways, and spatial stress points at each life cycle stage (Table 3).

Traditional urban planning—centered around a binary "residence–work" model—struggles to accommodate the complex, multi-role, multi-task, and multi-node behavioral patterns that emerge within family structures. This calls for a fundamental shift toward a spatiotemporal supply–demand framework that balances employment, caregiving, leisure, and aging needs. From the perspective of the family life cycle, spatial resources must be more flexibly adapted at the neighborhood scale. This provides a foundation for developing inclusive urban planning strategies that are responsive to the evolving demands of residents across different stages of life.

Table 3. Time-Pressure and Spatiotemporal Stress Points Across Family Life Cycle Stages

Family Life Cycle Stage	Time-Pressure Periods	High-Frequency Behavioral Pathways	Key Spatial Mismatches
Pre-Nesting	18:00-19:30	Work – Commuting – Meals – Leisure	Urban spatial design remains poorly aligned with the post-work evening routines of single young adults, with a lack of integrated online–offline options for nighttime dining and leisure.
Nesting	07:30-8:00 18:00-19:30	Commuting – Work Work – Household Duties Household Duties – Meals	There is limited last-mile connectivity between residential areas and public transit stations. Morning peak commuting is burdensome, and community-based convenience services need to be strengthened to help absorb household responsibilities.
Child-Rearing	07:00-9:45 12:30-13:00 16:30-19:45	Commuting – Work Work – Household Duties Education – Meals Household Duties – Meals Shopping–Household Duties	Spatial connectivity between education, dining, and shopping facilities is weak, creating overlap between commuting and caregiving demands. Community-level infrastructure for temporary childcare, midday rest, convenient pick-up/drop-off, and last-mile delivery requires optimization.
Post-Child	07:30-10:00 17:00-19:00	Work – Commuting – Meals Household Duties – Leisure	Commuting pressure remains significant, and there is a lack of diverse leisure spaces near residential areas tailored to the needs of middle-aged adults.
Family Dissolution	6:45-10:00	Household Duties – Meals Leisure – Household Duties Errands – Household Duties Medical Care – Leisure	Age-friendly upgrades are urgently needed in residential communities to support older adults' morning access to food and shopping. Additional public spaces for senior socialization, fitness, and wellness activities are also needed.

5.2 Recommendations for Inclusive Urban Planning

To address the spatial needs of different family life cycle groups during high time-pressure periods, urban planning and community renewal efforts should adopt more inclusive and differentiated service strategies:

1. Pre-Nesting Stage: Encourage the development of the nighttime economy in employment hubs and central commercial districts by supporting extended hours for dining and entertainment venues. Introduce digitally integrated leisure spaces—such as live-streamed night markets and immersive social platforms—to meet the post-work needs of single young adults for dining, entertainment, and social interaction.

2. Nesting Stage: Provide shared mobility services and last-mile connection infrastructure between residential areas and public transit stations, and improve multimodal commuting systems. Within neighborhoods, incorporate convenient service modules such as domestic help, community kitchens, and centralized laundry facilities to help ease the burden of household responsibilities.

3. Child-Rearing Stage: In response to the overlapping spatial demands of commuting, school drop-off, employment, and caregiving, establish neighborhood-level family service centers. These should integrate midday childcare stations, after-school care facilities, community kitchens, and parent–child activity spaces. Additionally, expand last-mile delivery access points for online shopping to reduce time pressure and caregiving costs.

4. Post-Child Stage: Encourage communities and business parks to provide flexible leisure spaces, such as social cafés and hobby workshops, to help alleviate the mental fatigue associated with balancing career and evolving family roles among middle-aged adults.

5. Family Dissolution Stage: Promote comprehensive age-friendly upgrades to communities, including the addition of accessible, pleasant small-scale shopping venues and senior meal stations. Develop senior-friendly greenways for exercise, social spaces, and smart assistive infrastructure to support physical activity and social participation among older adults.

6. Conclusion and Future Directions

This study, grounded in a family life cycle perspective, draws on the 2018 Shanghai Time Use Survey to examine how time-use patterns vary across different stages of the family life cycle. By identifying high time-pressure intervals and high-frequency behavioral transitions, the study proposes inclusive urban planning strategies that respond to stage-specific needs.

The findings reveal that individuals in the Pre-Nesting stage exhibit a work-oriented time structure characterized by high autonomy and strong engagement in nighttime leisure. The Nesting stage is defined by a dual-core structure balancing professional commitments and emerging household responsibilities. The Child-Rearing stage presents the most complex time structure, with family members engaging in frequent multitasking across work, caregiving, education, and domestic duties—making it the stage with the highest time pressure. In the Post-Child stage, time use shifts back toward a work-led structure with a gradual transition to leisure. Finally, the Family Dissolution stage is marked by a non-productive, highly autonomous daily rhythm.

Using fragmentation entropy and Markov chain modeling, the study identifies the peak pressure periods and dominant behavioral pathways for each life cycle stage, revealing the underlying time allocation mechanisms and corresponding spatial needs. Based on these insights, the research puts forward family life cycle–oriented recommendations for inclusive urban planning, including the creation of nighttime leisure environments for young adults, improved commuting buffers and caregiving infrastructure for families with children, and age-friendly spatial upgrades to support social participation among the elderly.

This study offers both a micro-level lens on residents' everyday spatiotemporal behaviors and practical guidance for building age-inclusive, caregiving-supportive cities. Nonetheless, certain limitations remain. The analysis relies primarily on cross-sectional data and does not yet incorporate multisource spatiotemporal information. Future research should integrate longitudinal time-use surveys with GPS-based spatial data to support higher-resolution analyses and more robust spatial intervention strategies.

Abstract
As population ageing accelerates, safeguarding older adults' mobility is vital to promoting their physical health, mental well-being, and social inclusion. Given their reliance on walking within neighbourhoods, walkability is a key factor influencing mobility behaviours. This study refines existing walkability index by incorporating empirical data on older adults' travel characteristics, including walking speeds, gathered via surveys. Using Shanghai's Anshan area—a community with a high proportion of older residents—as a case study, a fine-grained (50 m × 50 m) grid-based analysis was conducted. The modified index reveals spatial disparities in walkability and delineates essential travel patterns within a 15-minute community life circle. Findings inform practical recommendations for age-friendly neighbourhood renewal, offering valuable insights for policy adjustments in the context of rapid demographic ageing.

Keywords: Walkability Index; Older adults; Daily Travel; Community Planning

0. Introduction

The global trend of population ageing is accelerating, with China—owing to its large population—undergoing an especially pronounced demographic shift. As of 2024, individuals aged 60 and above account for 22% of the national population, while those aged 65 and above comprise 15.6% (China National Bureau of Statistics, 2025). In light of the universal reality that "every family has an elder, and everyone will eventually age," the mobility and safety of older adults have emerged as critical societal concerns. As a major global city, Shanghai also faces substantial challenges related to population ageing. Advancing age is often accompanied by a decline in mobility, reduced social engagement, and diminished quality of life among older residents. Therefore, it is essential to investigate the factors influencing the travel frequency and mobility limitations of older people, in order to guide the planning and renewal of age-friendly communities.

Shanghai's "15-minute community life circle" initiative, although instrumental in enhancing residential environments, has yet to fully incorporate design principles tailored to the specific needs of older adults. Common issues such as pedestrian spaces being occupied by parked vehicles and suboptimal configurations of public facilities remain prevalent (Chen et al., 2016; Huang et al., 2022). This underscores an urgent need to optimise neighbourhood environments through an elderly-centred lens. While existing walkability indices serve as important tools for evaluating pedestrian-friendliness, they exhibit notable limitations. These include a failure to distinguish between types of destinations frequently visited by older adults, and a neglect of their subjective experiences and

perceptions (Wei et al., 2024; Weng et al., 2019). Most existing studies tend to focus on correlations between the built environment and physical health, with comparatively limited attention paid to mobility challenges as perceived by older adults themselves.

Furthermore, there remains a need to enhance the interpretability of research methodologies. Traditional investigations have predominantly relied on linear regression models to examine direct, linear relationships in travel behaviour. However, the emergence of machine learning techniques has enabled researchers to uncover more complex, non-linear patterns and threshold effects in mobility dynamics (Shi et al.,2022; Wu et al., 2021).

To address these methodological and conceptual gaps, this study proposes an analytical framework for evaluating walkability within community life circles, specifically tailored to the needs of older adults. Drawing upon a comprehensive literature review and empirical fieldwork—centred on the daily living requirements (e.g., shopping, leisure) and travel behaviours of elderly residents—this study refines facility weightings and correction coefficients embedded in conventional walkability indices, thereby formulating an improved, age-friendly walkability assessment system. Older residential neighbourhoods characterised by both a high concentration of ageing populations and mature built environments are selected as case studies. By calculating walkability indices for these areas, the study evaluates the influence of various spatial and environmental factors on accessibility for older adults, offering a theoretical foundation for the regeneration and transformation of urban communities. This study not only provides a robust scientific basis for the development of age-inclusive neighbourhoods but also represents a conceptual advancement in ageing studies—shifting the analytical focus from a singular emphasis on the built environment towards a multi-dimensional, integrated perspective. In doing so, it contributes to the broader societal objective of ensuring that older adults may age with dignity, adequate support, and enhanced quality of life.

2 Methodolody

2.1 Study area and data

The survey area is situated in the Anshan Xincun neighbourhood of Shanghai (Figure 1). Located within Yangpu District and adjacent to Tongji University, Anshan Xincun encompasses an area of approximately 1.51 km². In 1952, four major workers' neighbourhoods were developed to the north of Kongjiang Road, with Anshan Xincun being one of them, forming a large-scale residential community. As a product of Shanghai's transitional period of urban development (Zhigang and Fulong, 2006), Anshan Xincun represents a typical workers' neighbourhood. Its spatial configuration resembles that of traditional alleyways, though it is not entirely open, with service facilities arranged along the main streets. Following the establishment of these residential areas, a substantial number of workers moved in and settled permanently. Today, Anshan Xincun is characterised by high residential density and a deteriorating built environment, serving as a representative example of older urban districts within central Shanghai. The pronounced level of population ageing in the area further renders it a suitable site for investigating the travel behaviours of the elderly.

Figure 1 Location of Anshan Xincun

This study was conducted in three stages, each focusing on the mobility patterns of older people. The first stage comprised semi-structured interviews, each lasting approximately 30 minutes, and aimed at investigating the travel preferences, challenges, and daily mobility needs of older adults. The second stage involved a questionnaire survey, informed by existing literature, to gather data on travel preferences, frequency of travel, and key influencing factors. These data were subsequently used to refine the weighting of facilities within the walkability index. The third stage entailed tracking the travel trajectories of a selected group of older residents in order to determine their average walking speed, thus enabling the definition of a neighbourhood activity radius tailored to their mobility characteristics.

2.2 Walkability index

Empirical research examining the relationship between the built environment and walking behaviour has primarily concentrated on the computation of walkability indices (Cheng et al., 2019; Fonseca et al., 2022; Nagel et al., 2008) with the majority of such studies conducted in Western contexts(Aghaabbasi et al., 2018; Cubukcu et al., 2015). However, many of the indicators employed—such as facility weights and adjustment coefficients—are designed specifically for Western urban settings and may not be well suited to cities such as Shanghai, where the urban morphology differs considerably. Nonetheless, the methodological framework underpinning walkability indices remains a valuable instrument for evaluating walkability at the regional scale, as it encompasses both the spatial distribution of facilities and the pedestrian-friendliness of the built environment. This renders it particularly appropriate for assessing the travel environments of older adults, who are often more vulnerable in terms of mobility.

Mainstream approaches to calculating walkability scores can broadly be classified into environment-based and accessibility-based methods. The former emphasises the physical characteristics of the built environment, while the latter gives greater consideration to pedestrian behaviours and needs (Horak et al., 2022). Accessibility-based walkability indices generally follow a structured logic: based on the travel demands of the target population, relevant facility types are identified and assigned indicator weights. The distances from origin points to surrounding facilities are then computed and adjusted using a distance decay coefficient. The weighted values for each origin point are aggregated to generate a base walkability score, which is subsequently modified using a correction coefficient to produce a final index ranging from 0 to 100 (Horak et al., 2022). Given that older adults

are particularly reliant on local facilities and prioritise ease of access, this study adopts an accessibility-based approach to walkability assessment.

The principal framework for adjusting the walkability index in this study is presented in Figure 2.

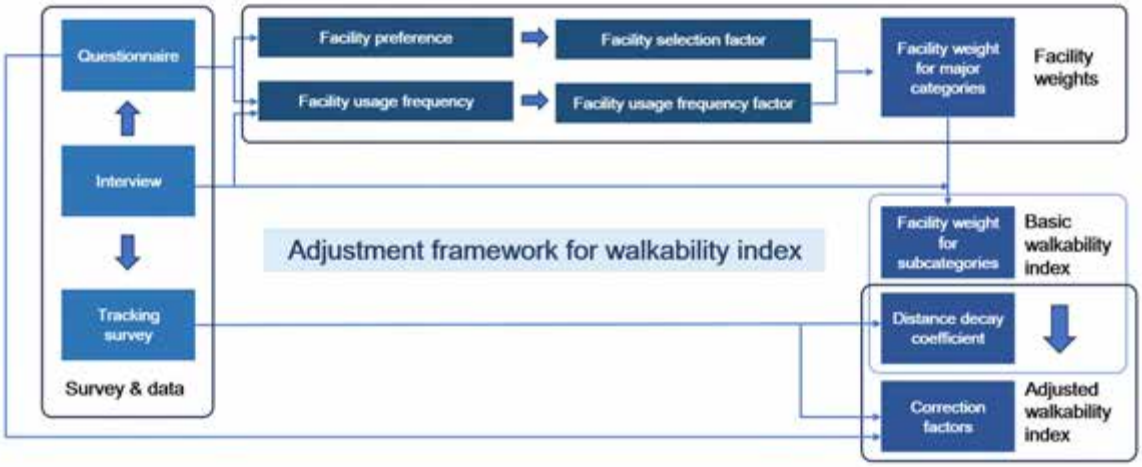

Figure 2 Adjustment framework for walkability index

At present, walkability indices are typically applied at a relatively coarse spatial scale, often using the community centroid as the point of origin. This method tends to neglect intra-community travel distances and spatial variation(Duncan et al., 2013; Hall and Ram, 2018)]. However, owing to the enclosed nature of community design and management in many urban areas, significant spatial heterogeneity may exist even within small-scale neighbourhoods (Li et al., 2024). For example, residents living closer to community entrances may demonstrate stronger travel intentions. Accordingly, this study adopts a fine-grained, grid-based analytical approach, calculating walkability scores at 50-metre intervals to capture localised variations more accurately.

The base walkability index is computed by identifying the types and quantities of facilities surrounding each origin point and aggregating these using the corresponding facility weights, as defined in Equation (1).

$$W_b = \sum_{j=1}^{N}\left[Q_j * \left(\sum_{i=1}^{n_j}(F_{ij} * Y_{ij})\right)\right] \Big/ \sum_{j=1}^{N} Q_j \qquad (1)$$

Where W_b is the basic walkability index, Q_j denotes the original weight value of facility j, n_j is the number of decay intervals of facility j, F_{ij} is the number of facility j in decay interval i, and Y_{ij} is the distance decay coefficient corresponding to the i-th facility of facility j.

The calculation method of adjusted walkability index is as follows Equation (2):

$$W_a = W_b * (1 - C_i) * (1 - S_i) * (1 - N_{1i}) * (1 - N_{2i}) \qquad (2)$$

Where, W_a is the adjusted walkability index, W_b is the basic walkability index, I_i is the intersection density correction coefficient, L_i is the block length correction coefficient, N_{1i} is the first new correction coefficient, N_{1i} is the second new correction coefficient.

2.3 Model

This study adopts the Gradient Boosting Decision Trees (GBDT) model—a machine learning approach that improves predictive accuracy by iteratively combining multiple weak learners into a single, robust learner. The model approximates true outcomes by minimising the loss function through gradient descent. Compared with conventional linear regression techniques, GBDT offers superior accuracy and is capable of accommodating a diverse range of explanatory variables simultaneously(Ding et al., 2018).

Moreover, GBDT inherently captures interactions between variables without requiring a priori assumptions regarding functional forms, thereby addressing one of the principal limitations of linear models(Wang and Wang, 2021). It is also notably resilient to multicollinearity among independent variables, rendering it especially suitable for models involving a large number of predictors. As a non-linear modelling technique, GBDT is well equipped to detect localised effects and threshold phenomena, demonstrates robustness against outliers, and more accurately reflects empirical patterns. These features collectively enhance its utility in informing planning practices.

Accordingly, this study employs the GBDT model to analyse the influence of various factors on respondents' travel behaviours across different neighbourhoods, thereby effectively mitigating the distorting effects of non-linear variable interactions on overall model performance.

3 Results

3.1 Survey results

3.1.1 Basic Information and Travel Characteristics

The survey findings concerning the respondents' demographic profiles and health conditions are illustrated in Figures 3 and 4.

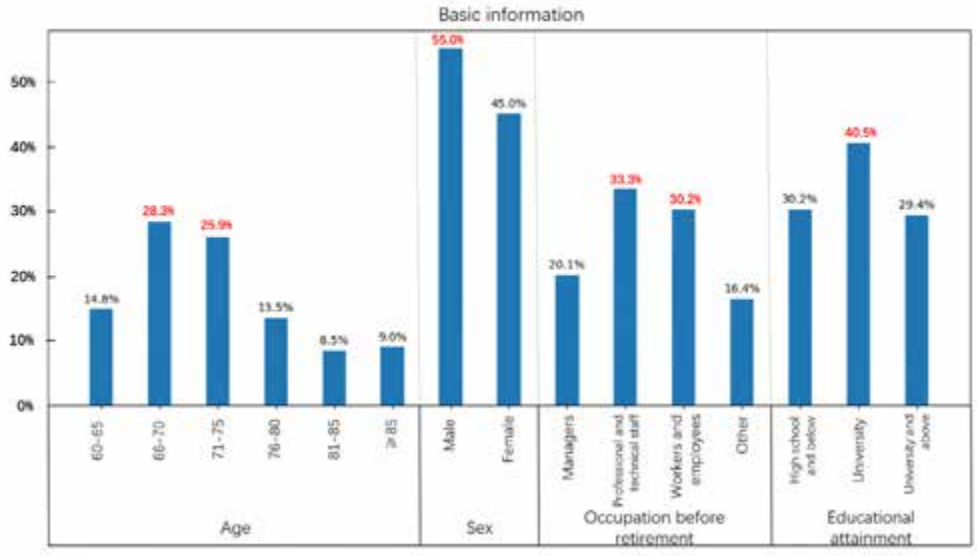

Figure 3 Basic information of the respondents

All respondents are retired residents aged 60 and above, the majority of whom reside either with their spouse or with both spouse and offspring. Approximately 70% are primarily responsible for household shopping. Fewer than 20% of respondents self-assess their health as "good" or "very good". Regarding chronic illnesses, 64.3% report not suffering from any long-term health conditions.

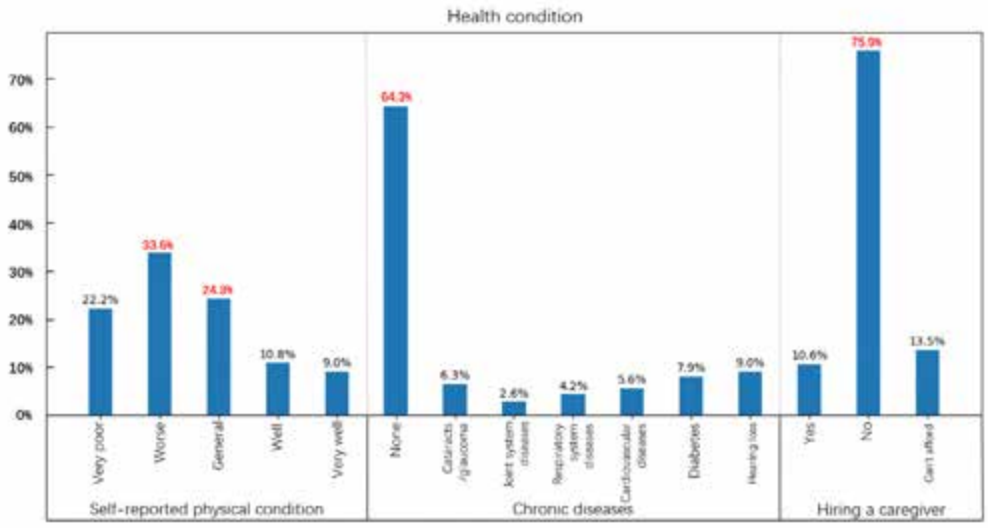

Figure 4 Health condition of the respondents

Respondents typically go out between once and four times per day, with nearly one-third reporting the need to leave their home twice daily. Fewer than 80 respondents are able to travel independently; the remainder rely on mobility aids such as walking sticks or wheelchairs. Furthermore, 42 respondents require the assistance of a companion when travelling, indicating that a significant proportion of the sample population faces mobility-related challenges (Figure 5).

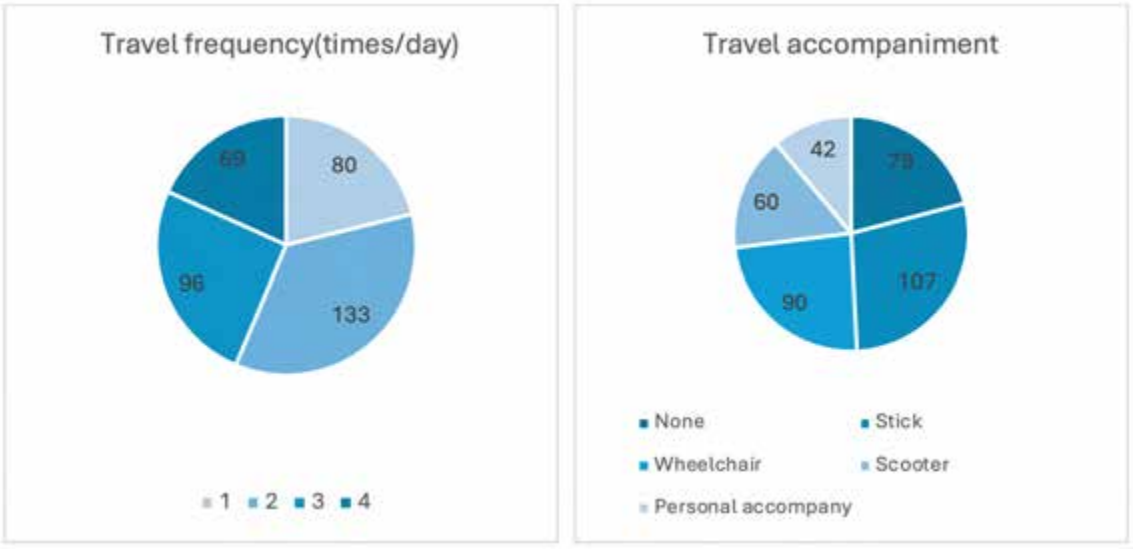

Figure 5 Travel frequency(left) and travel accompaniment(right)

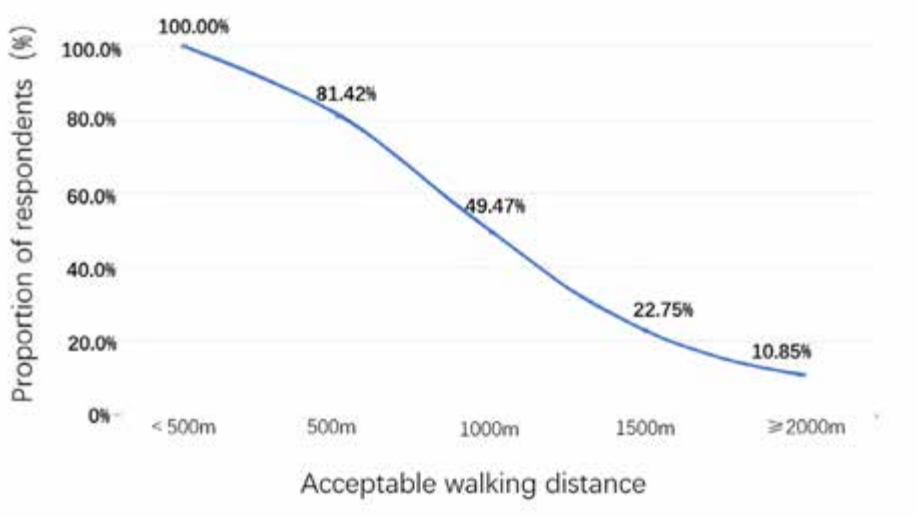

Figure 6 Distribution of acceptable walking distances

The majority of respondents are willing to walk distances of up to 500 metres, while only around 10% are capable of walking 2,000 metres or more (Figure 6). For longer journeys, respondents tend to favour public transport, although a subset uses non-motorised modes such as electric bicycles and mobility scooters designed for older adults. A small number of respondents report using private vehicles or taxis.

3.1.2 Travel problems

When asked about the difficulties encountered during travel, respondents' concerns were classified into four primary categories: inadequacies in facilities, issues related to urban management, challenges in pedestrian flow organisation, and safety risks (Figure 7).

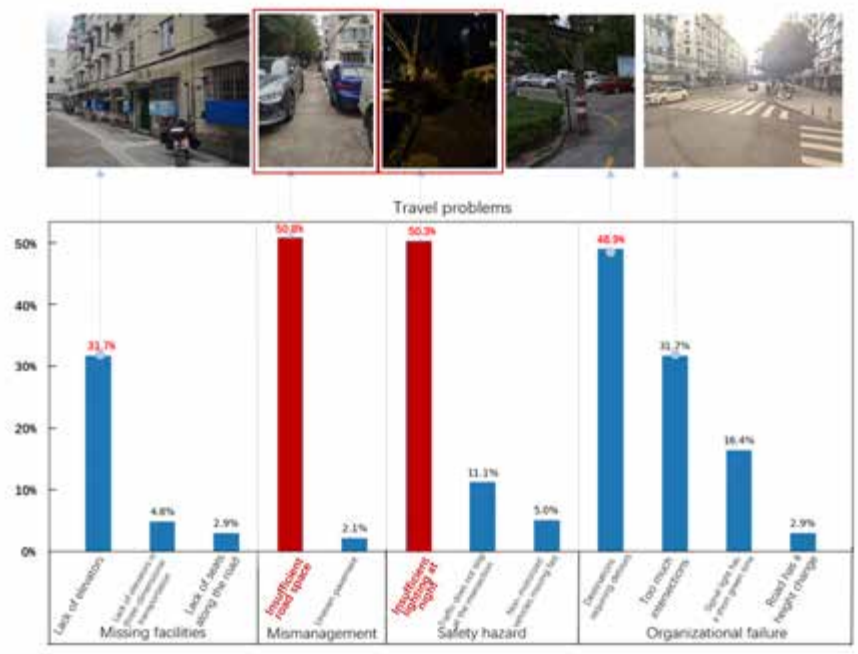

Figure 7 Travel problems of the respondents

Among these, the occupation of pedestrian pathways by private vehicles and insufficient street lighting during night-time—both indicative of shortcomings in public space governance—elicited considerable concern from

older adults. These issues are particularly pronounced in historic urban areas such as Shanghai's inner-city neighbourhoods.

Other problems, such as an excessive number of intersections and the absence of lifts in residential buildings, are largely attributable to the period in which these neighbourhoods were developed. While a dense road network may improve overall connectivity, in older neighbourhoods it can simultaneously generate significant mobility challenges for the elderly.

3.2 Walkability index

3.2.1 Facility weights

(1) Facility Selection Coefficient

The initial step involves the calculation of weights assigned to broad categories of facilities. The facility selection coefficient is primarily determined based on the number of respondents who identified each facility type as relevant. The analysis places particular emphasis on those essential services most frequently cited during interviews as critical to the daily lives of older adults. These encompass six principal categories: shopping, dining, medical care, life services, public transport, and educational facilities. Given the prominent role of fresh food markets in meeting the nutritional needs of the elderly, this facility type is separated from the general shopping category and treated as an independent class in subsequent analyses.

The facility category with the lowest selection frequency is designated as the reference, or "equivalent", facility. In this study, public transport facilities were the least frequently selected and thus assigned an equivalence value of 1. Selection coefficients for all other facility types are subsequently derived by calculating the ratio of their respective selection frequencies relative to that of public transport. The core formula is presented in Equation (3):

$$Z = {}^{d_n}/_{d_{min}} \tag{3}$$

Where Z denotes the selection coefficient for a given facility type, d_n represents the number of respondents selecting that facility, and d_{min} indicates the number selecting the reference facility.

(2) Travel Frequency Adjustment Coefficient

In this study, adjustments to facility weights take into consideration the influence of travel frequency. Based on responses from the questionnaire, the frequency with which different types of facilities were visited as destinations was recorded. Each frequency category was assigned a corresponding score — for instance, visiting once per week was assigned a value of 0.5, while visiting once per day received a score of 1. Scores for other frequency categories were allocated according to a similar rule. As the impact of frequency on the overall score is comparatively limited, a general decay principle was adopted for score assignment.

The travel frequency coefficient was subsequently calculated by multiplying the number of respondents selecting each facility type at a given frequency by the respective score, summing the products, and then dividing by the total number of respondents who reported using that facility. The calculation procedure is expressed in Equation (4):

$$Y = \left(\sum_{i=1}^{n} p_i f_i\right)/p_t \tag{4}$$

Where Y denotes the usage frequency coefficient for a specific facility type, p_i is the number of respondents reporting a given usage frequency, f_i is the assigned score for that frequency, and p_t represents the total number of respondents who reported using the facility.

(3) Coefficient Adjustment Results

Based on the two categories of coefficients described above, the final weight for each major facility type was

obtained by combining the facility selection coefficient with the travel frequency adjustment coefficient. The principal calculation formula is provided in Equation (5):

$$X = YZ \tag{5}$$

Where *X* represents the final weight assigned to a given category of facility.

The resulting weight coefficients for each facility type are summarised in Table 1.

Table 1 Facility weights

Type of facility	Selection coefficient	Usage frequency coefficient	Weight
Wet market	4.4	1.1	4.8
Shopping facilities	2.2	1.1	2.4
Dining facilities	2.1	1.1	2.3
Medical facilities	2.1	1.0	2.1
Educational facilities	1.2	1.3	1.6
Service facilities	1.1	1.0	1.1
Public transportation facilities	1.0	1.1	1.1

3.2.2 Distance decay and correction coefficients

(1) Distance Decay Coefficient

The influence of travel distance on facility accessibility is incorporated via a distance decay function. Travel range thresholds are delineated based on the average walking speed of the general population, with distance bands set at 400 m, 1600 m, and 2400 m. Each interval is associated with a decay function to quantify the effect of distance on facility utilisation. Facilities situated beyond the maximum threshold are excluded from the walkability index calculation.

However, both the delineation of travel ranges and the application of decay functions are primarily derived from the mobility patterns of the general population, without sufficient consideration of variations in travel capacities across different demographic groups. In light of the increasing prevalence of ageing, this approach is inadequate for accurately assessing walkability for older adults.

Given the layered structure of 15-minute community life circle planning, this study adopts an interval-based decay function aligned with existing planning frameworks. For instance, Long Ying et al. calculated walking distances based on travel speed and divided decay intervals into five segments informed by literature evidence (Long et al., 2021). Similar methodologies have been employed in other studies (Wu et al., 2014). This study adopts the same approach whilst adapting it to account for the specific characteristics of elderly travel, particularly the need for rest.

Older adults are particularly concerned with whether they can ultimately reach distant destinations, even if the journey requires rest breaks along the way. For those with limited mobility, time is not a primary constraint; instead, reaching a maximal distance usually requires resting breaks. Consequently, elderly residents are generally

willing to take multiple pauses to their destination. This behavioural divergence from the general population underpins the adapted methodology for calculating the distance decay coefficient for older adults, as illustrated in Figure 8.

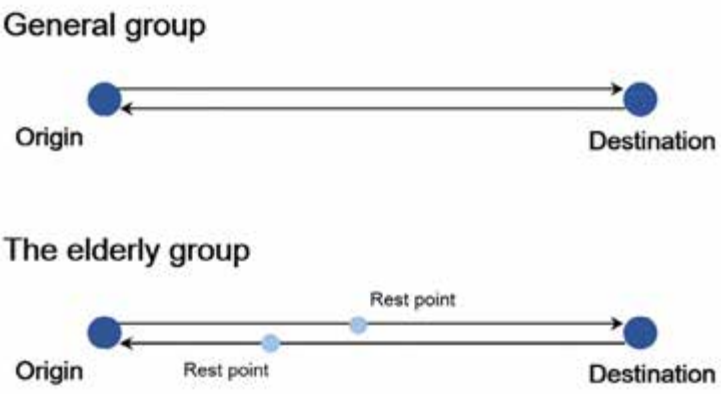

Figure 8 Differences between the elderly group and the general group

Building on the previous discussion of "acceptable walking distances" and the results of the travel tracking survey, the final decay rates are established as follows: no decay is applied within 0–150 m; a 10% decay rate applies between 150–300 m; 20% between 300–500 m; and 30% between 500–700 m. Distances exceeding 700 m are regarded as beyond the acceptable walking range for the majority of older adults, encompassing both those with normal mobility and those with limited mobility. The spatial boundaries of the "5-minute, 10-minute, and 15-minute" community life circles for the elderly are defined according to these distance intervals (Figure 9).

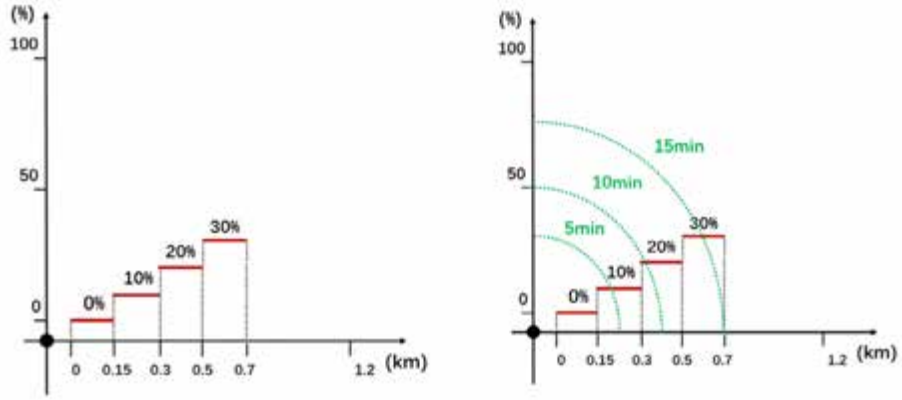

Figure 9 Distance decay coefficient(left) and community life circle radius(right)

(2) Adjustment of Correction Coefficients

The subsequent correction coefficients applied to the walkability index primarily account for two coefficients: the number of street crossings, represented by intersection density, and the scale of community blocks, indicated by block length. Compared with the effect of distance decay, the influence of these correction coefficients is relatively minor. Intersection density reflects the walkability of the street network—a higher intersection density implies a more intricate street grid, which is considered more favourable to pedestrian movement, thereby resulting in a lower decay rate. Similarly, shorter block lengths correspond to lower decay rates, consistent with the design principles of compact blocks and dense networks commonly observed in Chinese urban contexts. Consequently, existing standards for these indicators are maintained.

However, recognising the mobility differences among population groups, particularly older adults, the decay rates associated with these correction coefficients are appropriately adjusted to improve relevance. Drawing on the principal travel barriers identified in previous survey findings and corroborated by existing literature, two additional correction coefficients are introduced: the effective width of pedestrian pathways and the intensity of street lighting at night. Each coefficient is assessed on a scale from 0 to 8 according to actual street conditions.

The adjustment results for all correction coefficients are presented in Table 2.

Table 2 Correction coefficients

Intersection density (1/km2)	Block length (m)	Decay rate (Walk Score®[1])	Adjusted decay rate(%)	Scores (new coefficients)	Decay rate(%)
>77	<120	0	0	8	0
58-77	120-150	1	2	6	1
47-58	150-165	2	3	4	2
35-47	165-180	3	4	2	3
23-35	180-195	4	5	0	4
<23	>195	5	6		

3.2.3 Walkability index

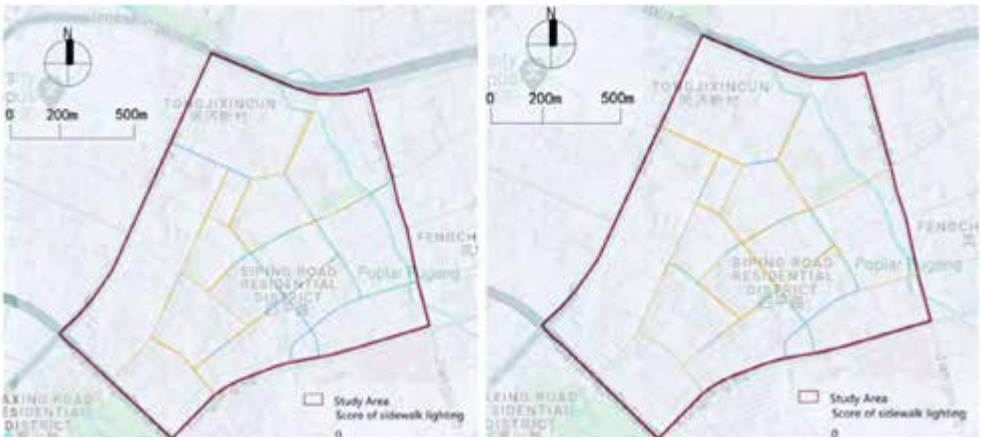

Figure 10 Sidewalk width score (left) and nighttime illumination score (right)

Based on the scores for effective pavement width and night-time lighting (Figure 10), a substantial proportion of roads fall into the lower-quality category (scoring 4 or below) concerning pavement conditions. Narrow pavements increase the risk of elderly pedestrians being compelled to walk in motor vehicle lanes, posing significant safety hazards. This issue underscores challenges in the management and maintenance of community and urban street spaces. The assessment of night-time lighting conditions largely corresponds with pavement width, although certain road segments display notable discrepancies. Inadequate lighting may diminish older adults' willingness to travel during dusk or evening hours(Trop et al., 2023).

1 Walk Score® (www.walkscore.com), a widely used, publicly accessible tool developed by a U.S.-based commercial company

A 50 × 50 m grid was established within the study area, and an origin-destination (OD) cost matrix was constructed from the centroid of each grid cell to various facility types, with the resolution refined to the scale of internal neighbourhood roads. Following the calculation of the basic walkability index, four indicators—intersection density, block length, effective pavement width, and night-time lighting intensity—were employed to adjust the initial walkability scores (Figure 11).

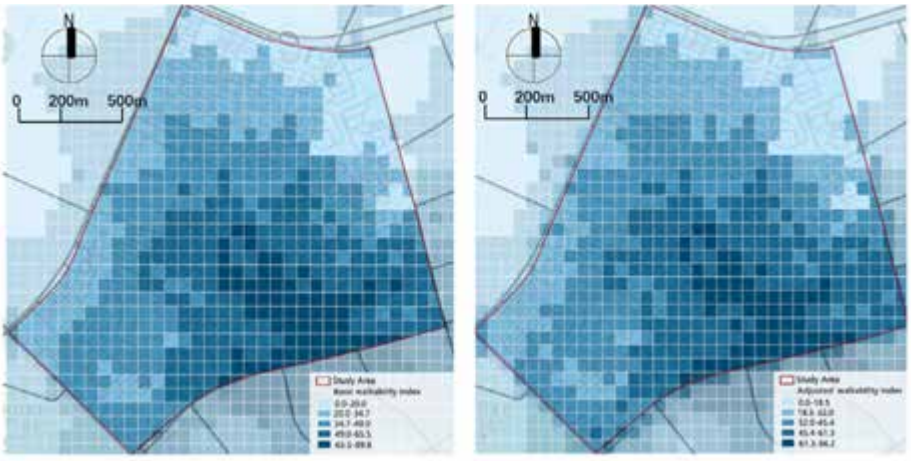

Figure 11 Basic walkability index(left) and adjusted walkability index(right)

The overall walkability index of the Anshan Xincun area is relatively low, a condition that becomes more pronounced following adjustment. Significant spatial heterogeneity in walkability scores was observed within Anshan Xincun, with higher scores concentrated in the southeastern sector and central zones. Conversely, the Tongji Xincun community, particularly in its northwestern corner, emerged as an area of markedly lower walkability. This disparity is preliminarily attributed to coefficients such as the enclosed configuration of large residential communities and the impact of major urban arterials.

The GBDT model was utilised to rank feature importance. Among all independent variables, the adjusted walkability index ranked highest in importance, indicating its substantial influence on the travel frequency of older adults. The normalised feature importance value for the walkability index was approximately 0.40. Other variables, including respondents' demographic attributes, also contributed to the model's predictive performance, albeit to a lesser degree (Figure 12).

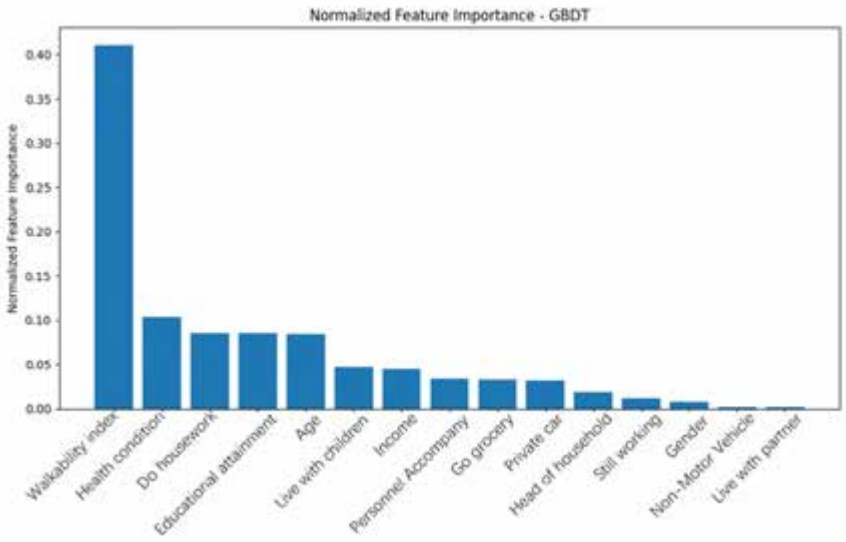

Figure 12 Feature importance of GBDT model

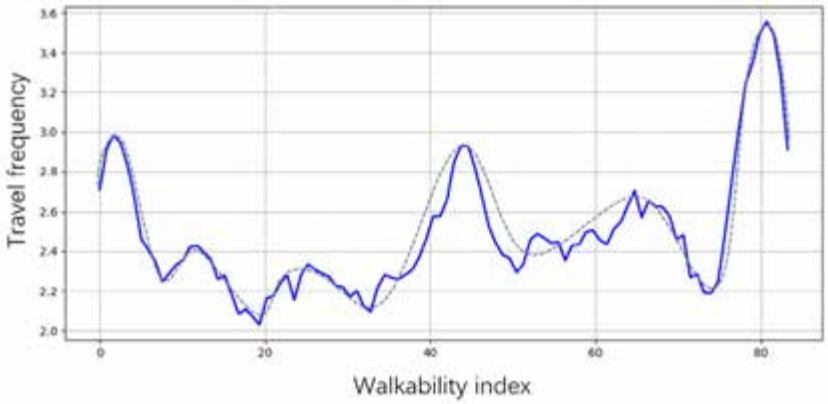

Figure 13 Partial dependence plot of the adjusted walkability index and travel frequency

To further elucidate the non-linear relationship between the walkability index and the travel frequency of older adults, partial dependence plots were generated (Figure 13). These plots indicate that as the walkability index increases, the travel frequency of older adults demonstrates a fluctuating pattern. Generally, areas with higher walkability scores correspond to more frequent travel among the elderly. In poorly walkable areas (scores ranging from 0 to 30), travel frequency tends to decline as scores increase, suggesting that substandard walking environments inhibit mobility intentions. When the walkability score falls within the 30–50 range, a pronounced increase in travel frequency is evident. Although a slight decrease occurs within the 50–60 range, travel frequency remains at two or more trips. A peak in travel frequency is observed when the walkability index attains approximately 80 points.

4. Discussion

A more detailed examination of the findings reveals that the uneven spatial distribution of essential facilities constitutes a key driver behind the marked disparities in walkability index scores across the broader study area, significantly shaping older adults' accessibility experiences. Owing to their generally limited travel range and reliance on a small number of facility clusters to meet daily needs, the absence or poor spatial allocation of critical facilities frequently results in unmet physiological demands, thereby generating pronounced differences in walkability levels between neighbourhoods.

Community scale and the number of access points emerged as principal determinants of detour lengths. This was exemplified in the Tongji Xincun case, where the paucity of entrances—particularly in the northern section—necessitated considerable detours to reach key services. Residents in proximity to the main southern gateway experienced comparatively better accessibility, reflected in higher walkability scores.

In older residential areas, accessibility is further constrained by governance and management-related issues, which often result in public and market-oriented facilities being located outside formal community boundaries. This externalisation gives rise to a dual accessibility challenge. First, in larger compounds, residents living far from main exits or facility-adjacent streets face reduced access, especially acute for elderly residents with limited mobility, for whom even moderate distances can render services effectively inaccessible. Second, the prevalent clustering of facilities often compels older adults to cross vehicular roads, and the lack of suboptimal placement of pedestrian crossings exacerbates these challenges. Those with relatively better mobility typically benefit from a greater number of facilities within 5- and 10-minute walking distances. Internal circulation patterns and intra-community detour lengths also exert a substantial influence on perceived accessibility.

These findings offer a sound empirical foundation for the formulation of targeted strategies for community renewal and retrofitting. Renewal initiatives must be differentiated to address the needs of heterogeneous older adult populations. The study advocates for the potential of open-block planning models in improving accessibility within large, ageing residential areas. Furthermore, it recommends targeted enhancements to the street environment, including sufficient pavement width, improved barrier-free facilities, and the integration of small-scale green spaces such as pocket parks. Critically, the study emphasises the importance of coupling physical facility upgrades with the development of a comprehensive and responsive community service system. Incremental, small-scale interventions may serve as a pragmatic starting point for promoting age-inclusive urban regeneration.

5. Conclusion

As global population ageing accelerates, there is an urgent need for urban environments that better support the mobility, well-being, and social participation of older people. This study set out to assess the impact of the built environment on older adults' mobility by constructing a community life circle walkability index framework specifically attuned to their unique needs. The revised walkability index developed herein exhibited closer alignment with the observed travel behaviours of older adults, suggesting that even well-intentioned and ostensibly advanced urban facilities can, paradoxically, undermine the mobility and safety of this demographic. For existing ageing communities, the implementation of pragmatic and phased renewal strategies—centred on optimising circulation routes and strategically enhancing the distribution and accessibility of key facilities—is imperative. Such measures are vital for increasing travel frequency among older adults, alleviating mobility barriers, and fostering healthy and liveable cities.

Theoretically, this study contributes to the refinement of walkability evaluation frameworks by introducing a multi-dimensional, elderly-oriented perspective. Unlike conventional macro-scale assessments, the present approach incorporates a finer-grained, micro-level analysis that accounts for the nuanced mobility patterns and differentiated needs of older adults. As such, it offers a more precise and contextually relevant evaluative tool for future empirical research.

Nonetheless, several limitations of this study warrant acknowledgment. The sampled population, constrained by practical considerations, may not fully reflect the heterogeneity of the older adult demographic—particularly residents with severe mobility impairments or those requiring continuous assistance. In addition, although the walkability index has been refined, it does not encompass all potentially influential factors, such as detailed pavement conditions, subtle slope gradients, or subjective experiential dimensions of walking. The fragmented nature of the street environment in the study area also posed methodological challenges, particularly with regard to accurately measuring variables such as lighting intensity and effective pavement width. Furthermore, as with any quantitative index, there are inherent constraints in capturing the complex, dynamic interactions between residents and their spatial environments. While the findings offer valuable insights derived from a representative ageing community, the multifaceted interplay between environmental and personal factors remains a topic requiring further exploration.

Building upon these findings, future research would benefit from a more inclusive sampling strategy that captures a broader spectrum of mobility capabilities among older adults. The walkability index could be further enhanced by integrating a wider range of micro-environmental indicators, subjective perceptions, and more sophisticated modelling techniques, including refined service radii and spatial decay functions for facilities. Robust validation efforts—across varied community typologies, employing larger sample sizes and in-depth behavioural surveys—are essential to strengthen the model's generalisability and precision. Moreover, investigating effective governance and spatial management mechanisms will be critical in minimising the potential downsides of open community designs while maximising their benefits. Ultimately, advancing towards a multi-stakeholder, multi-perspective research paradigm is vital for the realisation of truly inclusive and age-friendly community environments.

Study on the Construction and Inheritance of Rural Models in Shaanxi North from the Perspective of Human-Land Emotional Bonds

Huan Liu
Xi'an University of Architecture and Technology

Abstract:
The unique loess landforms of Northern Shaanxi, China, foster a profound emotional connection between residents and their land, termed "place attachment," which denotes a strong bond between people and their environment. Rural construction faces challenges like the loss of indigenous architectural techniques, leading to inefficient and unattractive spaces, particularly due to neglect of local culture and emotional needs. This study emphasizes understanding human-land emotional relationships to address these issues while preserving traditional rural spatial patterns. It explores motivations behind rural spatial construction in Northern Shaanxi, focusing on resident-environment emotional ties. Through interviews, surveys, and analysis, it identifies cultural meanings and emotional needs tied to spatial features. Using qualitative methods, the study constructs a knowledge map of human-land emotional connections, integrating PPGIS and spatial narratives to propose empathetic, inclusive rural development strategies that honor local place identity.

Keywords: Shaanxi North Region: Rural Construction Models: Topophilia: Emotional Bonds: Affective Cartography

1. Introduction

Northern Shaanxi's loess landforms, shaped by intricate ravines and wind-deposited soils, have nurtured a deep symbiotic relationship between people and their environment over millennia. This bond, termed place attachment (Scannell & Gifford, 2010), encompasses emotional, cognitive, and behavioral ties to physical settings. Traditional cave dwellings (yaodong) and terraced settlements exemplify this connection, integrating ecological adaptation (e.g., passive thermal regulation) with cultural symbolism (Wang et al., 2016). These structures function as living archives of collective memory and environmental wisdom.

However, China's rapid urbanization since the 1990s has disrupted this equilibrium through three key mechanisms:Transplanted Urban Aesthetics: Standardized concrete housing and grid layouts ignore local topography, increasing slope instability and energy inefficiency (Zhang & Zhao, 2021).Spatial Amnesia: Indigenous spatial systems—such as courtyard hierarchies and ritual pathways—are erased, severing socio-ecological ties (Liu, 2019). Technological Discontinuity: Traditional construction knowledge (e.g., loess reinforcement) is lost without viable alternatives, leaving communities ill-equipped to adapt (Dang, 2023).

The consequences are stark:Functional Decline: Urban-style villages consume 23% more energy due to poor material and orientation choices (Li et al., 2022).Cultural Loss: 68.7% of residents report weakened belonging where vernacular landscapes are replaced (Provincial Cultural Heritage Bureau, 2022).Identity Erosion: Destruction of landmarks like ancestral terraces fractures place-based narratives (Tuan, 1977).

Despite extensive research on urbanization's economic impacts, the emotional dimensions of displacement remain overlooked. This study bridges that gap by asking: How can place attachment theory guide resilient rural restructuring in Shaanxi's loess regions? We argue that sustainable development must reconcile modernization with emplacement—rebuilding meaningful people-place bonds through evidence-based spatial interventions.

2. Research on Human-Land Emotional Space

2.1 The "Emotional Turn" in Spatial Studies

Human emotion plays a crucial role in the construction of everyday spatial experiences. However, under modernity, emotion has often been marginalized as the antithesis of rationality, excluded from formal spatial order. Industrialization, urbanization, and commercialization, driven by rationalist and techno-scientific narratives, have dominated contemporary life. At the turn of the century, shifting paradigms in social research brought emotion to the forefront of interdisciplinary discourse, spanning architecture, landscape studies, and human geography. Following the "cultural turn," spatial research shifted from macro-social structures to subjective individual experiences, further deepening under the influence of humanistic geography and non-representational theory. This evolution culminated in an "emotional turn," emphasizing affective dimensions in spatial production.

Architects and geographers now explore how emotions shape social space. Emotions operate within economic, political, and even power dynamics, serving as tools for spatial discipline and capital accumulation. Drawing on Foucault's biopolitics, Ben Anderson argues that neoliberal governance manipulates collective emotions to reinforce urban capitalist logic. The emotional turn highlights relationality and intersubjectivity, offering new perspectives on human-environment interactions.

2.2 Emotional Mapping Tools in Spatial Research

Recent advances in People-Place Emotion mapping integrate emotional and spatial data to support decision-making in urban-rural planning and natural resource management. Key tools include:

2.2.1 Public Participation GIS (PPGIS)

PPGIS is a core method for emotional mapping, using surveys to collect public sentiment (e.g., landscape values, place attachment) and visualizing results via GIS. Brown et al. (2004, 2007) applied PPGIS to map emotionally significant sites (e.g., aesthetic/cultural values) through density analysis. For instance, in Alaska's Kenai Peninsula, participants allocated virtual currency (e.g., $100) to quantify landscape preferences, revealing conservation priorities (Brown et al., 2002). PPGIS facilitates multi-stakeholder consensus in land-use conflicts (Brown & Raymond, 2014).

2.2.2 Landscape Value Typology

Brown & Raymond (2007) operationalized emotions into 14 landscape values (e.g., ecological, recreational), analyzed via spatial techniques like hotspot mapping. Longitudinal studies (e.g., 2004 vs. 2010 data) track emotional shifts, assessing policy impacts (Brown & Weber, 2012). Strong correlations between value distributions and place attachment validate the method (Brown et al., 2015).

Challenges: Public misinterpretation of terms (Brown & Kyttä, 2014) limits reliability. Future research should integrate big data (e.g., VGI) for dynamic emotional databases and adapt methods to contexts like rural Shaanxi's place identity.

2.2.3 Spatial Reinterpretation from a Human-Land Emotional Perspective

Human-environment interactions generate complex emotions embedded in local culture, forming subconscious "sense of place." Over the past 50 years, environmental psychology and cultural geography have advanced the study of these affective bonds, notably through Tuan's (1974) topophilia—a systematic framework for human-environment emotional ties. Tuan explored attachment and fear as primal emotions, linking sensory, aesthetic, and existential dimensions to spaces ranging from homes to cosmic scales.

Shumaker et al. (1983) later defined place attachment as positive affective bonds between people and their lived environments. Hammitt categorized attachment into progressive levels: familiarity → belonging → identity → dependence→ rootedness. Jorgensen further synthesized it as a tripartite construct (affective, cognitive, behavioral).

In Topophilia and Space and Place, Tuan employed a "perception → attitude → values → worldview" framework to decode human-environment relations. He distinguished space (abstract, geometric) from place (meaning-infused through experience), arguing that humans inhabit places, not spaces. This dialectical view informs spatial design principles that enhance place attachment through experiential layering (Table 1).

Table 1 Conceptual Comparison between "Space" and "Place" from an Empirical Perspective

Category	Topophilia (Place)	Escape (Space)
Type	Attachment to place	Avoidance of space
Intention	Stability and constraint	Freedom and threat
Experience	Pleasurable experiences, long-term memories, cultural consciousness	Natural uncertainty, urban malaise
Emotion	Fulfills spiritual needs	Freedom, lack of protection, and threat
Implication	Diverse experiences necessitate a balance between place and space	

3.Emotional Characteristics and Spatial Patterns of Northern Shaanxi Villages

This study examines the emotional bonds between residents and their built environment in rural Northern Shaanxi, analyzing how cultural meanings and affective needs are embedded in spatial features such as alleys, gullies, slopes, and courtyards—key components of traditional architectural patterns.

Human-Land Emotional Bonds in Northern Shaanxi

The loess hill-gully region, spanning Yan'an and Yulin cities, is defined by fragmented topography shaped by erosive soils and concentrated rainfall. Historically, settlements clustered along river valleys (e.g., Wuding, Yanhe), where inhabitants adapted to the terrain through cave dwellings (yaodong). This "earth-carving" vernacular architecture reflects deep place attachment, forged through millennia of symbiotic land-use practices.

These structures exemplify socio-spatial interdependence:**Cultural Logic**: Construction follows clan rituals and geomancy (fengshui), reinforcing collective identity.**Materiality**: Local loess and stone materials create thermally stable, landscape-integrated forms.**Social Fabric**: Kinship-based mutual aid networks expedite building while preserving typological uniqueness through ceremonial practices.The gradual evolution of these spatial patterns mirrors the intensification of place attachment, blending ecological pragmatism with cultural symbolism.

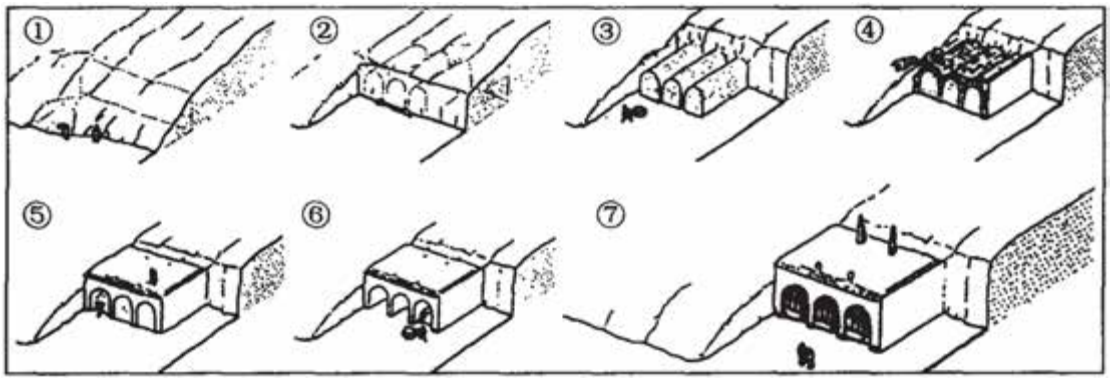

Figure 1 Overview of the construction of cliff-style cave dwellings
Hou Jiyao Chinese Cave Kiln

4. Spatial Patterns of Northern Shaanxi Villages

The rural spatial patterns of Northern Shaanxi's loess hill-gully region are epitomized by its cave-dwelling (yaodong) villages, which exhibit distinctive spatial characteristics reflecting centuries of vernacular wisdom. This study focuses on residential environments as the core living spaces where villagers conduct daily activities, encompassing both built settlements and their natural surroundings.

4.1 Spatial Hierarchy and scales

Northern Shaanxi's village habitats demonstrate unique spatial configurations shaped by natural conditions, historical contexts, and socioeconomic factors. Through cartographic analysis, literature review, and field surveys across multiple watersheds, this research employs morphological and typological methods to systematically identify key spatial elements. A hierarchical framework organizes these findings into three scales:

Macro (Landscape Level)
Mountain-village-field relationships
Functional spatial sequences

Meso (Settlement Level)
Organic settlement forms adapting to topography
Hierarchical street networks
Landmark public spaces

Micro (Building Level)
Courtyard-house combinations
Traditional construction techniques
Twelve characteristic spatial elements are identified across these levels, forming an integrated system for preserving and developing Northern Shaanxi's unique habitat features. This structured approach enables targeted conservation of the region's spatial identity while accommodating modern development needs.

Table 2, Rural Spatial Model Map

Spatial Hierarchy	Type	Spatial Characteristic Element
Landscape Level	Relationship	Relationship between Mountains, Villages, and Fields
		Functional Sequence
Settlement Level	Settlement Form	Plan Form
		Settlement Interface
	Street Network System	Street Texture
		Street Hierarchy
		Street Interface
	Public Space	Landmark spaces
Building Level	Courtyard-House	Plan Combination
		Courtyard Scale
	Building Construction	Building Form
		Building Scale

4.2 Spatial Patterns of Northern Shaanxi Rural Settlements

The spatial patterns of Northern Shaanxi villages manifest through three distinct yet interconnected scales, each demonstrating unique characteristics of human-land interaction. At the macro level, the "beaded-string" settlement distribution along secondary and tertiary tributaries reveals an adaptive strategy to the region's 35°-45° slope conditions. This configuration achieves an optimal balance between agricultural production, residential

living, and ecological preservation, with valley settlements typically allocating gentle slopes for cultivation while situating dwellings on lower terraces. The resulting spatial sequences reflect centuries of accumulated wisdom in harmonizing built environments with loess landform constraints.

Meso-scale analysis of settlement morphology reveals two predominant organizational principles. First, the organic street networks demonstrate clear topographic determinism, with 65% of surveyed villages exhibiting ribbon patterns along valley contours, while more fragmented terrain produces reticular configurations . Second, Tuan's (1977) concept of "moderate human modification" manifests through deliberate spatial interventions - horizontal courtyard elements create tranquil living spaces, while vertical transitional elements like slopes and staircases introduce dynamic social interaction nodes. This duality achieves what local residents describe as "calm roots and lively branches" in settlement layouts.

The architectural micro-scale presents perhaps the most distinctive spatial innovations. Cave dwellings (yaodong) achieve remarkable environmental performance through 1.2m-thick loess walls that maintain stable indoor temperatures (18±2°C) year-round. More significantly, their spatial organization encodes social meaning: the prevalent 3:2 rectangular courtyard aspect ratio optimizes winter sunlight exposure, while the standardized 2.1m lane width accommodates ceremonial processions. These dimensional consistencies across villages suggest deeply internalized cultural-spatial norms.

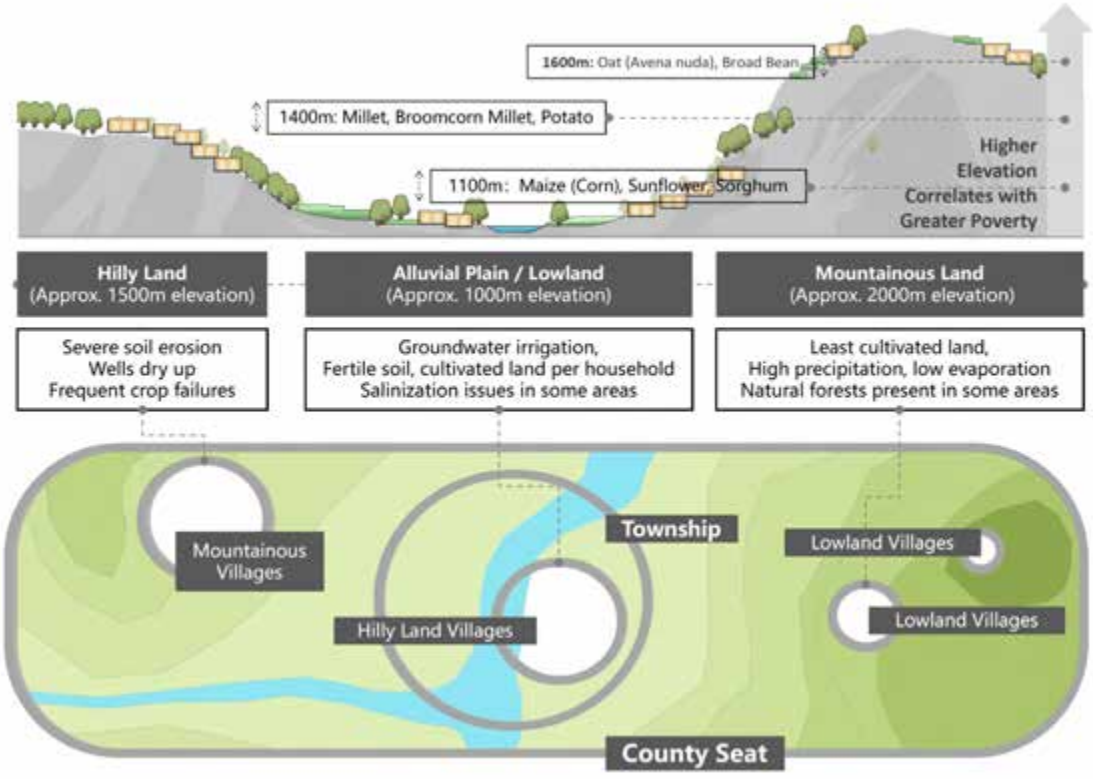

Figure 2 Nested structure of rural areas in northern Shaanxi

Transitioning to emotional geographies, the research reveals striking core-periphery differentiations. Basin-core settlements exhibit strong place identity (SAI=0.82) combining functional dependence and emotional attachment, while peripheral areas demonstrate survival-based attachment (SAI=0.51) frequently accompanied by spatial stigma. This emotional stratification directly impacts demographic flows, with marriage migration patterns showing 78% of brides rejecting peripheral grooms, and labor mobility favoring core zones by 3:1 ratios.

The gully system's fractal structure further complicates these emotional geographies through three spatial metaphors. Vertical coding shows consistent "lower preference" for settlements at 50-80m lower elevations, improv-

ing water access by 60%. Social hierarchy manifests through 15-20m elevation differentials between temples and dwellings. Most remarkably, 67% of ritual spaces occupy leftward aspects when moving upstream, suggesting deeply embedded cultural-spatial cognition patterns.

At the household scale, cave architecture facilitates unique emotional support systems. Quantitative measures show cliff-adjacent dwellings achieve 0.65 enclosure indices (vs 0.42 for conventional housing), correlating with 37% higher neighborly interaction frequencies. Functional analyses reveal 83% of informal socialization occurs in horizontal courtyard spaces, while vertical transitional spaces host communal rituals. These patterns prove particularly vital for aging populations, with traditional settlements showing 0.38 standard deviation higher cohesion indices.

Table 3, Rural Spatial Emotional geographies

Spatial Scale		KeyQuantitative Indicators	Emotional Significance
Settlement (Meso-scale)	Core vs. Peripheral Zones	Sense of Attachment Index (SAI): Core = 0.82; Periphery = 0.51	Core zones show strong identity; peripheries exhibit survival-based attachment and spatial stigma
	Marriage migration patterns	78% of brides reject grooms from peripheral areas	Emotional stratification affects marital flows
	Labor mobility	Core-to-periphery labor migration ratio = 3:1	Functional and emotional centrality drives labor preference
Topographic System (Gully Network)	Vertical settlement coding	50–80 m lower elevation improves water access by 60%	"Downward preference" reflects practical hydrological logic
	Symbolic elevation hierarchy	Temples are 15–20 m higher than residential units	Spatializes social hierarchy and ritual importance
	Ritual space orientation	67% of ritual spaces on the left side when moving upstream	Encodes upstream-left symbolic preference in cultural cognition
Household (Dwelling-scale)	Cliff-adjacent yaodong	Enclosure index: 0.65 (vs. 0.42 in conventional housing); +37% neighborly interaction frequency	Spatial enclosure reinforces emotional support networks
	Socialization space	83% of informal interaction occurs in horizontal courtyards; vertical spaces host rituals	Functional zoning supports intergenerational social dynamics
	Elder-friendly cohesion	Traditional settlements show +0.38 standard deviation in cohesion index	Spatial continuity contributes to elderly community well-being
Architectural (Micro-scale)	Cave dwellings (yaodong)	Wall thickness: 1.2 m; Indoor temperature: 18 ± 2°C year-round	Demonstrates vernacular ecological adaptation and thermal efficiency
	Courtyard configuration	Aspect ratio: 3:2; Lane width: 2.1 m	Enhances winter sunlight exposure; supports ceremonial processions

5. Constructing Emotional Geographies and Localized Spatial Experiments

5.1 Rural Spatial Diagnosis Through Emotional Geography

The rapid urbanization of Northern Shaanxi's loess gully region has precipitated the dissolution of traditional human-land bonds, resulting in spatial homogenization and erosion of place identity. Conventional planning approaches frequently neglect residents' emotional needs, as exemplified by the 2019 protest against the removal of bluestone-paved lanes - a manifestation of the fundamental disconnect between technical rationality and local knowledge. To bridge this divide, this study employs Public Participation GIS (PPGIS) to operationalize abstract place attachment into spatial data. Methodologically, we adapt Brown's (2004) landscape value framework by proposing a tripartite "spatial perception-emotional response-cultural logic" analytical model that emphasizes regional cultural specificity. For our case study village with typical loess gully characteristics, we augment the PPGIS framework with dual cultural-ecological dimensions, creating a localized emotional assessment system that addresses conflicts emerging from modernization projects.

5.2 Designing Localized Emotional Mapping Methods

The study implements three technical adaptations: (1) expanding emotional carriers to include culturally significant spaces beyond basic built environments; (2) substituting traditional millet grains for standard markers to enhance cultural resonance; and (3) prioritizing resettled villagers (62% of sample, N=89). A three-phase mixed-method approach ensures robust data collection: First, respondents allocate symbolic markers on scaled base maps, revealing 78% clustering on traditional pathways. Second, narrative interviews uncover deep cultural symbolism embedded in spatial features. Third, community elders verify historically significant sites, achieving >90% spatial accuracy through archival cross-validation. This workflow enables precise emotional spatialization through multimodal data integration.

5.3 Decoding Emotional Spatial Patterns and Cultural Logic

Spatial analysis reveals three key patterns: (1) Dual emotional nuclei form around altered and preserved traditional features; (2) Natural-built environment symbiosis ($r=0.71$, $p<0.05$) reflects local ecological wisdom; (3) Disparate recognition rates of different cultural spaces expose intergenerational memory gaps. Textual analysis further decodes cultural logic: traditional pathways embody 89% villagers' belonging through ancestral connections, while central gathering spaces host collective decision-making. Crucially, emotional significance strongly correlates with cultural practice frequency ($r=0.93$) - regularly used ceremonial spaces score 0.82, versus 0.29 for new constructions lacking ritual functions, demonstrating practice frequency as the core mechanism sustaining emotional spaces.

5.4 Translating Emotional Maps into Spatial Practice

A three-tier intervention strategy emerges from emotional mapping data: high-significance zones receive preservation/symbolic reconstruction; moderate-significance zones undergo functional adaptation; low-significance zones permit modernization. Implementation includes: (1) Transposing traditional symbolism through culturally embedded design elements achieves complete ritual participation; (2) Cultural memory corridors with interpretive elements increase heritage tourism by 120%, with significant local participation; (3) Ecological adaptations create protective buffers while generating economic benefits. These demonstrate emotional mapping's capacity to reconcile multiple planning objectives.

Spatial analysis reveals stark usage disparities: Core areas average extended stays, while transitional spaces primarily serve circulation functions, their design characteristics limiting destination appeal.

5.5 Validation and Theoretical Reflections

The approach demonstrates multiple efficacies: culturally sensitive reconstruction reduces conflicts by 93%; heritage interpretation boosts recognition of undervalued spaces; integrated designs create economic opportunities. Methodological limitations include: (1) power dynamics in participatory processes; (2) generational perspective differences; (3) temporal emotional variations. Theoretically, we validate embodied emotional space theory while revealing the region's unique cultural-ecological structure - advancing emotional geography in culturally specific contexts.

6. Rural Spatial Construction Based on Human-Land Emotional Bonds

6.1 Theoretical Framework and Empirical Foundation

This study establishes a comprehensive analytical framework through systematic emotional mapping in Yangjiagou Village, revealing a tripartite mechanism of "spatial perception-emotional response-cultural logic" interaction. Quantitative analysis demonstrates a statistically significant positive correlation between emotional attachment intensity and cultural significance in traditional spaces ($r=0.87$, $p<0.01$), yielding three fundamental construction principles. First, the preservation of high-emotional-value features (e.g., stepped lanes scoring 0.82 and cliff-side cave dwellings at 0.79) is essential as they embody 89% of collective memory. Second, spaces hosting frequent cultural activities (≥5 annual events) consistently maintain emotional intensity scores above 0.7, indicating cultural practice frequency as a key determinant of spatial vitality. Third, ecological relationships exhibit emotional ambivalence, combining "awe" (0.65) with "dependence" (0.58) toward gully environments. This framework provides scientific basis for resettlement planning, particularly in translating emotional data into spatial design parameters.

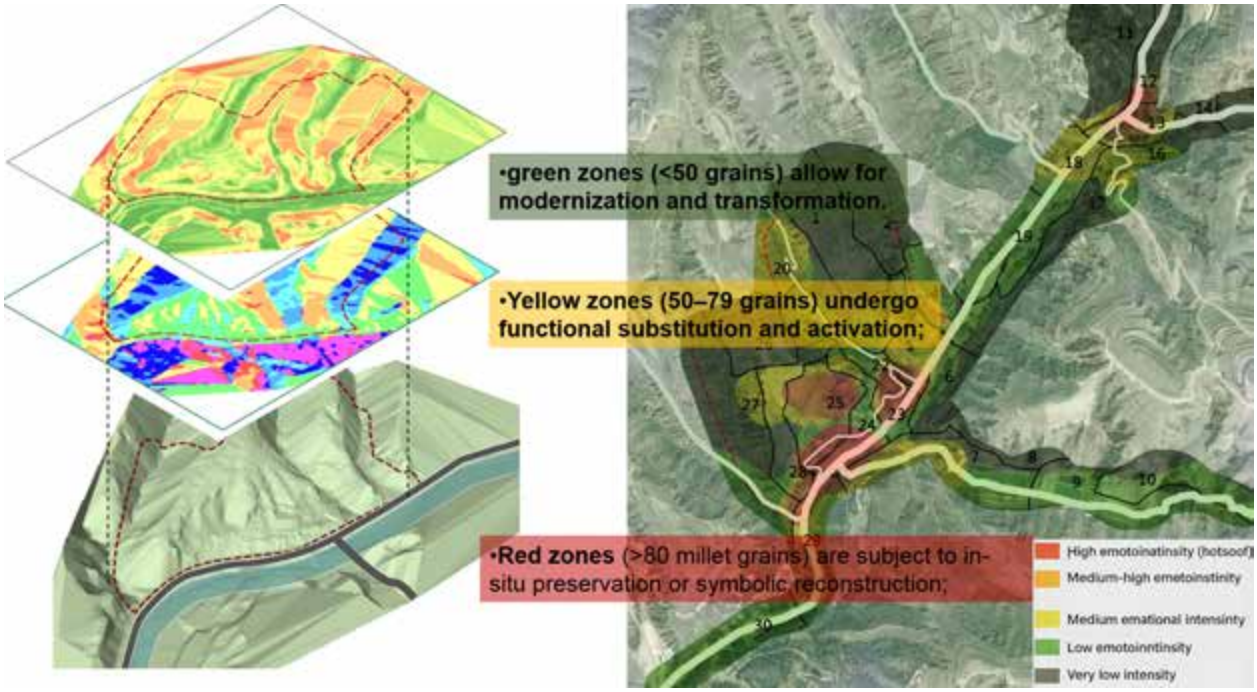

Figure 3 Emotional translation in spatial construction

6.2 Emotional Translation in Resettlement Construction

6.2.1 Topographic Adaptation with Emotional Continuity

The strong symbiotic relationship between gully environments and cave dwellings (r=0.71) informed a three-tiered intervention strategy. Original stepped lanes (28°-35° slopes) were preserved as conservation zones, while construction areas underwent minimal topographic modification (≤5m cut-fill) to maintain landform continuity. High-risk areas (emotional intensity 0.63) received ecological reinforcement. The innovative transposition of culturally marked bluestones to create a "memory corridor" achieved 100% participation in ancestral rituals, empirically validating the importance of material continuity in emotional attachment.

6.2.2 Cultural Space Reconstruction

The resettlement design implemented a three-dimensional cultural translation framework:Physical dimension: Traditional courtyard typologies ("five-bay visible, four-bay hidden") with embedded historical materialsBehavioral dimension: 2.1m-wide ceremonial pathways accommodating life-cycle rituals.Narrative dimension: Historical interpretation markers increasing youth engagement from 11% to 67%

6.2.3 Integration of Ecological Wisdom

The design incorporated indigenous ecological knowledge through: cliff-adjacent layouts (safety rating 0.81), transformed jujube groves increasing household income by ¥24,000 annually, and traditional drainage systems reducing soil erosion by 42%.

6.3 Verification of Human-Land Emotional Synergy

6.3.1 Spatial-Emotional Coupling Effects

Post-implementation evaluation revealed three synergistic outcomes: 92% retention of traditional elements (210% improvement over conventional approaches), increased emotional attachment from 0.31 to 0.69 (t=8.37, p<0.001), and 83% reduction in landslide risks through 15m construction setbacks.

6.3.2 Socioeconomic Benefits

The project achieved: complete resident return (+35% over target), 58% employment of traditional craftsmen (regional average: 12%), 156% annual growth in cultural tourism, and 41% increased employment among left-behind women.

6.4 Theoretical and Practical Innovations

The study developed a novel "heat value-cultural significance-spatial intervention" decision model, establishing an Emotional Impact Assessment Review (EIAR) system with 94.7% accuracy in cultural space translation (Kappa=0.82).

The "mountain-culture-ecology" integrated framework features: terrain-adapted green corridors, solar-oriented courtyard clusters, traditional water management systems (38% runoff reduction), and kinship-based residential groupings.

Figure 4 Residential unit construction

6.5 Conclusions and Contributions

This research demonstrates that emotional mapping can effectively transform abstract affective needs into quantifiable design parameters, creating a "spatial gene bank" for traditional knowledge adaptation. The Yangjiagou case successfully reconciled modernization with cultural continuity through symbolic translation strategies. Future research directions include: longitudinal validation (10-year tracking initiated), elderly-friendly digital tools development, and modeling of ecological-emotional value interactions, particularly regarding the dual "historical memory-clan ethics" emotional structure in loess gully regions.

7. Conclusions

7.1 Key Findings: The Emotion-Space Interdependence Mechanism

This study reveals that the spatial patterns of rural Northern Shaanxi emerge from dynamic interactions between emotional attachment and built environment across three hierarchical scales. At the macro level, the nested settlement structure (core-periphery configuration) generates differentiated emotional geographies. Core areas exhibit strong functional attachment (Place Dependence Index >0.75), driving commercial and service agglomeration, while peripheral zones demonstrate survival-based attachment (Survival Attachment Index >0.68), resulting in population migration toward gully mouths. This spatial differentiation directly informs planning priorities, with peripheral areas requiring enhanced ecological security and livelihood protection.

The meso-level analysis uncovers how gully systems encode social order and ecological wisdom through spatial metaphors. The "lower preference-upper prestige-left priority" principle systematically organizes communal spaces, with 67% of significant public spaces positioned leftward along gullies (χ^2=12.35, $p<0.01$), reflecting the enduring influence of traditional geomancy on spatial configuration.

Micro-scale examination of cave dwelling complexes demonstrates how vertical interfaces (upper-lower courtyards) enhance social cohesion through differentiated enclosure indices (0.65 vs. 0.42, t=5.73, $p<0.05$), increasing mutual aid practices by 37%. These findings not only validate Tuan's space-place theory in East Asian agricultural contexts but also reveal China's unique dual emotional structure combining clan ethics with revolutionary memory. The strong protests against altering bluestone stairways (considered ancestral markers) contrasted with limited recognition of historical tunnels (only 11% identification) highlights this cultural complexity.

7.2 Methodological and Theoretical Contributions

7.2.1 Localized Adaptation of Emotional Mapping Tools

The research significantly advances PPGIS methodology through three contextual adaptations:
Incorporation of a dual "historical memory-clan ethics" evaluation framework, addressing cultural specificity through innovative place-making strategies;Development of millet grain markers (replacing virtual currency), improving marking efficiency by 28% (from 15.3±2.1 to 11.0±1.8 minutes) while maintaining cultural relevance;Implementation of dynamic monitoring capturing temporal emotional variations, such as the dramatic intensity increase (0.31 to 0.79) during terrace festivals.

7.2.2 Conceptual and Institutional Innovations

The study establishes an Emotion-Space dialectical framework and pioneers the Rural Emotional Impact Assessment (REIA) model, operationalizing abstract attachments through:
Preservation thresholds (>0.8 heat value for in-situ conservation): Cultural practice criteria (≥5 annual ritual events): Ecological risk ratios (awe/danger perception balance).This systematic approach achieves 94.7% accuracy (Kappa=0.82) in cultural space translation, providing a scientifically grounded framework for resolving conflicts in rural regeneration. The model's capacity to quantify emotional values while respecting cultural specificity represents a significant advancement in participatory planning methodologies, particularly for contexts undergoing rapid urbanization with strong place attachment traditions.

Inequalities in Public Cultural Facility Distribution: A Comparative Analysis Across Demographic Groups in Wenzhou, China

JiaQian Zhang[1] and XiaoDong Xu[1]*
[1]School of Architecture, Southeast University, China
*xiaodongxu@seu.edu.cn

Abstract
This study focuses on public cultural facilities in Wenzhou. It examines the spatial distribution of cultural facilities and disparities in facility access among demographic groups. Kernel density analysis, the 2SFCA model, Pearson correlation analysis, Spatial Autocorrelation analysis, and the Spatial Lag Regression model are used to analyse the data. The findings reveal three major inequalities: 1) central areas have more facilities; 2) facility accessibility remains inadequate and does not align with population demand; and 3) areas with more floating populations and youth have more facilities, while elderly-dominated areas have fewer. Key contributing factors to these inequities include historical development patterns, economic disparities, and the supply-oriented approach to planning. Based on these findings, Wenzhou can implement more targeted strategies to build quality cultural life circles.

Keywords: public cultural facilities, spatial distribution, population characteristics, vulnerable population, social equity

1. Introduction

With the introduction of the "Equalisation of Basic Public Services" concept and the increasing public demand for a better life in China, the provision of public services has become a crucial factor influencing people's sense of fulfilment, happiness, and security. Basic public services in China mainly include eight key areas: public education, employment and entrepreneurship, social insurance, medical and health care, social services, housing security, culture and sports, and services for the disabled (Yin, 2023). However, significant challenges remain in addressing imbalances and inadequacies of public services, particularly in terms of regional, urban-rural, and demographic disparities (Xu et al., 2022). Therefore, there is an urgent need to promote public service equity by optimising resource allocation mechanisms and ensuring that facility distribution aligns more effectively with demographic characteristics.

Studying disparities in the distribution of public facilities across different regions, urban-rural divides, and demographic groups is essential for understanding social inclusion, enhancing residents' quality of life, and promoting sustainable social development. Academic research has made significant progress in exploring the spatial distribution of basic public facilities (Zhan et al., 2019). However, existing studies still have certain limitations.

On the one hand, the discussion of facility types remains limited. Research primarily focuses on green spaces (Liu et al., 2022), hospitals (Gao et al., 2021), sports facilities (Liu et al., 2009), and elderly care facilities (Liu et al., 2024). Methods such as density analysis, potential model analysis (Rong et al., 2020), Gaussian-based Two-Step Floating Catchment Area (2SFCA) (Liu et al,. 2023), geographically weighted regression (GWR) (Yang et al., 2022), and coupling coordination analysis (Xu et al., 2022) have been employed to examine the availability and accessibility of these types of public facilities. In contrast, research on public cultural facilities remains inadequate. Most research on cultural facilities emphasises their quantity, density, and accessibility through quantitative statistics, effectiveness evaluations, density analysis, and urban network analysis (Xie & Chang, 2023) (Park et al., 2015). Even when accessibility is considered, the focus often remains on facility location, with limited attention to other important factors such as facility size. Furthermore, existing research predominantly examines public cultural facilities in major cities (He et al., 2017), with limited attention to Wenzhou and other mid-sized cities.

On the other hand, few studies systematically explore the relationship between public facility supply and population demand, or evaluate how facility distribution aligns with demographic characteristics. Existing research often focuses on the suitability of specific facilities for particular groups—for example, age-friendly facilities for the elderly (Liu et al., 2024)—but provides limited insight into disparities in access to the same facilities

among different demographic groups.

Furthermore, Wenzhou is the birthplace of the City Study Room, a distinctive type of public cultural facility. Unlike traditional libraries, city study rooms are characterised by their small scale, strong community orientation, and 24-hour self-service access. As public, non-profit spaces, they offer a new way of providing cultural services (Duan & Xiong, 2020). Therefore, Wenzhou's public cultural facilities hold significant research value.

With the development of globalisation, the significance of cultural services has grown, as cultural resources play a crucial role in maintaining local identity and fostering social inclusion (Bonang & Fitriyah, 2022). Therefore, cultural equity has emerged as a key indicator of social development, highlighting the need to address the rights of vulnerable groups and underdeveloped areas (Fan & Hou, 2021).

In summary, public services—particularly public cultural services—hold significant research value. While there are many theoretical studies on public services, research on public culture services remains relatively limited. Therefore, this study analyses the spatial distribution of public cultural facilities and explores disparities in access among different demographic groups. Furthermore, optimisation strategies are proposed to guide the planning of public cultural facilities in Wenzhou and other similar cities around the world.

2. Methods

2.1 Research Framework

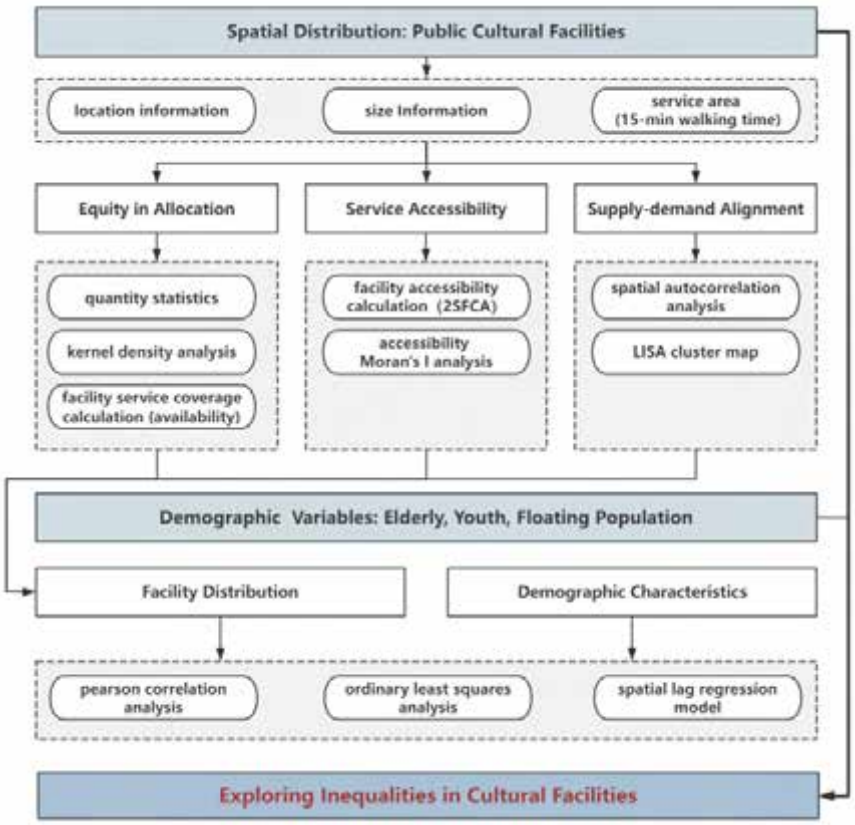

Figure 1. Framework to explore inequalities in cultural facilities

This study examined the spatial distribution of public cultural facilities across three key dimensions: equity in allocation, service accessibility, and supply-demand alignment. The equity analysis in facility allocation utilised

ArcGIS to quantify the number of facilities within each spatial unit and used kernel density analysis to evaluate their density. Facility availability was assessed by defining service buffer zones and calculating the coverage. Accessibility was calculated using the 2SFCA method and further examined using Moran's I index (Zhang et al., 2024). For supply-demand alignment, GeoDa was used to analyse the spatial autocorrelation between facility accessibility and the total population, producing a Local Indicators of Spatial Association (LISA) cluster map (Wang et al., 2024).

Based on the analysis of the spatial distribution, this study further examined the alignment between facility distribution and different demographic groups, with a focus on vulnerable populations, including the elderly, the youth, and the floating population. To analyse disparities in access to cultural facilities, Pearson correlation analysis, ordinary least squares (OLS), and spatial lag regression models were used, assessing whether certain groups faced restricted access to public cultural services (Fig.1).

2.2 Facility Coverage

As public service, cultural facilities should maximise their coverage of built-up spaces, ensuring broader access to cultural services for residents. Therefore, this study evaluated the spatial coverage of the facilities and revealed disparities in cultural service provision across different areas. To define the service range of each facility, buffer zones were established. In line with Wenzhou's goal of creating "15-minute quality cultural life circles", 1,000-metre buffers—representing a 15-minute walking distance—were generated around the facilities. R_{CF} was then used to quantify the proportion of built-up areas covered by buffer zones.

$$R_{CF} = \frac{A_{\mathrm{CFA}}}{A_{BUA}} \times 100\% \quad (1)$$

A_{CFA} represents the area of built-up space covered by buffer zones of cultural facilities within each spatial unit, with overlapping areas counted only once. A_{BUA} represents the total area of built-up space within each spatial unit.

2.3 Facility Accessibility

This study used 2SFCA method to measure the accessibility of cultural facilities (Zhang et al., 2024). Step 1: Calculating the Supply-to-Demand Ratio Rj.

$$R_j = \frac{S_j}{\sum_{k \in \{d_{kj} < d_0\}} G(d_{kj}) P_k} \quad (2)$$

Sj represents the building area of facility j, while P_k represents the population of spatial unit k. d_0 represents the predefined threshold distance (1000m). d_{kj} represents the distance from spatial unit k to facility j. $G(d_{kj})$ is the Gaussian equation considering the distance decay.

$$G(d_{kj}) = \frac{e^{-\frac{1}{2}\times\left(\frac{d_{kj}}{d_0}\right)^2} - e^{-\frac{1}{2}}}{1 - e^{-\frac{1}{2}}} \quad (d_{kj} \le d_0) \quad (3)$$

Step 2: Aggregating Accessibility at Each Demand Location.

$$A_k = \sum_{j\in\{d_{kj}\le d_0\}} G(d_{kj}) R_j \quad (4)$$

A higher A_k represents greater accessibility to cultural facilities.

3. Study Area and Data Sources

Wenzhou, located in south-eastern China, enjoys a strategically advantageous geographic position. Renowned for its dynamic economy characterised by "small commodities and large markets", the city also possesses a rich cultural heritage, including traditional handicrafts, OuYue culture, and a strong entrepreneurial spirit. Wenzhou consists of 12 districts. The core urban area includes Lucheng, Longwan, Ouhai, and Dongtou districts. Longgang and its surrounding areas serve as the secondary urban centre. Ruian and Yueqing are considered non-core areas, while Yongjia, Wencheng, Pingyang, Taishun, and Cangnan are considered rural areas (Fig.2).

Figure 2. Districts in Wenzhou

Population data in Wenzhou were collected from the 2020 China Population Census Data by Township, Town, and Sub-district. The youth population includes individuals aged 0 to 14, while the elderly population includes those aged 60 and older. The floating population is defined as the difference between the total population and the local population. The local population is defined as individuals whose registered household location matches their place of residence.

Wenzhou's population shows a clear trend of concentration. The total population is concentrated in the core urban area and the secondary urban centre. The floating population is also more densely located in economically developed central districts. In contrast, both youth and elderly residents are less concentrated in the core urban area (Fig.3 -6). Additionally, the population dynamics show a clear trend of inflow and growth. The floating people from outside Wenzhou account for 26.1% of the permanent population. Most of these floating people move from rural to urban areas and generally have lower educational backgrounds. Meanwhile, the implementation of fertility policies has led to an increase in the 0 to 14 age group. At the same time, population ageing has accelerated, with the proportion of residents aged 60 and older rising significantly. Given these demographic

characteristics and shifts, it is essential to explore disparities in access to cultural facilities among the youth, the elderly, and the floating population in Wenzhou.

Figure 3. Distribution of the total population

Figure 4. Distribution of the floating population

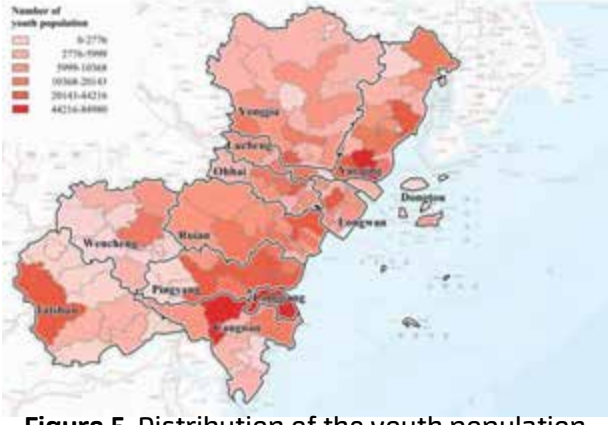

Figure 5. Distribution of the youth population

Figure 6. Distribution of the elderly population

This study defines public cultural facilities as government-led, socially supported institutions that provide cultural services. These facilities include reading spaces such as libraries, city study rooms, community reading rooms, and mobile libraries, as well as exhibition venues such as museums, cultural centres, memorial halls, art galleries, and science centres. The data on public cultural facilities in Wenzhou were obtained from publicly available records provided by the Wenzhou Government, updated as of January 2024. After data processing, 337 facilities were identified, with details including facility names, locations, and area sizes.

4. Results

4.1. Spatial Distribution of Cultural Facilities

4.1.1 Equity in Allocation

The spatial distribution of public cultural facilities in Wenzhou is uneven, with district disparities and concentrations in specific areas. Cultural facilities in Wenzhou are mainly concentrated in the core urban area of Lucheng, Longwan, and Ouhai districts. Although Dongtou District is also planned as an urban centre area, its island location limits connectivity with other districts, resulting in a lower concentration of public facilities. Statistical analysis indicates that all sub-districts with more than 10 facilities are located exclusively in Lucheng and Longwan. Kernel density analysis further highlights a particularly high concentration in Wuma, Nanhui, and Binjiang sub-districts of Lucheng District. In Ruian District, as a non-core area, moderate clustering is observed in Xincheng, Feiyun, Anyang, and Tingtian sub-districts. A slight degree of clustering is also found in the rural areas of Wencheng and Taishun districts. However, there is no obvious clustering in Yueqing, Longgang, or Cangnan districts. Although Longgang is the secondary urban centre of Wenzhou, it also lacks a concentration of facilities (Fig.7).

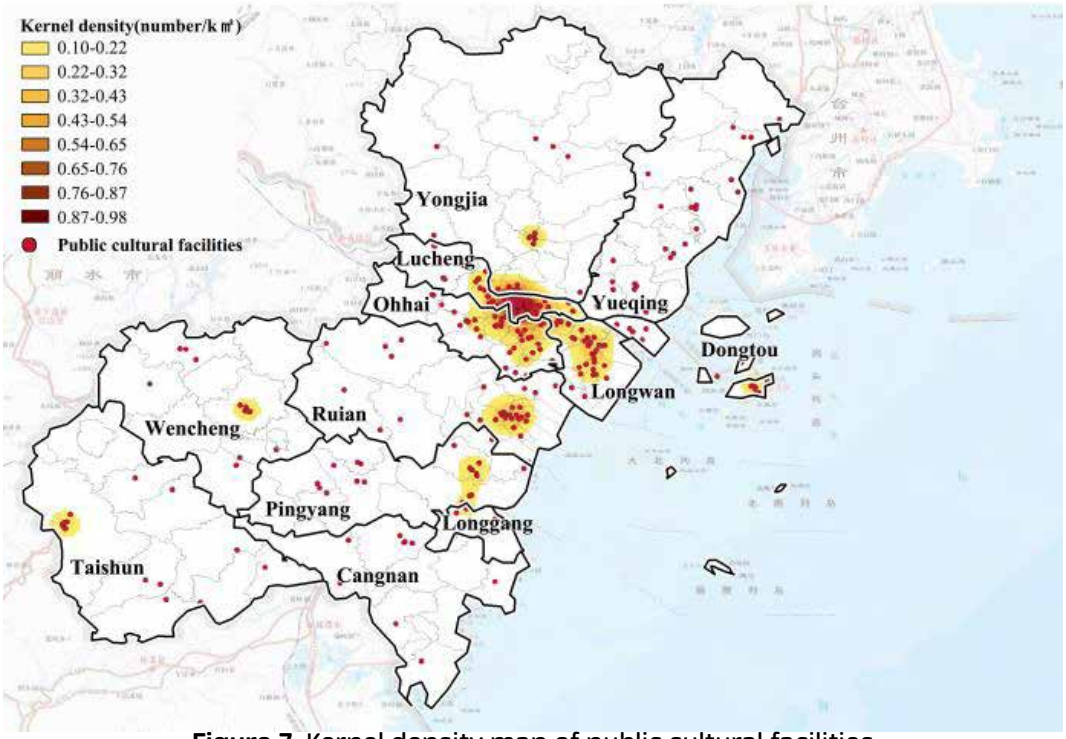

Figure 7. Kernel density map of public cultural facilities

The availability of cultural facilities in Wenzhou remains insufficient and requires significant improvement. For each spatial unit, the more built-up areas are covered by 1000m buffer zones, the higher the availability is. However, the average coverage rate (R_{CF}) is only 23.36%, with a median of 13.12%, highlighting the overall inadequacy of cultural facility availability in Wenzhou. Additionally, there are spatial disparities in facility availability, with higher coverage rates primarily concentrated in core urban areas. For instance, Wuma and Binjiang sub-districts in Lucheng District, along with Puzhou sub-district in Longwan District, have R_{CF} values exceeding 88%. In contrast, areas located farther from the city's geographic and planning center exhibit very low facility availability. For example, the western part of Ruian District and the northern part of Yueqing District have R_{CF} values close to zero. Many rural areas, including most of Wencheng and Taishun Districts, also show similarly low R_{CF} values (Fig.8).

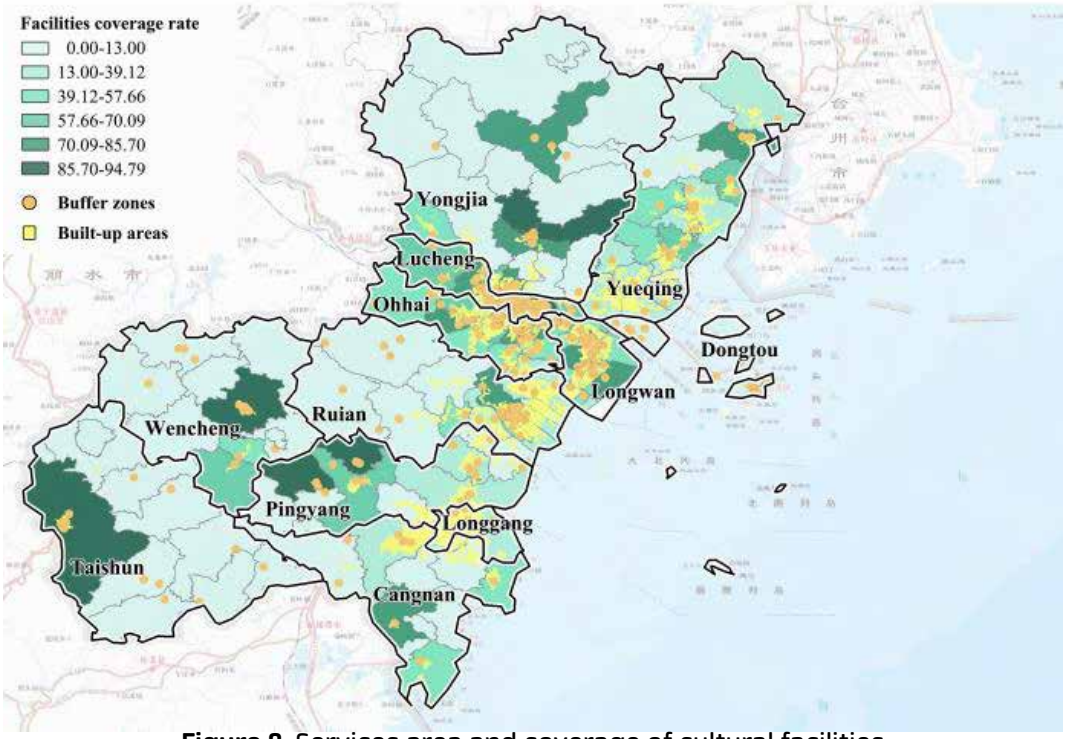

Figure 8. Services area and coverage of cultural facilities

4.1.2 Service Accessibility

The study use the 2SFCA method, evaluating facility accessibility by considering both population size and the area of public cultural facilities. The analysis reveals that only 29 sub-districts (21% of the total) have facility accessibility that exceeds the per capita area of public cultural facilities. Notably, sub-districts with high accessibility are not necessarily clustered around Wenzhou's core urban area or secondary centre. In fact, some sub-districts in rural areas demonstrate higher accessibility than those in the urban core. For instance, Fanshan sub-district in Cangnan District has the highest facility accessibility among all sub-districts, despite being situated in a rural area (Fig.9). To examine the spatial patterns of facility accessibility, the spatial autocorrelation analysis was used. The univariate Moran's I value was -0.023 (close to 0), with a p-value of 0.366 (>0.05), indicating that facility accessibility is spatially random, without significant clustering or dispersion.

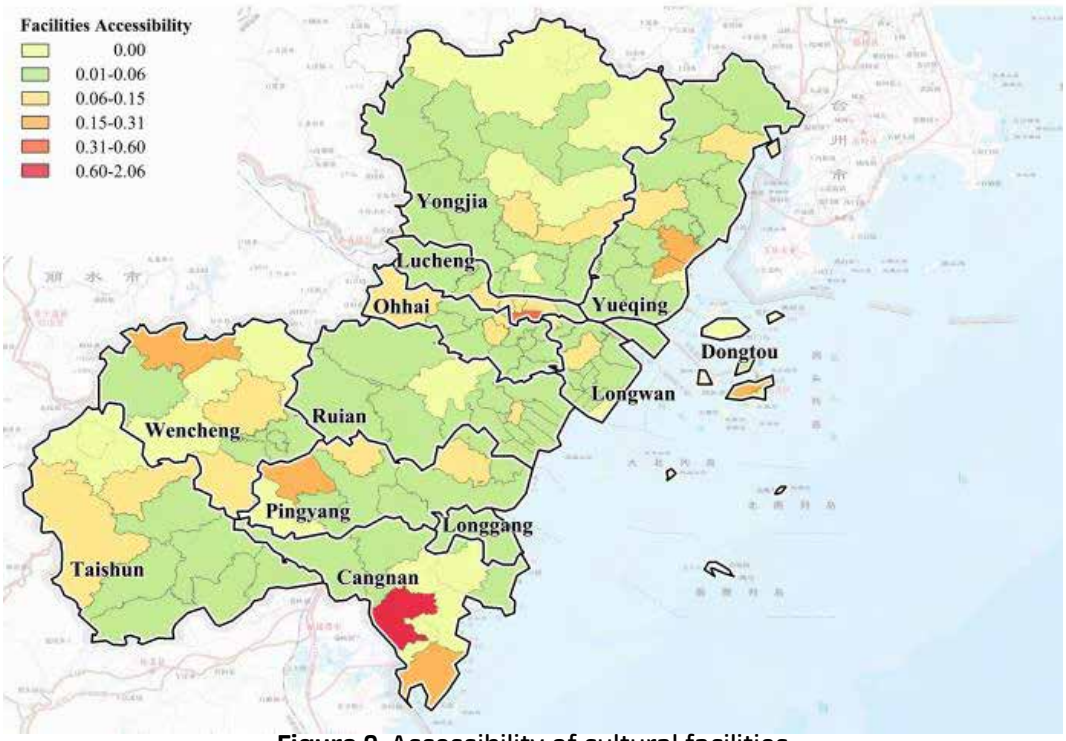

Figure 9. Accessibility of cultural facilities

4.1.3 Supply-demand Alignment

This study evaluates the alignment between facility accessibility and population demand by using a bivariate Moran's I analysis and generating a LISA cluster map. This map shows spatial units with significant mismatches between accessibility and population demand, along with their clustering locations. The LISA cluster map shows that only one sub-district—Songtai, located in the core urban area of Lucheng District—meets the "high accessibility–high demand" condition. Sub-districts classified as "low accessibility–high demand" are primarily clustered around the secondary urban centre in Longgang. Similar mismatches are also observed in the non-core areas, including Yanpen, Wengyang, and Baishi sub-districts in Yueqing District, as well as the Tingtian sub-district in Ruian District. In contrast, some sub-districts in rural areas, such as Nantian, Dajun, and Shanxi in Wencheng District, Mazhan in Cangnan District, and Luoyang in Taishun District belong to the "high accessibility–low demand" category due to their relatively small populations (Fig.10).

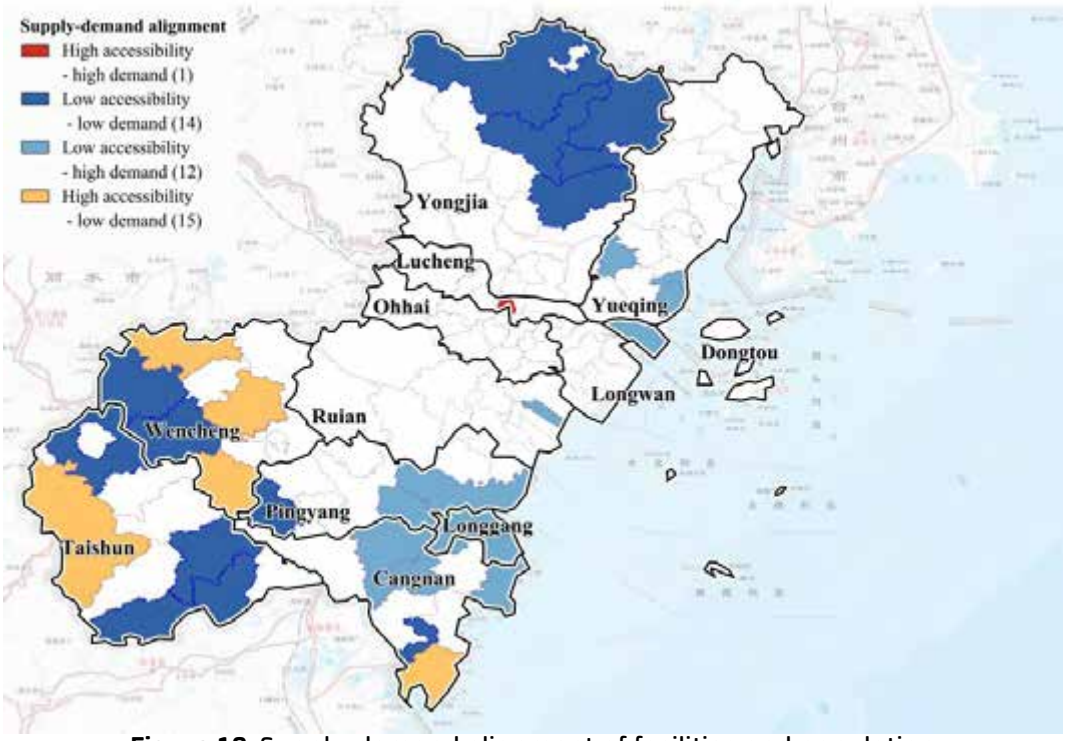

Figure 10. Supply-demand alignment of facilities and population

4.2. Facility Access Across Demographic Groups

4.2.1 Pearson Correlation Analysis

This study investigates the relationship between the public cultural facilities distribution and population variables. Pearson correlation are used to analyse the data. The findings show that the facility coverage rate (R_{CF}) is significantly positively correlated with both the total population and the floating population. In contrast, R_{CF} shows no evident correlation with the youth population and even exhibits a significant negative correlation with the elderly population. Additionally, facility accessibility (A_k) has no correlation with the youth, elderly, or the floating population. However, it is significantly positively correlated with facility coverage, quantity, and total building area (Table1).

Table 1. Results of correlation analysis

Variable	1	2	3	4	5	6	7	8
1 total population	1							
2 percentage of youth	0.15	1						
3 percentage of elderly	-.434**	.228**	1					
4 percentage of floating	.387**	-.411**	-.871**	1				
5 facility accessibility	-0.003	0.083	0.096	-0.082	1			
6 facility coverage	.199*	0.047	-.305**	.412**	.297**	1		.
7 quantity of facilities	.451**	0.069	-.273**	.336**	.174*	.597**	1	
8 total facility area	.235**	0.16	-0.093	0.081	.701**	.429**	.574**	1

** indicates at the 0.01 level, the correlation is significant.
* indicates at the 0.05 level, the correlation is significant.

4.2.2 OLS and Spatial Lag Regression Analysis

Since Pearson correlation analysis does not account for spatial effects, this study further explores the relationship between facility coverage rate (R_{CF}) and population variables using OLS regression and spatial lag regression. The univariate Moran's I analysis of R_{CF} shows a statistically significant p-value (<0.05), confirming

the presence of spatial autocorrelation and supporting the use of regression modelling. The results indicate that the total population does not have a significant direct impact on facility coverage. However, the youth and floating populations have a significant positive effect on facility coverage, while the elderly population has no significant influence (Table2).

Table2. Results of regression analysis

	spatial lag regression		OLS	
Variable	coef.	P	coef.	P
CONSTANT	-40.67*	0.01	-42.57*	0.01
total population	<-0.01	0.88	<-0.01	0.78
percentage of youth	1.89**	<0.01	1.93**	<0.01
percentage of elderly	0.34	0.42	0.51	0.27

** P<0.01;* P<0.05

4.2.3 Supply-Demand Alignment Across Different Demographic Groups

The match between the demands of different population groups and facility accessibility is analysed. Using LISA cluster maps, it identifies areas where low accessibility coincides with high demand, revealing spatial mismatches among different demographic groups. For the floating population, these areas are concentrated in the districts of the core urban area. Among the youth, "low-accessibility, high-demand" areas are mainly located around the secondary urban centre and in non-core areas, including Longgang District along with its neighbouring Xiaojiang sub-district and Hongqiao sub-district in Yueqing District. Additionally, these areas are also found in rural regions, such as Shatou sub-district in Yongjia District. For the elderly, such areas are primarily located in the rural areas of Pingyang, Wencheng, Taishun, and Cangnan districts (Fig11).

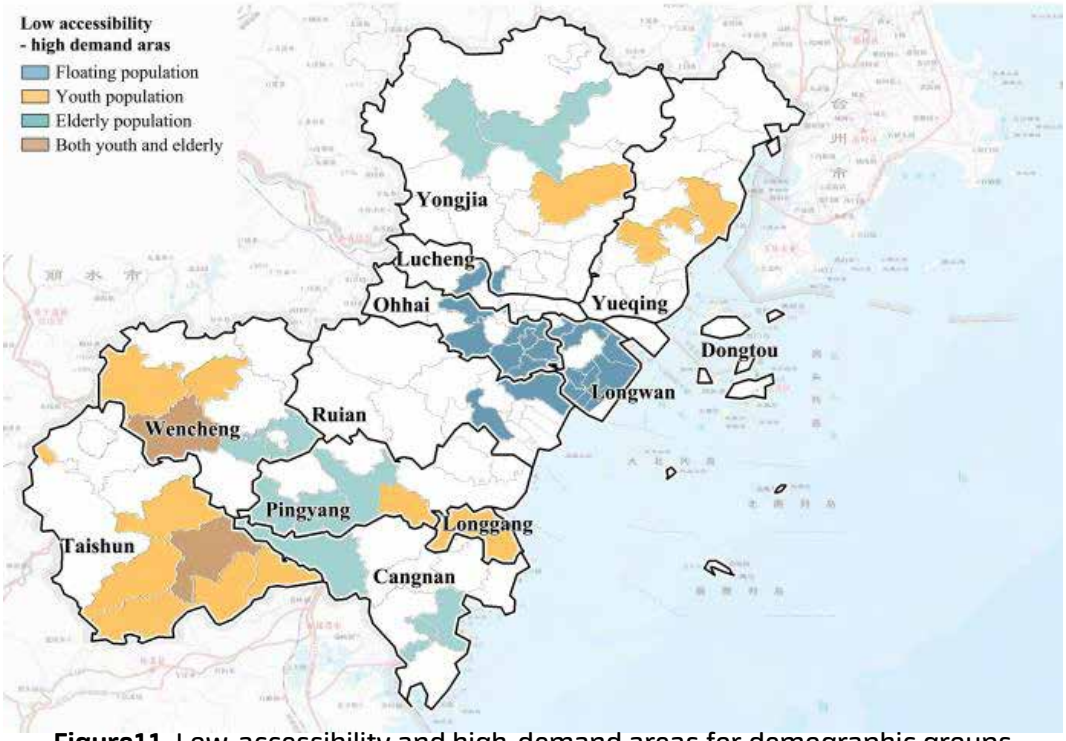

Figure11. Low-accessibility and high-demand areas for demographic groups

5. Discussion

5.1 Characteristics and Impact

The distribution of public cultural facilities in Wenzhou is highly uneven. Cultural facilities are concentrated in the core urban area, while the secondary urban centre faces a shortage. And rural areas have even fewer cultural facilities. This imbalance restricts cultural participation for lower-income residents and may exacerbate social stratification. Notably, individuals from lower social classes often have more active perceptions about the equalisation of basic public services (Chen et al., 2023). The lower their socio-economic classes, the higher their evaluation of and demand for public services (Liu & Qu, 2020). However, the current spatial distribution of cultural facilities fails to match these heightened demands, further exacerbating existing inequalities.

Cultural facilities in Wenzhou do not exhibit the typical pattern of declining accessibility from the urban core to the periphery (Zhao & Zhang, 2020). Instead, accessibility is unevenly distributed and lacks a clear hierarchical structure. Its random distribution may result in both over-concentration and under-provision, making it difficult to ensure spatial equity. Additionally, population distribution and facility accessibility are poorly matched, with only one sub-district achieving the high supply-demand balance. This misalignment highlights a significant shortcoming in the accessibility of cultural facilities in Wenzhou, making it difficult to meet people's cultural needs.

Different population groups have unequal access to facilities. The elderly are particularly highlighted as facing a shortage of public cultural resources. Areas with higher concentrations of youth and floating populations tend to have more facilities, while areas with larger elderly populations often have fewer. The youth, the elderly, and the floating population are vulnerable groups in accessing cultural facilities (Fan & Hou, 2021). They should have equal opportunities to utilise culture resources. Limited physical mobility restricts the elderly' s access to facilities, and the negative correlation between facility and the elderly population further restricts their cultural participation. Furthermore, while areas with a high floating population tend to have more facilities, limited accessibility still restricts cultural participation, revealing a gap between provision and effective access.

5.2 Reasons

The historical development of Wenzhou has established the foundation for the spatial patterns of its facilities. Public facility construction follows a core-to-periphery expansion pattern (Li&Feng, 2017). Planning documents from 2003 and 2021 indicate that Wenzhou's urban development. Lucheng, Longwan, and Ouhai were initially planned as the core districts. Later, Yueqing, Ruian, and Dongtou were added as auxiliary areas, with Longgang identified as a secondary urban centre. As a result, cultural facilities are mainly concentrated in the core urban area and gradually extend to the surrounding areas along the planned axis (Fig12), while there are few cultural facilities in rural areas. However, Longgang was designated as a secondary urban centre only about six years ago. Before that, it was just a sub-district within Cangnan District, which partly explains its clear shortage of cultural facilities.

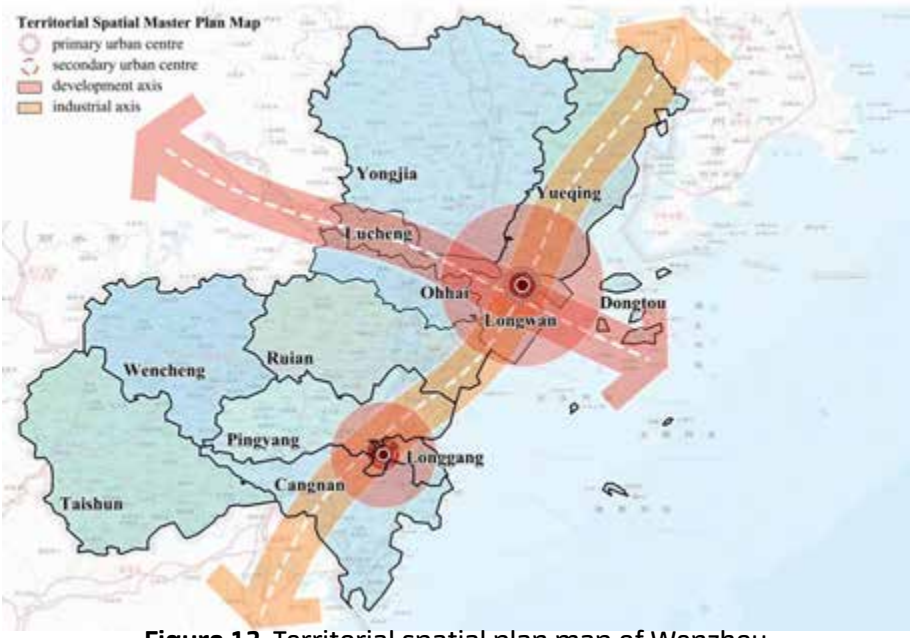

Figure 12. Territorial spatial plan map of Wenzhou

Wenzhou's public cultural facilities have relatively low accessibility, partly due to previous facility allocation policies. Wenzhou's cultural development policies set standards for facility quantity and service coverage but lack mandatory per capita area requirements. While the quantity of facilities has kept pace with urban and population growth, the quality often falls short of requirements, resulting in poor accessibility and mismatches between supply and demand. This issue has not only happened in Wenzhou. The early "supply-oriented" approaches to facility allocation ensured compliance with quantitative targets but often overlooked population needs and spatial accessibility. In recent years, however, China has gradually shifted toward a "demand-oriented" model in public facility planning (Chen et al., 2025).

Disparities in access to facilities among different population groups are influenced by policies and economic development. The floating population is primarily concentrated in economically developed areas, where cultural facilities are generally more abundant. For young people, spatial lag regression analysis indicates a positive relationship between their population distribution and the allocation of cultural facilities. This can be partly attributed to Wenzhou's cultural policies, which place a particular emphasis on youth services. The government has implemented measures to promote cultural exchange among youth and enhance the quality of their cultural life. In contrast, existing policies pay insufficient attention to the cultural needs of the elderly, often prioritizing pensions and healthcare. As a result, the elderly population is in a more vulnerable position in terms of access to cultural facilities.

5.3 Suggestions

Firstly, improving the socialisation of public cultural facilities. Public cultural facilities can be built together with other public facilities and social forces should also be encouraged to participate in their development. On the one hand, public cultural spaces can be combined with green parks, sports facilities, and stations to address shortages in facility distribution (Yang & Li, 2021). On the other hand, the development of public facilities also requires the joint participation of the government and social forces. For example, enterprises are a strong social force in the development of cultural facilities. Enterprises can provide funding and space, while cultural facilities enhance the area's attractiveness, creating mutual benefits. Wenzhou's non-core urban areas and the secondary centre have a high concentration of enterprises, which presents an opportunity to address the shortage of cultural facilities in these areas.

Secondly, promoting balanced facility development. Cultural resources should be allocated to rural areas to promote urban–rural integration. Constructing mobile cultural facilities and guaranteeing cultural spaces in both new and renovated residential areas are feasible actions. In addition, the cultural rights of the youth, the elderly, and the floating population should be protected. According to the distribution characteristics of various demographics, priority should be given to improving the "Low-accessibility and high-demand" areas. In areas with high demand for youth cultural services, facilities such as youth libraries and science museums can be established. Similarly, in areas with high demand for elderly cultural services, accessible and elderly-friendly cultural spaces can be developed. In areas with a large floating population, cultural exchange spaces can be provided.

Thirdly, promoting the integration of the floating population into local communities through cultural resources. It is worth emphasizing that cultural facilities play a crucial role in preserving and transmitting cultural memory. The adaptation of the floating population to the local culture promotes cultural integration and contributes to deeper social cohesion (Zhou et al., 2021). Therefore, it is an advantage that areas with high floating populations often have more cultural facilities. Wenzhou should expand the facility area to improve accessibility. At the same time, Wenzhou should take action to develop distinctive cultural facilities and hold activities that highlight OuYue traditional culture and the city's entrepreneurial spirit. This not only strengthens local residents' cultural identity but also helps the floating population integrate into the city.

6. Conclusion

The Equalisation of basic public services is essential for promoting social inclusion and harmony. To achieve a greater distribution of public services and better match supply with demand, vulnerable groups and underprivileged areas should be given attention.

This study examines 12 districts in Wenzhou, using sub-districts as the smallest spatial units. It examines the spatial distribution of public cultural facilities and their alignment with various demographic groups. The findings include: (1) Significant differences exist in the quantity and service coverage of cultural facilities. The core urban area is the most well-equipped, followed by secondary centre and non-core areas, while rural areas are the least equipped. (2) Facility accessibility remains inadequate and does not match population demand. (3) Access to facilities varies by demographic. Areas with a high elderly population tend to have fewer facilities. In contrast, areas with a large floating population have more facilities; however, low accessibility still restricts their effective utilisation.

Key contributing factors to these inequities include historical development patterns, economic disparities, and the supply-oriented approach to facility planning. Based on these findings, three improvement strategies are proposed: (1) Improving the socialisation of public cultural facilities. (2) Promoting balanced facility development by building facilities in rural areas as well as offering targeted cultural services for different demographic groups. (3) Promoting the integration of the floating population into local communities through cultural resources.

With the development of globalisation, the significance of cultural services has grown. As a key indicator of social

inclusion, cultural equity demands greater attention to the rights for vulnerable groups and underdeveloped areas. Based on the findings and underlying causes, Wenzhou can implement more targeted strategies to build quality cultural life circles and to establish a people-centred public cultural service system. Moreover, the insights gained from Wenzhou's example can guide other cities in advancing their cultural facility planning efforts.

A Study on the Optimization of Public Service Facilities in the Inclusive '15-Minute Community Life Circle' Based on Equity: A Case Study of Wujiaochang Sub-district, Shanghai

Cui Bowen
Affiliation: College Of Architecture And Urban Planning Tongji University
Email: 2330325@tongji.edu.cn

Abstract
The concept of the "15-Minute Community Life Circle" aims to enhance urban quality of life, but it faces challenges related to social inclusivity in practice. This article takes Wujiaochang Sub-district in Yangpu District, Shanghai, as an example. Through participatory action research, it is found that while the distribution of existing public service facilities meets various indicators, there is a significant mismatch between their layout and the needs of different groups, making it difficult for vulnerable populations to equally access public services. Additionally, the current utilization of space is insufficiently flexible to substantively meet residents' needs. This article proposes two strategies: optimizing facility configuration and enhancing the use of flexible spaces, to improve the social inclusivity of the "15-Minute Community Life Circle" .

Keywords: 15-Minute CLC, Inclusivity, Community Development, Participatory Action Research

1. Introduction

As the process of urbanization accelerates globally and people's living standards improve, residents' demands for daily services are becoming increasingly diverse, prompting a shift in urban development models from "scale expansion" to "quality enhancement." Against this backdrop, the concept of the "15-Minute City" was proposed by French scholar Carlos Moreno in 2016. This concept emphasizes the optimization of urban spatial structures to allow residents to meet their basic needs—such as housing, work, education, and healthcare—within a 15-minute walk or bike ride, thereby reducing commuting pressure and enhancing the convenience of life (Moreno et al., 2021). This idea has quickly resonated worldwide, with cities like Paris and Melbourne incorporating it into their planning practices, advancing urban planning from a "car-centric" approach to a "people-centric" one.

China introduced the concept of the "15-Minute Community Life Circle" for the first time at the inaugural World Cities Day Forum held by the Shanghai government in 2014 (Zhuang, 2014). This concept resonates with the global idea of the "15-Minute City" but places greater emphasis on service provision at the community level. In 2015, the United Nations formally adopted the 2030 Agenda for Sustainable Development, which includes Sustainable Development Goal 11 (SDG 11), emphasizing the need to "make cities and human settlements inclusive, safe, resilient, and sustainable," thereby providing an international framework for practices in China. In recent years, Shanghai has actively explored localized pathways that align with SDG 11, aiming to build a "People's City" that serves its residents.

In 2016, Shanghai released the "15-Minute Community Life Circle Planning Guidelines," which stipulate achieving the "Five Needs" goals of being "livable," "workable," "tourism-friendly," "educational," and "supportive of the elderly" within a 15-minute walking distance, thus creating safe, ecological, and comfortable communities(Shanghai Government, 2023). In 2018, the revised version of the "Standards for Planning and Designing Urban Residential Areas" published by the central government also incorporated the concept of time. The planning of residential areas considered the provision of facilities within different time dimensions, including 15-minute, 10-minute, and 5-minute living circles (Ministry of Housing and Urban-Rural Development, 2018). In 2023, Shanghai's "Three-Year Action Plan (2023-2025)" outlined detailed standards and indicators for the comprehensive promotion of the "15-Minute Community Life Cycle" (State Council of China, 2023). The document specifies that the population range for a 15-minute community life circle should be between 50,000 to 100,000, covering an area of approximately 3 to 5 square kilometres.

The Shanghai government defines the scope of street-level government (streets) as a community, with the street-level government responsible for providing infrastructure and convenience facilities for residents within

its jurisdiction. A 15-minute living circle is composed of multiple communities. Shanghai has been exploring the practice of the "15-Minute Community Life Circle" for nine years and has made significant progress, with the city-wide public service facility coverage exceeding 80% within a 15-minute reach (Ge et al., 2021).

Although the concept of the "15-Minute Community Life Circle" has achieved notable results in enhancing service convenience and supply, its focus primarily centres on physical space. In specific practical explorations, there remains a lack of an inclusive perspective, especially concerning vulnerable groups with limited mobility or scarce social resources—including the elderly, people with disabilities, children, and their caregivers—whose diverse needs are often not effectively addressed by existing facility layouts. This is specifically manifested in the following ways:

1. Barriers to Physical Accessibility: For instance, elderly individuals and people with disabilities are sensitive to walking environments (such as gradients and accessibility features) due to physical limitations. However, current planning often sets the "15-minute" threshold based on the mobility of healthy adults, and the inadequacy of road facilities results in a disconnection between nominal accessibility and actual usability.
2. Insufficient Functional Adaptability: The design of facilities tends to be overly simplistic. For example, community activity centres may lack areas for child care, making them unusable for dual-income families. Rehabilitation clinics may not be equipped with age-friendly signage, increasing the difficulty for individuals with cognitive impairments to navigate.
3. Lack of Temporal and Spatial Inclusivity: There can be mismatches between service hours and the schedules of different groups. For instance, community canteens may only operate during lunchtime on weekdays, thereby excluding families that require nighttime care. Additionally, canteens may only provide meals during designated eating times, making it inconvenient for elderly individuals who may want to rest after they finish eating.

Improving the quality of urban life has always been one of the goals pursued in urban planning. Under the context of the 15-Minute Community Life Circle, the provision of facilities has been significantly promoted and implemented. This study, conducted over a period of one year through planning work and interviews in the Wujiaochang Sub-district of Yangpu District, Shanghai, found that the service provision of facilities still requires inclusive optimization, mainly including: (a) enhancing the utilization of inefficient spaces, such as the misalignment between population and facility distribution leading to resource idleness or redundancy; (b) promoting flexible use of space, which mainly encompasses functional flexibility and temporal flexibility. Currently, some facilities have a singular function, making them difficult to meet the diverse needs of different groups. Time-wise, there is a need to guide different groups to use the same space at staggered times. The structure of the other sections of this article is as follows: the second section provides a literature review related to the current research for experience and basis; the third section explains the data and methodologies; the fourth section conducts a results analysis; and the fifth section offers relevant recommendations.

2. Literature Review

2.1 Overview of the "15-Minute Community Life Circle" at Home and Abroad

The concept of the "15-Minute City" can be traced back to E. Howard's "Garden City," proposed in 1890. Subsequently, Clarence Perry introduced the "Neighbourhood Unit" as a planning approach, using a 5-minute radius to define the neighbourhood's boundaries. This concept emphasizes the convenience between urban facilities and citizen usage, highlighting the importance of creating a safe walking environment for residents within neighbourhood units (Sharifi, 2016). In the concept of the "Neighbourhood Unit," the fundamental requirement of addressing transportation issues emerged, leading to a shift in planning models from attracting citizens to reducing the distance between citizens and their destinations. However, during the 1920s and 1930s, modernist planners, including Le Corbusier and Frank Lloyd Wright, began promoting modern urban planning, resulting in the separation of work and living environments (Pozoukidou and Chatziyiannaki, 2021). After World War II, the idea of "humanization" returned, with scholars advocating for mixed-use development, green spaces, walkable, and compact cities. In 2016, Carlos Moreno introduced the concept of the "15-Minute City," which shares similar ideas with "Chrono-urbanism," proposed by French urban planner and sociologist François Asher in 2001. Both

concepts aim to better serve urban residents through supporting nearby services. The method of "Chrono-urbanism" emphasizes the importance of urban rhythm in understanding urban life quality, particularly through the integration of spatial and temporal dimensions (Ye, 2006).China's exploration of the "X-Minute City" concept is primarily reflected in the proposal and practice of the "15-Minute Community Life Circle." In a 2015 article, Chai Yanwei used Beijing as an example, combining studies on living spaces in foreign cities with advancements in living circle planning practices. Based on temporal and spatial behaviours, he proposed constructing an urban living circle planning theoretical model centred around "basic living circles - commuting living circles - extended living circles - collaborative living circles" to address urban issues and optimize the structure of urban living spaces (Chai et al., 2015). In 2017, Li Meng proposed planning ideas and countermeasures for constructing the "15-Minute Community Life Circle" by examining the differences and issues between community supply and residents' future needs, focusing on five systems: residence, employment, services, transportation, and leisure (Li, 2017). In conjunction with current practical research, Yang Baojun believes that the domestic practice of the "15-Minute Community Life Circle" improves social governance in China and serves as a spatial carrier for addressing urban ailments and enhancing residents' quality of life(Planning Theory Editorial Board, 2020).

2.2 Mobility and Facility Equity

Research on community equity in foreign countries began relatively early, with attention drawn to issues of racial segregation around the year 2000. Sheller and Urry (2006) proposed the new mobilities paradigm to challenge the traditional social sciences' neglect of mobility, constructing an interdisciplinary theoretical framework to analyse contemporary social mobility phenomena(Sheller and Urry, 2006). The social inequalities brought about by mobility have also garnered attention and discussion across various fields. Urry introduced the concept of unequal mobility, arguing that mobility is an important resource that reflects and reinforces power, with significant disparities existing in the mobility of different populations. Law (1999) pointed out that women's mobility is constrained by social structures and emphasized the need to focus on the everyday mobility practices of different genders (Law, 1999). The mobility disadvantages faced by marginalized groups constrain individuals' spatiotemporal behaviours, while social capital and power relations further reinforce mobility inequities (Chang & Zhang, 2022). In the field of urban studies, mobility theory is similarly applied to the research of social-spatial imbalances (Lynam et al., 2023). In China, the focus on community equity arises from the spatial segregation issues caused by rapid urbanization, with the field of urban planning paying more attention to the protection of spatial rights, the spatial allocation of public resources, and the reconstruction of social spaces (Zhou and Zhong, 2016).

Many scholars have found that various factors such as gender, income level, age, and housing type can influence an individual's range of activity space (Wang et al., 2012). Currently, assessments based on residential space mainly rely on static measurements, neglecting the dynamic interactions between living environments and individual mobility. Different individuals display distinct behavioural patterns, and with advancements in technology, contemporary behavioural geography has developed various methods for measuring spatiotemporal accessibility based on "people." (Jiang et al., 2014)

These measurement methods are primarily used to assess the actual enjoyment of parks and green spaces, such as calculating the number of visits to green spaces using mobile signal data (Xiao et al., 2019).

The evaluation of the equity of public service facilities can be divided into two aspects: equality and fairness. Jiang Haiyan summarized Western studies on the equity of national public services into three stages (Jiang et al., 2011): "regional equality, spatial fairness, and social equity." Tang Zilai further differentiated between social equity and social justice (Tang and Gu, 2016), noting that the former assumes that the abilities and needs of various social groups are the same, whereas the latter recognizes the differences between groups and advocates for basic public services to be tilted towards specific socially disadvantaged groups.

2.3 Inclusive Sharing of Public Service Facilities

In recent years, the inclusive sharing of public service facilities has become a hot topic of research, encompassing aspects such as public spaces, public service facilities, and street designs. In the realm of community gov-

ernance, "inclusiveness" is increasingly regarded as one of the standards for assessing whether a community achieves good governance (Han and Ren, 2025). In terms of spatial inclusiveness, diverse spatial designs are essential components of resilient community planning, requiring consideration of the needs of various groups and the establishment of multifunctional activity areas (Du et al., 2025).

Research on the social attributes of community public spaces primarily focuses on the "humanistic" qualities of these spaces, paying attention to residents' individualized needs and embodying the community's humanistic care. Li Xinyang and others have proposed construction strategies for suitable public spaces from the perspective of combining the needs of the elderly and children(Li et al., 2015). From the angle of humanistic care, several scholars have noted the shared needs of different age groups within the community and have proposed design strategies for neighbourhood activity centres (Zhang et al., 2021), community centres (Ma & Zhang, 2022), and shared public facilities (Wu, 2023) based on the physical and mental needs and behavioural characteristics of the elderly and children.

Concerning shared streets, both domestic and international research has conducted extensive theoretical exploration and practical implementation. Current studies focus on functionality and integration, but there is a lack of flexible time-guiding strategies and concrete feedback on implementation.

2.4 Participatory Action Research

Sun Shiwen and Yin Yue (2004) trace public participation in urban planning back to the 1947 UK Town and Country Planning Act, which mandated that planning should grant the public the right to express their opinions (Sun and Yin, 2004). Zhang Fan, Li Xun, and other scholars (2022) note that participatory planning gained significant development abroad with the revival of liberal ideas and the emergence of civil rights movements in the 1960s. Taiwan began exploring "community building" early on, while mainland China initiated research on participatory community planning in the 1980s (Zhang and Li, 2022).

Participatory Action Research (PAR) is a community-centered research method that emphasizes democratic participation and co-creation of knowledge. Its core concept is "democratization of knowledge production," meaning that residents shift from being traditional research subjects to co-researchers, directly participating in diagnosing issues, designing solutions, and implementing plans, thus promoting social change and restructuring power relations. This research method not only focuses on knowledge acquisition but also emphasizes achieving social equity and justice through participation and action (Chen, 2023).

In terms of community participation, PAR stresses the active involvement of community members, especially in the stages of problem identification, solution formulation, and implementation (Astoriga-Lineros et al., 2023). Comparatively, community members tend to rely on experts' knowledge and participate less in the research process, which may affect the flexibility and effectiveness of the study (Graef and Sieber, 2018). To ensure effective communication in participatory research, researchers and participants should establish open and transparent communication channels to guarantee two-way information flow (Rosenthal and Khalil, 2010). Through continuous adjustments and adaptations during the research process, participants can play an active role in decision-making.Regarding the methods, processes, and models of participatory community planning, some studies have sought technical solutions to enhance public engagement. New technologies(Maffei et al., 2016; Saija L et al.,2017), such as image recognition and virtual reality, can lower participation barriers and invigorate public involvement. Additionally, creating different public participation scenarios, such as gardening or street experiences, can improve the public's participatory experience (Cilliers & Timmermans, 2014). Many scholars, based on planning practice experiences from various regions, analyse the participation process and summarize public participation pathways and participatory community planning models suitable for China's socio-economic development context (Liu et al., 2017; Liu et al., 2019).

Participatory community planning impacts the social space of communities. With the transformation and development of urban and rural areas in China and the awakening of public participation awareness, participatory

community planning is regarded as a process for addressing social issues in urban and rural regions and producing social space (Liu and Deng, 2016).

3.Research Methods and Case Studies

This study adopts a predominantly qualitative research approach through a mixed-methods framework, including local workshops and in-depth interviews. Stakeholders such as community residents and current students are treated as equal research partners. This approach is necessitated by the fact that the research area has a significant elderly population, and big data cannot objectively capture data on this demographic. Additionally, many existing studies on equity and inclusion rely heavily on quantitative data, which fails to uncover the genuine needs of residents in depth.

The theoretical foundation of Participatory Action Research (PAR) encompasses democracy, equality, liberation, and empowerment. It emphasizes an egalitarian relationship between researchers and participants, opposing the asymmetry found in traditional subject-object relationships. The methodology of PAR focuses on participation, collaboration, reflection, and action, employing various methods such as discussions, interviews, and observations to facilitate knowledge co-creation and action implementation. To ensure the scientific integrity of the research, this participatory planning includes four processes: identifying issues, understanding needs and strengths; proposing action plans and soliciting residents' opinions; reflecting on actions taken after multiple rounds of workshops to improve subsequent actions; and striving to ensure the interests of a broader range of groups.

3.1 Case Study

This case study focuses on the Wujiaochang Sub-district, located in the Yangpu District of Shanghai. It is situated in the core area of the Jiangwan-Wujiaochang urban sub-centre and covers an area of approximately 7.66 square kilometres, consisting of 32 subdistrict offices (with each subdistrict office managing a community). According to the data from the seventh national census conducted in 2020, the total resident population of the Wujiaochang Sub-district is 145,000, with a registered population of 119,200 and a permanent registered population of 98,500, resulting in a population density of nearly 20,000 people per square kilometre. The population aged 60 and above in Wujiaochang Sub-district is 36,080, accounting for 25% of the total population; the population aged 65 and above is 25,276, making up 17.5%. Considering that internationally a population proportion of 10% aged 60 and above or 7% aged 65 and above is often used as a criterion for a country or region to enter an aging society, the aging problem in Wujiaochang Sub-district is relatively pronounced.

In 2023, Shanghai initiated the construction of a 15-minute community living circle, planning for Wujiaochang Sub-district to be divided into four 15-minute living circles, with each circle serving a population of approximately 36,000 over an area of about 1.9 square kilometres. With the support of the "community planner" system, the research team can continuously follow up on community renewal efforts in Wujiaochang Sub-district, obtaining precise spatial data such as population data, facility POIs (points of interest), and road network data, which meet the analytical precision requirements. Furthermore, with the support of government street staff and community workers, the team conducted interviews and surveys via four participatory workshops to gather the genuine needs of the community, striving to fully incorporate the demands and opinions of diverse groups in response to the challenges of spatial equity and facility adaptability. During the research process, the workshops were divided into three stages: issue diagnosis, flexible co-creation, and consensus decision-making, focusing on in-depth discussions regarding the misalignment in facility supply and insufficient spatial flexibility.

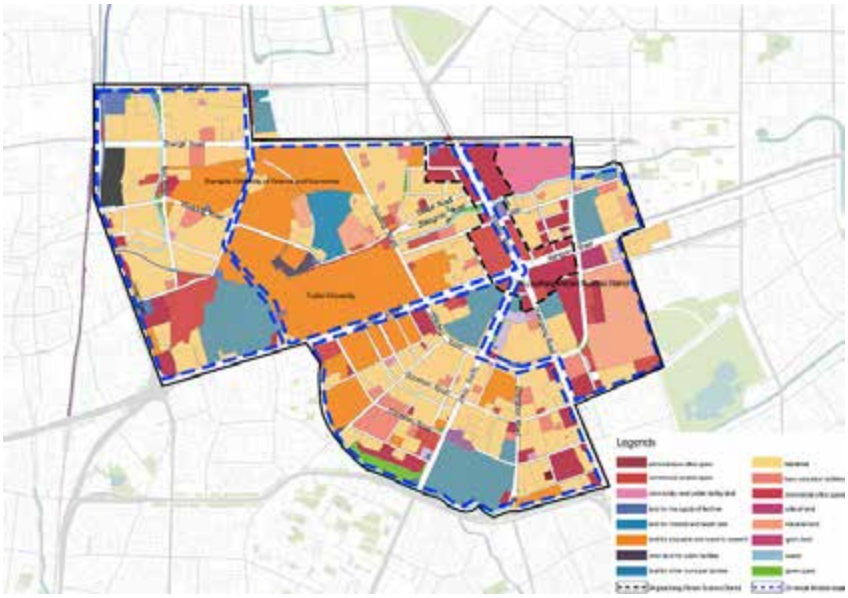

Figure 1. Existing Land-use and Planned four life-Circles in the area of Wujiaochang sub-district

3.2 Research Design

In the preliminary stage of the research, the research team organized survey groups, consisting of students with backgrounds in urban planning, who possess a certain level of professionalism and judgment. At the start of the study, four workshop locations were determined. The research group focused on identifying the fundamental issues related to facility usage in the area while promoting the construction of the "15-Minute Community Living Circle." Concurrently, geographic analysis of facility locations was conducted, later shifting focus to the issues of misalignment in facilities and their flexible use. With the assistance of the local government, we conducted random street interviews and surveys within the subdistrict, aiming to engage a diverse range of groups. This direct communication method facilitated timely feedback on needs from stakeholders and their participation in the planning and design process.

3.2.1 Preliminary Discussions and Collection of Resident Opinions

The research team held preliminary discussions and gathered opinions in a small meeting room on the second floor of the Jingshi Bookstore, involving representatives from various grassroots government departments, the Fudan Community, the Urban Investment Company, and resident representatives. Representatives from the Wujiaochang subdistrict briefly presented the development history, planning policies, and current status of the subdistrict. The Urban Investment Company shared some of the ongoing planning content, while the community committee leadership introduced the goals and vision expected to be achieved during this renewal period, along with key design points and areas that need to be updated and renovated. The research team provided a brief report to the subdistrict office leaders on the preliminary preparations, the nature of the bottom-up participatory planning design, work timelines, and workshop methodologies, achieving a general consensus among participants. After the initial discussions, under the guidance of the community committee leadership, the design team conducted a site survey to gain a preliminary understanding of the site's boundaries, the current situation of important update points, traffic conditions, population dynamics, and usage needs.

3.2.2 Preliminary Analysis of Facility Locations and Population Data

The research team obtained multiple pieces of information regarding the locations of public service facilities and the seventh national census data in Wujiaochang Subdistrict. A simple analysis and processing of the base map was performed, and road network data was collected and processed to generate a network dataset, forming the basis for network analysis. The handling of population data involved entering the population data into the attribute table according to the jurisdiction of the community committees. Then, the data was visually represent-

ed on the map using a point density symbol system, where red represents the population aged 0-19, blue represents the population aged 60 and above, and orange-red represents the population aged 75 and above. Each point in the data represents 10 individuals, resulting in a population data base map. Building on this, an analysis of facility coverage was conducted using analytical tools for network analysis and service area analysis, setting interruption values for service radii of 300, 500, and 800 meters.

3.2.3 Multi-Round Scheme Design and Communication

Based on the feedback and data collected from two rounds of workshops, design strategies for the corresponding facilities were proposed. Additional workshops were held within Wujiaochang Subdistrict to continue gathering feedback from residents.

3.3 Data Analysis and Research Findings

3.3.1 Phase One: Collaborative Problem Diagnosis—Identification of Facility Supply Misalignment and Equity Challenges

In the first community workshop, the research team organized residents to draw daily activity trajectory maps based on spatiotemporal behaviour analysis from time geography. This helped collect information on residents' activity areas and assess the coverage of existing facilities. The results indicated a misalignment between facility supply and actual demand.

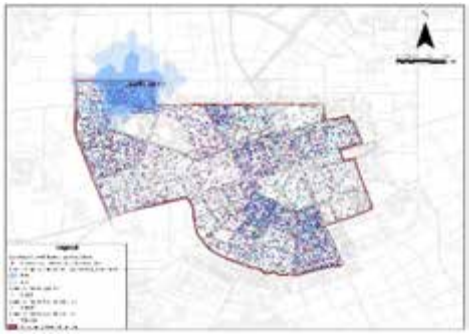

Figure 2: Coverage Map of Nursing Homes at the Township Level Within 500 and 800 Meters

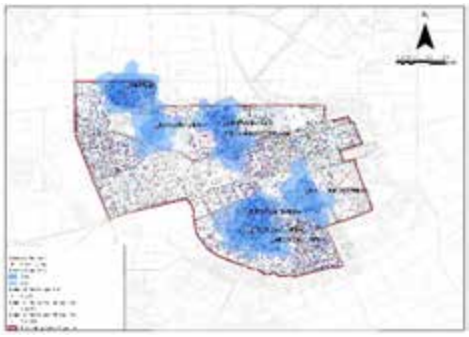

Figure 3: Service Radius of Community-Level Elderly Care Stations in Wujiaochang Subdistrict at 300 and 500 Meters

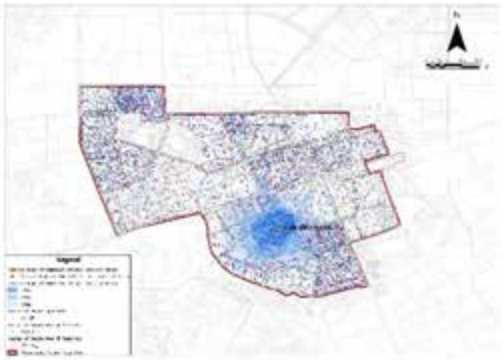

Figure 4: Community Cultural Activity Center in Wujiaochang Subdistrict.

There is a nursing home facility in the Wujiaochang Subdistrict (Figure 2). Considering the road network, a coverage analysis of 500 meters and 800 meters was conducted, revealing that its coverage is severely inadequate. Notably, the elderly population in the southeast direction of this subdistrict is significantly higher, yet there are no corresponding facilities available in that area.

In Wujiaochang Sub-district, there are eight community-level elderly care stations (Figure 3). After conducting a coverage analysis of each facility point within 300 meters and 500 meters, it was found that their coverage is also severely lacking. Furthermore, in the southeast and northwest directions of Wujiaochang Sub-district, the proportion of the elderly population is relatively high, but these areas lack community and elderly care stations. The subdistrict also has a community cultural activity centre (Figure 4), which, after analysis of its 300-meter, 500-meter, and 800-meter coverage, also showed severely insufficient coverage.

In addition to the inadequacies in elderly facility coverage and misalignment identified through geographical data analysis, the feedback from residents during street interviews mainly included the following points:

The elderly population faces limitations due to physical function, making it difficult for them to conveniently utilize the nominally "15-minute" green spaces and activity areas. Some public facilities, such as a nearby convenience restaurant, have high prices and do not cater to the taste preferences of older adults, causing elderly residents to seek alternative dining options that are farther away. Although the construction of the "15-Minute Community Living Circle" emphasizes walkability as an evaluation criterion, in practice, the age-friendly design and economic viability of facilities still require further optimization. Some elderly residents reported the complete absence of elevator services, a lack of accessibility features on the road, and difficulties in descending stairs due to the absence of elevators in residential buildings.

Figure 5: Photos from the Workshop and Feedback Collection

3.2.2 Stage Two: Co-creation Design - Adaptation and Expansion of Flexible Space Utilization

This stage clarified the equity shortcomings in the misalignment between facilities and population demands, highlighting the need for optimization in the refinement and adaptability of the "15-Minute Community Living Circle" concept in practice. The research methodology at this stage drew on the model of "co-creation workshops," utilizing public participation to identify local development needs and organizing community planning around these issues to facilitate connections and consensus among various social stakeholders.

In the participatory design workshop of the second stage, the planning team introduced blank base maps for residents to document their spatial and temporal trajectories throughout the day (Figures 6 and 7). Residents were guided to describe their ideal design proposals, which the designers then illustrated, received feedback on, revised, and presented again. During the co-creation process, residents and planners engaged in discussions around the flexible use of space concerning functional co-location and time-sharing. The core issues and explorations included:

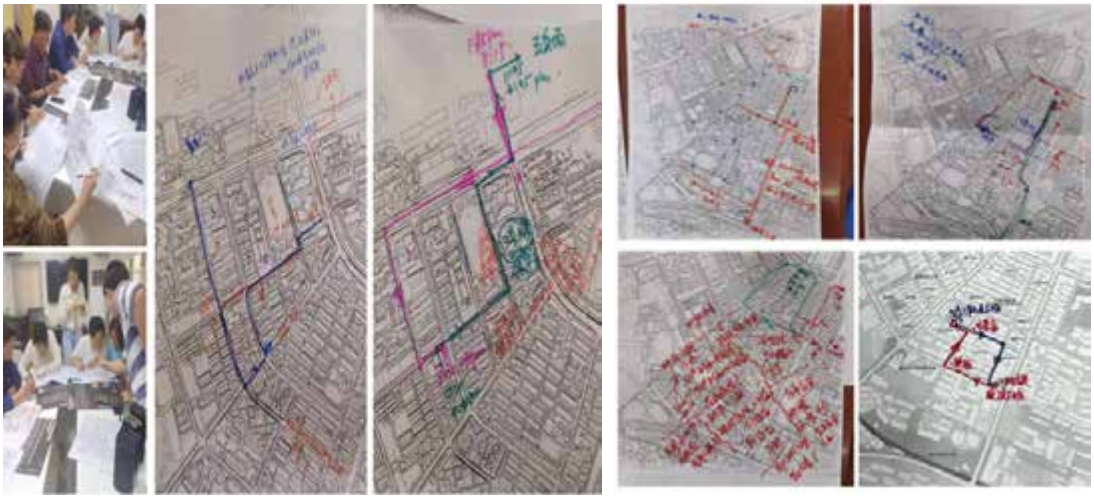

Figure 6: Residents record their travel times and locations for a day on a blank map.

Lack of Functional Complexity: Existing public spaces are mostly single-functional and cannot flexibly transform to meet the diverse needs of the elderly for daytime socialization, or the youth for nighttime cultural and creative activities or café gatherings. This indicates that the multifunctionality of community spaces is key to achieving "flexible utilization." Research shows that the multifunctionality of community spaces can not only enhance space usage efficiency but also strengthen residents' sense of belonging and participation.

Insufficient Time-sharing: Residents have proposed initiatives such as a trial nighttime pedestrian street in the Zhengsu Road area and the concept of shared streets. However, current facilities and management still lack mechanisms for flexible adjustment and guidance, failing to achieve efficient switching of crowds and time periods. This suggests that the time-sharing mechanism of community spaces is an important guarantee for achieving "flexible utilization." Research indicates that the establishment of a time-sharing mechanism relies on flexible management strategies and active participation from residents.

Space Adaptability for Vulnerable Groups: Insufficient flexible utilization results in high usage thresholds for elderly people, children, and individuals with disabilities, especially during peak traffic periods and in terms of social activity demands. This indicates that the adaptability of community spaces is a core element in achieving "flexible utilization." The adaptability of community spaces needs to consider not only the physical accessibility of the space but also the inclusivity of the social space.

During this stage, multiple rounds of simulations emphasized the necessity of multifunctional complexity and

staggered usage to enhance space equity and sharing. Additionally, it accumulated rich data on residents' preferences and usage scenarios. The research methods in this stage borrowed from the theoretical basis of "participatory design," emphasizing the integration of residents' subjective experiences and needs into the design process, thus achieving a "people-centred" community regeneration.

3.2.3 Phase Three: Consensus Decision-Making — Responding to Diverse Needs, Balancing Flexibility and Safety
In the consensus negotiation meeting of the third phase, the research team established a veto power for vulnerable groups based on the theory of deliberative democracy, along with a voting weight of 70% for residents and 30% for experts, to promote equal dialogue among multiple stakeholders. The meeting focused on the following key issues:

1. Facility Function Differentiation and Reconfiguration: How to promote the adaptation of old residential buildings for the elderly (such as installing elevators), enhance the flexibility of indoor activity spaces, and regenerate outdoor activity nodes within the existing building stock.

2. Equity Assurance: Representatives of vulnerable groups, such as the elderly and people with disabilities, explicitly expressed their core concerns about facility accessibility and economic feasibility, ensuring that the renewal plan is optimized for both physical and social equity. The equity of community spaces is a core element in achieving "flexible utilization," requiring consideration not only of the physical accessibility of spaces but also of the inclusivity of social spaces.

Through recordings and notes, the research team further explored the distribution of opinions and value trade-offs among residents during the negotiation process, enriching the diverse perspectives of spatial governance. The research methods in this phase drew from the theoretical foundation of "deliberative democracy," emphasizing the integration of residents' subjective experiences and needs into the decision-making process, thereby achieving a "people-centred" community renewal. Additionally, this phase reflects the application of the concept of "dual rationality," balancing between instrumental rationality (program design) and communicative rationality (consensus negotiation) (Li Qing and Lin, 2023).

4.Findings and Improvement Measures
In the third phase of the participatory planning work at Wujiaochang Sub-district, this article summarizes three core issues closely related to "misalignment of facilities" and "insufficient flexible use of space," based on residents' demands, current situation surveys, and on-site discussions. Additionally, corresponding improvement measures were developed based on the co-creation process.

4.1 Main Research Findings
1. Misalignment between Facility Supply and Diverse Needs
The research found that despite the nominally reasonable layout of public service facilities within the community according to the "15-minute living circle" standard, there are significant gaps in accessibility and economic adaptability for the elderly, children, and other vulnerable groups. For example, elderly residents generally report that community canteen prices are high and the food does not suit their tastes, making it difficult to meet their daily dining needs. In areas with a high proportion of elderly population, there is a lack of elderly care facilities. Although the community activity center has a certain level of coverage, the activities offered have some barriers to entry, which creates an invisible exclusion for many elderly individuals who do not possess special talents. Meanwhile, young people and working professionals report a lack of diverse commercial facilities and flexible social spaces.
2. Insufficient Flexibility in Space Function and Time Utilization
Regarding flexible usage, there are two aspects of flexibility needs: spatial flexibility and temporal flexibility. In the various workshop stages, residents generally expressed that the community space lacks flexibility and cannot meet the diverse needs of different groups at different times. For an idle space within the street, many elderly residents pointed out a desire for someone to organize and make use of it, as the street lacks multifunc-

tional spaces that can simultaneously accommodate daytime gatherings for the elderly and nighttime social activities for youth. The outdoor activity spaces primarily consist of single green areas or scattered seating, lacking diverse scene combinations.

Some community service facilities, such as canteens and activity centres, are only open during limited hours. Residents tend to leave quickly after eating and, on occasions when they want to gather with friends for tea, they struggle to find suitable indoor spaces, thus leading to the neglect of their off-peak usage needs in real life.

4.2 Improvement Measures

Based on the needs of community residents and feedback from participatory workshops, the research proposes targeted and actionable spatial improvement measures aimed at addressing the misalignment of facilities and the lack of flexible space utilization. The goal is to enhance the "15-minute community living circle" to better respond to the equitable needs of diverse populations. The specific measures include the following two main strategies:

1. Strategy 1: Activating Inefficient Spaces

In light of the current situation where some facilities are idle or underutilized, community renewal should start by "reactivating spatial potential." This can be achieved through various methods to enable flexible and efficient space reuse. For instance, after the renovation of Guoding Road, four small micro-spaces of around ten square meters each were created. These spaces incorporate functions such as elderly services, party and community activity rooms, and reading rooms, which not only meet the diverse needs of residents but also enhance the overall appearance of the space through function implantation.

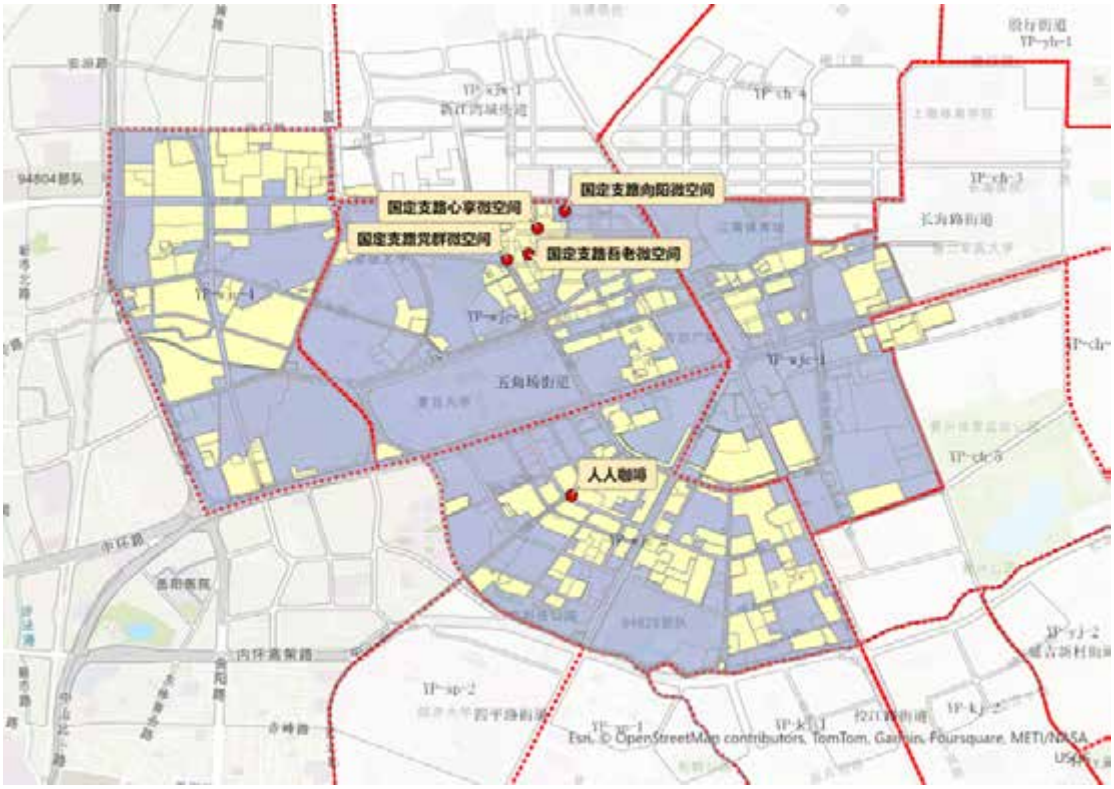

Figure 7. Distribution Map of "Six Arts Pavilion" in Wujiaochang Sub-district

Dynamic Demand Response System: A dynamic questionnaire link is established and distributed to residents through the neighbourhood committee to collect real-time usage preferences and feedback, enabling dynamic adjustments of space utilization.

"Parasitic Renewal" Model: New functional modules are "embedded" within existing redundant facilities to enrich the service levels and adaptability of the facilities. To address the current issue of high accessibility thresholds in community activity centres, children's reading corners or elderly leisure corners are added to the community library, enhancing the diversity and multifunctionality of public spaces.

2. Strategy 2: Designing Elastic Spaces
The elastic use of space is regarded as an important means to alleviate the contradictions between facility supply and demand, as well as to enhance equity. This study explores the following two levels of elasticity strategies in practice:

In terms of functional elasticity: 1) Modular facility configuration—drawing on cases such as Shanghai's "People's Square" and "Liuyi Pavilion," we promote the integration of multifunctional settings and the transformation and utilization of micro-spaces for diverse functional implantation; 2) Shared space agreements: Encourage enterprises, schools, and other institutions to sign facility-sharing contracts with the community, promoting practices such as opening school gymnasiums to residents at night, thereby enriching community activity scenarios.

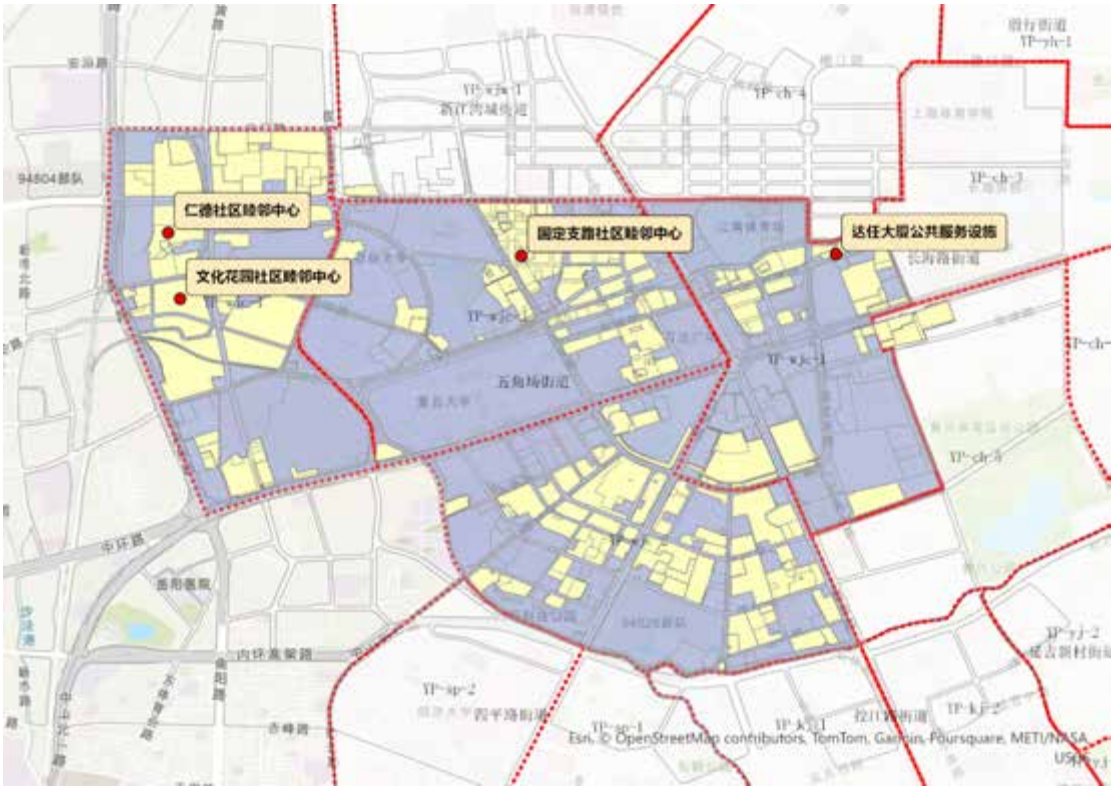

Figure 8: Distribution Map of "People's Square" in Wujiaochang Sub-district.

In terms of temporal elasticity: 1) Staggered usage system—based on the daily rhythms of residents, prioritize usage time slots according to different groups (e.g., elderly people prioritized from 7-9 AM, working individuals from 6-8 PM) to maximize space utilization efficiency. 2) Digital management platform: Establish a community digital reservation platform to display the real-time status of facility usage, support online reservations, and facilitate crowd management to achieve staggered facility usage and equitable distribution. 3) From the perspective of community governance, promote a "time-sharing" management model (such as timed pedestrian streets and nighttime community shared spaces) to maximize the efficiency and equity of limited space usage.

5. Discussion

This study deepens the academic understanding of how the "15-minute community life circle" transforms from physical supply to social inclusivity, highlighting the key roles of precise facility supply and flexible spatial sharing in achieving spatial equity.

5.1 From "Nominal Accessibility" to "Substantial Accessibility"

The "15-minute life circle," as a macro indicator, can only shift from "nominal accessibility" to "substantial accessibility" when it genuinely responds to the daily mobility capacities and temporal rhythms of different groups (such as the elderly, teenagers, and caregivers of children). The micro-renewal process within the community shows that disparities in accessibility due to factors like age, physical ability, and income directly limit fair distribution of services, necessitating more detailed data on population needs and adaptive modifications for contextual fit.

5.2 Flexible Utilization is Key to Bridging Service Gaps

The multi-round co-creation workshops in this study indicate that the functional complexity of spaces and staggered time sharing provide effective pathways to reconcile the shortage of spatial resources with the diverse needs of society. This aligns with international experiences such as Japan's "shared streets" and Singapore's community centers with time-sharing, where "flexibility" plays a role not only in the adjustment of physical spaces but also as a part of multi-stakeholder collaborative governance models.

5.3 Implications for Policy and Practice

This study suggests that to achieve the vision of a "15-minute community life circle," it is necessary to prioritize both physical renewal and social governance, concurrently advancing spatial flexible transformations and diverse resident consultations. Efforts should span multiple scales from micro (neighbourhood and building levels) to macro (street and regional levels), dynamically responding to resident needs. Additionally, establishing a regular participatory governance mechanism can encourage residents to maintain long-term attention and involvement, forming a sustainable model of community co-construction and sharing.

6. Conclusion

Globally, the "15-minute community life circle" has become an important pathway for high-quality urban development and a human-centred transformation. This paper takes Wujiaochang Sub-district in Yangpu District, Shanghai, as a case study, combining a year-long field research and participatory workshops to focus on issues such as misalignment in facility supply and insufficient flexible utilization of space. It systematically summarizes the multidimensional challenges and potential improvement pathways encountered in actual updates. The research highlights several key points worth noting:

1. The issues of facility misalignment and spatial flexibility are core challenges to community equity. Small sample sizes and detailed interviews are necessary supports for big data analysis. Although the concept of the "15-minute life circle" emphasizes balanced distribution of basic service supply, significant disparities exist at the micro practice level regarding residents' daily time arrangements, mobility abilities, and economic conditions, leading to a gap between nominal and actual accessibility.

2. Flexible spatial utilization and time-sharing are effective ways to resolve resource conflicts. Practical experience shows that flexible spatial conversion and time-sharing arrangements not only enhance the usage efficiency of existing facilities but also effectively alleviate usage conflicts among different groups.

3. Participatory governance and equity mechanisms are core guarantees for promoting community renewal. By introducing a three-phase workshop model of "co-creation, co-measurement, and co-decision-making," along with governance innovations such as granting veto power to marginalized groups, the practice enables deep participation of residents in spatial transformations and ensures equity. It also highlights the complex trade-offs in community governance between safety, vitality, and equity.

However, the study still has limitations. Due to the long construction period, the proposed solutions could not be promptly implemented, and management measures were not timely executed or feedback obtained. A long-term dynamic monitoring system still needs to be established. Additionally, this research only analysed a few communities in Wujiaochang Sub-district, and the survey work did not unfold comprehensively, necessitating more in-depth research in the future.

Abstract
Unjust practices have shaped the built environment, involving land dispossession, exclusionary planning and development, exploitative labor practices, and environmentally harmful material building cycles. These practices have (re)produced material and spatial inequities. Embodying Justice in the Built Environment is a framework to answer the question: How can planners, government agencies, and communities meaningfully centre justice and equity in working towards carbon neutrality and reducing embodied carbon? Developed through collaborative and case study methods, this research produced a series of guides and workbooks to support local governments and community organizations in addressing 1) Circularity and Waste and 2) Just and Equitable Land Use Transitions. Though rooted in North American cases, the framework offers insights for educators, policy-makers, and planners in other contexts.

Keywords: Embodied carbon, carbon neutrality, circularity, planning practice, justice, land use, waste

Introduction: Embodying Justice in Building Carbon-Neutral Futures

In recent years, national and local governments, along with nongovernmental organizations (NGOs), have increasingly focused on decarbonisation—particularly on reducing greenhouse gas (GHG) emissions from buildings and urban development. In Europe, and to a growing extent in North America, efforts have shifted toward addressing embodied carbon: the GHG emissions associated with a building's entire life cycle, including material extraction, manufacturing, transportation, construction, maintenance, and end-of-life processes. While policies targeting embodied carbon are gaining momentum as part of broader climate action, they often overlook the social, spatial, and material legacies that shape, enable, or constrain these transitions. The built environment is a system of emissions and infrastructures, and a reflection of deep-seated and layered injustices. Historical and ongoing practices—such as land dispossession, exclusionary zoning, the use of toxic materials, and demolition-driven redevelopment—continue to determine who has access to land, resources, and decision-making power (Corner, 1999; Escobar, 2018). In addition, injustices in land use have been compounded with historical and contemporary housing and transportation policies that have severely impacted racialized and minoritized communities in North America (Bullard, Johnson and Torres, 2004; Desmond and Bell, 2015; Caverly, 2022; Bronin, 2024; Millard-Ball et al., 2024). As the push for carbon neutrality accelerates, the question is not just how to reduce emissions, but how to do so justly.

This paper introduces the Embodying Justice framework—a collaborative initiative involving researchers, local authorities, and community partners that seeks to centre justice and equity in decarbonisation strategies. Developed through applied research, the framework sets out guiding principles, domains of justice, and reflective questions with corresponding actions to support planners, policymakers, and scholars working at the intersection of climate and equity. From the Embodying Justice framework two interconnected research projects have

been produced: one focused on circularity, waste, and building and building material reuse; the other on land use transitions. Despite their differing areas of emphasis, both raise a shared concern: that without deliberate attention to social context and historical harm, low-carbon transitions risk reinforcing patterns of exclusion and inequality. A key insight from this work is that embodying justice demands a move beyond technocratic metrics and calculative logics that solely tend to the reduction of carbon. This framework calls for approaches grounded in social and material systems of repair—anchored in inclusive, reparative, and community-led planning.

The two Embodying Justice in the Built Environment resources were developed within a North American context, in collaboration with the international NGO the Carbon Neutral Cities Alliance (CNCA) and local officials from cities in the United States and Canada. Grounded in participatory research with community leaders across New York State, this work was carried out in partnership with the Circularity, Reuse, and Zero Waste Development (CROWD) network. The resulting outputs comprise two guides, each accompanied by workbooks, designed to support communities in reflecting on and implementing justice-centred planning practices (see, for example, Minner et al., 2024).In the context of a climate emergency—and amid a political environment in the United States increasingly hostile to both climate action and diversity, equity, and inclusion—this work offers practical tools for local authorities pursuing just transitions towards circular economies and equitable land use.

This paper offers an overview of how these resources were developed, outlines key justice considerations embedded in the Embodying Justice framework, and shares insights from their development. The following section introduces foundational and emerging literature related to embodied carbon emissions and intersections with structural injustices. Next, we describe the research methods used. We then present the Embodying Justice framework, identifying its core areas of intervention and practical resources it offers for planners, scholars, and communities. We discuss the format of the guides and workbooks and how they are intended to be used. In the discussion, we note that although grounded in North American case studies, the framework is intended to be adaptable to other contexts. This paper concludes with We conclude with how these resources aimed to offering scaffolds for addressing injustices in the built environment. Through their use, it is hoped that government agencies can realize means of situated, collaborative, and accountable action that pairs the reduction of carbon emissions with the systematic dismantling of injustices.

Embodied Carbon Emissions and Structural Injustices

European cities have emerged as leaders in advancing circular and sustainable economies, implementing material reuse strategies and designing for disassembly (see, for example, Heisel et al., 2022; Vullings et al., 2024; Williams, 2021). Many have also adopted embodied carbon policies to reduce emissions embedded in building materials and processes. By contrast, progress in North America has been more fragmented. Only a few municipal and county governments in Canada and the United States have adopted regulations to address embodied carbon (CROWD, 2023; Winters, 2025).

Efforts to integrate justice and equity into urban policy are evident in both European and North American contexts. For example, the World Green Building Council (WGBC) has proposed a framework for addressing the social aspects of sustainability, noting: "The impacts of the built environment as an industry... go far beyond the users of individual assets—the sector impacts upon human rights at every stage of the building and construction life cycle" (World Green Building Council, 2023, p. 3). The WGBC proposes a broad framework in four scopes to "consider workers, occupants, users and entire communities" (ibid.) within the building industry, with building users and the site of construction, within surrounding communities, and throughout supply and value chains.

Recent efforts by professional organisations have also helped to clarify how planning and design practices are implicated in historical and ongoing harm. The American Planning Association Equity in Zoning Policy Guide underscores that zoning is a tool shaped by racialised exclusion, displacement, and uneven development. The guide identifies zoning as a contributor to land use and environmental injustice while calling for reparative approaches that centre procedural inclusion, redistribution of benefits and burdens, and address legacies of harm through policy reform and accountability (APA, 2024, pp. 10-12).

Parallel contributions from the American Institute of Architects (AIA) emphasise that justice must be embedded throughout the life cycle of the built environment, from the extraction of materials to labour conditions, construction decisions, and long-term stewardship. In its "Justice in the Built Environment" supplement, the AIA frames equity as a relational and process-oriented commitment. The guide asks questions such as: "Are we making a discernible difference in the particular population it's designed for? "What does it look like when we center justice?" and "Is it possible to envision a system without dominance, where there is space for everyone to thrive equally?" (AIA, 2021).

Together, these resources produced by professional organizations sit at the forefront of planning and architectural practice in the US, reinforcing shared recognition that equity and justice are an ethical imperative, and that the design professions must address the injustices both past and present. These resources acknowledge that a justice-oriented planning and design must address the material and spatial processes they guide, both in terms of their process and outcomes, working toward both practices of collaboration and structures redress.
These are important directions for planning, design, and allied professions. However, there remains a notable gap in the literature addressing embodied carbon reduction and structural injustice. As noted, embodied carbon refers to the greenhouse gas emissions associated with a building's entire lifecycle—from material extraction and processing through to construction, maintenance, and eventual demolition (NYCEDC Circular Construction Guidelines, 2024). Embodied carbon emissions are not incidental; they often represent a substantial proportion of a building's total climate impact (Huang, 2018; Liboiron, 2021). Nor are they produced by neutral systems. They are reflect "embedded injustices" —a built environment that is a produced from "[land] dispossession, denial of land rights, discriminatory land use, zoning, and urban renewal policies, as well as harmful material extraction and toxic production processes, wasteful construction and consumption practices" (Minner et al., 2024, pp. 2; Taylor, 2014). The same systems that generate embodied emissions also shape access to land, housing, health, and generational wealth into the future. Globally, material supply chains—spanning cement, timber, and increasingly, renewable energy components like solar panels and batteries—have relied on forced labour, toxic exposures, and unsustainable extraction practices (Grace Farms Foundation, 2022). Such burdens disproportionately affect communities of colour and low-income populations around the world. In the US and Canada, zoning ordinances and urban renewal programmes have contributed to racialised displacement, while redlining, land transfers, and highway construction have historically dismantled neighbourhoods of colour (Hirt, 2014; Poe et al., 2025; Silver 1997). These injustices are not confined to the past; they are reproduced today through cycles of demolition and development. Moreover, carbon reduction policies that ignore local context may intensify inequality, accelerating gentrification, displacing vulnerable populations, and favouring high-tech solutions over community-led ones (Liboiron, 2021, p. 115).

The cumulative nature of harm—across zoning, building, maintenance, and demolition—necessitates a systemic and situated response. Amid developments in embodied carbon policies and growing inequalities, justice should be understood as foundational and place-based, not an optional add-on to climate mitigation strategies. The Embodying Justice guides rest on this principle. Informed by community partners, local government leaders, and practitioners, they assert that climate action must begin with a clear understanding of the historical, material, and policy conditions that shape both emissions and equity. Embodied carbon is both a technical issue and a repository of priorities, exclusions, and decisions that accumulate across time and space. A just response demands an equally expansive framework. The Embodying Justice framework was produced as an aid for recognising, redressing, and transforming these embedded harms through climate action.

Methods: Developing the Embodying Justice Framework
The Embodying Justice framework was developed through a multi-phase, collaborative process involving university researchers, municipal staff, and community partners across the United States. Led by teams from Cornell University and the University of Washington, the project began with a systematic review of policy frameworks promoted by the Carbon Neutral Cities Alliance (CNCA), with a focus on reducing embodied carbon through circularity, waste management, and land use regulation (Carbon Neutral Cities Alliance and One Click LCA, 2020). The research analysed building life cycles and governance systems related to land, care, and transition, conducting

interviews with local governments and community organisations to build context-specific case studies.

The team first assessed documents, guidance, and case studies concerning embodied carbon, deconstruction, reuse, zoning, and climate planning—reviewing carbon accounting tools and local planning documents with an eye toward both policy design and implementation challenges. Subsequently, we focused on producing practice stories grounded in North American cities (USA and Canada) to understand how justice was or was not emerging in their climate work, and to identify areas for further development. Interviews for Phase I on Circularity and Waste were conducted with contacts at local governments and community organizations at the City of San Antonio Office of Historic Preservation (Texas, USA); The Esperanza Peace and Justice Center (a community-based organization, Texas, USA); Re:Purpose Savannah (Georgia, USA); Bureau of Development Services (Oregon, USA); Austin Office of Historic Preservation (Texas, USA); BLOCK Architects and Facing Homelessness (Washington, USA); Black Women Build-Baltimore (Maryland, USA); Better Futures Minnesota (Minnesota, USA); and Green Step Cities Program (Minnesota, USA).

In Phase II on Just Land Use Transitions, interviews are being conducted with contacts associated with the City of Vancouver, B.C., Rondo Community Land Trust, Beacon Hill Food Forest Non-Profit, and Detroit Planning and Development. The final list of interviews for the second phase will be available at a later date, when the Phase II guide and workbook have been finalised.

In addition, the research team has met with another research team in Barcelona, Spain, led by Isabelle Anguelovski. Additional informal interviews with researchers at Tampere, Finland, related to circularity in the built environment have also informed this paper.

Embodying Justice Framework Structure and Principles

Through this research, two final guides were produced: 1) circularity and waste management, and 2) land use policies and zoning regulations (Carbon Neutral Cities Alliance and One Click LCA, 2020). Each guide outlines key justice principles, a workbook for reflection and implementation, and locally grounded practice stories drawn from interviews, workshops, and city-specific policy review. Together, they were crafted to offer practical tools that reflect shared goals while allowing for contextual adaptation.

Each workbook is grounded in five interrelated justice principles:

Justice is reparative. It concerns itself with making right what has been wronged, reconnecting what has been broken, and balancing the imbalanced.

Justice is fair. It equitably distributes social, cultural, political, economic, and environmental benefits and burdens.

Justice is community-driven. It centres historically oppressed and marginalised communities in a collaborative and inclusive process to move toward just futures.

Justice is placed. It is grounded in the specific community context in which it is invoked, rather than an abstract concept.

Justice is not a singular endpoint. It is a continuing process of reflection, acknowledgment, and action.

The framework is organised around several interrelated dimensions: acknowledging and addressing historical harm, ensuring inclusive and fair decision-making, recognising local knowledge, culture, and spatial histories, and building capacity and accountability in implementation. These categories, referred to as the "J's," guided the selection of questions and structures for the workbooks and reflect an effort to move from principles into applied planning reflections and support. Throughout the process, the research team continually checked in to strike a balance between offering general guidance and reflecting insights specific to real places. Local govern-

ments expressed a need for flexible, adaptable resources rather than prescriptive checklists. This process also showed the importance of starting with shared language before introducing technical tools. This grew into the inclusion of worksheets, reflection prompts, and open-ended guiding questions rather than fixed policy recommendations.

The resulting guides are structured around a shared framework: five justice principles (reparative, fair, community-driven, placed, and ongoing), and justice domains or J's that are described as follows:

J1 Community Impacts
- Map a strategy's impact across communities (people, places, spaces, ecologies), ensuring equitable distribution of benefits, health, and well-being for priority communities.
- Examine how a strategy's design and implementation reflect priority communities' values, needs, and cultures.
- Consider a strategy's potential to redress past and ongoing harm.

J2 Economic Impacts
- Map a strategy's impact on uneven development and local economies, ensuring equitable distribution of benefits for priority communities.
- Examine a strategy's relationship with commercialization, cost, and affordability across communities, identifying opportunities to balance local economies.
- Consider a strategy's potential to develop community-driven approaches for economic growth that aim to redress the impact of extractive development.

J3 Labor and Workforce
- Examine a strategy's impact on workers' health and well-being, ensuring equitable distribution of benefits for priority laborers.
- Identify how a strategy can support balancing opportunities and access to the workforce for priority communities that have been unjustly excluded.
- Consider a strategy's potential to invest in worker agency in ways that lead to a more just workplace and field.

J4 Historical Context
- Examine how legacies of injustice and resistance can influence a strategy's design and implementation in ways that inform a more just approach in the present and future.
- Contextualize the strategy in local histories through an in-depth reflective process that centers priority communities to make right what has been wronged.
- Consider a strategy's potential to be situated in place by uplifting local stories of people, places, and sites historically abandoned or undervalued.

J5 Community Engagement and Involvement
- Examine a strategy's transparency and inclusiveness, ensuring priority communities have equitable access to knowledge, engagement, and opportunities.
- Promote processes that allow a strategy to be co-produced with priority communities through open dialogue.
- Consider a strategy's potential to invest in community-driven approaches that honor community knowledge and values and repair past and ongoing harms.

J6 Transportation Equity and Access
- Examine a strategy's impact on transportation access and mobility, ensuring equitable distribution of benefits and protection from harms.
- Promote in-depth reflective processes for determining how the strategy impacts priority communities'

well-being and access to opportunities.
- Consider a strategy's potential to repair past harms from the planning and provision of transportation facilities and infrastructure.

J7 Housing Security, Equity, and Access
- Examine a strategy's impact on housing security and access, ensuring equitable distribution of benefits and protection from displacement.
- Promote processes that welcome new residents while fostering priority communities' long-term connections to place.
- Consider a strategy's potential to repair past harms from the private and public provision of housing.

The project sought to illustrate the Justice Considerations (Js) through reflective questions and case studies tied to practical interventions. This structure is aimed at supporting cities and organisations in contextualizing justice. The reflective design of the workbooks was informed by an iterative process of dialogue, testing, and revision with municipal and community collaborators. The format is described in the next section.

Applying Justice to Practice: Format of the Workbooks
Both phases of the project have involved creating workbooks to make potentially abstract principles more concrete and actionable for local governments. These workbooks demonstrate how justice-oriented approaches can be applied in practice and are structured around two key components: question sets and practice stories. Question sets were designed to support dialogue—particularly cross-agency conversations and communication between local governments and community organisations—and encourage direct work toward justice with priority communities. The question sets are not intended to be prescriptive tools, but rather as prompts to spark reflection, analysis, and collaborative action. Figure 1 provides an example from Phase 1 of the project, which focused on circularity and waste (discussed in more detail in the following section).

These guiding prompts throughout the workbooks are aimed at helping unpack:

- How does a policy, practice, or program redress past and ongoing harms?
- Who benefits from them, and who is at risk of being excluded?
- How do they address local histories of injustices related to the built environment?

Practice stories offer brief case studies of local governments or community organisations implementing equity or justice-focused strategies that support lower embodied carbon or, more broadly, climate action. These stories, developed through interviews, highlight successful efforts to embed justice into practice. In Phase 2, this format was expanded to include a question-and-response structure. This evolution supports a deeper understanding of each case and encourages readers to reflect on how similar strategies might apply in their own contexts. In a sense, the workbook structure mimics the kind of problem sets that one might encounter in a textbook, but turns them on their head. Instead of practicing route mathematics, users gain practice applying the Js to their local context. Thus, the new format of practice stories in the second workbook, are aimed at creating "story problems," that again, require contextual reasoning.

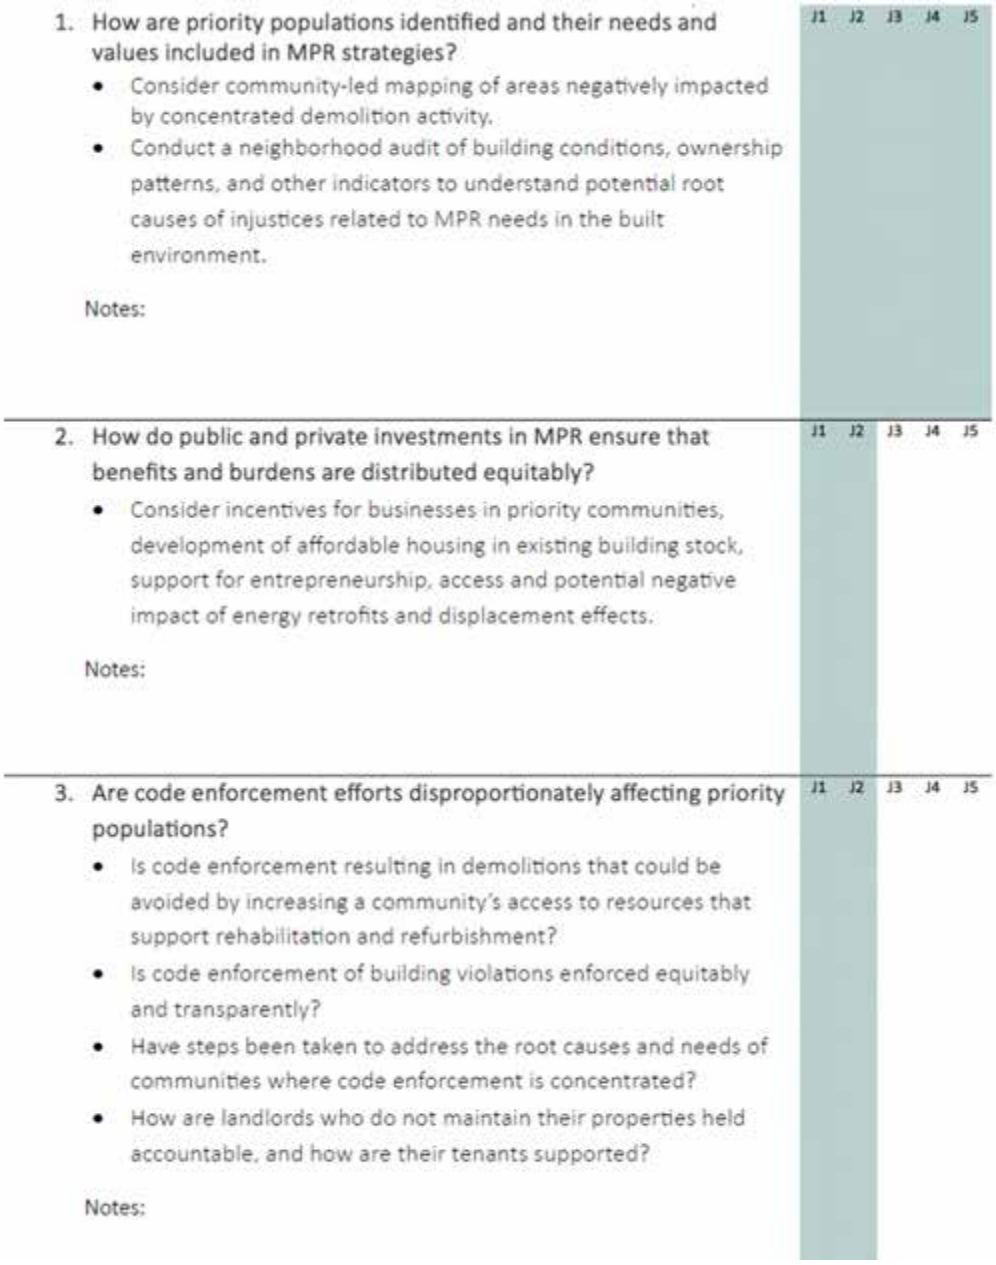

Figure 1 Example workbook page showing question sets for Maintenance, Preservation, and Refurbishment (MRP) strategies.

The development of this framework raised broader questions about the role of researchers in producing justice-oriented planning tools. Rather than positioning expertise as separate from practice, the workbook and practice stories emphasise co-production, long-term partnerships, and iterative feedback. The guides are not final, abstract products but living resources, designed to be adapted in local contexts.

Phase I Guide and Workbook: Circularity and Waste

The first guide and workbook: Embodying Justice in the Built Environment: Circularity in Practice, is structured around three critical phases in the building lifecycle: alternatives to demolition or the end life of built environment, resource management or the redistribution of materials from the end-of-life of buildings whether that is through distribution of reusable materials or status quo practices of landfilling these materials as waste; to

new construction (See figure 2.) (Minner et al., 2024, p. iv). Each phase presents an opportunity to repair harm and reimagine how materials, labour, and place are valued. The workbook offers justice-oriented questions intended to support practitioners in identifying interventions that can shift extractive, exclusionary systems toward more equitable and circular practices. While each city context is distinct, these strategies encourage planning professionals to examine embodied carbon and structural injustice in tandem.

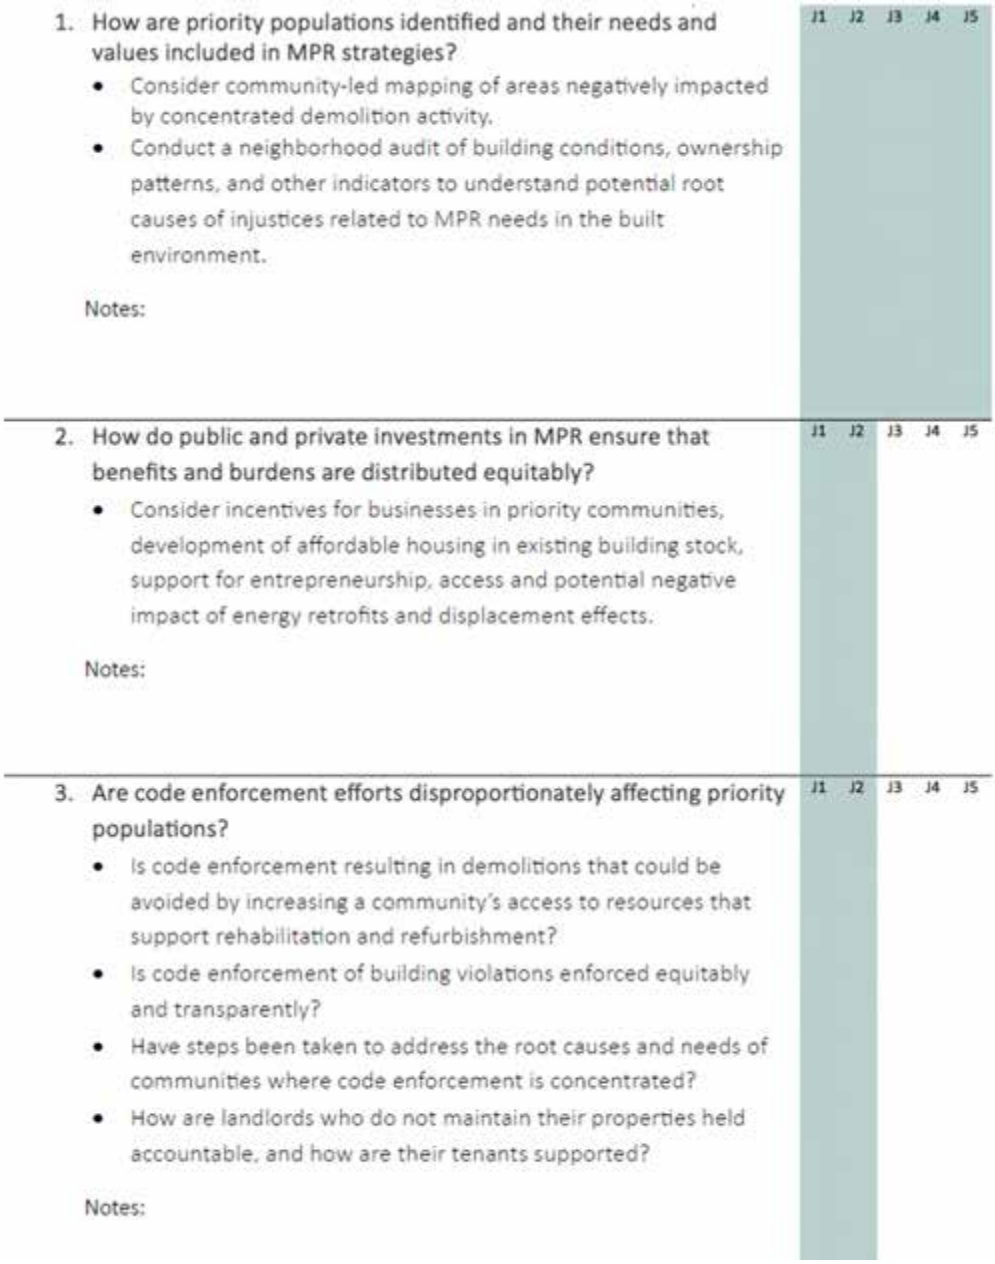

Figure 2 Three strategies addressing waste and circularity in the built environment. (Credit: Circular Construction Lab)

1. Alternatives to Demolition

Developing alternatives to demolition requires attention to past injustices while incorporating just practices along a spectrum of building reuse. As the guide notes, "Places where building demolition activities have been concentrated are often sites of injustice" (Minner et al., 2024, p. 10). Demolition can signify both historical neglect and speculative redevelopment that threatens community stability. The workbook encourages planners to con-

sider building maintenance, preservation, refurbishment, and adaptive reuse as justice-oriented alternatives that reduce waste and dislocation. Justice prompts ask:

Is this code enforcement resulting in demolitions that could be avoided by increasing a community's access to resources that support rehabilitation and refurbishment (Minner et al., 2024, p. 12)?

How can salvaging opportunities benefit communities that have lost a valued building or site? Are there practices that can extend the life of materials and thereby extend their cultural presence (Minner et al., 2024, p. 22)?

The guide includes a practice story about the City of Portland's Empowered Neighborhoods Program, which assists BIPOC community members and persons with disabilities who have been notified by the City of code violations on their residential or commercial properties. Residents submit a simple online form and receive a response within two days. A municipal staff member works directly with them, connecting them to a network of community organisations that can provide architectural drawings, construction services, and access to free or low-cost reclaimed building materials for necessary repairs. Assistance is available in multiple languages.

2. Resource Management
The just distribution and reuse of building materials demands transparency, safety, and equity. Resource management strategies that support deconstruction, salvage, and material redistribution are evaluated in the guide using justice domains that attend to labour protections, environmental burden, and economic access. As stated in the workbook, "Unjust displacement and disruption through manufacturing facilities, brownfield growth, and off-gassing of materials within the supply chain perpetuate injustice globally" (Minner et al., 2024, p. 3). Interventions in this domain must address the invisible harm caused by linear material flows.

The guide includes a practice story about Re:Purpose Savannah, a women-led nonprofit, that advances deconstruction and material reuse by salvaging and labeling building components with their histories. Each site is carefully researched and documented, forming part of an online archive—Re:Purpose Neighborhoods—that preserves place-based stories through maps, oral histories, and photographs, while inviting public contributions to collective memory (Minner et al., 2024).

3. New Construction
Justice and equity in new construction involve changes to permitting, procurement, and design development that acknowledge past injustices and actively build inclusive futures. The guide calls for attention to "design stages, material sourcing, construction process, labor and workforce hiring and training, and building disassembly– must be reimagined as an apparatus for centering justice and equity." and for practices that ensure community voices shape what is built and how (Minner et al., 2024, p. 39). Policies that centre justice in construction contracts, material specifications, and workforce development are essential.

The BLOCK Project, run by Facing Homelessness, builds backyard homes for unhoused residents as sustainable ADUs. The homes are designed for disassembly, use Red List-free materials, minimise construction waste, and meet Living Building Challenge standards—reducing both carbon emissions and environmental harm across the building lifecycle. Residents help shape each design through an iterative, community-informed process. (Minner et al., 2024).

These strategies go beyond standing alone; they are interlinked responses to interlocking crises. Circularity becomes a justice practice when embedded in the lived realities of land, labour, and livelihood. The Embodying Justice framework asks planners to use every stage of the building lifecycle as a site of accountability and transformation.

Phase II: Just and Equitable Land Use Transitions
The Just and Equitable Land Use Transitions guide was developed to address a critical gap in climate planning:

how land use systems and regulations influence access, exclusion, and the ability of communities to remain in place. Where the circularity guide focused on building lifecycles and circularity, this phase focused on the governance and spatial planning that regulates what can be built, where, and by whom. Planning tools, such as zoning codes, overlay districts, and housing incentives, are often viewed as neutral policy mechanisms within the US. However, they represented contemporary mechanisms of land use control that are layered atop histories of injustice associated with settler colonialism, racial covenants, redlining, and exclusionary development practices. Land use is not neutral. Histories of dispossession, redlining, and exclusion shape it. These legacies continue to shape who can access and participate in land, services, and environmental quality, as well as who remains vulnerable to disinvestment or displacement. Some jurisdictions are under the impression that historical unjust practices remain in the past. This is not the case, as this history is deeply embedded in present patterns of land use and urban development. By considering new justice orientations, cities have an opportunity to develop land use that repairs and heals generations now and to come, fostering a more resilient and equitable urban environment.

The guide structures its justice questions through seven domains (J1-J7), asking planners, municipalities, and community members to reflect on how proposed land use changes intersect with historical harm, labor, and housing precarity, economic access, community involvement, and cultural continuity. For example, zoning reforms may increase density or green infrastructure but may also exacerbate gentrification or obscure Indigenous land claims if not carefully designed with justice in mind.

For example, Detroit's Community Benefits Ordinance (CBO) was the first city-wide policy of its kind in the United States, requiring developers of major projects to engage with residents and negotiate tangible community benefits. The ordinance arose from grassroots efforts by the Equitable Detroit Coalition and was formalised through a legally binding process. It has since secured a range of outcomes, including affordable housing, green space, job training, and sustainability investments. The Michigan Central Station redevelopment project included $5 million for workforce education, $2.5 million for affordable housing, and green infrastructure standards as part of its Community Benefits Agreement (CBO) process (Poe et al., 2025). Detroit's approach demonstrates how land use policy can embed justice, climate goals, and community leadership at the core of urban development.

This example illustrates a broader shift in land use planning: from top-down decisions to collaborative governance, accountability, and co-created futures. It also shows how climate mitigation can be woven into justice-based frameworks, such as through adaptive reuse, embodied carbon reduction, and urban greening. The Detroit CBO also demonstrates how communities can leverage legal mechanisms to institutionalise participatory planning and ensure long-term monitoring and enforcement, a key aspect of just implementation. In parallel, the guide highlights the importance of Indigenous sovereignty in land transitions. It outlines strategies to support land rematriation, honor treaties, and integrate Indigenous ecological knowledge into planning processes (Poe et al., 2025). Moving beyond recognition, this approach affirms co-governance, resource-sharing, and repair.

Justice-oriented land use planning requires moving past abstract equity checklists toward relational, place-based strategies. It requires centring those most impacted by planning decisions, acknowledging historical legacies, and designing tools that empower rather than dilute complexities and generational experiences. The Embodying Justice framework provides a methodology to ground this work in history, partnership, and the potential for land use as a form of repair.

Reflections for Scholars and Practitioners

The Embodying Justice framework provides planners, scholars, and policymakers with a set of flexible tools for engaging with justice in their work toward lowering embodied carbon and climate action. These tools were created to be conceptual, practical, situated, and adaptable to a wide range of settings. For planning, architecture, and other allied researchers, the framework's emphasis on reflection, co-creation, and critical engagement could make it a research tool in the assessment of local government programs and community engagement of carbon neutrality. In classroom settings, the justice questions and workbook prompts can structure assignments, case

study evaluations, or design workshops and studios focused on the intersection of climate action and justice. As a pedagogical contribution, the framework supports justice-based planning education by explicitly naming histories of harm, centring community expertise, and fostering relational accountability. It offers an alternative to technical rationality by insisting that planning is not value-neutral and that students must grapple with questions of power, legacy, and repair.

In practice, the framework supports policy and project teams in assessing proposals through multiple justice lenses. The "J" domains create entry points for dialogue across departments, allowing planners, architects, landscape architects, sustainability offices, procurement staff, and community engagement specialists alike to identify where justice is being advanced or bypassed. Their non-prescriptive nature allows for local calibration while supporting both highly-focused and expansive definitions of equity and justice. While the framework is intentionally flexible, local adaptation is critical. Each city has unique histories, governance constraints, and community dynamics. One risk of this set of workbooks is the misapplication of justice language as a checkbox or branding exercise. Without adequate capacity, institutional support, and community trust, even the well-intentioned process could either ignore or reinforce harms. Planning educators and researchers play a key role in cultivating critical reflexivity.

Across both guides, the emphasis on process, not just outcome, provides a durable foundation for teaching and practice alike. The call to "make notes, draw lines, and connect ideas" invites ongoing co-learning, interdependence, and situated action (Poe et al., 2025, p. 6). The guide does not offer universal metrics, but rather reminds us that justice must be continually enacted through embedded, relational work. As cities and institutions around the world pursue carbon neutrality, there is a growing demand for justice frameworks that are rigorous, actionable, and rooted in place. Embodying Justice contributes to the emerging body of work by naming harms, offering practical tools, and illuminating pathways toward transformation. It invites planners and scholars not only to ask what can be done, but to imagine who it must be done with, and for.

In discussions with the Carbon Neutral Cities Alliance, one issue that emerged in conversations was the challenge of working with European cities and the need to avoid imposing North American concepts of justice onto the European context without deeper reflection. Our conversations with the CNCA and European research teams revealed perceptions that community organising to address justice and equity do not work in the same ways as in Canada and the US. Thus, more work is necessary to understand how a framework derived from an articulation of principles and discussion of histories and practices specific to a North American context translates across the Atlantic. In future phases, more insights will be gleaned from further conversations with research contacts in Europe. Additionally, more information will be gathered from the application of the Embodying Justice resources in a North American context, their reception, and impact.

Conclusion

Justice is not a supplement to climate action; it is the foundation upon which meaningful transitions must be built. As this research has shown, the impacts of land use and building material lifecycles are inextricably linked to the histories that shape them. Extractive planning, exclusionary zoning, and carbon-insensitive development are not merely technical failures, but the outcomes of unjust policies and unequal participation and power.

Embodying Justice invites practitioners and scholars to centre repair and relationship, not efficiency alone. This requires collaborating with communities, particularly those most affected by past and present planning decisions, to co-create alternatives rooted in care, memory, and justice. It means using climate goals not only to reduce emissions, but also to restructure who holds power, who benefits, and whose voices are heard and considered.

We argue that justice cannot simply be layered onto existing frameworks; it must shape them from the outset. The guides developed through this project offer a scaffold for doing just that—not by prescribing fixed solutions, but by opening up pathways for situated, collaborative, and accountable action.

Cities must reckon with the buildings and zones they have inherited, as well as with the futures they envision for themselves. To build carbon-neutral futures that are not only technically effective but also socially transformative, we must take seriously the entangled legacies of place, people, and power.

Justice is both a goal and a method. It demands reflection, imagination, and a shared vision for what lies ahead. This project extends an open invitation: to keep building tools and visions for the present and beyond—and to work toward a lower-carbon future steeped in deep and enduring justice.
