This study aims to develop a robust, data-driven spatial framework for assessing and forecasting the land suitability of Integrated Mangrove Aquaculture (IMA) systems in the Sundarbans Impact Zone (SIZ) of southwestern Bangladesh, as an adaptive strategy to mitigate the impacts of climate-induced salinity intrusion and associated environmental challenges. Specifically, the objectives of this research are:

1) To implement and compare the performance of advanced machine learning and deep learning algorithms in assessing the IMA suitability, identifying key drivers of IMA suitability and evaluating model strengths and weaknesses in spatial inference.

2) To project future suitability scenarios (2030, 2050, and 2080) under anticipated environmental and climatic changes, providing actionable insights for climate-resilient coastal production system.

2. Data and Methodology

2.1 Study Area

With an area of about 15,458.90 km2, the Sundarbans Impacted Area (SIZ) is located in the south-west coastal zone, including five districts (Khulna, Bagerhat, Satkhira, Pirojpur, Barguna). The study area spans approximately between latitudes 21°36'N and 23°00'N, and longitudes 88°54'E and 90°00'E. Geographically, the SIZ is positioned adjacent to the Sundarbans mangrove forest, one of the largest tidal halophytic forests in the world and a critical natural barrier against storm surges and coastal flooding. This coastal region is bounded by the Bay of Bengal to the south, forming a significant ecological transition zone where freshwater from the river systems meets the saline waters of the sea.

2.2 Data Collection

Based on a literature study, a multi-class classification framework was implemented to assess IMA suitability using a total of 19 biophysical, environmental and socioeconomic variables across four suitability classes (Not suitable, Marginally Suitable, Moderately Suitable, and Highly Suitable), categorized into four domains: (1) Hydro-chemical Characteristics, including surface water salinity, soil salinity, water total dissolved solids (TDS), water pH, water temperature, dissolved oxygen (DO), and tidal inundation depth; (2) Geomorphological & Soil Properties, encompassing soil texture, soil PH, elevation, slope, and distance to river channel; (3) Ecological and environmental Factors, comprising distance to mangrove area, Land Surface Temperature (LST) and Land Use and Land Cover (LLLC), among others ; and (4) Socioeconomic & Infrastructure, involving distance to drainage, road density, and embankment density. More details are given in Table 1.

2.3 Criteria and Sample Data

In this study, we mapped all the selected criteria factors to convert those into thematic raster layers using GIS and RS techniques. A total of 16 distinct criteria layers were prepared under four components including water parameters, soil parameters, geographic-condition, infrastructure. Each raster layer was aligned and resampled to a common resolution (30m*30m cell) with the Universal Transverse Mercator (UTM) zone 65 north and World Geodetic System (WGS)-1984 datum to ensure spatial consistency. We used ArcGIS 10.8 software with natural break and defined interval (e.g. classes of soil salinity) statistical methods to create all the raster layers. The relevance of chosen criteria with details are provided in below.

To ensure robust and spatially balanced sample set for training and validation of the machine learning and deep learning models for Integrated Mangrove Aquaculture (IMA) suitability assessment, an MCDM-based suitability index map was developed using the Analytic Hierarchy Process (AHP) integrated with GIS overlay techniques. The index incorporated 19 standardized criteria weighted by expert-derived scores. Suitability scores were classified into four categories, from which a total of 3,200 georeferenced sample points were randomly selected using stratified sampling—800 per class - to ensure class balance and spatial dispersion. To avoid spatial autocorrelation and clustering bias, a minimum distance threshold of 300 meters between points was enforced. Approximately 70% of the sample points (n = 2,240) were used for model training, while the remaining 30% (n = 960) formed the validation set. This method is particularly appropriate for complex land-use planning problems such as IMA, where suitability is determined by the interaction of multiple biophysical, environmental, and socioeconomic factors. The sample generation process enables the integration of both quantitative spatial data and qualitative expert knowledge.

Fig 2-3. Feature maps of geographic-condition factors for IMA suitability.

2.4 Methodology

To predict the spatial suitability of Integrated Mangrove Aquaculture (IMA), a supervised multi-class classification framework was implemented based on prior spatial analysis of the 19 biophysical, environmental, and socioeconomic features. Specifically, spatial autocorrelation diagnostics (e.g., Moran's I and Local Indicators of Spatial Association) revealed significant non-stationarity and spatial heterogeneity across several key variables - such as surface water salinity, soil texture, and tidal inundation depth—indicating that suitability patterns vary considerably over space. These findings justified the adoption of models capable of incorporating spatial context and handling high-dimensional, non-linear, and multi-class classification tasks.

Accordingly, three algorithms were selected: Geographically Weighted Random Forest (GWRF), Extreme Gradient Boosting (XGBoost), and Convolutional Neural Networks (CNN). GWRF was chosen for its capacity to account for spatially varying relationships between predictors and response variables. XGBoost was included as a state-of-the-art ensemble method offering computational efficiency and strong generalization. CNN, a deep learning architecture, was employed for its ability to capture complex spatial dependencies and multi-scale patterns directly from the gridded input data.

All models were trained to classify each spatial unit (i.e., raster cell) into one of four suitability categories: Not suitable, Marginally Suitable, Moderately Suitable, and Highly Suitable. To evaluate model performance and interpretability in predicting IMA suitability, multiple diagnostic tools were employed, including confusion matrices, multi-class ROC curves, spatial suitability maps, and SHAP (SHapley Additive exPlanations) analysis. These tools not only quantified model accuracy but also enabled in-depth exploration of feature importance and spatial inference quality across the study region.

3. Results

3.1 Model Performance and Interpretation

The Pearson correlation heatmap revealed several linear associations among the 19 biophysical and environmental variables used in IMA suitability modeling. For instance, surface water salinity showed positive correlations with soil salinity (r = 0.63) and tidal inundation depth (r = 0.54), reflecting saline water intrusion mechanisms typical of low-lying coastal zones. In contrast, water temperature was strongly negatively correlated with both water pH (r = -0.82) and dissolved oxygen (r = -0.82), suggesting possible ecological stress or eutrophication. To account for such nonlinear relationships, machine learning models such as GWRF, XGBoost, and CNN were employed, which are better suited to capture high-dimensional and nonlinear patterns in ecological suitability data.

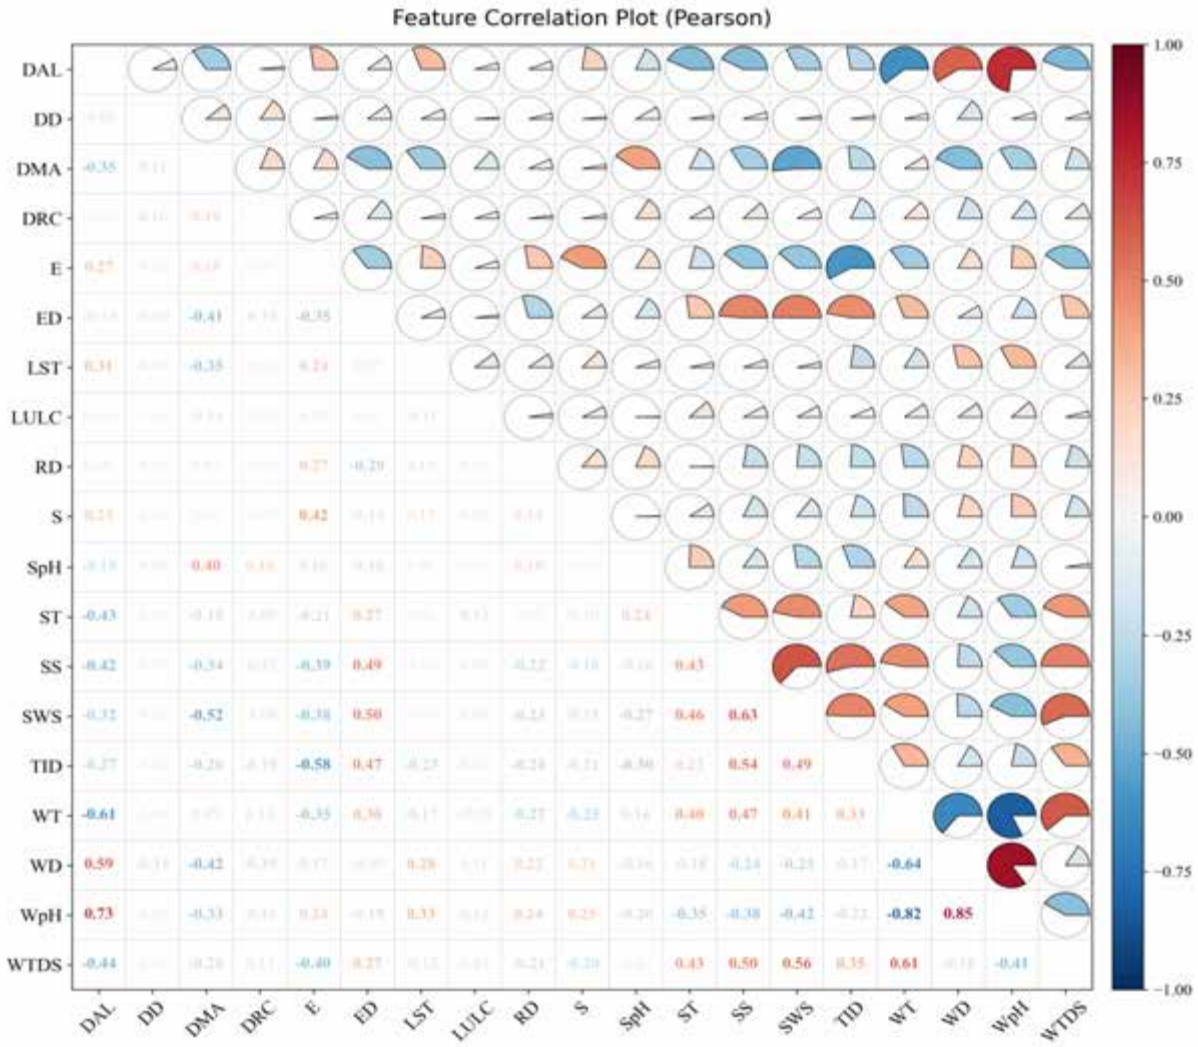

Fig 4. Feature maps of geographic-condition factors for IMA suitability

While these correlations indicate non-spatial associations, spatial dependence among variables was further assessed using Global Moran's I. The results showed that most variables exhibit statistically significant positive spatial autocorrelation ($p < 0.01$), with particularly high Moran's I values observed for soil salinity (I = 1.10), water pH (I = 1.11), and water temperature (I = 1.09). These findings confirm strong spatial clustering of key environmental conditions across the study area, reinforcing the need for spatially explicit modeling approaches. Notably, even typically static features such as distance to aquaculture land (I = 1.05) and surface water salinity (I = 1.01) displayed strong spatial structure, whereas variables like slope (I = 0.16) and land use/land cover (I = 0.38) showed relatively weaker spatial patterns.

Table 2. Global Moran's I statistics for spatial autocorrelation of input variables.

Feature	Moran I	p value
Distance to aquaculture land	1.0526987996024457	0.001
Distance to drainage	0.9605616756041764	0.001
Distance to mangrove area	1.0016094773476731	0.001
Distance to river channel	0.8768663531565697	0.001
Elevation	0.5754581473503295	0.001

Water temperature	1.0936460986686316	0.001
Water DO	0.9386793823138038	0.001
Water pH	1.1137741311873608	0.001
Water TDS	0.9453313275142926	0.001

The GWRF model demonstrated the highest predictive performance among the three, achieving an overall accuracy of 89.49%, with an F1-score of 0.89. The SHAP analysis (Fig. 5) revealed that surface water salinity, water pH, and distance to mangrove area were consistently dominant features across all suitability classes. The suitability map (Fig. 6a) indicates a more spatially coherent distribution of "Highly Suitable" areas, especially along mid-salinity estuarine zones. Importantly, the geographically weighted structure of this model allowed for localized variation in feature importance, making it highly suitable for modeling environmental heterogeneity - a critical factor in coastal delta systems. However, its reliance on spatial weight matrices introduces potential sensitivity to bandwidth selection and may limit scalability across broader geographies.

The XGBoost model achieved slightly lower predictive performance compared to GWRF, with an overall accuracy of 86.09% and precision, recall, and F1-score all registering at 0.86. As a robust gradient-boosted ensemble method, XGBoost is particularly effective at capturing complex, non-linear relationships and interactions among high-dimensional input variables. To account for potential spatial autocorrelation and overfitting, the model was trained and validated using a spatial cross-validation framework implemented via the BlockCV package, which partitions the study area into spatially contiguous folds. This approach ensures that model evaluation reflects true spatial generalizability, avoiding overly optimistic metrics that may result from traditional random sampling. SHAP-based feature attribution revealed that surface water salinity was the top-ranked predictor in both XGBoost and GWRF models, reinforcing its central role in determining IMA suitability across the study area (Fig. 8). For GWRF, the next most important features were water pH and distance to mangrove area, suggesting that the model captured ecologically meaningful local gradients linked to both water chemistry and proximity to natural buffer ecosystems. In contrast, XGBoost identified soil texture and water TDS (Total Dissolved Solids) as key predictors after salinity. This shift toward soil-based and generalized water quality variables likely reflects XGBoost's global optimization approach, which favors variables with consistent predictive power across the entire study area, rather than those with strong but spatially localized effects. However, unlike the geographically adaptive structure of GWRF, XGBoost assigns global feature weights, which may lead to underestimation of localized spatial effects. This limitation was reflected in the resulting suitability map (Fig. 9a), where the spatial boundaries of suitability zones appeared broader and less sharply defined, suggesting a tendency toward regional smoothing and potential overgeneralization in ecologically heterogeneous zones.

The Convolutional Neural Network (CNN) model, while achieving slightly lower overall performance metrics compared to the GWRF and XGBoost models - 84.79% accuracy and an F1-score of 0.85 - demonstrated unique strengths in learning spatial patterns and feature interactions from gridded data. The IMA suitability map produced by the CNN model (Fig. 12a) exhibited greater spatial granularity and higher sensitivity to fine-scale landscape heterogeneity, reflecting the model's capacity to detect ecological transitions - such as embankment boundaries, soil texture shifts, or micro-salinity zones - that may be underrepresented in coarser models. SHAP analysis (Fig. 10) revealed that the CNN model prioritized a distinctive set of influential variables. The top-ranked features included surface water salinity, soil texture, embankment density, and soil salinity, indicating that the model was sensitive to both hydrological and physical infrastructure factors. Notably, the high importance assigned to embankment density - a variable less emphasized in GWRF and XGBoost - suggests that CNN was particularly adept at identifying the influence of anthropogenic structures in shaping land suitability patterns, likely due to its spatial feature extraction capabilities. The prioritization of soil texture also highlights CNN's potential to capture interactions between micro-topography and hydrological properties that are difficult to model using traditional approaches. However, the CNN model's complexity comes with certain trade-offs. Its training process is computationally intensive and more data-hungry than tree-based algorithms. The relatively moderate dataset size (n = 3,200) may have limited its full learning capacity, and overfitting risks were mitigated through regularization and dropout techniques. Moreover, while SHAP was used to enhance interpretability, the black-box nature of deep learning still poses challenges for transparent decision support in applied contexts.

3.2 Spatial Verification of IMA Suitability Using Sentinel-2 NDWI Data

In order to verify the spatial rationality of the IMA model prediction results, this study conducted a spatial overlay analysis between the model-predicted suitability zones and the actual water body distribution derived from Sentinel-2 satellite imagery. Specifically, NDWI (Normalized Difference Water Index) was calculated using cloud-free Sentinel-2 surface reflectance data to extract surface water features for the year 2024. The resulting water body vector layer was then intersected with the suitability maps generated by the GWRF, XGBoost, and CNN models.

The results showed that the majority of NDWI-detected water bodies were spatially concentrated within areas predicted as "Moderately suitable" and "Highly suitable" by all three models, indicating strong spatial consistency between model predictions and real water features. Specifically, as shown in Table 3, the GWRF model identified 42.19% of the water bodies within "Highly suitable" areas and 27.51% within "Moderately suitable" areas, with marginal representation in "Marginally suitable" areas (3.41%) and none in "Not suitable" zones. This distribution suggests a clear spatial preference of GWRF predictions toward ecologically plausible IMA zones. In contrast, the XGBoost and CNN models further enhanced spatial alignment, with over 69% of the water body area located within "Highly suitable" zones. These two models also reduced the proportion of water bodies falling into "Not suitable" areas to below 3.5%, demonstrating better exclusion capability for unsuitable zones.

Overall, the spatial overlay verification supports the reliability of the model outputs, particularly those generated by the XGBoost and CNN frameworks, which exhibit strong agreement with actual hydrological patterns captured by NDWI. These findings reinforce the ecological validity of the predicted IMA suitability zones and provide robust support for their application in integrated aquaculture planning.

Table 3. Distribution of NDWI water body area within model-predicted suitability classes

suitability_level	GWRF	XGBoost	CNN
Not suitable	0	3.51%	3.47%
Marginally suitable	3.41%	28.09%	27.73%
Moderately suitable	27.51%	41.46%	40.02%
Highly suitable	42.19%	69.50%	69.25%

4. Conclusion

This work advances the integration of machine learning in nature-based adaptation planning, offering a replicable methodology for vulnerable coastal regions globally. The findings have direct implications for climate-resilient aquaculture planning in coastal Bangladesh, where salinity intrusion and livelihood vulnerability necessitate adaptive, nature-based interventions. The proposed methodology supports strategic zoning for IMA expansion, aligning ecological restoration with sustainable development objectives. More broadly, this study contributes to the growing literature on machine learning for nature-based adaptation, offering a transferable framework applicable to other deltaic and estuarine systems facing similar biophysical constraints. Future work may integrate temporal dynamics, stakeholder preferences, or economic optimization to further enhance the practical deployment of IMA in climate-sensitive coastal regions.

Optimizing Decision-Making for Climate-Neutral Post-War Buildings: The Architect's Role in Sustainable Transformation

Kathrin Meyer
HafenCity Universität Hamburg
Email: kathrin.meyer@hcu-hamburg.de

Abstract
The paper examines the role of architects in decision-making processes for the sustainable transformation of the existing building stock, focusing on early planning phases where demolition, preservation or redevelopment of post-war buildings is considered. Based on a multidimensional theoretical framework, it develops a heuristic model identifying five dimensions of influence: design framing, mediation, normative legitimation, political positioning and navigating planning uncertainty. Combining approaches from architectural sociology, professions theory and planning theory, the paper derives a qualitative analytical framework. The aim is to systematically reconstruct modes of influence and professional agency. It presents the theoretical basis, the conceptual model, the methodological approach and initial empirical findings from expert interviews. A more detailed analysis of the interview data will follow in the next stages of the research.

Keywords: Climate Neutrality; Post-War Buildings; Architects' Role; Sustainable Transformation; Decision-Making Processes

1. Introduction

Climate change and the increasing scarcity of resources make a more efficient use of existing materials and the reduction of greenhouse gas emissions ever more urgent. In addition to achieving climate neutrality in the building stock by 2045, the provision of affordable housing is among the core challenges facing the building sector in Germany.

The existing building stock plays a central role in the social and ecological transformation of the construction sector and holds substantial potential for sustainable transformation.

With the Renovation Wave (European Commission, 2020) as part of the European Green Deal, the European Union aims to at least double the renovation rate in the building sector by 2030. The initiative highlights refurbishment and extension of existing buildings as essential strategies to meet climate goals, emphasising their role over demolition and new construction. At the national level, the Circular Economy Strategy (BMUV, 2024) refines these goals by calling for longer service lives, the reduction of construction and demolition waste, and the promotion of closed-loop material flows. Preservation and transformation of existing buildings are explicitly named as priorities over demolition and new construction.

Figure 1: Demolition of a multi-family building from the 1950s and 1960s, Billhorner Röhrendamm (Hamburg)

Particular attention is given to the post-war housing stock, especially multi-family buildings from the 1950s and 1960s (see Figure 1). These buildings were constructed before the introduction of Germany's first thermal insulation regulation in 1977, tend to be poorly modernised (BSW, 2023), and exist in large numbers[1]. They significantly shape the urban fabric of many German cities and reflect the planning paradigms of the time: they were built as part of both inner-city reconstruction on war-damaged sites and new, loosely arranged settlements on previously agricultural land. Due to subsequent urban development, many of these former urban peripheries are now situated in inner-city areas. The original low-density design and wide building gaps offer substantial potential for upgrading these neighbourhoods in line with contemporary demands for density and mixed uses.

Given the limited availability of urban land, rooftop extensions have become increasingly important. As a key strategy for densification, they contribute simultaneously to resource efficiency, energy refurbishment, and the creation of new housing units without consuming additional land.

Studies by Steger et al. (2022) and Hafner and Storck (2023) show that both the retrofitting and the rooftop extension of existing multi-family buildings, when combined with updated technical systems and energy sources, are ecologically preferable to demolition and new construction over the life cycle. Typically, such measures result in lower primary energy use and reduced greenhouse gas emissions, with the conservation of embodied energy and reduced operational emissions playing a decisive role.
Despite these well-documented benefits, the practical potential of working with the existing stock remains underutilised. Although demolition rates are relatively low overall, with only 0.07% of multi-family buildings

1 According to the 2018 Microcensus Housing in Germany conducted by the Federal and State Statistical Offices, approximately 16.7 million apartments are located in buildings constructed between 1949 and 1978, with 10.5 million of these in multi-family buildings. This represents around 42% (or 26% for multi-family buildings) of the total housing stock.

demolished in 2013[2] (ARGE, 2016), a striking two-thirds of replacement constructions were built on sites previously occupied by structures from 1949 to 1978. This is precisely the stock that holds particular urban and ecological potential for sustainable transformation.

ARGE (2016) points to deep-rooted structural barriers hindering the development of the existing stock, including a lack of strategies among housing providers, inadequate tools for systematic resource assessment, and institutional or economic preferences for new construction. Uncertainties regarding cost forecasts, approval processes, and legal frameworks often lead to retrofitting or rooftop extension being perceived as risky, with demolition favoured as a seemingly safer alternative.

Demolition decisions are frequently made without systematic assessment, often driven by aesthetic, pragmatic, or speculative motives. In most federal states, demolition does not require a permit, meaning that no expert review of the building's structural integrity or environmental value takes place (Abrisskollektiv & Rieniets, 2025). Planning decisions are often based on individual experience and assumptions. The idea that retrofitting is not worthwhile frequently functions as an implicit planning premise (Abrisskollektiv & Rieniets, 2025).

The social consequences of demolition, particularly in high-cost urban areas, are increasingly being scrutinised.[3] A growing profitability gap between old rents and anticipated returns on new construction is seen as a major driver, linking economic exploitation to planning decisions (Calbet Elias, 2025). In addition to a lack of regulation, insufficient environmental accounting standards are also criticised, since current planning processes largely ignore embodied energy as well as social impacts such as displacement or the loss of housing types relevant to urban policy (Abrisskollektiv & Rieniets, 2025).

The gap between the theoretical potential of building transformation and actual practice underscores that decisions on demolition, refurbishment, or rooftop extension are not based purely on technical, social, or ecological criteria. Rather, they result from complex negotiation processes shaped by conflicting interests, uncertainties, and institutional frameworks.

Early planning phase 0[4] provides the analytical starting point for this study, as it is particularly decisive in determining outcomes for the existing building stock. Fundamental decisions are often made in this phase, frequently under conditions of uncertainty, competing objectives, and limited information. Whether a building is demolished or retained and extended is often prefigured at this stage, implicitly shaped by assumptions about feasibility, economic routines, or institutional practices that promote certain options while excluding others.

This paper is therefore not solely concerned with the question of why the potential for rooftop extensions and retrofitting remains unused. Rather, this issue serves as a framework for the core analytical perspective: the qualitative reconstruction and analysis of decision-making processes in early planning stages.

Against this background, the focus shifts to a professional group whose relevance to sustainability-oriented decision-making in the building stock deserves particular attention: architects. As key actors in early planning stages, they are often the first to assess and communicate the architectural potential, spatial constraints, and design opportunities of a building, whether in a commissioned, advisory, or initiating role. Their influence often arises not through decision-making authority, but through the framing, visualisation, and mediation of options.

Based on the overarching dissertation project, which addresses the question "How can decision-making processes for managing post-war building stocks be optimised to achieve climate neutrality effectively and efficiently?", this paper focuses on the sub-question: **"What role do architects play in influencing and guiding decision-making processes towards sustainable and climate-conscious outcomes?"**

2 In 2013, a total of 2,114 buildings were demolished across Germany, within an overall building stock of 3,120,696. Of these demolitions, 866 were carried out as part of replacement construction measures (ARGE, 2016).

3 See Calbet Elias (2025) on this: In Berlin, the proportion of demolished multi-family buildings replaced by new constructions rose from 43 per cent in 2020 to 63 per cent in 2022, particularly in high-price areas such as Charlottenburg, Mitte or Kreuzberg.

4 The so-called phase 0 is not officially part of the Official Scale of Fees for Services by Architects and Engineers in Germany (HOAI), but it is increasingly understood in planning practice as a preliminary phase for project development and clarification. It precedes service phase 1 (Preliminary Planning) and serves the strategic preparation of construction projects. Typical components include needs assessments, site evaluations, initial feasibility considerations, and the exploration of objectives, potentials, and constraints.

2. Research Context: Previous Investigations and Preliminary Work
In the first, quantitative part of the overarching research project, the potential for rooftop extensions on three- to four-storey apartment buildings from the 1950s and 1960s, owned by Hamburg housing cooperatives, was examined. The aim was to provide decision-making support for future densification strategies through rooftop extension. The analysis of potential was carried out on three levels.

(1) Urban scale
At this level, the quantitative potential for new residential units through rooftop extensions on the relevant buildings was assessed using digital maps and aerial imagery. The findings revealed significant numerical capacity: in the case of the housing cooperatives alone, approximately 9,725 new flats could be added through one-storey rooftop extensions, and around 14,588 through two-storey extensions (up to a maximum of five storeys). This extension potential corresponds to roughly one to one and a half times Hamburg's annual housing demand. Including comparable building typologies under municipal or private ownership would further increase the relevance of this building stock (Meyer & Klotz, 2023).

(2) Building scale
This level focused on analysing 83 construction projects with regard to typological similarities. The results revealed a high degree of standardisation in terms of building depth, floor height, and construction methods, which is especially relevant for developing serial solutions for retrofitting and rooftop extension (Meyer & Klotz, 2023).

(3) Structural scale
However, the technical prerequisites for rooftop extensions are not uniformly met. Structural analyses of existing buildings showed that foundations often provide little to no load reserves. In most cases, load capacity was between 90 and 100 percent. This means that in the majority of cases, rooftop extensions cannot be implemented without additional structural interventions, such as underpinning or foundation reinforcement (Meyer & Klotz, 2023).

In principle, rooftop extensions are feasible, but often require considerable constructional effort. Their technical and economic viability depends heavily on the extent of additional structural measures needed. For this reason, it is crucial to assess candidate buildings individually and thoroughly at an early stage. Only then can reliable judgements be made regarding their suitability for rooftop extension. Despite these challenges, the refurbishment and transformation of the existing building stock often represent both technically feasible and ecologically imperative alternatives to demolition and new construction.

3. Theoretical Framework: The Role of Architects in Decision-Making on the Existing Building Stock
Architects occupy an intermediary role in decision-making processes concerning the existing building stock. This role is shaped by design-based mediation, professional interpretive competence and situational influence. Although they usually do not hold formal decision-making authority, architects shape key directional choices through design options, scenarios and the framing of planning alternatives. This is particularly relevant in the early planning phase 0, which is characterised by uncertainty, goal conflicts and incomplete information.

A culturally informed perspective on the role of architects is developed by Führ (2004), who understands them as translators in dealing with the existing building fabric. Architects operate in a field of tension between material substance, architectural heritage and current demands. Their practice is marked by reflexivity, multidimensionality and contextual sensitivity.
They do not act as neutral service providers or autonomous authors but as actors who moderate meaning, shape spatial continuities and translate cultural values into present decisions.

Beyond cultural attributions, the role of architects can be further differentiated through institutional theory. Drawing on Scharpf (2000), decision-making processes in the built environment can be understood as interactive constellations within institutional frameworks, in which actors operate with divergent resources, interests and claims to interpretation. Architects navigate these constellations between technical requirements, legal regulations, social objectives and design-based quality standards.

An actor-oriented perspective is offered by Kurath and Eisinger (2010), who describe the role of architects as an emergent function within dynamic actor networks. Based on actor-network theory as developed by Callon and Latour, they locate architectural agency not within clearly defined professional roles but within situational and project-based negotiation settings. Architects are understood not as autonomous authorities but as negotiating partners who exert influence on decision-making through translation processes between social, political, technical and design-based logics. In this model, architecture is conceptualised as an intermediary practice that not only generates meaning but also translates and mediates it.

In light of increasing demands for climate neutrality, this intermediary role is becoming increasingly normatively charged. Haines (2010) argues that architects possess a systemic understanding of problem-solving that can integrate ecological, economic and social requirements. The design process offers a structured way to engage with goal conflicts and is particularly suited to embedding sustainability as a cross-cutting principle in decision-making. Donovan (2018) likewise highlights that architects are equipped, through their interdisciplinary mode of work, not only to implement sustainability in technical terms but also to culturally anchor it. She advocates for architectural education to place greater emphasis on transformative responsibility.

A more comprehensive theoretical framing is provided by Lavaf-Pour and Meraz (2023), who propose an integral understanding of architecture. In their model, sustainability is not reduced to quantifiable measures such as energy consumption but is conceptualised as an emergent quality located between objective requirements such as COΔreduction and subjective spatial experience. Architects assume the role of mediators between rationality and meaning, as well as between technology and atmosphere.

This responsibility is given an ethical and political dimension in the concept of “critical care” developed by Fitz and Krasny (2019). Architecture is here not understood as an instrument of progress but as a practice of care, contributing to the preservation, repair and resilience of a vulnerable environment. Architects are responsible for making long-term sustainability goals visible, for negotiating them and for defending them within concrete decision-making contexts.

A related position is put forward by the collective ANA (2025), which, in response to increasing demolition dynamics and politically embedded market logics, argues for an expanded professional understanding. This approach includes not only design but also mediation, moderation and discursive positioning. Such an engaged architectural practice involves, for instance, making hidden qualities of existing buildings visible, actively negotiating goal conflicts among stakeholders or critically questioning supposed economic constraints. Here, demolition is not framed as a technical issue but as a matter of societal negotiation in which architects participate through both design and communication. This expands the understanding of the profession to include an explicitly political and transformative dimension.

A power- and discourse-theoretical perspective on the role of architects is formulated by Stumm (2025), who shows that demolition decisions are rarely made in purely technical or neutral terms. Rather, they are grounded in historically developed knowledge orders and societal imaginaries. From this point of view, architecture is not an objective planning service but part of a political order that defines, through norms and expectations, what is considered worth preserving, functional or future-oriented.

A deeper layer of analysis is added by Rellensmann and Stumm (2025), who reconstruct demolition practices as a constitutive element of modern urban production. Architects are not only designers but also historical co-producers of a culture of devaluation, erasure and re-creation.
Against this background, their role in sustainability-related decision-making is revealed not only as technical or communicative but also as politically and historically embedded.

In summary, this results in a profession-oriented approach to the research question. Architects possess specific resources, integrative design capacities, cultural translation skills and normative mediation abilities that enable them to influence decisions on the existing building stock towards more sustainable and climate-conscious options. Their role is not defined by position or authority but by their capacity to translate complex goal conflicts into actionable design strategies. The empirical study aims to systematically reconstruct these mechanisms of influence.

4. Hypothetical Model: Architects as Intervening Variables

Based on the previously developed theoretical framework, this section presents a differentiated understanding of architects as mediating actors in decision-making processes concerning the sustainable development of existing buildings. Although they generally do not possess formal decision-making authority, they exert influence through specific contributions in the early stages of planning processes, particularly in situations where decisions must be made about demolition or preservation. To analyse these dimensions of influence systematically, the following hypothetical model conceptualises architects as an intervening variable within institutional decision-making structures. The model distinguishes five primary mechanisms through which architects can shape decision-making processes.

(1) Design-Based Framing

By developing design variants and feasibility studies, architects structure the perception of available courses of action. What is perceived as technically feasible, architecturally compelling or economically viable is largely shaped by their design proposals. Especially in phase 0, when many parameters remain undetermined, the design prefigures decision logics. It creates spaces of possibility while simultaneously narrowing the field of options. This formative function of design is emphasised by authors such as Führ (2004), Haines (2010) and Lavaf-Pour and Meraz (2023), who position the design process at the intersection of cultural interpretation, systemic complexity and creative mediation.

(2) Mediation and Moderation

Architects operate at the interfaces between technical disciplines, public authorities, building owners and the broader public. In this role, they bring contradictory demands, such as cost constraints, sustainability goals and architectural quality, into structured dialogue. The task is not neutral translation but active negotiation. The manner in which arguments are introduced, and by whom, influences which objectives are pursued and which criteria become decisive. Kurath and Eisinger (2010), Donovan (2018) and the collective ANA (2025) describe this mediating role as situationally emergent and network-based, where architects do not only act as technical coordinators but also shape discursive and design-oriented moderation.

(3) Normative Legitimation

Architects possess both aesthetic authority and cultural interpretive power, which they can employ to assert normative positions, especially with regard to sustainability. By linking certain design solutions with terms such as “resource-efficient,” “future-oriented” or “climate-neutral” and presenting them in compelling visual formats, they frame construction options in ways that are not only technically but also ethically and culturally persuasive. This symbolic framing can legitimise specific approaches even when they are not economically or functionally superior. In early phases of planning, where sustainability is often just one of many competing priorities, this normative plausibilisation can be decisive for the continued consideration of specific options. Donovan (2018), Fitz and Krasny (2019) and Lavaf-Pour and Meraz (2023) describe this process as part of a design-based ethics of sustainability, which culturally legitimises technical measures and thereby alters the scope for decision-making.

(4) Political Positioning

Beyond design and communication, architects also have the capacity to act publicly, civically and politically. This includes involvement in civil society initiatives, participation in the reform of regulatory frameworks or questioning of existing assessment standards. In this way, they can act as political agents within a field of contested norms and values.

The collective ANA (2025), Stumm (2025) and Fitz and Krasny (2019) demonstrate how architects make visible that demolition decisions are not purely technical necessities but societal issues that require open negotiation and collective engagement.

(5) Dealing with Planning Uncertainty

Planning in the context of existing buildings is frequently shaped by unpredictability, incomplete data and limited controllability. While architects cannot eliminate uncertainty, they can make it productive by offering robust design variants, open process structures and spatial scenarios that allow for informed decisions despite limited knowledge. This requires not only technical knowledge but also tacit experiential knowledge, for example, in dealing with undocumented structures, material variability or changing usage requirements. In practice, this

experiential knowledge often replaces formalised evaluation tools and thus becomes a key resource in the planning process. Rellensmann and Stumm (2025) highlight the relevance of such experiential insights, while Kurath and Eisinger (2010) point to the situational generation of knowledge in hybrid settings.

This model serves as the basis for the empirical investigation of when and how architects influence decision-making processes towards more sustainable and climate-resilient outcomes, and under what conditions this influence remains limited. It also functions as a foundation for developing a category system for the qualitative analysis of expert interviews.

5. Methodological Approach

To empirically investigate the assumptions formulated in the hypothetical model, a qualitative-exploratory research design was chosen. The model does not serve as a hypothesis in the strict sense, but rather as a heuristic framework that guides the structure of the analysis and supports the development of the coding system.

The aim is to reconstruct decision-making processes in relation to existing buildings, particularly in the early planning phases where fundamental decisions are made under conditions of uncertainty and in the absence of robust decision-making criteria. The role of architects is not presupposed normatively but is to be analytically reconstructed from the perspectives of those involved. The study focuses on how architects frame decision-making options, incorporate sustainability into design and communication, and how they are either included in or excluded from negotiation processes.

The research follows a mechanism-oriented explanatory strategy that focuses on understanding the social processes through which specific decisions, between demolition, retrofitting or rooftop extension, are reached. Rather than testing quantitative hypotheses, the goal is to gradually reconstruct the conditions and constellations under which particular decision options are enabled or constrained.

The central data collection method is expert interviews based on semi-structured interview guides, following Gläser and Laudel (2010). The concept of the expert is defined in institutional terms: interviewees are not selected based on personal experience alone, but because of their access to structurally relevant decision-making contexts. The goal is to gain insight into operational and institutional "process knowledge", such as routines, evaluation patterns and decision logics that are often not documented formally. The interview guides are narrative and reconstructive in nature. They follow real decision-making trajectories across project phases and provide insight into conflicts, uncertainties and path dependencies.

Three sets of interview guides were developed, each tailored to a specific actor group: architects (as the central group of this paper), representatives of housing owners (as formal decision-makers), and structural engineers (focusing on technical assessments under uncertainty). All guides are based on a common thematic structure consisting of seven core sections. The guide for architects includes: (1) introduction and contextualisation, (2) specific decision-making situation, (3) process and influencing factors, (4) understanding of roles and communication, (5) institutional framework, (6) reflection and evaluation, and (7) additional perspectives. The guide was pre-tested in pilot interviews and allows for flexible emphasis based on the respondent's experience.

Substantively, the guide for architects focuses on interpretative patterns in dealing with the existing building stock, the integration of design perspectives into institutional decision-making, and normative argumentation strategies. The guide for structural engineers explores how technical assessments emerge, are weighted and communicated, especially under incomplete information. For housing owners, the emphasis is on internal decision routines, economic logics and the framing of options such as preservation, extension or demolition as (im)plausible.

Interview partners were selected through two pathways: based on specific planning projects involving post-war buildings undergoing retrofitting, extension or demolition, and through recommendations provided by interviewees. To reflect the diversity of relevant decision-making contexts, institutional and contractual variation was ensured, including private, municipal and cooperative housing providers, as well as architectural offices with different client structures. The projects examined are either implemented or currently under planning, and include various pathways such as demolition and replacement, retrofitting or rooftop extension.

Interview analysis follows the methodology of qualitative content analysis according to Gläser and Laudel (2010) and Kuckartz (2018), and is conducted in two steps. First, a category system is developed deductively based on the hypothetical model and inductively extended through empirically derived subcategories. This allows the analysis to capture both theoretically anticipated and unexpected factors. In the second step, causal mechanisms and interrelations are reconstructed from the material. The analysis focuses on how decisions are made, under what conditions certain options are prioritised or dismissed, and how uncertainty is dealt with. A typology is then developed to systematically compare different decision-making logics and forms of influence.

The empirical results aim to contribute both to the theoretical refinement of the model and to practical implications for the early integration of sustainability expertise in planning processes.

6. Planned Empirical Implementation and Preliminary Results

Although the empirical study is still in its early stages, the interviews conducted so far already reveal initial tendencies that confirm and further differentiate central assumptions of the research project. At the time of writing this paper, six expert interviews have been conducted: four with architects and two with structural engineers. Additional interviews are currently being prepared.

The initial insights suggest that the effectiveness of architects in decision-making processes concerning existing buildings varies significantly. Crucial influencing factors include the structure of the client organisation, the prevailing planning culture and the political environment. In one case, the decision to demolish had already been made. The commissioned architect had no influence on defining the objectives and was only tasked with designing a replacement building. In another case, an architectural office was involved in an integrative planning team that brought together expertise in building services, building physics and architecture. Within this setting, sustainable alternatives, such as a timber-based rooftop extension and a façade refurbishment without conventional external insulation („Wärmedämmverbundsystem (WDVS)“), were introduced into the discussion at an early stage. Another interview case illustrated that arguments for sustainability were only successful if they aligned with economic objectives. It also became evident that political support, for instance from a city administration‘s leadership, was a crucial condition for the implementation of ambitious retrofitting concepts. At the same time, the interpretation of technical regulations was shown to be highly dependent on individual officials. In one case, a fire safety concept that had previously been approved for a different project was initially rejected and only approved after a change in staff responsibility. In several projects, overarching urban planning objectives prevented the implementation of rooftop extensions. In two cases, a higher building density was required than could be structurally achieved in the existing stock. In another project, a social conservation ordinance prohibited the use of ecological building materials on the grounds that they would lead to an impermissible increase in quality.

Several interviews also indicate that sustainability is rarely a formal part of the decision-making process. Instead, it is often introduced through design plausibility, communicative competence and institutional proximity to the client. These forms of influence are closely tied to the situational role that architects assume within a given project context. One structural engineer described his role in the decision-making process as the “late-stage technical confirmation” of previously developed design variants. This supports the hypothesis that technical assessments are often secondary, and that architectural framing may in fact become the primary decision-shaping factor.

Based on the case studies conducted thus far, three ideal types of architectural influence in decision-making can be identified:

(1) Architect as sustainability agent

This type is characterised by a proactive stance and a clear commitment to climate-conscious solutions. Architects in this role are involved in planning processes at an early stage and explicitly address sustainability in both communication and design. A typical example is the deliberate integration of strategies for the preservation and development of existing buildings as a guiding ecological and design principle.

(2) Architect as process moderator
This type assumes a mediating role between competing interests. Sustainable options are considered, but not framed as normative imperatives. Instead, they are embedded in broader strategic arguments. In one interview example, an architect succeeded in structuring a political decision-making process by visually presenting design alternatives, without explicitly advocating for one.

(3) Architect as neutral service provider
This type adheres closely to the client's specifications. Sustainability is not actively addressed, but may appear as a secondary condition. This type includes the case of the architect who was brought into the project only after the decision to demolish had already been made, and who was then commissioned to design a replacement building. Another interviewee explicitly described his role as apolitical and purely execution-oriented.

These ideal types are analysed in terms of the institutional and planning contexts in which they arise. Relevant factors include the type of project tender, the underlying project logic and the institutional setting. The key question is whether specific institutional or planning configurations systematically correspond with certain types of architectural influence. The results aim to identify the conditions under which architects can act effectively as transformative agents in the development of existing buildings, and the conditions under which their influence is systematically limited.

7. Conclusion and Outlook
The climate-conscious transformation of the existing building stock is one of the key challenges of the coming decades. Given the architectural significance of post-war buildings and the limited resources available for new construction, increasing attention is being paid to the conditions and processes of decision-making. This paper has shown that these decisions are shaped not only by technical, legal or economic factors but also, and in particular, by professional actors involved in early planning phases. In this context, architects play a central role.

Building on a multidimensional theoretical framework, this paper has developed a heuristic model that conceptualises architects as intermediary actors in decision-making processes on sustainable development of the existing building stock. The model identifies five mechanisms through which architects can influence decisions in the direction of climate-conscious and sustainable outcomes: design-based framing, mediation and moderation, normative legitimation, political positioning and the dealing with planning uncertainty. These forms of influence are not solely the result of individual agency but are institutionally embedded. Their effectiveness depends on the configuration of clients, organisational and planning conditions, the presence of political support and the quality of collaboration with other involved actors.

At the time of writing, the empirical implementation of the research project is ongoing. Six interviews have provided initial insights into typical patterns of architectural influence. The objective is not only to refine the model based on empirical findings but also to formulate practice-oriented questions. Of particular interest are strategies for integrating architectural perspectives earlier in decision-making processes, identifying institutional formats that strengthen design agency and exploring how the professional self-image of architects can be sharpened so that their cultural, communicative and normative competencies are strategically employed in socio-ecological transformation processes.

The research follows a dual objective. On the one hand, it expands theoretical perspectives from the sociology of professions and planning theory by offering a differentiated analysis of intermediary influence in the built environment. On the other hand, it proposes a practice-oriented framework for reflection that may be relevant for education, planning practice and institutional development strategies. The paper positions itself at the intersection of architectural sociology, professional studies and planning theory. It contributes to ongoing discourses in transformation governance and offers a perspective that connects institutional change with profession-related and architectural-theoretical insights on the built environment.

By focusing on the role of architects in addressing uncertainty, goal conflicts and normative ambiguity, this paper contributes to the question of how sustainability can become not only a subject of discussion but also a design and strategic factor in planning processes.

It thus aims to be both an analytical reconstruction of existing decision-making practices and a contribution to the debate on expanding professional agency in the context of sustainable development.

Investigating the impact of Urban Form Elements on carbon emissions at Different Development Stages: Based on GWR Models

Yihuan Wang, Junyan Yangβ
School of Architecture, Southeast University, Nanjing 210096, China
yihuanwang@seu.edu.cn

Abstract
With rapid urban expansion, cities consume 78% of global energy and are major carbon emitters. Due to uneven urbanisation, Chinese cities at different development stages show varied relationships between urban form and carbon emissions. This study explores the impact of 3D urban form elements on carbon emissions across development stages to promote low-carbon development and carbon neutrality. Using Geographically Weighted Regression (GWR) and Random Forest models, the study analyzed spatial heterogeneity and non-linear relationships. Key steps included classifying city development stages, estimating city-level emissions using inventories and Night Time Light data, and examining spatial autocorrelation. Results indicate that factors such as building height and built-up area have a significant impact on emissions. These findings provide targeted recommendations for carbon reduction and sustainable urban development

Keywords: Carbon emissions, Urban development Levels, Urban forms, Geographically Weighted Regression Model

Introduction

Carbon emissions have impacted global climate change, leading to a rise in global average temperature, causing extreme weather events to become more frequent, and affecting human production and life(n.d.). With the gradual advancement of global urbanisation, cities are the most vulnerable to climate change and major contributors to it. According to statistics from UN-Habitat, cities consume 78% of the world's energy, and more than 60% of greenhouse gas emissions come from urban areas(Xia et al., 2020). To address this issue, the international community has proposed the Sustainable Development Goals, the United Nations Framework Convention on Climate Change, and the Special Report on Global Warming of 1.5ºC. As the world's largest carbon-emitting country, China has also actively participated in carbon reduction and control actions, proposing the goals of peaking carbon emissions by 2030 and achieving carbon neutrality by 2060 based on its national circumstances.

China's urbanisation process is rapid. According to data from the National Bureau of Statistics, the urbanisation rate in China was 65.22% by the end of 2022, with the urbanisation rate in nine provinces exceeding 70%. Previous studies have shown that the optimisation of urban spatial form plays a significant role in reducing carbon dioxide emissions(Xia et al., 2020). Urban form is generally considered the spatial arrangement and organisational pattern of human activities, affecting land use structure, resource utilisation efficiency, transportation configuration, infrastructure construction, and even the urban heat island effect(Liang et al., 2020). Numerous studies demonstrate that urban form is closely related to urban CO2 emission levels(2012; Xia et al., 2020; Zuo et al., 2020).

Traditional studies mainly focus on analyzing the impact of two-dimensional urban form indicators on urban carbon emissions. For instance, Ou et al. found that the fragmentation pattern of urban land leads to increased CO2 emissions across all city levels(J. Ou et al., 2019). Yasuyo Makido et al. studied the relationship between CO2 emissions and urban form in Japanese urban areas(Makido et al., 2012), while Fragkias et al. pointed out that during rapid urbanisation, population growth and resource consumption lead to the expansion of urban form, which significantly contributes to the increase in CO2 emissions("Investigating the differentiated impacts of socioeconomic factors and urban forms on CO2 emissions: Empirical evidence from Chinese cities of different developmental levels - ScienceDirect," n.d.). However, with high-density cities becoming an important goal for global carbon reduction and control, three-dimensional urban form indicators can better reveal the vertical spatial development and built environment of high-density cities as compared to traditional two-dimensional urban form indicators(Lin et al., 2021; Tian et al., 2024; Wang et al., 2025). Therefore, it is necessary to analyze the impact of the three-dimensional built environment on urban carbon emissions to promote green and low-carbon development models.

At the same time, due to the varying urbanisation progress across Chinese cities, there are significant differences in the socio-economic development, energy consumption structures, and carbon dioxide emission patterns among different cities(Ou J. et al., 2019). Additionally, urban spatial morphology elements, such as the scope of built-up areas, land use structures, urban compactness, and urban spatial forms, also show considerable variation. However, how the differences in urban development levels influence the relationship between urban morphology and CO2 emissions has not been thoroughly explored in the current literature. Taking Chinese cities as an example, most studies investigating the impact of urban morphology on CO2 emissions focus on megacities while neglecting underdeveloped and low-income cities. Although it is well-known that there are substantial disparities in carbon dioxide emissions across cities with different development levels(Behera and Dash, 2017; Wang et al., 2018), existing studies lack sufficient evidence to explain the differential impacts of multidimensional characteristics of urban morphology on carbon emissions. Furthermore, they do not clarify whether compact development models have universal emission reduction effects across cities with varying economic levels in China. Given this, there is an urgent need to construct a systematic research framework to explore the differentiated mechanisms through which urban spatial structures affect carbon emission intensity, while incorporating the dynamic characteristics of urban development stages for comprehensive analysis(Ou J. et al., 2019).

This study analyses the carbon emission characteristics of cities at different developmental stages based on their three-dimensional spatial form and explores targeted sustainable development models. Cities are first classified by development levels, and a carbon emission dataset derived from energy consumption and nighttime light data is used to calculate annual city-scale emissions. Key three-dimensional urban morphological metrics are then summarized and analysed. Geographically Weighted Regression (GWR) is applied to quantify the spatial heterogeneity of COΔemissions in relation to urban morphology and socioeconomic factors. The Ordinary Least Squares (OLS) regression model identifies global driving factors of city-level COΔemissions, while the GWR model reveals local variations by providing unique parameters for each observation. This approach uncovers the spatial characteristics and carbon emission patterns of cities, offering insights into sustainable urban development models and valuable references for policymakers.

Date and methodology

Study areas

This study examines prefecture-level and above cities in mainland China, focusing on the impact of industrialisation and urbanisation since the reform and opening-up policy. From 2000 to 2016, China's GDP increased sevenfold to 74.4 trillion yuan, accompanied by rising energy consumption and greenhouse gas emissions. China accounts for 23.0% of global energy consumption and 27.3% of carbon emissions, making it the largest emitter(Shi et al., 2018). Due to regional resource endowment, industrial structure, and energy efficiency, cities show significant spatial differences in carbon emission trajectories. Identifying the dynamic evolution of carbon emission drivers is crucial for creating differentiated emission reduction strategies that consider regional heterogeneity and sustainable development.

Figure 1 The geographical distribution of five-tier cities in mainland China.

The traditional classification of cities primarily relies on indicators such as built-up area size, city GDP, urban population, and population density. To evaluate the impact of socioeconomic factors and urban morphology on carbon dioxide emissions while considering differences in development levels, this study adopts the city classification system published by China Business Network (CBN) in 2024, which categorises Chinese cities into five tiers: first-tier, second-tier, third-tier, fourth-tier, and fifth-tier cities.

These metrics are sourced from commercial and internet data, reflecting various aspects such as the level of economic development, household consumption ability, local fiscal income, education level, educational resource level, and urban infrastructure quality. Subsequently, a comprehensive commercial development index for each city is calculated through principal component analysis and a weighted scoring method(Bai et al., 2018).

As shown in Figure 1, according to the 2024 rankings of the index, there are 19 first-tier cities, 30 second-tier cities, 70 third-tier cities, 90 fourth-tier cities, and 128 fifth-tier cities in China in 2024. The first-tier cities are, in order: Beijing, Shanghai, Shenzhen, Guangzhou, Chengdu, Hangzhou, Chongqing, Suzhou, Wuhan, Xi'an, Nanjing, Changsha, Tianjin, Zhengzhou, Dongguan, Wuxi, Ningbo, Qingdao, and Hefei.

Data sources

City-level CO2 emissions

Generally speaking, carbon dioxide emission data originate from energy statistics based on standard IPCC methods(Castles and Henderson, 2003; Li et al., 2021). The current national statistical system exhibits a clear hierarchical attenuation characteristic in energy data: energy consumption data released by the National Bureau of Statistics is mostly focused on the macro level, and there are significant data gaps at the prefecture-level (particularly in central and western cities).

To address the lack of urban-scale energy statistical data, a substantial amount of work has been successfully conducted to estimate urban-scale CO2 emissions based on nighttime light imagery. Nighttime light imagery has been proven to be a potential data source for estimating CO2 emissions, as it can detect artificial light associated with human activities.

In terms of carbon emission calculations, this study utilises the carbon emission gridded data for months 1-12 from the ODIAC 2023 dataset. The primary sources of this dataset are statistical data from fields such as energy consumption and industrial production. This dataset is pioneering in its use of nighttime light data combined

with emission/location profiles of individual power plants to estimate the global spatial distribution of fossil fuel CO2 emissions. Through an innovative emission modeling approach, it has achieved a 1x1 kilometer resolution data product for global fossil fuel CO2 emissions.

This study processed the outliers of carbon emissions as 0 and greater than 10,000 in the dataset, summed up the annual carbon emissions for 2023 within the urban areas of each prefecture-level city, and assigned the results to each city boundary to obtain the annual carbon emissions within the city boundary. The formulas are as follows:

$$E_{i,j}^{annual} = \sum_{m=1}^{12} E_{i,j}^{(m)}$$

$$E_k^{total} = \sum_{(i,j)\in A_k} E_{i,j}^{annual} \times A_{i,j}^{k}$$

where $E_{(i,j)}^{annual}$ represents the annual carbon emissions of grid cell (i,j) in 2023. E_k^{total} represents the total carbon emissions within the city boundary k in 2023.$A_{(i,j)}^{k}$ represents the area proportion of grid cell (i,j) within the built-up area of city k.

Comprehensive Indicators of Socioeconomic Development and Urban Form

This study selected two types of indicators related to socioeconomic development and urban morphology to analyse their impact on CO2 emissions. The first type includes socioeconomic variables such as GDP and population density, which are often used to represent economic performance and population scale; thus, they are important factors influencing changes in urban CO2 emissions. This study utilised GDP data, population data, and population density data of various cities. GDP data for 2023 of each city and the corresponding GDP data for the Primary Industry, Secondary Industry, and Tertiary Industry were obtained from the "China Urban Statistical Yearbook" and some city statistical yearbooks. For data consistency, some cities without statistical data were excluded from this analysis. Additionally, spatial distribution raster data of China's population at 1km resolution for 2023 were obtained from the LnadScan platform. Outliers were processed during usage, and population density within each city in 2022 was derived by summing the raster data.

The second type is the urban morphology indicator. Urban morphology can influence economic functions and efficiency, produce social impacts within urban environments, and ultimately affect the design and regulation of urban spatial uses(Fang et al., 2015).

Based on previous studies(Biljecki and Chow, 2022; Chen et al., 2025; Fang et al., 2015), this paper selects the following indicators to represent urban morphological characteristics: Total Area of Urban Built-up Area (TA), Average Building Height (ABH), Shape Index of Urban Built-up Area (SI). Transportation and urban expansion also have significant impacts on CO2 emissions(Lopez-Aparicio et al., 2025; Wu et al., 2022). This paper selects Road Density (RD) to represent the transportation characteristics within urban morphology.

Table 1 summarises the calculation formulas and units of the aforementioned indicators. To facilitate subsequent analysis, these variables are subjected to Z-score standardisation to eliminate the effects of dimensionality and outliers.

Research steps

Spatial autocorrelation

Moran's I index is an important tool for evaluating spatial autocorrelation, used to measure the dependency and heterogeneity characteristics among spatial objects. From a spatial scale perspective, Global Moran's I describes the overall degree of spatial association, while Local Moran's I reflects the similarity and differences among local spatial units(Wang et al., 2023). Both range from [-1,1], with positive values indicating similarity among spatial units and negative values indicating differences.

In statistical testing, z-scores and p-values are used to assess the strength of correlation and its significance.

Table 1 Detailed information on the indicators used in this study

Indicator	Calculation Formula/Definition	Unit
PD (Population density)	P_i represents the population of grid i; i represents the area of grid i.	People/km²
IS (Proportion of secondary industry)	The proportion of the secondary industry (e.g., industry, construction, etc.) in the gross domestic product (GDP).	%
RD(Road density)	L_d represents the total road length; $\llcorner$ represents the total area of the district	km/km²
TA (Total Area of Urban Built-up Area)	Area of developed and constructed zones within the city	km²
BH (Building height)	$H_{avg} = \frac{\sum_{i=1}^{n} h_i \cdot A_i}{\sum_{i=1}^{n} A_i}$ A_i represents the building height of grid i; A_i represents the area of grid i.	m
SI (Shape index)	P represents the perimeter of the built-up area, A represents the area of the built-up area	/

In spatial clustering analysis, the global mean and local mean are key parameters. A local mean higher than the global mean forms a high-high (HH) cluster, while a local mean lower than the global mean forms a low-low (LL) cluster. Observed values higher than the local mean form a high-low (HL) cluster, while those lower than the local mean form a low-high (LH) cluster(Su et al., 2014). These cluster types are distributed in four quadrants in the Moran scatterplot, corresponding to the central trend of regression models.

The geographically weighted regression model

The Geographically Weighted Regression Model (GWR) is a local spatial technique that can be used to examine the spatial variability of regression parameters and model performance. Relationships in geographic space often vary due to differences in geographic locations. Compared to general models, while classical Ordinary Least Squares (OLS) regression is a simple linear regression, its coefficients reflect the generalised relationships within the study area but do not account for the spatial components behind these effects. The introduction of the GWR model allows regression coefficients to change with spatial location by fitting a local regression model at each geographic location, thereby better explaining spatial heterogeneity.

The GWR model can be regarded as a spatial decomposition extension of the general linear regression model. The form is as follows:

$$y_i = \beta_0(\mu_i, v_i) + \sum_{i=1}^{k} x_{ij}\beta_j(\mu_i, v_i) + \varepsilon_i, \qquad (i = 1,2,\dots,m, j = 1,2,\dots,k)$$

where Δis the error term satisfying the spherical disturbance assumption; Δ_0 (μ_i,Δ_i) is the intercept term; k represents the number of factors, and i represents the i-th city.
Δ_j (μ_i,Δ_i) is the local regression parameter to be estimated at the regression point (μ_i,Δ_i), representing the latitude and longitude coordinates of the i-th city.

Results

The spatial features of city-level CO2 emissions

Based on the aforementioned methods, due to defects in CO2 emission data in some cities, this study estimates the 2023 CO2 emissions of 371 cities in China, as shown in Figure 2. The total CO2 emissions of Chinese cities amount to approximately 12.6 billion tons. About 249 cities have carbon emissions below the average (33.9 million tons). It can be observed that cities with relatively high CO2 emissions are mostly concentrated in the Yangtze River Delta (YRD), the Pearl River Delta (PRD), the Beijing-Tianjin-Hebei region (BTH), the Chengdu-Chongqing economic circle, and the northeastern regions of China, such as Changchun and Harbin.

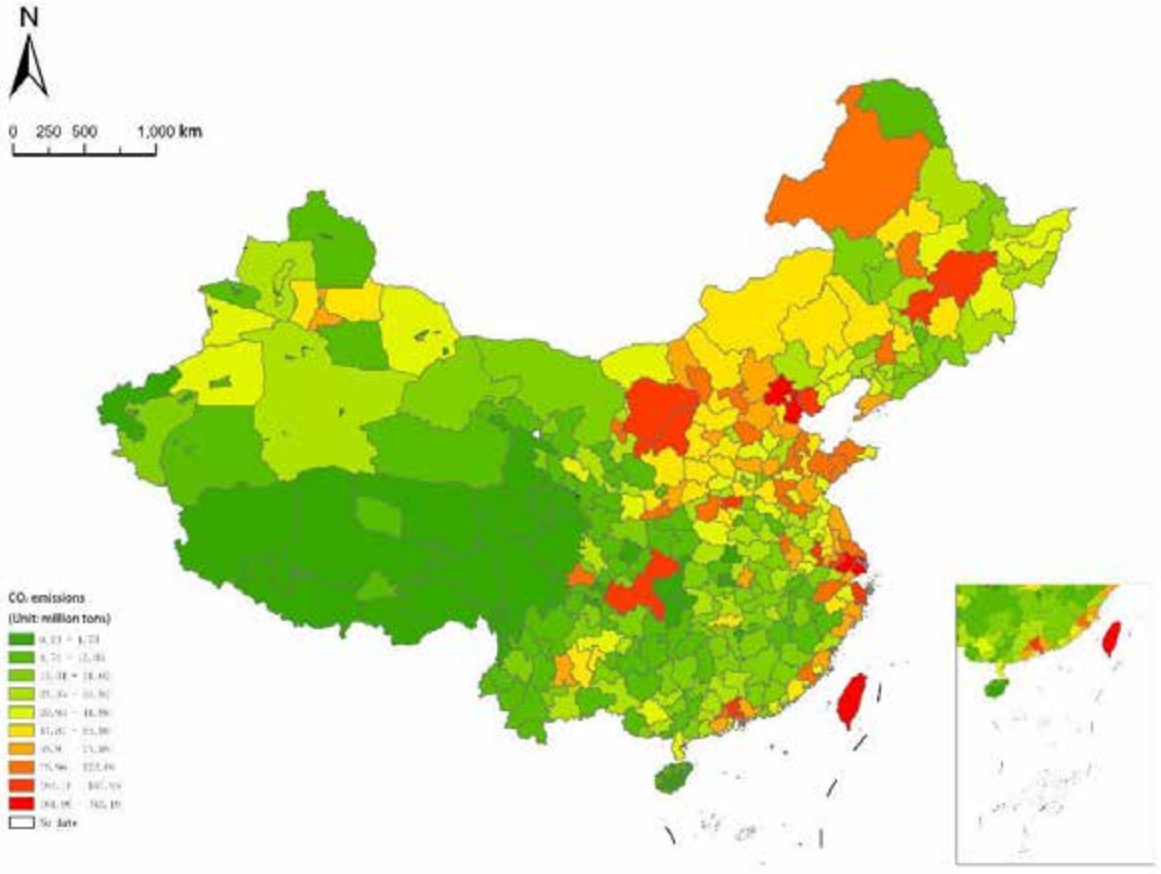

Figure 2 China's City-Level CO2 Emissions in 2023 (Million Tons)

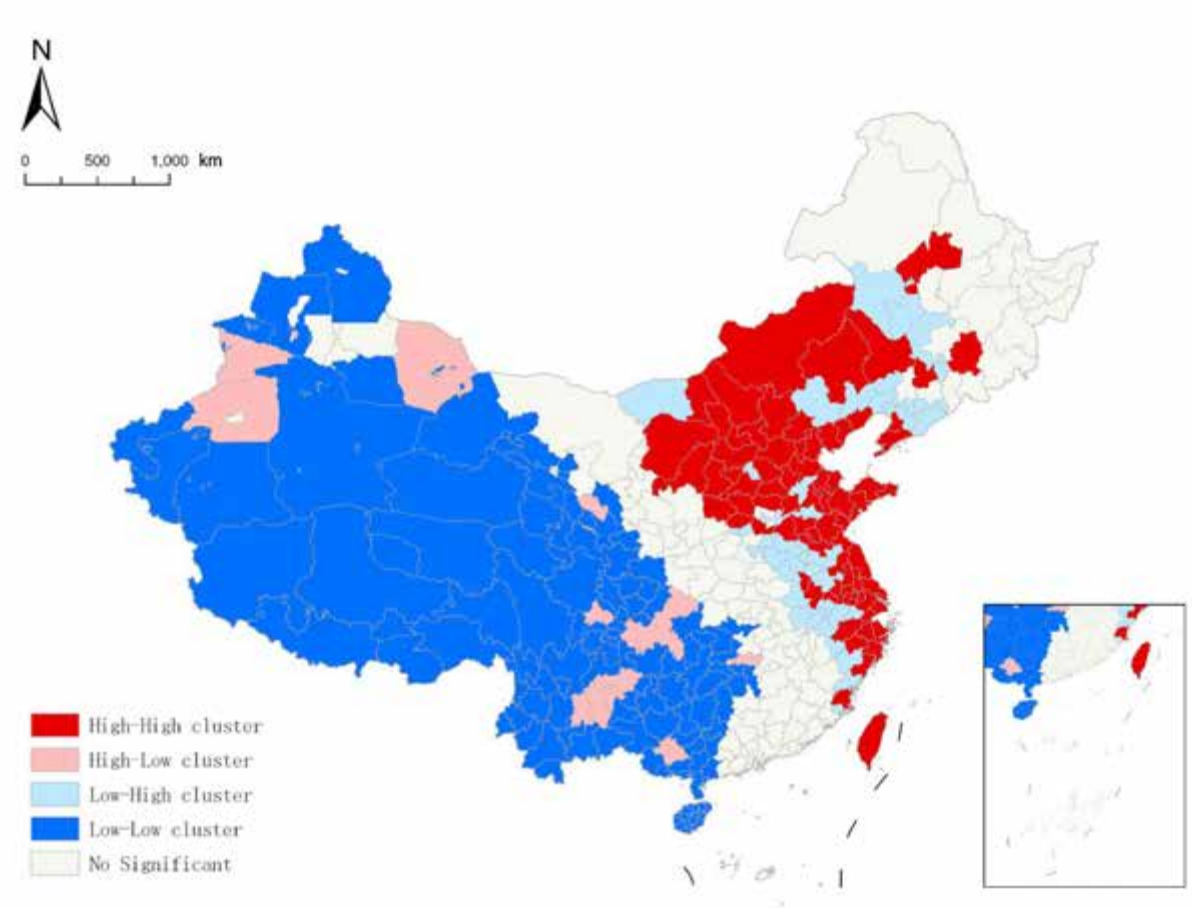

Figure 3 Local Moran's I clusters of CO2 emissions of Chinese cities

The spatial distribution of such CO2 emissions is closely related to regional development patterns. Among the top 10 cities with the highest carbon dioxide emissions, 7 are first-tier cities. These cities with higher carbon dioxide emissions benefit from favourable geographic locations or policy advantages, resulting in faster urbanisation, larger populations, more developed economies, and more intensive industries compared to other cities, particularly in the YRD, PRD, and BTH regions. In contrast, the northeastern region of China, which was once the heavy industrial base of the country, is currently undergoing policy initiatives aimed at addressing population loss in the area.

Cities with lower carbon dioxide emissions are typically located in less developed regions, including southern, northwestern, western, and parts of central China. Among these, the central region has historically sustained a large population, mostly consisting of second-tier and third-tier cities. In contrast, the western region, due to factors such as geographical conditions, has developed at a relatively slower pace. Although it occupies over 70% of China's territory, it accounts for only 30% of the population, with low urbanisation rates and slower economic development, mostly consisting of fourth-tier and fifth-tier cities.

This study calculates the global Moran's I to assess the spatial clustering of city-level CO2 emissions in China. It finds that the global Moran's I of CO2 emissions is 0.17 ($p < 0.01$), indicating a significant positive spatial autocorrelation of CO2 emissions. To further analyse the spatial characteristics of city-level CO2 emissions in China, this study employs the local Moran's I.

The CO2 emission LISA map shown in Figure 3 geographically depicts the local spatial correlation of CO2 emissions. HH clusters are mainly concentrated in YRD, BTH, parts of the Shandong Peninsula, and a few northeastern cities in China, which are densely populated and economically developed. LL clusters are primarily distributed in the northwestern and southwestern regions of China, involving some cities in the central region. HL clusters are relatively dispersed, mainly distributed in the Xinjiang region of northwestern China, the Chengdu-Chongqing

region of southwestern China, parts of Shanxi, Guizhou, and Guangxi, and form a relatively continuous concentration in Yunnan. LH clusters are mainly distributed around HH clusters. A particularly notable aspect is that HH clusters do not appear in the PRD region, which features a developed and prosperous economy and a high level of urbanisation. One possible reason for this could be the impact of CO2 emissions from surrounding cities.

Major factors influencing city-level CO2 emissions

To comprehensively understand the driving factors and effects behind city-level carbon dioxide emissions, this paper first uses the OLS model to detect the impact of eight explanatory variables on urban CO2 emissions. The Z-score standardisation is performed on these explanatory variables to eliminate the effects of dimensions and outliers. The ANOVA F-test shows that the overall model has statistical significance ($p < 0.001$), and the adjusted R-squared value (0.79) indicates a relatively high goodness of fit.

There is no issue of multicollinearity, as all variance inflation factors (VIF) reported for the variables are far below 10.

The results are presented in Table 2. The coefficients indicate that most explanatory variables are positively correlated with CO2 emissions, particularly the area of developed land, building height, and significantly contribute to urban CO2 emissions. PD and IS promote urban CO2 emissions, while RD has a significant effect on reducing urban CO2 emissions, and SI has a minimal impact.

Table 2 OLS analysis results

	Coefficient	Std. Error	T value	Pr.(>|t|)	VIF
Constant	38.5688	1.3974	27.5999	0.0000*	
PD	9.0387	5.6237	1.6072	0.1093	3.9287
IS	-10.1902	2.3048	-4.4212	0.0000*	3.5577
RD	17.5675	1.9847	8.8516	0.0000*	2.6662
TA	27.9687	3.0078	9.2986	0.0000*	5.7252
BH	0.7631	2.0443	0.3733	0.7093	2.7712
SI	9.1118	1.4244	6.3968	0.0000*	1.1014

As mentioned above, the global regression model assumes that the relationship between CO2 emissions and each explanatory variable is the same across all locations, and the results of this model fail to explain the local heterogeneity of driving factors. Therefore, the GWR model in this paper is set with the same variables. The spatially distributed local R-squared values described in Figure 4 also indicate that the comprehensive statistical effects of our explanatory variables on CO2 emissions vary between 0.702 and 0.925 among Chinese cities.

As shown in the figure, the local R-squared values roughly exhibit a ring-shaped distribution, gradually decreasing from the eastern coastal areas. The R-squared values of the GWR model for the vast majority of studied cities are higher than those of the global regression model, with only some cities in the southwestern region, parts of the central region, and parts of the northwestern region falling below the OLS threshold (0.79).

The results indicate that the range of regression coefficients relative to their standard deviations is quite broad, with the minimum value (road network density) being -8.749 and the maximum value (built-up area) being 22.438. The greater the range of variable coefficients, the greater the spatial variation in the contribution and influence of the factors, which demonstrates the appropriateness of the GWR model in providing better explanations for local estimates.

To further explore the spatial heterogeneity in the relationship between each explanatory variable and CO2 emissions, we generated maps representing the spatial distribution of coefficients for each factor (Figure 5). Consistent with the OLS model, the average building height, built-up area, and secondary industry GDP of cities were shown to have a positive impact on CO2 emissions in the studied cities, but their relationships with CO2 emissions varied spatially.

Meanwhile, other factors exerted bidirectional influences on cities' CO2 emissions, with certain differences observed among different cities—an aspect not revealed by the global regression model.

Research and development, in all the studied cities, TA is a key driver of urban CO2 emissions, maintaining a still significant coefficient. Among socio-economic indicators, the regions most affected by IS are concentrated in the eastern coastal area, the northeast region, some central cities, and some cities in the northwest. In terms of urban development levels, in some Tier 1 cities located in the eastern coastal areas, CO2 emissions are still influenced by IS. Relatively speaking, the influence degree in Tier 1 cities in the Chengdu-Chongqing area, PRD, and BTH region is smaller compared to other Tier 1 cities. This is mainly because Tier 1 cities like Beijing, with urbanisation progress and economic structure upgrades, have gradually transferred high-energy-consuming and high-pollution industries to surrounding areas (such as Hebei Province, Jiangsu Province, etc.). They have also implemented stricter environmental protection policies and carbon emission control measures.

The secondary industry in Tier 2 and Tier 3 cities overall has a significant impact on carbon emissions. This is because the economic development of Tier 2 and Tier 3 cities still primarily relies on the secondary industry, especially traditional industries with high energy consumption and high pollution (such as steel, chemical industry, cement, coal, etc.), which have high energy consumption and carbon emission intensity. At the same time, due to the division of labor in regional economies, much of the secondary industry eliminated by Tier 1 cities has shifted to Tier 2 and Tier 3 cities due to factors like costs, labor, and policies. Additionally, some Tier 2 and Tier 3 cities are resource-based cities (e.g., those rich in coal, oil, and minerals), and their economic development is highly dependent on resource extraction and processing, activities that are typically accompanied by high carbon emissions.

Interestingly, in the southwestern regions such as Yunnan, Guizhou, Guangxi, and parts of Shandong's cities, the secondary industry has a relatively small impact on urban carbon dioxide emissions. These cities are mostly Tier 4 and Tier 5 cities, with slow urbanisation processes, and some are just beginning to develop. Additionally, influenced by geographical and natural conditions, Sichuan, Yunnan, Guizhou, and Guangxi possess abundant water resources. Hydropower occupies a significant proportion in their energy structure, making them key provinces for clean energy output. Moreover, in recent years, due to low-carbon policies and eco-priority strategies, the country has implemented strict ecological protection policies in these regions, emphasizing the introduction of energy-saving and emission-reduction technologies. All these factors have resulted in the secondary industry having a minimal impact on urban carbon dioxide emissions in these cities.

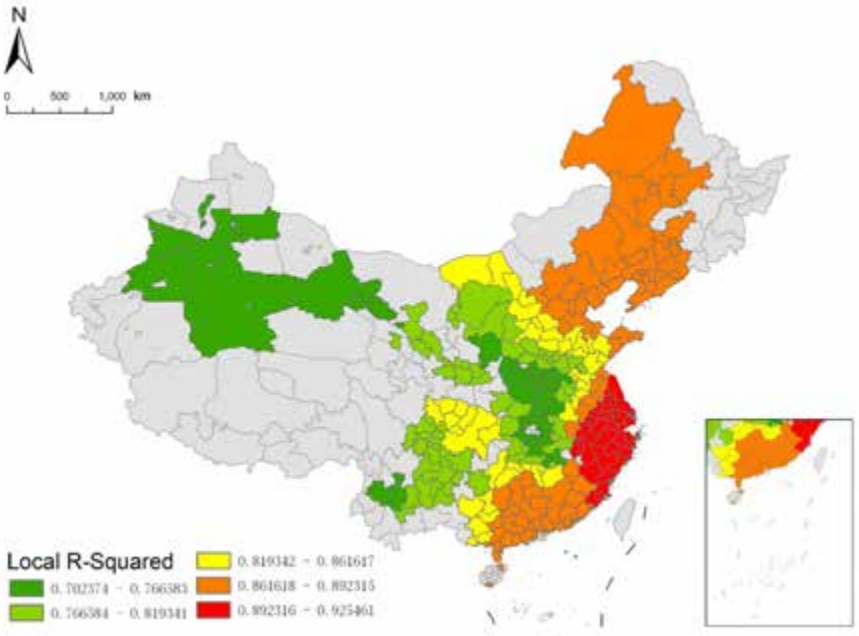

Figure 4 The spatial distribution of R-squared values from the GWR model.

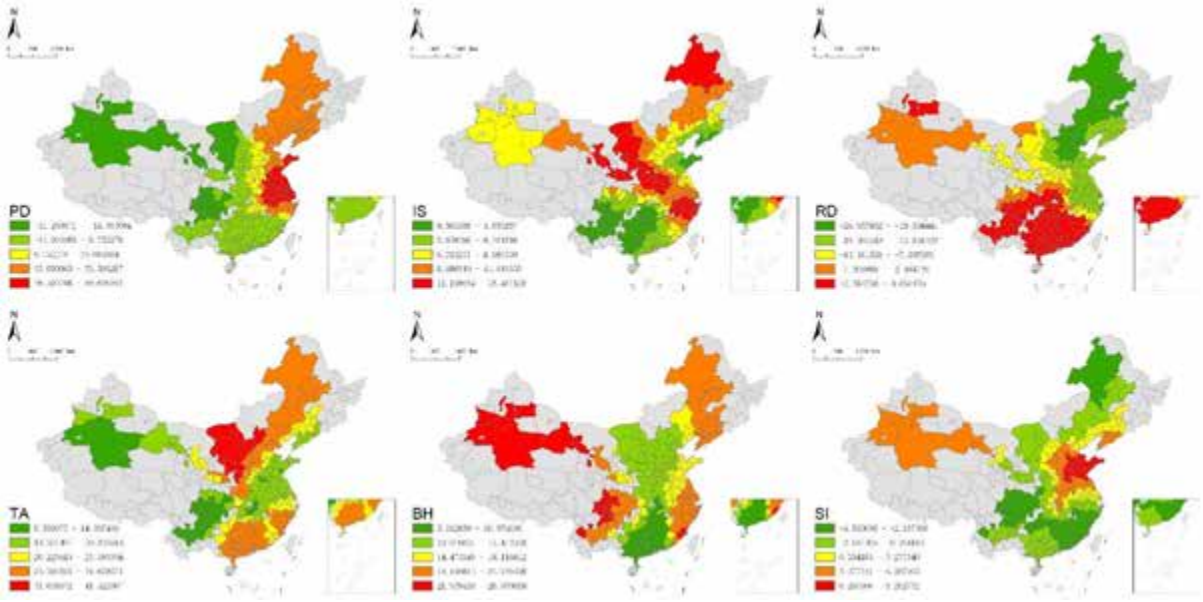

Figure 5 Spatial distribution of GWR local coefficient

Moreover, the study also found that PD has a bidirectional impact on urban CO2 emissions, generally showing a positive effect in the eastern and northern regions, while exhibiting a negative effect in the western, southwestern, and certain southern coastal regions. China's Tier 1 and Tier 2 cities are extensively distributed in areas such as the YRD and BTH regions. These areas are characterised by a generally high level of urbanisation and developed economies, which strongly attract populations, leading to significant migration to these regions. High population density implies more residential, transportation, commercial, and industrial activities, which directly result in increased energy consumption, thereby driving the rise in CO2 emissions. At the same time, high population density is usually accompanied by increased traffic pressures. Although the public transport systems in the YRD region are relatively well-developed, with further increases in population density, the use of private cars remains quite common, which can lead to traffic congestion and increased vehicle emissions, further driving up CO2 emissions.

In the central and western regions, most cities are Tier 3, Tier 4, or Tier 5 cities. These lower-level cities exhibit lower economic activity and energy consumption intensity, wherein an increase in population density actually enhances resource utilisation efficiency and reduces per capita carbon emissions. At the same time, due to their lower economic levels, cities with low development levels have limited demand for urban expansion and large-scale infrastructure construction. Compared to cities with high development levels, an increase in population density does not lead to large-scale construction activities that result in increased carbon emissions.

In the indicators of urban morphology, research has found that both BH and TA positively influence urban CO2 emissions. The impact of BH on urban CO2 emissions shows a trend of being high in the eastern coastal and western regions and low in the central region. The impact of TA on urban CO2 emissions exhibits a trend of being high in the southeastern coastal and northern regions, while relatively low in the northern coastal, southwestern, and northwestern regions.

The eastern coastal region is the core area of China's economy and industrialisation, featuring a rapid urbanisation process. Over the years of urbanisation, this has resulted in large urban built-up areas and generally taller building heights, gradually transforming into high-density cities. Greater building heights often indicate higher energy consumption, such as for elevator operation, air conditioning systems, as well as increased heating and lighting demands, leading to higher CO2 emissions. At the same time, due to greater ventilation, lighting, and cooling demands, high-rise buildings typically consume more energy per unit area than low-rise buildings, further exacerbating carbon emissions.

Additionally, eastern coastal cities concentrate a large amount of industry and services, with high population and economic activity densities. In the course of urbanisation, city expansion is required to accommodate significant population influxes, generally accompanied by substantial infrastructure construction, industrial activities, and transportation, all of which are major sources of CO2 emissions.

In the central and parts of western regions, Tier 2 and Tier 3 cities account for a large proportion. In recent years, rapid urbanisation and economic development have shown strong growth potential. Through policy support (such as the Western Development strategy), the urbanisation process has been accelerated in recent years. Some central cities (such as Chengdu, Chongqing, and Xi'an) are undergoing rapid growth, with the expansion of built-up areas and an increasing number of high-rise buildings. The energy consumption patterns of these buildings resemble those of the eastern coastal regions, resulting in building height having a significant impact on carbon emissions. In regions such as Yunnan, Guizhou, and Guangxi, where there are a larger number of Tier 4 and Tier 5 cities, most cities exhibit lower levels of urbanisation. The expansion of built-up areas is more evident in low-density urban development, with lower intensity in economic activities and energy consumption, thereby making the impact of built-up area size on CO2 emissions relatively small. In the northwestern regions (such as Xinjiang and Gansu), although the built-up area size has expanded somewhat, the low population density, relatively simplistic urban functionality, and industrialisation and economic activities concentrated in a few sectors (such as resource extraction) result in the built-up area size having a weaker impact on overall CO2 emissions.

The influence of RD on urban CO2 emissions is mainly negative, with only a few areas showing a positive impact (mostly in the PRD region). In northern regions, an increase in road density significantly reduces urban CO2 emissions, as these regions originally have low road density, potentially causing insufficient transportation networks, vehicle detours, and traffic congestion. High road density enhances connectivity within cities, providing residents with more travel options, shortening commuting distances, and reducing overall traffic carbon emissions. In contrast, the generally higher road density in the southern regions results in relatively smaller reductions in urban CO2 emissions with increased density. Additionally, the high road density in the Pearl River Delta region contributes to an increase in urban CO2 emissions. On the whole, cities at all development levels still need to further improve their road density, which aligns with the national requirement for road density to exceed 8km/km2.

Research findings indicate that SI factor also exhibits a bidirectional effect. In urban built-up areas of cities located in the northern coastal region, certain eastern coastal areas, parts of central regions, and specific regions of Xinjiang, an increase in the shape index of urban built-up areas leads to an increase in urban CO2 emissions, while an increase in the shape index in neighboring areas results in a reduction in urban CO2 emissions. This is because the irregular shape of urban built-up areas in these regions leads to increased transportation demand, thereby raising carbon emissions.

Discussion and Conclusion

Numerous studies have examined the driving factors of CO2 emissions, most of which rely on traditional regression models. These models fail to reveal spatial variations in these impacts, thereby overlooking the fact that due to differences in conditions and development statuses of these locations, the effects of factors may vary between different places. This study adopts a GWR model, which, instead of generating a single set of model parameters for the entire study subject, enables us to identify local variations in statistical relationships, where closer observations have a greater influence on the parameters than more distant ones.

Under the support of traditional regression models and geographically weighted regression models, we compared the coefficients of each driving factor globally and locally. The traditional ordinary least squares model shows that built-up area and building height are the main factors promoting CO2 emissions, while road network density negatively correlates with CO2 emissions. The remaining factors do not play a significant role in influencing CO2 emissions. Moreover, our geographically weighted regression model shows that the impact of these remaining factors varies spatially. Built-up area and building height still maintain a consistent positive correlation with urban CO2 emissions.

It is worth noting that the geographically weighted regression model used in the study also provides many important results not revealed by the ordinary least squares model, such as the bidirectional influence relationship

between factors like population density and shape index with urban CO2 emissions. For Tier 1 cities, most of the CO2 emissions are greatly influenced by factors like building height and built-up area, while being less influenced by secondary industry and shape index. Tier 2 and Tier 3 cities are greatly influenced by built-up area and also by secondary industry, building height, and road network density but are less influenced by other factors. Tier 4 and Tier 5 cities are significantly influenced by secondary industry and built-up areas.

In the eastern and central-western regions (e.g., Zhejiang, Henan, Hubei, Gansu, etc.), due to the dominance of traditional high-energy-consuming industries or high industrial aggregation, the secondary industry has a significant impact on carbon emissions. In contrast, coastal regions (e.g., the Pearl River Delta, Beijing-Tianjin-Hebei) and some Tier 1 cities (e.g., Beijing) experience a smaller impact due to industrial upgrading, relocation of high-energy-consuming industries, and strict carbon emission control policies. Population density exhibits a bidirectional impact on carbon emissions; in the eastern coastal areas, due to their strong economic attractiveness, increased habitation, transportation, commercial, and industrial activities lead to higher energy consumption. The impact of road density varies regionally; an increase in road density reduces carbon emissions in the northern regions, while in some cities of the Pearl River Delta, excessive road density increases carbon emissions. Building height and built-up area have a significant positive impact on carbon emissions, with building height having a greater influence in the eastern and western regions and a smaller impact in the central region. The built-up area has a higher impact in the southeastern coast and northern region and a lower impact in the central and northwestern regions. The shape index of built-up areas positively affects carbon emissions in the eastern and northern regions, whereas in other regions, the shape index factor reduces carbon emissions.

The advent of climate change has drawn global attention to how urban carbon dioxide emissions can be reduced. From this perspective, China's rapid development not only threatens the country's sustainable development but also impacts future climate change. However, due to varying levels of urban development and differing processes of urbanisation, it is crucial to study how disparities in urban development levels affect the relationship between urban morphology and CO2 emissions.

Despite our research findings demonstrating the increasing trend of carbon dioxide emissions, economic development remains a prerequisite for the vast majority of cities in China. However, cities at different stages of development can make industrial layout choices based on their respective carbon emission characteristics. Additionally, renewable energy sources such as wind and tidal energy can be introduced, or cities can continue developing advantageous renewable energy industries according to natural conditions. For example, cities in Sichuan and Yunnan can further develop hydropower. Policies related to population also need to be improved by controlling the population size in economically developed cities along the southeast coast and directing labor migration toward cities in the western and northeastern parts of the country. Suitable urban built-up area intensity development should be undertaken according to city rank and population density, controlling building heights and road network density to achieve compact urban development or appropriately expanding urban built-up areas to advance urbanisation processes. China undoubtedly faces significant challenges in reducing and maintaining carbon dioxide emissions according to internationally recognised standards; we hope our research contributes to this endeavor to some extent.

Abstract
Aligned with global sustainability goals, this study examines how facility service and sharing structures influence urban carbon emissions. Using Nanjing as a case, a multi-scale system is developed across four facility types: education & health, culture & sports, convenience & utility, and commercial & leisure. Shared community clusters are identified via isochrone analysis and strongest-link mapping. Carbon emission impacts are evaluated using both univariate and multivariate regressions. Results reveal type-specific differences in spatial sharing patterns and emission sensitivities, with cultural facilities showing the strongest effects. A carbon-oriented planning strategy is proposed, advocating differentiated configurations of self-sufficient and shared facilities based on facility-type characteristics and spatial service structures.

Keywords: community life circle; facility sharing; cluster identification; carbon emissions

1.Introduction

Driven by sustainability goals, developing low-carbon spatial governance models has become a vital strategy for urban development. As the fundamental spatial unit of everyday life, the community life circle plays a critical role in shaping activity distribution, mobility patterns, and service efficiency, making it a key focus in low-carbon urban research (Hong et al., 2020)it is necessary to reduce energy use and associated greenhouse gas emissions in buildings through energy conservation and efficiency improvements. Computational tools empowered with rich urban datasets can model performance of buildings at the urban scale to provide quantitative insights for stakeholders and inform their decision making on urban energy planning, as well as building energy retrofits at scale, to achieve efficiency, sustainability, and resilience of urban buildings. Designing and operating urban buildings as a group (from a city block to a district to an entire city. By integrating essential services—such as education, healthcare, commerce, and cultural amenities—within walkable or short-travel distances, life circles encourage more compact, efficient, and greener lifestyles, thereby contributing to city-wide carbon reduction efforts (Bruno et al., 2024)in particular, heralded a new vision for cities where essential services must be easily accessible. Despite its undoubted merit in stimulating discussion on new organization of cities, the 15-minute city cannot be applicable everywhere, and its very definition raises a few concerns. Here we tackle the feasibility and practicability of the 15-minute city model in many cities worldwide. We provide a worldwide quantification of how close cities are to the ideal of the 15-minute city. To this end, we measure the accessibility times to resources and services, and we reveal strong heterogeneity of accessibility within and across cities, with a pivotal role played by local population densities. We provide an online platform (https://whatif.sonycsl.it/15mincity/

Most existing studies on community life circles emphasize internal completeness, focusing on service sufficiency, accessibility, or equity within individual communities. However, in practice, significant service overlap and facility sharing exist between communities. These shared connections form interconnected clusters, where multiple life circles are functionally linked through shared facilities (Pan, 2023)ΔSuch clusters often transcend administrative or physical boundaries, reflecting more complex patterns of service coverage and functional interdependence. While this configuration may enhance facility utilization and spatial flexibility, its systemic implications for mobility, service reliance, and local carbon emissions have yet to be fully understood or quantified (Chai and Li, 2019)Δ

As cities become more polycentric and resource allocation more distributed, the structure of these shared clusters may play a key intermediary role in shaping urban carbon emissions. Identifying these clusters and clarifying their impact mechanisms is crucial—not only for refining life circle planning, but also for advancing precision carbon governance at the community scale. The lack of integrated models that combine spatial structure, facility interaction, and environmental outcomes remains a critical gap in current literature.

This study takes Nanjing, China as a case to examine how spatial accessibility and facility sharing patterns influence carbon emissions at the local level. First, a multi-scale life circle system is constructed based on 5-, 10-, and 15-minute isochrones, covering four essential service categories: education & health, culture & sports,

convenience & utility, and commercial & leisure. Second, based on accessibility and spatial overlap, functionally connected shared clusters are identified through a strongest-link network approach. Third, service intensity (number of accessible facilities) and sharing intensity (the share of facilities engaged in cross-community use) are used in univariate regression models to evaluate their individual effects on carbon emissions. Finally, a multivariate regression model incorporates the combined characteristics of multiple facility types to reveal potential synergistic or compensatory effects on emissions.

This research addresses the following questions:

- How do facility configuration and inter-community sharing jointly shape shared cluster structures?
- How do service and sharing intensities across different facility types influence carbon emissions?
- Do multidimensional sharing patterns lead to synergies or trade-offs in emission outcomes?

The findings provide new insights into the functional logic linking urban facility networks and emission patterns, offering evidence-based guidance for carbon-oriented planning and optimized life circle service configurations. The proposed framework contributes to both academic understanding and practical strategies for managing the spatial-energy nexus in future sustainable cities.

2.Methodology

This study focuses on the central urban area of Nanjing and develops an analytical framework that links facility types and accessibility, sharing structures, and carbon emission impacts. Using multi-scale isochrone analysis, community-specific facility access was identified to define facility bundles for each neighborhood. Based on the overlap between these bundles, sharing relationships were established to construct facility sharing networks and delineate shared clusters. Finally, integrating community-level carbon emission data, the analysis evaluates how service intensity and sharing intensity influence emission outcomes.

2.1Classification of Facility Types and Definition of Facility Bundles

The appropriate composition of facilities within community life circles has been widely discussed in prior research. Frameworks for defining such systems typically consider two key dimensions: accessible travel time (He et al., 2024; Logan et al., 2022, p. 10; Staricco, 2022) and facility type (Liu et al., 2024; Moreno et al., 2021)there is a lack of comprehensive measures and an overall understanding of the 15-minute city status. By using the latest population census data and POI data in Hong Kong, this study proposes a 15-minute city index that holistically measures the 15-minute city status by incorporating the accessibility, which is measured by a modified two-step floating catchment area (2SFCA. Based on daily living needs, this study establishes a facility system comprising four core service functions: education & health, culture & sports, convenience & utility, and commercial & leisure. Building upon this classification, 5-, 10-, and 15-minute isochrones are introduced to define three levels of service space—self-sufficient (5-minute), neighborhood-level (10-minute), and shared (15-minute) life circles. Each level corresponds to a different spatial scale of facility provision and is associated with a set of representative facility types. The detailed facility composition is as follows (Table1):

Table 1 Facility Composition Across Life Circle Scales and Service Categories

	5min (Self-Sufficient)	10min (Neighborhood)	15min (Shared)
Commerce & Leisure (C&L)	Restaurants	Dessert shops, beverage stores Teahouses, mahjong clubs, karaoke Pet and plant markets Bathhouses, salons	Cinemas, theaters Shopping malls, amusement parks
Education & Health (E&F)	Pharmacies	Kindergartens Primary schools Clinics, specialty hospitals	General hospitals Middle schools
Culture & Sports (C&S)	Small public spaces	Cultural store Gymnasium	Museums, art galleries, cultural centers Parks, squares, stadiums Scenic spots, zoos, aquariums
Convenience & Utility (C&U)	Parcel stations Public transport (bus/metro) Convenience stores Parking lots	Telecom service centers Charging stations Wet markets	Postal services Banks Gas and fueling stations Elderly care centers

Specifically, the education & health category includes various levels of medical and educational facilities, reflecting the progressive expansion of basic healthcare and compulsory education services. The culture & sports category spans from small public spaces and local sports venues to parks, squares, and museums, covering both everyday and occasional cultural and recreational needs. The convenience & utility category comprises parcel stations, convenience stores, public transport (bus/metro), parking lots, charging stations, banks, wet markets, gas stations, and elderly care centers, addressing daily goods acquisition and mobility support. Lastly, the commerce & leisure category ranges from local entertainment facilities—such as restaurants, dessert shops, and teahouses—to cross-community consumption venues including cinemas, shopping malls, and amusement parks.

Subsequently, 5-, 10-, and 15-minute isochrones were generated for each community using central point locations and the Mapbox API. Through spatial overlay analysis, all reachable facilities within each time threshold were identified. This resulted in a multi-scale dataset of community facility bundles, recording the number and types of accessible facilities—across the four service categories—for each community at each isochrone level.

2.2 Identification of Shared Community Clusters

Based on the constructed facility bundles, sharing relationships between communities were identified by examining the overlap of accessible facilities. If two communities shared one or more facilities within the same isochrone threshold, they were considered to have a facility-sharing connection. This sharing logic was applied across two dimensions: three isochrone levels (5, 10, and 15 minutes), and four facility categories (education & health, culture & sports, convenience & utility, and commerce & leisure), resulting in a set of multi-dimensional facility sharing networks.

In each network, nodes represent communities and edges represent facility-sharing links, with edge weights indicating sharing intensity (e.g., number or proportion of overlapping facilities). To capture the most significant sharing relationships, each community's strongest sharing partner—the community with the highest sharing intensity—was identified. These links were used to construct a strongest-link sharing network, from which shared community clusters were delineated. Each cluster comprises communities that are directly or indirectly connected via their strongest facility-sharing ties.

Each facility-specific network yields a corresponding set of Shared Community Clusters, reflecting the spatial sharing structure and functional distribution of that facility type across the city. These clusters not only reveal patterns of inter-community service reliance, but also serve as the fundamental spatial units for the subsequent analysis of carbon emission impacts.

2.3 Carbon Emission Patterns under Facility Service-Sharing Structures

Following the identification of shared community clusters, this study incorporates community-level carbon emissions data and conducts a two-level regression analysis to systematically evaluate the impact of service and sharing characteristics on carbon outcomes. The analysis includes:

- Univariate regression analysis (cluster level): Each analysis unit corresponds to a set of shared community clusters derived from one specific facility type. The average carbon emission of all communities within each cluster is calculated. Two explanatory variables are extracted: the service intensity (total number of facilities within the cluster) and the sharing intensity (proportion of shared facilities). Linear regression is employed to assess the direction and significance of emissions impact across different facility types, revealing the emission patterns associated with single-type sharing structures.
- Multivariate regression analysis (community level): Each individual community serves as the unit of analysis. A multidimensional vector of service and sharing intensities is constructed, encompassing all four facility types. A multiple linear regression model is applied to evaluate the composite influence of different facility types within the overall sharing network, exploring whether their effects on carbon emissions are synergistic, complementary, or substitutive.

To enhance interpretability, the model incorporates standardized variables and controls for multicollinearity. This analytical framework facilitates a macro-level understanding of how facility sharing structures shape urban carbon emissions, while also uncovering the complex interactions among multiple services at the micro (community) level.

3.Results

3.1Shared Facility Structures in Community Life Circles

Figure 1 illustrates the facility sharing network structures across communities in Nanjing's central urban area, differentiated by isochrone thresholds (5, 10, and 15 minutes) and facility types. From the perspective of overall sharing networks, inter-community connections intensify significantly as the time radius expands. In the 5-minute life circle, only 574 sharing edges are observed, with an average degree of 0.94, indicating that most facility use is confined within individual communities. In contrast, the number of sharing edges increases to 2,517 and 7,346 in the 10- and 15-minute networks, with corresponding average degrees rising to 4.12 and 12.02, respectively. This reflects a transition from "local self-sufficiency" to "regional sharing," with a progressively higher level of spatial integration.

Facility-specific sharing networks also exhibit clear variations in network connectivity and cluster configuration. The culture & sports (C&S) network shows the highest average degree (18.77), indicating the strongest and widest sharing pattern. The commerce & leisure (C&L) and convenience & utility (C&U) networks also show relatively high degrees of connectivity (15.61 and 15.86, respectively). In contrast, the education & health (E&H) network has a lower average degree of 11.77, suggesting weaker inter-community ties and a more localized pattern of service provision.

The red edges in the figure highlight each community's strongest sharing connection, further revealing the diversity of shared community cluster structures. Across different facility types, the same community often links to distinct target communities, resulting in divergent cluster affiliations in each facility-specific network. This indicates a functional divergence in sharing behavior: communities exhibit varying patterns of cooperation and service coupling depending on the facility category. Such differentiation reflects the complexity of multi-dimensional sharing structures in urban space and lays the groundwork for analyzing how different types of facility sharing influence carbon emissions.

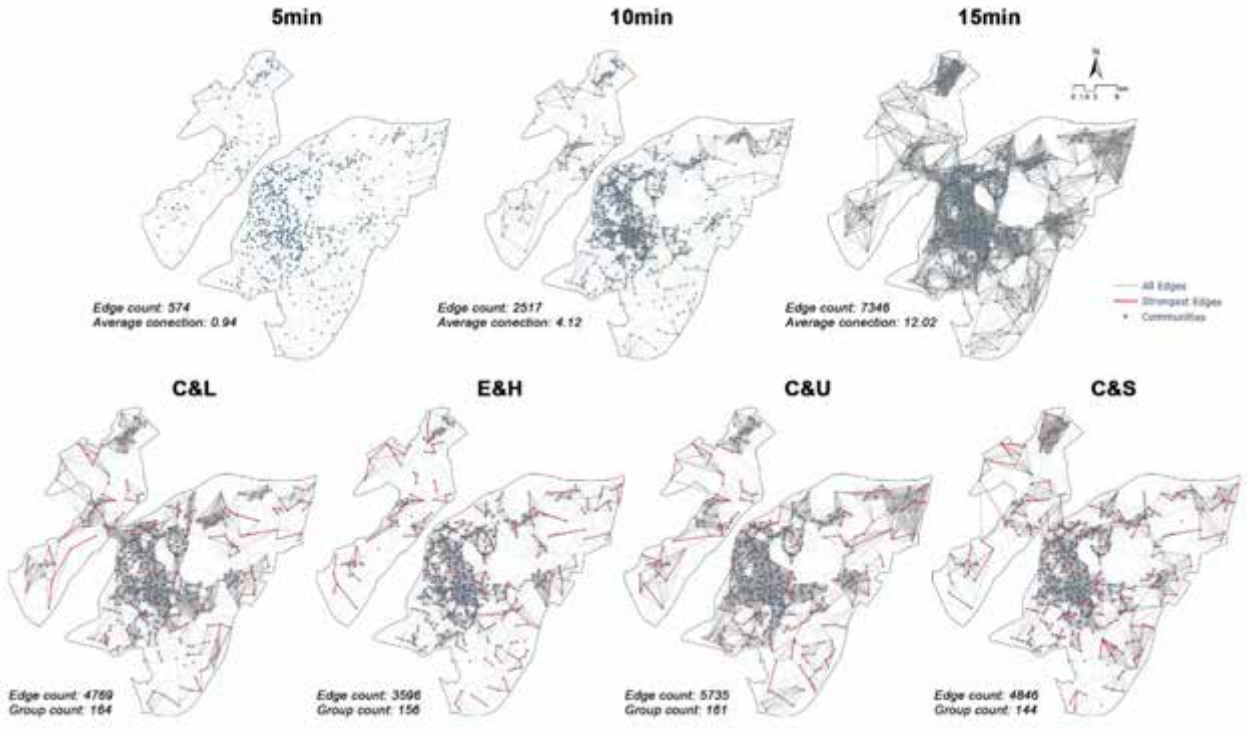

Figure 1 Community facility sharing networks under different time scales and facility types

Building upon the constructed sharing networks, two key indicators—service intensity and sharing intensity—were calculated for each community (or shared community cluster) across different facility types (Figure 2).

In terms of service intensity (left panel), the four facility categories exhibit substantial variation in spatial distribution. Commercial & leisure (C&L) facilities are markedly more abundant and widespread than the other types, with service intensity exceeding 3,000 in some communities, indicating a high-density clustering pattern. In contrast, the median and upper quartile values for education & health (E&H), culture & sports (C&S), and convenience & utility (C&U) are consistently lower, reflecting compact distributions with generally low intensity. This suggests these facilities are more evenly distributed across the city but exhibit lower localized density.

As for sharing intensity (right panel), all four categories present broadly similar distribution patterns, yet subtle differences emerge. Culture & sports (C&S) and convenience & utility (C&U) facilities show slightly higher sharing intensities, implying a greater propensity for overlapping usage across communities and stronger sharing potential. By contrast, education & health (E&H) exhibits lower sharing intensity overall, with some communities showing near-zero sharing proportions—suggesting spatially confined service areas with limited cross-community reach. Despite the high service intensity of commercial & leisure (C&L) facilities, their sharing intensity is more dispersed, indicating strong shared usage in some regions while remaining locally concentrated in others. Collectively, service intensity captures the spatial density of different facility types, while sharing intensity reflects their potential for inter-community connectivity. The combination of these metrics provides a quantitative basis for characterizing the shared facility structures within urban life circles and supports the subsequent analysis of their association with carbon emissions.

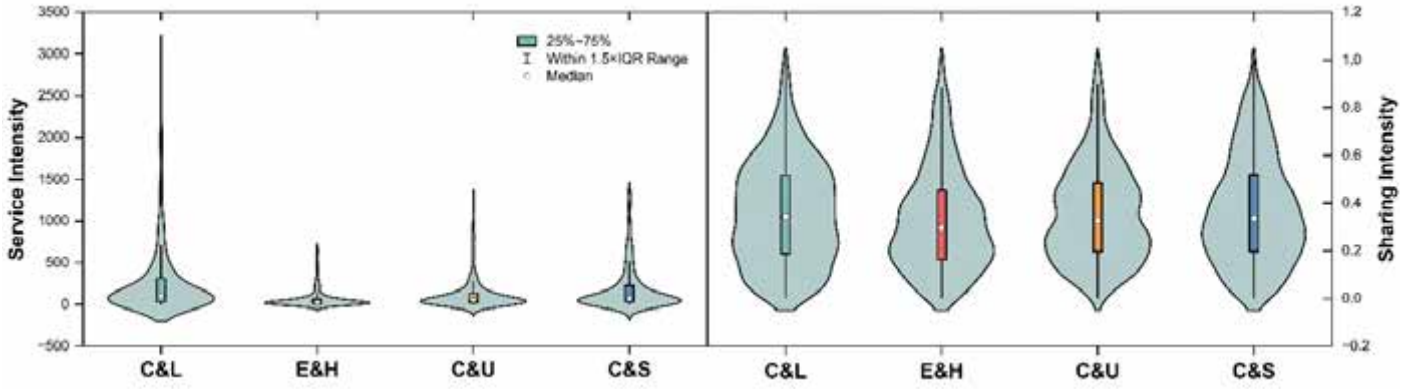

Figure 2 Distribution of service intensity and sharing intensity across facility types

3.2 Carbon Emission Patterns across Single-Type Sharing Clusters

Figure 5 presents the spatial distribution of carbon emissions at both the community level and the shared cluster level. The left panel illustrates carbon emissions at the community level, derived by overlaying ODIAΔC gridded data with community boundaries(Tomohiro Oda and Shamil Maksyutov, 2015). The results reveal a clear spatial pattern of "high in the center, low in the periphery" across Nanjing's central urban area. The emission values are right-skewed and spatially asymmetrical, aligning with the concentration of population and built-up intensity in the urban core.

The four maps on the right display carbon emissions aggregated by shared community clusters for each facility type: commercial & leisure (C&L), education & health (E&H), culture & sports (C&S), and convenience & utility (C&U). These cluster-based maps reveal notable differences in emission distribution. Clusters derived from C&L and C&S sharing networks tend to reinforce carbon concentration in central areas, indicating strong overlap of high-emission communities within their shared structures. In contrast, clusters based on E&H and C&U display more dispersed carbon emission values, suggesting a broader spatial distribution of functional dependencies and a weaker centralizing effect.

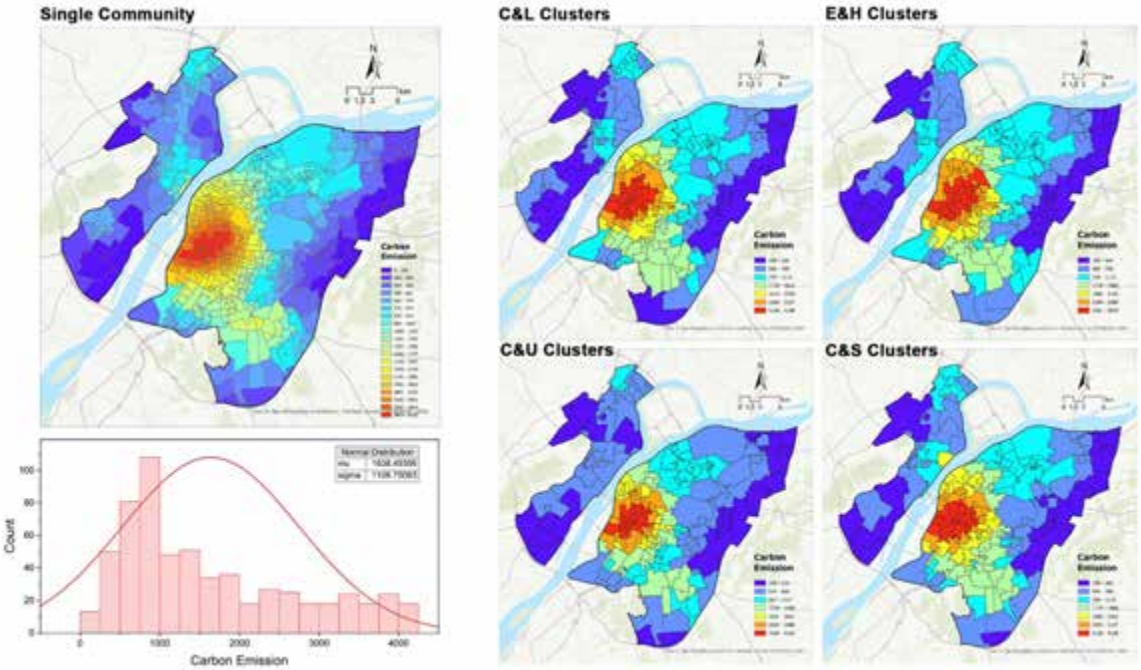

Figure 3 Spatial distribution of carbon emissions at the single community level and facility-based sharing cluster level

To further quantify the carbon implications of different facility sharing structures, Figure 6 presents the results of univariate linear regression models using service intensity (left) and sharing intensity (right) as independent variables. All four facility categories exhibit a statistically significant positive correlation with carbon emissions ($p < 0.001$), but differ notably in both explanatory power and marginal impact.

In the service intensity models, culture & sports (C&S) and convenience & utility (C&U) demonstrate the highest model fit ($R^2 = 0.351$ and 0.336, respectively), indicating their facility counts have the strongest explanatory power for community-level emissions. Education & health (E&H), in contrast, shows the steepest regression slope (22.276), meaning each additional unit of service intensity contributes the most to carbon emissions, reflecting a stronger marginal emission effect. Commercial & leisure (C&L) performs moderately in both R^2 (0.258) and slope (2.261).

In the sharing intensity models, overall explanatory power is slightly lower (highest $R^2 = 0.204$ for C&S), but the gradient of impact across facility types remains clear. E&H and C&S exhibit the steepest slopes (632.992 and 540.703), suggesting their cross-community usage significantly amplifies emissions—likely due to increased travel distances or facility aggregation effects. In contrast, C&L and C&U show weaker slopes and lower R^2 values, implying a more limited marginal effect, potentially constrained by their proximity-based service characteristics. In summary, service intensity reflects the facility provision baseline and acts as the primary determinant of carbon emissions, while sharing intensity captures the spatial extension of facility usage and contributes a type-dependent marginal modulation effect.

From a planning perspective:

- In areas with facility oversupply or high density, uncontrolled expansion of E&H and C&S facilities should be avoided, especially where local service is sufficient but sharing value is low, to mitigate marginal carbon impacts.
- For C&L and C&U, which exhibit weaker carbon implications, improving sharing efficiency through strategic coordination can help avoid redundant investments and spatial inefficiencies.
- New infrastructure should prioritize local self-sufficiency for foundational services like E&H, reducing inter-community trips.
- In contrast, C&L and C&S may benefit from enhanced sharing configurations, where well-placed nodes promote broader service coordination without compromising emission control.

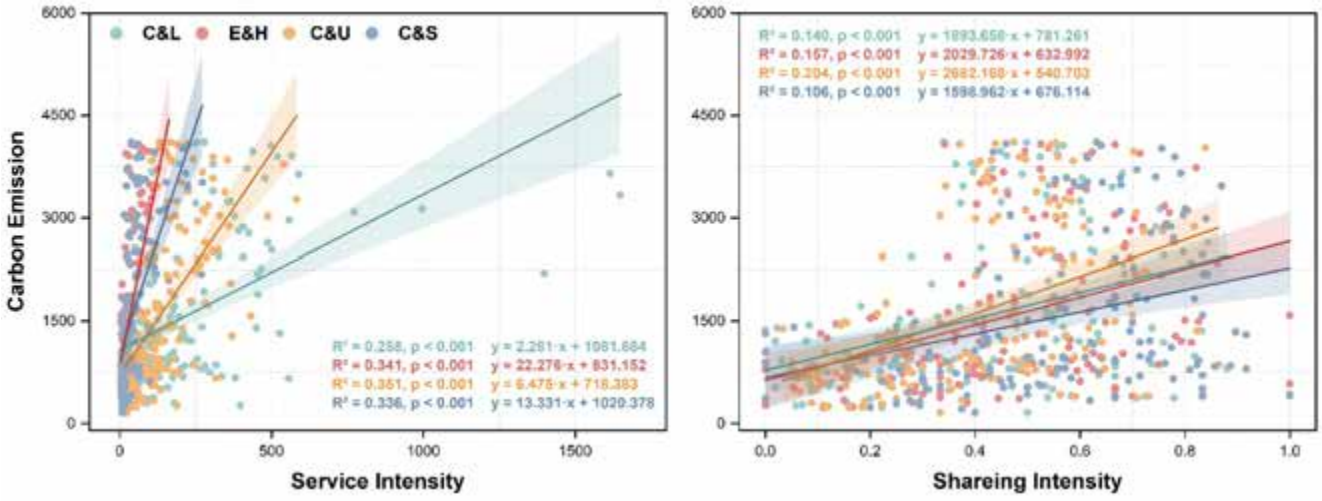

Figure 4 Univariate regression between service/sharing intensity and carbon emissions across facility types

3.3 Carbon Emission Patterns under Multi-Dimensional Sharing Structures

To further evaluate the joint effects of different facility types across both dimensions—service intensity and sharing intensity—Figure 7 presents standardized coefficients and 95% confidence intervals from a multiple linear regression model. Compared with the previous univariate results, the multivariate model controls for cross-variable interactions and reveals a more structured mechanism of carbon emission drivers.

On the service intensity dimension, culture & sports (C&S) and convenience & utility (C&U) facilities continue to show significant positive effects. Notably, C&S holds the highest coefficient, suggesting that even after adjusting for other facility types, the service density of C&S facilities remains one of the strongest drivers of carbon emissions. In contrast, commercial & leisure (C&L) and education & health (E&H) show significant negative coefficients in the multivariate model—opposite to their positive trends in the univariate analysis. This suggests that, once the effects of C&S and C&U are accounted for, higher service intensity of C&L and E&H may actually correlate with reduced carbon emissions, potentially indicating a substitution effect or mixed-use efficiency in highly integrated facility zones that mitigates marginal emission pressure.

On the sharing intensity dimension, C&S again emerges with the strongest positive effect, reaffirming its high-emission association through cross-community usage. E&H also maintains a positive effect, albeit with lower magnitude. C&U shows no significant impact in the multivariate model, while C&L retains its negative association, suggesting that over-sharing in some cases may result in inefficient trips due to redundant facility usage.

Overall, the multivariate model reveals differentiated roles and interactions among facility types:

- C&S facilities contribute to increased emissions in both service and sharing dimensions, highlighting them as critical intervention targets in low-carbon facility planning.
- E&H facilities show a duality—while sharing may raise emissions, enhancing localized service capacity could yield mitigation benefits, supporting a “proximity-based” planning logic.
- C&L facilities exhibit negative marginal contributions in the multivariate context, indicating that concentrated deployment with efficient sharing could improve carbon performance.
- C&U facilities show relatively mild carbon impacts, suggesting that optimizing sharing coverage may enhance system-level efficiency without large emission trade-offs.

These findings underscore the need to avoid one-size-fits-all expansion strategies. Instead, urban planning should adopt a type-sensitive approach by aligning facility density, sharing structure, and carbon responsiveness in a coordinated framework—guiding community-scale infrastructure development toward greater efficiency, lower emissions, and structural synergy.

Figure 5 Regression coefficients of service and sharing intensity on carbon emissions in a multivariate model

4.Discussion

Using Nanjing as a case study, this research systematically constructed the facility sharing network structure across communities and examined the impact mechanisms of different facility types on community-level carbon emissions through the dual dimensions of service intensity and sharing intensity. The network was established by delineating isochrone-based service areas and identifying the strongest shared facility edges between communities, forming functionally connected structures. These were further categorized into four shared community clusters, each dominated by a specific facility type. Spatial analysis revealed significant differences in emission patterns among cluster types: clusters dominated by commercial & leisure (C&L) and culture & sports (C&S) facilities exhibited dense emission hotspots in central areas, while education & health (E&H) and convenience & utility (C&U) clusters showed more dispersed distributions.

Regression analyses further highlighted the heterogeneous impacts of service and sharing intensity across facility types. In the univariate models, service intensity consistently exhibited stronger explanatory power for carbon emissions than sharing intensity, confirming facility density as a primary driver. Nonetheless, sharing intensity showed significant positive effects in C&S and E&H types, suggesting that shared facility usage may increase inter-community travel and energy consumption under certain conditions. In the multivariate models, some variables (e.g., service intensity of E&H, sharing intensity of C&L) reversed direction, indicating that spatial substitution and functional coupling among different facility types can mediate carbon outcomes.

These findings provide important implications for low-carbon urban facility planning. First, C&S facilities, which significantly contribute to emissions in both dimensions, should be key targets for emission control—through capacity regulation, spatial optimization, and managed sharing mechanisms. Second, E&H facilities are better

suited for self-sufficient local provision, minimizing reliance on inter-community travel. Lastly, C&L and C&U facilities demonstrate carbon-efficient sharing potential, and should be enhanced through regional coordination strategies to maximize service efficiency and resource utilization.

In sum, the impact of facility sharing structures on urban carbon emissions is structural and multidimensional. Effective planning must adopt type-specific strategies that align facility density, sharing patterns, and carbon responses, enabling synergistic control toward more efficient and sustainable urban living environments.

5.Conclusion

This study proposes an integrated analytical framework that combines isochrone analysis, facility sharing network construction, and carbon emission response evaluation to investigate how the sharing structures of different facility types within community life circles influence urban carbon emissions. Using Nanjing as a case study, we constructed cluster structures based on facility types and sharing intensity, quantified the dual-dimensional contributions of service intensity and sharing intensity, and employed both univariate and multivariate regression models to reveal differentiated impact patterns across facility types. The main conclusions are as follows:

- Facility sharing networks exhibit clear spatial and typological variations, with clusters dominated by different facility types displaying distinct emission concentration patterns;
- Service intensity acts as a key driver of carbon emissions, particularly for culture & sports and convenience & utility facilities, while the effect of sharing intensity is more type-sensitive, with culture & sports and education & health showing significant positive associations;
- Multivariate models reveal interaction effects and sign reversals among facility types, suggesting that the regulatory role of sharing structures on carbon emissions is complex and structural;
- Low-carbon urban planning should adopt type-specific strategies: fostering self-sufficiency where appropriate, and promoting shared usage where beneficial, to advance low-carbon and synergistic optimization of community life circles.

This research provides an empirical basis for understanding the intrinsic relationship between urban spatial structure and carbon emissions, offering concrete typological guidance for urban facility allocation and emission mitigation policies. Future studies may incorporate dynamic mobility behaviors, big-data-based flow metrics, and lifecycle emission accounting to develop more refined models of urban carbon response.

Abstract
Introduced by the UN, the carbon trading mechanism aims to balance countries' GHG emissions and decrease CO2. It allows developed countries to compensate for their excessive emissions by assisting developing countries in boosting their climate resilience. However, offset projects are often criticized for prompting neocolonial practices by promoting land grabbing and overlooking local needs. This research investigates how spatial planning can support more just and effective carbon offsetting with focusing on Uganda's experience. Through policy analysis and comparative case studies, a landscape of project implementation is presented. Findings show that multilevel governance, community involvement, and land-use management are critical to deliver justice. Drawing from Uganda's experience, the study proposes that spatial planning is crucial for aligning global carbon policies with local justice goals.

Keywords: carbon trading systems, environmental justice, climate colonization, spatial planning

1.Introduction

Climate change is one of the most pressing global challenges, and although all countries share responsibility, its impacts are felt unevenly. Particularly, vulnerable regions and communities in the Global South are disproportionately affected (IPCC, 2023). These unequal impacts deepen existing social, economic, and environmental inequalities, raising fundamental questions about who contributed the most, who should act, and who has the resources to do so (Mohai et al., 2009). To address these issues, the United Nations introduced the carbon market mechanism in 1997 within the Kyoto Protocol. However, in its short but intense history, the mechanism has faced serious criticisms. Even though each country operationalized the projects in different ways regarding their own environmental, political, social, and economic contexts (Purdon & Byakagaba, 2022), the negative outcomes of the projects have raised concerns for what costs these projects have been operationalized, and the criticisms included that the mechanism laying the groundwork for neocolonization under the guise of green initiatives (Carton et al., 2020; Enríquez-de-Salamanca, 2024)

Introduced under the Kyoto Protocol in 1997, and later expanded into voluntary markets, carbon trading systems were designed to reduce global greenhouse gas (GHG) emissions by allowing countries or companies to offset their emissions through investments in mitigation projects elsewhere (UNFCCC, 1998; Michaelowa et al., 2019). In theory, these mechanisms were expected to serve both global environmental goals and local development needs. Yet in practice, carbon offset projects have often been criticized for excluding local communities, marginalizing indigenous knowledge, undermining sovereignty over land, and prioritizing market efficiency over social and ecological justice (Bachram, 2004; Gonzalez, 2021; Sultana, 2023).

Among the Global South countries, Uganda is a particularly relevant case study in this context. As one of the Least Developed Countries (LDCs), with high levels of climate vulnerability and a strong reliance on foreign investment, it has emerged as a hotspot for carbon offset initiatives. Uganda is currently the fourth-largest producer of carbon credits in Africa (EAA, 2022), the country's colonial legacy (Gebremichael, 2016), fragmented land tenure system (Fisher, 2012; Fisher et al., 2018), decentralized governance structure (Ojambo, 2012), and institutional weaknesses (Ampaire, et al., 2018; Fisher, 2012; Fisher et al., 2018) complicate the implementation of such projects.

These challenges often lead to uneven outcomes across regions and communities, where some benefit while others are displaced or excluded from decision-making.

1 The title of the proposal was changed from "Geographies of Carbon Trading: Spatial Planning Approaches for Equitable Offset Projects" to better reflect the focus of the paper.

2 The author used AI-assisted tools to improve the clarity and correctness of the language.

Although traditionally underexplored in climate finance discussions (Bumpus & Liverman, 2008), spatial planning can play a central role in operationalizing more just and effective carbon offset mechanisms (Knuth et al., 2025). Concerned with land management, policy integration, and stakeholder participation, it offers practical tools for navigating these challenges and can help guide land allocation, manage competing interests, and ensure that global climate strategies align with local needs and capabilities (Ay, 2025).

This paper aims to contribute to this discussion on how spatial planning tools can enhance the operationalization of carbon markets by analyzing how carbon offset projects are conducted in Uganda, which has a long history with such kind of mechanism, having both successes and failures. Drawing on policy analysis, a comparative case study of two offset projects, and insights from interviews with local experts, the paper investigates how governance structures, stakeholder dynamics, and land management systems shape project outcomes. The central argument is that spatial planning, if meaningfully integrated, can address many of the criticisms levelled at carbon markets, particularly around governance, inclusivity, and land management.

After this brief introduction, Section 2 sets the context for the subject at stake, introducing carbon markets from a critical standpoint and reflecting on how spatial planning can contribute to bridging the gap with Climate Justice. Then Section 3 explains the methodology implemented in this research, and Section 4 presents the outcomes. The concluding section rounds off the contribution, summarizing its main messages and paving a number of avenues for future research on the matter.

2.Carbon Markets, Justice and Spatial Planning

This section provides a brief overview of carbon markets and the critiques they have sparked in environmental and climate justice debates. Finally, it explores how carbon markets, justice concerns, and spatial planning intersect.

2.1. Carbon Markets

Aiming to balance responsibilities between developed and developing countries, the carbon market mechanism is designed to channel financial resources by converting GHG emissions into tradable units and allowing their exchange. It enables industrialized countries that exceed their annual GHG limits to invest in emission reduction projects elsewhere and, in return, purchase unused emissions allowances (Michaelowa, 2019; EAA, 2022). The main objective is to compensate for environmental damage caused by high-emitting developed countries by supporting mitigation efforts in more vulnerable countries (Bond et al., 2012). The focus of projects varies based on national needs and investor interest (EAA, 2022).

Figure 1 System of Carbon Market Mechanism (Ay, 2025)

Over the years, the mechanism has evolved under the influence of new regulations and market forces. Currently, with one of them cancelled but still having operational projects, there are three different carbon market mechanisms:

Kyoto Protocol's Mechanism

As the initiator of the carbon offset mechanism, the Kyoto Protocol offers two different mechanisms for carbon trading, namely Joint Implementation (JI) and Clean Development Mechanism (CDM). While JI has been mostly operated among developed countries (Annex A), CDM has operated between developed and developing countries (Annex B). These mechanisms were started to be operated in 2005 and they lasted until 2020. During this period of time, CDM has been a preferred mechanism to compensate GHG emissions. In these operational processes,

the main stakeholders that took roles are the UN's Executive Bodies, project developers which is also Investors, the Host's Designated National Authority, and Designated Operational Entities as the third-independent party (Pollack and Wilson, 2009; UNDP, 2015).

Figure 2 CDM's Project phases, governance structure (adapted from Kollmuss et al., 2008)

Voluntary Carbon Market

The voluntary carbon market was created by private market actors as an alternative to the Kyoto Protocol's rigid and complex mechanism in the early 2000s, and still actively used by a wide range of market players ranging from big companies to individuals (Pagop & Savard, 2024). And instead of having strict rules about the countries, projects, and actors, VCM is regulated by a set of rules and frameworks that have been created by organizations. Seven different[3] standards have been most commonly used by the market actors, and they vary based on the project types they usually accept (Kollmuss et al., 2008). Alongside the regulatory flexibility, VCM also allows all the bodies that want to be a part of the mechanism to participate in the market with almost no rules and no regulations (Ahonen et al., 2022; Bumpus and Liverman, 2008). Therefore, even though the stakeholders that take roles in the processes vary, the key actors in the process are project designers and investors; Carbon Standards; and the auditors; and, depending on the host countries' regulations, National and Local Authorities take part in the implementation of the projects (Kollmuss et al., 2008; Streck et al., 2021).

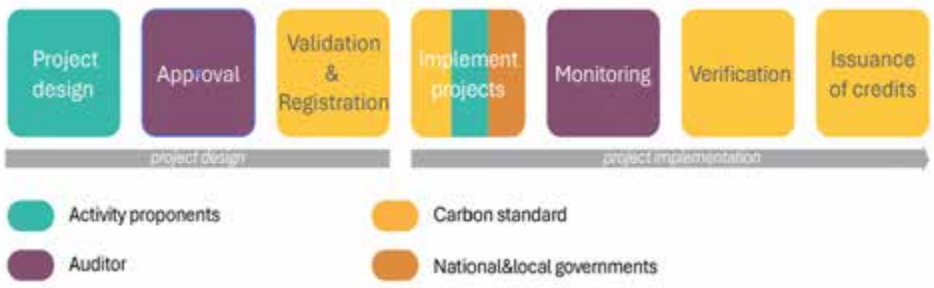

Figure 3 VCM project cycle (adapted from Streck et al., 2021)

Operationalization and Critics

These two mechanisms have been criticized for different aspects. One of the most discussed points about the Kyoto Protocol's carbon trading mechanism is its top-down approach, which starts at the supranational level and rarely reaches local levels. This has led to an oversimplification of national and subnational governance structures, prioritizing market benefits over global environmental objectives (Carton et al., 2020). Alongside that, the complexity of the documents and administrative burden have made the mechanism less accessible, especially for countries with limited institutional capacity. Moreover, the division between "developed" and "developing" countries has deepened existing inequalities, with investment flowing primarily to certain countries while others, particularly in Africa, were left behind (Akrofi, 2024).

As a result, CDM has been criticized for its complicated structure, the decisions it generated, and its failure to

3 As of 2025, the most commonly used Voluntary Carbon Market (VCM) standards include Verra (VCS), Gold Standard, Plan Vivo, Climate Action Reserve (CAR), American Carbon Registry (ACR), and Cercarbono. Project developers select the standard based on the type of project they aim to implement. While Verra, Gold Standard, ACR, CAR, and Cercarbono accept a wide range of greenhouse gas (GHG) reduction projects, Plan Vivo primarily focuses on Land Use, Land-Use Change and Forestry (LULUCF) projects (Kollmuss et al., 2008; Ecosystem Marketplace, 2024).

include or empower critical actors involved in implementation.

On the other hand, while the VCM made the mechanism more accessible by allowing various actors to participate, it has also been criticized for its lack of regulation and oversight, leading to low accountability and transparency (Pagop & Savard, 2024). As project quality declined and questionable credits continued to circulate, many initiatives were eventually labeled as greenwashing, which caused a significant loss of credibility (Oakland Institute, 2017). Overall, both mechanisms have been accused of deepening inequalities and facilitating neocolonial dynamics. While industrialized countries benefited from GHG allowances and market mechanisms, host countries, which are already dealing with internal and global injustices, were left to absorb the negative impacts (Bond et al., 2012; Enríquez-de-Salamanca, 2024). In many cases, these host countries, lacking carbon pricing mechanisms, became suppliers of credits, offering up their natural and social resources in exchange for limited benefits. Meanwhile, investors from developed countries continued to grow economically. The capitalist cycles embedded in the system, and their resemblance to colonial resource extraction, have been widely criticized for reproducing exploitative structures under the guise of environmental solutions (Bumpus & Liverman, 2008; Lahsen, 2009; Oakland Institute, 2017).

2.2.Justice and Colonization Discussion

While carbon markets are often promoted as flexible tools to mitigate climate change, they are also criticized for their role in reinforcing global inequalities. This has given rise to the concept of carbon colonialism, which was introduced to address the negative outcomes of carbon offset projects. These critiques are also directly related to broader debates on climate justice, which emphasize fairness, responsibility, and inclusion, especially for those who are most affected but least responsible.

Debates around responsibility emerged as early as the 1990s, when Agarwal and Narain (1991) coined the term "environmental colonialism." They argued that developing countries emit less, primarily for basic needs, yet suffer more, while industrialized countries emit more for luxury consumption and are more insulated from climate impacts. The term "carbon colonialism" gained traction in the mid-2000s, initially used by journalists reporting on harmful reforestation projects in Uganda. These initiatives, often led by foreign investors, were developed with little local consultation and led to displacement and ecological harm (World Rainforest Movement, 2000; Bachram, 2004). Since then, the term has been embraced by indigenous and environmental justice movements to describe unequal power dynamics in global climate governance. After that, the term started to be widely used by environmental and social justice organizations, particularly by the indigenous people and local communities (Bachram, 2004).

Aiming to call attention to these uneven distributions and responsibilities of climate change impacts, the concept of Climate Justice has started to be discussed. The concept questions the core reasons for the inequalities, including capitalist and neoliberal policies, overextraction of natural resources, and dependency on nonrenewable sources (Sultana, 2022). Rather than focusing only on local issues, the concept spans across scales and geographies, and questions the global inequalities, particularly looking at the vulnerable communities and how they experience adverse impacts of climate change (Okereke and Coventry, 2016; Sultana, 2023; Tramel, 2016).

2.3.Bridging Climate Justice, Carbon Markets, and Spatial Planning

While carbon markets are accepted as flexible tools for reaching global climate goals and balancing the impacts of climate change, their implementation on the ground reveals spatial and social inequalities. Given the deeply political and geographical nature of these mechanisms, carbon offset projects can produce a wide range of outcomes for both the local environment and affected communities. And as growing practices, these outcomes have been widely explored within economics and geography, yet there remains a notable gap in the spatial planning discourse (While, 2008; Bumpus and Liverman, 2008; Knuth et al., 2025). Considering the multilevel nature of governance, the multi-actor structure of climate projects, and their direct implications for land use, spatial planning has much to offer in understanding and addressing the uneven outcomes of carbon markets. This section examines how the operationalization of carbon markets causes injustices, and how spatial planning tools can support more equitable and inclusive solutions.

In particular, Land Use, Land Use Change and Forestry (LULUCF) projects have triggered critical discussions about justice in their implementation. While aimed at restoring degraded lands through reforestation and afforestation,

many of these projects have capitalized on low land prices in the Global South, resulting in the displacement of local communities and the exploitation of natural resources, often with minimal or no benefits for the inhabitants (Bond et al., 2012; Gonzalez, 2021; Carton et al., 2020; Vieira & Bauer, 2023). As a result, the mechanism has been criticized as a new form of imperialism that uses the resources of developing countries to generate emission allowances for developed ones (Vieira & Bauer, 2023). While industrialized countries profit from offset credits, local communities are left to bear the environmental and social burdens. Bumpus and Liverman (2008) describe this phenomenon as "accumulation by dispossession," highlighting how carbon markets can reproduce historical patterns of inequality.

To address these challenges, scholars have emphasized three key areas. First, the complex governance structure, spanning from supranational to local levels, requires more coherent, multilevel policy design with a holistic perspective (Benites-Lazaro & Mello-Théry, 2019; While, 2008; Fogel, 2004). Second, meaningful stakeholder engagement across scales is essential to ensure that the diverse needs, knowledge, and rights of communities are included, thus supporting fairness and equity (Bond et al., 2012; Tramel, 2016; Michaelowa et al., 2019). Third, careful project sitting that aligns with local needs and ecological realities is critical to avoid reinforcing spatial injustices (Cavanagh et al., 2017; Carton et al., 2020).

Carbon markets have been widely criticized for reinforcing spatial and social inequalities through top-down decision-making, poor stakeholder inclusion, and ecologically insensitive siting. These concerns are central to the climate justice discourse, which emphasizes not only who contributes to emissions, but also who suffers the consequences and who participates in shaping solutions. As a discipline concerned with governance, coordination, and land use, spatial planning holds practical tools that can help operationalize climate justice. By integrating spatial planning into carbon offset governance, it is possible to move toward more inclusive, equitable, and place-sensitive outcomes.

3.Methodology

The methodology for this research includes an iterative process of desk research and interviews that takes their basis form of qualitative approaches. Firstly, desk research has been conducted to set the background for the Ugandan context through their history, environment, and social characteristics.

Following that, policy analysis has been conducted to understand how legal frameworks set the ground for carbon markets, and how the relationship between environmental management and carbon offset projects has been formed. Thirty-nine policy frameworks that are related to spatial organization (11), environmental management and climate change (19), and their implementation (9) were selected for the content analysis. Before operating the analysis, the key terms that are important in the carbon market and urban planning fields have been selected, and they are expanded based on the terminology used in the policy frameworks. Ultimately, the content analysis was conducted with forty-two keywords under eight main topics, including the UN, international agreements, climate finance, carbon credits and markets, inclusivity, local governments, low carbon development, and sectoral terms. In addition, relevant grey and peer-reviewed literature was reviewed to further understand the policy formulation and implementation environment at the national and district levels.

Thirdly, two contradictory case studies have been examined to understand the ways the policy frameworks have been reflected in the operationalization processes of the projects. While the first case study, the Kachung Forest Project (KFP), is an initiative run by foreign stakeholders with a top-down approach, the second case study, Trees for Global Benefits (TGB), is a grassroots project led by a local NGO with a bottom-up approach. These two case studies standing as poignant examples of carbon market operationalization processes with their management styles, and environmental and social outcomes. The differences between top-down and bottom-up approaches caused to while reflected themselves in the outcomes of the project with being called as "market failure" and "best example of the practice". In order to compare two case studies, firstly, the project management processes examined by looking at stakeholders, he lagel frameworks projects relied on, site selection procedure; then implementation and operation processes have been researched through land use and zoning management, plantation procedure, and participatory approach in these operations; lastly, the social, environmental and political outcomes have been compared.

Lastly, aiming to understand the implementation processes better, experts and researchers are interviewed in order to have a broader insight. Nine people from international, national, and local institutions and universities, with different affiliations, have been contacted, including UN representatives, high-level officers from the ministries and municipalities, and researchers from universities and research institutions. The interviewees are selected from the climate change and land management departments of the institutions while the researchers are contacted based on their focuses. After that, snowball sampling has been used to by targeting the practitioners in the fields. The interviews are conducted online in a semi-structured way. Before the interviews, all participants were informed about the purpose of the research, their consent was taken with ensuring their confidentiality would be strictly maintained. Regarding the geographical distance and language barriers, any representative from the local communities could not be reached out to, however, their perspective towards the projects has been added to the research through secondary data from the existing literature. The interviews are used to complement the findings of the research and present a general overview of the operationalization processes.

Through a four-step methodology; desk research, policy analysis, comparative case studies, and interviews; this research aims to present a broader perspective on the operationalization of carbon offset projects. By starting with the historical and natural context, Uganda serves as a key case to understand how environmental justice and injustice manifest through policymaking, project management, and community engagement. The multilayered structure of carbon market projects, from the supranational to the local level, is explored through policy integration, implementation practices, and expert perspectives. This methodological approach lays the groundwork for discussing how spatial planning can contribute to the field through three key tools: multilevel governance and policymaking, community engagement, and land management and tenure.

4.Operationalizing Carbon Markets in Uganda

Uganda, like many African countries, has become a hotspot for GHG emission reduction projects due to its vast natural and degraded areas, institutional weaknesses (Bond et al., 2012; Pagop & Savar, 2024), and high climate vulnerability (Trisos et al., 2022). As one of the LDCs, Uganda has increasingly attracted carbon market investments intended to strengthen climate resilience. Given the need for investment and the conditions that facilitate project management, Uganda became the fourth-largest carbon credit producer in Africa (EAA, 2022). Understanding the implementation of carbon offset projects in Uganda requires attention to three interrelated dimensions: its colonial legacy, land tenure complexity, and institutional structure.

The colonial period and its legacies still impact Uganda's legislative system and land management practices. Historically, land in Uganda was communally owned by tribal systems. After the declaration of the British protectorate in 1894, which lasted for 68 years, private land ownership was introduced through the mailo system, under which land was owned by a single individual or group, and inhabitants became tenants without formal agreements (Tukahirwa, 2002). Colonial authorities also appointed chiefs to manage rural communities, a practice that laid the groundwork for today's decentralized governance system (Ojambo, 2012). Coupled with an easily exploited land tenure system and fragmented decentralization, colonization planted the first seeds of Uganda's current challenges.

Even though the colonial period ended in 1962, its legacies persist. The land tenure system still includes mailo along with three other types: customary (communal ownership), leasehold (limited-time rental), and freehold (unlimited ownership) (UN-Habitat, 2007). Over time, even though local groups and families gained some recognition, tenure insecurity remains widespread (UN-Habitat, 2007). Similarly, the decentralized system, though promoted by the government as a way to involve local communities in decision-making, has been criticized for weak coordination, political interference, and high levels of corruption (Friis-Hansen et al., 2013; Ampaire et al., 2018; Ojambo, 2012).

Alongside these governance issues, Uganda's land cover has further attracted carbon market interest. Agricultural land comprises 44.5% of the country's territory and is the main source of income (MLHUD, 2017), but it is also a key driver of deforestation. Although forests cover 32% of the land (MWLE, 2001), forest areas are shrinking due to expanding agriculture, urban growth, and overharvesting (MWLE, 2001). Colonial overexploitation of forest resources has also contributed to long-term environmental degradation (RoU, 2007; Oosterveet & van Vliet, 2010). Combined with increasingly frequent extreme weather events and climate-related disasters, the country's vulnerability continues to grow (MAAIF, 2018).

Taking all these facts into account, Uganda's administrative and policy design structure in spatial planning reveals a complex system. The planning scheme is divided into national and local levels, with each producing its own legally binding documents. While local authorities are responsible for preparing their own plans, they must align with directives from the national level (MLHUD, 2017; NPA, 2014). Uganda's decentralized system, which dates back to colonial times, aims to empower local governments and communities through hierarchical governance structures (Oosterveet & van Vliet, 2010; Ojambo, 2012). However, despite the apparent autonomy of local governments, their actual capacity is limited due to insufficient human resources and institutional weaknesses. Interviews with officials emphasized the shortage of skilled personnel needed for spatial planning at the district and sub-county levels (Int8, Int9). Moreover, Uganda's classification as one of the LDCs with high vulnerability to climate change allows for considerable influence from the UN and its agencies. This influence predominantly shapes national-level frameworks, but their implementation often remains weak at the local level, leading to inconsistencies and disjointed planning practices (Oosterveet & van Vliet, 2010; MWE, 2024).

Figure 4 institutional organization for spatial planning and plan types and levels (adapted from NPA, 2007; NPA, n.d.)

In this context, carbon markets appear to be a tempting instrument for building both climate resilience and economic development with posing challenges in the implementation processes. Uganda's combination of ecological potential, foreign investment needs, and governance weaknesses makes it a prime site for project developers. However, the same combination raises critical questions about justice in how these projects are implemented. In the following sections, Uganda's carbon market operationalization will be explored through a policy framework analysis and a comparative case study of two offset projects.

4.1.Policy frameworks

Uganda began enacting climate change-related policy frameworks after becoming a signatory to the UNFCCC in 1993. Since then, the country has adopted a number of frameworks aimed at environmental protection and land management. During the late 1990s, the Government initiated reform to replace colonial-era legislation, starting with the land and environment management-related policies. In 1995, the National Environment Act, in 1997, the Local Government Act, and in 1998, the Land Act were decreed to make the groundwork for future environment management and nature protection. These laws laid the institutional foundation for environmental governance and decentralized planning. The National Land Use Policy (2006) further established a formalized planning structure, reinforcing land resource protection and land use management.

In 2007, following UN requirements for Least Developed Countries (LDCs), Uganda adopted the National Adaptation Programs of Action (NAPA) to have a guideline for coping with climate change impacts with particular focus on managing degraded areas and drought. Tree planting and benefitting from indigenous knowledge and integrating climate resilience into development plans were among the proposed solutions (RoU, 2007).

NAPA marked a turning point by introducing a holistic and decentralized governance model, encouraging participation from multiple actors—particularly local communities, in climate response initiatives (Nyasimi et al., 2016; Ampaire et al., 2017).

In 2013, the Government of Uganda released Vision 2040, which shows the main path for the country's development for the next 25 years, and the following policy documents were prepared accordingly. This was followed by the National Climate Change Policy (NCCC) in 2015, which was the first climate change-focused policy framework and the cornerstone to implement projects for coping with climate change impacts. The policy frameworks emphasize the importance of international agreements and mention carbon markets for the first time in the policy frameworks (RoU, 2014; MWE, 2015). In the following years, the National Development Plan II of 2015, Green Growth Strategy of 2017, National Development Plan III of 2020, and lastly Nationally Determined Contributions (NDC) of 2022 have been prepared with taking basis from Vision 2040 and NCCC, and they prioritized sustainable development with integrating the objectives of international frameworks into their agendas while also taking into account the needs of the country. In these policy frameworks, carbon market projects have been mentioned as a tool to support development of the country (NPA, 2010; 2013; MWE, 2015). The NDC, in particular, functions as an umbrella framework for all former policy frameworks and defines a clear pathway for the country to adapt to climate change impacts. In this document, carbon market has been mentioned as one of the ways to "reach a climate-resilient and low-carbon society by 2050 that is prosperous and inclusive" (NDC, 2022, p. 15). Within this document, the LULUCF sector is prioritized, with focus areas including climate-smart agriculture, REDD+ projects, agro-industry, forest restoration, and energy efficiency.

Uganda's post-colonial policy trajectory reflects a genuine effort to build cross-sectoral, forward-looking frameworks for sustainable development and environmental resilience. Starting with Vision 2040, national policies have increasingly combined land management, environmental protection, and climate adaptation. National Development Plans have become key vehicles for implementing these objectives. Allied with recently decreed and upcoming policy frameworks, NDC acts as a connector between different policy frameworks and sectoral plans that focus on climate change actions to strengthen the country's climate resilience.

Despite this progress, significant gaps remain in the operationalization of these frameworks. Firstly, institutional structure and policy frameworks' implementation pose challenged in the country. Given the decentralized structure of the government, operationalizing the policy frameworks is a shared responsibility between different levels, and local communities are a key plank in the process with being custodians of nature, (Oosterveet and van Vliet, 2010). yet their inclusion in actual decision-making remains inconsistent. While roles and responsibilities are clearly defined in principle (Oosterveet & van Vliet, 2010; Lubega, 2019), in practice, the influence of international agreements and elite stakeholders has resulted in top-down policy design that frequently overlooks local priorities (Friis-Hansen et al., 2013; Ampaire et al., 2017).

Secondly, the multiple stakeholder structure in the policy design lays the groundwork for conflicts of interest. Given the high level of corruption in the country, coupled with the decentralized system, the decision has been made with a bias in support of the ideas of powerful stakeholders (Ampaire, et al., 2018; Ojamba, 2018). During implementation, the proliferation of overlapping policies often causes confusion at the district level, where capacity and resources for enforcement are limited (Atakunda, 2020).

All these conditions make policy implementation challenging, particularly on the local level. The policies that have been designed on the national level fall short for finding reflecting the local levels, especially when it comes to climate change-related policies (Friis-Hansen et al., 2013).

Most critically, even though the country has been operationalizing carbon projects for more than 20 years, there is still no policy framework that focuses just on the procedural side of the mechanism. Although carbon markets are referenced as a climate financing tool and resilience strategy in national policy documents, there are no clear guidelines for project development, approval, monitoring, or spatial allocation. Interview respondents noted that various ministries are currently working on carbon pricing and offset regulation frameworks (Int4, Int9), yet the date for formal adoption remains unclear (Int4). As a result, even after two decades of carbon project activity, Uganda continues to operate without a cohesive framework to govern the institutional, spatial, and social dimensions of the carbon offset mechanism.

4.2.Comparative case studies

Aiming to represent how the operationalization processes of carbon market projects in the Ugandan context, two contradictory case studies have been elucidated. The first, the KFP, is widely regarded as a top-down, externally driven initiative. The second, TGB, is often cited as a grassroots, participatory model. Together, they illustrate the diversity of governance structures and outcomes in Uganda's carbon market landscape.

KFP was initiated under the framework of Kyoto Protocol projects as a reforestation activity on degraded savannah land in 2006, through a collaboration between companies from Norway and Sweden. The project has been operated on land leased from the National Forest Authority, which was formerly classified as savannah land. However, its top-down implementation, land selection process, lack of inclusivity, and overall operationalization have been widely criticized, and the project has been described by scholars as a market failure (Oakland Institute, 2014, 2017, 2019; Carton & Edstedt, 2021). Although the project involved multiple stakeholders, including the UN, international actors, and government ministries, it excluded local authorities and communities from the decision-making process. To implement the project, local communities were displaced and lost access to their lands. The project site was fenced off, and entry was strictly controlled (Gebremichael, 2016; Edstedt, 2017; Carton & Edstedt, 2021). Furthermore, while the project had promised to create job opportunities and support biodiversity, its single-species plantation approach harmed biodiversity (Oakland Institute, 2014, 2019; Edstedt, 2017), and the limited employment options left many people in poverty (Edstedt, 2017; Oakland Institute, 2017, 2019). Some reports claim that the project brought economic benefits to the country by attracting foreign investment (Gebremichael, 2016; PDD, 2012; Edstedt, 2017), and argue that it displaced informal inhabitants rather than evicting formal residents (Oakland Institute, 2019; Edstedt, 2017; Carton & Edstedt, 2021). However, overall, the project has been widely criticized for the negative social and environmental outcomes it produced.

In contrast, TGB has been recognized as one of the strongest examples of carbon market projects in Uganda, thanks to its bottom-up approach and its positive impacts across environmental, social, economic, and policy domains. The project was initiated by a local NGO, EcoTrust, to reverse deforestation in vulnerable areas and support nature protection. TGB participants—mostly small-scale landholders—are paid based on the number of trees they plant on their land, which are then sold on the global carbon market ("Trees for Global Benefit", n.d.). The project began in a region of the country affected by frequent landslides, and over time, it has expanded with support from the UN and other international organizations such as the World Bank, WWF, and IIED (EcoTrust, 2013; 2020; Lee et al., 2016; Schreckenberg et al., 2013). Given the grassroots nature of the initiative, project design and management included local perspectives from the beginning. During implementation, regular meetings were held with community members, and land use and zoning plans were developed collaboratively (EcoTrust, 2020; Schreckenberg et al., 2013). As a result, the project has contributed to environmental protection by enhancing biodiversity, while also generating alternative income sources for participants. Additional benefits, such as improved social infrastructure, have supported better living conditions for local communities. In some districts, the project has even been incorporated into policy agendas as part of broader strategies for sustainable development (EcoTrust, 2024; Schreckenberg et al., 2013; Int9).

In conclusion, these two case studies demonstrate that carbon market projects are more likely to succeed and deliver justice when they are built on inclusive governance structures, active community engagement, and context-sensitive land use planning.

5.Discussion

Ugandan case study shows that the relationship between environmental justice, sustainable development, and spatial planning is highly connected, and in order to reach the optimum level, policy making and governance, stakeholder management and land management are crucial.

Even though numerous laws, regulations and other policy frameworks have been accepted, the country still lacks regulation about carbon pricing and carbon markets, which poses a big challenge for the management of existing and upcoming projects. Lack of integration between the policy framework and deficiencies for policy frameworks' reflection on the local levels are keystones in the governmental aspects, as well as, the weak institutional structure and lack of human capacity and financial support. Moreover, in the implementation processes of the projects, the decentralized structure of the government also held the country back from more efficient operationalization processes. The confusion created by the various policy frameworks, and lack of

guidelines for the local governments causes various practices that end differently at the local level, which in some cases worsen the injustices. In these terms, the urgent need for newly-baked policy frameworks for carbon pricing and operating carbon markets have been highlighted by the all respondents.

Moreover, the participation of different stakeholders have also been a problem in the operationalization processes of carbon market projects. Given the market-based nature of the system, while the market actors (project developers, investors, and so on) are superior in the processes, the governmental bodies and local communities are excluded. The projects show that even though the governmental authorities might be involved in the projects' management, it is very limited. Despite the fact that the local communities are the main groups that know the local characteristics best, excluding them from the processes affecting not only their well-being but also causes missing opportunities to conduct projects better. And enhancing community engagement in the project design processes and strengthening collaboration with governmental bodies can be one of the solutions for better operationalization processes (Oosteerveet and van Vliet, 2010). And, one of the reasons the projects lack inclusivity is the gap in the policy frameworks regarding the participatory approaches for the implementation of the projects.

Another important aspect for the operationalization of the projects is land management. Firstly, the land tenure system puts people's property in jeopardy since they do not have any formal ownership on the land, people were evicted from the places they lived for years (Edstedt, 2017) or they had to accept the projects' land use plan without consent (Edstedt and Carton, 2018; Oakland Institute, 2014;2017). Moving further from plot-based injustices, the lack of a planning mechanism also caused problems on different levels. Firstly, given the country's inefficient physical planning mechanism, the projects' locational distribution is not organized. And this situation deepens already existing inequalities between the regions (Fisher, 2012; Edstedt and Carton, 2018; Oakland Institute, 2014; 2017). Secondly, local development plans are either have not been prepared yet or have not integrated the carbon trading mechanism into their agenda. Therefore, the location of the projects is still mostly dominated by the market actors, rather than local experts and practitioners (Int3; Int8; Int9).

In these whole processes, as a part of the institutional organization and mechanism, the lack of land management and spatial planning mechanisms impact how the projects have been implemented. The cycle of capital accumulation enabled by carbon trading mechanisms—often intensified by neoliberal environmental policies—has been widely critiqued in the literature for exacerbating spatial and social inequalities (Bumpus & Liverman, 2008; Bachram, 2004; Carton et al., 2020). These markets reshape social and economic geographies through capital accumulation and spatial impacts (Bond et al., 2012; Bumpus & Liverman, 2008), aligning them closely with spatial planning discourse. Literature highlights that the most criticized aspects of carbon market operationalization include policy design (Bachram, 2004; Fogel, 2004; Michaelowa et al., 2019; Carton et al., 2020), stakeholder engagement (Fogel, 2004; Tramel, 2016), and project siting (While, 2008; Gonzalez, 2021)—all of which fall within the domain of spatial planning.

These problems are also clearly visible in the Ugandan context. The weak administrative organization, incoherence between policy frameworks, exclusion of communities, and underdeveloped land management systems have emerged as the most pressing challenges. Interviewees confirmed that these gaps significantly hinder the operationalization of carbon market projects. One of the main problems identified was the lack of alignment between existing laws and frameworks, which creates institutional confusion and leads to uncoordinated implementation across different administrative levels. Officials noted that although multiple policies exist, there are no clear procedural guidelines or coordination mechanisms that explain how carbon offset projects should be executed, monitored, or managed spatially. In addition, stakeholder participation, especially that of local communities, was seen as more symbolic than practical. Although consultation is often mentioned in project proposals and policies, in reality, communities are rarely involved in project planning or benefit-sharing decisions. This exclusion not only affects community wellbeing but also limits the long-term sustainability of the projects.

Despite these challenges, many interviewees expressed optimism about the role of spatial planning in improving project implementation.

They emphasized that integrating planning tools into carbon market mechanisms could support fairer land use decisions, better regional coordination, and more transparent governance. In their view, spatial planning can act as a bridge between global climate agendas and local needs by helping to direct projects to suitable locations, supporting land tenure clarity, and strengthening communication between institutions and communities.

Addressing environmental injustice requires complex policy-making across local, national, and global levels, particularly in systems involving multilevel governance and multiple stakeholders, such as carbon markets (Mohai et al., 2009; Bond et al., 2012). Spatial planning can enhance equity in carbon market implementation through three key contributions. First, its role in multilevel policy-making enables the integration of supranational frameworks into national and local governance. Second, as "knowledge keepers" (Janin Rivolin, 2012), planners can support inclusive stakeholder engagement by bridging knowledge gaps and facilitating dialogue across levels. Third, land use management and zoning, which is core spatial planning functions, can guide more just project siting and land allocation.

Given the alignment between carbon market challenges and spatial planning capacities, integrating spatial planners into climate finance governance could lead to more effective and equitable outcomes. This is particularly important in contexts where capacity-building and coordination are lacking (Okereke & Coventry, 2016). As supported by interview findings from Uganda, spatial planning can support implementation at national, regional, and local levels by directing project siting, enhancing institutional mechanisms, and connecting local stakeholders with decision-makers.

6.Conclusion

This paper has explored how carbon market mechanisms are operationalized in Uganda and what justice-related implications emerge in the process. Although carbon markets, particularly those introduced through the Kyoto Protocol and later through Voluntary Carbon Markets, are framed as tools to mitigate climate change and mobilize finance for climate-vulnerable countries, their implementation reveals a more complex and often problematic reality. Uganda, with its vast natural resources, decentralized political structure, and postcolonial legacies, offers a particularly illustrative case of how such mechanisms unfold on the ground.

The analysis has shown that the challenges in Uganda are not merely technical but deeply embedded in structural and governance-related issues. Fragmented policy frameworks, institutional weaknesses, and the absence of a regulatory structure specific to carbon markets have contributed to inconsistencies in project management and limited local benefits. Furthermore, land tenure insecurity and the weak spatial planning system have made it easier for private actors to access land for offset projects, often at the expense of local communities. Despite the existence of national policies that call for decentralization and public participation, these principles are not effectively practiced in carbon project governance.

The comparative case studies further illustrate this point. The Kachung Forest Project exemplifies how exclusionary, top-down approaches can lead to negative social and ecological outcomes, including displacement, biodiversity loss, and lack of community benefits. In contrast, the Trees for Global Benefit project demonstrates the potential of locally driven, participatory models to deliver positive environmental and socio-economic results, particularly when grounded in community engagement and collaborative land use planning.

These findings support broader critiques in the literature that argue carbon markets, in their current form, risk reproducing patterns of inequality and exploitation, often referred to as "carbon colonialism." As the interviews in this research confirmed, the lack of regulatory guidance, professional capacity, and coordination between national and local authorities only amplifies these risks.

Spatial planning, however, holds significant yet underexplored potential in addressing these issues. By facilitating multilevel coordination, guiding land allocation, and promoting inclusive governance, spatial planning can serve as a practical tool to operationalize climate justice on the ground. It can help ensure that carbon offset projects are not only technically sound but also socially equitable and locally responsive.

Looking ahead, integrating climate finance into spatial planning discourse, and particularly into carbon offset governance, could be a step toward bridging the gap between global climate goals and local realities. For Uganda

and other countries with similar vulnerabilities, doing so is not only a matter of efficiency but one of justice. Future climate action must not only aim to reduce emissions but also to challenge and transform the unequal structures that shape who benefits, who decides, and who bears the costs.

Temporal-Spatial Distribution Characteristics of PM2.5 and Noise in the Under-Viaducts Space

Siying Li
Tsinghua University

Zeyin Chen
Tongji University

Abstract
As large cities grow in size and density, they come under increasing pressure for space and regeneration. Many under-viaducts spaces (UVSs) are being converted into open-air sports fields, but such spaces can cause air and noise problems for people playing sports. There is a lack of research on the pollution of the UVS. To fill this gap, this study selected a case area of an UVS in central Shanghai that has already been renovated into a sports field, and investigated the spatial and temporal distribution patterns of air and noise pollution and the factors influencing them. Based on site monitoring and data analysis, this study found that: 1) Air pollution in the UVS is significantly higher than the background levels, the higher the background levels, the greater the difference between the concentrations in the UVS and the surrounding area. 2) The noise intensity in the UVS is also higher than the background value with a more constant variation. 3) Air pollution is highly correlated with the built environment and traffic flow, while noise is more closely related to traffic flow and less so to the built environment, both of which have a negative correlation with temperature. This study provided valuable empirical evidence on the exposure to air and noise pollution in the sports space under viaduct in the micro-environment, which can help planners to adequately consider pollution reduction in the planning and management of urban renewal.

Key Words: Under-Viaducts Space, Noise, $PM_{2.5}$, Spatio-temporal distribution, Urban renewal, Shanghai

1.Introduction

With the rapid development of urbanization, there is an increasingly prominent conflict between limited land and high population density in major metropolitan areas. Elevated highways and viaducts have become essential solutions to traffic problems in many cities. The viaduct itself has public attributes [1], and the under-viaduct space (UVS) is regarded by scholars as a potential public space or site for activities [2]. In this study, the UVS was defined as the space covered by the orthographic projection under the viaduct and the surrounding neighbourhood space significantly affected by the viaduct. Effective utilization of the UVS is highly significant for urban renewal, but due to the relatively closed nature of the main space, the UVS has become an area where particulate matter pollution caused by traffic increases [3], resulting in its poor environmental quality. Noise pollution is also a major issue in the UVS [4], and the horizontal and vertical sound fields in the road space of the viaduct are greatly altered compared to ordinary roads, causing more severe noise pollution on both sides of the road [5]. Consequently, the impact of viaducts on the urban environment and the use of space around viaducts are receiving more and more attention in high-density cities.

1.1 $PM_{2.5}$ in the UVS

Air pollution caused by traffic is a major health hazard for urban dwellers worldwide [6]. Particulate matter with a diameter less than or equal to 2.5 microns ($PM_{2.5}$) is an essential criterion for determining air pollution [7]. Most $PM_{2.5}$ emissions in cities originate from transportation, especially diesel trucks and buses [8]. In Toronto, motor vehicle-related emissions account for about 40% of $PM_{2.5}$ [9]. Abu-Allaban et al. [10] found that the percentage contribution of motor vehicles to $PM_{2.5}$ at seven U.S. sites ranged from 20% to 76%. In London, the mean incremental traffic contribution to $PM_{2.5}$ near motorways can be as high as 50% [11]. $PM_{2.5}$ can also cause many adverse health effects [12]. Lelieveld et al. [13] found that outdoor air pollution, mainly $PM_{2.5}$, causes 3.3 million premature deaths each year. At the same time, short-term or long-term exposure to high $PM_{2.5}$ concentrations can elevate the risk of heart disease, while potentially triggering respiratory diseases, asthma and other diseases, and may also induce cancers such as lung cancer and increase the risk of mental disorders such as major depression [14,15,16,17].

The combination of surface roads and viaducts pollution can result in 1.6 to 4.5 times the amount of pollution compared to road surfaces alone [18]. Urban roads in the UVS have become priority areas for particulate pollution [19]. $PM_{2.5}$ concentration distribution of viaducts is attracting increasing attention, but there are still relatively few relevant studies. Most existing studies have focused urban roads, such as highways, roadsides, intersections and arterials (Table 1). The urban road spaces have high similarity with the UVS, so the experimental methods and results of the studies can be used as references. Around the 2000s, studies on the $PM_{2.5}$ concentrations of major roads became more frequent, and found that the closer to the road, the higher the $PM_{2.5}$ concentration and higher

than the background concentration [20,21]. In addition, some studies found that there is an attenuation effect of $PM_{2.5}$ concentration in the 200 meters range of highway [22,23]. Similar results were verified at intersections, where $PM_{2.5}$ concentrations at the downwind curb of the intersection were significantly higher than background values and were significantly higher during peak traffic hours [24,25]. Many studies have also focused on influencing factors, with traffic conditions such as traffic volume, meteorological conditions such as wind speed, local topography and surroundings, barriers or noise walls all affecting the distribution of $PM_{2.5}$ in road space [26,27].

Most studies on viaducts concentrate on the street canyons [28,29], and there are fewer studies on the horizontal distribution of $PM_{2.5}$ in the UVS. It is discovered that viaducts increase $PM_{2.5}$ concentrations in street canyons, particularly on the ground. Li et al. [30] utilized a mobile monitoring method to measure the space beneath three viaducts with different types of barriers in Xi'an, China and found that $PM_{2.5}$ concentrations have a single-peak decay trend in locations with noise barriers and combined barriers, meaning they initially increase then decrease to background levels within 300 meters. In Wuhan, China, Yin et al. [19] monitored 14 UVSs and 9 potential environmental parameters such as temperature to study spatial and seasonal differences in particulate matter like $PM_{2.5}$. They also found that $PM_{2.5}$ concentrations were related to the surrounding environment and that $PM_{2.5}$ concentrations in the UVS were higher compared to surrounding roads in winter, and vice versa in summer. The study contributes to understanding the factors influencing $PM_{2.5}$ concentrations in the UVS, but lacks spatial analysis at the microscopic scale. In summary, the realistic distribution pattern of $PM_{2.5}$ in the planar dimension and the influence mechanism of parameters are not clear, and further spatial and temporal studies are needed to guide the assessment and judgment of spatial reuse.

Table 1. Summary of research findings on $PM_{2.5}$ concentrations in road space.

Research Object		Monitoring Methods	Results	Sources
Road	Highway	Mobile monitoring	•Within 200m, $PM_{2.5}$ concentrations usually increase as the highway approaches. • $PM_{2.5}$ increases with the onset of peak hours and is strongly influenced by temperature changes in colder months.	Patton et al., 2014 [22]
			•Before sunrise and peak traffic volume, downwind concentrations are highest within 100-250m of the highway. • After sunrise, pollutant levels drop sharply and the gradient becomes less pronounced.	Durant et al., 2010 [31]
		Fixed monitoring	The reduction in urban traffic helps to reduce the concentration of particulate matter pollution.	Azhari et al., 2021 [32]
			Particulate concentrations decay exponentially with increasing distance within 100-150m from the road and return to background levels within a few hundred meters from the road.	Zhu et al., 2009 [23]
			Wind speed, prevailing wind direction, daily cycle of the atmospheric boundary layer and traffic density are the main influencing factors.	Charron & Harrison, 2005 [33]
	On-road & Roadside	Fixed monitoring	Higher $PM_{2.5}$ concentrations were observed in Madrid during the cold season.	Kassomenos et al., 2014 [34]
		Mobile and fixed-site monitoring	•$PM_{2.5}$ concentrations on the road are highly correlated with nearby roadside $PM_{2.5}$ concentrations in winter and summer. • Seasonal effects need to be considered, and short-term exceedances of particulate matter concentrations may occur in early spring.	Cheng et al., 2010 [35]; Lozhkina et al., 2016 [36]
	Intersection	Fixed monitoring	There was an overall decreasing trend in $PM_{2.5}$ concentrations with increasing distance from the roadside. The incremental $PM_{2.5}$ decreased by 75% between 5 m and 30 m from the road.	Mukherjee et al., 2020[37]
		Mobile monitoring high-flow gravimetric personal samplers	$PM_{2.5}$ concentrations are higher in the morning, decrease at noon, and rise in the early afternoon and are even higher in the evening. This phenomenon is related to the traffic activity in the surrounding area.	Kaur et al., 2005 [24]
		Fixed monitoring	• Roadside concentrations were higher than those simultaneously monitored at urban sites away from the road. • Average pollutant concentrations at downwind roadside stations are higher than at background stations. • $PM_{2.5}$ concentrations during peak traffic hours are higher than during off-peak hours.	Wang et al., 2018 [25]; Kinney et al., 2011 [38]
	Arterial	Fixed monitoring near-road continuous air monitoring station (CAMS)	•$PM_{2.5}$ concentrations are usually elevated close to roads. • Traffic-related $PM_{2.5}$ concentrations are usually highest at night, followed by the morning peak, evening peak and midday respectively.	Askariyeh et al., 2020 [39]
			$PM_{2.5}$ quality is more related to regional sources and meteorological conditions, with a limited role of traffic volume.	Kendrick et al., 2015 [40]
	Street canyon	Mobile monitoring	Street canyons have a significant impact on the accumulation of $PM_{2.5}$ concentrations on Hong Kong's roads.	Rakowska et al., 2014 [41]
		Fixed monitoring three heights (0.20 m, 1.0 m and 2.60 m)	The concentration decreases exponentially with increasing canyon height.	Kumar et al., 2008 [42]

Viaduct	Street canyon	Fixed monitoring	Particle mass concentrations in street canyons are negatively correlated with height, and particle mass concentrations in street canyons are negatively correlated with temperature.	Feng et al., 2015 [28]
			Viaducts increase $PM_{2.5}$ concentrations in street canyons and significantly affect airflow fields.	Zhi et al., 2020 [29]
	UVS	Mobile monitoring	$PM_{2.5}$ concentrations decay exponentially near the viaduct without any obstacle.	Li et al., 2021 [30]
		Mobile and fixed-site monitoring	•$PM_{2.5}$ concentrations in the UVS are lower in summer than in the adjacent road environment, but higher in winter. Meteorological factors, green structure, viaduct structure and surrounding built environment have a significant impact on $PM_{2.5}$ concentrations.	Yin et al., 2021 [19]

1.2 Traffic noise in the UVS

Road traffic noise is one of the main sources of noise pollution in urban areas and has become a global problem [43]. Traffic noise has harmful effects on health [44,45], including anxiety [46,47], sleep disturbance [48], and reduced cognitive performance in school-aged children [49] and an impact on cardiovascular diseases [50]. Traffic-related noise is one of the major environmental impacts of roads [51]. Therefore, the proper assessment of the noise impacts in urban traffic areas is crucial for the rational use of urban space and the preservation of human health.

At present, there have been numerous studies on the spatial and temporal analysis of traffic noise and its influencing factors in urban traffic spaces (Table 2). These studies indicate that noise levels in spaces along the main roads entering and passing through the city are relatively high and that the traffic noise increases during peak hours [52,53]. Some studies have found a positive correlation between urban density and traffic noise through software simulations [54] and between urban road network density and traffic noise [55]. At the same time, there is a strong inverse relationship between the area of green space on both sides of the traffic space and traffic noise [56]. In terms of space design, the height and shape of building facades on both sides of the street are closely related to the noise levels of the traffic space [57] and other aspects. These factors have varying effects on urban road traffic noise.

The results of existing studies are summarized in Table 2. However, relatively few studies have been conducted on the noise of the UVS and its associated temporal and spatial distribution patterns. Additionally, there is a scarcity of research on the effects of human activities under traffic noise exposure.

Table 2. Summary of research findings on noise concentrations in road space.

Research Object		Monitoring Methods	Results	Sources
Road	highway	-	For outdoor environment, sound barrier, low-noise pavement and soundproof window are the most common solutions to reduce the noise generated by main noise sources	WHO, 2018 [58]
	On-road & Roadside	Fixed monitoring	The address noise level along the main roads entering and passing through the city is the highest As the density increases, the street noise will also increase	Thacher et al., 2020 [52]
		Mobile and fixed-site monitoring	There is an inverse relationship between greening area and noise pollution	Lopez et al., 2018 [56]
		Mobile and fixed-site monitoring	Increased traffic noise pollution during peak hours The noise pollution in the space near the road is large	Shakya et al., 2019 [53]
	Arterial & Roadside	Mobile and fixed-site monitoring	The more urban activities, the more noise the street	Mohareb & Maassarani, 2019 [59]
	Arterial	Software simulation	There is a positive correlation between road network density and traffic noise	Wang et al., 2011 [55]
		Software simulation	The higher the urban density, the more important the noise insulation measures	Bouzir & Kang, 2017 [54]
	Street canyon	Fixed monitoring	Street canyon architectural design has a significant impact on street space noise	Sanchez et al., 2016 [57]

1.3 Monitor and analysing method review

Fixed monitoring and mobile detection are two types of effective methods for measuring air and noise pollution in urban environments. These methods have been tested by numerous scholars and have been proven to be successful. However, fixed measurements has limitations, such as the cost of equipment and maintenance for fixed-site air quality monitoring stations (AQMS) [60], which can make it challenging to accurately reflect pollutant distribution over short distances [61]. Mobile monitoring technology can help to overcome these limitations and provide a spatial map of population exposure in the micro-environment with higher spatiotemporal resolution [62]. Additionally, it is also an effective way to obtain noise data [63]. The specific methods include platforms such as instrumented cars and vans [60,64], public transportation such as trains and trams [62,65], bicycles [63], and backpack walking measurements [66,67,68]. In this study, backpack walking measurements were used to directly assess personal exposure to pollutants and noise in the traffic micro-environment.

The main methods of analyzing pollutants and noise include spatial analysis, temporal analysis, and correlation analysis of influencing factors. Spatial analysis is mainly divided into two categories: the differences in pollutant and noise distribution in different road spaces [35,66,69], and the continuous distribution characteristics of pollutants and noise in larger spaces, such as cities and districts [63,70], with insufficient attention given to small-scale horizontal space. Temporal analysis focuses on the differences in pollutant concentrations and noise levels during different seasons such as winter and summer [36], working and non-working days [41], and different time periods of the day [22,24,31]. The correlation analysis of impact factors includes meteorological factors such as temperature and humidity, road factors such as traffic volume, and built environment factors such as distance from the main road and height to width ratio [19].

In conclusion, there is a lack of research on the small-scale UVS, and most studies do not consider the combination of particulate and noise pollution in the same space. Many current studies focus on statistical analysis, with limited exploration of the spatial layout and potential for built-up space reuse.

To address these gaps, the research goals of this paper are as follows: 1) expand the scope of the study, and analyze the spatial and temporal distribution characteristics of particulate matter and noise under the viaduct and within a block or so (about 250m) of the surrounding space; 2) enrich the research objectives, and investigate the factors affecting particulate matter and noise in the UVS and further propose planning countermeasures for spatial reuse.

2.Data and methodology

2.1Study Area

The study area is the UVS of Tianmu Middle Road (31°14'32.7"N, 121°27'45.2"E), which is located on the south side of the intersection of Hengtong Road and Gonghexin Road in Jing'an District, Shanghai, China. As an international metropolis with a high population density and elevated roads throughout the city, Shanghai is representative in its exploration of the quality of the urban spatial environment. The city has carried out a lot of practices and explorations in the use of the UVS and has issued relevant policies and standards to guide the development and utilization. The study area is currently designed as a basketball court, with a large number of people exposed to the environment of the viaduct. Therefore, the area is of great practical importance in evaluating the fine particulate matter and noise environment under the viaduct.

The study area is located in the most prosperous centre of Shanghai, on the north side of the intersection of the North-South viaduct and the Suzhou Creek (Fig.1). The north side is close to the intersection of arterial roads, the south side is only separated from the Suzhou Creek by a branch road, and the east and west sides of the base are urban roads. The viaduct has 12 lanes and heavy traffic, while ground level has 2 lanes on either side of the space underneath the viaduct. The sports field is located under the main bridge of the North-South viaduct and consists of four basketball courts, which are sheltered on east and west sides are sheltered by the overhanging eaves of the viaduct deck. On the east side of the site there is a ramp departure point, and the degree of screening is less than on the west side. During weekday peak hours (7:00-9:00 and 17:00-19:00), slow and congested traffic is common, while road traffic is relatively smooth at other times. In summary, the study area was selected for analysis of the particulate and noise environment assessment of the UVS due to its good regional location, site shape, traffic characteristics, and pollutant sources.

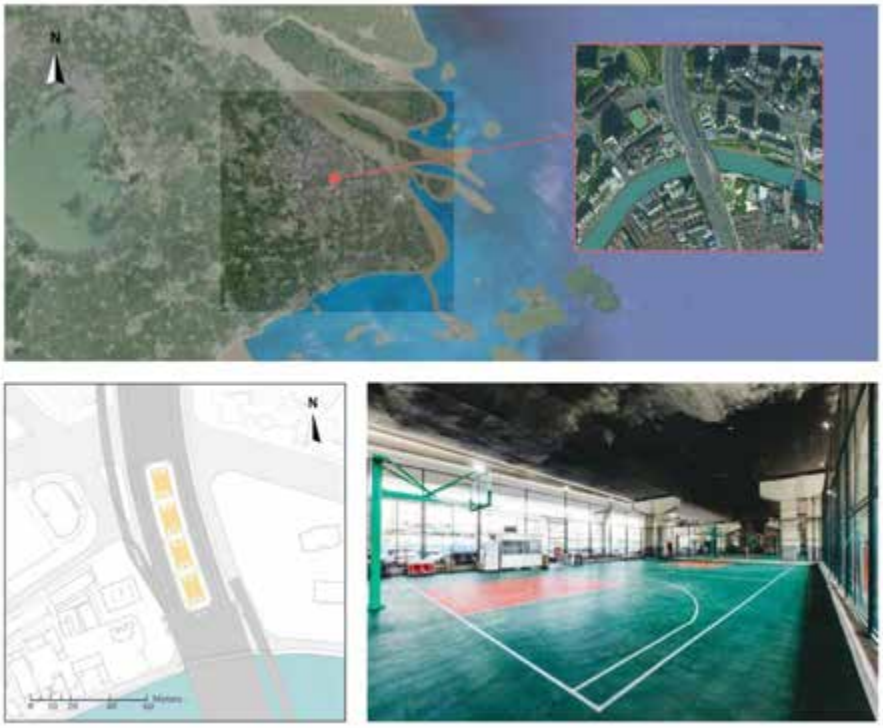

Fig.1 Sketch map and the general plan of the study area.

2.2Data preparation

2.2.1 Mobile site measurements

The mobile monitoring route covered the UVS and the surrounding space within 250 meters on both sides of it. The starting point of the route was a reference point used to measure background levels, which had no influence of pollution sources such as factories and parking lots within 50 meters of its surroundings, and no more than 3,000 vehicles pass through it per day (Hoek et al., 2002)[71]. Meanwhile, 32 measurement points were set up along on the route in sequence, and peripatetic measurements were performed at each point using handheld instruments. The clocks of all real-time instruments were checked for synchronization prior to the measurement. Points 3, 4 and 15-26 were located in the projected space of the viaduct, specifically indicated as the UVS-P. The remaining 18 points were peripheral spaces not covered by the viaduct and were set up to investigate the attenuation effects of pollutants and noise, specifically designated as the UVS-NP. There was a continuous wall interface on the east side of the viaduct, with green space in front of the interface (Fig. 2). The selection of this monitoring route was based on the following needs:

1) Since the site had different built environments in the north-south and east-west directions, the monitoring points were set up homogeneously in the UVS and in the road space around the viaduct respectively, to measure the distribution characteristics.

2) The viaduct had differences in the morphology of its eastern and western branches, so double rows of monitoring points were set up in the UVS to objectively reflect the numerical situation of pollutants, noise distribution and the various influencing factors. It was confirmed in advance that there were no industrial sources near the entire study area.

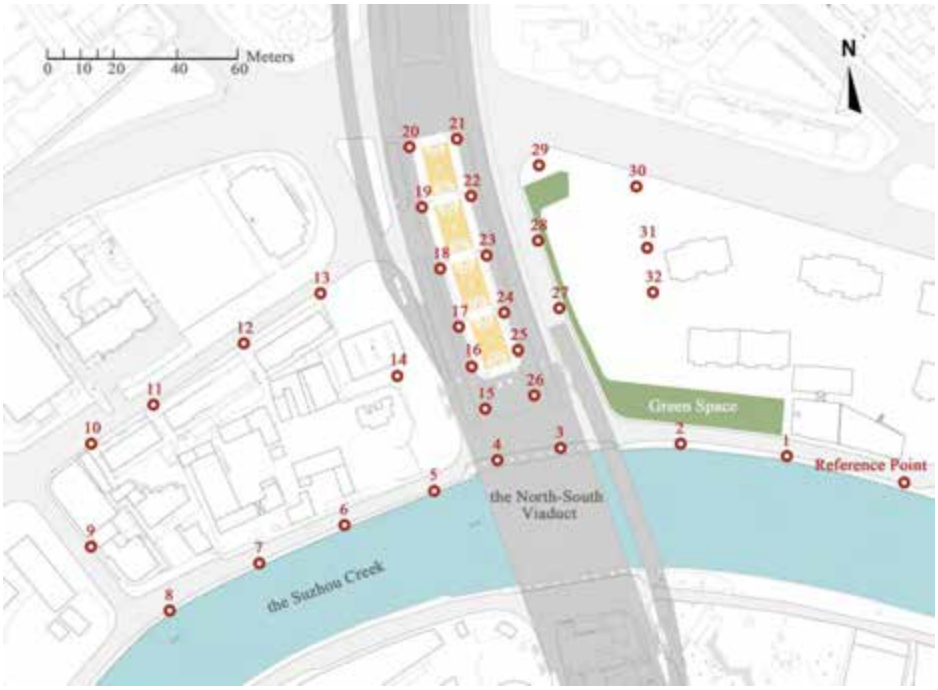

Fig.2 The locations of all the monitoring points set up on the route are numbered from small to large according to the sequence from the beginning to the end.

2.2.2 Data collection

According to previous studies [19,62,70], it is recommended to conduct environmental monitoring for more than 10 days, including both working and non-working days, to ensure the accuracy of the results. Therefore, our experiment was conducted over a 12-day period in winter (February 25th to March 8th, 2022), encompassing both working and non-working days, with 4 different time segments (8:00, 11:00, 15:00 and 18:00) per day. To prevent fatigue of the backpack walking monitoring experimenters from affecting the results, each experiment was kept to a total duration of less than 30 minutes [72] and each measurement point was monitored for 20 seconds

[73]. The portable sensors used to monitor environmental elements such as $PM_{2.5}$ concentrations, noise, and meteorological parameters, were deployed at a height of approximately 1.5 meters above the ground to ensure accurate correspondence with human activities [71].

Taking into account the specifics of the environment under the viaduct, the experiment data collected in this study included geographical data, pollution and noise data ($PM_{2.5}$ concentrations, equivalent sound level), and information about the factors that influence pollution and noise (temperature and humidity, distance from the viaduct, distance from the river, and traffic volume above and below the viaduct). Table 3 shows the various instruments used for data collection. The $PM_{2.5}$ concentrations data was collected using the PM: SidePak Aerosol Monitor AM520 air particulate experiment instrument, which is designed to provide accurate mass concentrations of particulate matter at 1-second intervals. To ensure the validity of the data, the $PM_{2.5}$ monitor was factory calibrated and further verified based on the configured standard method at an outdoor site in Shanghai prior to the study. The noise data was collected using the AWA6228 multi-function sound level meter instrument. Location and distance data were collected using Unistrong handheld GPS instrument and got GPS data. This study analyzed the relationship between $PM_{2.5}$ concentrations, equivalent sound level (Leq) and each of the influencing elements separately, and evaluated the suitability of exercising at the site with all the data.

Table 3. Summary of instruments and influencing parameters

Type	Parameter	Description	Instrument and model	Sampling resolution
Geographic information	GPS positioning data	Location of each data point (m)	Unistrong handheld GPS instrument	1s
Pollutant data	$PM_{2.5}$ concentration	The 20-s average data at the sample sites (μg/m³)	PM: SidePak Aerosol Monitor AM520 Air particle test instrument	1s
	Equivalent sound level (Leq)	The 20-s average data at the sample sites, representing the intensity of the noise (dB)	AWA6228 multi-function sound level meter instrument	1s
Influence factor	Traffic volume	Traffic volume data of the overall environment (up and down the viaduct) (vel/h)	Mobile phone recording 5 minutes of video	-
	Distance from the viaduct	Distance from the centerline of the viaduct (Fixed values, pre-measured) (m)	Unistrong Handheld GPS instrument	1s
	Distance from the river	Distance from river bank (Fixed values, pre-measured) (m)	Unistrong Handheld GPS instrument	1s
	Temperature	Average value of temperature (	HOBO Temperature and humidity recorder	1s
	Humidity	Average value of humidity (%ph)		

2.3 Data preprocessing and analysis method

2.3.1 Data preprocessing

The study retained high $PM_{2.5}$ concentrations (several hundred μg/m³ or higher) and Leq data (90 dB or higher) to represent real measurements in time and space [62,74]. During pre-processing, data affected by unusual weather conditions, such as strong winds and heavy rain, and the first 2 minutes of on-site monitoring data were removed to reduce errors. The corresponding average measurements of $PM_{2.5}$ concentrations, Leq, temperature and humidity were then calculated for each monitoring site by taking the arithmetic mean of the 20-second samples. Traffic volume data was obtained by averaging the measured data over a five-minute period at the beginning and end of each measurement, to obtain the two-way hourly motor vehicle throughput. The GPS data was imported into the GIS software for subsequent analysis. The final sample consisted of 1188 geographical

coordinates, 1188 $PM_{2.5}$ concentration data, 1188 noise data, 1188 temperature and humidity data, 36 traffic volume data and 66 distance data from the viaduct or the river.

2.3.2 Analysis method

After obtaining the monitoring data, this study conducted descriptive analysis, spatial analysis, temporal analysis, and correlation analysis with influencing factors for $PM_{2.5}$ concentrations and noise intensity respectively. First, a significance test was performed using SPSS Statistic 25.0 software to determine the overall distribution of pollutants and noise, and to assess the presence or absence of attenuation in the surrounding area. The Kriging interpolation technique was used to map the spatial distribution of pollutants and noise and to examine individual exposure within the site [75,76,77], which can be expressed as:

$$\mathbf{Z}^*(s_0) = \sum_{i=1}^{n} \lambda_i \mathbf{Z}(s_i)$$

where $Z^*(s_0)$ denotes the observation at point i; Δ_i is the unknown weight of the observation at point i, s_0 is the point to be estimated, and n is the total number of observations. The temporal analysis focused on the characteristics of $PM_{2.5}$ concentrations and noise intensity during working versus non-working days, as well as peak versus non-peak hours. Finally, a backward multiple stepwise regression model was used to quantify the relative contribution of influencing elements to the changes in $PM_{2.5}$ concentrations and noise intensity in winter. The prediction model can be expressed as:

$$Y = a + b_1X_1 + b2X_2 + b_3X_3 + \ldots + b_nX_n \ (n \leq 5)$$

where Y denotes $PM_{2.5}$ concentration or Leq; a is a constant; $b_1, b_2, \ldots b_n$ denote the coefficients of the independent variables; $X_1, X_2, \ldots X_n$ are impact factor parameters. In the specific comparative and correlations analysis of $PM_{2.5}$ concentrations, the relative exposure concentration (REC) was used to reduce the confounding effect of ambient concentration differences [74,78,79]. A positive concentration difference indicates that the $PM_{2.5}$ concentration in the UVS exceeds the background concentration and vice versa. The REC is defined as:

$$REC = C_{exposure} - C_{background}$$

where $C_{exposure}$ is the actual concentration measured at the monitoring site and represents the exposure of the active population in the UVS, and $C_{background}$ is the background concentration monitored at the background site.

3.Results

3.1Results of $PM_{2.5}$ concentrations in the UVS

3.1.1Statistical analysis of $PM_{2.5}$ concentrations in UVS

Figure 3(a) shows the objective fact that the sample data for $PM_{2.5}$ concentrations in the UVS are higher than the background values at an overall level. The background $PM_{2.5}$ concentrations are the measured values at the starting point of the route, with a mean value of 86.2 μg/m³. The UVS-P $PM_{2.5}$ concentrations are directly influenced by the viaduct, with a mean value of 107.0 μg/m³. While the UVS-NP $PM_{2.5}$ concentrations represent the monitored values at peripheral points not covered by the viaduct projection, with a mean value of 99.9 μg/m³. The mean UVS-P $PM_{2.5}$ concentration is the highest, approximately 7.1% higher than the mean UVS-NP $PM_{2.5}$ concentration and 24.1% higher than the mean background $PM_{2.5}$ concentration.

The sample data for particulate matter concentrations in the UVS varied significantly, with a maximum daily mean of 167.1 μg/m³ corresponding to a background concentration of 131.0 μg/m³, and a minimum daily mean of 52.2 μg/m³ corresponding to a background concentration of 46.3 μg/m³. This study found that the background concentration had a "magnifying effect" on the $PM_{2.5}$ concentration in the UVS, with the higher the background concentration value, the greater the difference between the UVS and the background value. The differences between the daily data in Figure 3(b) are also similar, reflecting a consistent distributional trend, except for 26 February and 28 February, when the variance of the data is relatively large.

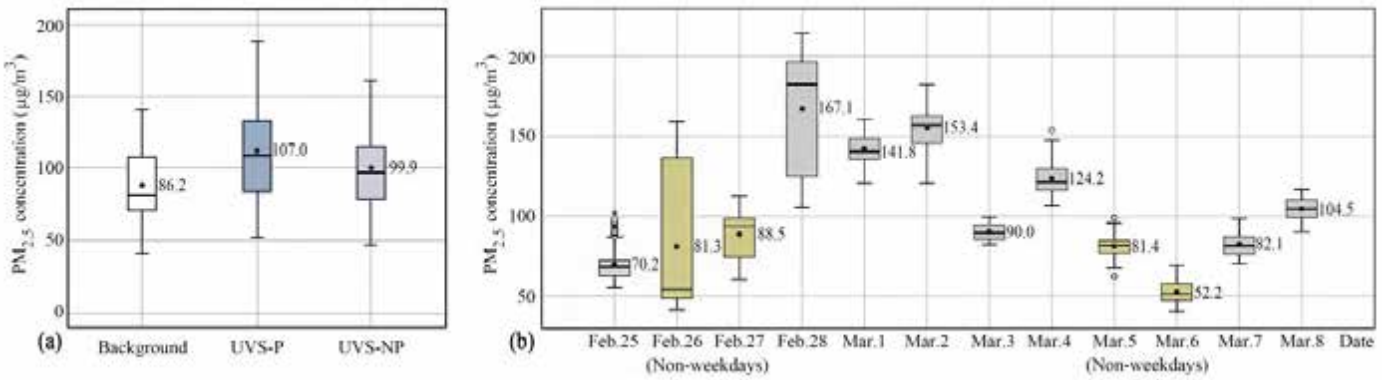

Fig.3 (a) Box plots of all $PM_{2.5}$ concentration data for background points, viaduct projection coverage, and non-viaduct projection surrounding space; (b) Box plots of $PM_{2.5}$ concentrations for each day of UVS. The dots in each box represent the mean (marked by numbers) and the solid line represents the median. Each box extends from the lower quartile to the upper quartile. Whiskers (error bars) below and above the boxes represent maximum and minimum values, and other circles represent outliers.

3.1.2 Spatial-temporal map

At the overall spatial distribution level, estimates of $PM_{2.5}$ concentrations at unmonitored sites were calculated by interpolation using GIS software. Figure 4 presents the 12-day map of mean $PM_{2.5}$ concentrations, which vary considerably between spatial sites, with differences in concentrations between monitoring sites as high as 15.4 μg/m³, accounting for up to 15% of the mean concentration of all sites. There is a discernible trend of significant attenuation from the viaduct to the east and west over a distance of approximately 210 meters along the road. The areas of high mean $PM_{2.5}$ concentrations occur to the north of the UVS-P, particularly at the intersection with the main road on the north side, with all values above 107 μg/m³. This indicates higher levels of pollutant exposure and more severe pollution in these areas. There were two areas of low $PM_{2.5}$ concentrations: one is in the green space between the viaduct and the buildings to the east, where a continuous wall of about 2m height between the building and the green space sharply reduces the pollutant concentration to about 99 μg/m³. The other area of low concentration is the space along the river, with a clear reduction seen, particularly in the section covered by the viaduct, where the mean $PM_{2.5}$ concentration drops to 98 μg/m³, a much lower value than in the north. This shows that urban water bodies can reduce $PM_{2.5}$ concentrations in nearby areas.

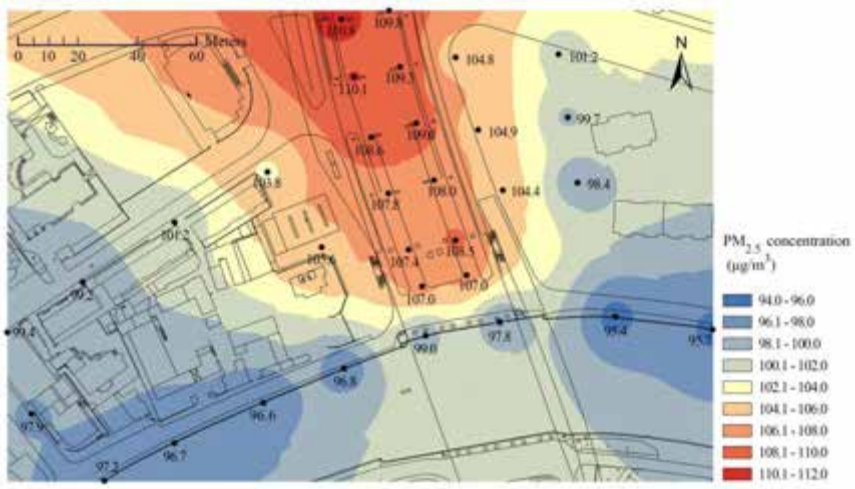

Fig.4 Map of mean $PM_{2.5}$ concentrations in the study area, black dots are actual sample locations, numbers are mean $PM_{2.5}$ concentrations at actual monitored location.

At the overall temporal level, Figure 5 shows that $PM_{2.5}$ concentrations are generally lower on non-working days than on working days. Overall, $PM_{2.5}$ concentrations at different times of the day also shows regular variations. The peak traffic periods tends to have the highest $PM_{2.5}$ concentrations of the day, especially in the evening peak period, while $PM_{2.5}$ concentrations are relatively low in the morning peak and off-peak periods. Sometimes the morning peak values are even lower than the midday off-peak values, presumably due to the difference in traffic volumes and the deposition of $PM_{2.5}$. This phenomenon is more pronounced on working days or when background $PM_{2.5}$ concentration is high.

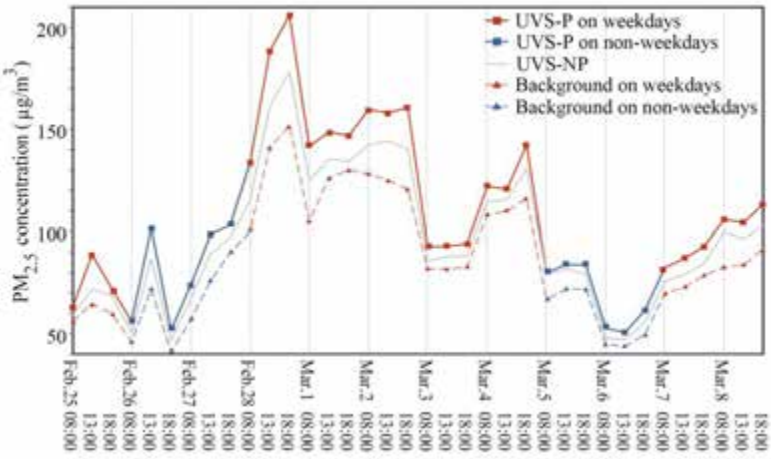

Fig 5. Mean value of $PM_{2.5}$ by time period.

On this basis, two typical days (27 February and 4 March) with similar meteorological backgrounds and traffic volumes are selected for detailed analysis of REC distribution characteristics for each time period between working and non-working days. Figure 6(a) shows that the overall REC values for the three periods on the typical non-working day are small. Figure 6(b) indicates that on a typical weekday the difference in REC between the two peaks and the midday period is greater. The trend of increasing REC towards viaducts and major roads and decreasing REC towards water bodies can be clearly seen in the morning and evening peaks. Two further findings are that 1) the distribution of $PM_{2.5}$ concentrations during a single period on a typical non-working day is more homogeneous and REC is smaller compared to the typical working day; 2) the range of high $PM_{2.5}$ concentrations on the typical working day has a wider impact, almost significantly affecting the area within 240m of the viaduct.

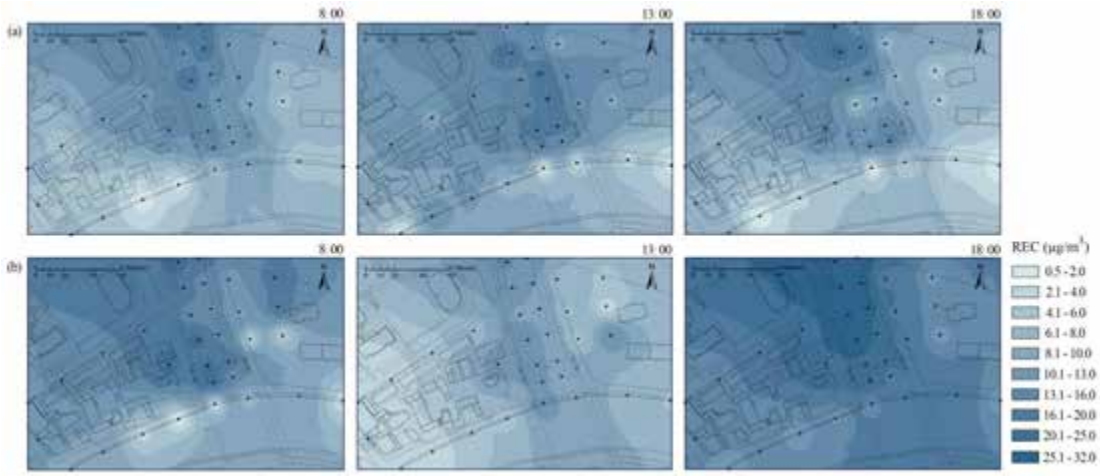

Fig.6 Spatial distribution of REC, black dots are measuring points. (a) includes values for three measurement periods on 27 February, representing non-working days. (b) includes values for three measurement periods on 4 March, representing working days.

3.1.3 Results of influencing factors

A multiple linear regression model (backward method) was used to investigate the effect of different influencing parameters on the distribution of REC in the UVS during winter. All the influencing variables listed in Table 4 have relatively small p-values (<0.05), indicating a statistically significant relationship between the predictor variables and the corresponding $PM_{2.5}$ concentrations. The standardization coefficient (beta coefficient) shows the relative contribution of different parameters to the change in REC. Furthermore, the adjusted R-squared of 0.573 indicates that the model has good explanatory power for the data.

REC is sensitive to changes in traffic, the built environment, and meteorological factors such as temperature and humidity. Among there, traffic volume has the greatest influence on REC, followed by temperature, with beta coefficients of 1.213 and -0.298 respectively. Distance to the viaduct and distance to the water body have no correlation with REC, but the ratio of the two is significantly correlated with REC. This suggests that sports venues should be located as close as possible to water and away from viaducts, and that people should choose times of high temperature, low humidity and low traffic volume to exercise.

Table 4. Regression analysis of the influencing parameters.

Variables	p-value	Beta [b]	
$PM_{2.5}$_TV	0.000	1.213	
$PM_{2.5}$_DD	0.000	0.225	**adjusted R^2**
$PM_{2.5}$_TP	0.013	-0.298	
$PM_{2.5}$_HM	0.041	0.121	0.573

Note: Beta [b] is standardized coefficient; $PM_{2.5}$_TV = traffic volume; $PM_{2.5}$_DD = the ratio of distance to viaduct and distance to river; $PM_{2.5}$_TP = temperature; $PM_{2.5}$_HM is humidity.

3.2 Results of traffic noise in the UVS

3.2.1 Statistical analysis of traffic noise in the UVS

Figure 7(a) shows that the measured equivalent sound level (Leq) of both the UVS-P and the UVS-NP is significantly higher than the background value. The background Leq has a mean value of 58.9 dB. The mean Leq of the UVS-P is 69.4 dB, which is 17.8% higher than the background level, while the mean Leq of the UVS-NP is also high at 63.2 dB, which is 7.3% higher than the background level, indicating that both are influenced by the viaduct.

Within a single day, there is a large difference in Leq, which can vary by about 10 dB (Figure 7(b)). This suggests that the noise intensity in the study area changes significantly throughout the day. Furthermore, while Leq is slightly higher on working days than on non-working days, the distribution trend is consistent, with median and mean values mostly varying in the range of 60-70 dB, and exceeding 70 dB in a few cases. Since the noise mainly comes from traffic and the activity behavior of the UVS, and the noise intensity from this type of source does not vary much from day to day, the Leq over the 12-day period varies less between single days, but varies considerably within a single day.

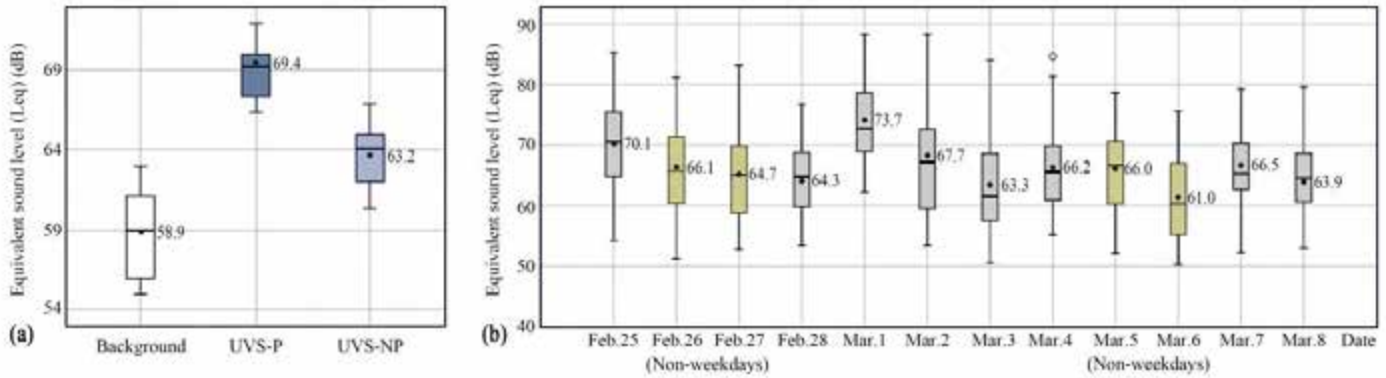

Fig.7 (a) Box plots of all Leq data for background points, viaduct projection coverage, and non-viaduct projection surrounding space; (b) Box plots of Leq for each day of the UVS. The dots in each box represent the mean (marked by numbers) and the solid line represents the median. Each box extends from the lower quartile to the upper quartile. Whiskers (error bars) below and above the boxes represent maximum and minimum values, and other circles represent outliers.

3.2.2Spatial-temporal map

At the overall spatial level, the mean noise distribution over 12 days was calculated using kriging interpolation with GIS software, and the results are shown in Figure 8. The noise levels vary widely across different spaces, with relatively high levels of Leq in the UVS-P, the north side road, and its surrounding areas, where it can reach over 70 dB. The noise levels also show a trend of gradual decay outward from high-traffic areas such as the viaduct and main road intersections. The Leq decreases sharply near the waterfront area on the south side away from the high-traffic area in the UVS-P. In addition, low Leq values appear in the waterfront area and on the west side of the viaduct, where the Leq remains at 59 to 63 dB. The noise is lower away from high-traffic areas and near the waterfront space on the south side, where the noise of the waterfront space remains around 60 dB. The existence of continuous greenery and walls on the southeast side of the viaduct allows the noise to dissipate more quickly.

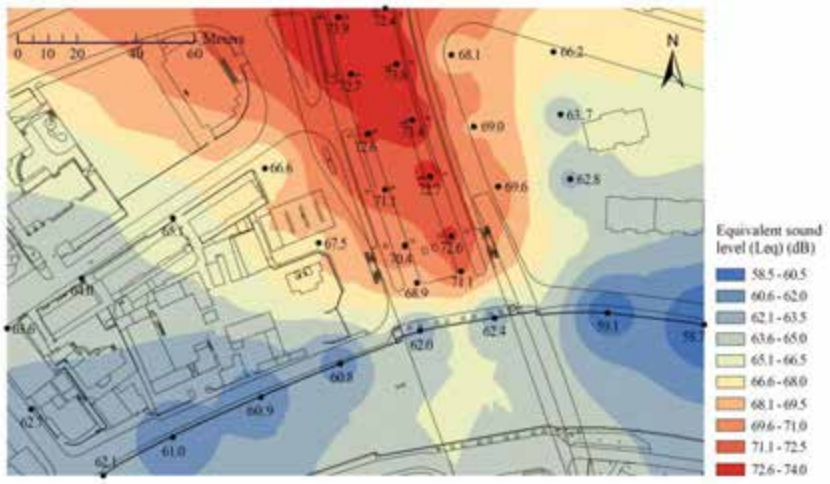

Fig.8 Map of mean Leq in the study area, black dots are actual sample locations, red numbers are mean Leq at actual monitored locations.

At the overall temporal level, the Leq of the UVS-P does not differ much between weekdays and non-weekdays, and is in a stable range of values that are about 10 dB higher than the background value for all time sections. The Leq of the UVS-NP is in the middle of the range. During the day, the Leq of the UVS-P in the morning and evening peaks is usually significantly higher than the midday value, and the difference between the former and the background values is greater than that between the latter and background values. This phenomenon is particularly evident on weekdays such as March 1st.

Overall, the Leq is higher in the morning and evening peak periods for most days, especially on weekdays. The Leq of the UVS-P basically appears as an amplification of the background value, while the Leq of the UVS-NP is in the middle.

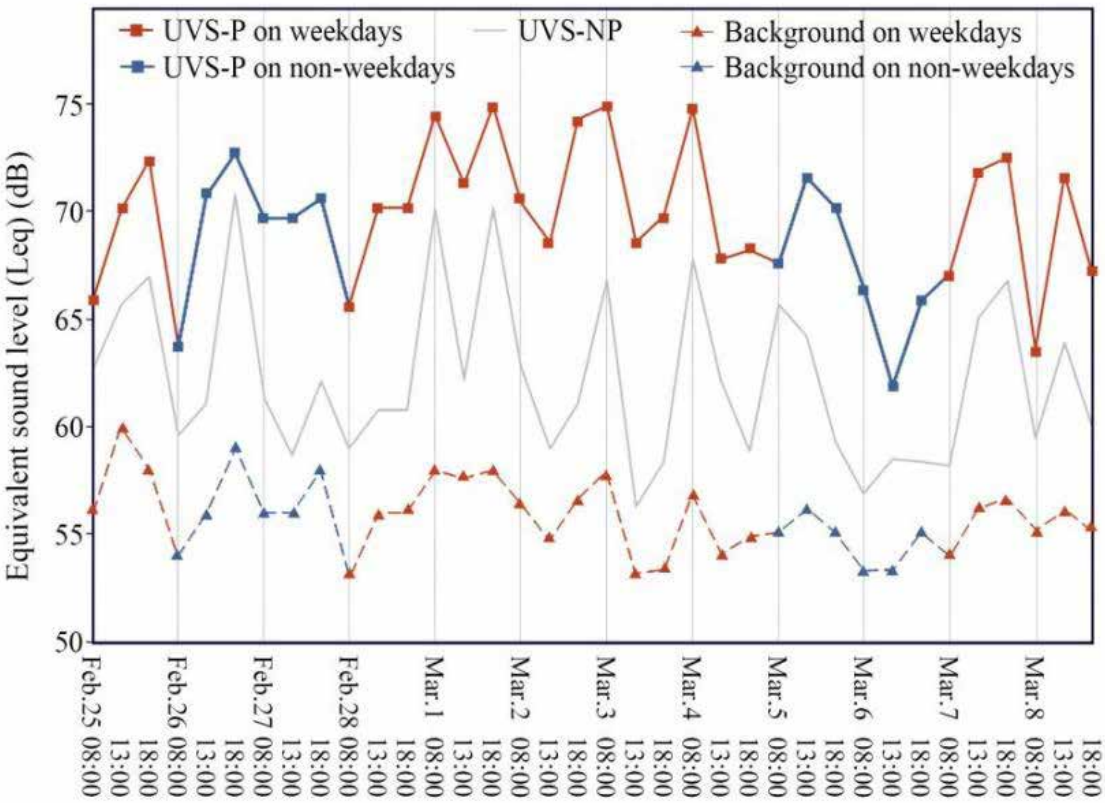

Fig 9. Mean value of Leq by time period.

Continuing with the selection of typical days above, the noise distribution characteristics of the three periods of working and non-working days are presented in Figure 10. In general, the Leq of the UVS-P is significantly higher than that of the UVS-NP and the background value in all time periods for both types of typical days, reflecting the inherent nature of noise under the viaduct. This may be due to the resonance and other characteristics of the viaduct itself, which amplify the traffic noiseΔK.W. NGAI et al., 2002Δ[80], and non-motorized Traffic vehicles and human activities, which also contribute to the noise pollution.

In addition, the overall difference between working and non-working days is less significant than the corresponding characteristics of $PM_{2.5}$ concentrations, with morning and evening peaks about 5-10 dB higher than normal. The Leq values at each point during the three periods of non-working days are similar, similar to the distribution characteristics of the midday period of working days. While the Leq of the UVS is still significantly higher during the working days peak period, the Leq of the UVS-P is 10-15 dB higher than the background value, indicating that the noise levels are still significantly influenced by the traffic flow. The range of noise attenuation is larger for working days (at least 50-100 meters), while the attenuation characteristics for non-working days are relatively small (between 20-100 meters). In addition, the noise attenuation effect of water bodies is not as obvious as for the $PM_{2.5}$ concentration, and it can be seen that the noise is relatively high at the monitoring sites along the river covered by the viaduct.

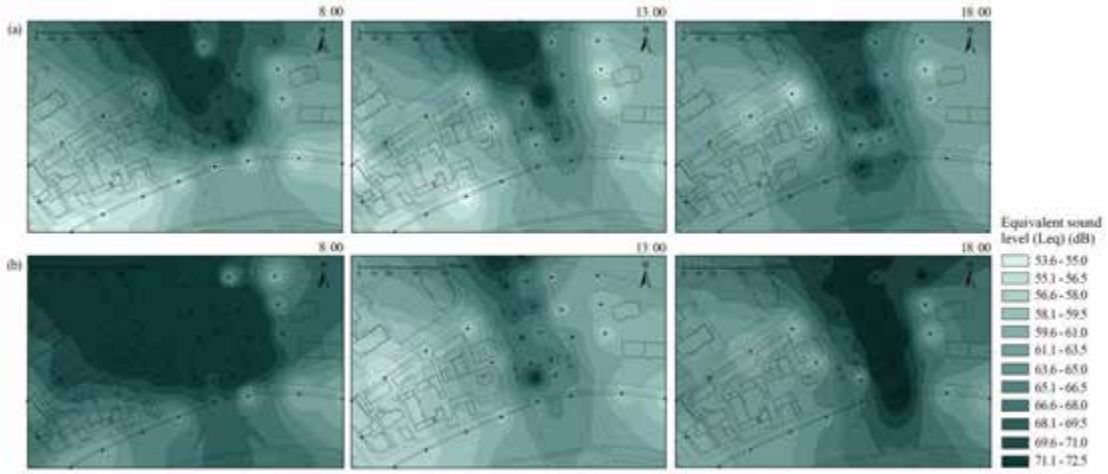

Fig.10 Spatial distribution of Leq, black dots are measuring points. (a) includes values for three measurement periods on 27 February, representing non-working days. (b) includes values for three measurement periods on 4 March, representing working days.

3.2.3 Results of influencing factors

In the case of traffic noise, the effect of different influencing parameters on the distribution of Leq in the UVS during winter was also investigated. Table 5 shows the p-values for various influencing variables, including traffic volume, humidity, and temperature. The p-values for traffic volume, humidity, and temperature are relatively small, with traffic volume having the smallest p-value. This indicates a significant relationship between these influencing factors and Leq. The adjusted R-squared value of 0.718 suggests that the model provides a good level of explanation of the data. The Leq data indicates a clear positive correlation with traffic volume, with a beta coefficient of 0.902, implying that traffic volume is the most influential factor on Leq. Additionally, it shows a negative correlation with winter temperature. This finding suggests that in order to reduce noise hazards, sports stadiums in the UVS should be located in spatial and temporal locations with low traffic flow and humidity.

Table 5. Regression analysis of the influencing parameters on traffic noise

Variables	p-value	Beta [b]	
Noise_TV	0.000	0.902	
Noise_DD	0.191	0.052	adjusted R^2
Noise_TP	0.106	-0.046	
Noise_HM	0.08	0.132	0.573

Note: Beta [b] is standardized coefficient; Noise_TV = traffic volume; Noise_DD = the ratio of distance to viaduct and distance to river; Noise_TP = temperature; Noise_HM is humidity.

4.Discussion

The $PM_{2.5}$ concentration and Leq data, as well as influencing factors in the UVS in central Shanghai, were collected based on mobile monitoring and used to analyze spatial and temporal distribution characteristics and factor correlations.

4.1 Contribution of $PM_{2.5}$ and noise distribution pattern

This study found and confirmed the spatial and temporal distribution characteristics of $PM_{2.5}$ concentrations and noise in the UVS, and also found similarities and differences between the two. Firstly, the spatial findings are as follows: 1) $PM_{2.5}$ concentrations and noise in the UVS-P are higher than the background case, consistently the highest values in the study area, and have some attenuation distance in the USP-NP. This is consistent with previous studies [19,22,31]. 2) Pollution levels along the river area are significantly lower and the water bodies

contribute to the reduction of $PM_{2.5}$ concentrations as well as noise, which is in agreement with the study finding that lake wetlands can significantly reduce PM concentrations within 300 meters [81]. Furthermore, urban open spaces, green spaces and roadside continuous walls can partially offset air and noise pollution from viaducts [82,83] and effectively reduce $PM_{2.5}$ concentrations and noise attenuation distances [19,56], although the influence on $PM_{2.5}$ is much higher than that on noise, suggesting that pollution can be optimized and mitigated through appropriate design measures.

The temporal findings are as follows: 1) $PM_{2.5}$ concentrations in the UVS and its surrounding space are significantly higher on working days than on rest days, which is not reflected in the noise, a side indication that the main factors influencing the two are different: traffic flow mainly influences $PM_{2.5}$ concentrations, while both traffic flow and crowd activity influence noise [84]. 2) $PM_{2.5}$ concentrations and noise in UVS and its surrounding space are basically higher during the morning and evening peak hours than during normal times of the day. In particular, $PM_{2.5}$ concentrations are more pronounced when the background concentration itself was higher, which is consistent with existing studies [24].

This study found that the enclosed environment of the viaduct significantly increased $PM_{2.5}$ concentrations and noise intensity in the UVS, both of which were significantly and positively correlated with traffic volume. Humidity was also positively correlated with the two pollutants. While there is a negative correlation between temperature and $PM_{2.5}$ concentrations, the negative correlation between temperature and noise is weaker, supporting previous microscopic studies [85]. Additionally, $PM_{2.5}$ concentrations are more sensitive to changes in the built environment, as its formation and dispersion are often influenced by urban buildings, floor area ratio and vegetation [86], while noise intensity is not significantly correlated with the built environment.

4.2 Contribution to policy

This study innovatively focuses on the characteristics of particulate matter and noise distribution in the sports space in the UVS, which is a less studied but important topic. Building on this, the study also selects the spatial quality of the UVS as the ultimate perspective to explore the appropriateness of reusing negative spaces in high-density cities. The results of this study have relatively high application value and provide an intuitive understanding of the changes in particulate matter and noise in the UVS microenvironment. This study is expected to provide theoretical support for the future development of the UVS spatial design and urban form optimization in large cities, represented by Shanghai. According to the spatio-temporal study, the overall $PM_{2.5}$ and noise pollution in the UVS in winter is more severe than in the surrounding areas, and there is attenuation. We recommend not placing open-air sports fields under the viaduct and in the surrounding space within 240 meters to avoid health damage to sensitive people. Noise and $PM_{2.5}$ have different attenuation characteristics and are less affected by the built environment, a difference that needs to be factored into future government decisions. Considering the influence of various factors, the exercise space around the viaduct should preferably be close to the water body, and people should be guided to exercise in places with appropriately high temperature, low humidity and low traffic flow to mitigate the adverse effects of these two types of pollution.

The space for sports under existing viaducts can be transformed into an enclosed indoor space, and mitigation measures can be taken for spaces under viaducts where transformation is difficult. Firstly, they can be converted into indoor spaces by adding spatial barriers to the road or greenery. Secondly, the airflow under viaduct spaces can be maximized by using new materials such as acoustic panels and mitigation measures for the viaducts [30], as well as enhancing the microclimate design of the UVS.

4.3 Limitation

This study only selected 12 days in winter to conduct the experiment, which lacks comparability to the summer season or to a full year's worth of data, and the limited timeframe may have had an impact on the correlation analysis. Secondly, as the dispersion of airborne particulate matter is influenced by aerodynamic mechanisms, the dispersion of polluting particulate matter in the UVS is the result of a combination of meteorological factors. Although this study avoided the effects of strong winds and rain, it did not specifically consider wind environmental factors such as wind speed and direction. In the future, more factors, such as the types of moving vehicles, need to be incorporated.

This study reveals the spatial and temporal characteristics and summarizes the influencing factors of particulate matter and noise pollution in a typical UVS in a high-density city through a field experiment with high accuracy. This provides an important basis for scientifically and effectively assessing the health and comfort of the UVS.

The study has both guidance and practical significance for the design of existing or new UVS, and provides more ideas and references for the concept of urban renewal in high-density cities.

Abstract
The spread of renewable energy sources (RES) is nowadays a key goal at European level, being "decarbonization" crucial to counterbalance climate change. However, current push towards energy transition is opening new questions, such as the need of balancing the positive environmental impacts arising from the spread of the RES and the landscape transformations it may entail. This contribution, with reference to the Italian context, explores the role of landscape planning tools in ensuring a proper balance between landscape quality and increase of energy generation from RES, with specific reference to agrivoltaic systems (APV), providing hints for their location, according to landscape quality, and criteria for designing APV. tailored to the peculiar features of the heterogeneous agricultural landscapes.

Keywords: agrivoltaic systems, landscape planning, agricultural landscapes

Introduction

Energy generation from renewable sources represents, nowadays, a primary goal at both European and national levels, being "decarbonization" one of the key solutions to counterbalance climate change. By 2030, the share of energy produced from renewable energy sources (RES) in the European Union is expected to reach 42.5% (binding) and 45% (indicative) with a key contribution from solar photovoltaics (European Commission, 2022). According to the data provided by Terna1, in 2024 energy produced by RES recorded the highest ever demand coverage level of 41.2 percent (up from 37.1 percent in 2023). This level is up mainly due to the increase in hydroelectric and photovoltaic production. With the Integrated National Energy and Climate Plan, Italy aims at achieving a target of 39.4% of gross final energy consumption from renewable sources in 2030 (Ministero dell'Ambiente e della Sicurezza Energetica, 2024).

In line with the European and national targets to 2030, the Italian Ministry of Environment and Energy Security, in July 2024, issued a Decree setting the distribution among Italian regions of the national target of additional power from renewable sources to be achieved by 2030. The same Decree also established the criteria for identifying unsuitable areas, leaving it up to the regions to identify eligible areas, maximizing the achievement of the assigned targets in terms of energy production from renewable sources.

However, a recent verdict issued in May 2025 by the Administrative Court of the Lazio Region, and namely by a competent judge for the matter whose decisions are valid for the entire national territory has cancelled the articles of the Decree specifically related to the identification of the suitable and unsuitable areas, forcing the Ministry of Environment and Energy Security to re-edit the criteria for identifying areas suitable and unsuitable for the installation of plants for energy generation from RES2.

Despite the significant uncertainty that characterizes current legal and regulatory framework, the push toward energy transition is opening issues related, first and foremost, to the need of balancing the positive environmental impacts of RES deployment with the territorial and landscape transformations that such deployment entails

1 TERNA manages the Italian Electricity Transmission Grid (NTG) and it is the largest independent grid operator (TSO) in Europe. Data are available at: https://www.terna.it/it/media/comunicati-stampa/dettaglio/consumi-elettrici-2024.
2 Sentence of the TAR Lazio n. 9155 of 13 May 2025

(Greco, Cresta, 2023). Although energy transition is nowadays an undisputed priority, also in relation to the goals set by Agenda 2030[3], the protection of landscape constitutes one of the fundamental principles of the Italian Constitution (Article 9), which has been more recently extended to the environment, ecosystems, and biodiversity.[4] Thus, some authors, considering energy generation from RES as a matter relevant to environmental protection, state that when two principles, such as landscape and environmental protection, represent both foundational constitutional values, a non-hierarchical priority is established between them (Ferraro, 2012). Others, emphasize the existence of a "clear separation between environment and energy", even in the case of energy generation from RES, highlighting the conflicts between environmental/landscape protection instances and wind and photovoltaic energy development policies (Calabrò, 2021).

Based on the above, the thesis here supported is that landscape planning tools could represent key tools for achieving a proper balance between the conflicting instances of landscape protection and enhancement and the current policies for the development of energy generation from RES. According to the Legislative Decree 42 of 2004 (Art. 145, paragraph 3), in fact, the forecasts of landscape planning tools cannot be derogated from by national or regional economic development plans, programs and projects. Moreover, they are binding for urban planning tools issued by municipalities, metropolitan cities and provinces as well as for sectoral interventions; their forecasts immediately prevail over any dissimilar provisions included in urban planning tools; they establish safeguard rules applicable pending the necessary revision of the urban planning tool.

Hence, this paper explores the role that landscape planning could and should play in ensuring a balance between landscape quality and the spread deployment of energy generation from RES, with specific reference to agrivoltaics systems (APV). In detail, this paper provides some hints to identify areas for the location of APV, based on landscape protection needs, and criteria to design APV tailored to the peculiar features of the heterogeneous agricultural landscapes.

Although APVs have a lower environmental impact than other types of RES, since they reduce the consumption of agricultural land and ensure a number of potential benefits to agricultural activities (shading, reduction of water demand, protection from extreme weather winds, etc.), their massive introduction can result in substantial transformations of agricultural landscapes, especially in regions characterized by a high extensions of agricultural land, also reducing the acceptability by local communities of APVs that are, in turn, carriers of innovation and fundamental tools towards a sustainable energy transition.

How to reconcile the location choices of APVs with the needs of landscape protection?
The latest generation of landscape plans in Italy has definitively marked the transition from a constraint-based approach towards a landscape plan intended as a tool to guide the sustainable transformation and enhancement of environmental, territorial and landscape heritage. It was precisely these plans that attempted to provide criteria and rules to guide both the localization and the landscape compatibility of renewable energy sources (Paolinelli, 2012; Magnaghi, 2016).

All the examined landscape planning tools (Apulia, Tuscany, Piedmont) recognize the significant changes to the landscape features that renewable energy production plants could cause and provide hints for their location and for minimizing their impact on landscapes. Nevertheless, most of them do not provide regulations specifically addressed to APV, focusing above all on wind farms and ground-based photovoltaic systems.

However, numerous European scholars have provided hints to determine suitable and unsuitable areas for APV, suggesting some useful landscape criteria. Among the latter, the studies aimed at assessing the agrivoltaics potential in Germany have to be mentioned (Rösch, Fakharizadehshirazi, 2024): they suggest, in detail, the widespread adoption of small-scale APV (<2.5 ha), privileging areas not easily visible and accessible, and minimizing visual impact through the planting of hedges. They also identify some typologies of areas in which the location of APV should be prohibited:

3 See in particular Goal 7 (Clean and Affordable Energy), which identifies increasing energy produced from RES and improving energy efficiency as key strategies for combating climate change.
4 https://www.riformeistituzionali.gov.it/it/la-legge-costituzionale-in-materia-di-tutela-dell-ambiente/

- biodiversity protection areas (nature reserves, national parks, biosphere reserves, landscape protection areas, natural parks, natural monuments, legally protected biotopes and Natura 2000 areas);
- water protection areas;
- floodplains;
- landscapes of special significance.

Finally, they identify as unsuitable areas for APV, the 200 mt. buffer zones around residential and commercial areas, to avoid visual interference with the most populated and frequently visited areas.

Similar studies have been conducted with reference to Sweden (Elkadeem et al. 2024): in this case, restrictive criteria for APVs' location include all protected areas, with a buffer zone equal to 1 km; water bodies, with a buffer zone of 100 mt. for rivers and 300 for lakes. In addition, with the aim of limiting the visual impact of installations, Elkadeem et al. consider a protected strip along roads equal to 50 mt. and a buffer value of 1 km with respect to urbanized areas.

Similar studies, carried out with reference to the Italian context, show some minor differences from those previously recalled, because they do not include, for example, the use of buffer zones, but provide similar exclusion criteria (Fattoruso et al., 2024):

- national and regional parks;
- areas included in the NATURA 2000 network;
- areas reserved for biodiversity conservation in European countries (established by the Habitats Directive) for the conservation of natural and semi-natural habitats and wildlife.

Fattoruso et al. provide also relevant insights into the heterogeneous regional distribution of the areas potentially suitable for agrivoltaics, that range from 12% of the total agricultural area in Apulia to 0% in Liguria and Valle d'Aosta. These data clearly underline the importance of adopting flexible criteria that can be adequately tailored to heterogeneity of landscapes that characterize at least the Italian regions.

In June 2024, a Ministerial Decree was approved in Italy to drive Regions in determining suitable and unsuitable areas for the installation of renewable sources energy plants. In detail, the Decree, in addition to establishing the regional distribution of the national 2030 target of an additional 80 GW of power from renewable sources compared to December 2020, asks Regions to identify:

a) suitable areas, where an accelerated and facilitated procedure is provided for the installation and operation of RES facilities and related infrastructure;
b) unsuitable areas, showing features incompatible with the location of specific types of RES;
c) ordinary areas, where ordinary authorization regimes set forth in Legislative Decree No. 28 of 2011 can be applied;
d) areas where the installation of photovoltaic systems with ground-based modules is prohibited.

According to the criteria set by the 2024 Decree, unsuitable areas are those included in the perimeter of properties subject to protection under Article 10 and Article 136, paragraph 1, letters a) and b) of Legislative Decree n° 42 of January 22, 2004. Such properties can be listed as follows:

- immovable assets having artistic, historical, archaeological or ethnoanthropological interest and distinguished by peculiar features of natural beauty or geological singularity;
- villas, parks and gardens of artistic or historical interest or distinguished by their uncommon beauty;
- all urban open spaces (streets, squares, etc. of artistic or historical interest); mining sites of historical or ethno-anthropological interest; rural architecture having historical or ethno-anthropological interest as evidence of the traditional rural economy.

The Decree provides Regions also with the opportunity to define as unsuitable all the areas included in the perimeter of other assets protected under the same Legislative Decree (n° 42, January 22, 2004). Regions can, therefore, exclude from suitable areas, additional areas, such as those protected by the article 142. Moreover,

Regions may establish a buffer zone, having different width depending on the type of plant and protected asset, from the perimeter of the protected asset up to a maximum of 7 kilometres, but only if this choice does not compromise the possibility of achieving the production targets set for each Region by the Decree.

Finally, Regions are required, following the identification of the suitable areas, to update all energy, environmental and landscape planning acts and any other regulations, programs, plans or legislation previously approved at the regional, provincial or municipal level. Hence, according to the Decree, the identification of suitable areas prevails on any previously made provision, including those referred to landscape protection.

In this sense, the 2024 Ministerial Decree entails a substantial reversal from Ministerial Decree 219/2010, aimed at providing Guidelines for the authorization of plants powered by RES. The latter assigned, in fact, to the Regions the task of identifying unsuitable areas, taking into account what already established in the landscape regional plan, and indicated a broader list of areas that for their sensitivity/vulnerability features could be identified as unsuitable for the location of specific types of plants.

It seems useful to remind that, according to current Italian legislation, the main task of landscape planning tools is the identification of necessary measures to ensure a proper integration in the different landscapes, of any intervention, with the aim to guarantee the compatibility between territorial development and the different recognized and protected landscape values, with particular attention to the preservation of rural landscapes and sites included in the UNESCO World Heritage List (Dlsg. 42/2004).

Moreover, as previously mentioned, the articles of the 2024 Decree related to the identification of suitable and unsuitable areas have been currently cancelled and will have to be re-edited.

Thus, despite the lack of certain regulatory references, it is here considered of paramount importance to identify unsuitable areas for the location of APVs, in compliance with the protection regimes and requirements already set by the landscape plans. Nevertheless, it is possible to identify some relevant landscape assets, whose quality could be altered by the installation of APVs, that were only partially included by the articles, currently eliminated, of the Ministerial Decree issued in 2024. In particular:

- landscape assets regulated by Articles 10 and 136 of Legislative Decree 42/2004;
- landscape assets regulated by Article 142 of Legislative Decree 42/2004;
- landscape assets as identified in accordance with Article 143, paragraph 1 (d) and (e) of the 2004 Legislative Decree ;
- areas included within the Natura 2000 network;
- wetlands falling under the Ramsar Convention;
- Important Bird Areas (I.B.A.);
- UNESCO sites;
- rural landscapes listed in the National Register of Rural Landscapes of Historic Interest, Agricultural Practices and Traditional Knowledge by the Ministry of Agriculture, Food and Forestry (Decree No. 17070, November 19, 2012).

Nevertheless, an adequate attention to the quality of landscapes does not imply only the exclusion of selected areas from the possibility of installing APVs; it requires, first and foremost, the definition of criteria aimed at guiding the design of APVs towards a greater attention to the features and quality of the agricultural landscape in which each AVP will be located (Toledo, Scognamiglio,2021; Fattoruso et al., 2023].

To this end, this contribution aims at providing some landscape criteria useful to guide the APVs' design towards a better understanding, and consequently to a greater respect, of the peculiarities of each agricultural landscape, especially in selected "*warning*" areas, where the compliance with detailed landscape criteria must be mandatory. The identification of these areas, which must be carried out within the framework of regional landscape plans too, can be based on some general criteria:

- presence of quality agricultural and food production;
- historical-testimonial value;
- presence of visual cones drawn from viewpoints located in scenically unsuitable areas and/or in historic centres or along roads, pedestrian or bicycle paths that have historical and/or scenic value;
- presence of protected areas of local significance.

In the "*warning*" areas, the potential for the location of APV has to be determined through detailed analyses at local scale, aimed at identifying areas that, due to their landscape-cultural value, relevance in the local agricultural tradition (traditional crops that currently survive only in limited portions of the regional territory), visibility from routes characterized by a high landscape value or from relevant points of the territory, cannot be considered suitable to the location of APV, falling into the category of unsuitable areas. Within all the other "*warning*" areas, the respect of landscape criteria in the design of the APVs must be considered always mandatory.

Figure 1 summarizes the suggested methodological path to ensure that both location and design of APVs are compatible with the features of the agricultural landscape they will be included in.

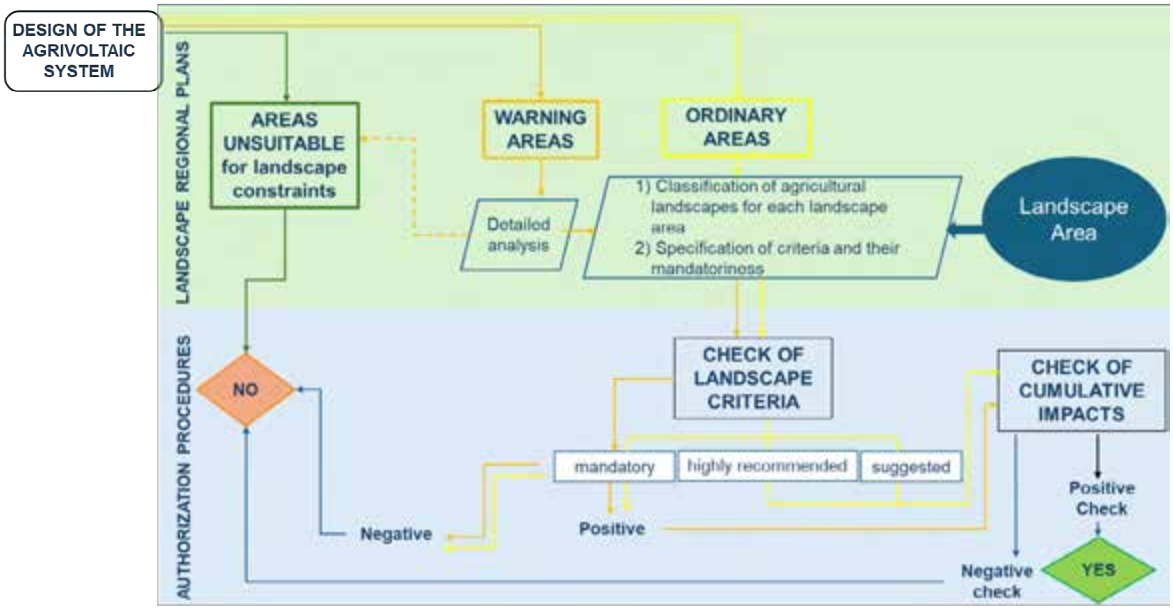

Figure 1 - *The methodological path to ensure localization choices based on landscape protection needs and an APVs' design tailored to the peculiar features of the different agricultural landscapes. Source: Authors' elaboration*

Landscape criteria to guide the design of agrivoltaics systems.
The definition of landscape criteria to guide the design of APVs has been the most challenging aspect of the research work, due both to the limited references in scientific literature, being this aspect a quite recent research field (Scognamiglio, 2016), and to the heterogeneity of agricultural landscapes that characterize, in particular, the Italian context.

Indeed, there are few studies aimed at providing criteria for designing an APV according to the peculiar features of agricultural landscapes. Most of them focuses on the visual impact of APV, which is considered particularly relevant because of the elevated structure of PV modules, which are clearly visible even from a significant distance, especially in flat areas. Some studies examine, in particular, issues related to visual openness, visibility, and relationships between PV modules and crop patterns (Sirnik et al., 2023); others underline the importance of considering both the view from inside the agricultural area where the PV modules will be located, and the visibility of the PV modules from the surrounding areas; other studies consider visual openness, i.e., the amount of space visible from a user located in the centre of the APV, and its visibility from valuable assets located in the surrounding area (Weitkamp et al., 2011). The same authors suggest the identification of a 10-m buffer, around

the perimeter of the area were the APV is located, and the check of the presence of valuable elements from which the system could be visible, regardless of the presence of infrastructural elements such as roads or pedestrian paths.

The few studies focusing on the relationship between the shape of agricultural plots and those of PV patches have identified three types of configurations: responsive, irresponsive, split, island, incidental (Figure 2) (Oudes, Stremke, 2021; Sirnik et al., 2023).

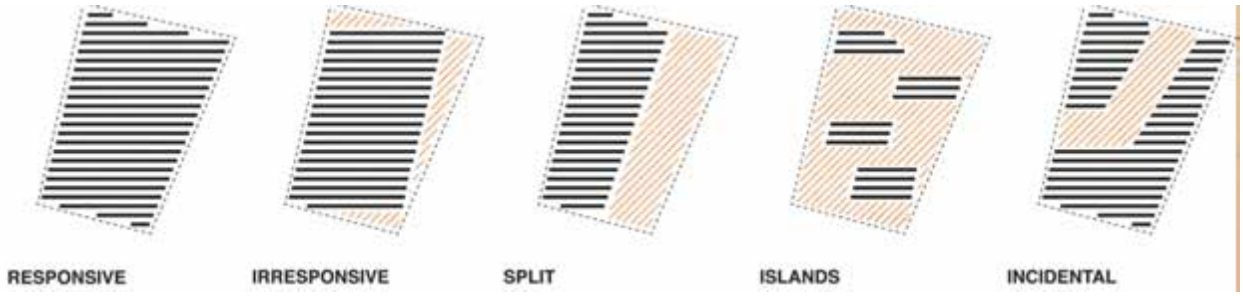

Figure 2 - *Geometric relationships between agricultural plots and PV patches. Source: Oudes, Stremke, 2021*

In the *responsive* configuration, the arrangement of PV patches conforms to the shape of the agricultural plot, covering its entire extent. This preserves the recognizability of both the shape and size of the agricultural plot.
In the *irresponsive* configuration, the arrangement of PV patches does not compare with the size and shape of the agricultural plot. As a result, there are residual spaces in the agricultural plot, but they do not reflect the shape of the plot itself.

In the *split* configuration, the arrangement of PV patches conforms to the shape of the agricultural plot, but they cover only partially the plot. The result is a subdivision of the agricultural plot that, however, does not alter the shape of the plot itself.

In the *island* configuration, only small parts of the agricultural plot are covered by the PV patches, with shapes completely independent of the plot itself.

In the *incidental* configuration, the arrangement of PV patches depends on the presence of specific elements, such as buildings or infrastructure.

Some scholars have also investigated the relationship between the orientation of the PV modules and that one of the crops: *so* far mainly related to optimizing energy performance, this relationship could be usefully varied, using criteria for consistency between crop and PV modules orientation, both in the case of vertical and inclined modules, to meet different objectives (Toledo, Scognamiglio, 2021).

Birò-Varga et al. (2024) carried out studies on the perception of different types of APV by those who enjoy a given landscape, using questionnaires. The authors, with reference to an overhead and a vertical interspace agrivoltaics power plant, examine the different perception of the two systems: in both cases the attractiveness of the landscape is considered lower, but it is perceived as drastically lower in the case of the overhead agrivoltaics power plant, Studies specifically aimed at providing criteria for better integration of APV into the landscape include the work of Fattorusso et al. (2023) who identified three general criteria related specifically to:

- the relationships between the size of APV and the size of other landscape elements;
- the relationships between the geometrical features of the PV modules and those of the landscapes' elements;
- the different densities between the PV pattern and the landscape pattern.

The study, based on the principles of *landscape ecology*, provides some metrics to quantify analyse the landscape structure (e.g., size and number of patches within predefined areas) and suggests the possibility of using these criteria to guide the integration of APV into the landscape.

However, the variety of agricultural landscapes requires careful consideration regarding the appropriateness of general criteria and metrics: the latter should be outlined, on the opposite, taking into account the morphological, geometric, cultural and contextual peculiarities of each landscape typology in which each APV has to be located. Therefore, a classification (certainly not entirely exhaustive) of the most widespread typology of rural landscapes, at least in Italy, has been outlined to define, for each typology, adequate landscape criteria, characterized by different levels of compulsoriness depending, above all, on the urbanization level of the considered agricultural area. In addition, some criteria for the assessment of cumulative impacts have been defined for each typology of agricultural landscapes.

Agricultural landscapes are composed of cultivated areas and their features depend on the peculiarities and different aggregation of some "structuring" elements"; in particular (Table 1):

- the morphology of the area;
- the agricultural plots;
- the type of crop;
- the presence of historical remains;
- the road network;
- the water network;
- the natural vegetation.

However, a correct classification of agricultural landscapes cannot disregard the complex relationships between agricultural areas and urbanization processes: the latter induced, in fact, significant changes in rural landscapes, especially in lowland areas, where there has been the greatest growth of both settlements and infrastructure. Data from the 7° General Census of Agriculture (ISTAT, 2021) show that in Italy, between 1982 and 2020, almost two out of every three farms disappeared, while the total agricultural area shrunk by more than 20%. Therefore, starting from the analysis of the recurring relationships between agricultural and urbanized areas, four typical contexts in which rural landscapes can be placed have been identified, as highlighted in table 2.

The different contexts identified in Table 2 are useful both for a better classification of agricultural landscapes and for assigning different levels of compulsoriness to the landscape criteria for the design of APV (Table 3). In areas where settlement pressure is very low, in fact, the adoption of landscape criteria in the design of APV must be mandatory, while such adoption can be only suggested, in case of APV to be located in agricultural areas enclosed or located in peri-urban areas, where the spread of APVs should be largely "favoured", being them useful to counteract the abandonment of agricultural activities and in promoting their multifunctionality.

Regarding the criteria useful to improve landscape compatibility of APV in different types of agricultural landscapes, also based on the available scientific literature, four categories of criteria were identified: morphological, dimensional, geometric and visual criteria (Table 4).

Table 1 - Structuring elements of agricultural landscapes. Source: Authors' elaboration

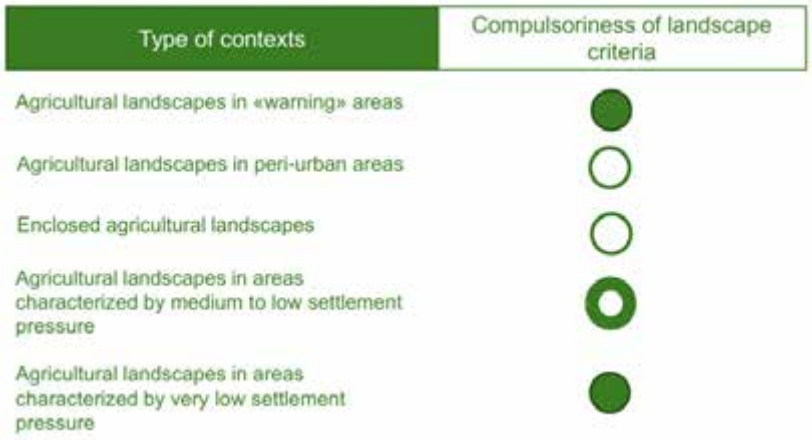
Elements	*Description*	
Morphology	Lowland or hillside landscapes have heterogeneous characteristics and determine distinct categories of agricultural landscapes, which are also decisive for the characterization of additional elements (plots, crops, etc.), as well as for different visibility conditions.	
Plots	Agricultural plots are highly dependent on the morphology of the site and area characterized by different shapes, sizes and type of aggregation. They also depend on the road network and on the type of cultivation, and show different geometries, more or less regular.	
Crops	The different crops can be distinguished into four macro-types: arable land, stable grassland, woody crops, arboriculture, and floricultural crops. The different crops result in variations in texture, size, grain, and colour, which are also very important in the characterization of agricultural landscapes.	
Remains	Traces of the historical stratification, which can be both buildings (e.g. historical farms, rural villages) or linear elements (such as historical tracks, or forms of organization of the agricultural territory, such as the Roman "centuriatio"). Other types of remains are, for example, the drystone walls, which were included in the UNESCO heritage list in 2018.	
Networks	Networks constitute decisive elements in the structuring of the agricultural mosaic: the main roads and the dense network of inter-modal roads, together with the possible presence of waterways and the more or less dense network of irrigation canals constitute fundamental elements in the design and characterization of agricultural plots.	
Natural vegetation	It is made up of the set of arboreal or shrubby elements bordering the field (hedges, isolated trees, tree patches or trees in rows) and plays a fundamental role from both a landscape and environmental point of view, representing elements with high ecological value within the cultivated areas.	

Table 2 - Different types of agricultural landscape contexts. Source: Authors' elaboration

Type of contexts	*Description*	*Images*
Agricultural landscapes in peri-urban areas	They are generally characterized by multiple uses, where agricultural tracks intersect with fragmented settlements, industrial areas, landfills, etc. and/or characterized by extensive urban *sprawl* and the presence of major infrastructure axes.	
Enclosed agricultural landscapes	Residual agricultural areas surrounded by densely built urban fabrics	
Agricultural landscapes in areas characterized by medium to low settlement pressure	Agricultural areas characterized by the presence of historically established rural settlements and more recent urban fabrics, generally concentrated along secondary road networks	
Agricultural landscapes in areas characterized by very low settlement pressure	Agricultural areas characterized by a very limited presence of settlements and a high presence of natural vegetation	

Finally, with exclusive reference to landscape aspects, some criteria to limit the cumulative impacts, resulting from the albeit desired spread of APVs, have been defined.

Table 3 - Types of contexts and level of compulsoriness of landscape criteria for the design of APVs. Source: Authors' elaboration



To date, apart from the guidelines provided by the Apulia Region in 2012 (Resolution of the Regional Council 2122/2012) for the assessment of cumulative impacts of projects for electricity production from wind and ground-mounted photovoltaic systems, which also explicitly consider cumulative impacts on landscape views, no guidelines specifically addressed to APVs are available.

Table 4 – Landscape criteria for APV design. Source: Authors' elaboration.

Criteria	Description
Morphological	These criteria refer to the coherence between the design of APV and the morphological features of landscape, determined by the morphology of the site and of the agricultural plots, by the organization of the networks (road, irrigation channels) and/or by presence of historical traces (centuriatio, paths, etc.). These criteria are also aimed at ensuring that the layout of PV modules does not induce a loss of continuity of non-crop vegetation networks (hedges, rows, swaths of spontaneous vegetation, wooded patches, etc.), ensuring that these elements can effectively play their role as ecological connections in contexts that are often already heavily artificialized.
Dimensional	These criteria are related to the "size" of the different elements that agricultural landscapes are made of. As highlighted by several scholars, a better integration of APV in agricultural landscapes requires that the size of the APV is consistent with the average size of the landscape elements, and namely of the agricultural plots, avoiding the so called out-of-scale effect, also relevant from a perceptual point of view. To this aim, metrics extremely common in landscape analyses, such as the average size of agricultural plots in the area affected by the APV, are suggested. Dimensional criteria can be also used to define buffers to be respected in the areas contiguous to the APV, useful to interrupt the continuity of the PV modules, especially in the selected "warning" areas.
Geometric	These criteria refer to the consistency between the orientation of PV modules and that one of agricultural crops, taking into account the possibility of using modules with such "mobility" characteristics as to maximize their sun exposure.
Visual relationship	These criteria are the most widely used in scientific literature, with reference to the visibility of both APV from surrounding areas and surrounding areas from APV. The key objective is to avoid that PV modules obstruct relevant views (e.g. landmarks) or alter the view of agricultural landscapes from viewpoints located in protected areas, along routes with high historical and landscape value or from centres or artifacts of historical-architectural importance.

Again, due to the heterogeneity of agricultural landscapes, it is not appropriate to provide unambiguous rules for all of them: while for some landscapes it is essential to avoid the "sprawl" effect, in fact, for others, a widespread presence of APV can be relevant to counteract settlement pressures and the increasing phenomena of land take and soil sealing, currently affecting numerous agricultural areas. These are two extreme cases: between them, some intermediate cases can be identified. For example, in agricultural landscapes falling into the "warning" areas or in areas with low settlement pressure and high presence of natural vegetation, it is essential to provide limits on the maximum extension of the total agricultural area that can be devoted to APV, as well as on the mutual distance between new APV and pre-existing or authorized ones, with particular attention to the portions of landscape perceptible from viewpoints located in areas and/or along roads of particular historical and landscape significance. Conversely, in peri-urban and enclosed agricultural landscapes, it seems relevant to maximize the presence of APV even as replacements for existing greenhouses.

The methodological path here briefly outlined was tested on the Campania Region, which to date has a Preliminary Landscape Plan, approved in 2019.

Specifically, from the 51 Landscape Areas identified by the Preliminary Plan, an Abacus of the agricultural landscapes in the Campania region was outlined. For each of the identified agricultural landscape types, a sheet describing their structuring elements (geometry and size of agricultural plots, crop type, etc.) and relationships with settlements (Figures 3a, 3b) was drawn up. These sheets also indicate the different levels of compulsoriness of the landscape criteria for the design of APVs. Finally, with reference to each type of agricultural landscape, a matrix of criteria to be adopted for guiding the design of APVs and for assessing the cumulative impacts has been developed (Figures 4, 5).

Concluding Remarks

The definition of criteria for improving the compatibility of APVs with agricultural landscapes represents a complex and meanwhile an unavoidable challenge to ensure a proper balance between the needs related to the sustainable energy transition and the equally relevant needs related to the protection and enhancement of landscape heritage.

APV represents, nowadays, an important innovation in renewable energy generation, enabling the coexistence of energy and agricultural production and, in many cases, allowing an increased agricultural productivity; nevertheless, the spread of APV, if not carefully planned and in the lack of landscape criteria guiding their design, could induce uncontrolled landscape transformations, with negative consequences both for the quality of agricultural landscapes and for the social acceptability of APV.

Therefore, landscape planning tools have been here identified as the most suitable tool to achieve a better balance between landscape quality and the spread of APV: these plans are, in fact, endowed with binding and prevalent effectiveness compared to other planning tools and they might guide both the location and design of APV through guidelines, tailored to the peculiarities of the heterogeneous regional landscapes.

LANDSCAPE AREA	
20-Ufita	
Rural system with cultural value

Thus, based on the national and regional regulatory framework for the location of energy generation plants from RES, the state of the art of regional landscape planning in relation to energy and agricultural landscapes, and the scientific literature on the relationship between APV and landscape, this paper has outlined a methodological path to guide landscape planning tools in guiding:

- the location of APV through criteria for identifying unsuitable and warning areas;
- the design of APV, through morphological, dimensional, geometric and visual criteria tailored to different agricultural landscapes;
- the compulsoriness of these criteria, depending on the degree of urbanization of the context;
- the assessment of cumulative impacts.

The methodological path, tested on the Campania region, has led to outline specific Guidelines, useful to support the dissemination and application of the proposed methodology at national level. The Guidelines are addressed to different categories of end-users (regional and local administrators, landscape planners and people in charge of the authorization procedures of individual APV system) and are user-friendly, including numerous explanatory examples of the different steps of the methodology.

2. Irregularly meshed lowland arable land.	Dimensional	Morphological	Geometric	Visual relationships
LANDSCAPE ELEMENTS — *Site morphology*				APV must avoid obstructing relevant views
Shape and size of agricultural plots	APV must occupy an area ranging from 0.5 ha (minimum lot size) to 4.5 ha (average parcels' size). The area covered by the APV must have a buffer on each side equal to, at least, the largest dimension of the area occupied by the APV.	APV can fully or partially cover the agricultural parcel, preserving the recognizability of its shape.		In the first level visibility bands (500 mt), calculated from relevant viewpoints located in unsuitable or in warning areas, APVs are not allowed; in the second-level visibility bands (1200 mt), calculated from the same viewpoints, APVs are allowed on a maximum area of two hectares.
Type of crop			The warping of PV modules should be consistent with the warping of different types of crops.	The different elements of the APV system should be shielded with hedges or tree rows along the sides visible from roads, including inter-farm roads. The colors of the PV modules should harmonize with the predominant colors of the surrounding landscape.
Punctual historical traces				In case of presence of artifacts of historical-artistic-architectural value, the non-visibility, also through natural screens, of the different elements that make up the APV system for at least 100 m, from all accessible observation points, inside or outside the artifact, must be ensured.
Linear historical traces		In the presence of historical traces (e.g., Roman centuriatio), APV must ensure the legibility of these traces, respecting their geometries and proportions.		In case of presence of roads (vehicular or pedestrian) of historical significance, the non-visibility of the different elements that make up the APV system must be ensured, also through natural screens, for at least 100 m, from all accessible viewpoints, along the entire route.
Road network		In the presence of road networks (including inter-farm tracks), APV must ensure the legibility of these networks, respecting their geometries and proportions.		In case of presence of road routes of landscape significance, the non-visibility of the different elements that make up the APV system should be ensured, also through natural screens, along the entire route.
Water network		In the presence of water networks (canals, rivers, etc.), APV must ensure the legibility of these networks, respecting their geometries and proportions.		
Network of natural vegetation		In the presence of networks of natural vegetation (hedges, rows od trees, strips of spontaneous vegetation, wooded patches, etc.), APV must avoid the alteration or the loss of continuity of these elements, since these networks have a key ecological role		
CUMULATIVE IMPACTS	**1. In the second-level visibility bands (1200 mt) calculated from relevant viewpoints located in unsuitable or warning area, new are allowed up to a maximum cumulative limit of the 40% of the agricultural area visible from the viewpoint, taking into account any existing, authorized or pending permit energy production systems.** **2. In case of existing, authorized or pending permit energy production systems, new APVs must be located at a distance equal to at least twice a buffer zone established, on each side, according to the largest size of the area occupied by the APV.** **3. An adequate number of viewpoints must be identified along the routes crossing the first and second level visibility bands in order to evaluate the cumulative impact due to the simultaneous perception of the new APV with other energy generation systems located in the same area. Viewpoints must be even more numerous along elevated routes that have a wider view field**			

Figure 4 - The criteria matrix for the landscape type shown in Fig. 3a. Source: Authors' elaboration

5. Complex peri-urban mosaic and enclosed agricultural areas.	Dimensional	Morphological	Geometric	Visual relationships
LANDSCAPE ELEMENTS — *Site morphology*				
Shape and size of agricultural plots	The size of APV must be compatible with the maximum size of agricultural parcels in the area.	APV can fully or partially cover the agricultural parcel, preserving the recognizability of its shape.		
Type of crop			The warping of PV modules should be consistent with the warping of different types of crops.	Where APV affects areas characterized by low-lying crops (e.g., vegetables, flowers, etc.), the presence of its elements should be screened with hedges or tree rows along the sides visible from roads, including inter-farm roads.
Punctual historical traces				In case of presence of artifacts of historical-artistic-architectural value, the non-visibility, also through natural screens, of the different elements of the APV for at least 100 m, from all accessible observation points, inside or outside the artifact, must be ensured.
Linear historical traces		In the presence of historical traces (e.g., Roman centuriatio), APV must ensure the legibility of these traces, respecting their geometries and proportions.		In case of presence of roads (vehicular or pedestrian) of historical significance, the non-visibility of the different elements of the APV must be ensured, also through natural screens, for at least 100 m, from all accessible viewpoints, along the entire route.
Road network		In the presence of road networks (including inter-farm tracks), APV must ensure the legibility of these networks, respecting their geometries and proportions.		In case of presence of road routes of landscape significance, the non-visibility of the different elements of the APV should be ensured, also through natural screens, along the entire route.
Water network		In the presence of water networks (canals, rivers, etc.), APV must ensure the legibility of these networks, respecting their geometries and proportions.		
Network of natural vegetation		In the presence of networks of natural vegetation (hedges, rows od trees, strips of spontaneous vegetation, wooded patches, etc.), APV must avoid the alteration or the loss of continuity of these elements, since these networks have a key ecological role.		
CUMULATIVE IMPACTS	**In case of existing, authorized or pending permit energy generation systems, greenhouses and other landscape detractors, new APVs should be preferably located adjacent to such elements.**

An Examination of the Environmental Impacts of Mega Projects on Rural Areas: A Case Study of Two Villages in the South Marmara Region of Türkiye

[1] Beyzanur Uzun, [2] Gökçen Kılınç Ürkmez
[1] City and Regional Planning Programme, Institute of Graduate Studies, Bursa Technical University, Türkiye
[2] Department of Urban and Regional Planning, Faculty of Architecture and Design, Bursa Technical University, Türkiye

Abstract
Mega projects are investments that make significant changes to land use structures and have the potential to cause major damage to the natural environment. Their impact is often discussed in relation to cities. However, they are much more fragile in rural areas. In Turkey, these projects are primarily located in the Marmara Region and encompass a series of initiatives aimed at creating a transportation corridor within the 'Golden Ring' framework and promoting the decentralisation of industry in the region.

The study will examine the rural areas of Yalova and Bursa in terms of the environmental impacts of mega projects. The reason for conducting the study in these rural areas is that the large investments are located at the intersection and focal point of these areas.

In this study, qualitative and quantitative data methods will be used in combination to concretely reveal how rural areas that are critical in economic, ecological and social terms have undergone a process of change over the last 10 years as a result of mega projects, and what effects this may have in the future.

Keywords: Mega Projects, Rural Areas, Sustainable Environment, Ecological Balance

Introduction

In recent years, increasing technological developments and innovations have brought about a rapid transformation process in both spatial and social structures. While the effects on the built environment are a subject of debate, the effects on the natural environment are much more fragile and irreversible. These effects in cities and natural areas are causing the social structure to disintegrate. Among the factors influencing this situation are mega-projects created to meet the needs of urbanisation and urban structures. In recent years, these projects have expanded beyond the boundaries of urban spaces and into rural areas. While this expansion benefits the projects, it causes damage to the natural environment. Research on this issue has generally focused on the urban scale. The ways in which rural areas are affected are explained within an urban context, and the visibility of the impact created by the projects on the natural environment is overlooked (Çalışkan, 2010; Ercan, 2020; Flyvbjerg, 2014; Flyvbjerg, Bruzelius, & Rothengatter, 2003; Keydal, 2021; Kızılay & Zorlu, 2020; Köksal & Öztürk, 2017; Özbay, 2019; Öztürk P. Ç., 2017; Sönmez, 2017).

This study aims to analyse environmental transformation in a multifaceted way by examining the environmental impacts of mega projects in the rural areas of Yalova and Bursa in Turkey's Marmara Region, together with social vulnerabilities. It aims to reveal the concrete reflections of the natural environment created by agricultural lands through land transformation analysis. Through thematic analysis, it seeks to support these analysis results and convey the social dimensions of environmental impacts in a comprehensive manner.

Results of the study. By presenting the environmental transformation process created by mega projects in rural areas in a multi-layered manner, including the social dimension of participation processes, it will serve as a guide for researchers and decision-makers.

Mega Projects and Their Environmental Impact on Rural Areas

Mega projects are projects that range from historically significant developments to large monumental structures. These projects have been followed by railways, infrastructure works and industrial developments (Söderlund, et al., 2017). Flyvbjerg (2014) defines mega projects as large-scale, complex ventures that typically cost a billion dollars or more, take years to develop and build, involve multiple public and private stakeholders, are transformative, and affect millions of people.

Mega projects are increasingly being preferred in many sectors. Examples of mega projects include railways, motorways, airports and industrial areas, among many other sectoral structures (Baysal, 2017; Flyvbjerg, 2014; Kızılay & Zorlu, 2020).

Mega projects should not be defined solely by their size, as this growth is steadily increasing. Although these formations, which were referred to as 'mega projects' in the 1970s, are now reaching giga and tera proportions, the term has remained largely unchanged (Flyvbjerg, 2014). However, the size of mega projects varies depending on the size of the areas they are located in. Both the areas covered by mega projects and their numbers are increasing (Baysal, 2017; Flyvbjerg, 2014). This quantitative growth also increases the risks involved and can have negative effects on cities in environmental, economic, social and cultural areas (Gellert& Lynch, 2003; Dündar, 2010). Projects of this scale can be large enough to change the spatial structure of cities (Aysev, 2022). For this reason, it has been emphasised that the resulting growth should be characterised as unpredictable and frenzied, and that it must be prevented (Ercan, 2020).

Regardless of geography, 90% of mega projects experience cost overruns. These cost overruns occur in both the private and public sectors. However, the benefits initially anticipated have generally turned into losses (Flyvbjerg, et al., 2003). Despite this loss, projects are increasing (Flyvbjerg, 2014). This inconsistency has been defined as a paradox by Flyvbjerg et al. (2003). It has been noted that cost overruns are sometimes considered insignificant in long-term investments, and that most monumental structures have suffered from cost overruns. However, the cost overruns of projects undertaken today are of such magnitude that they can affect the benefits and losses of all nations (Flyvbjerg, et al., 2003). For this reason, the time frame in which projects are evaluated is important (Söderlund, et al., 2017).

Despite the increase in their numbers and their growing influence in many areas, resources and management remain in the background in mega projects. In management processes, project officials tend to disregard all participation processes and leave civil society behind. In such cases, local communities and civil society organisations do not have the same say as other stakeholders. This situation leads to the public approaching projects with suspicion and certain negative developments emerging during the process (Flyvbjerg, 2014).

Mega projects are also uncertain and often do not turn out as planned, but can be used to serve various interests. This situation causes social and economic disruptions (MüllerMahn, et al., 2021). Such ruptures do not only appear in an abstract form, but also influence the shaping of the space and the city as a whole in a broader context (Robbins, 2014). When the studies are examined, it is seen that mega projects are generally emphasised for their significant impact on the shaping of urban spaces, but their impossible effects are also mentioned. In these studies, the effects on rural areas have been addressed mainly in relation to cities, and the direct changes and transformations they cause have been addressed to a limited extent (Çalışkan, 2010; Ercan, 2020; Flyvbjerg, 2014; Flyvbjerg, et al., 2003; Keydal, 2021; Kızılay & Zorlu, 2020; Köksal & Öztürk, 2017; Özbay, 2019; Öztürk, 2017; Sönmez, 2017; Tolunay, 2015;).

Mega projects located in city centres have gradually spread to rural areas due to land constraints. With the arrival of these projects in rural areas, rent formation has begun, and their attractiveness in rural areas has increased because they generate more economic profit than rural production (Özbay, 2019; Tekeli, 2014). Rural areas, which serve as the primary source of land resources, are undergoing uncontrolled urbanisation due to the expansion of cities and mega projects, resulting in the degradation and loss of rural lands (Çalışkan, 2010; Keydal, 2021; Özbay, 2019; Uysal & Albayrak, 2024).

Looking at the case studies examined, projects related to transportation and industry stand out (Arslan & Üzülmez, 2024; Debela et al., 2020; Döner, 2016; Kolukırık, 2016; Morshed et al., 2024; Mothorpe et al., 2013; Ramachandraiah, 2014; Robbins, 2014; Song et al., 2016; Uysal & Albayrak, 2024). These projects, which have a profound impact on the country and region, are generally constructed through tenders carried out by the public sector and through private sector investors. Although the public sector takes the lead in the decision-making and implementation processes related to the projects, the lobbies in the background are the biggest drivers of these projects (Robbins, 2014). At the same time, large-scale businesses in rural areas have benefited more, leaving individuals behind (Delphine et al., 2019; Ramachandraiah, 2014).

In most projects, it is known that certain external investors begin purchasing agricultural land and, in a sense, engage in land speculation at stages when the local community has no information, while planning and decision-making processes are still ongoing (Döner, 2016; Kolukırık, 2016). As the process continues, expropriations are carried out by the public sector, and compensation is paid to the local community. Typically, to prevent social opposition, efforts are made to maintain expectations that the project will create a high level of employment for the local community. However, it is argued that the employment generated by the investments will fall short of expectations once the projects are implemented. In this case, large businesses have benefited more, leaving individuals behind (Arslan & Üzülmez, 2024; Debela et al., 2020; Delphine et al., 2019; Döner, 2016; Kolukırık, 2016; Ramachandraiah, 2014; Rashid et al., 2024; Robbins, 2014; Song et al., 2016). However, while it is argued that these projects will have a significant economic impact on national and regional development, they exceed their own cost limits and place the existing system under a financial burden (Müller Mahn et al., 2021; Robbins, 2014).

With mega projects, agricultural areas have been opened up to residential areas, and the urban fabric has begun to shift towards agricultural land. With this situation, rural areas have been merged with each other and added to the borders (Debela et al., 2020; Mothorpe et al., 2013). Rural areas have been concretely affected by these projects through the loss of agricultural land and damage to natural areas. The loss of land has increased in the context of these projects (Arslan & Üzülmez, 2024; Morshed et al., 2024). The change in land affects many factors, including production quantities and types. Farmers whose income sources have changed have been unable to continue their production activities or have had to limit their activities. Farmers whose land has shrunk can only engage in irrigated or dry farming, depending on the nature of their expropriated land (Arslan & Üzülmez, 2024; Debela et al., 2020; Döner, 2016; Kolukırık, 2016; Ramachandraiah, 2014). At the same time, these projects have also damaged the natural structure and ecosystem. They have resulted in air pollution, water pollution, and noise pollution (Delphine et al., 2019; Döner, 2016; Morshed et al., 2024; Robbins, 2014; Song et al., 2016). Furthermore, it has caused the fragmentation of the landscape structure in rural areas and led to changes in land quality, resulting in the formation of new landscape patterns (Morshed et al., 2024; Song et al., 2016).

All these environmental and spatial impacts also have social and economic repercussions. Although the economic impacts of projects are sometimes seen as positive at the outset, they have led to changes in or the loss of livelihoods. In particular, the agriculture and livestock sectors have been severely affected (Debela et al., 2020; Delphine et al., 2019; Morshed et al., 2024; Mothorpe et al., 2013; Ramachandraiah, 2014; Robbins, 2014; Song et al., 2016). Socially, the sudden disruption of traditional lifestyles in rural communities, forcing them to change their ways of life and livelihoods, has increased individuals' concerns (Kolukırık, 2016)

Impacts of Mega Project Trends on Rural Areas within the Framework of the Golden Ring

When looking at the historical process of mega projects in Turkey, it can be seen that the intensity of the projects is concentrated in Istanbul (Çalışkan, 2010; Ercan, 2020; Keydal, 2021; Kızılay & Zorlu, 2020; Köksal & Öztürk, 2017; Özbay, 2019; ÖztürkP. Ç., 2017). The projects have spread from Istanbul to the Marmara region and other provinces in conjunction with the industrial sector and central government strategies in this context (Ercan, 2020; Köksal & Öztürk, 2017).

When examining Turkey's development plans for the last 20 years within the scope of mega projects, it is seen that large-scale projects began to be mentioned in the 8th Development Plan (2001-2005), with particular reference to incentives in the industrial sector. At the same time, the development of infrastructure works was also mentioned during this period ((DPT), 2000). 9. The development plan (2007-2013) includes policies related to creating a competitive environment that addresses technological developments. Improvements in other areas are also addressed. ((DTP), 2006). 10. When it comes to the development plan (2014-2018), it is seen that large-scale investments are mentioned more frequently and that projects and policies are developed in this context ((SBB), 2013). Along with this, mega projects that will have a significant regional and national impact on Istanbul have begun to emerge and their foundations have been laid in recent years. Subsequent development plans have focused on mega projects on a much larger scale than the national level. In the latest development plan, the concept of sustainability has gained greater prominence (SBB, 2019; SBB, 2023).

During and after the 10th Development Plan (2014-2018), which saw a particular concentration of mega projects, major transportation projects were carried out in the northern region of Istanbul, including the 3rd Bridge, 3rd Airport, Northern Marmara Motorway, Istanbul-Izmir Motorway, and the Osmangazi Bridge. During the

construction of the 3rd Bridge, 3rd Airport, and Northern Marmara Motorway, it was noted that the area contained dense ecological habitats, a fact that was either clearly stated in the Environmental Impact Assessment (EIA) reports or overlooked due to the inadequacy of the reports. The projects were located in the peripheral region, one of the few areas in Istanbul with rich natural structures that had not been opened up for settlement. The fact that these projects were implemented without undergoing a detailed analysis phase has created negative environmental impacts on the region (Tolunay, 2015). This process is also mentioned in the assessment of the EIA report submitted in the context of the 3rd Bridge. It is emphasised that the process will negatively affect natural areas and rural settlements in the northern region, which will come under pressure. At the same time, it is stated that the transport routes built in this context will increase this pressure. Although the EIA reports do not fully reflect the current situation, the project has disregarded the inconsistencies with these reports (Çalışkan, 2010). Due to the ecological richness of Istanbul's northern region, which extends to the Black Sea coast, it is insufficient to carry out applications and interventions solely under the name of protection. In addition to protection decisions, comprehensive plans and models are essential for this region (Altınok, 2023).

Projects in the northern region of Istanbul have spread beyond Istanbul's sphere of influence to neighbouring provinces and the Marmara Region. Projects such as the Osmangazi Bridge and the Istanbul-Izmir Motorway have been carried out within this scope. In this context, a line called the Golden Ring has been created with the aim of connecting Istanbul, Kocaeli and Bursa Metropolises with Yalova (Doğu Marmara Kalkınma Ajansı, 2012).

This line, which has also been reported in the news as the Marmara Ring (Milliyet, 2011), is 400 km long and surrounds the Marmara region. (Doğu Marmara Kalkınma Ajansı, 2012). The Golden Ring route, which begins with the 3rd Bridge and Northern Marmara Motorway project, continues with the Çanakkale Strait Bridge between Lapseki and Gelibolu, and continues with the Gulf Crossing-Istanbul-Izmir Motorway (Kural, 2014), reduces the time required to travel around the Marmara Region to 4 hours. (Doğu Marmara Kalkınma Ajansı, 2012).

It is emphasised that the Golden Ring line is important for easing Istanbul's current traffic and preventing transit traffic from outside the city from putting pressure on central traffic. However, the Istanbul-Izmir Motorway, which is part of the line, has facilitated transportation between important industrial cities (Haber, 2022; Karaca, 2019; Ünal, 2022). However, other news sources have noted that the project continues to advance destructive initiatives toward regions in northern Istanbul that include agricultural lands and other natural areas, creating irreversible environmental pressure (Kural, 2014; Sendika.Org, 2016). It is also described as a 'concrete shackle around the Marmara Region' (Kural, 2014).

The Golden Ring project in the region does not only include transportation projects; the industrial zones affected by these projects are also located in the area. It is stated that 58 new industrial zones have been established in the region in 8 years. The establishment of industrial zones along the Istanbul-Izmir Motorway route has had a particularly significant impact. This has accelerated the development of both transportation and the industrial sector in the region (Haber, 2022).

The concept of the Golden Ring is not found in literature. It is only mentioned in reports on cities' visions, etc. Although this concept is found on news websites, it has not been included in scientific articles and research, but has been discussed in the context of Istanbul's northern axis and other projects.

Materials and Methods

The study used both quantitative and qualitative research methods. Quantitative research methods included land use analysis, while qualitative research methods included thematic analysis, allowing for a multi-layered examination of the environmental impacts of mega-projects in rural areas.

Land change analysis was conducted using data from 2000 to 2025. Since CORINE land cover data for the period 2000-2018 and current data sets were not available, 2025 data were used, which were manually drawn using Google Earth. In the study conducted in Yalova (Çiftlikköy)-Kılıç village and Bursa (Karacabey)-Taşpınar village, the data were classified and analysed using the QGIS programme. The analysis results were calculated numerically and mapped. The analysis provides a concrete framework for understanding the environmental dimensions of land conversion.

Before the thematic analysis, field research was conducted in the villages identified. Semi-structured interviews were conducted with the local community during the research. In order to examine the environmental impact of mega-projects in a multi-layered manner, the study also considered the social impact dimension, with interviews conducted with 25 individuals (Table 5). The interviews were categorised into themes within the scope of the environmental, spatial, social, economic, and participatory dimensions of mega-projects. Relevant codes were created for each theme, and these codes were organised into a diagram (Figure 5).

Study Are

Kılıç and Taşpınar Villages

Kılıç Village is located in the Marmara Region of Turkey, in the Çiftlikköy district of Yalova province, while Taşpınar Village is located in the Karacabey district of Bursa province. Both villages are Muhacir settlements. Kılıç Village is located at the toll booth exit of the Izmir-Istanbul Motorway, on the border of the Yalova Machinery Specialised Industrial Zone. TEKNOSAB is located around Taşpınar Village, and the İzmir-İstanbul Motorway is located on its periphery. Kılıç Village has a population of 727 (TÜİK, 2024), while Taşpınar Village has a population of 229 (Vural, et al., 2020). The economic structure of the villages is largely based on agricultural activities.

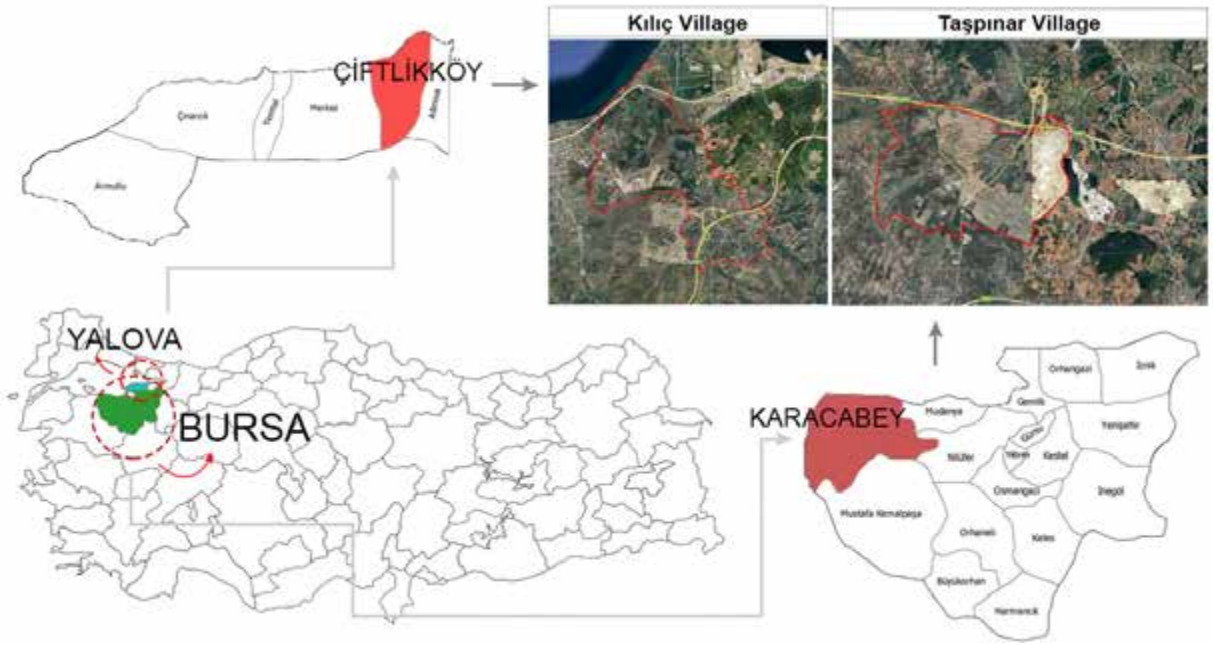

Figure 1. Study Area Location (Prepared by the author using Google Earth data)

Motorways and Industrial Areas

One of Turkey's largest transportation projects, the Izmir-Istanbul motorway, opened in 2019. The 426 km long motorway (Directorate, n.d.) passes through the villages of Kılıç and Taşpınar in the project area. The route of the highway has led to the establishment of industrial areas along its path (Ünal, 2022). The Yalova Machine Specialised Industrial Zone and TEKNOSAB area are examples of such industrial sites.

Yalova Machine Specialised Organised Industrial Zone (OSB) was established in 2017 and became operational in 2020. It was planned within the scope of the Green OSB model. The OSB, which was established on an area of 625 hectares, covers an area of 625 hectares. The settlement process has not been completed, and the occupancy rate is 20% (Çağlar, et al., 2022).

TEKNOSAB acquired legal personality in 2019, began infrastructure work in 2019, and commenced operations in 2021. The factories were constructed using a gallery reinforced concrete system, and the aim is to source a significant portion of the electricity from renewable energy sources (TEKNOSAB, n.d.).

Figure 2.Location of Mega Projects in the Field of Work (Prepared by the author using Google Earth data)

Findings

Land Cover Area Change Analysis

In this section, land change analysis was performed using CORINE land cover data for the villages of Kılıç and Taşpınar. Land use in the villages between 2000 and 2025 was calculated in hectares and percentages, and absolute and percentage changes in the area were analysed. The analysis was digitised in tables and visualised with maps.

Note: Since CORINE 2025 land cover data has not been published, data for 2025 has been manually generated based on Google Earth satellite imagery and project area data.

Table 1. Kılıç Village-Land Distribution Table by Year (Prepared by the author using CORINE data)

Code	Land Type	2000		2006		2012		2018		2025	
		ha	%	ha	%	ha	%	ha	%	ha	%
1.2.2.	Highways, Railways and Related Areas	0	0,00%	0	0,00%	0	0,00%	46,685	2,41%	46,685	2,41%
1.3.1.	Mining Areas	0	0,00%	0	0,00%	0,3004	0,02%	0,3004	0,02%	0,3004	0,02%
1.3.2.	Dumping Areas	0	0,00%	0	0,00%	0	0,00%	28,976	1,49%	28,976	1,49%
1.4.2.	Sports and Recreation Areas	65,43	3,37%	65,389	3,37%	66,651	3,44%	66,651	3,44%	66,651	3,44%

2.1.1.	Non-Irriga-ted Arable Land	527,13	27,17%	530,65	27,35%	577,06	29,74%	541,56	27,91%	541,56	27,91%
2.3.1.	Pasture Land	335,71	17,30%	241,57	12,45%	244,38	12,60%	243,1	12,53%	243,1	12,53%
2.4.2.	Mixed Agricultural Areas	367,29	18,93%	444,08	22,89%	442,17	22,79%	419,27	21,61%	419,27	21,61%
2.4.3.	Agricultural Areas with Natural Vegetation Cover	640,32	33,01%	556,48	28,68%	577,24	29,75%	561,25	28,93%	561,25	28,93%
3.2.4.	Plant Transition Areas	4,1748	0,22%	101,9	5,25%	31,997	1,65%	31,997	1,65%	31,997	1,65%
5.2.3.	Sea and Ocean	0	0,00%	0,2423	0,01%	0,5124	0,03%	0,5124	0,03%	0,5124	0,03%

Table 1 shows that agricultural areas accounted for 96.41% of the total land cover in 2000. However, agricultural areas with natural vegetation cover accounted for 33.01% of the total land cover, which was the highest land type. This was followed by non-irrigated arable land with 27.17%. In 2006, agricultural land types again accounted for the most land use at 91.37%. Marine and ocean areas accounted for a very low percentage of 0.01%. By 2012, artificial areas began to appear, and mining areas emerged as a new land use type, accounting for a very low percentage of 0.02%. In 2018, new land types emerged. Roads, railways, and related areas accounted for 2.41%, and disposal sites accounted for 1.49%. By 2025, the data from 2018 remained unchanged.

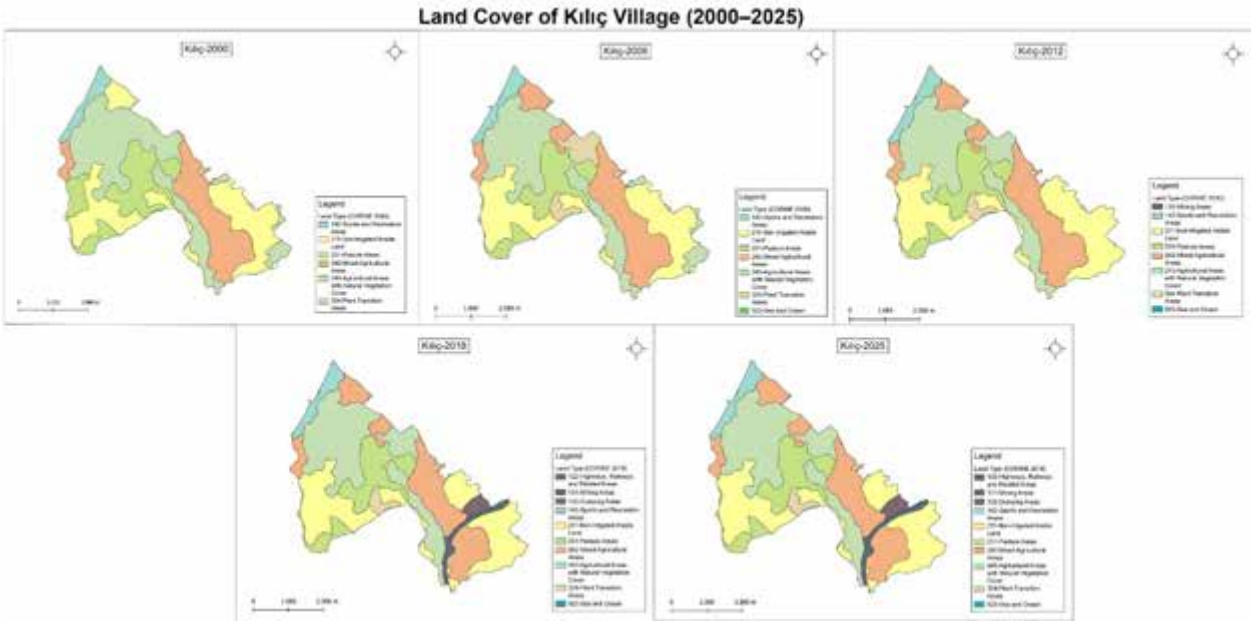

Figure 3. Kılıç Village - Land Distribution Map by Year (Created by author)

When examining the tables in Figure 1, it can be seen that agricultural areas in Kılıç village are spatially distributed over a wide area. Although artificial areas show limited growth, the general land structure of the area has not changed.

Table 2. Taşpınar Village-Land Distribution Table by Year (Prepared by the author using CORINE data)

Code	Land Type	2000		2006		2012		2018		2025	
		ha	%	ha	%	ha	%	ha	%	ha	%
1.1.2.	Discontinuous Urban Structure	47,403	2,51%	28,938	1,53%	28,937	1,53%	28,937	1,53%	28,937	1,53%
1.2.1.	Industrial and Commercial Units	0	0,00%	0,6599	0,03%	0,027	0,00%	0,027	0,00%	790,64	41,85%
2.1.1.	Non-Irrigated Arable Land	1649,4	87,31%	1686,3	89,26%	1687,5	89,32%	1687,5	89,32%	950,52	50,32%
2.3.1.	Pasture Land	190,78	10,10%	146,4	7,75%	146,04	7,73%	146,04	7,73%	94,231	4,99%
2.4.2.	Mixed Agricultural Land	0	0,00%	0,7763	0,04%	0,7665	0,04%	0,7665	0,04%	0,7665	0,04%
2.4.3.	Agricultural Land with Natural Vegetation Cover	1,5393	0,08%	0	0,00%	0	0,00%	0	0,00%	0	0,00%
3.2.4.	Plant Transition Areas	0	0,00%	26,042	1,38%	25,678	1,36%	25,678	1,36%	23,799	1,26%
5.1.2.	Water Bodies	0	0,00%	0	0,00%	0,2248	0,01%	0,2248	0,01%	0,2248	0,01%

Looking at Table 2, agricultural land accounts for 97.49% of the land use in Taşpınar village. The land type with the highest value is non-irrigated arable land, accounting for 87.31%. However, the settlement type included in artificial areas covers 2.51% of the land. In 2006, the land type with the highest land density was again non-irrigated arable land, accounting for 89.26%. At the same time, new land formations were observed. Industrial and commercial units accounted for a very low percentage of 0.03%, while plant change areas (scrub/semi-scrub, transition areas) accounted for 1.38% of new formations. Settlement areas covered 1.53% of the land. In 2012, the land structure remained similar. New formations were observed at a very low rate of 0.01%. In 2018, the land structure remained unchanged. By 2025, non-irrigated arable land will cover 50.32% of the area, while industrial and commercial units will cover 41.85% of the area. The ratios for other land types have remained largely unchanged.

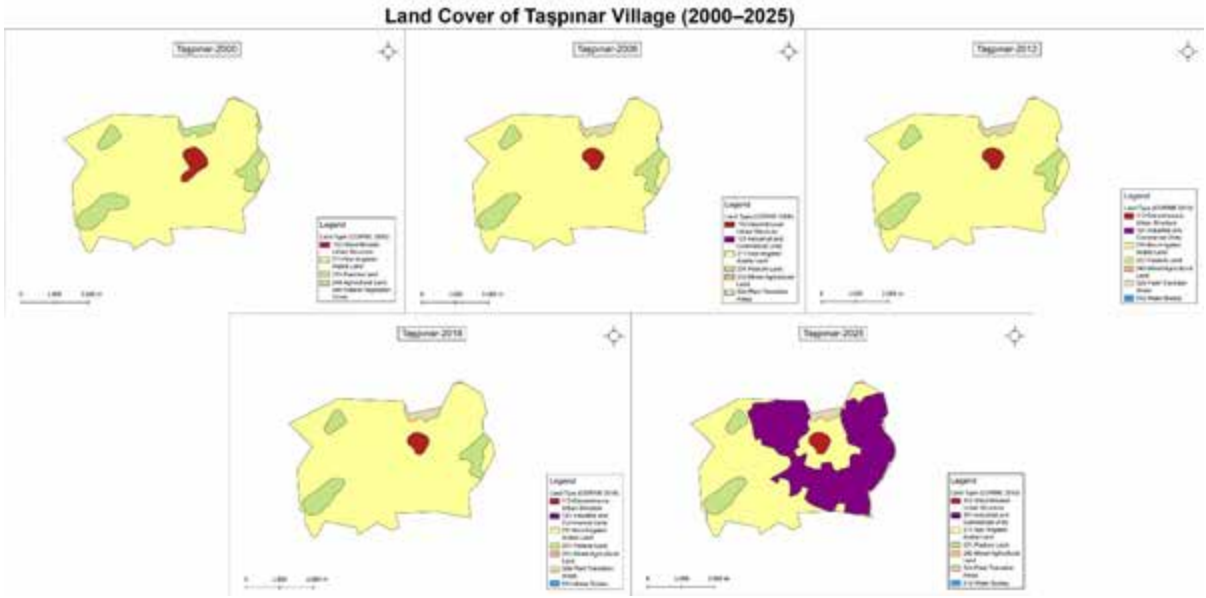

Figure 4. Taşpınar Village - Land Distribution Map by Year (Created by author)

When examining the tables in Figure 2, it can be seen that agricultural areas in Taşpınar village are spatially distributed over a wide area. However, newly formed areas have affected land use distribution. Industrial and commercial units have increased significantly and have come close to the proportion of non-irrigated arable land.

Table 3. Kılıç Village - Land Cover Change Table by Year (Prepared by the author using CORINE data)

Code	Land Type	2000–2006		2006–2012		2012–2018		2018–2025		2000–2025

2.3.1.	Pasture Land	-94,14	-28,04%	2,8119	1,16%	-1,2836	-0,53%	0	0,00%	-92,61	-27,59%
2.4.2.	Mixed Agricultural Areas	76,788	20,91%	-1,915	-0,43%	-22,893	-5,18%	0	0,00%	51,981	14,15%
2.4.3.	Agricultural Areas with Natural Vegetation Cover	-83,84	-13,09%	20,755	3,73%	-15,984	-2,77%	0	0,00%	-79,07	-12,35%
3.2.4.	Plant Transition Areas	97,722	2340,76%	-69,9	-68,60%	0	0,00%	0	0,00%	27,822	666,43%
5.2.3.	Sea and Ocean	0,2423	Newly occurred	0,27	111,41%	0	0,00%	0	0,00%	0,5124	Newly occurred

Looking at the analysis results for Kılıç village, the greatest decrease in land types between 2000 and 2006 was observed in pasture areas, with a rate of 28.04%. The highest increase in land area was observed in plant change areas, with a very high rate of 2340.76%. Marine and ocean areas showed new formations. Between 2006 and 2012, mining areas showed new formations. While an overall increase was observed in agricultural areas, the mixed

agricultural land type decreased by 0.43%. At the same time, a significant decline occurred in plant change areas, with a decrease of 68.60%. The boundaries of sea and ocean areas within land boundaries expanded, showing an increase of 111.41%. Between 2012 and 2018, a decrease of 14.62% was observed across all agricultural areas. Meanwhile, 46,685 hectares of roads, railways, and related areas, and 28,976 hectares of disposal sites have emerged as new formations. Changes between 2018 and 2025 have remained constant.

Looking at the changes between 2000 and 2025 in general, new land formations are noteworthy. Here, roads, railways and related areas, mining sites and disposal sites, which have formed in a different way from the natural structure, have developed by changing the quality of agricultural land. At the same time, a decrease of 27.59% in pasture areas and 12.35% in agricultural areas with natural vegetation cover is noteworthy. Additionally, a significant increase of 666.43% has been observed in areas with vegetation changes.

Table 4. Taşpınar Village - Land Cover Change Table by Year (Prepared by the author using CORINE data)

Code	Land Type	2000–2006		2006–2012		2012–2018		2018–2025		2000–2025	
		Δha	%	Δha	%	Δha	%	Δha	%	Δha	%
1.1.2.	Discontinuous Urban Structure	-18,466	-38,95%	-0,0002	0,00%	0	0	0	0,00%	-18,47	-38,95%
1.2.1.	Industrial and Commercial Units	0,6599	Newly occurred	-0,6329	-95,91%	0	0	790,62	2929845,03%	790,64	Newly occurred

2.3.1.	Pasture Land	-44,389	-23,27%	-0,3585	-0,24%	0	0	-51,806	-35,47%	-96,55	-50,61%
2.4.2.	Mixed Agricultural Land	0,7763	Newly occurred	-0,0098	-1,26%	0	0	0	0,00%	0,7665	Newly occurred
2.4.3.	Agricultural Land with Natural Vegetation Cover	-1,5393	-100,00%	0	0,00%	0	0	0	0,00%	-1,539	-100,00%
3.2.4.	Plant Transition Areas	26,042	Newly occurred	-0,3646	-1,40%	0	0	-1,879	-7,32%	23,799	Newly occurred
5.1.2.	Water Bodies	0	0,00%	0,2248	Newly occurred	0	0	0	0,00%	0,2248	Newly occurred

Looking at the analysis results for Taşpınar village, the greatest decrease between 2000 and 2006 was in settlement areas, at a rate of 38.95%. This was followed by a 23.27% decrease in pasture areas. However, there was a 100% increase in agricultural areas with natural vegetation cover, and industrial and commercial units, mixed agricultural areas, and plant change areas showed new formations. Between 2006 and 2012, there was a slight decrease in agricultural and natural areas. However, there was a 95.91% decrease in industrial and commercial units. At the same time, water bodies showed new formations. The values between 2012 and 2018 remained constant. Between 2018 and 2025, a decrease of 86.46% was observed in agricultural areas and natural areas combined. However, there was a very high increase of 2929845.03% in industrial and commercial units.

Looking at the changes between 2000 and 2025 in general, new areas of development are noteworthy. Here, industrial and commercial units that have formed in a manner distinct from the natural structure have developed by altering the nature of agricultural land. At the same time, a decrease of -192.98% in the total agricultural area is noteworthy. Additionally, there has been a 38.85% decrease in residential areas, and water bodies have shown new formations.

Participant Profile

The participant profile is provided in Table 5. In the study, interviews were conducted with 11 people from Kılıç village and 14 people from Taşpınar village. The interviews addressed demographic variables such as gender, age, and occupation of the participants. While most of the interviews were conducted as in-depth interviews, some participants showed limited participation. Additionally, information provided by a village headman from a neighbouring village outside the study area was used in the study but was not included in the participant table.

Table 5. Demographic Distribution of Participants Interviewed in Kılıç and Taşpınar Villages (Created by author)

Code	Gender	Age Range	Occupation	Place of Residence	Type of Participation
P1	Male	30–40	Farmer (business owner)	Kılıç Village	Individual
P2	Female	70–80	Housewife (former village head)	Kılıç Village	Individual
P3	Female	40–50	Housewife	Kılıç Village	Individual – limited participation (general conversation)

P24	Male	60-70	Retired farmer	Taşpınar Village	Individual
P25	Female	60-70	Retired/Private sector	Taşpınar Village	Individual – limited participation

Thematic Analysis Findings

In this section, a thematic analysis was conducted using data obtained from field research conducted in the villages of Kılıç and Taşpınar. As a result of the analysis, main themes were identified and supporting themes were created (Figure 5). The central themes, 'Loss of Natural Areas and Environmental Degradation' and 'Changes in Land Use,' form the basis of the environmental impacts of mega-projects. The conversion of agricultural and pasture lands into projects has led to multifaceted degradation in rural areas.

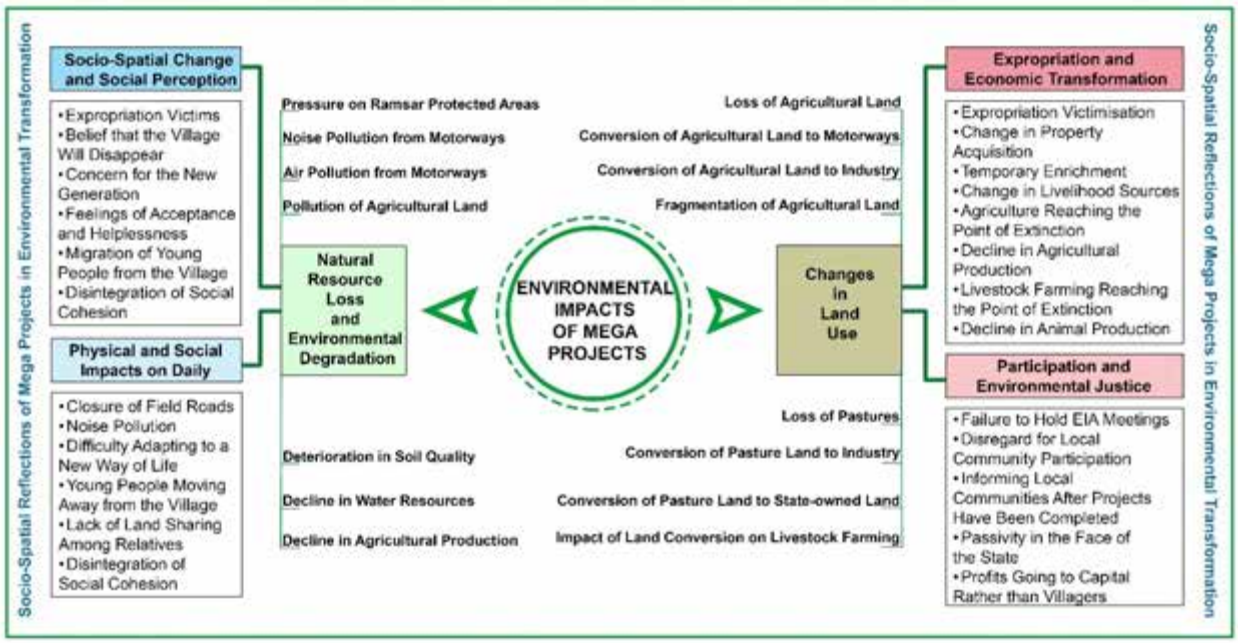

Figure 5 Themes and Related Codes Obtained Within the Scope of the Analysis (Created by author)

The themes on the periphery of the diagram reflect the environmental dimension of the transformation. The expropriation of agricultural and pasture lands has led to a change in their nature. At the same time, the inadequacy of EIA processes has led to environmental justice issues, and the lack of sufficient information provided to the public has left the participation process in the background. Furthermore, this has led to the emergence of effects such as the deterioration of rural community structures, migration, and a decline in production.

Theme 1: Natural Resource Loss and Environmental Degradation

The first theme that stands out in the study covers environmental degradation caused by the loss of natural resources. In particular, the conversion of agricultural and pasture lands into infrastructure projects such as industry and roads has increased environmental pressure.

Upon examining the codes, it was found that agricultural lands in the border region of the Ramsar protected area were expropriated for TEKNOSAB in Taşpınar village. The public believes that the remaining Ramsar areas will also be incorporated into industry through certain legislation and practices. One participant described the situation as follows:

"It didn't enter Ramsar, for example, the field was 10 acres, 5 acres were left for Ramsar. But it left the exact border. Now what will happen to these areas? Dry storage, water storage... Slowly, Ramsar will disappear." (P16)

Traffic caused by vehicles has reached an annoying level in both villages. Several people have stated that there is too much traffic and noise. Air pollution has also begun to be observed in Kılıç village due to the motorway. One user described the situation as follows: 'There is fog over the village in the mornings' (P1). This situation is also confirmed by the village headman of the neighbouring village:

'There is pollution from the motorway. Students from Istanbul came and took measurements, and it turned out to be polluted.' (Village Head)

Industrial waste has been dumped on olive groves in the village of Taşpınar. One participant described the situation as follows:

"The guy took the filth, there are olive groves here, and dumped it there. The factory said, 'Take it away, get rid of it.' So he did what he was told and dumped a truckload of filth on the olive groves." (P24)

The local population states that the agricultural land is very fertile, but that the quality of the agricultural land has been downgraded and expropriated for projects. One participant expressed this situation as follows:

'Whenever it suited them, they came and said, "agricultural land, barren land"; they took over our land.' (P15)

They also mention that water sources affecting agricultural land in Kılıç village have dried up. One group of participants stated:

"The land was expropriated, and our water disappeared. We had artesian water." (P10)

It has been noted that agricultural production has declined due to factors such as the loss of agricultural land, fragmentation of land, and water shortages.

Theme 2: Changes in Land Use
Another prominent theme in the study concerns changes in land use associated with the transformation of agricultural and pasture lands. The nature of the land has changed with the transformation of expropriated areas in the context of projects.

When the codes are examined, it is stated that a large part of the agricultural and pasture lands in both villages have been lost. It is stated that there is no land left in either village. In Kılıç village, the situation has been expressed many times as 'agricultural and wetland areas are gone' (P1, P2, P7). In Taşpınar village, it has been stated with expressions such as 'Our village had 30,000 acres of land; 3,000 acres of it was pasture. They took the pastures without paying' (P24) and 'The pasture business is over' (P23). Furthermore, with the conversion of pasture areas, there are no longer any areas available for livestock farming. Additionally, the nature of agricultural and pasture areas has been altered, with the highway in Kılıç village and the majority of the land in Taşpınar village being converted into TEKNOSAB. At the same time, agricultural lands have been fragmented, leading to the loss of their functionality and subsequent conversion. One participant described the situation as follows:

"Since half of the land is outside the border, the remaining agricultural land has become unusable. Instead of fertile land, the rightful owners were given infertile land on the edge of cliffs. Access to these areas is also impossible." (P5)

Theme 3-4: Socio-Spatial Change and Social Perception & Physical and Social Effects in Daily Life
These themes, which are both indicative of environmental impacts and supportive in nature, reflect not only the physical dimension of the transformation but also its social aspect and the perceptions of the local population. They also encompass the effects on the daily lives of local residents.

Upon examining the codes, it was revealed that agricultural and pasture lands in both villages were expropriated by force, leaving the local population feeling powerless. Participants expressed this situation with statements such as: "They seized our property here!" (P21), and "You cannot go against the state." (P2). Other reactions followed a similar pattern.

Due to the impact of mega projects, young people have migrated, and their ties with the village have weakened. One participant expressed this situation as follows:

There are no young people left. What would they even do here? There's no animal husbandry, farming is finished. A man is already 40 or 50 years old—what job could he possibly find? Even if he gets into a factory, what difference does it make? Everyone's life has been turned upside down." (P23)

In both villages, feelings of concern and hopelessness about the future are prevalent. Participants expressed this sentiment as follows:

"In the future, we'll be strangers in our own village—there's no land left. Every piece of land has been sold, and now outsiders hold power. Our land is gone, only the village centre remains. The water is gone—it's over." (P7)
As a result of the projects, particularly in Taşpınar village, there is a strong belief that the village will undergo complete transformation in the future. One participant stated, "If they open it for development, the village will be no more!"

With the introduction of these projects, especially in Taşpınar, some individuals have begun living in urban centres and only travelling to the village occasionally. This has led to a decline in social relations. One participant articulated the situation as follows:

"We used to have peace and comfort here. My own house... Look, my uncle is here, my maternal uncle is here. Now, when I sit in the café and look around—who's next to me? None of them." (P16)

The sale of land has also caused rifts within families. One participant described the situation as follows:

"My brother says, 'Brother, divide the fields with stone markers; divide them while our father is still alive...'" (P16)

Noise pollution is another disturbing factor, frequently mentioned in both villages. Participants voiced similar complaints, such as: "Traffic and noise have affected us greatly; now they're constant." (P9)

They also reported difficulties in accessing existing agricultural lands and pastures due to the projects implemented in the area.

Theme 5-6: Expropriation and Economic Transformation & Participation and Environmental Justice
Two additional themes reflecting the environmental impact, while also encompassing the social dimension, relate to economic transformation and the effects of participation processes.

An analysis of the codes reveals that in both villages, the expropriation of agricultural lands is frequently mentioned. As a result of these expropriations, the local population argues that their lands were sold below market value. They express that the lands acquired from them at low prices are now significantly more valuable. Participants note that the financial benefits of the land sales were granted to investors rather than the locals, and they also stated that there was nothing they could do about this situation. Participants expressed their frustration as follows:

"Most people's lands were sold at very low prices; those who didn't sell were forced to do so by the state. There was no other option. Our best lands were taken for nothing." (P7)

"What would happen if we objected? We are up against the state; everyone is intimidated." (P9, P10)
"The municipality is on their side anyway; whether you want it or not, they take it." (P15)

Due to land expropriation, a significant portion of the local population stated that they could no longer engage in agriculture or animal husbandry. Consequently, a sharp decline in production was reported. Participants described this situation as follows:

"They destroyed agriculture; dry and irrigated farming is over." (P9)

"They took the lands; farming declined, animal husbandry declined." (P13)

"It wiped out the young population, livestock farming, and agriculture." (P16)

"There used to be cattle in our village; now there's none left." (P25)

"Farming was affected by 90%. There's no farming anymore; there are no fields left." (P24)

It was stated in both villages that there was little to no prior information given before the projects began, and that they only became aware after the decisions had already been made. Moreover, Environmental Impact Assessment (EIA) meetings were held without properly informing the public, with only a few individuals being notified. Participants voiced their dissatisfaction with the participation process as follows:

"An EIA meeting was held, but it took place far from our village. In a way, people were deceived." (P9)

"No proper EIA meeting took place. A few people gathered at dawn; they handed out a couple of bagels and left." (P15)

On the other hand, the village headman (muhtar) of Kılıç village at the time of the projects claimed that the public was informed but chose not to participate in the meetings. The headman's statement is as follows:

"I was an expert witness in all of them. Everything was done; nothing happened without consulting the public. Why didn't anyone object? The industrial zone wasn't up to us; it wasn't even our land. It was built in an area with farms and private property. Still, no one asked us anything." (P2)

Finally, the sale of land brought temporary wealth to many individuals, enabling them to purchase homes, cars, and other assets. Particularly in Taşpınar, those who did not oppose the projects stated that farming no longer provided sufficient income, which is why they didn't resist much. Participants described this situation as follows: "The village became rich; everyone got a car after the expropriation." (P2)

"What did I do? I bought three houses and a car. Now we're struggling in the city, trying to survive. I used to be a respected man here; now I drive a taxi, trying to make ends meet." (P16)

"When the land was sold by presidential decree, everyone got their money — from Bursa, from Karacabey... Some bought taxis, others minibuses, some bought houses. The money is gone, and so is the land." (P24)

"Villagers were struggling to make ends meet; people were borrowing from their future. If you had a wedding or bought a tractor, you were already in debt for the next three years. When TEKNOSAB arrived, we all rushed to sell — just to get the money quickly. Everyone had kids renting in Bursa, weddings to pay for, already in debt. We all waited in line at the Provincial Directorate in Bursa for our payments." (P20)

Conclusion and Discussion

The findings of the study yielded results in two distinct analytical contexts. Firstly, looking at the results of the land use change analysis, it was found that agricultural areas constitute the majority of the land cover. When examining the changes over time, the motorway in Kılıç village emerged as a significant factor, passing along the edge of the settlement area and resulting in the loss of priority agricultural lands for the local population. Additionally, due to the village's proximity to the industrial zone, newly constructed industrial areas have also affected the agricultural lands.

Beyond this, the emergence of these artificial zones has caused environmental degradation by disrupting areas where agricultural and natural landscapes coexisted in a mixed form. In Taşpınar village, the recently constructed TEKNOSAB in particular has led to the loss of a substantial portion of the village's agricultural land. Together with the newly built motorway, it has also encircled the settlement area.

This transformation has led to significant destruction of the natural environment and has altered the environmental structure of the rural landscape. The analysis has clearly demonstrated the environmental transformation occurring in rural areas.

Alongside the land use analysis, thematic analysis has concretely revealed social, economic, and participatory dimensions in an inclusive manner. Upon examining the results obtained, the environmental and land transformations corroborate the findings of the land use change analysis. The indigenous population, who were actively engaged in production, have lost both their livelihoods and the natural environment in which they lived. However, unlike the land use change analysis, Kılıç village experienced less land loss relative to its existing land assets. Consequently, it was observed to be less affected than Taşpınar village. Furthermore, the village's more developed infrastructure has diminished the economic visibility of individual grievances. Nevertheless, the loss of fertile lands used for irrigated agriculture and water sources has led to the disappearance of some of the village's prominent characteristics.

In Taşpınar village, a substantial portion of the land has been expropriated for industrial purposes, causing a significant rupture in the community. The local population became aware of this situation rather late. Due to financial difficulties, they reluctantly accepted the situation, considering its economic dimension. However, the loss of their lands has led to various challenges in maintaining rural livelihoods. Lacking their own land, they have continued farming activities by renting fields, yet this constraint has resulted in competition among the locals. Additionally, in both villages, it was expressed that information dissemination was limited and that the views of the local people were largely ignored. The indigenous population frequently emphasised their lack of power to oppose decisions taken by the state.

From an environmental justice perspective, Taşpınar village, a rural settlement, has been encircled and constrained by an industrial zone of massive scale even by urban standards, without an adequate buffer zone, and bordered by a motorway. This has caused significant hardship for both the natural habitat and the local population. Similarly, although not within the boundaries of Kılıç village, the industrial zone at the edge of the settlement and the motorway crossing over the most fertile agricultural lands exert pressure on the natural environment and the lifestyles of the local inhabitants.

In both rural areas, environmental pressures arising from projects of a scale far beyond the local context and the social ruptures they have caused are clearly observed. Rural areas are not merely instruments for urban profiteering; they constitute the foundational pillars of sustainable development centred on production and host a diverse array of living beings within their complex, multilayered landscapes.

Accordingly, policies to be developed must carefully consider this fragile structure, incorporating the living organisms within it into the process, which is of critical importance.

By employing a multifaceted analytical approach, this study offers a holistic assessment that spatially and socially reflects the complex environmental degradations occurring in rural areas. Among the limitations of the study are the unavailability of up-to-date data, which introduces a margin of error—albeit not excessively large—in measurements and analyses. Future research conducted over broader temporal scales and with wider perspectives will enhance the significance of such studies.

In conclusion, mega projects primarily cause environmental degradation in rural areas. Although the destructive impacts of this environmental deterioration may not become immediately apparent in tangible terms, their reflections on social life are clearly evident.

Deep Learning-Based Commercial Building Energy Consumption Prediction Model Considering Occupant Density Using Mobile Network Big Data: A Case Study of Seoul

Havva Elmalı, Seung-Nam Kim
Chung-Ang University Graduate School, Seoul, South Korea
havva.elmali@outlook.com, snkim@cau.ac.kr

Abstract
This study proposes a multidimensional modelling framework to estimate annual energy consumption in commercial buildings across Seoul by integrating physical, environmental, economic, and behavioural variables. While previous research has predominantly focused on structural and environmental factors, this study addresses a critical gap by incorporating high-resolution spatial data and temporally disaggregated floating population variables derived from mobile network data, segmented into three time periods: late night, daytime, and evening. This enables a more refined representation of occupant dynamics in dense urban settings. Separate regression models for annual electricity and gas/heating consumption per unit floor area provide a contextual and scalable analytical approach. In the next phase of the research, a non-linear modelling technique based on a Multi-Layer Perceptron (MLP) will be implemented, along with SHAP (SHapley Additive exPlanations) analysis to enhance model interpretability. These advanced methods aim to capture complex interdependencies among variables and improve predictive performance. Ultimately, the proposed framework offers a robust foundation for data-driven energy policies and smart urban planning strategies in high-density metropolitan areas.

Keywords: Energy Consumption; Occupant Density; Commercial Buildings; Deep Learning; Prediction Model

1. Introduction

The building sector accounts for approximately one-third of global final energy consumption, making it a vital domain for achieving energy efficiency and climate resilience (IEA, 2022). Among various building types, commercial buildings located in dense urban areas represent key targets for sustainability interventions due to their high energy intensity and operational complexity. In highly urbanised contexts such as Seoul, energy consumption at the building level is shaped not only by structural and environmental characteristics but also by spatiotemporal variations in occupant density, especially in areas with high human mobility.

Traditional models of building energy consumption have typically emphasised physical variables such as gross floor area (GFA), building age, and structural type. While such models provide a basic analytical framework, they often fail to account for the behavioural dimension of energy use, particularly in cities where occupancy patterns fluctuate throughout the day. A comprehensive understanding of urban energy demand therefore requires a multidimensional modelling approach that incorporates physical, environmental, economic, and behavioural factors.

Recent advancements in spatial data infrastructure and mobile sensing technologies have made it feasible to integrate time-segmented floating population data into energy consumption models. Unlike static population indicators, these data capture dynamic occupant presence across three key time zones—late night (00:00–06:00), daytime (06:00–18:00), and night-time (18:00–24:00)—enabling more nuanced insights into the behavioural drivers of energy demand in commercial buildings.

In response to these developments, this study proposes a multidimensional analytical framework to estimate the annual electricity and gas/heating consumption of commercial buildings in Seoul. The model integrates four categories of explanatory variables: physical (e.g., GFA, building age, structural type), environmental (e.g., green space ratio, average temperature), economical (e.g., land price), and behavioural (e.g., floating population by time zone). The analysis begins with a set of multiple linear regression models to assess the explanatory power of each variable group, using energy consumption per unit of gross floor area as the dependent variable. In subsequent phases of the research, deep learning methods—Multi-Layer Perceptron (MLP) models—along with SHAP (SHapley Additive exPlanations) values will be applied to enhance prediction accuracy and interpretability.

Through the integration of high-resolution spatial datasets and advanced modelling techniques, this study aims to contribute both theoretically and practically to the understanding of urban energy demand.

The findings are expected to inform data-driven strategies in building energy management, policy development, and sustainable urban planning.

2. Literature Review

Building energy consumption has been widely studied across four major dimensions: physical attributes, socio-economic context, behavioural dynamics, and environmental factors.

Physical characteristics such as building age, structural system, and gross floor area (GFA) are frequently cited as key determinants of energy use. Empirical research indicates that newer buildings typically consume less energy due to improved insulation, efficient systems, and stricter building codes (An et al., 2014). Structural systems also significantly influence energy performance; for instance, reinforced concrete buildings tend to be more energy-efficient than masonry structures due to higher thermal mass and better envelope integrity (Kim, 2013). While GFA is often used as a proxy for operational scale, especially in commercial facilities, its explanatory power improves when paired with use type and occupancy characteristics that influence internal loads and activity schedules (Zhang et al., 2020).

Socioeconomic indicators help capture spatial and behavioural heterogeneity in urban energy consumption. Factors such as income level, land value, and population density have been used as proxies for energy service demand and urban activity intensity. In the Korean context, where income data is often limited at the building level, official land price has emerged as a practical proxy for economic intensity and urban development pressure (Kim et al., 2017; Shi et al., 2021). These variables provide important context for interpreting energy patterns within the built environment.

A growing body of research emphasises the importance of human activity and occupant dynamics. Traditional models often rely on static or assumed schedules, failing to capture the actual spatial and temporal variability in occupancy. To address this gap, recent studies have introduced floating population data derived from mobile communication networks as a spatially disaggregated and temporally sensitive measure of real-time human presence (Kim and Park, 2021; Chen et al., 2022). Such data is especially useful in commercial zones, where occupancy patterns fluctuate markedly across different times of day. Segmenting this data into discrete time periods—such as late night, daytime, and night-time—offers a more accurate behavioural input for urban energy models.

Environmental conditions also remain central to understanding energy demand. Temperature extremes significantly affect electricity and gas/heating consumption by increasing cooling and heating loads (Li et al., 2018; Jo et al., 2022). Furthermore, environmental features such as vegetation, green spaces, and water bodies can mitigate urban heat through shading and evapotranspiration, contributing to lower cooling energy needs, especially during summer months (Ewing and Rong, 2008; Ko, 2013).

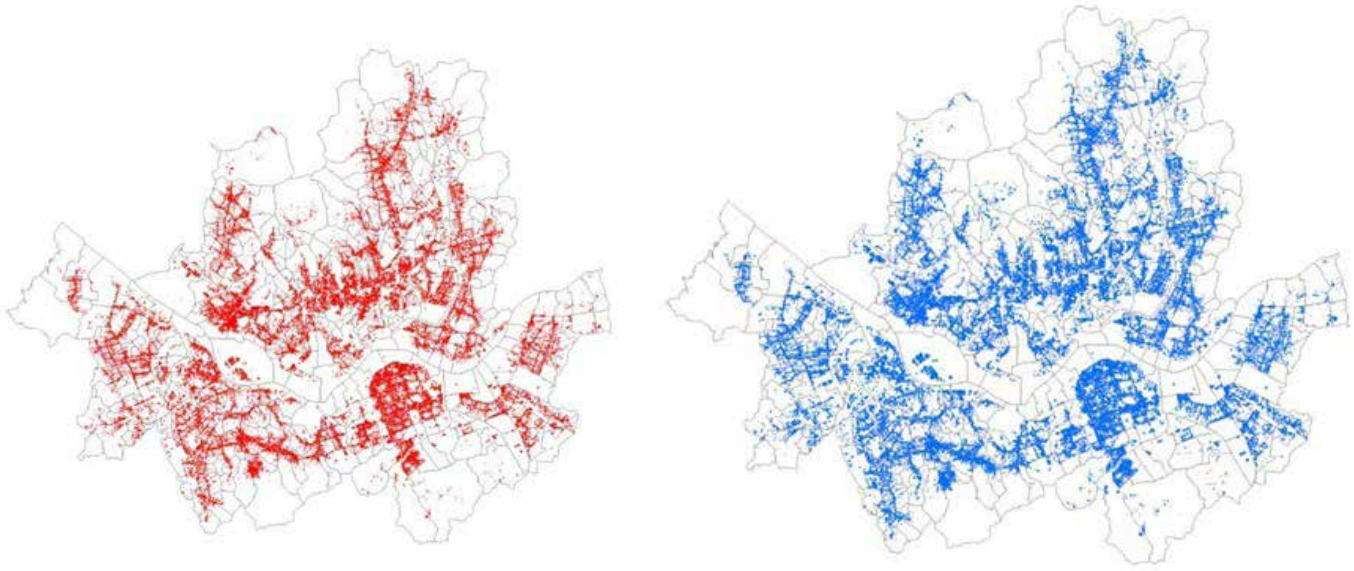
Despite these advances, many previous studies rely on aggregated spatial units—such as neighbourhoods or districts—which may mask variability at the building level. Moreover, the lack of high-resolution behavioural and environmental data has limited the explanatory power of many models. This study addresses these limitations by utilising a building-level dataset that integrates physical, environmental, economic, and behavioural indicators for commercial buildings in Seoul. Specifically, it incorporates mobile-based floating population data segmented by time of day to better reflect occupancy-driven variation in energy consumption. By doing so, the study aims to bridge the gap between temporal human activity and granular urban energy modelling, providing a more realistic and actionable framework for analysis.

3. Research Subject and Data

This study focuses on Seoul, the capital of South Korea, as the spatial and analytical unit for investigating commercial building energy consumption. As a highly urbanised and technologically advanced metropolis, Seoul is characterised by dense population clusters, a compact and heterogeneous building stock, and the availability of rich, high-resolution spatial datasets. These features make the city a particularly suitable case for building-level energy consumption analysis. The scope of the study is limited to commercial buildings, specifically those categorised as first- and second-class neighbourhood living facilities and office buildings. These building types were selected due to their wide spatial distribution, extended operating hours, and relatively high user intensity

throughout the urban landscape. The spatial distribution of valid energy data for electricity (a) and gas/heating (b) consumption is presented in Figure 1a and Figure 1b, respectively.

The study utilises two dependent variables to represent energy intensity: electricity consumption intensity and gas/heating consumption intensity, both based on data from the year 2023. These are defined as the natural logarithm of the total annual energy consumption (electricity or gas/heating) divided by the natural logarithm of the gross floor area (GFA), allowing for size-normalised comparisons across buildings. After data cleaning and preprocessing, the final sample consists of 88,293 buildings for electricity consumption and 67,918 for gas/heating consumption.



1a. 1b.

Figure 1a and Figure 1b: Spatial distribution of electricity (a) and gas/heating (b) consumption

To comprehensively reflect the determinants of urban energy demand, the independent variables are categorised into four analytical dimensions: physical, environmental, economic, and behavioural. Physical variables include the gross floor area, building age, structural type (classified as reinforced concrete, brick, or other), and usage function (office, first-class neighbourhood facility, or second-class neighbourhood facility). Environmental characteristics are measured through average annual temperature and the green area ratio within a 50-metre buffer around each building, derived from NDVI satellite imagery. Economic factors are represented by officially registered land price values, which act as proxies for development intensity and land-based economic value. Behavioural characteristics are captured through mobile network-based floating population data, segmented by three time periods—late night (00:00–06:00), daytime (06:00–18:00), and night-time (18:00–24:00)—as well as an overall daily average.

All variables used in this study were obtained from official government sources or authorised public data platforms. Annual energy consumption data were provided by the Ministry of Land, Infrastructure and Transport (MOLIT), while building characteristics were derived from the national spatial data platform V-World. Environmental indicators were sourced from the Seoul Metropolitan Government's S-DoT sensor network and Sentinel-2 satellite imagery. Official land price data were retrieved from the national land valuation registry, and floating population data were obtained from mobile network big data repositories. A summary of all variables, including definitions, measurement units, types, and data sources, is presented in Table 1. Because the study models electricity and gas/heating consumption separately, all statistical outputs and visualisations are reported accordingly to reflect the unique patterns of each energy type.

Table 1: Summary of variables and descriptions

Variable Name	Variable Type	Description	Unit	Data Source
elect_gfa	Dependent	Log-transformed electricity consumption per gross floor area (2023)	log(kWh/m²)	MOLIT (2023)/ V-World
gasheat_gfa	Dependent	Log-transformed gas and heat consumption per gross floor area (2023)	log(kWh/m²)	MOLIT (2023)/ V-World
GFA_log	Independent	Gross floor area	log(m²)	V-World
bldg_age	Independent	Age of the building	0	V-World
str_reinfo	Independent (Dummy)	Structural type: Reinforced concrete	0/1	V-World
str_brick	Independent (Dummy)	Structural type: Brick	0/1	V-World
str_others	Independent (Dummy)	Structural type: Others	0/1	V-World
bldg_use_1neigh	Independent (Dummy)	Use type: Type 1 Neighborhood Facility	0/1	V-World
bldg_use_2neigh	Independent (Dummy)	Use type: Type 2 Neighborhood Facility	0/1	V-World
bldg_use_office	Independent (Dummy)	Use type: Office Building	0/1	V-World
green_ratio	Independent	Proportion of green space within a 50-meter buffer around the building (NDVI)	%	Copernicus Data Space
temp_avg	Independent	Average temperature within a 50-meter buffer around the building (IDW)	°C	S-DoT Sensor Data
gongsi_jiga	Independent	Official land price of the parcel where the building is located	KRW/m²	MOLIT
avg_lifepop_tot	Independent	Annual average floating population (00:00–24:00)	Persons	Mobile Network Data
avg_lifepop_late	Independent	Annual average floating population (00:00–06:00)	Persons	Mobile Network Data
avg_lifepop_day	Independent	Annual average floating population (06:00–18:00)	Persons	Mobile Network Data
avg_lifepop_night	Independent	Annual average floating population (18:00–24:00)	Persons	Mobile Network Data

4.Methodology

The methodological approach of this study consists of three primary phases: data preprocessing and integration, statistical modelling using multiple linear regression, and the application of a deep learning-based prediction model in the form of a Multi-Layer Perceptron (MLP).

In the initial phase, datasets covering energy consumption, building characteristics, environmental variables, land value, and behavioural data were integrated spatially using unique building identifiers or geocoded addresses. This integration ensured both spatial alignment and content consistency across all records. Missing values were addressed using listwise deletion, and extreme outliers were removed by applying the interquartile range (IQR) method, with thresholds set at the 1st and 99th percentiles. These decisions were visually validated using boxplots.

Categorical variables, including structural type and building use, were transformed into dummy variables to enable their inclusion in the regression model. Additionally, natural logarithmic transformations were applied to electricity consumption, gas/heating consumption, and gross floor area to reduce skewness and improve interpretability. Other continuous variables, such as land price, temperature, and green area ratio, were retained in their original form. In all regression models, dummy variables were constructed for categorical features. Specifically, office buildings were set as the reference group for building use type, and others for structural type, enabling interpretation of coefficients relative to these baseline categories.

Environmental indicators were assigned at the building level using ArcGIS Pro. Average annual temperature was interpolated from point-based sensor data using the Inverse Distance Weighted (IDW) method. The green area ratio was calculated based on NDVI values within a 50-metre buffer surrounding each building. Floating population data, originally provided in a 50-by-50-metre grid format, were overlaid with building footprints. For each building, average values were computed from the intersecting grid cells corresponding to late night, daytime, night-time, and daily periods.

All preprocessing, spatial operations, and feature engineering tasks were conducted using Python, with relevant libraries including Pandas, GeoPandas, and Scikit-learn. Following data preparation, multiple linear regression models were estimated separately for electricity and gas/heating consumption intensities.

All explanatory variables from the four thematic categories were entered simultaneously to evaluate their joint and relative contributions to energy use.

In the subsequent phase of the research, a deep learning approach is planned to be implemented using a Multi-Layer Perceptron (MLP) model. The dataset will be randomly divided into training (70%), validation (15%), and test (15%) subsets. All continuous variables will be standardised, and the MLP architecture will include multiple hidden layers with ReLU activation functions. The model will be optimised using the Adam algorithm, with mean squared error (MSE) as the loss function. To mitigate the risk of overfitting, regularisation techniques such as dropout and early stopping will be employed. Model performance will be assessed using standard evaluation metrics, including R^2, root mean square error (RMSE), and mean absolute error (MAE), based on the test set.

To enhance transparency and interpretability of the deep learning models, SHAP (SHapley Additive exPlanations) analysis will be conducted to quantify the marginal impact of each explanatory variable on the prediction outcomes. All model results, performance evaluations, and SHAP visualisations will be presented separately for electricity and gas/heating, offering differentiated insights into the determinants of each energy type. This methodology enables a high-resolution, multidimensional analysis of urban energy consumption that incorporates spatial, temporal, and behavioural complexity.

5.Analysis Results

This study investigated the annual electricity and gas/heating consumption per unit of gross floor area in commercial buildings in Seoul through a series of multiple linear regression models, constructed separately for each energy type. The analysis utilised large-scale 2023 data, comprising 88,293 building-level observations for electricity and 67,918 for gas/heating. A five-stage modelling framework was adopted to evaluate the contribution of physical, environmental, economic, and behavioural variables, with a particular focus on the impact of time-segmented floating population data. The results reveal distinct determinants for each type of energy consumption and underscore the explanatory value of incorporating spatiotemporal population data.

In the case of electricity consumption, the baseline model includes fixed variables representing physical attributes (log-transformed gross floor area, building age, building use, and structural type), environmental factors (green area ratio and average temperature), and economic conditions (official land price). This initial model demonstrates relatively high explanatory power, with an adjusted R^2 of 0.584. Interestingly, the log of gross floor area shows a statistically significant negative coefficient, suggesting that larger buildings tend to consume less electricity per square meter, potentially reflecting economies of scale. Building age has a positive and significant effect, indicating that older structures are associated with higher energy use, possibly due to outdated equipment or insulation.

In terms of building use, neighbourhood living facilities consume less electricity compared to office buildings, while reinforced concrete structures display lower consumption than other structural types. Environmental variables exhibit notable effects: the green area ratio is positively associated with electricity use, possibly reflecting increased human activity in greener areas. Average annual temperature also contributes positively, likely driven by cooling demands during warmer periods. The official land price emerges as a statistically significant and positive factor, implying that buildings located in higher-value zones tend to consume more electricity, which may be indicative of more intensive building operations. (see Table 2 for regression results of Electricity Consumption per GFA).

Table 2. Regression Result of Model 1 of Electricity Consumption per GFA

Category	Variable Name	Coef.	Std.Err.	t-value	p-value	VIF
Physical	Building Age	0.000644	2.68E-05	24.07526	1.2E-127***	1.157005
	Gross Floor Area (log)	-0.16122	0.000679	-237.501	0***	1.907705
	Structural Type: Reinforced Concrete	-0.1244	0.002012	-61.8237	0***	2.842248
	Structural Type: Brick Masonry	-0.08187	0.002222	-36.8445	6.3E-295***	2.491508
	Use Type: Class 1 Neighborhood Facility	-0.04137	0.002282	-18.1293	2.54E-73***	5.116019

* p < 0.05, ** p < 0.01, *** < 0.001

Dependent Variable: Annual electricity consumption per unit of gross floor area
Independent Variables: Physical, Environmental, and Economic Characteristics of Buildings

As floating population variables are introduced progressively in subsequent models, the explanatory power improves modestly. The final model, which includes late-night population density (00:00–06:00), achieves the highest adjusted R^2 value of 0.588 and the lowest Akaike Information Criterion (AIC), suggesting an improved model fit. This outcome highlights the role of 24-hour commercial activities or night-time operations—such as lighting, security, and maintenance services—in shaping electricity demand. All models yield Durbin–Watson statistics close to 1.68, indicating no significant autocorrelation. F-statistics and p-values confirm the overall statistical robustness of the models on Table 3.

Table3: Regression Results for Models with Floating Population on Electricity Consumption per GFA

Model	Variable	Coef.	t-value	p-value	Adj. R2	DW
Model 2	Average Total Population	0.000110404	19.80503643	4.17E-87***	0.5859	1.6835
Model 3	Late Night Population (00:00-06:00)	-0.000296387	-20.12045846	7.78E-90***	0.5878	1.6847
Model 4	Daytime Population (06:00-18:00)	0.000107928	4.846908526	1.26E-06***	0.586	1.6841
Model 5	Evening Population (18:00-24:00)	0.000501439	21.58245971	4.86E-103***	0.5881	1.6797

Durbin-Watson: 1.6837, * p < 0.05, ** p < 0.01, *** < 0.001

For gas and heating consumption, the baseline model including fixed variables explains 53.1% of the variance. Similar to the electricity model, the log of gross floor area is negatively and significantly associated with consumption intensity, reinforcing the view that larger buildings operate more efficiently. Building age once again exerts a positive influence, consistent with ageing infrastructure leading to increased energy usage.

In contrast to electricity, the effects of building use and structural type appear less pronounced in gas/heating models, suggesting that heating demand is more strongly governed by physical and climatic factors. Average annual temperature shows a strong and statistically significant negative effect, as expected in colder environments. However, the green area ratio is found to be statistically insignificant, possibly due to its limited relevance

to internal heating systems. As with electricity consumption, the land price variable remains a significant positive predictor. (see Table 4 for regression results of Gas/Heat Consumption per GFA).

Table 4. Regression Result of Model 1 of Gas/Heat Consumption per GFA

Category	Variable Name	Coef.	Std.Err.	t-value	p-value	VIF
Physical	Building Age	0.000218	4.08E-05	5.341784	9.23E-08***	1.186283

N=67918, Durbin-Watson: 1.8720, Adj. R-square: 0.531
* p < 0.05, ** p < 0.01, *** < 0.001

Dependent Variable: Annual gas/heat consumption per unit of gross floor area
Independent Variables: Physical, Environmental, and Economic Characteristics of Buildings
Incorporating floating population variables leads to a modest increase in explanatory power, reaching an adjusted R^2 of 0.533. Notably, the model including late-night population data performs best in terms of model fit, exhibiting the lowest AIC value. This supports the interpretation that night-time human presence is linked to greater heating requirements, particularly in buildings with 24-hour occupancy or operational activities. Durbin–Watson values hover around 1.87, indicating no evidence of autocorrelation in the residuals. (Table 5 and Figure 3)

6.Conclusion

This study proposes a multidimensional modelling framework to examine energy consumption in commercial buildings in Seoul by integrating physical, environmental, economic, and behavioural factors within a unified analytical structure. Separate regression models for electricity and gas/heating consumption reveal both shared and distinct drivers across energy types. Among the explanatory variables, temperature emerges as a particularly strong determinant of heating energy use, while official land price reflects patterns of energy demand in economically dense urban areas. Although floating population variables contributed modestly to the overall explanatory power of the models, they nonetheless provided valuable insight into the behavioural dimension of urban energy use.

The proposed framework enables a more comprehensive interpretation of energy consumption patterns by incorporating temporally segmented mobility data alongside building attributes and environmental indicators. Such integration allows for more context-sensitive predictions, especially in highly dynamic urban environments. In the subsequent phase of this research, a non-linear modelling approach using a Multi-Layer Perceptron (MLP) will be implemented to capture complex interdependencies that are beyond the scope of traditional linear models. The application of SHAP (SHapley Additive exPlanations) will further enhance model interpretability by quantifying the contribution of each input variable. Together, these methodological advancements aim to expand both the predictive power and the policy relevance of building-level energy models.

Overall, the findings underscore the importance of adopting a holistic perspective in urban energy modelling—one that accounts not only for physical infrastructure but also for the social and environmental dynamics that influence energy demand. The study contributes a scalable, data-driven approach that can inform future energy efficiency strategies, smart city initiatives, and evidence-based urban sustainability policies.

These findings carry several policy implications for energy-efficient urban development. First, retrofit programmes should prioritise ageing commercial buildings, particularly in areas with high official land values, where energy consumption is significantly elevated. Second, urban energy models should incorporate behavioural data, such as time-segmented floating population, to better reflect actual occupancy-driven energy demand. Third, planning authorities may consider expanding green infrastructure and optimising thermal environments to indirectly influence energy use patterns. Lastly, the integration of spatially granular data and advanced pre-

dictive models can support smarter zoning decisions, resource allocation, and the design of targeted energy policies in high-density urban contexts such as Seoul.

7.Discussion and Limitations

This study provides important insights by analysing the energy consumption of commercial buildings in Seoul within a multivariate analytical framework. However, several methodological and contextual limitations should be taken into account when interpreting the findings.

First, the analysis relies exclusively on cross-sectional data from the year 2023. This temporal limitation prevents the examination of seasonal fluctuations or longer-term trends in energy use. In practice, energy consumption is influenced by dynamic factors such as economic cycles, climate variability, and policy shifts. Future research could address this limitation by incorporating panel datasets or time-series analyses, allowing for a more robust understanding of temporal patterns.

Second, the study focuses solely on Seoul, a city with unique urban characteristics including high population density, advanced infrastructure, and extensive availability of digital data. These context-specific conditions enhance the resolution of the analysis but also constrain the generalisability of the findings. Comparative studies across different urban settings would be beneficial to assess the external validity of the proposed modelling framework.

Third, the behavioural variables in this study—namely, floating population indicators—are derived from mobile network data, which may contain inherent biases due to variations in data collection methodologies, coverage across providers, or limitations in capturing nuanced human mobility. Future work should consider integrating multiple data sources, such as public sensor networks or multimodal mobility datasets, to enhance measurement accuracy and behavioural representation.

Finally, the regression-based methodology employed in this study assumes linear relationships between variables. While useful for interpretability, this assumption may oversimplify the complex interactions that characterise real-world energy consumption. To overcome this limitation, the study outlines a plan to implement a deep learning-based approach using a Multi-Layer Perceptron (MLP), which can capture non-linear dynamics and improve prediction accuracy.

Despite these limitations, the study contributes meaningfully to the urban energy modelling literature by demonstrating how high-resolution, multi-source data can be operationalised within a consistent analytical framework. The proposed methodology supports both academic inquiry and practical decision-making in the pursuit of energy-efficient and data-informed urban environments.

Accounting beyond boundaries: Exploring consumption-based carbon approaches in Paris and Gothenburg

Deshayes Eloïse, Brown Will
Affiliation: Universitat Internacional de Catalunya (UIC), Cambridge University
Email: edeshayes@uic.es

Abstract
This article examines how Paris and Gothenburg have integrated Consumption-Based Carbon Accounting (CBCA) into local climate governance. As cities increasingly confront emissions beyond their borders, CBCA offers a framework to address the carbon impacts of urban consumption. Through a comparative qualitative case study, the research identifies 16 enabling conditions for CBCA implementation, organized into four themes: (1) data transparency and accessibility, (2) institutional and technical capacity, (3) political legitimacy and stakeholder engagement, and (4) multi-level and cross-sectoral support. The findings reveal how different governance models - Paris's institutionalized approach and Gothenburg's pioneering model - can both foster CBCA adoption. This study contributes to understanding the political, institutional, and participatory dynamics that enable cities to engage meaningfully with consumption-based emissions.

Keywords: Consumption-based carbon accounting; Carbon neutrality; Climate governance

1. Introduction

As cities around the world increasingly commit to achieving carbon neutrality, they rely on greenhouse gas (GHG) inventories to assess their emissions and guide climate action. These inventories are typically structured around internationally recognized frameworks, such as the Global Protocol for Community-Sc ale Greenhouse Gas Emission Inventories (GPC) , that primarily rely on a production-based carbon accounting (PBCA) methodology (Harris et al., 2020). However, a growing body of academic literature and policy discourse has highlighted the limitations of PBCA, arguing that it captures only a partial representation of urban emissions (Balouktsi, 2020; Millward-Hopkins et al., 2017; Pellan et al., 2024). In particular, PBCA overlooks the substantial carbon footprint embedded in goods and services consumed by urban populations but produced outside city boundaries. On the contrary, consumption-based carbon accounting (CBCA) estimates the life-cycle emissions of goods and services consumed within a city's boundaries, regardless of where those emissions occur geographically offering a more comprehensive and equitable framework for addressing urban GHG emissions, incentivizing the adoption of policies that promote less carbon-intensive consumption (Grasso, 2016; Lombardi et al., 2017). The claim for the switch towards a more CBCA-focus framework is especially relevant in high-income cities in Europe and North America, where local production-based emissions have declined due to deindustrialization, while consumption-based emissions continue (Millward-Hopkins et al., 2017).

Despite its appeal, the implementation of CBCA remains limited and uneven. Most existing research focuses on methodological and technical challenges (i.e., data availability, input-output modeling), while the political and governance dimensions are mostly studied at the national level. Therefore, the governance dimensions of CBCA at the city level remain largely underexplored, particularly with regard to the political, institutional, and organizational conditions that enable its operationalization within local governments.

This article seeks to address this gap by asking the following research question: What are the governance conditions that enable cities to implement consumption-based carbon accounting and associated policies to reduce emissions?

To answer this question, the article conducts a comparative case study of two European frontrunner cities – Paris and Gothenburg - which have formally adopted CBCA approaches and integrated consumption-based targets into their climate strategies. By analyzing these two cases, the study identifies key enabling governance conditions, ranging from data systems and institutional capacity to political leadership and stakeholder engagement.

The article is structured as follows. Section 2 reviews the terminology and key concepts. Section 3 outlines the methodological approach, including the case selection and analytical framework. Section 4 presents the empirical findings, identifying five thematic clusters of governance enablers. Finally, Section 5 discusses the broader implications of the findings for climate governance and outlines directions for future research.

2. Definition and key concepts

It is essential to define the key terms used throughout this study, as terminology in the field of urban carbon accounting is often used interchangeably or inconsistently.

Most GHG reporting frameworks currently focus on territorial or production-based emissions (Harris et al., 2020). PCBA is a method for quantifying GHG emissions that attributes all emissions to the country, region, or organization where the emissions physically occur during the production of goods and services (Franzen & Mader, 2018). At city level, these emissions largely correspond to Scope 1 of the GPC – meaning emissions from industrial activity, transportation, energy use in buildings, and waste management (Balouktsi, 2020; Fan & Guan, 2025). However, PBCA overlooks the embodied emissions in imported goods and services, which can be considerable, particularly in high-consumption urban contexts with limited local production.

In contrast, CBCA allocates emissions to the final consumers of goods and services, regardless of where in the world those emissions occur along the supply chain. This approach accounts for all emissions generated throughout the supply chain, including production, transportation, and distribution (Volden, 2018). It closely aligns with what is considered Scope 2 and Scope 3 emissions under the GPC framework.

The GPC categorizes emissions as follows:

- Scope 1: Direct emissions from sources located within the city boundary (e.g., local transport, buildings, industry).
- Scope 2: Indirect emissions from the consumption of grid-supplied electricity, heat, steam, and cooling within the city.
- Scope 3: Other indirect emissions that occur outside the city boundary as a result of activities within the city

While Scope 3 provides the most comprehensive perspective on urban emissions, it remains largely optional and is often excluded from official city-level inventories or only partially addressed. As a result, most cities continue to focus on reducing production-based emissions, leaving a significant portion of their carbon footprint unaccounted for (Millward-Hopkins et al., 2017). This gap has crucial implications for the effectiveness of urban climate strategies, particularly in "consumer cities" such as those in Europe, where a significant share of emissions stems from imported goods and service (Harris et al., 2020). Furthermore, it is argued that integrating consumption-based accounting, and particularly Scope 3 emissions, into local governance is critical for developing more effective and equitable climate mitigation strategies. A full accounting of urban emissions - beyond territorial boundaries - enables better-targeted policies that reflect the real carbon emissions drivers in service-oriented urban economies.

To explore this shift, the article focuses on the governance conditions necessary to support the integration of CBCA into city-level climate policy. Governance here is understood in a broad sense, encompassing formal and informal norms, procedures, institutions, and instruments that structure decision-making and implementation processes (Grasso, 2016). As Grasso underlined in his study on the political feasibility of CBCA, governance mechanisms for consumption-based accounting may not yet be fully established or even conceptualized. In this study, governance will be analyzed as a multidimensional framework - including policies, institutional structures, political will, and administrative practices - that can either enable or hinder the implementation of CBCA.

3. Study framework

This study draws upon data originally collected in a broader comparative research project that analyzed the barriers to implementing consumption-based carbon accounting (CBCA) in 17 European cities. These cities were purposefully selected to ensure diversity in terms of geographical location, size, and climate policy maturity. Within this wider research effort, certain cities stood out as exemplary cases in integrating CBCA into their local climate governance frameworks. Among them, Paris and Gothenburg were identified as particularly progressive to advance CBCA and have been chosen for a more in-depth comparative study case study on the governance conditions. Drawing from the main study, the authors formulated a set of hypotheses regarding the political, institutional, and technical enablers necessary for successful CBCA integration. These hypotheses guided the subsequent research design and data analysis strategy.

3.1 Main hypotheses

Two principal hypotheses shaped the analytical framework of this study. The primary hypothesis argues that the successful implementation of CBCA at the city level is contingent upon a combination of enabling governance conditions. These include high institutional capacity, strong data transparency, stakeholder legitimacy, and effective multi-level coordination. The second hypothesis states that the successful implementation of CBCA at the city level is contingent upon a combination of enabling governance conditions. These include high institutional capacity, strong data transparency, stakeholder legitimacy, and effective multi-level coordination.

Each of these hypotheses is underpinned by theoretical and empirical insights from climate governance literature and were broken down into more specific analytical categories, as described below.

High institutional capacity

It is anticipated that cities advancing CBCA possess robust institutional capacity. This includes not only administrative competence and specialized staff, but also financial resources sufficient to develop and sustain complex policy instruments such as CBCA.

Data availability and transparency

An expected key enabling factor is the presence of mechanisms to gather, estimate, and communicate consumption-based emissions data. This may involve standardized methodologies, collaboration with national statistical agencies or academic institutions, and innovative approaches to address data gaps. Moreover, transparency in how data are collected and what they represent is considered essential for credibility and stakeholder engagement.

Political legitimacy

Successful implementation is also linked to the legitimacy of CBCA within the local governance ecosystem. Two factors are anticipated to support legitimacy, measurable targets and the active engagement of both internal and external stakeholders in shaping and delivering on the policy objectives.

Multi-level coordination and stakeholder engagement

Effective coordination across governance levels; horizontal (within municipal departments), vertical (with regional or national authorities), and cross-sectoral (with businesses and civil society), is assumed to be a central enabler. The engagement of diverse stakeholders is also crucial to reinforcing legitimacy and ensuring long-term policy durability.

3.2 Research design

From the broader dataset of 17 European city case studies, Paris and Gothenburg were selected for deeper qualitative analysis. The selection was guided by their advanced engagement with CBCA defined here as going beyond compliance with national or EU mandates. Another selection criterion was for the city to have a consumption-based emissions reduction goal that does not only encompass organizational emissions (i.e., from the municipality) but also include city-wide emissions in their climate targets.

Semi-structured interviews were conducted with key stakeholders involved in the climate governance of each city. Interviewees were initially identified through the NetZeroCities (NZC) platform and selected based on their role and knowledge of CBCA implementation. Complementary to the interviews, documentary analysis was conducted on municipal climate action plans, technical reports, and official data-sharing agreements. During the initial research, a codebook was developed. As this research was exploratory, an inductive coding approach was preferred to discover unexpected themes and patterns and limit researcher bias. These codes were then refined through an iterative validation process involving a second researcher, ensuring inter-coder reliability and interpretative coherence.

From the results of the coding of the main research data, an initial focus was placed on the codes that reflected governance enablers. This preliminary review made it possible to identify recurring patterns and key governance conditions necessary for the implementation of consumption-based carbon accounting (CBCA). These conditions form the analytical framework presented in the results section. Subsequently, a comparative analysis was conducted by reviewing all codes linked specifically to the interviews from Paris and Gothenburg. This step aims

to identify the concrete governance mechanisms present in these two cities, which are considered frontrunners in CBCA. Additional patterns that complemented the initial findings were identified through this city-specific review. Finally, a close re-examination of the interview transcripts for both cities was carried out to validate and deepen the analysis of the governance conditions that have facilitated progress on CBCA at the local level.

Table 1: Summary of Interviews Conducted in Paris and Gothenburg

City	Date	Duration
Paris	19-07-2024	45:58
Gothenburg	07-08-2024	53:28

The transcription of the interviews conducted in Paris and Gothenburg serve as the primary empirical basis for this study and directly inform the analysis of governance conditions for implementing consumption-based carbon accounting (CBCA). In addition to the interviews, several key documents provided by the municipalities were analyzed, including, the Paris Climate City Contract (CCC), the Paris Climate Action Plam, the Gothenburg CCC. Further desk research was also conducted to clarify specific aspects of local governance and policy context not directly covered in the interviews or official documents.

It is worth noting that, throughout the research process, the terms *consumption-based carbon accounting (CBCA)* and *Scope 3 emissions* were frequently used interchangeably by stakeholders. While technically distinct, in this context they were often treated as synonymous in practice and discourse.

3.3 Paris and Gothenburg case studies

Paris and Gothenburg were selected as case studies due to their advanced commitments to climate action, particularly regarding the integration of consumption-based carbon accounting (CBCA) into their urban climate strategies.

Table 2: Key Climate Commitments of Paris and Gothenburg

City	Covenant of Mayors adhesion	Date of CCC publication	Consumption based objectives
Paris	2008	2024	Achieve carbon neutrality, including consumption-based emissions, by 2050
Gothenburg	2009	2024	Reduce per capita consumption-based emissions to 1.9 tCO$_2$e by 2050

Paris emerged early in the research as a leading example, having set an ambitious carbon neutrality target that explicitly includes Scope 3 emissions. Its 2018 Climate Action Plan and subsequent strategies reflect a comprehensive approach, integrating both territorial and consumption-based emissions into its monitoring and objectives. As stated in the Plan:

> *"Through the Climate Plan, the City of Paris has set an ambitious objective to reduce its carbon footprint by 80%. In this way, it is going beyond the legal requirements by integrating indirect emissions that come mainly from aviation, the production of goods, and the food consumed in Paris. To attain this target, the City of Paris plans to encourage the aviation and food industries in particular to make their practices more sustainable"* (p.92)

Gothenburg also represents a strong case, albeit with a slightly less integrated approach than Paris. Nevertheless, it has set clear and measurable targets for reducing consumption-based emissions. The city aims to lower per capita consumption-based emissions to 3.3 tonnes by 2030, 3.5 tonnes by 2035, and 1.9 tonnes by 2050. These goals encompass all goods and services consumed by residents, regardless of where the emissions occur, and imply an annual reduction of approximately 7.6%.

4. Results

4.1 Initial Coding Results

The initial coding process based on the original codebook revealed several recurring governance conditions that enable the implementation of Consumption-Based Carbon Accounting (CBCA). This led to the identification of 16 enabling conditions, organized across four overarching themes: (1) Data transparency and accessibility, (2) Institutional and technical capacity, (3) Political legitimacy and stakeholder engagement, and (4) multi-level and cross-sectoral support. These enabling conditions are presented in the framework below:

Table 3: Enabling Governance Conditions for CBCA Implementation

Themes	Enabling Conditions	Explanation
Data transparency and accessibility	Standardized process	The city has established procedures for collecting and/or analyzing consumption-based emissions data
	Innovation	The city uses alternative data collection approaches where direct data is missing
	Data agreements	The municipality has institutional arrangements with external actors (e.g., private companies, agencies) for data sharing
	Open access	When working with an external stakeholder to collect the data, the city has access to the datasets and methodologies used
Institutional and technical capacity	Dedicated expertise	The municipality has in-house staff or department with expertise in CBCA
	Human and financial resources	The department in charge of the carbon accounting has sufficient technical, administrative, and financial resources
	Strategic cross-departmental collaboration	All relevant departments are being included in CBCA implementation
Political legitimacy and stakeholders' engagement	Strong political mandate	The political commitment goes beyond minimal compliance, supporting ambitious CBCA targets
	Clear communication	There are active efforts to explain CBCA logic and relevance to stakeholders
	Historic commitment	The city has a long-standing engagement in climate action
	City wide and multi-sectoral targets	The consumption-based emissions targets address a broad range of emission sources within the scope of the entire city
	Stakeholders' inclusion	The municipal strategy plans for the engagement of external actors (e.g., citizens, business)
	Clear framing of the objective	A numerical objective with a timeframe is set out from the reduction of consumption-based emissions. This objective is written in the Climate Plan.
Multi-level and cross-sectoral support	National level support	The national ecosystem is favourable of the implementation of CBCA
	Horizontal coordination	Formal agreements are being signed with other public or private organisations allows to enlarge the scope of committed actors

The following sections detail how each theme is manifested in the case studies of Paris and Gothenburg, with insights triangulated through case analysis and complementary data sources.

4.2 Data transparency and accessibility

Four factors have been identified as enabling conditions for CBCA implementation: (1) Standardized data collection and analysis, (2) Use of innovative methods to fill data gaps, (3) Existence of formal data-sharing agreements, (4) Open access and transparency in data communication.

Standardized data collection and analysis processes

A standardized data collection and analysis process appeared essential to strengthen the legitimacy of the accounting process. One the one hand, Paris utilizes the nationally standardized *Bilan Carbone* methodology developed by ADEME[1], ensuring consistency across French cities and reinforcing data legitimacy. The city also relies on INSEE[2] for robust demographic and economic statistics critical to emissions estimation, especially for sectors like food. Paris estimates average daily meal consumption based on residential and commuting populations to approximate food-related emissions. As expressed in the interviews, the existence of national level process allows to strengthen the legitimacy: "*It's good to have in France this "Bilan Carbone" methodology, because then every city would use the same rate for emissions. So, it gives more legitimacy as well for these figures.*"

Gothenburg, while lacking standardized local systems, leverages data provided by the Stockholm Environment Institute (SEI), which, for all cities in Sweden, broke down national data to postal code areas, using market segmentation and local adjustments. However, Gothenburg notes this approach is externalized and lacks sufficient clarity. They also work with a state-sponsored research institute to calculate the impact of food consumption. Therefore, Gothenburg relies on externalized processes, carried on by research institutions, and unified at a national level.

Innovative Approaches

Paris uses innovative methods for categories with data gaps. For example, freight emissions are estimated through regional surveys and applying proportional calculations to allocate emissions to the city. The city also calculates material usage based on construction waste data: "*We do the math from the waste to upstream, because we don't know the amount of materials purchased. So we estimate it from construction waste.*"

Gothenburg began with a bottom-up approach in 2008, assessing household consumption categories using available data, despite its fragmented nature. As exposed in the interview: "*We used like more of a bottom up approach that we looked at on various consumption categories and which day-to-day had available and tried to see how difficult the households in Gothenburg consumed and what the emissions were from the different groups*". Nowadays, this work still complements SEI's data.

Formal data-sharing agreements

These data sharing agreements appear to be particularly done with the air travel industry. Paris has a formal agreement with Aéroports de Paris (ADP), providing free annual data on air travel by Parisians, including departure and arrival information. On the other hand, Gothenburg previously received local air travel data from the airport, but this was discontinued due to political sensitivities, highlighting the fragility of this type of voluntary agreement.

Open access and transparency

In the case of Paris, getting the data from national institutions guarantees the transparency of the processes and access to the data sets. However, Gothenburg, while benefiting from SEI's mapping tools, notes that the opacity of the underlying model makes it hard to explain variations between areas, illustrating a trade-off between using relying on an external stakeholder and transparency; "*It's a little bit of a black box. It's a bit difficult to explain why some areas are higher in emissions and some are not*",

1 ADEME (Agence de l'environnment et de la maîtrise de l'énergie) : French Environment and Energy Management Agency
2 INSEE: French National Institute of Statistics and Economic Studies

4.3 Institutional and technical capacity
The institutional and technical capacity depends on 3 enabling factors: (1) Dedicated expertise within the municipality, (2) Human and financial resources, (3) Cross-departmental collaboration.

Dedicated expertise within the municipality
Paris also works with the Association Bilan Carbone (ABC) association, a national organization that trains professionals on carbon inventories and methodologies, ensuring the upskill process in French municipalities. Furthermore, the city also created a Department for Ecological Transition and Climate in 2022 to oversee its Climate Action Plan. This department monitors actions across administrative departments, conducts greenhouse gas emissions assessments. Gothenburg has a small, dedicated team, with one or two people focusing specifically on carbon accounting, led by a climate strategist responsible for monitoring emissions. "*We have people working with the carbon accounting, but it's not a big team. It's one or two people that are really working with this in detail.*"

Cross-departmental collaboration
Both cities are involving a large number of departments into the strategy to reduce consumption-based emissions. **Paris** promotes shared responsibility by involving various departments and external partners. Carbon accounting data is shared internally to build awareness and ownership: "*We try to involve all the stakeholders of the municipality. So we have different ways to raise awareness and to discuss with them*". **Gothenburg** collaborates with departments like transport and procurement, though it acknowledges that challenges remain: "*There is some collaboration with the transport department and with the procurement department, because their decisions have a big impact on emissions.*" The CBCA strategy is embedded in the normal environmental governance in Gothenburg: "*The City's climate goals are deeply embedded in its ordinary governance structures, notably outlined in the Environmental and Climate Program, backed by a broad political consensus. Central to this program is the aim for near-zero emissions, driving action across all municipal administrations*".

4.4 **Political legitimacy and stakeholders' engagement**
Seven enabling conditions emerged: (1) Strong political mandate, (2) Clear communication, (3) Historic climate commitment, (4) City-wide, cross-sectoral scope, (5) Inclusion of external stakeholders, (6) Legitimacy through leadership and continuity.
.
Strong political mandate
Both cities have a strong political support that goes beyond the mandatory obligations in terms of climate engagements, as highlighted in the interview: "*We have a very ambitious climate plan, and the mayor is very committed to including all emissions, not just the ones happening inside the city.*" Indeed, Paris's commitment to carbon neutrality by 2050 includes scope 3 emissions. The interviewees also highlighted the role of the COP21 Conference in Paris, and the mayor's leadership as a formal president of the C40 network, as key factors explaining Paris high-level commitment.

Gothenburg has robust, cross-party political support for its 2030 goal of near-zero carbon footprint, targeting both territorial and consumption-based emissions. "*The City's climate goal for 2030, 'a carbon footprint close to zero,' has robust support from a broad political majority, and is particularly highlighted by The Environment and Climate Programme for the City of Gothenburg 2021-2030.*" However, as underlined by the interviewee, it might be more complicated to get a political consensus about the methods to adopt to reach the emissions reduction objectives: " *It was quite universal support for these kind of goals, and there have been some discussions when it comes to like individual choices when it comes to like food or what politicians should not do when it comes to emissions related to citizens. But the goals in themselves and not so much discussion*".

In both cases, the cities are pushed by what could be called a moral obligation, as expressed by Gothenburg in the following quote: "*We thought we also have an obligation to see how we affect the other parts of the world through our consumption*".

Clear communication
Paris actively communicates the importance and methodology of CBCA to stakeholders, both inside and outside the municipality, to foster understanding and engagement:

"*We explain to them that it's not just about the emissions from buildings or transport in Paris, but also about what we consume, like food, clothing, and electronics.*"

"*We have meetings and workshops to explain the logic of including consumption-based emissions and why it's important for the city's climate goals.*" Gothenburg supports public participation, but less detail is available regarding structured communication campaigns.

Historic commitment:
The fact that both cities have been leading on climate action and consider as "champion" is perceived as a clear enabler, pushing cities to further extend their actions towards Scope 3 emissions. Paris has demonstrated a long-standing commitment to greenhouse gas accounting and climate action, reflected in the establishment of specialized departments and the use of standardized methodologies. The city began assessing the impact of its activities in terms of greenhouse gases as early as 2004 and published its first comprehensive greenhouse gas assessment in 2006, identifying key emitting sectors and establishing a knowledge base for further action. They were also calculating the carbon footprint of the city since 2004: "*We were already known as a leader on climate for for a long time, and that's what we want to still carry on*".

Gothenburg began measuring consumption-based emissions in 2008, integrating scope 3 in climate policy despite limited data at the time: "*We had our first time goal for the city, we chose to include the consumption emissions also, even though we had very little data or anything on it*". Initially, the city was separating between territorial and consumption-based emissions before adopting the scope 1, 2, 3 framework as part of their involvement with the Covenant of Mayors and other reporting schemes.

City-wide and cross-sectoral focus
Both Paris and Gothenburg have adopted climate strategies that extend well beyond municipal operations, encompassing a wide range of emissions sources, including those linked to citizen behavior, urban infrastructure, and procurement practices.

In Paris, the city's climate policy is explicitly designed to address emissions across all sectors - not just those occurring within city boundaries. This includes emissions from energy, transport, food, construction, and the consumption of goods and services by Parisians. As one official explains, "*The city's climate plan covers all emissions, including those from energy, transport, food, construction, and even the consumption of goods by Parisians.*" Another emphasizes the city's broader scope: "*We don't just look at what happens inside the city boundaries. We want to reduce the footprint of everything Parisians consume, even if it happens outside Paris.*" The ambition is clear and comprehensive: "*Our goal is to reduce all emissions by 100%, not just the ones we control directly.*"

Similarly, Gothenburg has adopted a wide-ranging climate objective that integrates both territorial and consumption-based emissions. As described by a city representative: "*The climate goal of the City of Gothenburg has a broader scope than required in the Mission. The goal targets emissions from both a territorial and a consumption-based perspective.*" At the organizational level, Gothenburg closely monitors emissions associated with municipal procurement. The city has conducted a detailed analysis of all its programmatic requirements, comparing them against a national emissions database that calculates greenhouse gas intensity per monetary unit. This allows the city to assess the carbon impact of everything it purchases: "*We did this analysis on all our programme requirements, checking them against the database that has data on emissions per krona or monetary unit in Sweden.*" As one official notes, this gives the municipality considerable influence: "*We have much more say in what we as a city consume and procure, and we can do much more with that.*"

At the citizen level, Gothenburg also aims to capture emissions associated with individual consumption. While recognizing limitations in influencing certain areas - such as the embedded emissions in imported goods - the city still exerts significant control through local systems: "*When it comes to what our citizens consume, we still have a lot of say in how our transport system is set up and our energy system within the city, but not so much when it comes to the cost of goods and services.*". To operationalize this broad approach, Gothenburg has developed a climate program structured around seven strategic focus areas - or "strategies" - that require radical transformation.

Stakeholders inclusion:
Both Paris and Gothenburg prioritize inclusive governance by actively engaging a wide range of stakeholders in their climate initiatives - from large corporations and public institutions to local associations and citizens.

In Paris, the city has developed a collaborative framework to bring together stakeholders from across sectors. One key initiative is the Pacte Action-Climat-Biodiversité (Climate Action–Biodiversity Pact), a publicly available charter that outlines stakeholder commitments and reinforces transparency. "*It's like a kind of charter that some actors and stakeholders agree to sign to say that they will work alongside the city to implement measures that have an impact on the carbon footprint of the city.*" The pact not only encourages joint action but also provides open access to information about partners and their objectives. Among the participating actors are major energy providers such as **GRDF** and **EDF**. As one official described, "*We have big energy companies like GRDF, EDF... the idea is to embark all of them and to share experience and good practices between all of them.*" This approach reflects a deliberate effort to keep institutionalizing cooperation and knowledge exchange across organizational boundaries.

In Gothenburg, a similarly inclusive approach is taken, particularly with local associations and community-based actors. The city provides targeted support mechanisms that encourage grassroots involvement in climate work. For instance, associations, including sports organizations, can apply for municipal grants to fund environmental initiatives. "*You can, as a sports association, ask the city for grants for doing that kind of work, and you can get access to the city's buildings*", explained one representative. Notably, these programs have been expanded to include organizations working on issues such as circular economy, allowing for greater diversity in the types of projects supported: "*We extended those programmes to associations that want to work with circular economy issues and things like that.*"

Clear objectives
The presence of clearly defined goals - particularly those that are quantitative and time-bound - plays a fundamental role in enabling consumption-based climate action (CBCA). These objectives serve not only as guiding principles but also as concrete benchmarks that drive prioritization, mobilize resources, and ensure accountability. In both Paris and Gothenburg, long-term climate ambitions are formally documented in strategic plans, providing an essential foundation for implementing CBCA measures.

In Paris, the city's objectives are explicitly articulated in the Climate Action Plan and the Climate, Air, and Energy Plan (PCAET). These plans commit Paris to reducing all local emissions - including both territorial and consumption-based - by 100% in the long term. More specifically, the city aims to cut total emissions (including consumption-based ones) by 40% by 2030 and by 80% by 2050, relative to 2004 levels: "*Paris established targets in its Climate Action Plan to decrease territorial and consumption-based emissions (the Paris carbon footprint) to 40% below 2004 levels by 2030 and 80% below 2004 levels by 2050.*"[3]

Similarly, Gothenburg has committed to a clear and ambitious consumption-based emissions reduction pathway. Its goals are both quantified and tied to a defined timeline, providing a strong political mandate for CBCA implementation. By 2030, the goal is to reduce consumption-based greenhouse gas emissions to 3.3 tonnes CO e per person per year, down from a baseline of 9.25 tonnes in 2017. This requires an annual reduction rate of at least 7.6%. The final goal is to reach 1.9 tonnes CO e per person per year by 2050.

4.5. Multi-level and cross-sectoral coordination
The successful implementation of CBCA depends significantly on coordination across multiple levels of government and sectors. This is enabled by two key factors: a supportive national governance system and a horizontal coordination across sectors and stakeholders.

National governance ecosystem
Paris benefits from a strong national framework that provides substantial institutional support for implementing CBCA. National-level entities - including government agencies, research institutions, and statistical offices - supply cities with the methodologies, data, and standards necessary for consumption-based carbon accounting. These tools not only strengthen the technical foundation of Paris's climate policy but also lend political legitimacy and

3 Paris Climate Action Plan

coherence to local actions. In contrast, Gothenburg operates within a more fragmented national governance context. While it receives technical support from organizations such as the Stockholm Environment Institute (SEI) - which plays a crucial role in developing methodologies for CBCA - there is no formal governmental mandate or support at the national level for consumption-based accounting.

Horizontal coordination
Both cities also rely heavily on horizontal coordination, meaning collaboration across sectors and with various public and private stakeholders.

In Paris, this is exemplified by initiatives such as the Pacte Action-Climat-Biodiversité, an open, online charter where stakeholders voluntarily commit to actions aligned with the city's climate goals, as explained above. Similarly, in Gothenburg, CBCA is not the responsibility of a single department but is instead embedded across the city's governance structures. The Environment and Climate Program for 2021–2030 was adopted by a wide political majority and applies to all city departments and city-owned companies. This ensures that the goal of reducing consumption-based emissions is shared across the entire municipal apparatus.

5. **Discussion**
This study identifies two contrasting yet complementary models of consumption-based carbon accounting (CBCA) governance: Paris's institutionalized model and Gothenburg's pioneering approach. These cases illustrate that there is no singular pathway to implementing CBCA. Instead, diverse strategies - shaped by political cultures, institutional configurations, and external support systems - can all serve as viable routes to operationalizing this ambitious climate accounting framework.

5.1. Two different models: Institutionalized vs. Bottom-up CBCA Approaches
Paris advances CBCA within a highly institutionalized and nationally supported governance environment. It benefits from a structured ecosystem comprising national research institutions (e.g., INSEE, ADEME, ABC), legal mandates, and standardized methodologies, which provide a robust backbone for methodological consistency and policy legitimacy. CBCA is embedded within the city's broader climate strategy, supported by cross-sectoral coordination and formal target-setting. This reflects what Bulkeley and Kern (2006) describe as "governing through enabling," where higher-level institutions provide cities with tools and frameworks for climate action. In contrast, Gothenburg exemplifies a more bottom-up, pioneering approach. Despite the absence of strong national mandates or standardized frameworks, the city has pushed CBCA forward through close partnerships with expert institutions like the Stockholm Environment Institute (SEI), bottom-up data collection, and partnerships with local institutions. The reliance on external actors has enabled methodological innovation and credibility, though it also introduces potential vulnerabilities in terms of continuity, autonomy, and long-term data governance. Studies shows that, while introducing expertise and standardized methods, the reliance on external stakeholders also include challenges in maintaining consistent methodologies over time, risks of data discontinuity if external partnerships dissolve, and potential limitations on local autonomy and data ownership (Fünfgeld & McEvoy, 2012; Turnhout et al., 2016).

5.2 The Role of National Ecosystems
These two cases highlight the enabling role, but not deterministic function, of the national ecosystem. While Paris's success is deeply tied to a supportive national framework, Gothenburg demonstrates that local innovation can substitute for national direction. Paris thrives in an ecosystem with clear national institutions and policies that underpin CBCA, from macroeconomic data (INSEE) to methodological standards (ADEME). The relationship between national frameworks and local climate action is well documented in the literature. National institutions can provide essential data, methodological standards, and legitimacy, enabling cities to develop robust climate policies (Bulkeley & Kern, 2006; Kern & Bulkeley, 2009).

Conversely, research shows that cities can also innovate in the absence of strong national direction by leveraging local academic and technical expertise. For example, Gothenburg does not benefit from national institution data but draws on the academic expertise of the SEI. However, such innovation may be less stable or scalable without institutionalized national support (van der Heijden, 2019; Castán Broto & Bulkeley, 2013).

5.3 Political framing and target settings as a key enabler towards CBCA
A shared enabler in both contexts is the framing of CBCA through clear, time-bound targets embedded in official climate strategies. Paris aims to reduce territorial and consumption-based emissions by 80% from 2004 levels by 2050. Gothenburg targets a per capita reduction to 3.3 tonnes CO$_2$e by 2030. The literature demonstrates that setting ambitious and specific targets not only structures implementation but also acts as a powerful tool for political mobilization, stakeholder engagement, and accountability (Rogge & Reichardt, 2016; Hsu et al., 2020).

Closely tied to target-setting is the integration of CBCA across departments and sectors. Paris exhibits more formalized coordination through interdepartmental mechanisms and city-wide climate charters. Gothenburg relies on horizontal integration, embedding CBCA objectives across all departments and city-owned companies through its Environmental and Climate Program (2021-2030). This integration ensures that scope 3 data informs procurement, planning, and budgeting processes which are key for mainstreaming beyond symbolic commitments. The mainstreaming of CBCA objectives across municipal departments and city-owned companies, as seen in both Paris and Gothenburg, is also recognized as a best practice for effective climate governance (Bulkeley & Kern, 2006; Reckien et al., 2018).

5.4 The crucial role of stakeholder engagement
Stakeholder engagement is central to the legitimacy, operationalization, and sustainability of CBCA governance. In Paris, structured participation is institutionalized through the Pacte Action-Climat-Biodiversité, a publicly accessible charter that mobilizes actors across sectors, from energy companies to grassroots organizations. This charter formalizes commitments, ensures transparency, and reinforces co-responsibility. It embeds climate action within a network of shared governance, illustrating that a broad societal buy-in is needed in order to carry out actions to counter consumption-based emissions. Gothenburg mainly focus on society organizations, sports associations, and NGOs are encouraged to align with the city's environmental objectives through financial support and access to public infrastructure. This fosters bottom-up engagement and reflects a high-trust model of participatory governance. The city has expanded its collaborative programs to include circular economy initiatives, highlighting the dynamic evolution of stakeholder roles in CBCA. Such bottom-up approaches are shown to be effective in mobilizing local actors, fostering innovation, and ensuring that climate actions are contextually relevant and widely supported (Aylett, 2015; Arnouts et al., 2012).

5.5 Normative Framing and Cities as Global Climate Actors
The deliberate inclusion of consumption-based emissions in local climate plans reflects a normative redefinition of urban responsibility. Rather than limiting themselves to territorial emissions under their direct control, both Paris and Gothenburg embrace a broader ethical mandate that connects local governance to global sustainability. This shift positions cities not as passive implementers but as active shapers of post-territorial climate governance. This framing aligns with emerging literature on cities as global actors (van der Heijden, 2019).

Therefore, it can be argued CBCA equips cities with tools to address climate change systemically but also imposes new demands. Cities must negotiate responsibilities beyond their formal jurisdictions, build internal expertise, and ensure accountability for emissions they do not directly control. To succeed in this role, they require enhanced support - access to funding, methodological guidance, and platforms for international collaboration. The cases of Paris and Gothenburg reinforce the view that cities can lead in addressing global challenges when empowered with the right frameworks and coalitions. Their experiences suggest that CBCA is not just a technical exercise but a transformative approach to rethinking urban sustainability and governance in the age of climate crisis.

Conclusion
This article has examined the governance conditions of consumption-based carbon accounting (CBCA) through an in-depth comparison of Paris and Gothenburg, two cities that, despite distinct institutional contexts and levels of national support, each have advanced ambitious and pragmatic CBCA strategies. The findings reveal that while Paris operates within a highly institutionalized, nationally backed model and Gothenburg advances a more bottom-up, normatively driven approach, both demonstrate that local governments can lead on scope 3 emissions governance, even in the absence of a harmonized international framework.

The Paris case illustrates the strengths of a mature governance ecosystem where national institutions provide the methodological and legal infrastructure necessary to support robust CBCA integration. In contrast, Gothenburg shows that municipal innovation, when coupled with collaboration with expert institutions, can pioneer new methodologies and mainstream CBCA into city operations, even with limited national guidance. Across both cases, the success of CBCA governance is tied not only to technical capacity or institutional design, but also to the political and ethical reframing of urban climate responsibility. By choosing to include emissions beyond their direct territorial control, both cities expand the boundaries of local climate governance toward a more globally accountable model. Clear targets, cross-sectoral integration, and meaningful stakeholder engagement emerge as critical levers for embedding CBCA within policy and society. At the same time, the analysis underscores the fragility of such efforts when they rely too heavily on individual champions, external expertise, or voluntary mechanisms. To sustain and scale CBCA, cities need institutional safeguards such as binding mandates, integrated planning processes, and sustained national support.

Moreover, the broader governance landscape must evolve to recognize and support cities as global climate actors, providing the financial and technical resources needed to monitor, manage, and reduce consumption-based emissions.

Ultimately, the Paris and Gothenburg experiences show that CBCA is not only a technical tool but a political and ethical project. It calls for reimagining the role of cities in a globally interconnected carbon economy and for crafting governance arrangements that enable urban actors to lead climate action far beyond their borders. CBCA thus offers a vital lens through which to rethink both the responsibilities and the capabilities of cities in the age of planetary crisis.

Acknowledgements
This research was made possible through the valuable support and collaboration of numerous individuals and institutions. We would like to express our sincere gratitude to the municipal representatives and experts who generously shared their time, insights, and experiences during the interviews. Their openness and critical reflections were instrumental in shaping the findings of this study.

Abstract
The sources discuss climate adaptation challenges in Brazil, noting that most municipalities lack capacity and plans. Local adaptation and community participation are crucial, especially in vulnerable settlements. Duque de Caxias, a flood-prone municipality, exemplifies these issues, marked by unregulated development and political resistance to public debate. The FORAS movement emerged, advocating for urban rights. A conflict centres on Campo do Bomba, a key floodplain, which the municipality wants for economic development despite its ecological role. FORAS mobilized, arguing its "sponge" function is its social function. Collaborating with academics, the community proposed the Quilombo do Bomba Ecological Park, featuring nature-based flood control, green areas, improved mobility, and community facilities. This case illustrates the struggle between economic interests and environmental/community needs

Keywords: climate adaptation, local government, community participation, vulnerable settlements;

Introduction

Addressing climate adaptation at the local level in Brazil represents a significant challenge due to the lack of institutional capacity and challenges in integrating sectoral policies. In Brazil, there are 5,570 municipalities. Data from the National Confederation of Municipalities indicate that between January 2013 and December 2024, a total of 5,279 Brazilian municipalities (95%) were affected by different kinds of disasters. Drought and excessive rainfall were the disasters that most affected Brazilian municipalities between 2013 and 2024 (Confederação Nacional dos Municípios, 2025) On the other hand, data from the AdaptaBrasil Platform indicate that more than 65% of Brazilian municipalities have low or very low capacity to adapt to natural disasters, such as heat waves, droughts and heavy rains.

The Rio de Janeiro Metropolitan Area (RMRJ) has twenty-two municipalities and only two of them have a Climate Change Mitigation and Adaptation Plan. Despite the Metropolitan Region of Rio de Janeiro (RMRJ) having an Integrated Urban Development Plan (PDUI) and a collegiate metropolitan governance body that brings together both local and state-level representatives, the urban actions that have been implemented remain fragmented, lacking a mitigating or adaptive approach to climate change. These projects are fragmented not only in their territorial scope but also in terms of the cross-sectoral integration of public policies.

Literature on climate change highlights the importance of cities and the local level in building adaptation strategies. The United Nations Development Programme (UNDP) highlights that climate adaptation is local in nature and that local governments should focus on adaptation activities and develop local strategies and action plans; the European Union's (EU) Strategy on Adaptation to Climate Change stress the importance of climate adaptation at the local level; the Global Commission on Adaptation (GCA) places an important emphasis on locally-led adaptation, which aims to shift "power to local stakeholders (OCDE, 2023). For Wannewitz and Garschagen (2023) adaptation is at least partly a communal task given that communities are in many ways bound together through infrastructure, geography, or resource management. They shared a common perception of hazard risk.

The authors propose a definition of collective adaptation "as actions of a group of individuals or subcultures collaborating according to shared rules to reduce their climate risk, exploit climate change opportunities and/or achieve additional common development objectives adopting a long-term perspective" (Wannewitz and Garschagen, 2023, p.2).

Peeling argues that adaptation agenda has local and global components and indeed national level action too. High level legal frameworks and voluntary agreements can support local action, but local level action is also a potential driver for higher level policy. But when this agenda is absent at higher levels, local action has the potential to be decisive in determining capacity and action and influencing the construction of a higher-level policy (Pelling, 2011).

Even if adapting to climate change is an important issue for the local environmental agendas, it is also a growing challenge for local communities, especially in marginalized informal settlements. Many informal settlements face high risks of floods and landslides a result of poor-quality buildings and a lack of infrastructure to prevent flooding, withstand heavy storms, and cope with heat waves (Wannewitz and Garschagen, 2023; Satterthwaite et al. 2020). The literature highlights the importance of social participation in the construction of adaptation strategies. Communities, and especially people who are marginalized, excluded, or especially vulnerable, must have some control over how their community will adapt (Adger et al. 2011).

But participation in adaptation strategies or policies at informal and vulnerable settlements is a complex issue. The question is if a vulnerable population has the political power – or political capability – to influence adaptation decisions, or if people most vulnerable to harm are politically capable of having control over their environment reveals opportunities to address the root causes of their vulnerability, as well as barriers to transformational outcomes. Informal communities often face a lack of political power, as their voices are marginalized in decision-making processes and their needs are overlooked by formal governance structures.

The local arena of environmental and climate adaptation politics includes elected officials and bureaucrats, as well as non-governmental actors, such as business entities, non-profit organizations, independent academics, political advocacy groups, and ordinary citizens who have a stake in climate adaptation decisions. It is a space where different interests are expressed and is therefore marked by conflict. Scientific expertise holds a privileged position in this arena. The privileged role of expertise can then function to diminish the voice and disregard the experience of those exposed to environmental harms (Ottinger 2013). Holland stresses the importance of alliances built by vulnerable or marginalized communities to enhance their capacity to be politically capable of shaping adaptation decisions, such as alliances with media or academics.

This paper addresses this topic through a case study in Duque de Caxias, a municipality in the Metropolitan Region of Rio de Janeiro that is severely vulnerable to flooding. Data on flood susceptibility indicate that 45% of households are in high-risk situations (Casa Fluminense, 2024). Focusing on the issue of social participation in discussions about climate adaptation projects and based on the definition of collective adaptation mentioned before, the paper focuses on a case study related to the protection of an area, Campo do Bomba, that has an important function in preventing floods. It highlights a community-driven project of sponge park, built from an alliance between the Urbanism Post-graduate Program at the Federal University of Rio de Janeiro and FORAS, an articulation of local social movements. The paper is organized into three parts in addition to this introduction. The first introduces the municipality of Duque de Caxias, its social characteristics, and its challenges concerning climate change and the local social movement, FORAS, which articulates the second proposal. The second section discusses the clash between the two proposals. The third focuses on the FORAS proposal and its development.

The case study area: Duque de Caxias and its vulnerabilities

Duque de Caxias is a municipality situated in the Metropolitan Region of Rio de Janeiro. The city has a population of 808,161 inhabitants (IBGE, 2022) and represents one of the major poverty areas within the metropolis. Regardless of this inequality scenario, the municipality holds the fourth largest GDP in the state (IBGE, 2021), with a per capita value of R$57,170.07. The industrial production at the Duque de Caxias Refinery (Reduc), operated by Petrobrás, accounts for 80% of Brazil's lubricant production, in addition to processing the largest volume of natural gas in the country. This generates significant revenue for the municipality through the collection of oil royalties.

Although Duque de Caxias ranks among the municipalities with the highest per capita tax revenue in the state, its Human Development Index (HDI) was classified as *Medium* in 2021, with a value of 0.711, placing it 49th in the state ranking—below the state median.

When considering the Income component of the HDI, the municipality ranks even lower, at 57th position.

Geographically, Duque de Caxias is in the Baixada Fluminense, at the foothills of the Serra do Mar, with a mangrove coastline bordering the Guanabara Bay. The municipality lies within the Guanabara Bay hydrographic region, the outlet for the main rivers that traverse the metropolis and is frequently affected by flooding.

The city is drained by three major hydrographic basins: Iguaçu-Sarapuí, Estrela, and São João de Meriti, in addition to other smaller continental catchments that drain directly into the bay. The rivers descending from the Serra do Mar do so along stepped gradients formed by fault lines. These rivers exhibit a torrential regime with significant erosive power. Upon reaching the lowlands, their flow becomes depositional, lacking an intermediate sediment transport phase between the slopes and the plains. The violently descending waters from the slopes encounter difficulty in draining across the plain due to the low terrain gradient, resulting in extensive flooded areas, such as swamps and marshes (Prefeitura de Duque de Caxias, 2017).

According to the diagnostic report prepared for the Municipal Sanitation Plan, the drainage difficulties in the municipality are primarily attributed to its geomorphological genesis. These natural conditions of floodplain formation are further compounded by unregulated urban development and a lack of basic infrastructure, which exacerbate the flooding issues. The soil sealing increases surface runoff, while the silting and obstruction of rivers with sediment and domestic waste diminish their drainage capacity. The frequent overflowing of watercourses is also affected by tidal fluctuations, thereby extending the duration of flood events (Prefeitura de Duque de Caxias, 2017).

The history of urban occupation in Duque de Caxias is closely tied to the establishment of petroleum-based industrial parks. The industry, by generating employment opportunities, attracted many low-skilled workers to occupy positions along the production chain. However, the strategy of locating industrial plants was not accompanied by a broader process of urban and regional planning to address housing and basic sanitation needs. This lack of integrated planning has contributed to the current scenario of pronounced social inequality.

According to Neves et al. (2019), between 2007 and 2016, Duque de Caxias experienced a significant expansion of its urban footprint, encroaching substantially upon areas of herbaceous vegetation. Beyond the direct suppression of vegetation resulting from urbanisation in Duque de Caxias, Neves et al. (2019) highlight a concerning trend: the direction of this urban expansion towards areas highly susceptible to flooding. This raises significant concerns regarding occupant safety, particularly given the region's known susceptibility to riverine flooding events (Britto, Quintslr and Pereira, 2019).

Despite environmental issues constituting the primary urban challenges in Duque de Caxias, the municipality's political and administrative culture continues to prioritise strategies for attracting industries at any cost, often without adequately assessing the associated benefits and drawbacks across various industrial sectors. Historically, public administration in Duque de Caxias has operated to serve the parochial interests of specific family groups, promoting ventures that have contributed minimally to the reduction of social inequality. Consequently, the socio-environmental outcomes in the region have generated hybrid risks, characterised by the superimposition of environmental threats such as floods, water and soil contamination from landfills and refinery leaks, atmospheric pollution originating from oil industry chimneys, and significantly substandard basic sanitation infrastructure.

By the early 2000s, the city was compelled to initiate an urban planning process, driven by Federal Law 10.257, known as the City Statute. The master plan was approved on 31st October 2006. In 2009, a study on the drafting process of the Municipal Urban Master Plan of Duque de Caxias highlighted that public participation was not adequately accommodated. It was observed that during over a six-month of plan elaboration, only 14 public meetings were held. Furthermore, some of these meetings were cancelled due to a lack of quorum.

One of the most flagrant indicators of inadequate participation was the fact that the Master Plan was voted upon without public presence and without the inclusion of amendments.

Nonetheless, Duque de Caxias has a set of social movements that were structured in the 1980s. In 1983, the Municipal Federation of Residents' Associations of Duque de Caxias (MUB) was created at a meeting attended by 27 residents' associations. The MUB emerged in a context in which several popular movements and community organizations were organized in the municipality, such as residents' associations, CEBs (Base Ecclesiastical Communities) and the Friends of the Neighbourhood Movement. These movements were organized during the military dictatorship, with their main causes being the fight for democracy, the right to health, basic sanitation, education and housing. A few other movements that also focused on environmental issues were also organized. However, the various local governments resisted the democratization of public management through participatory processes.

The process of the plan shows this local government unwillingness, demonstrating the extent to which the administration is refractory to the concept of planning and regulating the territory through public debate. Such planning typically reveals conflicts and establishes rules for reconciling different urban land uses. Without stringent regulation, any type of enterprise can establish itself in the municipality, which offers minimal or no restrictions on activities that could cause environmental damage. In the case of Duque de Caxias, there is a discernible lack of concern on the part of governmental authorities regarding whether new ventures embraced by the municipality as an economic strategy conflict with public health considerations.

The land-use zoning imposed by the Duque de Caxias Master Plan was not revised within the stipulated 10-year period for its renewal. Amendments to the Master Plan have been enacted through complementary laws whenever the administration deems it necessary to alter provisions to accommodate specific political projects. Between October 2006 and May 2025, the Master Plan's text has been subjected to 14 alterations. All these changes have specifically modified land use to permit the economic exploitation of areas that were frequently designated as areas of environmental interest or subject to occupation restrictions. Out of the 14 modifications to land use within the Master Plan enacted by the municipality, five pertain to the suppression or reduction of the delimitation of Special Environmental Interest Zones to accommodate Special Business Zones. Furthermore, two complementary laws relate to the intensification of land use in Controlled Occupation Zones, reclassifying them as urban expansion areas. This paper reports on the community mobilisation in São Bento concerning the land-use changes affecting a parcel of land. This area was decoupled from the São Bento Environmental Protection Area and subsequently reclassified as a business interest zone.

In 2014, faced with the imminent construction of a multi-activity complex that included a shopping centre, office towers, and an aparthotel planned for the last remaining green area in the central region of Duque de Caxias at the time, the local population, recognizing the scale of the initiative, organized in opposition, creating the Forum of Resistance to the shopping mall named FORAS.

From the perspective of promoting greater public participation in city management and pressuring municipal authorities to prioritize the interests and needs of the population, FORAS positioned itself against the construction. It denounced its various social, cultural, urbanistic, and environmental impacts of the project and proposed, instead, the creation of an urban park. This park would contribute, among other things, to preserving the city's memory.

The chosen format for organizing this initiative was a People's Forum—a space where various organizations and grassroots movements could participate without losing their unique identities. Institutions involved in this process included among others: local cultural associations, environmental movements, feminist movements, Federation of Residents' Associations of Duque de Caxias (MUB); the Forum of Communities Affected by the Petroleum and Petrochemical Industry near Guanabara Bay (FAPP-BG); the State Union of Education Professionals (SEPE); the Duque de Caxias Oil Workers' Union (SINDIPETRO-CAXIAS; the National Movement for Housing Rights (MNLM); the National Union of Black Men and Women in Duque de Caxias (UNEGRO) and Catholic Church leaders and members.

During the movement against the shopping mall, meetings were held with public authorities, workshops were conducted in schools, and participation in municipal participatory councils and conferences was emphasized. Other activities included publishing educational booklets, organizing public hearings, distributing pamphlets, graffiti campaigns throughout the city, and filing public civil actions. The Institute of Urban and Regional Planning and Research (IPPUR-UFRJ) was a key partner of FORAS, contributing activities to enhance public discourse, equipping activists with the technical knowledge necessary for effective dialogue and advocacy with local authorities.

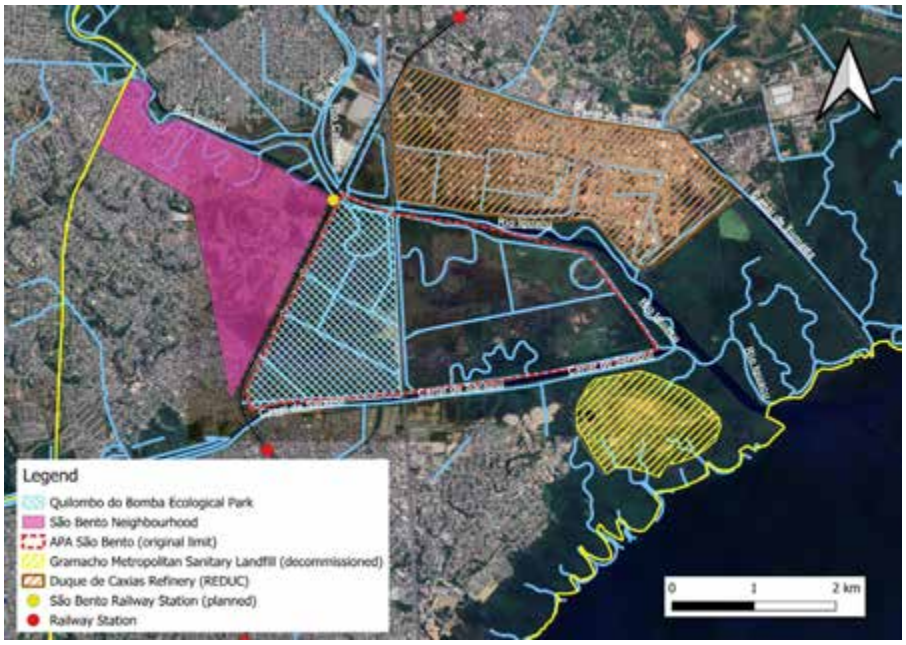
The movement organized by FORAS was victorious, bringing the conflict beyond the city's boundaries, to the extent that, to this day, the Central Park Caxias project has not been realized. In the process, FORAS established itself as a unifying force for major grassroots movements in the city, advocating for community libraries, protecting the city's historical heritage and the environment, and fighting for urban rights. Despite an unfavorable political climate in the city, FORAS members remained vigilant regarding new projects, denouncing the predatory occupation of public lands and deforestation.

Another critical moment of mobilization arose in response to the 2018 Metropolitan Urban Development Plan proposals for Duque de Caxias, which sought to promote logistics activities in the municipality, compromising environmental quality. One proposal that faced significant opposition involved an area known as "Campo do Bomba", in the São Bento neighbourhood, which will be explained in the following section.

The fight for Campo do Bomba preservation

The São Bento neighbourhood, situated between the estuaries of the Iguaçu and Sarapuí rivers, was historically part of the São Bento Farm. This land was transferred by the Ministry of Agriculture to the National Institute of Colonization and Agrarian Reform (INCRA) upon its establishment in 1970. A portion of this region now constitutes a Municipal Environmental Protection Area (APA de São Bento). The São Bento APA is divided into the eastern part and western part. The eastern part, under the possession and supervision of the Navy, has different communities settled by the Ministry of Agriculture, the State Government, social movements, and militia members who illicitly sold Union lands without the knowledge of the National Institute for Colonization and Agrarian Reform. The western contains archaeological and historical heritage sites and one of the last remaining fragments of the Atlantic Forest in close proximity to the municipality's urban centre (Figure 1)

On October 27, 2006, the then-mayor of Duque de Caxias enacted Law No. 2003/2006, which excluded the areas known as Campo do Bomba 1 and Campo do Bomba 2 from the São Bento Environmental Protection Area (APA). Together, these areas covered approximately 315 hectares. The justification for this exclusion was unclear.



São Bento neighbourhood has long been regarded as a metropolitan sacrifice zone, owing to its location adjacent to the Duque de Caxias Refinery (REDUC) and the former metropolitan landfill of Gramacho. The APA de São Bento is highly valued by the local population, serving as a natural barrier against atmospheric pollution emanating from REDUC and acting as a buffer zone against the risk of chemical leaks from the industrial area. Furthermore, it plays a critical role in the region's hydrological dynamics by absorbing a portion of the flow from the Iguaçu and Sarapuí rivers, thereby mitigating the effects of flooding in the Baixada Fluminense lowlands.

In 2017 Duque de Caxias government announced a project to build in the Campo do Bomba area a new State Central Supply Market (CEAERJ), and it requested INCRA to donate the land to the municipality. The Municipality initiated a process of landfilling the area, thereby suppressing native vegetation. Concerned by the potential consequences of this undertaking, FORAS initiated a political mobilisation against the project arguing the environmental role of the area, and the negative consequences of its occupation.

The municipal government's idea was to build the new State Central Market to replace the old one located in Rio de Janeiro suburb since the 70's. The Association of Ceasa Merchants were against the change. The decision concerning the relocation of CEASA was under the state government's responsibility, and the project from Caxias municipality wasn't approved. But the idea of giving an economic function to the area remained.

Between 2017 and 2018 the state government developed the Integrated Urban Development Strategic Plan for the Metropolitan Region of Rio de Janeiro (PDUI/RMRJ). Discussion groups were created to address different subjects, followed by integration discussion groups that consolidated scenarios and subsequently the proposals for priority actions included in the plan. One of these actions concerned the Campo do Bomba area.

The project was part of the subprogram "Living in the Metropolis," and it aims to mitigate flooding in the Iguaçu-Sarapuí River basin through macro-drainage interventions in the Campo do Bomba area. The metropolitan project was aligned to the municipal interests to give to this area an economic use. It aimed to install a canal between the Iguaçu and Sarapuí rivers to reduce the over flood of the two rivers. This canal would ensure the flood mitigation function, thereby allowing the remaining (3,000,000 m² of Campo do Bomba) to be utilized for industrial, logistical, and other purposes (Consórcio Quanta-Lerner, 2018).

The project mobilized FORAS that organized meetings to discuss the metropolitan plan projects to Duque de Caxias. But until then, the occupation of Campo do Bomba was only a non-developed project. The situation changed. With the approval of the guidelines included in the Metropolitan Plan, the government of Duque Caxias took up the project to give the area an economic purpose, now in the form of a logistics centre, similar to CEAERJ. A bidding process was conducted, and the area was granted to the territory's winning consortium—the sole bidder.

When the landfilling of the area began, in 2020, members of FORAS (researchers, environmentalists, lawyers and fishermen) began to meet every week to discuss strategies for action against the landfill. The dispute ended up in the Federal Public Ministry (MPF), which requested that the work be suspended and that studies be carried out to assess the impacts it could cause. The land is, in fact, owned by the National Institute for Colonization and Agrarian Reform (Incra), a federal agency, and ceded to the municipality. Due to the non-compliance with clauses of the donation agreement that conditioned the donation to a socio environmental project to the area, and the accomplishment of the social function of the land- a principle of Brazil's Constitution- the Federal Public Prosecutor's Office, ordered the reversal of the donation term.

Although the Public Prosecutor's Office successfully suspended any ongoing interventions by the municipality in the area, the local government maintained its agenda. In 2021, Duque de Caxias, presented a reformulated project, including a study for the channel between Iguaçu and Sarapuí river, elaborated by un expert in hydrology, which was responsible for the Iguaçu Sarapui River Basin Plan, elaborated within a contract with the state government's environmental agency (INEA).

In march 2021 a public hearing was conducted by the Federal Public Prosecutor's Office and mediated by Federal Prosecutor Júlio José Araújo Júnior. It included the participation of representatives from the Duque de Caxias municipal government, the Rio de Janeiro State Environmental Agency (INEA), the National Institute for

Colonization and Agrarian Reform (INCRA), the Public Defender's Office, and civil society—comprising teachers, residents, and individuals connected to social movements. The hearing was held remotely via the YouTube platform and streamed live. At that time, due to the health emergency caused by COVID-19, it was not possible to hold in-person public hearings to prevent the spread of the disease.

During the herring, the representative of the municipal government argued that Campo do Bomba wasn't fulfilling a social function and that there was a risk of the area becoming a "slum,". He states that economic development will prevent a disorderly occupation and will create about 50,000 jobs and an increase in tax revenue for the municipal administration. The municipality also emphasized the area's strategic location, adjacent to the Washington Luís Highway and near the Duque de Caxias petrochemical hub. The government's project shows a cluster of plots occupied by warehouses with highly waterproofing. The study conducted by the expert for the canal that will prevent the floods and allow a non-residential occupation of the area was not presented.

The proposal of the municipal representative was contested by FORAS members, who presented studies showing the importance of Campo do Bomba as a sponge site, absorbing water from flood water from rivers and preventing worsening flooding in the surrounding occupied area. The population living around Campo do Bomba considers that the site already fulfils its social function, which is its ecological function. The climate change impacts were highlighted. Sarapuí and Iguaçu rivers are silted up due to mud and trash, which hinders water drainage during rainfall. The progressive rise in sea level caused by climate change is expected to further worsen this situation because both rivers have a configuration highly prone to flooding. When it rains, the sea acts as a wall holding back the flow and preventing the floodwaters from receding. In the coming years, climate change could increase rainfall volumes by up to 30%.

To counter the potential occupation of Campo do Bomba, FORAS organized a petition to transform the area into a state-protected park. The document was presented to deputies in the Legislative Assembly of the State of Rio de Janeiro, leading to the proposal of a bill by a deputy who embraced FORAS's cause, presented in the Legislative Assembly in the end of august 2021.

In the process of the drafting of a bill, this representative organized three public hearings in 2021 at the Legislative Assembly, attended by representatives from the Caxias municipal government, FORAS, INCRA, the Federal Public Prosecutor's Office, and INEA, all of whom were given the right to speak. During the debate in the public hearing in September 2021 the representative of Duque de Caxias mentioned the project of the canal between the two rivers, but did not present it. The representative of the State Environmental Agency, INEA, stated that the area is highly complex and requires technical studies conducted by a multidisciplinary team to issue the Environmental Technical Opinion. These studies are necessary because the area involves an entire ecosystem, including fauna and flora; however, such studies have not yet been conducted by the state agency. It was emphasized that, due to the proximity of the Sarapuí and Iguaçu Rivers and its coastal location near Guanabara Bay, the region functions as a floodplain, it was important to conduct a more detailed study of the area's hydrological behavior.This study should outline the advantages and disadvantages of implementing the Duque de Caxias government project, as well as all environmental consequences. This instrument will then be reviewed by INEA, and after analysis by the technical team, a decision will be made regarding the area.

The Campo do Bomba's community planning

Concurrently, within the political discourse and community leadership mobilisation, Bill No. 4773/2021 was submitted to the Legislative Assembly in 2019, proposing the establishment of the Quilombo do Bomba State Park in the area. However, the bill remains under discussion, and the ultimate designation of the area is still uncertain. The name of the park was chosen by FORAS members because the site was also home to the Quilombo do Bomba. Quilombos are settlements established by escaped enslaved people (known as quilombolas) in Brazil during the colonial period. These communities were often formed in remote areas and served as places of resistance, refuge, and self-determination. Quilombo do Bomba was part of the most famous quilombo complex in Rio de Janeiro, known as the Hydra of Iguaçu, a reference to the mythical monster and the river that crossed the settlement. To this day, residents find ancient artifacts in the surrounding area. For researchers, building on Campo do Bomba is equivalent to permanently burying the memory of the place.

Given the local community's recognition that the land's social function should be maintained as an environmental protection area and considering the context of climate change and the already observed alterations in natural phenomena, the community has sought partnerships to assist them in developing an alternative proposal for the land parcel. Despite the existence of the Bill for park creation, the community fears that the proposed urban and landscape design may not adequately consider aspects they value. In this regard, a local effort was made to establish contact with the Federal University of Rio de Janeiro's Faculty of Architecture and Urbanism, seeking academic cooperation with residents in preparing a preliminary study for a viable park in the area.

Within the scope of the Professional Master's Programme in Landscape Architecture, a design studio course facilitated the development of a preliminary study for the Quilombo do Bomba Ecological Park. The professors and students implemented a participatory design process. Members of FORAS participated in all the studio classes and lectures on water sensitive cities and nature-based solutions. Field work and discussions with the community were held in numerous meetings.

As a result, the local population prioritised five key strategies to be integrated within the park's spatial framework.

Water Strategy
Given that flooding and sanitation are central issues in the neighbourhood, the population advocated for these problems to be primarily addressed with nature-based solutions. Initially, however, the completion of the unbuilt dikes from the Projeto Iguaçu and the expansion of polder areas along the Sarapuí and Iguaçu rivers were proposed. Recognising that urban occupation no longer permits the river's original meandering, engineering methods are necessary to ensure the local population's safety from floods.

In contrast to the landfilling proposed by the municipality, the community favoured excavating the area to create a large detention basin, allowing the interlinking of both rivers for promoting flow control in both river basins. Excavation would enable the construction of various cells at different elevations, which would be inundated as river levels rise. The objective is to retain this water during peak flow periods and gradually release it after the crisis subsides. Furthermore, the excavation aims to establish a constant water surface across a significant portion of the terrain for planting phytoremediation species, accelerating water purification processes.

For the neighbourhood, the installation of water distribution, sewage, and drainage networks is a key guideline. During this process, there is a strong demand for replacing asphalt with permeable pavements and installing rain gardens to reduce the volume of surface runoff from rainwater.

Green Strategy
The green strategy is intrinsically linked to drainage issues, particularly concerning the maintenance of dike structures and the role that vegetation plays in soil stability and permeability levels.

The project anticipates the restoration of riparian forests along the rivers through planting on dike slopes. The aim is for roots to stabilise the slopes while creating a continuous tree canopy along the dike to facilitate genetic material transit via fauna. The dike structure must also support the passage of dredging tractors, with accessible points to the river for maintaining the macro drainage channel.

In addition to the dike strategy, the Quilombo do Bomba Ecological Park area is traversed by Furnas' high-tension energy distribution infrastructure. The "non aedificandi" (no-build) zone beneath the power lines has the potential to be utilised as a strategy for promoting corridors to form a system of green areas and interconnect conservation units within the Baixada Fluminense.

Furthermore, part of the territory could also be used for establishing urban gardens, mitigating issues related to food security in the area.

Mobility Strategy
Considering the precarious conditions in the area, the widespread absence of private vehicle ownership in the neighbourhood, and the need for access to the job market, the São Bento population demanded accessible (physically and financially) public transport for the project. Research conducted by students, based on community

statements, revealed a historical plan for a train station within the neighbourhood at the perimeter of the Quilombo do Bomba Ecological Park. This proposal was subsequently incorporated into the preliminary study.

The devised strategy was to utilise the tops of the dikes that connect to the railway line as a large cycle path, allowing flow from the neighbourhood to the train station and the centre of Rio de Janeiro. This cycle path would reach other Baixada Fluminense municipalities, such as Belford Roxo and São João de Meriti, potentially increasing the use of urban trains, mitigating greenhouse gas emissions from bus use, and influencing a modal shift among car owners.

The dikes would be structured with appropriate paving and shaded by the planned riparian forest. Additionally, the station could be located on the banks of the Iguaçu River, which was historically navigable and has the potential to integrate with fluvial transport to Guanabara Bay. For the consolidation of bicycle use, residents highlighted the need for bicycle parking associated with the new station, as well as the implementation of shared bicycle stations for access by those who do not own one.

Mobility also encompasses the redesign of local streets, incorporating level, permeable, and shaded pavements.

Regional integration was also considered by incorporating the Park as a connecting route between the São Bento neighbourhood and the Pilar and Jardim Gramacho neighbourhoods, as well as with the Washington Luís Highway, through suspended walkways and viewpoints constructed at their intersections. In this sense, these walkways, which would also include cycle paths, would allow residents of São Bento and Pilar easy access to facilities such as the Federal Institute of Rio de Janeiro, located in Jardim Gramacho, an area currently "distant" due to various existing spatial fragmentation elements: the railway line, rivers, impenetrable land parcels, etc.

Social and Environmental Development Strategy
Throughout the discussions concerning the preliminary design of the Quilombo do Bomba Ecological Park, the need to integrate the area into the community's daily life was frequently highlighted, ensuring the space would not be occupied by housing or economic activities incompatible with the proposed model. To achieve this, the strategy would involve the urbanisation of the land's periphery as a mechanism to protect its ecological functions while simultaneously endowing the periphery with public uses necessary for the local community.

One frequently cited demand was for a creche (daycare centre). This is due to the high incidence of households headed by women in the area, and their need to secure childcare for young children to enable economic activity. The 2022 census indicates that the São Bento, Pilar, and Jardim Gramacho neighbourhoods have 52.40%, 51.75%, and 52.77% female-headed households, respectively.

In addition to a daycare centre, the necessity of a community centre for meetings of various organised groups lacking a formal meeting space was mentioned. This community centre could also host courses and lectures for the community and provide an area for exhibiting local artisanal production.

The periphery should also include leisure areas not hegemonically used by men and boys, as is often the case (e.g., multi-sport courts, skate parks). Instead, it should feature meeting areas for the elderly, spaces for caregivers adjacent to playgrounds, and playgrounds with specific equipment for different age groups.

The park's needs program also included the use of environmental education-promoting furniture, where air quality sensors, rain gauges, and anemometers could be installed, or which could narrate the local community's history. In this sense, the Quilombo do Bomba Ecological Park could be concretely integrated into residents' lives, reinforcing local identity.

Housing and Urban Infrastructure Strategy
While much of the discussion revolved around the preliminary design of the Quilombo do Bomba Ecological Park and the integration of this new space into local dynamics, reflection on the concrete reality of the population was recurrent and important for incorporating aspects related to residents' living conditions into the project guidelines.

To enable the strategies described previously, articulated action through housing policy is crucial. The population residing on top of the dikes, who are the primary victims of annual floods, must be relocated to new housing. Consequently, this housing must be within the neighbourhood's perimeter so that the population does not lose social ties with their neighbours or their solidarity network, nor lose the benefits of the park to be realised due to their own resettlement.

For the consolidated areas of the São Bento neighbourhood not within environmental risk zones, the guideline is the implementation of water, sanitation, and drainage infrastructures. As it is an INCRA area, the community's land regularisation process could also be initiated through a REURB-S process, where public investments would be directed towards installing this basic infrastructure.

Conclusions and Future Developments

This paper discusses how organized social participation can build alternative projects for climate adaptation. The literature analysed on the subject highlights the role of the local level in constructing adaptation agendas and the importance of social participation in shaping these agendas. However, it also underscores the challenges of participation in contexts of socio-environmental vulnerability, where social actors are deprived of power., and their capacity to influence decision-making remains a limiting factor. Government practice continues to be largely resistant to the demands of the population, as the local political arena for climate adaptation is a contested space where competing interests collide.

Urban and environmental projects that impact areas vulnerable to climate change and claim to mitigate these effects are often top-down initiatives, disregarding the experiences, knowledge, and interests of those living in these areas. One way to counter these projects is through the creation of collective adaptation projects, built by forming alliances.

The case study focuses on the municipality of Duque de Caxias, where the local government lacks both institutional capacity and political will to address the climate emergency. On the other hand, there are organized social movements in the region that address this issue and oppose government projects that negatively impact the environment and increase the local population's vulnerability to the effects of climate change.

Beyond mere opposition, these social movements strive to propose alternative projects to official initiatives, where climate adaptation becomes a crucial aspect. To achieve this, strategic alliances are formed to provide the projects with technical and political support. It is within these alliances and the articulation built in the territory that the concept of collective adaptation lies.

The paper analyses the construction of a collective adaptation project by social movements in São Bento, Duque de Caxias in alliance with progressive political actors, the Federal Public Prosecutor's Office, and the university. The project addresses a context where socioeconomic vulnerability combines with vulnerability to flooding. It emerged as a counterpoint to another project, driven by dominant economic interests and supported by municipal and state government spheres, which overlooked local demands.

Government's project prioritizes economic development in a narrow sense and seeks to promote the installation of large-scale logistics infrastructure. This would require landfilling an area that, until recently, was part of an environmental protection zone and which plays a critical ecological role, providing natural mechanisms for mitigating environmental impacts. On the other hand, there is the counterproject from the São Bento community, which values environmental preservation and integrated socio-environmental development. This vision is embodied in the proposal for the Parque Ecológico Quilombo do Bomba, a community-led plan that seeks recognition of the area's ecological function as its social function, using the site as a space for sustainable climate adaptation.

Despite social mobilization and legal actions, the legal status and fate of contested areas such as Campo do Bomba remain uncertain, depending on the outcomes of political and technical processes at various levels of government. There remains an urgent need for in-depth technical studies carried out by multidisciplinary teams. The future development of vulnerable areas such as Duque de Caxias will depend on the ability of social movements and communities to overcome local political resistance, foster public debate, and defend development models

that integrate climate adaptation, environmental preservation, and basic social needs — as opposed to models focused exclusively on unregulated economic growth.

Addressing Climate Equity Through Community Engagement on Virginia's Eastern Shore

Ozlem Edizel Tasci
Institute for Engagement & Negotiation, University of Virginia
Email: umk4dz@virginia.edu

Abstract
The Eastern Shore of Virginia (ESVA) is experiencing severe climate impacts, including sea-level rise, flooding, and groundwater salinization, which disproportionately affect its rural, resource-dependent, and underserved communities. The ESVA Climate Equity Project, funded by the National Science Foundation's Coastlines and People (CoPe) program, employs a participatory framework that integrates local knowledge with scientific modelling to co-develop a climate adaptation decision-support tool. Through community workshops, stakeholder interviews, and the guidance of a diverse Community Advisory Committee, the project fosters inclusive engagement, deepens local understanding of climate risks, and strengthens collective capacity. Findings highlight the importance of addressing structural barriers, investing in civic infrastructure, and embedding local priorities into adaptation strategies. The article offers practical lessons and policy recommendations for equitable climate resilience planning in similarly at-risk coastal communities.

Key words: climate equity; community engagement; rural coastal communities

Introduction

Coastal communities are on the front lines of climate change, facing mounting risks from sea-level rise, intensifying storm events, saltwater intrusion, and hydrological variability. Rural coastal regions, in particular, are highly vulnerable due to their dependency on natural resource-based economies, limited infrastructure investment, and geographic isolation (Bhattachan et al., 2018). These areas frequently contend with aging or inadequate public systems, declining population trends, and chronic underfunding—conditions that compromise their adaptive capacity in the face of escalating climate pressures (Vogel et al., 2007; Marino, 2015).

The Eastern Shore of Virginia (ESVA) exemplifies this intersection of physical exposure and socio-institutional vulnerability. Located between the Chesapeake Bay and the Atlantic Ocean, the Eastern Shore of Virginia is a narrow peninsula experiencing one of the highest rates of relative sea level rise along the U.S. Atlantic coast, due to both global sea level rise and localized land subsidence (Sweet et al., 2022). According to the NOAA Technical Report, the Mid-Atlantic region, which includes the ESVA, is projected to experience a relative sea level rise of approximately 10 to 14 inches (0.25 to 0.35 meters) by 2050 (Sweet et al., 2022). This rate is among the highest along the contiguous U.S. coastline. The region's low elevation, shallow aquifers, and rural character make it highly susceptible to coastal and inland flooding, groundwater salinization, and septic system failures (Walker et al., 2019; DeMaria et al., 2020). These environmental hazards are compounded by socio-economic disparities, limited access to scientific resources, and fragmented governance structures—factors that hinder cohesive, long-term planning (Jurjonas & Seekamp, 2018; Commonwealth of Virginia, 2020).

This article examines these challenges through the lens of the ESVA Climate Equity Project, a National Science Foundation (NSF)-funded project aimed at fostering participatory, equity-oriented climate resilience strategies in the region. Grounded in principles of co-production, the project integrates community engagement with environmental modelling to develop a Livability Tool that supports localized climate adaptation. This article, hence, contributes to growing scholarly and policy discussions on how participatory processes can enhance addressing equity issues in changing climate and produce more just and effective climate solutions in rural regions.

These environmental threats intersect with deep-seated social inequities. The region's rural character, socio-economic disparities, and fragmented governance limit the development and implementation of long-term resilience strategies (Jurjonas & Seekamp, 2018; Commonwealth of Virginia, 2020). In response to these challenges, a participatory, equity-centred framework for co-developing climate adaptation tools with and for the community was adopted by the Eastern Shore of Virginia (ESVA) Climate Equity Project.

This article examines how the project's participatory design—anchored in co-production and sustained community engagement—has helped identify climate priorities, foster trust, and inform the development of a "Livability Tool" for local decision-making. By situating this work within broader debates on inclusion and rural

adaptation, the article contributes to a growing literature on the transformative potential of collaborative, community-centred climate planning (Norström et al., 2020; Schlosberg et al., 2017, Edizel-Tasci and Evans, 2021).

Climate Challenges in the Eastern Shore of Virginia

The Eastern Shore of Virginia is experiencing the compound effects of climate change at both severe and chronic scales. Relative sea-level rise in the Chesapeake Bay region has been measured at approximately 3–5 mm per year—nearly twice the global average—due to a combination of land subsidence and global sea level trends (Boon et al., 2010). These changes increase the frequency and severity of both coastal and inland flooding, endangering transportation infrastructure, agricultural fields, and residential properties. In addition, the region's shallow aquifer systems are becoming increasingly saline due to saltwater intrusion, threatening drinking water supplies and farm irrigation.

Climate impacts in the ESVA manifest across multiple systems. Flooding events disrupt access to schools, health services, and employment centres, while declining groundwater quality strains the viability of domestic wells and small-scale agriculture. Many households rely on decentralized wastewater systems, such as septic tanks, which are increasingly vulnerable to saturation, failure, and backflow under rising water tables (Agbasi et al, 2025). These risks are unevenly distributed, with low-income and historically marginalized communities more likely to reside in low-lying areas, lack resilient infrastructure, or face financial barriers to adaptation (Kaufman & Williams, 2021). In this way, climate impacts amplify existing structural inequities and threaten basic livelihood systems (Chang et al., 2017, Edizel-Tasci and Evans, 2021).

The region's agricultural economy—anchored in poultry, soybeans, and vegetable production—is increasingly unstable due to shifting rainfall, saltwater intrusion, and declining water quality (Bhattachan et al., 2018). Meanwhile, the physical infrastructure (roads, bridges, culverts) is aging and often ill-equipped to handle extreme weather or stormwater, which undermines both economic mobility and emergency response systems.

Disruptions to water and transportation systems intersect with public health vulnerabilities. Children, elderly residents, and migrant workers are especially at risk, particularly during heatwaves, flood events, and disease outbreaks exacerbated by compromised sanitation. For example, blocked roadways can delay emergency medical services, while overcrowded or inadequate housing can intensify exposure to environmental stressors (Jurjonas & Seekamp, 2018; Walker et al., 2019). These cascading impacts highlight the interconnectedness of environmental and social systems and underscore the urgency of coordinated, equity-focused adaptation.

Disparities in Resilience

In rural coastal regions such as the Eastern Shore of Virginia (ESVA), exposure to climate-related hazards is unevenly distributed across communities. These disparities are shaped by historical land use patterns, demographic segregation, and unequal access to basic infrastructure and planning processes. Many of the region's most at-risk populations—including long-established African American communities and Latino farmworker groups—live in low-lying areas with poor drainage and limited stormwater infrastructure, often a result of historical exclusion from safer or better-serviced zones (Schlosberg et al., 2017; Kaufman & Williams, 2021).

These communities frequently face additional barriers: substandard housing, unreliable transportation, limited access to healthcare, and low political visibility. For migrant and seasonal farmworkers, for instance, overcrowded housing, limited mobility, and temporary work arrangements reduce access to reliable climate information or emergency support (Bhattachan et al., 2018). Language barriers and precarious employment further limit access to climate information or public support systems.

This dynamic reflects what Edizel & Evans (2017) describes as the spatial and institutional marginalization of underrepresented communities—where barriers to participation are embedded in both the physical environment and the formal processes of planning. Addressing these disparities requires more than technical solutions; it calls for participatory approaches that recognize lived experience, redistribute access to decision-making, and challenge dominant narratives about urban space.

As others have noted, adaptation efforts that do not attend to these underlying disparities may inadvertently reinforce the very vulnerabilities they seek to address (Schlosberg et al., 2017). Equitable resilience planning,

therefore, must attend to questions of who is most at risk, who is heard, and how systems can be restructured to deliver fairer outcomes.

Participatory Approaches in Climate Adaptation

Participatory approaches have become central to contemporary climate adaptation strategies, particularly in regions facing complex socio-environmental challenges. Over the past three decades, scholars and practitioners have developed a wide array of methods designed to involve communities in shaping the policies, practices, and infrastructures that affect their lives. As Beierle (2002) outlined, the goals of public participation often include educating and informing the public, incorporating local values into decision-making, enhancing the substantive quality of policies, building institutional trust, and reducing conflict.

These aims are especially relevant to climate adaptation, where scientific uncertainty, local variability, and contested values converge. Participatory methods—ranging from community mapping and deliberative workshops to scenario building and citizen science—enable residents to articulate lived experiences, prioritize risks, and shape policy solutions that are contextually meaningful (Few et al., 2007; Armitage et al., 2011).

A growing body of scholarship distinguishes between levels of engagement, emphasizing that meaningful participation goes beyond informing or consulting the public. Trench (2008) and Rowe & Frewer (2005) conceptualize public engagement along a continuum—from dissemination (one-way information flow), to dialogue (two-way consultation), to full collaboration or co-production (shared decision-making and mutual learning). Chang and Moore (2017) similarly stress the importance of designing enabling conditions that support inclusive processes—particularly those that shift power and resource control toward local communities.

In the context of climate resilience, co-production has gained traction as a framework that foregrounds equity, accountability, and situated knowledge. Norström et al. (2020) define co-production as an iterative process where power, knowledge, and responsibility are equitably distributed among actors. This is not merely a methodological choice but a normative stance—aimed at disrupting hierarchical knowledge systems that historically excluded marginalized voices. Edizel & Evans (2017) reinforces this perspective through her exploration of participatory mapping, highlighting how spatial practices can reveal embedded, often invisible forms of marginalization that shape both the physical and institutional landscapes—what she frames as the politics of representation and exclusion in planning processes.

In sum, participatory approaches in climate adaptation are most effective when they are designed not only to gather input, but to reshape power dynamics, institutional relationships, and governance outcomes. As the ESVA Climate Equity Project illustrates, co-production can serve as both a method and a political commitment—one that redefines how resilience is imagined, measured, and achieved.

Methodology

The ESVA Climate Equity Project adopts a participatory engagement framework rooted in principles of knowledge co-production. Rather than treating community engagement as a supplemental or extractive component of research, this project positions engagement as central to shaping research questions, methods, and outputs (Norström et al., 2020; Turnhout et al., 2020).

The project is supported by the National Science Foundation's Coastlines and People (CoPe) program, which supports interdisciplinary, place-based research to advance climate resilience in coastal communities. A core objective of the project is the development of an open-source data and visualization platform—referred to as the Livability Tool—that integrates scientific modelling with community knowledge. This five-year (2021-2026) collaboration between the University of Virginia, Old Dominion University, and regional community leaders aims to build local capacity for climate adaptation by foregrounding lived experience, historical context, and locally relevant priorities.

The project applies co-production as both a normative and methodological commitment, engaging diverse stakeholders in all stages of the research cycle. Drawing on the work of Lemos et al. (2018) and Howell and Wilson (2018), the research design emphasizes iterative feedback processes to ensure that outputs reflect the practical needs and values of the community. A core methodological focus of the project is the integration of

local knowledge—such as lived experience, oral histories, and cultural memory—with scientific tools including spatial modelling and hydrological analysis. For instance, flooding and groundwater models were developed and refined based on insights shared during workshops. Community members provided maps and narratives documenting salinization of wells, historical drainage patterns, and land use changes that would have been otherwise invisible in top-down datasets.

The project team is also advised by a Community Advisory Committee (CAC which serves as both a governance body and a bridge between the research team and broader community. The CAC includes 12 local leaders from education, public health, planning, nonprofit, and economic sectors, including representatives from public schools, community colleges, migrant advocacy groups, and social services. CAC members play a key role in shaping research questions, advising on engagement strategies, reviewing draft deliverables for accessibility, and supporting outreach and dissemination. Their guidance ensured that community voices were embedded in all stages of tool development and public engagement.Throughout the process, the research team met regularly with the CAC to refine outreach strategies and align engagement activities with evolving community concerns. This integrated, iterative approach aimed to strengthen trust, encourage local leadership, and embed community knowledge throughout the development of adaptation tools.

Stakeholder Identification and Outreach
Stakeholders were identified through a combination of network-based and snowball sampling methods, initiated through referrals from CAC members and extended via existing community relationships. Outreach efforts included targeted emails, local event tabling, word-of-mouth, and phone calls. This approach was designed to ensure representation from across the region's geographic, socio-economic, and institutional spectrum. Participants included elected officials, school staff, tribal leaders, public health professionals, nonprofit directors, small business owners, and civic volunteers. This diversity strengthened the relevance of the engagement process and contributed to the development of locally meaningful climate adaptation resources.

Community Workshops
Three in-person community workshops were held between January 2023 and August 2024, drawing a total of over 200 participants (67 in Winter 2023, 83 in Winter 2024, and 50 in Summer 2024). Each workshop was structured as an open-house event featuring 6–8 interactive stations. Topics were developed in collaboration with community members and included:

- Sea level rise and storm surge
- Septic system vulnerability
- Groundwater depletion and salinization
- Land use history and community memory
- Climate adaptation and planning scenarios

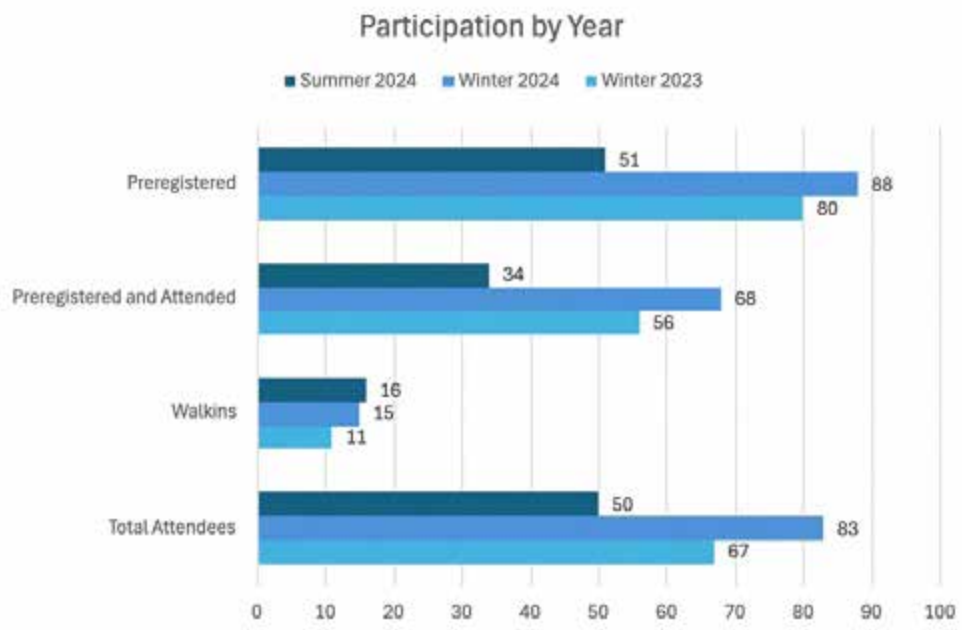

Figure 1: ESVA Workshop Participation Numbers by Years (2023-2024)

Each station was facilitated by a member of the research team. The format enabled participants to move freely, explore areas of interest, and engage in informal dialogue. Data collection methods included sticker voting, written comments, annotated maps, and structured conversation prompts (e.g., "What climate changes are you most concerned about?"). This iterative design supported multiple entry points for participation and fostered mutual learning among participants and facilitators.

Semi-Structured Stakeholder Interviews

Between September 2023 and May 2024, 20 semi-structured interviews were conducted with representatives from local government, education, public health, environmental NGOs, and media. Many of these interviewees were first introduced to the project through the workshops and later volunteered for follow-up discussions.

Interviews were designed to capture institutional perspectives on climate risk, planning processes, and community resilience needs. Each interview lasted approximately 60–90 minutes and was audio-recorded and transcribed for analysis. The interviews informed the framing of the Livability Tool and provided additional context for interpreting community engagement data.

Analysis and Discussion

The ESVA Climate Equity Project reflect a layered process of community engagement and knowledge co-production. The three community workshops—Winter 2023, Winter 2024, and Summer 2024—served not only as educational and participatory events but also as recruitment mechanisms for deeper engagement through interviews. During these workshops, community members were invited to sign up for follow-up interviews, which were conducted from September 2023 to May 2024. This sequential methodology ensured continuity between broad-based community feedback and more detailed institutional perspectives, enabling the project team to triangulate across qualitative inputs and refine project goals iteratively. The process also offers a grounded example of how participatory, equity-oriented climate research can generate meaningful insights, foster institutional trust, and support more just adaptation planning in socio-ecologically vulnerable regions.

1. Enhanced Community Understanding of Climate Risks

Throughout the engagement efforts, there has been an increase in community understanding of localized climate risks through iterative, station-based workshops and embedded institutional dialogue. The open-house format and use of visual tools (e.g., flood maps, story timeline boards) enabled participants to explore complex topics—such as groundwater salinization or septic vulnerability—in accessible and meaningful ways which emphasizes that tailored, place-based approaches foster greater comprehension and trust (Kahan et al., 2011; Lemos et

al., 2018, Edizel & Evans, 2017). Stakeholder interviews reinforced these insights, revealing how participatory activities informed internal agency conversations and community-level planning. For instance, concerns about septic system failures and saltwater intrusion—initially shared anecdotally in workshops—were later echoed by institutional actors who confirmed their growing salience in infrastructure and public health planning (See Table 1).

This convergence between community knowledge and institutional awareness aligns with Daniels and Walker's (2001) concept of Collaborative Learning, which highlights the importance of systems thinking, mutual learning, open dialogue, and constructive conflict resolution in support of adaptive decision-making. It further reflects Lemos et al.'s (2018) framing of *knowledge usability* as the central aim of co-production—emphasizing that knowledge becomes usable when it is not only credible and salient but also co-created through sustained relationships, iterative feedback, and contextual alignment with community needs. In this sense, the co-production process bridges technical expertise and lived experience, fostering actionable outcomes grounded in both scientific insight and local relevance.

Together, these participatory methods supported the ongoing calibration of scientific models with local experience and helped surface tensions between technical planning needs and lived realities. The iterative engagement strategy not only enriched the project's empirical base but also contributed to broader efforts to democratize climate adaptation. As Wyborn et al. (2019) and Fazey et al. (2014) argue, science must be co-shaped by communities if it is to advance meaningful and durable responses to complex social-environmental change.

Table 1: ESVA Resilience Priorities

Priorities identified by the Institutional Stakeholders	**Community Priority Questions Identified during the Workshop & CAC**	**Overview**
Water and Groundwater Management	How will septic systems, salinization of soils and groundwater be affected by land use change?	Stakeholders emphasized SLR's threat to infrastructure, such as the Chincoteague Causeway, and community displacement. Concerns included tourism, erosion, and uneven exposure.
Sea Level Rise and Coastal Resilience	How will sea level rise, flooding from storm surge, and intense rainfall affect ESVA communities and populations differently?	Interviewees raised concerns about septic system failures and saltwater intrusion, especially in Cape Charles and Chincoteague. Desalination is costly, and groundwater salinization threatens drinking water.
Agriculture and Land Use	What can our community do to mitigate and adapt to the effects of changes in land use and climate?	Changing rainfall patterns affect agriculture and water quality. Adaptive practices like regenerative agriculture were recommended.
Housing and Insurance Pressures	How can we create affordable retrofitting for homes and structures to withstand the increase of powerful storms and hurricanes?	Housing pressures include displacement due to short-term rentals, unaffordable insurance in flood-prone zones, and lack of affordable retrofitting options. These dynamics reflect broader vulnerabilities in coastal housing systems.
Public Health and Transportation Access	What can our community do to mitigate and adapt to the effects of changes in land use and climate?	Stakeholders advocated for mapping at-risk populations and improving rural healthcare access. Extreme heat, flooding, and lack of access to safe housing increase public health vulnerabilities were mentioned.
Community Engagement and Education	What practices would encourage and ensure input and collaboration from residents of underserved communities crucial to the planning process, and from local government officials vital to the implementation.	Stakeholders stressed the importance of youth education, decision-support tools, and inclusive processes. Initiatives aim to train residents in climate resilience.

The ESVA Climate Equity Project demonstrates how sustained engagement, shared governance, and co-production can lead to both more relevant science and more equitable adaptation outcomes. Both the workshops and interviews surfaced consistent climate resilience priorities across the community and institutional levels. The use of participatory methods to calibrate scientific models and scenario planning tools enhanced both the legitimacy and accuracy of project outputs. Rather than imposing static data products, the project adapted its design to community inputs—renaming the "Climate Equity Atlas" to the "Livability Tool," simplifying data visuals, and adding place-based filters. These changes underscore the value of participatory adaptation as not only an epistemic exercise but a procedural one that prioritizes responsiveness, relevance, and contextual sensitivity (Bremer & Meisch, 2017; Norström et al., 2020). Later workshops tested draft models, generating actionable suggestions such as clearer visuals, scenario planning, and localized data filters. Institutional interviews provided additional guidance on decision-making contexts and integration into existing planning workflows.

2. Trust-Building and Collective Action Outcomes

Trust-building emerged as both a goal and an outcome of the participatory process. In a region with a history of institutional disinvestment and marginalization, the opportunity for community members to express their perspectives and see them acknowledged served as a meaningful form of validation. The participatory nature of the project helped bridge historic divides between researchers and residents, government and underserved populations, and between institutions and lived experience. The project team's consistent responsiveness to community input—via workshops, interviews, and the advisory role of the Community Advisory Committee (CAC)—helped shift perceptions of research from extractive to collaborative.

Interviews with local leaders affirmed that consistent engagement, responsiveness to feedback, and the visible integration of community knowledge into the Livability Tool helped foster collective ownership. Trust, as defined by Leach and Sabatier (2005), is a necessary condition for collaborative capacity, particularly in politically fragmented or resource-constrained environments. These examples reflect the catalytic potential of inclusive engagement when paired with institutional alignment and sustained facilitation (Few et al., 2007; Wyborn et al., 2019).

Moreover, the project contributed to broader civic infrastructure by creating space for shared governance. The ESVA Climate Equity Project exemplifies the application of co-production in climate adaptation planning. Rather than positioning local stakeholders as passive recipients of expert knowledge, the project operationalized participatory methods through an iterative, multi-scalar design. This included the formation of a Community Advisory Committee (CAC), participatory workshops, and stakeholder interviews—all of which fed directly into the development of a Livability Tool that integrates both scientific data and community-defined priorities.

3. Barriers and Facilitators to Community Engagement

Despite success, the ESVA project encountered significant challenges associated with rural engagement: geographic isolation, transportation gaps, and uneven internet access. These barriers—identified by both community participants and institutional stakeholders—illustrate how infrastructure deficits can significantly undermine the effectiveness of otherwise well-designed participatory processes

The cross-cutting insights from workshops and interviews revealed systemic barriers to climate resilience, many rooted in long-standing inequities. For example, stakeholders noted how historical land use patterns left Black communities disproportionately exposed to flood risk, while limited transportation and digital connectivity constrain adaptation options for isolated residents. In response, the project's participatory model fostered pathways for both immediate input (e.g., through interactive workshop stations) and sustained dialogue (e.g., through advisory roles and interviews). Participants across both methods consistently emphasized the need for culturally relevant, economically accessible, and community-centred adaptation strategies.

Institutional silos posed another barrier, as many agencies struggled to coordinate across sectors (e.g., housing, health, water). However, the cross-sectoral design of the ESVA project—bringing together diverse actors in shared workshops and interviews—helped mitigate this fragmentation. As Chang and Moore (2017) note, enabling conditions for participation include institutional flexibility, relational trust, and distributed leadership, all of which were present in the CAC structure and workshop design.

Facilitators included strong local leadership, consistent CAC involvement, and the use of culturally resonant tools. By enabling participants to engage on their own terms—selecting stations, voting on priorities, and sharing experiences—the project lowered both cognitive and procedural barriers. This approach supported more inclusive engagement by fostering mutual understanding and shared meaning-making. Trench (2008) characterizes such interaction as symbolic of a participatory model of science communication—moving beyond unidirectional dissemination to emphasize reciprocal engagement, transparency, and co-constructed knowledge. By adopting this framework, the ESVA Climate Equity Project contributed to the ongoing evolution of public engagement practices, reinforcing the value of sustained dialogue and community agency in climate resilience planning.

4. Inclusive Participation Approaches for Underserved Populations

A central analytic contribution of the project is its emphasis on inclusion without dilution—ensuring broad participation while avoiding tokenism. The intentional recruitment of participants to overcome structural exclusions, as well as the CAC's diverse composition, helped counter structural exclusion.

Interviewees emphasized the importance of representation and access, noting that previously underrepresented groups now had a seat at the table—though challenges remain in sustaining participation over time. As Arnstein's (1969) classic "Ladder of Participation" model warns, engagement without real influence can breed cynicism. It also responds to the critique advanced by Schlosberg et al. (2017), who argue that adaptation must challenge the systemic marginalization embedded in planning processes themselves. The ESVA team addressed this by visibly integrating feedback into tool revisions and workshop themes.

Further, partnerships with educational institutions and local media outlets helped reduce language and accessibility barriers. The recognition that climate adaptation also requires investments in civic infrastructure—mentoring, training, and translation—demonstrates a mature understanding of participation as an ongoing process, not a one-time event (Tschakert et al., 2016; Wyborn et al., 2019).

Workshops employed a station-based open house format that invited reflection, discussion, and localized knowledge sharing. This format aligns with Edizel & Evans's emphasis on participatory mapping not just as a tool, but as a "relational and place-based practice" that strengthens community agency and makes structural inequalities visible. Similarly, Chang and Moore (2017) underscore the importance of relational trust, leadership, and institutional flexibility as enabling conditions for sustained participation—features that were embedded in the ESVA project design through continual feedback loops and collaborative decision-making.

Importantly, the project's participatory framework also addressed barriers to engagement, such as digital exclusion, transportation inequities, and language access. Rather than viewing participation as a one-off event, the project treated engagement as an ongoing process—responsive to community needs and grounded in transparency, accessibility, and respect. This echoes calls in the literature to move beyond technocratic, extractive engagement and toward dialogic, adaptive partnerships (Bremer & Meisch, 2017; Tschakert et al., 2016).

Conclusion

This paper demonstrates how participatory, place-based approaches can strengthen climate adaptation planning in rural, under-resourced coastal regions. Through community workshops, stakeholder interviews, and co-design of a decision-support tool, the project demonstrated that participatory methods are not only ethically necessary but also empirically effective in generating actionable, locally grounded adaptation strategies (Few et al., 2007; Norström et al., 2020). The integration of scientific models with community-defined priorities—facilitated through a Community Advisory Committee and iterative engagement—strengthened both the legitimacy and the usability of the Livability Tool. Beyond generating data, the project cultivated relationships, built institutional trust, and expanded the adaptive capacity of both community members and local institutions.

Policy Implications for Equitable Climate Adaptation

The ESVA experience underscores several key policy implications for equitable adaptation, particularly in underserved and rural communities:

- **Community-Driven Planning as Core Practice**: Meaningful engagement must go beyond consultation and involve co-decision-making structures. Embedding advisory committees or resident-led councils into governance processes increases legitimacy and aligns adaptation strategies with lived realities.
- **Data Democratization and Knowledge Co-Production**: Climate data must be transformed into usable formats that reflect local knowledge and priorities. Co-production frameworks support the design of tools that are both scientifically robust and socially relevant (van Kerkhoff & Lebel, 2015; Bremer & Meisch, 2017).
- **Cross-Sectoral and Multi-Level Coordination**: As seen in the ESVA case, siloed decision-making hinders effective adaptation. Adaptive governance requires cross-agency collaboration that bridges public health, housing, water, and transportation sectors (Adger et al., 2005; Armitage et al., 2011).
- **Civic Infrastructure as Climate Infrastructure**: Effective engagement depends on investments in civic infrastructure—such as translation services, facilitation training, and community organizing—not just in physical systems. Such support builds long-term capacity for adaptation (Chang & Moore, 2017).
- **Procedural and Distributive Fairness**: Without explicit mechanisms to address historical and structural marginalization, adaptation may reinforce existing inequities. Justice-oriented frameworks call for redistributive policies that prioritize frontline communities and expand access to adaptation funding and services (Schlosberg et al., 2017; Tschakert et al., 2016).

Lessons and Recommendations for Similar Coastal Communities

While climate risk is highly localized, the process lessons from the ESVA are widely applicable to other small, coastal communities grappling with sea level rise, water insecurity, and socio-economic vulnerability.

1. **Centre Community Priorities Early and Often**

Engage communities from the outset—not just to gather feedback, but to shape research questions, define engagement approaches, and guide outputs. This builds trust, legitimacy, and relevance (Reed et al., 2010). Tools like participatory mapping and story-based workshops can surface valuable localized knowledge that might otherwise be excluded (Edizel & Evans, 2017).

2. **Develop Long-Term Relationships, Not One-Off Consultations**

Avoid one-off or superficial engagement efforts. Build long-term relationships through advisory committees, recurring workshops, and feedback loops that allow communities to see how their input shapes outcomes. This fosters collective ownership and supports sustained civic capacity (Few et al., 2007).

3. **Address Structural Barriers to Participation**

Transportation challenges, limited internet access, language barriers, and institutional mistrust often block full participation. Engagement must be designed with these barriers in mind. Culturally resonant, locally hosted, and multi-lingual strategies increase accessibility (Chang & Moore, 2017; Tschakert et al., 2013).

4. **Embed Cross-Sector Collaboration**

Create engagement formats that convene stakeholders from multiple sectors—health, housing, environment, and education—together with residents. This promotes systemic understanding and supports more integrated, durable planning outcomes (Armitage et al., 2011).

5. **Treat Engagement as a Form of Adaptation Infrastructure**

Just as coastal communities invest in seawalls and drainage systems, they must also invest in the infrastructure of inclusion: facilitation, capacity building, digital access, and leadership development. These investments improve adaptive capacity and resilience over time (Lemos et al., 2018; Norström et al., 2020).

In summary, just and effective climate adaptation develops not only from scientific modelling or hazard mitigation, but also from the shared labour of co-producing knowledge, redistributing voice, and embedding equity in institutional practice. For other coastal communities seeking to navigate the complex terrain of climate change, this article offers a roadmap grounded in humility, collaboration, and the transformative potential of local leadership.

Abstract
Despite growing global interest in energy poverty and gender issues, limited research explores their intersection from a female perspective. This study examines the feminization of energy poverty in China, contrasting urban and rural experiences. Drawing on data from the China Family Panel Studies and applying mixed methods, the research finds that rural women face significantly higher levels of energy poverty than their urban counterparts. This disparity is linked to traditional Confucian gender norms, limited financial autonomy, and restricted access to education. Offering a feminist lens, the study enhances understanding of gendered energy disparities in China and proposes targeted strategies to support a more equitable and sustainable energy transition.

Keywords: Energy poverty; Gender bias; Urban-rural disparity; Confucian culture; China

1. Introduction

Promoting gender equality and access to affordable, reliable, sustainable and modern energy are two pivotal components of the Sustainable Development Goals (SDGs) outlined by the United Nations. Specifically, SDG7 calls for reducing dependence on biomass materials (carbon-based fuel like wood, leaves, straw, cow dung, coal, etc.) as the main source of cooking fuel. The progress toward achieving SDG7 has, however, been slow. As of 2023, around 2.3 billion households worldwide continue to suffer from energy poverty, lacking access to clean and efficient cooking solutions (International Energy Agency et al., 2023). Energy poverty is considered to have a woman's face (Sánchez et al., 2020). Earlier studies have revealed that the use of biomass in cooking imposes time, health, and environmental costs on households (World Economic Forum, 2022), with such costs often falling on women due to their traditional roles. For instance, Acheampong et al (2023) noted that using biomass fuels has disproportionately impacted women as they generally take on the more significant burden of household chores, including cooking and fuel collection. Moreover, energy poverty issues also affect women's well-being, as acquiring biomass fuels is time-consuming and often leads to indoor air pollution, posing significant health risks (Opoku, Kufuor, & Manu, 2021). In fact, the World Economic Forum (2021) has estimated that women are likely to spend close to 20 hours per week searching and collecting biomass fuels, whereas cooking with these fuels can take up to 4 hours per day. Furthermore, geographical inequalities in energy poverty further intensify these gendered burdens, particularly the urban-rural disparity. Research by Moniruzzaman and Day (2020) has underscored that rural woman, particularly in developing countries, face significant barriers to accessing clean and affordable energy, often due to limited infrastructure and low-income levels. These gendered responsibilities are compounded by the fact that rural communities, in comparison to urban areas, suffer from more frequent energy access disruptions, inefficient energy systems, and higher reliance on polluting energy sources (Revolve, n.d.). This phenomenon is rooted in the urban bias theory where social amenities provision and resource allocation (including energy access) disproportionately favors urban cities relative to rural communities. Moreover, rural women often have fewer opportunities for advocacy or policy engagement, leaving them more vulnerable to the negative impacts of energy poverty (Moniruzzaman & Day, 2020). As such, the urban-rural disparity in energy access not only deepens existing gender inequalities but also hinders progress toward energy justice, sustainable development, and human well-being (Scheier & Kittner, 2022).

China, as both the biggest developing economy and the world's largest carbon emitter, has committed to reducing energy poverty (Luan, Zou, & Huang, 2023). To address this issue, the Chinese government has launched a series of policy measures, such as the 'Household Biogas Project,' 'Photovoltaic Projects for Poverty Alleviation,' and 'Coal-to-electricity Project' (Shen et al., 2020). By 2013, China has achieved 100% access to electricity (World Bank, 2020), and the electricity consumption per capita has already surpassed the average level of the country's upper middle income (National Energy Administration, 2024). However, China is still facing serious challenges concerning energy accessibility, affordability, and service availability. According to Zhang et al. (2019), approximately 48.98% of Chinese households are still experiencing energy poverty, with over 400 million Chinese individuals relying

on traditional biomass and coal for cooking. The challenge is even more serious in terms of energy disparity. More than 75% of rural households primarily used coal and firewood as fuel sources (i.e., 17.1% and 58.6% with coal and biomass respectively), while 8.2% and 36.1% of households in urban and township areas used solid fuels for cooking (XX). Additionally, households using clean fuels accounted for 62.7% of the total townships, while the proportion was only 23.2% for rural areas. These facts indicate that the urban-rural disparity in energy poverty is still a pressing issue in China, which is one of the focal issues of this study.

Undoubtedly, gender inequality in the context of energy poverty is also a critical issue in China. This issue is particularly associated with the Chinese Confucian culture (Li, Leng, Hu, Cao, & Guo, 2023), which has long emphasized traditional gender roles and hierarchical social structures. As the core of traditional Chinese culture, Confucianism historically positions men as the primary decision-makers within the household, while women are largely restricted to domestic responsibilities (e.g., household chores and childcare). This cultural framework continues to influence contemporary societal norms, limiting women's access to energy resources and involvement in energy-related decisions, particularly in rural areas (Johnson et al., 2020). As such, households influenced by Confucian culture tend to exhibit gender bias and are more likely to experience energy poverty. Therefore, promoting gender equality in energy poverty requires not only an economic solution but also a deep understanding of the cultural norms that shaped gendered access to energy.

Despite the importance of gender inequality and geographical disparity in energy poverty, few studies have accounted for the geographical gender disparity and cultural norms' influence on women experience of energy poverty. We contend that such consideration is critical in ascertaining the fuller impact of energy poverty and to devise robust economic and social measures in countering the plights of women. Thus, the two main research gaps we seek to address include the following. Firstly, Gender Perspective: the general situation of women's vulnerability to energy poverty in China is still unclear, particularly the disparity in urban and rural area. Secondly, culture perspective, although the existing literature has explored the impact of culture on energy poverty, it has covered a wide range of cultures and has rarely focused on a country or region-specific culture.

Therefore, the aim of this study is to explore how energy poverty affects women in the Chinese context, with a specific focus on the disparities between urban and rural areas. It seeks to understand the risks women face in these settings and to examine how cultural norms (i.e. Confucian culture) shape women's experiences of energy poverty. By addressing these questions, this study may provide a nuanced understanding of the intersection between gender, culture, and energy poverty, contributing to more equitable energy policies and practices in China. This study contributes to the following aspects. First, this paper integrates feminization and energy poverty into a unified research framework. Accordingly, this paper can better analyze the factors of household energy poverty from the perspective of female. To the best of current knowledge, few studies have explored the situation regarding the feminization of energy poverty. Second, the possible factors (e.g., age, education level, financial status) concerning the feminization of energy poverty are captured. Third, the feminist approach can enhance our co. Therefore, this study adopts a feminist perspective while considering energy systems will establish the structure for creating a fair and equitable transformation in the energy sector. Understanding gender in energy concerns may help create alternatives to a more equitable and sustainable energy framework. The remainder of this study proceeds as follows. **Section 2** presents the background of this research, which includes a review of the relevant literature and the theoretical foundation guiding the study. **Section 3** introduces the data sources and empirical methodology. **Section 4** shows and discusses the empirical results of this study. **Section 5** offers further discussion based on qualitative data. **Section 6** concludes and provides policy implications.

2. Literature Review

2.1. Feminization of Energy Poverty

Research on energy poverty and gender dynamics, particularly in the Global South (Listo, 2018; Petrova & Simcock, 2019), highlights the specific vulnerabilities faced by women. While existing studies have recognized the feminization of energy poverty (Bartiaux et al., 2018), comprehensive evaluations remain limited, especially in Asian contexts. Wilson (2018) reframes feminization not as a purely feminist concept, but as a promising analytical lens to understand how gender shapes energy poverty, a perspective especially relevant in countries like China. The concept of feminization of energy poverty aligns with Chant's (1998, 2006, 2013) broader theory of feminization of poverty, which underscores women's lower income levels, their disproportionate burden as household heads, and their greater exposure to long-term poverty. These patterns are echoed in studies across both developing

(Sovacool et al., 2013; Winther et al., 2018) and developed countries (Fraune, 2015), reinforcing the need for gender-sensitive energy policies that prioritize care, health, and equity (Wilson, 2018; Bell et al., 2020).

Evidence shows that rural women are particularly affected. Cecelski (1995) and Bhattasali (2005) document the physical toll of traditional energy use, with women often walking long distances to collect firewood and facing severe indoor air pollution—comparable to inhaling the smoke of 20 cigarettes daily. These conditions underscore the urgency of integrating feminist perspectives in energy transition strategies, especially in rapidly developing nations like China.

2.2. Energy Poverty and Regional Disparities in China

Energy poverty in China exhibits pronounced disparities across urban-rural divides and regional geographies, with rural households and those in central and western regions disproportionately affected (Zhang et al., 2019; Cai et al., 2021; Zhao et al., 2022). For example, while 15% of urban families rely on solid fuels for cooking, the figure rises to 52% in rural areas. Moreover, recent studies underscore the growing regional divide in energy poverty levels, necessitating a more nuanced understanding of spatial variations (Lu et al., 2022; Wan et al., 2024).

Although much of the existing literature focuses on rural energy poverty, less attention has been given to identifying vulnerable groups across both urban and rural contexts (Zhang et al., 2023). This gap is particularly salient in light of China's unique geographical, climatic, and resource endowment differences, which shape its energy poverty landscape in ways distinct from other countries (Wang et al., 2017; Lin & Wang, 2020).

Cultural factors—especially those rooted in Confucian traditions—intersect with socioeconomic dimensions to exacerbate gendered energy poverty. Confucian norms, which historically restrict women's autonomy through principles such as the "three submissives" and "four virtues," limit female participation in decision-making, financial independence, and educational access (Tsai, 2006; Li et al., 2023). These constraints are particularly pronounced in rural areas, where Confucian influence is stronger, and women often bear greater childcare burdens, further limiting their income-generating opportunities (Mijnheer, 2023).

While urban women are not immune to gender biases, their relatively better access to education and employment enhances their economic agency and household decision-making power. Nonetheless, the broader link between Confucianism and energy poverty in China remains underexplored, representing a critical gap in the literature on culturally embedded energy inequalities (Chaudhry & Shafiullah, 2021).

2.3. Social Role Theory and Confucian Cultural Norms

This study employs social role theory, integrated with Confucian cultural norms, to examine how entrenched gender roles contribute to the feminization of energy poverty in China. Social role theory explains how gendered behaviors are shaped and sustained, particularly in rural households where Confucian values prevail (Tang et al., 2020). These values promote hierarchical family structures and the "three submissions" principle, which constrain women's agency and reinforce their economic dependency.

Confucianism assigns women primary responsibility for domestic tasks such as cooking and heating—activities that often rely on traditional, inefficient energy sources (Tsai, 2006). In rural areas, where modern energy access is limited and women have lower levels of education and financial autonomy, their exclusion from household energy decisions further increases their vulnerability to energy poverty.

Framing this within the feminization of energy poverty, the study highlights how the gendered division of labor and restricted decision-making power intensify women's energy-related burdens. By embedding Confucian values into the analysis, the framework reveals how cultural norms shape not only gender roles but also societal expectations around women's involvement in energy management. While urban women benefit from greater autonomy due to improved access to education and employment, rural women remain more constrained by tradition.

This combined framework—linking social role theory, Confucian culture, and feminization of energy poverty—offers a culturally grounded explanation for why rural women in China face disproportionate energy hardships. It supports the study's broader aim to identify socio-cultural drivers of energy poverty and inform policy interventions that promote gender equity and inclusive energy access.

3. Data and Methodology

3.1. Data sources

We collected data from two sources: a nationwide survey and in-depth interviews. The nationwide survey utilized in this study is the China Family Panel Studies (CFPS). CFPS is a nationally representative annual longitudinal survey that examines Chinese communities, families, and individuals, with a focus on the economic conditions and well-being of the population. The data covers economic activities, education outcomes, family dynamics and relationships, migration, and health for 25 provinces in mainland China (exclude Xinjiang, Tibet, Inner Mongolia, Ningxia, and Qinghai), which represent 95% of China's population. CFPS has been widely used to explore energy poverty in China, since it collects information on household fuel usage and energy expenditures related to heating, cooking, and other purposes (Li et al., 2023; Zhang, D., Li, J., & Han, P., 2019). For this study, we follow in the spirit of Li et al., (2023) and rely on the 2018 wave which is the most recent to construct our cross-sectional energy usage and gender disparities variables. The choice of 2018 wave is due to data availability and to align with our research focus (i.e. gender disparities in energy poverty), only data pertaining to women were retained for the analysis. Following the data filtering process, we ultimately employed a sample of 18,452 female-headed households.

In addition to the survey, we conducted a total of 43 in-depth, semi-structured, face-to-face interviews in Jiangsu, Zhejiang, and Shanghai between January and April 2024. The interview respondents include 20 women; 20 husbands of these women, and 3 related experts. Each interview lasted 60-100 minutes. We recorded and transcribed all the interviews. Data from the interviews were qualitatively coded using Atlas.ti, where we developed a coding framework and coded each interview.

The purpose of these interviews is to extend our quantitative findings by providing a more holistic understanding of energy poverty, considering the influence of socio-cultural factors that may not have surfaced in the statistical analysis but are crucial to addressing the issue comprehensively. This is indeed, lacking in the extant literature. We acknowledge that while these interviews may not be representative of the entire population of Chinese women, achieving representation was not our main goal. Instead, we hope to draw insight from this sample, which will be critical for comprehensive policy action towards tackling the gendered impact of energy poverty issues among rural women in China.

3.2. Variable selection

Table 1 outlines the definitions of the key variables used in this study. The dependent variable is energy poverty. Existing studies typically characterize household energy poverty based on energy accessibility and affordability (Li et al., 2023; Zhang et al., 2019; Llorca, Rodríguez-Álvarez, & Jamasb, 2020; Jayasinghe, Selvanathan, & Selvanathan, 2021). To effectively assess household energy poverty, we develop the following three proxy variables by integrating the dimensions of accessibility and affordability in the spirit of Zhang et al., (2019); Lloca et al., (2020); and Jayasinghe et al., (2021).

Energy accessibility is denoted as *EP1*, which reflects the type of fuel used for cooking by the respondents. Following Zhang et al. (2019), if a household primarily relies on solid fuels, such as firewood, coal, or charcoal, for cooking, it indicates limited access to modern energy sources. **Energy affordability** is measured as *EP2*, which captures the proportion of household income spent on energy. A commonly used threshold, known as the "Ten Percent Rule", categorizes households as energy-poor if their energy expenditure exceeds 10% of their total income (Zhang et al. (2019; Boardman, 1991). However, Hills (2011, 2012) argued that this rule could misclassify affluent households with high energy consumption as energy poor. To address this, Okushima (2016) proposed the adjusted Ten Percent Rule (aTPR), applying the 10% threshold to households within the bottom 30% of the income distribution. Another approach, known as After Energy Cost Poverty (AECP), defines energy poverty based on the household's remaining income after subtracting energy expenses. If the remaining income is less than 60% of the sample median, the household is considered to lack energy affordability (Hills, 2011). In this study, we adopt the AECP method to define energy affordability (*EP2*). Given that energy poverty in China reflects characteristics of

both developing countries (dependence on solid fuels) and developed countries (energy burden) (Wang and Lin, 2022), this study, following Zhang et al. (2019) and Luan et al. (2023), constructs a composite index (*EP*). We employ an equal-weight method to construct a multidimensional index by combining accessibility and affordability. Specifically, if a household has no issue with energy accessibility or affordability, *EP* is assigned a value of 1. If there is energy poverty in either aspect, *EP* is assigned a value of 2. *EP* is assigned a value of 3 for households experiencing severe energy poverty, defined as deficiencies in both energy accessibility and affordability.

Our independent variable captures the female population residing in both rural and urban locations, with the variable being represented as a dummy variable. The variable *urban_ruralfemale* is assigned a value of 1 if the female is in urban regions, and a value of 0 if she is not. Specifically, based on the person's identification and the identification of their respective families, the person was matched with the family, retaining only the data pertaining to females. For the control variables, we select age, schooling years, or education, which directly affect economic opportunities and knowledge of energy poverty following Wang and Lin, 2022; Luan et al., 2023). We also control for other socio-economic and demographic factors including personal income, total household assets, marital status and family harmony based on the literature (Dubois and Meier, 2016; Deller and Waddams, 2018; Llorca et al., 2020).

Table 1 Variable and their definitions

Variables		Label	Definition
Energy Poverty	Accessibility	EP1	Solid fuels (such as firewood and coal) for cooking, EP1 =1, others (such as gas/liquid, natural gas, solar energy, electricity) for cooking, EP1= 0
	Affordability	EP2	If remaining income after energy costs is < 60% of median income, EP2 = 1, others EP2 = 0
	Multidimensional	EP	EP = 1 if EP1 = 0 and EP2 = 0; EP = 2 if EP1 =1 or EP2 =1; EP = 3 if EP1 =1 and EP2 = 1
Locations of Female Householders		Urban_ruralfemale	1 = urban females, 0 = rural females
Age		Age	The age of the female householders. (years)
Education		Edu	The schooling years of the female householders. (years)
Personal Income		lnFincome	The individual's annual income generated from all personal sources, including wages, business profits, and other financial earnings. (in logs)
Total Asset of the Households		lnTotal_asset	The cumulative value of all assets owned by the households (real estate, vehicles, savings, investments, and other property). (in logs)
The Marital Status of the females		Marital_Status	The marital status of females, such as single, married, divorced, or widowed, rating from 1 to 5.
The Happiness of the females		Family_Harmony	The subjective happiness or harmony experienced by females within their family or household environment, rating from 1 to 5.

3.3. Descriptive statistics

The descriptive statistics for all variables are presented in Table 2 with a total of 17,004 households in our cross-sectional full sample. The average of EP (multidimensional Energy poverty proxy) is 0.278 with a standard deviation of 0.357, suggesting clear variability in the degree of energy poverty in the sample. EP1 (proxy for energy accessibility) and EP2 (proxy for energy affordability) show an average of 0.282 and 0.274 respectively with standard deviation of 0.450 for EP1 and 0.446 for EP2. These indicates that approximately 28.2% of households still rely on firewood or charcoal as cooking fuel mainly reflecting household energy accessibility concerns while at the same time, 27.4% of households face severe energy burdens, with their energy expenditures exceeding 10% of household income, reflecting energy affordability issues. Furthermore, approximately 49.1% of women live in

urban areas, while the rest reside in rural areas. This ratio is close to 1:1, indicating that the distribution of female samples in urban and rural areas is relatively balanced for the analysis. Given the dominant role of women in household energy use, this urban-rural disparity may have a significant impact on the two dimension of energy poverty. The average age of female householders is approximately 47.7 years, with a mean education level of 8.6 years. In terms of economic and social characteristics, the average personal income (fincome) is 10.955 with a substantial standard deviation, reflecting wide income disparities across the sample. Total household assets (total_asset) average 12.679 but exhibit high variability indicating large differences in household wealth levels. Marital status (Marital_Status) has an average value of 2.171, suggesting that a majority are married or in stable partnerships. Family harmony (Family_Harmony) has an average score of 4.657, showing relatively high levels of perceived family well-being among female respondents.

Table 2 Summary statistics

Variables	Samples	Mean	Min	Max	SD
EP	17004	0.278	0.000	1.000	0.357
EP1	17004	0.282	0.000	1.000	0.450
EP2	17004	0.274	0.000	1.000	0.446
Urban_ruralfemale	17004	0.491	0.000	1.000	0.500
Age	17004	47.673	10.000	100.000	18.039
Edu	7837	8.565	0.000	22.000	5.045
Age2	17004	2598.123	100.000	10000.000	1801.025
Edu2	7837	98.813	0.000	484.000	79.154
Ln(fincome)	17004	10.955	0.000	16.030	1.105
Ln(total_asset)	15712	12.679	0.000	17.737	1.392
Marital_Status	14989	2.171	1.000	5.000	0.934
Family_Harmony	14989	4.657	1.000	5.000	0.690

3.4. Identification strategies

This study aims to examine the association between feminization and household energy poverty and to further explore the internal mechanisms. Our empirical model can be expressed as follow:

$$\log\left(\frac{P(EP \le j)}{1 - P(EP \le j)}\right) = \theta_j - (\beta_1 urban_ruralfemale + \gamma control_variables) + \varepsilon$$

where EP is the explained variable, energy poverty; the explanatory variable *urban_ruralfemale* represents the location of residence of women, with urban-rural division being the part of the focus of this study. According to the social role theory of gender division of labor, women usually bear the main responsibility for household energy use, especially in the selection of cooking fuels. Therefore, the differences in the identity of urban and rural women may significantly affect the level of energy poverty in their families.

4. Empirical results

4.1. Correlation Analysis

The correlation analysis is shown in **Table 3**. The correlation coefficient between energy poverty (EP) and the urban-rural women variable (*urban_ruralfemale*) is -0.394, indicating a moderate negative relationship. This suggests that females living in rural areas are more likely to experience higher incidences of energy poverty compared to their urban counterparts. This preliminary finding aligns with Listo (2018) and Dutta and Sahu (2024) which have documented that rural populations, particularly women, tend to face higher energy poverty burdens than their urban counterparts due to limited access to modern cooking energy sources. We found the correlation coefficient between energy poverty and age and its squared term (age^2) to be close to zero (0.072), which indicates a weak linear relationship between age and energy poverty. This suggests that age alone may not be a significant predictor of energy poverty, and the role of age might be more complex, requiring the exploration of nonlinear or interaction effects to fully understand its impact. A significant negative correlation is found between energy

poverty and years of schooling (Edu), with a coefficient of -0.346. This finding indicates that individuals with lower levels of education are more likely to experience energy poverty, implying that education can play an important role in alleviating energy deprivation. Furthermore, the correlation between the squared term of education (Edu^2) and energy poverty is identical, which implies that the relationship between education and energy poverty may be non-linear, where increases in education levels may progressively reduce the risk of energy poverty. The positive correlation between the urban-rural women variable and education level (0.322) suggests that individuals in urban areas generally attain higher levels of education. This result is consistent with patterns in socio-economic development, where urban residents typically have greater access to educational resources and opportunities (Li et al., 2023). Additionally, the negative correlation between age and education level (-0.519) indicates that older individuals tend to have lower levels of education. This generational difference likely reflects varying access to education, with older cohorts having had fewer opportunities compared to younger generations, who benefit from improved educational systems. Income-related variables also show strong negative correlations with energy poverty: personal income (fincome) has a coefficient of -0.636, while total household assets (total_asset) show a coefficient of -0.494. These results indicate that households with higher incomes and assets are less likely to experience energy poverty, underscoring the critical role of financial resources in securing energy access (Bersisa, 2019). Lastly, the variables Marital_Status and Family_Harmony exhibit minimal correlation with energy poverty, with coefficients close to zero (-0.000 and -0.010, respectively). This suggests that these social factors may not have a direct impact on energy poverty as previously supposed, although they may still contribute indirectly through interactions with other socio-economic factors.

Overall, the correlation analysis reveals that urban-rural location, education, and economic resources are important variables related to energy poverty. Education, in particular, appears to be a key factor, as it is negatively correlated with energy poverty and positively associated with urban residency, which generally facilitates better energy access. While age shows a weak direct relationship, its interaction with education may provide insights into generational differences in energy poverty. These findings lay the groundwork for subsequent empirical analysis, where we employed an ordered logistic regression model to further investigate the specific impacts of these variables and their predictive power in explaining energy poverty.

Table 3 Correlation Analysis -- Spearman's rank correlation coefficients

4.2. Baseline results

Table 4 presents the benchmark results based on the ordered logistic regression models, which progressively incorporate additional control variables to analyze their influence on energy poverty (EP). Column (1) includes only the main independent variable, urban_ruralfemale, while Columns (2) and (3) introduce demographic and socioeconomic variables to progressively adjust the model. In all models, the coefficients for the urban-rural female variable remain negative, and statistically significant at the 1% level ($p < 0.001$), with values of -1.6526,

-1.3534, and -1.2098 in columns (1), (2), and (3) respectively. This finding indicates that women residing in rural areas experience significantly higher levels of energy poverty compared to the urban groups. These results reinforce the previous correlation analysis, highlighting the profound impact of urban-rural disparities on energy poverty. To better visualize the impact of the urban-rural female variable on energy poverty, Figure 1 presents the predictive margins with 95% confidence intervals for the probabilities of experiencing different levels of energy poverty. As shown in the figure, the probability of avoiding energy poverty (red line) increases significantly while the probabilities of experiencing moderate (blue line) or severe energy poverty (green line) are substantially higher for rural females. This further supports our regression results, showing that women living in urban areas are less likely to face energy poverty.

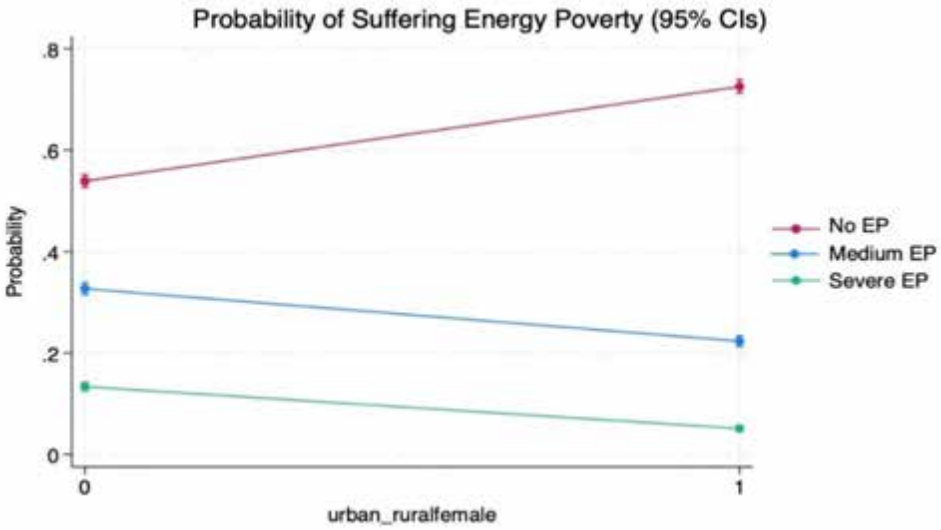

Fig.1 Marginalized plot for energy poverty and female in urban and rural areas

In column (2) we introduce age and education variables, along with their squared terms, to account for potential nonlinear effects. The coefficient for age is -0.0703 and statistically significant ($p < 0.001$), while its squared term (age^2) shows positive and statistically significant coefficient of 0.0006 ($p < 0.001$), indicating existence of a nonlinear relationship. This suggests that while energy poverty initially decreases with age, it begins to increase again as individuals grow older, potentially reflecting greater energy needs or financial constraints among older populations. Unlike most of the extant studies which found a more linear or straightforward impact of age on energy poverty, our results have shown that an inverse U-shape relationship might exist when one accounts for older age groups in energy poverty studies. Thus, our findings suggest a complex relationship between age and energy poverty, warranting further exploration of interaction effects or segmentation by age groups. Next, the Education level (Edu) also demonstrates a strong, and statistically significant negative association with energy poverty, with coefficients of -0.1546 and -0.1348 in columns (2) and (3) respectively ($p < 0.001$). This relationship suggests that higher education levels contribute significantly to reducing energy poverty, likely due to better economic opportunities or return on education and access to energy-efficient resources among educated individuals. Interestingly, the squared term for education (Edu^2) shifts from insignificant in column (2) to positive and significant (0.0027, $p < 0.05$) in column (3), indicating a more complex, possibly diminishing effect of education at very high levels. In column (3), we account for additional economic and social variables such as personal income (fincome) and total household assets (total_asset). Both variables show highly significant negative coefficients (-0.0000, $p < 0.001$), further affirming that economic stability and financial resources play a crucial role in mitigating energy poverty. More speficially, the results imply that households with higher incomes and assets are less likely to experience energy poverty, highlighting the importance of economic capacity in ensuring energy access and affordability. The variables Marital_Status and Family_Harmony do not show significant associations with energy poverty. This possibly suggests that, unlike economic factors, social dynamics may have a less direct impact on energy poverty.

The cut-off values (cut1 and cut2) provide thresholds for categorizing the levels of energy poverty. Each model iteration shows improvements in Pseudo R-squared, values, indicating a better fit as more control variables are

included. These improvements in model fit demonstrate that the inclusion of demographic and socioeconomic variables such as age, education, income, and assets significantly enhance the model's ability to capture variations in energy poverty. This progressive enhancement of fit metrics underscores the importance of a comprehensive set of control variables in accurately modeling the determinants of energy poverty among households. Overall, our baseline results emphasize the significant influence of urban-rural disparities, age, education, and financial resources on energy poverty. In particular, the complex relationships involving age and education suggest that addressing energy poverty may require targeted interventions based on age-demographic and economic characteristics.

Note: This table shows the results of the baseline regression using an ordered logistic model to examine the determinants of energy poverty (EP) among households. Column (1) of this table shows the results of the first regression model, which only contains the independent variable urban_ruralfemale. Column (2) expands the model by incorporating demographic variables, specifically age and education, along with their squared terms to capture potential nonlinear effects. Column (3) further extends the model with additional economic and social control variables, including personal income, total assets, marital status, and family harmony. The coefficients for each variable represent their estimated impact on energy poverty, with negative coefficients indicating a reduction in the likelihood of experiencing energy poverty. The **Cut1** and **Cut2** are the threshold parameters for the ordered logit model. They separate the different categories of energy poverty (e.g., no energy poverty, moderate energy poverty, and severe energy poverty).

4.3. Robustness checks

To enhance the reliability of the empirical results, the robustness of the estimation results given below. It employs the ordered probit (***oprobit***) model as an alternative to the baseline ordered logistic (***ologit***) model. While both models are appropriate for analyzing energy poverty problem, they differ in their underlying statistical assumptions. Specifically, the ordered logistic model assumes a logistic distribution for the error term, whereas the ordered probit model assumes a standard normal distribution. These differences in distributional assumptions allow for a thorough test of the stability of the results. The findings of this robustness analysis are presented in **Table 5**.

The results indicate that the primary conclusions remain consistent across the two model specifications. The independent variable urban_ruralfemale retains its negative and statistically significant effect on EP, although the magnitude of the coefficient is smaller under the ordered probit model. The demographic control variables, including age and education level, exhibit similar results across the two models. It also suggests that elder and less educated female householders are more likely to experience energy poverty, though this effect could diminish at older ages as indicated by the positive coefficient of the quadratic term (age2, education2). Plus, the control variables related to economic state remain highly significant and negative in both models, highlighting the importance of household financial capacity in mitigating energy poverty problem. On the other hand, those related to social well-being continue to lack statistical significance, potentially suggesting limited influence on energy poverty, which is left to be further discussed in the next qualitative analysis section.

Regarding the fitness of the model, the R^2 values and log-likelihood statistics demonstrate comparable levels of explanatory power across the two different models. Slight improvements in the R2 values in the ordered probit model suggest a marginally better fit when using a normal distribution assumption. Additionally, the threshold parameters (Cut1 and Cut2) in the ordered probit model differ from those in the baseline model, which is consistent with the theoretical differences in the error term distributions. However, these differences do not alter the substantive interpretation of the results.

log-likelihood	-14689.5192	-5909.4182	-4322.6643

Standard errors in parentheses * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

Note: This table shows the results of the robustness analysis using an ordered probit model to examine the determinants of energy poverty (EP) among households. Column (1) of this table shows the results of the simplest model, which only includes the independent variable *urban_ruralfemale*. Column (2) expands the analysis by incorporating demographic variables, specifically age and education, along with their squared terms to capture potential nonlinear effects. Column (3) further extends the model with additional economic and social control variables, including personal income, total assets, marital status, and family harmony. The coefficients for each variable represent their estimated impact on energy poverty, with negative coefficients indicating a reduction in the likelihood of experiencing energy poverty.

The **Cut1** and **Cut2** are the threshold parameters for the ordered probit model, separating the different categories of energy poverty (e.g., no energy poverty, moderate energy poverty, and severe energy poverty). The pseudo R-squared values and log-likelihood statistics indicate improved model fit as additional variables are included across the results, which helps to confirm the robustness of the results.

In conclusion, the robustness analysis confirms that the key findings of the baseline ordered logistic model are not sensitive to the choice of model specification. The consistent direction, significance, and interpretation of the coefficients across both models provide strong evidence for the stability and reliability of the conclusions regarding the determinants of energy poverty. These results enhance the credibility of the baseline analysis and further support the role of demographic and economic factors in shaping household energy poverty outcomes.

5. Results and discussions

The quantitative analysis reveals that factors such as urban-rural residency, age, education, and financial resources significantly influence energy poverty among female-headed households, while socio-cultural variables like marital status and family harmony show no direct statistical impact. However, these factors may still shape energy-related behaviors and coping strategies in indirect ways. To capture these nuanced dynamics, the following qualitative analysis explores how cultural norms, household roles, and societal expectations affect women's experiences of energy poverty, offering a more holistic understanding that complements the quantitative findings.

5.1. Limited financial independency

Interviews reveal a consistent perception among participants: women experience and cope with energy poverty differently from men. This disparity is largely attributed to the gendered division of labor, where women disproportionately bear responsibility for childcare and domestic work. As a result, they spend more time at home and have reduced access to income-generating opportunities, increasing their exposure to energy poverty (Mijnheer, 2023). One respondent observed: "*Women persist in shouldering the primary obligation of caring for their kids... while their husbands chase careers.*" (Female respondent 03). These dynamics are further exacerbated in rural areas, where traditional Confucian cultural norms remain deeply entrenched. Principles such as the "three submissives" and "four virtues" restrict women's autonomy in household decision-making, especially concerning energy use (Li et al., 2023). Household energy decisions, particularly those related to fuel choices and appliance purchases, are often made solely by men. "*When I try to talk to my husband about our enhanced energy requirements... he reprimands me.*" (Female respondent 07) This reflects the broader gender hierarchy embedded in Confucian family structures (Van, 2019).

By contrast, urban households—where Confucian influence has diminished due to socioeconomic development and shifting gender norms—offer women greater participation in household energy management. Women in these contexts often have access to financial resources and information, facilitating more equitable decision-making. As one urban participant noted: "*When I talk to my husband... he listens and tries to understand... we could discuss together how to make our home more energy efficient.*" (Female respondent 11)

Rural women also reported significant health concerns related to traditional fuels, such as smoke inhalation and heat exposure. Many advocated for adopting safer alternatives, like electric rice cookers, which improve efficiency and reduce hazards. However, resistance from male family members—grounded in perceptions of tradition, cost-effectiveness, and skepticism toward change—remains a barrier. "*Smoke poses no issue... our mums used firewood... Why is she unable to do it?*" (Male respondent 08). Furthermore, intra-household dynamics, particularly the influence of in-laws, pose additional challenges. Women often lack support from their husbands, who prioritize familial harmony and parental authority over spousal concerns. "*Whenever I mention replacing the gas range... he ends up resenting me... he always prioritises making [his mother] happy.*" (Female respondent 02) Nevertheless, the study also finds evidence of transformation in urban areas. Women who contribute financially to the household tend to wield greater influence over energy decisions, and younger husbands are more open to shared decision-making, regardless of their wives' income status. These findings suggest that shifting gender norms, financial autonomy, and intergenerational change are gradually enhancing women's agency in energy management, offering a pathway toward more equitable outcomes in energy access and use.

5.2. Limited education opportunities

Confucian cultural norms have historically constrained women's access to education, particularly in rural China,

due to deeply rooted beliefs about women's intellectual inferiority (Tsai, 2006). These norms reinforced traditional gender roles by relegating women to the domestic sphere and discouraging formal education, resulting in long-lasting effects that continue to shape gendered vulnerabilities to energy poverty. Less-educated rural women often lack awareness of energy-efficient technologies and available support systems, leaving them particularly exposed to energy-related hardships. The insularity of rural communities further exacerbates these challenges. Many women remain unaware of external assistance mechanisms due to limited exposure and economic barriers such as consultation fees or transportation costs. These constraints discourage help-seeking behavior, reinforcing passivity in the face of energy deprivation. As one expert noted, "*I am aware of a collective of individuals who, due to feelings of shame or apprehension about incurring supplementary expenses, are reluctant to be linked with the issue of energy poverty... leaving us unable to assist them.*" (Expert 03)

Education plays a pivotal role in enabling women to adopt modern energy solutions. Studies show that women with limited educational backgrounds are less inclined to utilize technologies such as solar water heaters, improved cooking stoves, LED bulbs, or water purification systems—despite their proven effectiveness in reducing energy poverty (Paudel et al., 2018; Belmin et al., 2022). "*When I first heard about solar water heaters, I thought they were too complicated to maintain... why change now?*" (Female respondent 06)

The continued influence of Confucian gender roles further delays the adoption of modern views, particularly in rural areas. Li et al. (2023) found that less-educated female householders are more likely to retain traditional energy practices, reinforcing their energy vulnerability. National survey data supports this trend: between 2010 and 2016, use of modern cooking energy increased modestly in rural households (from 1.30% to 3.90%) and more substantially in urban households (from 23.43% to 30.02%) (Adusah-Poku & Takeuchi, 2019). These figures underscore the persistent resistance to change in rural communities, where Confucian values remain deeply embedded. "*My husband's mother still insists on using firewood, saying it's what she knows and trusts.*" (Female respondent 08)

This cultural inertia presents significant barriers to the uptake of modern energy practices. Women are expected to maintain traditional domestic routines, and without adequate education or decision-making power, many lack the confidence or means to initiate change. As one respondent shared, "*When I realized how much energy our old heater was wasting... I found a much more efficient model. I knew it would save us money in the long run, so we made the switc.*" (Female respondent 11). Such proactive behavior, however, remains uncommon in rural contexts.

In contrast, urban women generally benefit from higher educational attainment, broader access to information, and greater financial autonomy. These conditions foster a more proactive approach to energy management. Empowered by education, urban women are more likely to seek out and adopt energy-efficient technologies, thereby reducing their exposure to energy poverty. Nonetheless, the urban-rural divide in energy awareness persists. As an expert noted, "*We had a meeting in the village about switching to cleaner energy, but only a few of the women attended... They feel they're doing just fine with what they've always used.*" (Expert 05)

In sum, Confucianism's enduring emphasis on women's subordinate roles and limited education continues to influence patterns of energy poverty in rural China. Addressing this issue requires not only technical interventions but also culturally informed strategies. Promoting energy literacy and empowering women through targeted educational programs are essential steps toward disrupting the intergenerational cycle of energy poverty, particularly in areas where traditional values remain dominant.

5.3. Mental health impacts of both factors

The mental health of rural women in China is deeply affected by the intersection of energy poverty and limited educational opportunities, both of which are shaped by enduring Confucian cultural norms. Confucianism reinforces traditional gender roles and the subordination of women, confining them to domestic responsibilities and restricting access to education. Consequently, rural women are disproportionately affected by energy poverty, a condition that not only undermines physical health but also imposes significant psychological burdens. In rural areas, the reliance on inefficient and hazardous energy sources—such as firewood and biomass—exacerbates this vulnerability. Prolonged exposure to smoke and odors from these fuels harms physical well-being and contributes to chronic psychological stress. The responsibility for managing household energy within

tight constraints often leads to anxiety, especially as women are expected to uphold familial well-being without the necessary resources. Confucian values amplify these pressures, reinforcing women's perceived duty to the home while limiting their autonomy. One woman remarked, "*I never imagined that I would be stuck using these old methods to keep our home warm... It's as if I'm trapped in the past, with no way out.*" (Female respondent 16) The absence of educational opportunities further compounds women's sense of powerlessness. Many lack the knowledge and confidence to seek alternatives or access support, leaving them emotionally isolated. The mental toll intensifies when women feel they cannot meet familial expectations, particularly under constant criticism or blame. As one participant shared, "*If the electricity bill is too high, he blames me, even though I'm just trying to keep the house comfortable for the children. It's exhausting.*" (Female respondent 09)

This psychological strain often leads to reduced self-confidence and deep emotional distress, especially in cultural settings where failure to fulfill domestic duties is associated with shame. The risk of depression and other mental health disorders increases under these conditions. Cultural norms discourage women from discussing their struggles or seeking help, for fear of being perceived as weak. "*They don't want to be seen as unable to handle their household duties. It's this feeling of shame that often prevents them from seeking help.*" (Expert 01)

Confucian traditions also inhibit women's capacity to advocate for change or adopt new energy practices. In many cases, women internalize their culturally defined roles, adhering to outdated energy use practices despite the harm they cause. "*My mother-in-law insists that we keep using the old stove, saying it's what we know and trust. It's hard to convince anyone otherwise.*" (Female respondent 08)

These cultural and psychological pressures are further exacerbated by familial discord. Many women report feeling incapable of satisfying their husbands' expectations, leading to emotional fatigue and withdrawal. A lack of emotional and social support compounds this experience, impairing women's ability to respond proactively to their circumstances. "*This society has a way of making us women feel completely powerless... I occasionally use the air conditioning to keep my home at a comfortable temperature. My husband was pleased with it initially, but when he saw the electricity bill, he scolded me again. There isn't much to discuss.*" (Female respondent 09)

Ultimately, the psychological effects of energy poverty are not merely the result of material deprivation but are deeply entangled with cultural and educational barriers. Addressing these challenges requires more than just expanding access to clean energy technologies. It also necessitates efforts to confront and transform the Confucian cultural norms that restrict women's roles, discourage education, and suppress their voices. A culturally informed, gender-sensitive approach to both mental health and energy policy is essential to breaking this cycle of vulnerability and enabling rural women to regain agency over their lives.

6. Conclusions and implications

Based on China Family Panel Studies (CFPS) data, this study finds that rural women are significantly more affected by energy poverty than their urban counterparts. Energy poverty is measured through access and affordability, and benchmark regressions confirm that rural women, especially those with lower education and older age, face higher risks. The correlation analysis reveals that variables such as educational attainment, age, and geographic location influence women's exposure to energy poverty, with little evidence of multicollinearity in the models.

The findings suggest a strong link between limited education and increased energy poverty risk, highlighting education and financial resources as key factors for mitigation. Age shows a nonlinear relationship, indicating evolving energy needs over the life course. Urban women are generally more resilient due to greater autonomy and access to social and economic resources, while rural women remain disadvantaged by household responsibilities, lack of voice in energy decisions, and entrenched social norms.

The study also explores energy injustice, pointing to rural women's restricted access to renewable energy, their heavy domestic burden, and mental health challenges stemming from energy deprivation. These issues are compounded by Confucian cultural norms that limit women's decision-making power, especially in rural areas where gender roles are more rigidly enforced.

To address these challenges, a multidimensional policy response is required. First, expanding access to education and skills training for rural women can strengthen their capacity to engage in energy-related decisions and

improve their socio-economic status. Second, building localized support systems—such as community networks, NGOs, and government-led initiatives—can provide emotional support and practical guidance to women in energy-poor households. Third, implementing sustained and regionally tailored subsidy programs for low-income rural households can ease their transition to modern, clean energy sources while reducing long-term dependency on traditional fuels. Finally, broader societal change is essential: challenging deeply rooted gender norms through public awareness campaigns and institutional reforms can promote greater gender equity in both domestic and public spheres. These interventions, collectively, will be crucial for reducing gendered energy inequalities and advancing an inclusive, culturally informed energy transition in China.

Abstract
Despite the widespread use of urban green spaces (UGS) as a climate change mitigation strategy, their cooling effects have not been thoroughly studied for public health benefits. This study, conducted in Guangdong Province, a subtropical monsoon region in China's Great Bay Area, assesses four UGS scenarios with different trade-offs regarding their impacts on school-age children's sleep health. Introducing around 2.5 to 2.7 km^2 of UGS significantly lowers temperatures by up to 1.13 °C monthly, benefiting populations with varying risk levels. Prioritizing small UGS yields the most profound benefits, especially investing in existing ones. Emphasizing large UGS has limited benefits, with constructing new ones the least effective. Careful planning and design highlighting social benefits and equity are crucial for addressing heat-related health risks under climate change.

Keywords: Urban green space; Heat exposure, Planning; Sleep health; Simulation

1 Introduction

The escalating climate change exposes individuals to greater health risks (Ebi et al., 2021), particularly in densely populated urban areas of subtropical and tropical regions (Dong et al., 2024), where the urban heat island effect (UHI) combined with high humidity increases the risks of heat stress (Ho et al., 2025), non-communicable diseases such as cardiovascular and respiratory diseases (Liu et al., 2022), sleep disorders and mental illnesses (Cianconi et al., 2020; Rifkin et al., 2017).

Having the potential to confer physical and psychological benefits, urban green space (UGS) has been increasingly adopted as a climate change mitigation strategy (Sugiyama et al., 2018; Zhang et al., 2022). Apart from bringing psychological relief and promoting physical activities and social contacts (Lachowycz and Jones 2013; Shuvo et al., 2020), research also indicates that UGS mitigates heat exposure, improve thermal comfort and thus improve public health (Markevych et al., 2017).

However, this specific cooling pathway remain largely underexplored, especially regarding its associations with public health benefits (Huang et al., 2025; Sadeghi et al., 2022). Current research on UGS's cooling effect lacks systematic perspective that positions UGS in an extensive urban landscape with various intricately-influencing factors (Aram et al., 2019), thus failing to offer constructive prescriptions (Zhang et al., 2017 a). Moreover, simulations seldom consider the real-world planning practices that are embedded in the urban land use system (Li et al., 2022), leading to a fundamental gap between theoretical results and practical guidance.

Therefore, using Guangdong Province as a case site, this study examines the health benefits of UGS's cooling pathway through assessing the performances of different UGS planning scenarios. Results from air temperature simulations are linked with a large-scale survey on school-age children' s sleep health status. How different planning approaches are influencing their sleep health is evaluated to shed light on the common trade-offs between small-large and new-old UGS. Section 2 reviews the established findings and remaining debates. Section 3 illustrates the research strategy. Section 4 presents the results, and Section 5 conveys discussions and policy implications.

2 Literature review

2.1 Heat exposure's impact on school-age children's sleep health

Sleep health is closely related with all kinds of mental disorders (Hudson et al., 2020; Scott et al., 2016), yet has received less attention than diseases and death in the realm of health research. Research indicates that global warming is leading to increased thermal discomfort, night sweats, breathing difficulties, and disrupted sleep patterns (Obradovich et al., 2017; Zheng et al., 2019), resulting in individuals worldwide losing around two weeks of sleep each year (Minor et al., 2022). Sleep efficiency decreased by 10% in temperatures between 25 °C and 30 °C (Baniassadi et al., 2023), and interruptions and awakenings significantly increased when ambient temperatures

exceeded 30 °C (Altena et al., 2023). Although air conditionings can mitigate outdoor heat exposure, they are typically used when temperatures rise to a relatively high degree; in their absence under mild and moderate exposure, indoor temperatures systematically surpass outdoor ones (Yan et al., 2022), causing significant sleep issues related to heat exposure (Lin and Deng, 2006).

Recently, the sleep issues of school-age children are receiving increasing attention, as the incidence of various sleep disorders among school-aged children, including sleep-related breathing disorders and circadian rhythm sleep disorders, may reach 30% to 40% around the world (Lim et al., 2023; Chen et al., 2021). School-age children are particularly prone to experiencing sleep disorders compared to adults, possibly due to their developing physiological and nervous systems that make them more sensitive to changes in thermal environment (Kansagra, 2020; Trosman and Ivanenko, 2024). Moreover, they are particularly sensitive to noise and artificial light (Wang et al., 2022) and indoor air quality (Fujii et al., 2015; Rahai et al., 2024), and the academic pressure they face may also make them more sensitive to the thermal environment (Qi et al., 2020; Steare et al., 2023). Since most current studies focus on vulnerable groups such as the elderly, the pregnant or outdoor workers (Baldwin et al., 2023; Gulia and Kumar, 2018), it holds theoretical and practical significance to examine the sleep health of school-age children and provide potential prescriptions.

2.2 UGS's health benefits and cooling capacity

UGS offers health benefits through various pathways, including emotional regulation, promoting physical activities and social contacts, as evident in extensive studies (McMahan and Estes, 2015; Lachowycz and Jones, 2013; Oliveira et al., 2014; Sallis et al., 2016). However, non-significant relationship between UGS and physical activities have also been reported (Triguero-Mas et al., 2015), partly due to some UGS's not being thermally comfortable or adequately designed for physical activities (Evenson et al., 2013). Additionally, UGS enhances air quality by absorbing, filtering, and decomposing harmful particles (Buccolieri et al., 2018; Ysebaert et al., 2021), yet concerns arise about the allergens and particles brought by UGS that may harm health (Osborne et al., 2017). Moreover, UGS confers public health benefits by reducing urban heat through evapotranspiration and shading[1](Probst et al., 2022; Wong et al., 2021). Research indicates that the temperature reduction contributed by UGS ranges from approximately 1 °C to 10 °C and even higher (Park et al., 2017; Rashid et al., 2014; Wu et al., 2012), further leading to profound decrease of air conditioning usage and promoting energy conservation (Zhang et al., 2014). Existing research has identified controversies regarding the size and layout of UGS. For example, some scholars highlight the extraordinary cooling effect of large UGS, pointing out UGS over 100 hectares can cool areas over several kilometers far (Du et al., 2017), while evidence also show that UGS as small as 0.49 to 2.04 hectares can generate a significant cooling effect of 1°C to 3 °C (Grilo et al., 2020). Some scholars highlight that a clustered pattern of UGS patches have greater cooling performances than a scattered pattern (Estoque et al., 2017; Rhee et al., 2014; Zhao et al., 2020), but there exist inconsistent findings (Zhou et al., 2011; Zhou et al., 2023). Some studies worry that UGS may increase humidity and thus hinder the cooling of the surrounding areas, yet studies from places such as Singapore and Malaysia have demonstrated UGS's profound cooling effect (Rashid et al., 2014; Shahidan et al., 2012).

However, current studies have not effectively linked UGS's cooling capacity to public health benefits through empirical investigations. Several gaps remain. First, Studies defining UGS boundaries often overlook the influence of the built environment, resulting in inaccurate definitions. Second, while some studies use simulation techniques to optimize UGS distribution for cooling effects (Zhang et al., 2017 b), they fail to include the real-world land use situations and leading to limited practical guidance. These ambiguities and gaps highlight the necessity of conducting location-based empirical research (Zhou et al., 2025).

2.3 UGS planning practices and equity debate

Recently, UGS has become a popular planning strategy aimed at improving public health (Sugiyama et al., 2018), as it is considered more economical in cost and can raise fewer concerns on environment and political sides than many other measures (Zhang et al., 2019). However, gaps remain between UGS research and planning practices. First, UGS is mainly provided by governments due to its competitiveness and non-exclusiveness as quasi-public goods (Chen et al., 2019) and thus less valued due to budget constraints (Chen and Hu, 2015; Lin et al., 2023; Wang,

1 Evapotranspiration reduces ambient air temperature through converting liquid water into water vapor and exchanging sensible heat for latent heat, while the shade created by plant canopies blocks heat transfer and contributes to lowering temperatures, especially in humid regions through delaying the peak air temperatures during the day.

2015), leading to UGS relatively small, not appropriately designed and suitable for recreational activities (Jiao et al., 2017; Wolch et al., 2014). Furthermore, compulsory demands from the higher-level governments regarding UGS have not prompted local governments to intricately plan UGS. Instead, they struggle to meet minimal quantity requirement2, disregarding spatial layout and interior design, as well as public participation (Miao, 2011; Yu and Padua, 2007). Additionally, that land developers placing high values of UGS construction turns them into private asses, exacerbating the inequalities in distribution and utilisation of UGS due to "green gentrification" (Liebelt et al., 2018; Shan et al., 2024). These practical obstacles embedded in the planning system hinder UGS from maximizing their potential to deliver comprehensive and equitable health benefits (Wang and Chan, 2019) and require more cautious planning interventions (De Haas et al., 2021; Kruize et al., 2019).

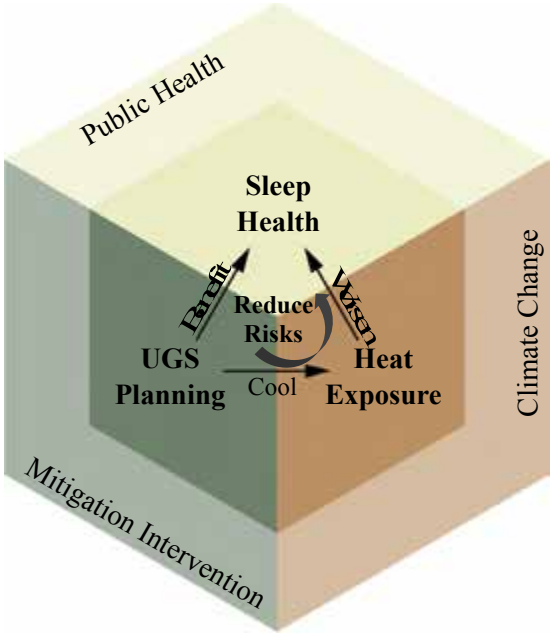

Figure 1 UGS's cooling pathway to mitigate climate change's impact on sleep health

3 Research strategy

3.1 Data source and research framework

This study focuses on Guangdong Province from the Great Bay Area of China, which features a subtropical and tropical monsoon climate zone (20°09'N to 25°31'N, 109°45'E to 117°20'E) with its average temperature between 19 °C and 23.5 °C and averagely over 30 °C during the summer, thus facing significant heat exposure-induced health issues (Ho et al., 2025).

Six cities from the Guangdong Province that cover both economically developed and developing cities were selected to conduct a survey of school-age children, including Guangzhou, Shenzhen, Foshan, Zhongshan, Zhuhai and Maoming **(Figure 2**). The six cities cover both the coastal and inland part, 41.50% of the impermeable area, 41.45% of the population, and 65.43% of the GDP of the entire Guangdong province3, representative regarding climate and population. A large-scale survey was conducted across almost all months from 2016 to 20184, obtaining information on sleep health, home address and family's socioeconomic status from 131,412 school-age children in 105 randomly-selected primary and middle schools. The average atmospheric temperature within 500 meters of the residence is matched according to students' home address and used to represent heat exposure (Venter et al., 2020).

2 For instance, Guangzhou does not provide detailed definition and calculation method for the different requirements of UGS. Shenzhen sets the rate of green space for each district, which is a different indicator compare to Guangzhou. The planning documents do not specify the calculation method as well.

3 These percentages are calculated based on the 30m resolution land use data from 2016 to 2018, the 100m resolution population and GDP density data in 2019. Detailed data sources are in Table 1.

4 The protocol was approved by the Sun Yat-sen University Institutional Human Ethics Committee (Ethics Approval Number: 026).

This study comprises three stages (**Figure 3**). The first models the link between air temperature and sleep health and explores whether UGS has the potential to mitigate heat exposure's exacerbating influences on sleep disorders, with sampled school-age children as a focused group. The second constructs a prediction model for air temperature based on various factors, including planning interventions that can be linked with different planning approaches. The third applies the four UGS scenarios representing different trade-offs regarding small-large and new-old to established models in the first two stages, evaluating their nuanced potentials in improving school-age children's sleep health.

Multiple factors are included in the second stage (**Table 1**), including climate and geographic factors such as precipitation, relative humidity, wind velocity, solar radiation and digital elevation model (DEM) (Cristóbal et al., 2008; Yang et al., 2017), socioeconomic factors such as population and GDP density (Shen et al., 2020; Sun et al., 2018). Normalized difference vegetation index (NDVI) and land cover data are also included to link with planning interventions in different scenarios. Air temperature better represent people's perception of temperature exposure (Bernhard et al., 2015), yet land surface temperatures (LST) are also included as factors as recommended (Hu et al., 2019; Janatian et al., 2017).

Figure 2 Research site5

3.2 Model setting

3.2.1 Model between air temperature and sleep disorders

A logistic model is utilized to examine the impact of heat exposure on sleep health, considering sleep disorder indicators such as overall sleep disorder (SD), disorders of initiating and maintaining sleep (DIMS), and sleep hyperhidrosis (SH). Covariates include age, gender, body mass index (BMI), exercise time, secondhand smoke exposure, household income level, housing area per capita, presence of mold at home, proximity to main road or factory, and average NDVI in the neighborhood.

$$Prob(Y_i = 1|X_i, Z_i) = \Phi(\beta_0 + \beta_1 T_i + \theta G_i + Z_i\gamma + \varepsilon_i) \quad (1)$$

where Prob(Y_i=1|X_i,Z_i) represents the probability of sleep disorders. R denotes the temperature exposure variable. G refers to the average NDVI of the surrounding neighborhood. Z represents the control variables.

A generalized structural equation model (GSEM) is used to test UGS's cooling pathway in mitigate heat exposure's adverse impact on sleep health. The formula (1) and (2) are estimated in a structed way (Yu et al., 2025).

$$T_i = \mu_0 + \mu_1 G_i + \varepsilon_i \quad (2)$$

If both μ_1 and Δ_1 are significant, UGS's cooling pathway in mitigating heat exposure's adverse impact on sleep health is significant. If both μ_1 and Δ_1 are not significant, product-of-coefficients tests are performed. If Δ is nonsignificant, the full mediating effect is further verified. Otherwise, there is a partial mediating effect.

A natural cubic spline (NCS) method is used to detect the nonlinear impact.

$$Prob(Y_i = 1|X_i, Z_i) = \Phi(\beta_0 + \beta_1 ns_1(T_i) + \beta_2 ns_2(T_i) + \beta_3 ns_3(T_i) + \beta_4 ns_4(T_i) + \theta G_i + Z_i\gamma + \varepsilon_i) \quad (3)$$

where $ns_1(T_i)$, $ns_2(T_i)$, $ns_3(T_i)$, $ns_4(T_i)$ indicate the functions generated using NCS method. Each disorder-specific model is determined using the lowest Akaike's Information Criterion (AIC) values that indicates the best fit across the three different knot specifications (Lee et al., 2020).

3.2.2 Model for predicting air temperature

A two-stage training approach using random forest method is adopted to construct an air temperature prediction model for each month across the survey time. UGS in this study is defined as all forest, shrub and grass within the "urban area"[6] (Sun et al., 2021) based on the land cover data of 30 m resolution (Yang and Huang, 2021), as employed by many other studies to exclude hard pavements and allow for the actual cooling effect from plants (Feltynowski et al., 2018; Kuang et al., 2021). The two-stage training method allows for the consideration of UGS impact on the environment through LST (Janatian et al., 2017), with marine areas omitted due to data unavailability. Urban areas and human habitats mostly situate to the southern area, allowing for the exclusion of the confounding effects from bordering regions. The importance of each factor and goodness of fit are reported in **Appendix Table 1**.

3.3 UGS scenarios

Four UGS scenarios are proposed based on the real-world practices and debates, including expanding current large UGS (s1), expanding current small UGS (s2), constructing new large UGS (s3), and constructing new small UGS (s4) (**Figure 4**). Expanding current UGS can be costly but beneficial for densely populated areas nearby. Building new UGS may be more feasible with lower costs, benefiting residents in the vicinity, although their impact may be limited if located in remote areas.

In China, local governments determine the UGS quota based on the total new urban land allocation set by higher

6 The urban area in this study is the minimum bounding rectangle based on the urban built-up area published by Sun et al. (2021) using the "Minimum Bounding Geometry" tool in GIS. This approach maximizes interconnected urban green spaces in close proximity while excluding rural and ecological conservation areas.

authorities, typically ranging from 5-30% of the annual new urban land. City-specific ratios between 5-30% is set for converting to new UGS, and the total amount of new UGS range from approximately 2.5 to 2.7 km^2, with the six sampled cities accounting for over 60% (**Table 2**).

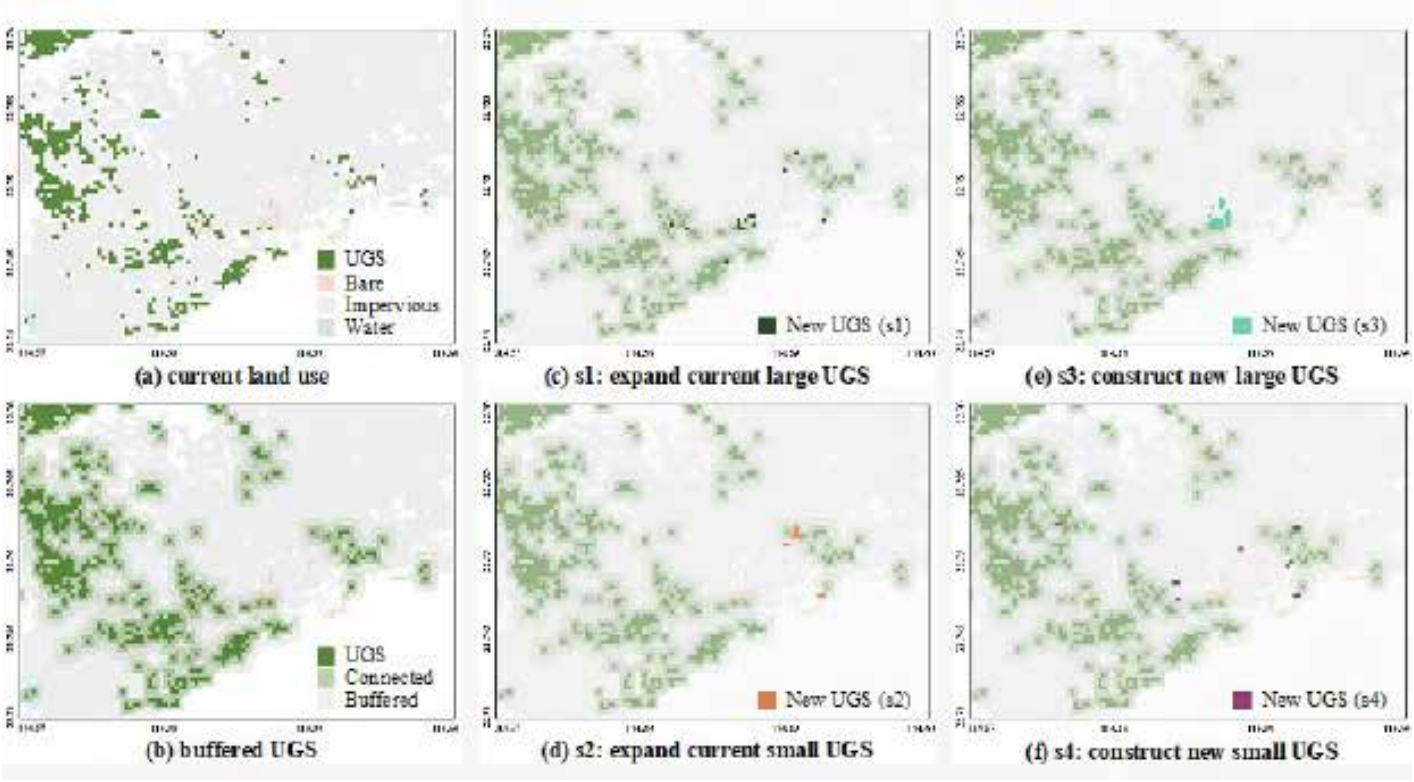

Figure 4 Simulation scenarios (Shenzhen example)

Table 2 The city-year-fixed total amount of new UGS (km^2)

	bare land			Increased UGS			Ratio
	2016	2017	2018	2016	2017	2018	
Foshan	4.028	4.193	4.233	1.209	1.258	1.270	30%
Guang-zhou	1.049	1.150	1.094	0.315	0.345	0.329	30%
Maoming	0.067	0.053	0.052	0.004	0.003	0.003	5%

Other	4.020	4.064	3.860	0.631	0.636	0.604	5-30%
Total	10.880	11.100	10.560	2.613	2.674	2.550	24%

4 Results

4.1 Modeling exposure-disorder relationship

Logistic models reveal that heat exposure significantly increases the risk of sleep disorders (SD, DIMS, SH) (**Table 3**, Model 1-3). lnNDVI significantly decreases of risks of sleep disorders. GSEM analysis examines the mediating role of UGS cooling effect on sleep health (**Table 4**), demonstrating a significant positive impact aligning with prior empirical evidence (Yu et al., 2025). The cooling pathway accounts for approximately 1% of the total effect using lnNDVI as a proxy.

The NCS method identifies the nonlinear impact of heat exposure (**Table 5**, Model 4-6). Each knot function shows significant estimated coefficients, especially ns(T)3 which falls around the moderate levels of exposure. The coefficients of lnNDVI are similar as those in normal logistic models. We focus on analyzing the predicted probabilities of experiencing sleep disorders rather than specific numerical results.

4.2 Simulating UGS's cooling potential

Figure 5 compares original and simulated temperatures in s1 within the built-up area, displaying monthly averages. The most significant cooling effect occurs in March and April, with a maximum decrease of 1.13 °C. Conversely, July and August show minimal cooling, with a potential increase of 0.04 °C, likely influenced by high humidity.

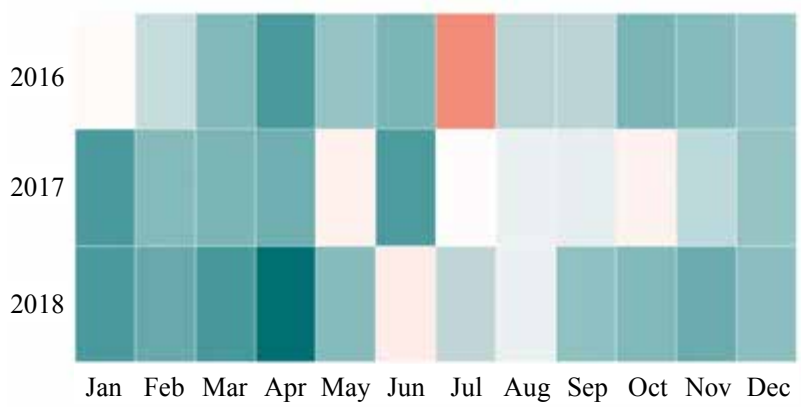

Figure 5 Temperature difference between the original and simulated (s1)

4.3 Simulating UGS's cooling impact on sleep health

Possibilities of developing sleep disorders are predicted based on the normal logistic and NCS models (Model 1-6). By incorporating simulated temperature exposures, new probabilities are generated for the four planning scenarios proposed in section 3.3. **Figure 6** presents the overall mean value and Gini coefficient. **Table 6** reports the t-test results of the mean value between four scenarios. **Figure 7** shows the decile-based probability changes, while **Table 7** reports the average risks of sleep disorders (measured using the NCS method) across different cities.

According to **Figure 6** and **Table 6**, Mean values from the NCS method are higher than those from normal logistic regression, with relatively lower Gini coefficients. Since prior research has highlighted that using a linear "exposure-response" relationship may underestimate health risks linked to high temperatures (Gasparrini et al., 2010), NCS results may provide a more reliable and accurate reflection of heat exposure's real-world impacts. The mean values in s2 are significantly lower than in s1 and s3 according to the NCS method), suggesting that enhancing large UGS may not provide substantial health benefits through cooling. In contrast, mean values in s2 are higher than s1 and s3 in normal logistic regression due to potential underestimation at high temperatures. Gini coefficients in s2 and s4 are lower than in s1 and s3, with s4 showing a more balanced distribution of sleep disorder risks compared to s2, indicating that focusing on small UGS improvements may lead to more equitable outcomes.

In **Figure 7**, blue indicates a decrease in the average probability of sleep disorders compared to the original situation in the simulated scenario, while yellow signifies an increase. An unpaired t-test between the original and simulated scenarios reveals a significant improvement in the first decile group in the NCS model of SD. Introducing UGS shows potential to enhance sleep health for populations at low and high-risk levels, but may not have the same effect for those with moderate risk levels due to increased humidity in some areas. The NCS results, considering nonlinear relationships, show greater improvements, underscoring UGS's ability to mitigate heat exposure's negative effects. UGS's cooling benefits are particularly advantageous for lower-risk groups (SD and SH), offering broad advantages across different risk levels. However, individuals in the extremely high-risk category (DIMS) may not experience significant improvements in sleep health, indicating complex factors beyond heat exposure may pose threats to DIMS.

In **Table 7**, the scenario with the lowest mean risk value for each city is highlighted in grey. Most cities show the greatest benefits from scenarios s2 and s4, with Foshan benefiting from scenario s4 across all three types of sleep disorders. Guangzhou and Zhuhai might derive the most benefit from scenario s1. Only a small number of cities appear to benefit from scenario s3.

5 Discussion and policy implication

This study focuses on Guangdong Province which features a typical subtropical monsoon climate. Using a "marginal increase" approach, the research examines how UGS provide health benefits through cooling effects in the region. A monthly air temperature prediction model is developed, incorporating various factors and achieving a good fit above 0.95. Four UGS planning scenarios are proposed based on real-world practices. Simulation results are then used to assess the risks of three types of sleep disorders among school-age children in six sampled cities.

Results confirm that UGS serves as an effective strategy in mitigating climate change impacts on sleep health, and the cooling pathway significantly accounts for at least 1%. Introducing around 2.5 to 2.7 km^2 of UGS can effectively cool urban areas, with the most substantial temperature reduction of 1.13 °C in April 2018. Approaches highlighting small UGS have a more profound and significant positive effects on school-age children's sleep health than scenarios focusing on large UGS. Particularly, expanding existing small UGS in s2 shows the greatest potential for balanced and equitable outcomes. In contrast, s3 performs poorly in terms of health impact and equity.

Results indicate that UGS provides health benefits for population with both low and high risks, as shown in **Figure 7**. In other words, UGS not only serve to mitigate heat-related risks but also contribute to enhancing public health in a preventive way (Lachowycz and Jones, 2013; Zhang et al., 2022), emphasizing the importance of introducing and improving UGS to confer public health benefits. However, UGS may have negative impacts on populations with medium risk levels. In some cases, UGS in humid areas may increase humidity levels, impacting thermal comfort (Yu et al., 2025). The complex dynamics between humidity and temperature (Yang et al., 2024) jointly affect thermal comfort, and elevated humidity coupled with extreme high temperatures may exacerbate heat discomfort (Ho et al., 2025). UGS may not effectively mitigate risks at very high levels, highlighting the need for targeted investigations into factors beyond the thermal environment affecting sleep disorders.

The size of UGS matter a lot in planning practices. Contrary to the emphasis on large UGS in studies specifically focusing on the cooling effect (Shah et al., 2021), this study indicates that prioritizing small UGS may yield greater cooling-induced health benefits. Expanding and improving small UGS and creating new ones can provide broader access to cooling benefits for the population, consistent with previous findings (Yan et al., 2021). In contrast, expanding the large UGS in s1 shows limited health benefits, likely due to its placement in non-residential central urban areas (Aram et al., 2019). Similarly, constructing new large UGS in s3 is ineffective and unbalanced, as many remaining plots are in suburban areas, repurposed from factories, and far from residents, limiting their benefits. This study warns that practices in s3 may lead to underutilized UGS, wasting resources and should be avoided.

Although expanding small UGS may incur higher costs, its cooling and health benefits could be greater with better long-term social and economic outcomes. Instead of just "greening the city" (Wolch et al., 2014), it is highly recommended to implement strategic UGS placement and ongoing improvement of existing parks to maximize public health and ensure equity.

This study offers two main innovations. First, it integrates UGS's cooling capacity with public health benefits by quantitatively simulating the specific performances of UGS's cooling pathways. Second, the real-world quota-allocation practices in simulation scenarios are incorporated to compare the common trade-offs between large and small, new and old UGS, and thus provide constructive planning prescriptions. Limitations include non-random sampling, though participants are widely distributed across six cities. Moreover, due to data constraints, the spatial resolution is only 1 km. Future work aims to enhance accuracy and recommendations.

Appendix

Table 1 The importance of factors and goodness of fit for air temperature prediction models

Abstract
Climate change is the principal global challenge demanding active community participation alongside governmental and corporate efforts. This article presents findings from GreenHack, a student hackathon at Istanbul Technical University (ITU), utilizing Participatory Geographic Information Systems (PGIS) to enhance campus sustainability. Participants developed creative PGIS-based prototypes addressing green space planning, waste management, water conservation, and energy economy, aligned with UI GreenMetric standards and ITU's Green Campus project. These applications demonstrated GIS technologies' ability to visualize data, engage users through gamification, and provide actionable insights. GreenHack showcases the potential of participatory hackathons to connect sustainability goals with community engagement, offering scalable, inclusive frameworks for sustainable design extending from campus environments to broader urban contexts.

Keywords: Campus sustainability; Climate change; Green campus; Public GIS; Hackathon

Introduction

Cities have become areas facing many interconnected problems such as the side effects of industrialization, population density, and unhealthy urbanization. The damage to the environment due to these problems requires the integration of technology and sustainability to address these issues and for society to take action. Universities and their campuses are important for this goal because their physical structures, technological infrastructure, and qualified student populations carry the potential to create collective awareness and perform environmentally beneficial actions. As centres of learning and innovation, university campuses are ideal environments for adopting new approaches. Their focused communities and infrastructure enable them to effectively test and demonstrate sustainability and technology initiatives that can inform and inspire change in the wider city. Thus universities can set an example for adopting a green and sustainable design approach and adapting to changing dynamics. Many universities have adopted UN sustainable development goals within their curriculums and campuses. Their local and international connections give these institutions the opportunity to be effective in achieving these goals at different scales. Istanbul Technical University (ITU) has already demonstrated significant progress in these areas. For instance, its commitment to a green campus has earned global recognition, with ITU ranking in the top 50 in the 'UI Green Metric' ranking in 2025. Furthermore, it achieved a top 100 placement in 'The Impact Rankings,' which assesses sustainable development goals, sharing first place in Turkey with METU. These achievements are underpinned by its robust technological infrastructure, including efforts to integrate GIS-based applications with 'ITU Mobil'. Such initiatives not only enhance environmental consciousness but also foster active participation, transforming the campus into a dynamic model for observable sustainable practices and digital transformation.

This paper focuses on the 'Istanbul Technical University GIS-Based User-Oriented Green Campus Application Alternatives Determination' (İTÜ CBS Tabanlı Kullanıcı Odaklı Yeşil Kampüs Uygulama Alternatiflerinin Belirlenmesi)

project, supported by the Scientific Research Projects (BAP) unit. This BAP initiative specifically aims to develop user-oriented pilot applications for ITU's Green Campus activities, leveraging GIS and mobile infrastructures. Within the scope of this project, the GreenHack hackathon, organized at Istanbul Technical University (ITU) from December 1st to 3rd, 2023, served as a key activity. The hackathon was designed to bring together students, planners, GIS experts, and other stakeholders to collaboratively develop integrated Participatory Geographic Information Systems (PGIS) application prototypes. This event directly supported the broader goal of the BAP project by fostering creative, user-cantered solutions for ITU's 'Green Campus' initiative and enhancing the university's standing in the UI Green Metric rankings.

The hackathon itself was a participatory activity, as students are key stakeholders in the campus ecosystem and they were directly involved in shaping its future. By participating in the event, students had the opportunity to voice their perspectives, share their ideas, and contribute to creating solutions that reflect their priorities and needs. This collaborative environment also enabled them to acquire new knowledge and essential skills in areas such as GIS, urban sustainability, and app prototyping, through seminars and hands-on experience. This collaborative approach not only generated innovative prototypes but also fostered a sense of ownership and responsibility among participants, strengthening their connection to the campus and its sustainability goals.

Building on the identified need for innovative and participatory approaches to sustainable urban development, particularly within academic settings, this paper seeks to answer key questions regarding the efficacy of the GreenHack hackathon as a transformative planning action within the framework of a BAP project. Specifically, this study explores: How can hackathons, specifically utilizing Participatory GIS (PGIS), serve as an effective mechanism for fostering collaborative and innovative solutions for sustainable campus planning within a university context, as exemplified by the ITU Green Campus initiative? What types of PGIS-based solutions, in this case, prototypes, emerged from the GreenHack hackathon, and what is their potential for applicability within the UI GreenMetric criteria and scalability for addressing broader urban sustainability challenges, offering a replicable approach for other institutions?

To address these questions, the paper is structured as follows: Section 2 provides a comprehensive theoretical framework, reviewing the literature on participatory planning, the role of universities as living laboratories for sustainability, the evolution and application of Participatory GIS (PGIS), and the emergence of hackathons as platforms for collaborative innovation. Section 3 outlines the methodology, detailing the case study approach cantered on the GreenHack hackathon, data collection methods including document analysis and participant observation, and the analytical framework applied to the hackathon's outcomes. Section 4 presents the GreenHack hackathon as a detailed case study, describing its context within ITU's BAP project and Green Campus initiative, its structure, key themes, and the characteristics of the developed prototypes. Section 5 elaborates on the findings and analysis, discussing the innovation and functionality of the solutions, the role of PGIS in empowering stakeholder participation, and insights from the jury's evaluation. Section 6 offers a discussion of the broader implications of the GreenHack model, exploring its replicability and potential for scaling participatory solutions from campus to wider urban contexts. Finally, Section 7 concludes the paper by summarizing key arguments and contributions, emphasizing the transformative potential of participatory, technology-driven approaches in addressing contemporary environmental challenges[BD02] .

Theory

From conventional, typically top-down, tactics to more sophisticated and diversified digital technologies, public involvement in urban planning has evolved significantly. Historically, public participation first surfaced in many industrialised nations in the middle of the 20th century when institutional planning frameworks were set up (Wilson and Tewdr-Jones, 2021). Early public participation mostly depended on representational democracy, when choices made by professional officials and elected politicians have less direct influence outside of local elections. Public criticism of expert-driven planning decisions intensified after the 1950s, which resulted in participatory democracy being more significant in planning choices (Campbell and Marshall, 2000). With the Skeffington report in 1969, which sought to change planning from something "done to people" to something "with people," this change was formalised in Britain. Arnstein's (1969) Ladder of Participation describes obstacles like incomprehensible technical and legal jargon, inflexible planning processes, and the over-representation of elite groups in participation, therefore showing how frequently early participatory attempts remained tokenistic despite these aims. With communicative and cooperative planning theories in the 1980s stressing public

involvement to oppose strong interest groups, the argument surrounding public participation changed (Forester, 1982). The notable transition to new technologies, referred to as the "digital turn," has commenced altering urban planning and public engagement in the planning process. Technology's impact on planning, including urban modelling and 3D visualisations, has been evident since the 1960s and 1970s to facilitate a scientific approach; however, its incorporation for public engagement is a more contemporary advancement. Planners initially exhibited reluctance in adopting the digital revolution, frequently perceiving it as beyond their area of expertise. The accessibility of digital technologies, especially through smartphones and social media, has significantly altered citizen interactions with government, impacting political discourse and campaigns (Batty, 2021). The increasing public demand, along with the constraints of conventional methods such as public hearings and written statements, has necessitated the development of more accessible and accountable planning processes. The COVID-19 pandemic expedited this transition, prompting local planning authorities to adopt digital working and engagement processes. During this digital transformation, various specific technologies have emerged. The Public Participation GIS (PPGIS) field has expanded considerably in the last ten years, acknowledging that GIS technologies possess both empowering and disempowering potential. PPGIS seeks to promote grassroots GIS applications through the integration of various local knowledge and participatory methods. This approach aims to modify GIS data structures to incorporate qualitative data, sketch maps, and images, in addition to quantitative data. This enhances the accessibility of complex spatial information. PPGIS techniques encompass collaborative mapping and community evaluation of spatial data (Sieber, 2000). The "SoftGIS" methodology in Finland serves as an internet-based PPGIS tool that gathers localised experiential knowledge from residents, including children. PPGIS has the potential to integrate expert and lay knowledge for mutual learning and is particularly effective in the early diagnostic phases of planning; however, challenges remain. The skills required and the significant financial and temporal costs associated with GIS use can exclude numerous individuals and groups. Concerns exist regarding the technology's tendency to prioritise quantitative and visual data, which may marginalise alternative forms of knowledge (Brown and Kyttä, 2014). Numerous PPGIS tools primarily offer information instead of promoting substantial engagement. The quality of spatial information gathered may be diminished if participants fail to allocate adequate time and effort to the mapping activity.

Mobile applications and social media platforms offer opportunities for "low-friction" and "in-situ" participation. Several apps have been designed to make people aware of proposed changes while they are physically in the built environment, allowing for quick, location-based comments and potentially influencing long-term planning policy. Social media serves as an informal platform for discussions related to place, reflecting individuals' lived experiences and providing a medium for commentary on observable changes (King and Brown, 2007). These platforms can expand discussions and engage individuals who are not typically involved in formal democratic debate (Twitchen and Adams, 2012; Wilson and Tewdwr-Jones, 2019). Exclusive reliance on applications and social media presents challenges, such as the digital divide and the potential exclusion of individuals who lack access to or confidence in using technology. Furthermore, many modern digital tools, similar to their offline equivalents, primarily facilitate one-way information distribution rather than fostering interactive dialogue (Conroy and Evans-Cowley, 2005). The speed and ease of participation, while beneficial for raising awareness and reporting issues, can sometimes undermine the quality and depth of comments, which may impede the acquisition of knowledge essential for long-term planning.

Approaches incorporating digital gaming and creative activities aim to encourage deeper, more reflective engagement. Technologies that allow people to express complex feelings and visions about their environment through drawing and talking provide a novel and tangible method for participation that moves beyond traditional text-based responses. These "serious games" are designed to make participatory processes more accessible and engaging by using game design techniques. Creative methods can allow a wider representation of people to include perspectives that digitized "traditional" technologies struggle to capture and help visual thinking about the future of places (Wilson and Tewdwr-Jones, 2019).Still, a major obstacle is bringing these innovative ideas into line with the formal, usually strict planning framework anchored in legal and procedural rules.

All things considered, digital technologies add extra complexity and reproduce certain current problems even if they provide chances to lower participation barriers and collect fresh points of view on urban development. Usually, the success of digital involvement depends on striking a balance between speed and efficiency with the depth and quality of interaction.Always in demand are a collection of solutions combining many digital and non-digital approaches aimed at certain planning activities and citizen needs.The ultimate aim is to produce citizen-

cantered involvement that guarantees that planning stays sensitive to the many experiences and ambitions of the people it serves and encourages significant communication.

The discussion on public participation in urban planning, particularly with the advent of new technologies, necessitates a deeper examination of 'equity' from both ethical and ecological perspectives. The historical evolution of planning participation reveals persistent issues of exclusion and unequal representation, where processes have often been "tokenistic" and dominated by specific, often more educated and affluent groups, or those with vested interests (Elwood, 2006) . This raises fundamental ethical questions about whose voices are heard and whose interests are served in planning decisions that affect a wide range of people. The planning system's traditional legalistic and technical language, coupled with its top-down, expert-driven nature, has historically disenfranchised many citizens, especially those in lower-income socio-demographic groups, ethnic minorities, and women, who are typically less involved in decision making (Arnstein, 1969; Forester, 1982). This inherent bias means that the rights of the minority often disappears once the majority has spoken. The input of these stakeholders can be omitted also due to dominant cultural norms and values that define legislation and planners' attitudes. From an ethical standpoint achieving genuine equity requires addressing these deeply rooted power imbalances and moving towards a more human-cantered approach that values diverse lived experiences and emotions, rather than solely focusing on the technical and procedural aspects of land use.

The concept of equity is also combined with ecological considerations especially within the broader discourse of sustainable development. While sustainable urban planning aims to create environments that are equitable, efficient, and resilient, there is often a tension between these goals (Wilson and Tewdwr-Jones, 2019). Particularly between economic growth and social equity or growth and environmental sustainability. For instance, the government may interpret "sustainable development" as economic growth and job creation, sometimes disregarding or minimizing important issues like climate adaptation, environmental protection, and resilience. Decisions on major projects such as airports or new housing often involve hard trade-offs between regional economic benefits, local quality of life and environmental costs. Achieving "environmental justice" requires that planners consider how their decisions may lead to inequitable distributions of environmental costs particularly for communities at risk. Therefore, a "just city" model emphasizes a collective identity that promotes diversity while supporting values such as democracy, equity, growth, and sustainability (Fainstein, 2005) ensuring that no single value is above others with equity being at the forefront.

From ethical as well as environmental perspectives, new technologies have a complicated and changing role in tackling equitable issues. Digital tools—including Public Participation GIS (PPGIS), applications, and social media—offer great chances to lower obstacles to participation by means of time and geographic restrictions, and by including those who do not usually engage in conventional planning procedures. PPGIS can locate cultural ecosystem services and social-ecological "hotspots" offering a geographical way to combine many values into environmental planning (Alessa et al, 2008). These technologies, however, can bring fresh ethical questions and potentially "exacerbate previously existing digital and representation disparities" (Wilson & Tewdwr-Jones, 2019, p. 161). Although technology presents a strong tool for increasing citizen involvement and openness, it needs careful design to guarantee inclusivity, balance various forms of knowledge and honestly empower communities to shape their surroundings in a more just and sustainable way, rather than just digitising current often unfair processes.

Increasingly acknowledged as effective citizen centred projects encouraging cooperation among many people to provide creative answers to public challenges are hackathons. These fast-paced, design-driven events unite people from several backgrounds—technical specialists, designers, and non-programmers—to turn ideas into real-world prototypes within designated timesframes (Falk Olesen and Halskov, 2020). While conventional crowdsourcing usually sees participants working independently on ideas, hackathons—especially those aimed at civic engagement—aim to encourage generative co-creation and collaborative discourse, whereby participants build upon each other's ideas to develop more complete solutions. This method leverages the "wisdom of people" and varied experience to provide a range of ideas that would not result from more expert led initiatives (Surowiecki, 2012). The objective is not just to produce plenty of ideas but also to deepen knowledge of issues and support original, creative solutions going beyond product innovation towards support of society impact.

Using hackathons to actively solve important environmental issues is under more and more importance. Combining end users, technological professionals, students, and citizens, these "green hackathons" address environmental challenges and support reflective practices and practical solutions (Adisa et al., 2023). Often functioning as "living laboratories," universities are very important in this regard as they use their people resources and capital to create test beds for Sustainable Development Goal (SDG) solutions (Purcell et al., 2019). Hackathons encourage multidisciplinary cooperation and inspire participants to create creative digital solutions that propel sustainable actions and environmentally friendly initiatives, including lowering CO2 emissions or supporting sharing economies, by tying academic knowledge with practical sustainability problems. These projects help to empower people economically and modify behaviour in addition to increasing sustainability consciousness and encouraging a green attitude among participants and society. By means of prototype creation, the group participation in local sustainability challenges emphasises the possibilities of hackathons to directly influence society well-being and hasten towards more general sustainable development objectives.

Method

This study employs a qualitative, in-depth case study approach to examine the GreenHack event as a model for participatory GIS (PGIS) in sustainable campus planning. In this research the GreenHack hackathon serves as the primary case. This approach allowed for an in-depth investigation into how participatory methodologies, specifically a hackathon utilizing PGIS, can empower stakeholders and generate actionable solutions for sustainable campus planning.

The research design for this paper centres on an in-depth case study of the GreenHack hackathon, held at Istanbul Technical University's Faculty of Architecture from December 1st to 3rd, 2023. The hackathon was specifically designed to support ITU's "Green Campus" initiative and enhance its standing in the UI Green Metric rankings by developing integrated PGIS application prototypes. The focus was on leveraging technology, creativity, and participatory design to contribute to environmental sustainability efforts at ITU.

The case study design enabled a comprehensive analysis of the hackathon as a "living lab" for sustainability, where students, as key stakeholders, were directly involved in co-creating solutions for their campus environment. This qualitative approach allowed for the exploration of the nuanced interactions between participants, the challenges they identified, and the innovative solutions they proposed within the specific context of ITU's sustainability goals. The dynamic nature of a hackathon, characterized by intensive collaboration and rapid prototyping, provided a unique setting to observe and analyse participatory innovation in action.

Data for this case study were primarily collected through two main methods: document analysis and participant observation.A comprehensive review of various official documents related to the GreenHack hackathon and ITU's sustainability initiatives was conducted. This included the GreenHack Booklet which provided detailed information on the event's concept, objectives, structure, themes (green spaces, waste management, energy efficiency, water conservation, participatory GIS), program flow, expected outcomes, key elements, evaluation criteria, jury composition, mentorship, and awards; the Jury Report which provided insights into the evaluation criteria and specific comments on the strengths and weaknesses of the submitted projects, particularly the three winning projects; BAP Project application and Progress Reports: These internal ITU documents provided the foundational rationale for the project, its objectives, planned methodologies, and updates on its progress.

The final part of the analysis focused on Project Submissions (Prototypes and Concept Descriptions). The outputs from the hackathon teams, including their PGIS application prototypes and detailed concept descriptions, provided concrete examples of the proposed solutions. Participants were instructed to use pseudocode and graphic narrative techniques (e.g., screen designs, diagrams, symbols, colours, animations) to present their prototypes, detailing the application's purpose, target audience, data and methods, and expected outcomes. They were also required to align their concepts with UI Green Metric criteria and ITU Green Campus objectives.

Findings

Istanbul Technical University (ITU) is actively committed to integrating environmental sustainability into its operations and campus design, a commitment underscored by its "Green Campus" initiative. This project aims to transform ITU's Ayazağa campus into an environmentally conscious, smart, and liveable space that prioritizes nature, conserves resources, and enhances the quality of life for its community. The ITU Green Campus initiative,

launched in 2008, emphasizes a respectful approach to both nature and people. Key features include preserving natural habitats, creating pedestrian and bicycle routes, and implementing solutions for individuals with disabilities, aligning with the "Accessible ITU" motto. Specific actions involve sustainable landscape design with high water permeability for hard surfaces, use of low-water-consuming and climate-appropriate vegetation, and optimized irrigation and lighting systems. Furthermore, the campus has increased its green area, developed a greenhouse gas inventory, expanded bicycle paths to a target of 6 kilometres, established a bicycle repair and sales shop, installed electric vehicle charging units, and implemented separate collection of rainwater for a campus pond.

ITU's dedication to sustainability is also reflected in its strong performance in global university rankings. In 2021 ITU ranked 31st among 100 universities in Europe and 57th globally out of 956 universities in the UI Green Metric ranking system. Nationally, ITU holds the leading position in green campus initiatives in Türkiye. The UI Green Metric established by Universitas Indonesia in 2010 evaluates universities' environmental performance and sustainability across six main criteria: Setting and Infrastructure, Energy and Climate Change, Waste, Water, Transportation, and Education and Research. In the 2020 UI Green Metric country rankings ITU excelled in education, transportation, and waste management categories. Beyond UI Green Metric, ITU also featured in "THE Impact Rankings," which assess universities' contributions to the UN Sustainable Development Goals. In 2021, ITU was ranked in the 101-200 range globally among 1117 universities in THE Impact Rankings, sharing Turkey's top position with Abdullah Gül University. The university's strategic plan (2017-2021) explicitly emphasizes ITU's transformation into a green campus, with specific goals such as reducing carbon footprint and achieving 100% UI Green Metric certification by 2020.

The GreenHack hackathon was an innovative event designed to promote student-driven solutions for campus sustainability. Held at the ITU Faculty of Architecture's Taşkışla Campus, the event aimed to bolster the "ITU Green Campus" initiative and improve the university's standing in the UI Green Metric rankings. The hackathon received applications from a total of eight student groups. Out of these, six groups actively participated in the hackathon and successfully submitted their projects in the required format. Participants were divided into interdisciplinary teams of 4-6 individuals, fostering a collaborative environment with diverse skills to address various facets of the challenge. The target audience for GreenHack included students from various ITU faculties, such as urban planning, architecture, and computer engineering.

The GreenHack hackathon was designed to foster civic engagement, encourage generative co-creation, and promote collaborative discourse among participants in developing sustainable campus solutions. The event, spanning three days from December 1st to December 3rd, 2023, at ITU's Taşkışla Campus, incorporated several key elements to facilitate this "wisdom of crowds" approach.

The initial phase, Day 0 (December 1st), began with a registration period, followed by a seminar focusing on Green Campus initiatives, Participatory GIS (PGIS), and mobile applications. This seminar served as an foundational element, providing participants with a common understanding of the core concepts and tools necessary for the hackathon's objectives. By equipping all teams with essential knowledge in GIS, urban sustainability, and app prototyping it ensured a baseline understanding upon which collaborative efforts could build. The next session for hackathon team introductions and a Q&A segment directly promoted initial interactions and the sharing of preliminary ideas among participants, laying the groundwork for collaborative discourse. The official kickstart of the 24-hour hackathon on the evening of Day 0 immediately immersed teams in an intensive co-creation environment.

Day 1 (December 2nd) was dedicated entirely to the core development phase, with the critical introduction of mentor participation. Mentors, experienced in GIS technology, urban planning, and app development, provided direct guidance and support, facilitating problem-solving and encouraging the refinement of ideas through expert feedback. This mentorship model allowed teams to benefit from diverse perspectives and build upon their initial concepts with informed input. Through informal breaks the event provided organic opportunities for inter-team discussion and sharing of ideas, contributing to the generative nature of the event.

The final day (December 3rd) featured a projects video sharing and award ceremony, which served as a platform for teams to present their developed solutions to a broader audience. This public presentation aspect is vital for civic

engagement, allowing for the dissemination of innovative ideas and fostering a sense of collective achievement. The subsequent networking session between teams, juries, and the project team further encouraged continued collaborative discourse and the potential for future development of the concepts generated during the hackathon. The overall structure of GreenHack, from foundational seminars to intensive collaborative development and public presentation, was designed to harness the collective intelligence of participants, leading to more comprehensive and actionable solutions for campus sustainability.

The GreenHack event was not only about technology and sustainability but also embodied these principles in its prizes and operational aspects, effectively "closing the loop" on its core themes. The prizes were strategically designed to reinforce the hackathon's dual focus. All winning team members received free registration for ESRI ArcGIS Pro training (face-to-face or online). This particular prize directly advanced technological skill development in GIS, a fundamental tool for sustainable planning, ensuring that the acquired knowledge from the hackathon could be further honed and applied in professional contexts. Furthermore, the event explicitly incorporated sustainability into its material outcomes. The hackathon featured a 3D work produced from waste materials. This contribution represented a technical innovation in the application of sustainable practices. It showcased an innovative approach to upcycling and material reuse, involving advanced design and fabrication methods for transforming discarded materials into a valuable, three-dimensional product. This initiative physically demonstrated the principles of a circular economy and waste reduction that the hackathon aimed to promote, moving beyond theoretical concepts to embodied, tangible solutions. By integrating this demonstration of sustainable production into the event, GreenHack reinforced the practical application of sustainable practices. All participating teams also received a Certificate of Participation, recognizing their contribution to an event dedicated to environmental sustainability. This comprehensive integration of tech-centric skill development and direct sustainability practices into the event's incentives and physical presence ensured that GreenHack served as a holistic demonstration of its central themes.

The Winning PGIS Entries

The intensive, collaborative nature of the hackathon facilitated interdisciplinary collaboration, motivating participants to develop innovative digital solutions aimed at driving sustainable actions and environmentally friendly initiatives on campus. The participants were tasked with developing PGIS application prototypes and concepts that could be integrated into the existing ITU Mobile application. This requirement specifically promoted the development of digital solutions that could seamlessly translate into real-world sustainable actions for ITU. The projects were evaluated based on their innovation, functionality, design, and impact, ensuring that the proposed solutions were not only creative but also practical and aligned with tangible sustainability goals.

Three winning prototypes emerged from the GreenHack hackathon, each offering a unique approach to enhancing campus sustainability through participatory GIS: Green Tracker (First Prize), BeeKe (Second Prize), and Green Bee Systems (Third Prize). These projects demonstrate how hackathons can connect academic expertise with real-world sustainability problems, encouraging innovative digital solutions that range from reducing waste and promoting sustainable mobility to fostering a sharing economy mindset. Each prototype included technical aspects, such as data collection, spatial analysis, and application development, in addition to social aspects by encouraging behavioural change, community engagement, and collaborative problem-solving.

Green Tracker: A Comprehensive Environmental Monitoring Tool

Green Tracker, the first-prize winning project, was designed to track and improve environmental sustainability efforts within the ITU campus. Its primary goal was to enhance the environmental consciousness of individuals residing in or using the campus and to encourage their active participation in sustainable practices. The project specifically targeted critical areas such as waste management, energy consumption, green space preservation, and air quality, enabling users to monitor and share their observations and proposed solutions. The project focused on the challenges of campus environmental management by providing a platform for real-time feedback and engagement. By focusing on data collection related to specific environmental parameters Green Tracker aimed to create a more transparent and accountable system for understanding and mitigating the campus's environmental footprint. This objective directly aligns with ITU's aim of becoming a greener university and improving its environmental performance.

Green Tracker used mobile application platforms and Geographic Information Systems (GIS) to integrate data from both campus users and the university's official sources. The prototype provided a user-friendly interface that facilitated map-based participation, allowing individuals to pinpoint and report environmental issues directly on a digital map of the campus. This spatial data collection mechanism is a core component of PGIS, enabling the visualisation and analysis of geographically referenced information. The application's design conceptually included pseudocode to detail the algorithmic steps for data input, spatial querying, and updating user scores based on their contributions. Graphic narrative techniques such as screen designs and diagrams, were used to illustrate how environmental observations, proposed solutions and activities would be visually represented within the application's interface. This dual approach ensured a clear communication of both the technical functionality and the user experience of the PGIS application.

The project was successful promoting active user engagement and participation which is a critical aspect that enables equity within campus sustainability initiatives. By employing gamification elements like a scoring and reward system Green Tracker promoted eco-friendly behaviours making participation accessible and appealing to a diverse range of campus users. The dual role of PGIS, helping as a technical instrument for data visualisation and spatial analysis while also functioning as a participatory mechanism that encourages stakeholders in shaping campus sustainability initiatives, was effectively illustrated through the GreenHack prototypes. This crowdsourcing approach democratizes environmental monitoring and problem identification enabling individuals from various backgrounds to contribute their local knowledge and perspectives, thus tapping into the "wisdom of crowds."

Green Tracker was recognized by the jury as innovative, effective in ensuring active user participation, and providing the most comprehensive and positive contribution to sustainable objectives. Its value proposition lies in offering a holistic tool for environmental monitoring and community-driven action, fostering a bottom-up approach to sustainability. The innovative use of gamification to drive civic engagement for environmental good sets a precedent for how digital tools can empower individuals to become active stewards of their surroundings.

BeeKe: Gamifying Sustainable Mobility

BeeKe, the second-prize winning project, was developed to significantly promote the use of bicycles and scooters within the ITU Maslak Campus. The initiative aimed to encourage campus residents, particularly students and academic staff, to adopt sustainable transportation modes, thereby contributing to a reduction in the campus's carbon footprint and fostering healthier commuting habits. The project promoted sustainable transportation adoption by introducing an engaging and rewarding incentive mechanism. By focusing on specific behavioural changes related to mobility BeeKe aimed to integrate eco-friendly choices into the daily routines of campus members moving beyond mere awareness to active participation in sustainable practices.

BeeKe used Geographic Information Systems (GIS) and Internet of Things (IoT) devices to contribute to making campus transportation greener and more sustainable. The application had a points system that incentivized sustainable mobility behaviours such as correctly parking bicycles. The project also included a feedback mechanism for bicycle paths, encouraging users to report issues or suggest improvements directly through the mobile application. The pseudocode for BeeKe outlined the logic for tracking bicycle and scooter usage, calculating points based on distance or compliant parking and managing the gamified reward system. The graphic narrative displayed the in-app interface for tracking rides, viewing accumulated points, and accessing a leaderboard, making the sustainable commuting experience interactive and competitive.

BeeKe's strength was its innovative use of gamification to drive user engagement in sustainable mobility. By providing a tangible reward system for eco-friendly actions, it aimed to make participation accessible and appealing to a broad spectrum of campus users, encouraging active adoption of sustainable transportation modes. The feedback mechanism for bicycle paths also allowed for direct user input on infrastructure improvements, fostering a sense of co-ownership in shaping the campus's sustainable mobility landscape and ensuring that the needs of all users were considered.

The jury found the project successful, acknowledging its innovative approach to promoting sustainable transportation through gamification. While its strong focus on mobility was noted, the effective use of a clear system algorithm and its impact on encouraging greener commuting habits were particularly appreciated.

The project's capacity to incentivize and engage users in real-time contributes to a more equitable and participatory approach to campus sustainability.

Green Bee Systems: A Social Platform for Sustainability

Green Bee Systems, the third-prize winning project was developed to support and enhance green and sustainable initiatives across the ITU Maslak Campus. Its core objective was to facilitate active participation from all segments of the ITU community including students, academics, administrative staff, student clubs, alumni, and retired faculty in sustainability-related data and projects.

The platform aimed to overcome information disconnect and foster a more connected and proactive campus community regarding environmental issues. By creating a centralized hub for sustainability efforts, Green Bee Systems aimed to empower individuals to contribute their observations, share their projects and collaborate on collective solutions to campus environmental challenges.

Green Bee Systems included a user-friendly platform, similar to a social media network, and utilized Geographic Information Systems (GIS) infrastructure alongside mobile and web platforms, data analysis, and visualization tools. A key technical feature was its ability to integrate official university data with location-based data provided by users. This hybrid data integration allowed for a comprehensive spatial understanding of sustainability initiatives on campus.

The project's design included features for data collection and input, mapping and visualization, community participation, and project collaboration development. Users could share their sustainability observations and projects through the platform and contribute to other ongoing initiatives. The pseudocode outlined the backend logic for managing user-generated content, linking it to spatial data, and facilitating communication and collaboration features, while graphic narratives illustrated the social feed, interactive map, and project pages.

The core strength of Green Bee Systems lay in its strong emphasis on community engagement and project collaboration, effectively creating a "social media platform" for sustainability. By enabling all ITU constituents to share observations and contribute to projects, it democratized access to sustainability initiatives and fostered a profound sense of collective action and ownership. This participatory approach is fundamental for ensuring that sustainability efforts are inclusive and genuinely reflect the diverse needs and priorities of the entire campus community, thus promoting equity by giving every stakeholder a voice in shaping the campus's future.

The jury commended Green Bee Systems for its well-designed information flow and database and its effectiveness in facilitating user communication. Its value proposition cantered on creating a centralized, interactive hub for sustainability initiatives, fostering a more connected and proactive campus community. The innovative integration of social media dynamics with PGIS offers a unique model for broad-based civic engagement in environmental protection.

SDGs

The winning prototypes from the GreenHack hackathon demonstrate a strong alignment with both the UI Green Metric criteria and the broader United Nations Sustainable Development Goals (SDGs), showcasing the university's role as a "living lab" for real-world sustainability solutions. Green Tracker, with its focus on waste management, energy consumption, and air quality, directly contributes to UI Green Metric's categories of Waste (WS) and Energy and Climate Change (EC). Furthermore, its objective to increase environmental awareness and encourage active participation aligns with SDG 12: Responsible Consumption and Production by fostering sustainable practices, and SDG 13: Climate Action by addressing energy and air quality. The project's emphasis on user observations and solution sharing also supports SDG 4: Quality Education by promoting sustainability literacy within the campus community.

BeeKe, by promoting bicycle and scooter use, directly addresses the UI Green Metric's Transportation (TR) criterion. This initiative directly contributes to SDG 11: Sustainable Cities and Communities by fostering sustainable transportation options, and indirectly to SDG 13: Climate Action by reducing carbon emissions associated with commuting. The gamified approach to encouraging behavioural change also touches upon aspects of promoting sustainable lifestyles under SDG 12. Green Bee Systems, functioning as a social platform for sustainability initiatives,

broadly supports all UI Green Metric criteria by enhancing awareness, facilitating collaboration, and integrating diverse data. Crucially, its emphasis on broad participation from all ITU constituents; students, staff, and faculty and directly reinforces SDG 17: Partnerships for the Goals, by building inclusive multi-stakeholder partnerships for sustainable development. Furthermore by providing a platform for sharing sustainability-related data and projects it contributes to SDG 4: Quality Education by disseminating knowledge and encouraging sustainability research and innovation. The prototypes collectively demonstrate how localized, technology-driven, and participatory solutions within a university setting can effectively advance global sustainability agendas.

Discussion

The GreenHack hackathon provided rich insights into the potential of participatory methodologies and GIS-based tools for addressing complex sustainability challenges within a university campus setting. The event successfully functioned as a "living lab," demonstrating how the collective intelligence of students, guided by academic and technical expertise, can generate innovative and actionable solutions.

The three winning prototypes: Green Tracker, BeeKe, and Green Bee Systems demonstrated innovation and functionality in addressing diverse sustainability challenges on the ITU campus. Green Tracker's approach moved beyond passive data reporting to actively incentivize and reward eco-friendly behaviours, thereby promoting a more proactive and engaged campus community in environmental monitoring and problem-solving. Its functionality revolved around intuitive data collection, sharing, and visualization, directly linking user actions to measurable sustainability impacts. BeeKe demonstrated innovation in sustainable mobility by gamifying bicycle and scooter usage. Their direct behavioural intervention, supported by a feedback mechanism for bicycle paths, aimed to shift commuting habits towards more environmentally friendly modes. Green Bee Systems, on the other hand, presented a broader social platform for sustainability. Its functionality focused on enabling wide-ranging participation from all ITU constituents in sustainability projects and data sharing, effectively serving as a social media-like hub for environmental initiatives. This platform's innovation lay in fostering collaborative project development and knowledge exchange, making sustainability a collective and highly interactive endeavour. Each prototype, while distinct in its primary focus, leveraged digital functionalities to make sustainability engagement more accessible, measurable, and engaging for the campus community. These ideas show how participatory design may effectively combine technical features with social interventions, therefore promoting not just technology innovation but also cultural and behavioural changes towards sustainability.

Participatory Geographic Information Systems (PGIS) proved to be a key element in empowering student participation and co-creation during the GreenHack hackathon. In GreenHack, students were provided with campus-related maps and land use data, transforming them from passive recipients of information into active contributors to a shared spatial understanding of campus sustainability. Green Tracker exemplifies this empowerment, allowing users to geographically pinpoint environmental issues and share solutions on a map, thereby democratizing the identification and visualization of campus challenges.

The requirement for prototypes to be compatible with ITU Mobile also meant that PGIS functionalities were designed to be user-friendly and widely accessible. This lowered the barrier to participation, enabling a larger segment of the student body to contribute their observations and ideas in a spatially intelligent manner. BeeKe's feedback mechanism for bicycle paths and Green Bee Systems' integration of location-based user data further highlight how PGIS empowered students to not only report but also actively shape and improve the physical and operational aspects of their campus environment. This direct engagement with geospatial data fostered a sense of agency among participants, aligning with the broader goal of democratizing spatial knowledge in planning processes.

Beyond the PGIS tools, the very structure and execution of the GreenHack event promoted the hackathon as a participatory process, focusing on student voices and fostering a deep sense of ownership. The event commenced with a comprehensive seminar that provided a common knowledge base on green campus concepts, PGIS, and mobile applications, ensuring that all participants were equipped to contribute meaningfully. This structure enhanced ownership and responsibility among participants, as students became partners of solutions, thus deepening their engagement with the campus's sustainability goals. This was critical for cultivating an environment where ideas could genuinely build upon each other, leveraging the "wisdom of crowds."

The inclusion of experienced mentors throughout the development phase was key in guiding participants and promoting the refinement of their ideas. This continuous feedback loop encouraged generative co-creation, where initial concepts evolved through expert input and inter-team discussions. As highlighted in a related social media article, "Hacking for Sustainability: How Students Are Redefining Our Future, One University Campus at a Time," the event's atmosphere fostered a collective drive, where students actively shaped solutions reflecting their priorities and needs, thus strengthening their connection to the campus's sustainability goals. The culminating video sharing and award ceremony served not only as a presentation platform but also as a celebration of this collective effort, further cementing a sense of ownership over the proposed innovations.

The jury's evaluation of the GreenHack prototypes provided crucial insights into the potential and pitfalls inherent in student-led innovation within a hackathon framework. The assessment criteria: Innovation, Functionality, Design, and Impact, were applied rigorously, highlighting both the strengths and areas for improvement in the submitted solutions. The evaluations also pointed to potential pitfalls. The insights from the jury underscore the balance required between innovative conceptualization and practical implementability, particularly regarding resource allocation and system integration, which are common challenges in transitioning hackathon prototypes to large-scale deployment.

The GreenHack hackathon, while specifically designed for the ITU campus, offers a model for scaling participatory solutions to broader urban contexts. The GreenHack model presents a highly replicable framework for participatory planning that extends beyond the university campus to wider urban settings. Its core strength lies in the synergistic integration of PGIS technology, the intensive hackathon format, and a deliberate focus on interdisciplinary collaboration. By providing foundational knowledge through seminars, offering continuous mentorship, and fostering a competitive yet collaborative environment, GreenHack effectively cultivated a space for generative co-creation. This approach, which actively engages end-users and diverse stakeholders in problem identification and solution development, directly taps into the "wisdom of crowds," generating solutions that are both innovative and locally relevant. The emphasis on developing digital prototypes (PGIS applications) ensures that the outputs are inherently scalable and can leverage existing mobile infrastructure, similar to ITU Mobile, for wider dissemination and impact.

The success of prototypes like Green Tracker, which uses map-based reporting and gamification for environmental monitoring, and BeeKe, which incentivizes sustainable behaviour, demonstrates that such user-cantered, technology-driven solutions are not limited to campus boundaries. These models can be adapted for city-wide waste management initiatives, public transport optimization, or urban green space planning. Green Bee Systems further highlights the potential for building community-wide social platforms for sustainability, fostering collective action across a diverse urban population. By systematically structuring the problem-solving process, providing necessary technical resources and guidance, and valuing direct citizen input, the GreenHack model offers a robust and adaptable framework for urban planners and policymakers seeking to implement more inclusive, effective, and scalable participatory planning initiatives for a sustainable future.

Conclusion

This research examines the GreenHack hackathon as a participatory framework for integrating digital technologies, especially Participatory Geographic Information Systems (PGIS), into sustainable campus design at Istanbul Technical University (ITU). The findings indicate that hackathons can be helpful in promoting community participation, innovation, and collaboration in addressing complex sustainability challenges. The three winning prototypes—Green Tracker, BeeKe, and Green Bee Systems—demonstrated how PGIS-based solutions can encourage active participation, promote environmentally responsible behaviours, and facilitate knowledge sharing across a diverse campus community.

The GreenHack event functioned not only as a technical exercise but also as a social and educational process, enabling students to become co-creators of their campus's sustainable future. Combining gamified digital tools, mentoring, and multidisciplinary cooperation, the hackathon succeeded in enabling participants to create meaningful solutions that meet UI Green Metric standards and help the United Nations Sustainable Development Goals (SDGs). Furthermore, the scalable nature of these digital prototypes emphasises the potential to apply such participatory strategies beyond the university into wider metropolitan environments.

In conclusion, GreenHack demonstrates that the integration of PGIS and participatory hackathons can bridge the gap between environmental objectives and community engagement, offering a replicable model for inclusive, innovative, and impactful planning practices. Involving students as participants of sustainability solutions enhanced their sense of ownership and strengthened their commitment to long-term environmental objectives. Future research could explore the long-term implementation of such prototypes and assess their effectiveness in driving sustainable behaviour and institutional change.

Acknowledgements
The authors would like to thank the Istanbul Technical University (ITU) Scientific Research Projects (BAP) Unit for funding the project titled *Istanbul Technical University GIS-Based User-Oriented Green Campus Application Alternatives* Determination (İstanbul Teknik Üniversitesi Cbs Tabanlı Kullanıcı Odaklı Yeşil Kampüs Uygulama Alternatiflerinin Belirlenmesi), which made the GreenHack hackathon possible. We are also grateful to the mentors, jury members, and administrative staff who contributed to the success of the event. Special thanks go to all participating students for their creativity, enthusiasm, and commitment to sustainable campus planning.

Abstract
The URBioPark project investigates the link between urban biodiversity, health, and climate action, promoting an integrated approach to sustainable planning. Coordinated by the University of Brescia and funded under the 2022 PRIN program with Next Generation EU resources, the project involves Italian universities and the National Research Council (CNR). Its aim is to assess the relationship between biodiversity in urban parks and the incidence of chronic diseases by integrating health and geographic data using GIS. Results will help identify critical areas, support re-naturalization efforts, and provide guidelines for urban planning. URBioPark contributes to reducing health inequalities, enhancing well-being, and offers a replicable model for other cities by combining scientific research, civic engagement, and territorial governance.

Keywords: biodiversity, climate change, resilience, urban green areas, public health

1. Introduction

Urban areas are at the forefront of environmental and public health challenges. Rapid urbanisation, combined with the accelerating effects of climate change, has intensified the demand for adaptive strategies that enhance urban resilience and sustainability. Among the tools available to city planners and policymakers, urban green spaces have emerged as multifunctional infrastructures that deliver a wide array of co-benefits. These include ecological services—such as carbon sequestration, temperature regulation, and habitat preservation—as well as social and health-related advantages, like improved air quality, stress reduction, and opportunities for physical activity.

Recent trends in urban planning reflect a growing emphasis on nature-based solutions (NBS) as cost-effective, inclusive, and sustainable alternatives to traditional engineering approaches. In this context, biodiversity is no longer seen only as an ecological resource, but also as a strategic asset for public health and social equity. The intersection of biodiversity, climate resilience, and health has therefore become a critical focus in the pursuit of sustainable urban development.

This paper presents the objectives, methodology, and preliminary findings of the URBioPark project—a multidisciplinary initiative designed to explore the correlations between urban park biodiversity and public health outcomes. Conducted in the city of Brescia (Italy), the project integrates spatial analysis, ecological fieldwork, and health data to support a replicable model of biodiversity-inclusive planning.

2. Background and theoretical framework

The positive effects of greenery on human health are well-documented in the literature. For instance, walking in a forest has been shown to lower anxiety levels (Li et al., 2016).

Increasing evidence links biodiversity to human health and ecosystem resilience: biodiversity enhances public health through multiple mechanisms, including exposure to diverse microbiota, improved air quality, opportunities for physical and recreational activity (Aerts et al., 2018), regulation of the immune system (Mills et al., 2017).

Green spaces, particularly in urban environments, have a wide range of positive impacts on human life. Areas with diverse plant and animal species offer consistent and beneficial outcomes for mental health (Carrus *et al.*, 2015; Sandifer, Sutton-Grier and Ward, 2015; Methorst *et al.*, 2021)selected on the basis of urban forestry expert criteria according to a 2×2 factorial design. The biodiversity level (low vs. high and a decrease in stress levels (Ward Thompson *et al.*, 2012)including stress reduction, but much pertinent evidence has relied on self-reported health indicators or experiments in artificially controlled environmental conditions. Little research has been reported using ecologically valid objective measures with participants in their everyday, residential settings. This paper describes the results of an exploratory study (n=25. The presence of urban greenery is positively associated with a reduction in the symptoms of many chronic diseases (Maas *et al.*, 2009) such as the type 2 diabetes (Astell-Burt, Feng and Kolt, 2014), cardiovascular (Giacinto *et al.*, 2021) and inflammatory diseases (Haahtela, 2019). In particular, the presence of greenery is positively associated with a higher chance of survival in ischemic stroke patients (Wilker *et al.*, 2014).

Urban biodiversity also plays a key role in reducing social inequalities in health. According to Becker et al. (2019), access to green environments is associated with lower public healthcare spending and better health equity. In addition, green areas that promote health contribute to reducing health inequalities associated with income (Mitchell and Popham, 2008)or so-called green space, has an independent effect on health and health-related behaviours. We postulated that income-related inequality in health would be less pronounced in populations with greater exposure to green space, since access to such areas can modify pathways through which low socioeconomic position can lead to disease.\nMETHODS: We classified the population of England at younger than retirement age (n=40 813 236.

The World Health Organization has formally recognised urban health as a central component of sustainable development, calling for stronger integration of health metrics into planning practices (Neira, 2015). In this context, biodiversity serves as both an ecological and socio-political determinant of health, being essential not only for the functioning of ecosystem but also for building resilient, equitable, and liveable cities.

3. Project description: URBioPark objectives

URBioPark is a multi-partner project funded by the 2022 PRIN programme and supported by Next Generation EU. The consortium includes the University of Brescia (coordinator), the National Research Council - Institute for BioEconomy (CNR-IBE) based in Florence, and the Universities of Padua and Verona.

The project aims to investigate the relationship between urban biodiversity and public health, focusing on the city of Brescia as a representative mid-sized European city actively engaged in sustainability and climate adaptation. Over the past decade, Brescia has launched several initiatives aimed at promoting environmental resilience, reducing emissions, and improving the quality of life for its residents. As part of its climate transition strategy, the city has expanded its green infrastructure, promoted sustainable mobility, and implemented nature-based solutions in urban planning. Brescia's participation in national and European climate networks further underscores its commitment to ecological transition. The relevance and potential impact of the URBioPark project have been recognized through formal endorsements by the Municipality of Brescia, Fondazione Cariplo, Urban Center Brescia, and AmbienteParco—key institutional and civic actors engaged in shaping the city's sustainable future. This strong local support highlights Brescia as an ideal case study for exploring how urban biodiversity can contribute to public health and territorial equity.

3.1 Project structure

The URBioPark project is structured around five interrelated Work Packages (WPs), designed to investigate and strengthen the link between urban biodiversity and public health, with a particular focus on the city of Brescia. The project will run over 24 months and follows a multidisciplinary and participatory approach.

The five WPs are as follows:

1. WP1 – Project coordination and management (UNIBS): Coordination of all research units, financial oversight, and risk monitoring through regular meetings and reporting.
2. WP2 – Brescia urban parks analysis (UNIBS): Mapping urban morphology, green space distribution, socio-economic and health data, and existing vegetation and soil characteristics using GIS and statistical tools. This package sets the baseline for the empirical research.
3. WP3 – Biodiversity and ecosystem services (CNR-IBE): Field and lab analyses on plant and soil biodiversity in selected urban parks. This includes microbial DNA sequencing, soil mesofauna identification, and eco-physiological plant assessments, to evaluate ecosystem services and health impacts.
4. WP4 – Good Practices Manual Development (UNIVR): Synthesis of research outputs to create actionable planning guidelines. These will support urban decision-makers in designing and managing biodiversity-friendly green spaces and integrating biodiversity into Strategic Environmental Assessments (SEA).
5. WP5 – Dissemination and Citizen Science (UNIBS): Stakeholder engagement through public events, citizen science activities (BioBlitz), and participatory surveys. The WP also includes educational actions and outreach in collaboration with local institutions to increase public awareness and co-design strategies with communities.

Each Work Package contributes to building an integrated, evidence-based framework for planning healthier, more biodiverse, and climate-resilient urban environments. By integrating diverse datasets and disciplinary approaches, URBioPark aims to develop practical guidelines and indicators that support biodiversity-inclusive urban governance, ensuring both scientific rigor and real-world applicability, and offering a replicable model for other cities.

4. Methodology

The URBioPark project adopts a multidisciplinary methodology to explore the complex interrelations between urban green areas, biodiversity, and human health. The study combines ecological, environmental, socio-economic, and epidemiological data to produce a comprehensive framework for biodiversity-inclusive urban planning. The method used is structured in the following phases: 1) selection of the parks on which to carry out the survey; 2) analysis of the spatial context in which the parks are located and health assessment; 3) Socio-economic and health analysis; 4) Economic value of ecosystem services analysis.

In the first phase, the parks are selected based on criteria such as size, vegetation structure, accessibility, and heterogeneity of the surrounding urban context; a 500m buffer zone is then defined around each park.

In the second phase, the following indicators are calculated for each park and each buffer zone:

- Land Surface Temperature (LST)
- Sky View Factor (SVF), measuring sky visibility from ground level and indicating a location's ability to dissipate heat.
- Tree Canopy Cover (TCC), to quantify the extent of arboreal coverage. Areas with denser tree cover consistently exhibited lower surface temperatures, highlighting the cooling function of vegetation and the importance of canopy density in mitigating urban heat island effects
- NDVI (Normalized Difference Vegetation Index) and NDMI (Normalized Difference Moisture Index). These indices allowed to evaluate the vitality and moisture levels of vegetation, providing a more detailed understanding of the parks' ecological conditions

In the third phase, the vegetation and soil components of the selected urban parks are analysed through a detailed ecological assessment that examine plant species composition, soil characteristics, and the presence of soil microarthropods. The collected data are subsequently analyzed and integrated to develop biodiversity indicators, offering a comprehensive picture of the ecological status of the parks and their contribution to overall urban biodiversity.

In the fourth phase, consistently with the project's focus on health, it is investigated how the exposure to urban green spaces—particularly those with higher levels of biodiversity—can influence the physical and mental well-being of nearby residents. This analysis takes place by employing spatial and temporal statistical analyses using georeferenced socio-demographic data to define and classify the socio-economic profile of the areas surrounding the selected parks.

In the fifth phase, the economic value of the ecosystem services provided by urban parks is estimated, using a questionnaire-based survey. Since these services are not traded on the market and lack a clear reference price, a simulated market approach is adopted to evaluate citizens' willingness to pay for their maintenance or enhancement. The survey features a discrete choice experiment involving 500 participants and examines preferences for five possible interventions, each associated with a hypothetical tax. In addition to these choices, the questionnaire gathers information on socio-demographic characteristics, attitudes toward biodiversity, and patterns of park usage. An informational treatment is also included to assess how participants understand and incorporate information into their responses. The analysis identifies attitudinal clusters, investigates correlations with socio-demographic and spatial factors, and performs a cost-benefit analysis of the proposed interventions based on the current state of the parks.

5. First results

The first results obtained by the URBioPark project derive from the phases of urban and morphological analysis of the selected parks, supported by the integration of data relating to the health of the population and the socio-demographic characteristics of the surrounding areas. (phases 1, 2, 4). This multidisciplinary approach has permit us to collect valuable information that, although preliminary, offers a first picture of the interconnections between the physical structure of cities, the green infrastructures present in the urban fabric and the well-being of the population.

5.1 Park selection

Four parks in the city of Brescia — Parco Gallo, Parco Giffoni, Parco Croce Rossa, and Parco dei Poeti — were selected based on criteria such as size, vegetation structure, canopy density, accessibility, and heterogeneity of the surrounding urban context. Data for the four parks are included in Table 1.

Tab. 1. Surface data about the four sel ected parks in Brescia

Park	Area (m^2)	Permeable surface	Semi-permeable surface	Non-permeable Surface	Trees (number)
Parco Gallo	34701	85%	2%	13%	191
Parco Giffoni	18574	90,6%	0,2%	9,2%	198
Parco dei Poeti	28895	84%	15,6%	0,4%	549
Parco Croce Rossa	32989	97%		3%	883

Fig. 2. Location of the four selected parks in Brescia

5.2 Spatial analysis and vegetation assessment

A 500m buffer zone was defined around each park to analyse environmental conditions and health outcomes. Firstly, using GIS technologies, the following elements were mapped within each buffer: land use, building heights, and street networks. Secondly, key climate indicators, have neem derived from satellite imagery, including Land Surface Temperature (LST) and Sky View Factor (SVF) — the latter measuring sky visibility from ground level and indicating a location's ability to dissipate heat. The Tree Canopy Cover (TCC) was also calculated to quantify the extent of arboreal coverage. Areas with denser tree cover consistently exhibited lower surface temperatures, highlighting the cooling function of vegetation and the importance of canopy density in mitigating urban heat island effects.

Tab. 2. Data about the four buffer parks

Park buffer (500 m)	LST	SVF	TCC	NDVI	NDMI
Parco Gallo	39,3°C	0,71	18%	0,14	0,30
Parco Giffoni	34,9°C	0,83	18%	0,38	0,54
Parco dei Poeti	34,8°C	0,87	12,05%	0,13	0,55
Parco Croce Rossa	37,8°C	0,88	19,9%	0,47	0,50

In addition to these spatial analyses, parks' vegetation health was assessed using remote sensing indices such as the NDVI (Normalized Difference Vegetation Index) and NDMI (Normalized Difference Moisture Index). These indices allowed to evaluate the vitality and moisture levels of vegetation, providing a more detailed understanding of the parks' ecological conditions. In particular, NDVI for all parks is between 0.3 - 0.4, indicating low vegetation cover with low vigour or very low vegetation cover with high vigour. NDMI for Parco Giffoni and Parco dei Poeti is between 0.4 – 0.5; these values indicate medium-high vegetation cover with high water stress or medium vegetation cover with low water stress. Parco Gallo and Parco Croce Rossa have slightly higher NDMI values, between 0.5 and 0.6, indicating high vegetation cover and no water stress. NDVI and NDMI were also calculated for the buffers (see table 2). In particular, NDVI around Parco Gallo and Parco dei Poeti it presents very low values (between 0.1 and 0.2) indicating almost no vegetation cover.

Tab. 3. Parks vegetation assessment

Park	NDVI	NDMI
Parco Gallo	0,34	0,53
Parco Giffoni	0,31	0,48
Parco dei Poeti	0,33	0,48
Parco Croce Rossa	0,38	0,55

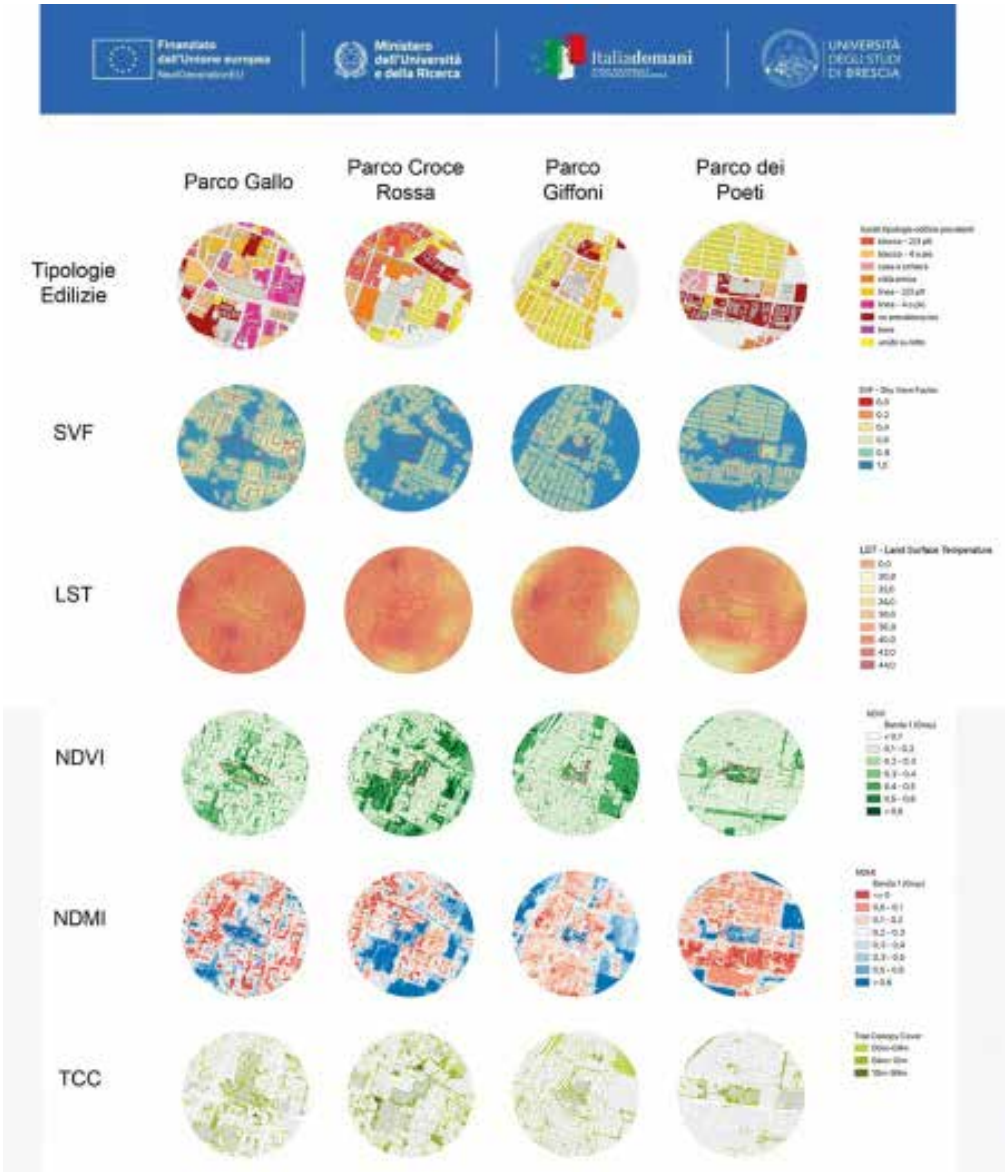

Fig. 4. Analysis of the urban fabric surrounding urban parks within a 500-meter buffer zone. Comparison of indices: Building Typologies, Sky View Factor (SVF), Land Surface Temperature (LST); Normalized Difference Vegetation Index (NDVI), Normalized Difference Moisture Index (NDMI), and Tree Canopy Cover. Source: Author's own elaboration.

5.3 Socio-economic and health analysis

To identify potential correlations between health outcomes and both proximity to and use of green spaces, aggregated data on health conditions and medication have been used. The source is the health database (BDA) of the Brescia Local Health Protection Agency (ATS). To capture these dynamics, disease frequencies are calculated for residents living within two defined buffer zones—250 meters and 500 meters—around each park. For each area, the Standardised Prevalence Rate (SPR) is computed by comparing the number of observed cases of chronic diseases to the expected number based on citywide averages. This methodology enables a robust comparison across different neighborhoods and helps assess whether variations in health status may be associated with environmental and ecological conditions, including biodiversity levels.

Tab. 4. Chronic disease cases in the observed buffers

Park buffer	Observed cases	Expected cases	SPR
250 m			
Parco Gallo	520	542.67	0.96
Parco Giffoni	570	520.88	1.09
Parco dei Poeti	375	342.17	1.10
Parco Croce Rossa	322	280.42	1.15
500 m			
Parco Gallo	2,754	2,808.02	0.98
Parco Giffoni	1,484	1,404.49	1.06
Parco dei Poeti	1,522	1,480.75	1.03
Parco Croce Rossa	1,091	1,069.04	1.02

Tab. 5. Demographic characteristic of the population within the 250 m. buffers

Park buffer (250m)	Population	Females (%)	Foreigners (%)	Median Age
Parco Gallo	1,250	54.2	29.3	48,9
Parco Giffoni	1,178	53.2	18.8	50,0
Parco dei Poeti	766	54.2	13.8	51,5
Parco Croce Rossa	619	54.8	2.9	50,6
Brescia (total)	**192,322**	**51,9**	**19,9**	**48,8**

6. Discussion

The first results of the URBioPark project are based on the urban and morphological analysis of the selected parks and the integration of health and socio-demographic data. These preliminary findings provide an initial understanding of the relationships between urban structure, green infrastructure, and public health.

The ecological assessments related to vegetation and soil biodiversity—crucial for establishing detailed biodiversity indicators—are still ongoing. Their integration will offer a more complete picture of how different components of urban biodiversity contribute to residents' well-being and health outcomes.

Preliminary analyses conducted across the four selected urban parks in Brescia reveal insightful correlations between urban biodiversity, socio-demographic factors, and public health outcomes.

From a demographic standpoint, the population distributions in the four park areas are broadly comparable to the rest of the city in terms of age and male/female ratio. However, significant differences emerge in the percentage of foreign residents: for example, the area surrounding Parco Gallo shows a notably higher share (29.3%) compared to the city average (19.9%), while the Parco Croce Rossa area registers just 2.9%.

In terms of environmental indicators, parks with higher NDVI values and greater canopy density were associated with lower Land Surface Temperatures (LST) and improved microclimatic comfort. Notably, areas with low Sky View Factor (SVF)—indicating a denser urban form—still benefited from significant heat mitigation when supported by robust green infrastructure. These findings confirm the essential role of vegetation and tree coverage in regulating urban temperatures.

From a health perspective, results from the ATS Brescia database suggest emerging patterns. In the 250 m buffer zones, areas around Parco Croce Rossa and Parco Giffoni show a 15% and 9% higher prevalence of at least one chronic disease, respectively—though these increases are not statistically significant. When disaggregated by disease type (hypertension, diabetes, hypercholesterolaemia, cardiovascular and respiratory diseases), the frequencies are slightly above expected values in some areas but remain within non-significant margins.

However, the 500 m buffer analysis confirms a statistically significant 6% higher prevalence of chronic diseases around Parco Giffoni, alongside a 10% increase in hypertension and a 12% increase in cardiovascular conditions. Interestingly, the Parco Croce Rossa area shows a 20% lower prevalence of diabetes compared to the city average.

Regarding mental health, the use of antidepressant medication was also assessed. Slightly higher percentages of antidepressant prescriptions were recorded near Parco Croce Rossa and Parco dei Poeti, though again, not statistically significant. Further logistic regression analysis indicates that women over 65 of Italian nationality are the most frequent users, which may account for some of the geographic variation. When broken down by frequency—at least one vs. at least two prescriptions over three years—only Parco dei Poeti shows a confirmed excess (around +8%) for the higher threshold.

Complementing the quantitative health data, survey responses collected from residents reinforce the correlation between perceived green space quality, biodiversity awareness, and individual well-being indicators.

Residents living closer to greener, more biodiverse parks reported reduced symptoms of chronic stress, improved mental health, and increased physical activity.

Lastly, the data also highlight social and environmental disparities. Lower-income districts with reduced green coverage and fewer biodiversity features tend to exhibit higher rates of chronic disease and report lower satisfaction with environmental conditions. These findings underscore the importance of equitable access to biodiverse green spaces as a means to support both public health and climate resilience in urban environments.

7. Project objectives: towards integrated urban governance

A core objective of the URBioPark project is to generate knowledge and tools that inform urban governance by integrating biodiversity and health into planning and policy frameworks. The project aims to provide actionable strategies that can be adopted at multiple levels—urban design, public health, and community engagement—to foster healthier, more resilient cities.

URBioPark's results are intended to support the inclusion of biodiversity and health criteria within Strategic Environmental Assessments (SEA), masterplans, and local regulatory instruments. The project envisions the establishment of a shared governance model that unites urban planning, environmental management, and public health.

Key strategic recommendations include:

- Urban planning: introduce mandatory biodiversity-health impact assessments in zoning revisions and urban redevelopment projects.
- Green infrastructure: promote tree planting, canopy connectivity, and soil permeability, especially in socio-environmentally vulnerable areas.
- Health integration: develop partnerships with local health authorities to monitor and respond to environmental determinants of chronic disease.
- Citizen engagement: encourage participatory approaches through citizen science, enabling communities to contribute to biodiversity monitoring and park stewardship.
- Education and awareness: launch targeted campaigns and integrate ecological literacy into school curricula to promote awareness from an early age.

Through these actions, URBioPark also aims to establish an interdepartmental governance framework, bringing together expertise and policy from health, urbanism, and environmental sectors under a unified strategy for sustainable and inclusive urban development.

8. Conclusions and future directions

URBioPark project exemplifies how urban biodiversity can be leveraged as a cross-sectoral asset, capable of addressing climate resilience, health equity, and urban sustainability.

By linking scientific research with practical applications and policy recommendations, the project contributes to a paradigm shift in urban planning where nature and public health are integrated rather than treated as separate domains.

The project's outcomes will culminate in a manual of best practices to guide municipalities in biodiversity-sensitive planning. Moreover, its GIS-based methodology offers a powerful decision-making tool for identifying areas in need of intervention and monitoring the impacts of implemented actions.

Future steps include refining the biodiversity-health indicator set, expanding the study to other cities involved in the project (Verona, Padua), and establishing transdisciplinary training programmes for professionals involved in urban health and spatial planning.

URBioPark serves as both a research initiative and a policy incubator. By embedding biodiversity into the core of planning practices, cities can become healthier, more equitable, and more resilient in the face of future challenges.

Between Walls and Water:
Technocratic planning of stormwater infrastructure and the reshaping of everyday life in flood-prone Mumbai

Lekha Samant
Affiliation: University of Amsterdam
Email: l.s.samant@uva.nl

Abstract
Mumbai has been experiencing an increasing frequency of extreme climate events that result in recurrent monsoon flooding. Challenging the prevailing view of flooding as an infrastructural crisis, this paper argues that flooding is instead an inevitable consequence of systemic failures in the city's technocratic planning regime. It critically examines the BRIMSTOWAD masterplan in developing the city's stormwater infrastructure. It attempts to understand how the absence of such infrastructure exacerbates existing spatial vulnerabilities, reshaping the everyday life of marginalised communities living in flood prone areas. Through a case study of the 2019 Malad wall collapse, the paper analyses how stormwater drainage, housing crisis, and regulatory planning practices intersect during a flood event, demonstrating that Mumbai's flooding crisis is deeply tied to its urban development model.

Keywords: stormwater infrastructure, technocratic planning, urban flooding

Introduction

The metropolitan city of Mumbai has been grappling with an increasing frequency of extreme rainfall events attributed to climate change and the subsequent flooding that follows them. Historian Miriam Dossal, narrating her observation of the city in 1990, wrote that 'water and drainage continue to be the bane of Bombay[1] and every monsoon the problems are aggravated' (Dossal, 1996). Today, even after two decades, her observations remain just as valid for Mumbai. In the period from 2000-2024, Mumbai has recorded 18 extreme rainfall events (greater than 204.5mm rainfall/day) and 11 very heavy rainfall events (115.6-204.4mm rainfall/day)(*IMD*). Based on IMD (Indian Meteorological Department) data (1985–2024), Mumbai's rainfall has become highly skewed and unevenly distributed, meaning a small number of extreme rainfall days contribute disproportionately to the total monsoon rainfall[2]. Every monsoon, heavy rains almost always wreak havoc in everyday life leaving several neighbourhoods inundated and residents struggling to adapt to the high waters. What should ideally be rare practices of coping have become an annual ritual making Mumbaikars habituated to regular flooding (Jamwal, 2017). Meanwhile, actions of the State have aimed at strategically deregulating environmental laws and policies meant to protect the city's riparian and coastal zones—which are vital socio-ecological systems actively sustaining livelihoods and mitigating flood impacts—for intensively constructing infrastructure and real estate projects aimed at the city's economic development (Indorewala, 2018; Menon et al., 2015; Nijman, 2002; Wagh, 2018; Wagh & Indorewala, 2025; Zope et al., 2015). Scholars and activists analysing the narratives of disaster and resilience of Mumbaikars expound that any city that regularly demands such a price for survival and such a toll on human life, is not unprepared for calamity – it is unprepared for normality (Indorewala & Wagh, 2018).

The response by the state's planning system to "fix" the problem of flooding has been highly technocratic—envisioned and implemented primarily through the augmentation of the city's stormwater drainage through mega infrastructural projects such as the BRIMSTOWAD (Brihan Mumbai Stormwater Drainage) masterplan (Gupta, 2007). Despite the massive investment of public funds into the building of stormwater infrastructure, 'technological-fixes' like the BRIMSTOWAD have been grossly ineffective in keeping majority of the city's areas from being water-logged and inundated during the monsoon, leaving its inhabitants with the perpetual daunting question: *why does Mumbai flood year after year?* Through this paper, I attempt to expound upon this seemingly simple yet fundamentally complex question of urban flooding by examining it through the lens of urban planning. Arguing against the mainstream notion that attributes flooding as an infrastructural crisis persisting due to "lack of planning", "corruption" or "non-implementation of infrastructure projects", I contend that flooding is a recurring symptom of the near-perfect implementation of a technocratic planning system—which produces infrastructural projects such as the BRIMSTOWAD—discriminately aimed at maximising the economic potential

1 The city's original name was changed from 'Bombay' to 'Mumbai' in 1995. The article will address the city as 'Bombay' while referring to contexts before the mid 90s, and 'Mumbai' while discussing contexts post the mid 90s.
2 Fewer than 5% of rainy days (approximately 4–6 days/year) deliver more than 50% of Mumbai's monsoon rainfall, with extreme events clustering in July and August. A single event accounts for 30-50% of the monthly rainfall in which occurred.

of Mumbai's land at the cost of systematically undermining the *socio-ecological* relationship between land and water. The paper explores the question of urban drainage within this paradigm by critically examining the role of technocratic planning in the development of stormwater infrastructure and its impacts on everyday life. It intends to understand how the 'constructed' presence or the 'planned' absence of formal stormwater infrastructure exacerbates existing spatial vulnerabilities specifically targeting marginalised classes and communities living in flood prone areas, and alters conditions of everyday life in the city particularly during flood events. In doing so, I seek to unravel the intersections between flooding and other connected urban crises pertaining to the city's built environment by studying how their relations shape the planning of the city's stormwater drainage and in turn get shaped by its outcomes.

The paper's theoretical framework delves into the critiques of technocratic planning in the development of public infrastructure for spatial water, layered by an engagement with perspectives of political ecology concerned with power relations underlying the practices that make and unmake such infrastructures. Furthermore, it synthesises insights from the socio-technical construction of infrastructural 'fixes' in planning literature and the socio-ecological construction of flooding within political ecology perspectives for building an analytical approach to unravel the material practices that shape everyday life. Discursively engaging with the notion of everyday life as the level where impacts of floods are observed, the paper explores how material practices, of both planning and the everyday, can serve as a lens to trace the linkages between stormwater drainage and the consequences of inter-related crises unfolding during flood events.

Guided by the theoretical framework outlined above, I address the research questions mentioned above by adopting a two-part methodological approach. The approach focuses on observing everyday practices of vulnerable inhabitants alongside state planning practices, revealing the complexities of stormwater drainage in Mumbai from its historical roots to its spatially uneven consequences. The first part (see section 3) critically examines Mumbai's BRIMSTOWAD (Brihan Mumbai Stormwater Disposal) project through a qualitative policy analysis, assessing its planning, implementation, challenges, and outcomes. In the second part (see section 4), I take the case of the 2019 Malad wall collapse, a disaster triggered by extreme rainfall that caused a periphery wall to collapse onto an adjacent settlement, resulting in significant loss of life and property. Taking this case, I empirically investigate the interplay between flooding and inter-connected compounding urban crises. Through this case study, the paper traces material practices of planning and everyday life to analyse living conditions before, during, and after the disaster. Using qualitative spatial analysis, the paper draws systemic linkages between flooding and other urban crises related as housing and environmental (de)regulation. The analysis is followed by a synthesis of its findings to understand how flood events do not merely expose but actively intensify these underlying compounding crises. In conclusion of the paper, I highlight the need to critically examine everyday life in cities to better frame the problem of flooding, and the urgency for reimagine stormwater drainage by prioritising the needs of marginalised communities in the city.

Theoretical framework

The planning of water in relation to the urbanisation of land has typically followed a modernist-technocratic infrastructural approach based on manipulating, modifying, containing and controlling water's accumulation and flow (Anand, 2017; Björkman, 2015; Kaika, 2005; Mathur & Cunha, 2009). Studying the historical flows of water in the various visions of city planning over the last century, Maria Kaika observes that as water became controlled, tamed, and domesticated, its presence and availability became "normalised" and taken for granted (Kaika, 2005). This is reflected in infrastructure planning dealing with water where practices have remained largely as rational, centralised, expert-driven systems up until the present, despite the planning regime becoming more socially oriented over the second half of the 20th century (Furlong et al., 2016). Critiques of technocratic approaches to stormwater planning have fundamentally challenged how urban planning as a discipline conceptualises and manages the relationship between water and land (Baviskar, 2017; Ranganathan, 2015). Over the second half of the last century, new directions in planning theory such as advocacy planning (Davidoff, 1965), communicative planning (Forester, 1980), and justice planning (Fainstein, 2010; Harvey, 2009; Marcuse et al., 2009) have sought to expose power relations latent within technocratic and rational planning practices, thereby challenging the institutional logics that prioritise certain interests over others. They have questioned and scrutinised the values, logic, ideals and power relations that underscore institutional processes and practices of technocratic planning, by asking—in whose interest are these practices undertaken, at what and whose cost, and aimed at what kind of environmental transformation? When combined with political ecology perspectives this critique from the

planning domain gains sharper focus, revealing how everyday injustices, from flood vulnerability to housing precarity, are not accidental outcomes but systemic consequences of planning paradigms (Henrique, 2023; Rusca & Cleaver, 2022).

Political ecology is concerned with the analysis of power in constituting of social and environmental conditions and how unequal power relations are often linked to conflicts over access to, and the use of, diverse environmental resources (Bryant, 1998). Comprehensive research on the political ecology of water has produced different knowledge perspectives—hydro-social territories (Boelens et al., 2016), social-hydrology (Liao & Schmidt, 2023; Linton & Budds, 2014), and waterscapes (Goh, 2019; Swyngedouw, 1999), to name a few—that look at water as a hybrid construct, emphasising its relational character with society, where technical representations of its economic, biophysical and engineering dimensions intersect with questions concerning social power and political economy (Karpouzoglou & Vij, 2017; Swyngedouw, 1999; Swyngedouw et al., 2002). These perspectives argue against the reductive logic—implicit in the technocratic usage of planning instruments such as land-use, zoning and built form regulations—that treats water as an external element to be contained and controlled through engineered solutions rather than as an intrinsic component of urban socio-ecological systems (Gandy, 2014; Swyngedouw, 1999; Swyngedouw et al., 2002; Wagh & Indorewala, 2025). They provide useful insights for understanding the ways in which water related problems may be socio-politically constructed and linked to other urban crisis, and how this process of social construction may facilitate the control of people and environments by powerful actors (Bryant, 1998). These perspectives enable us to interrogate why the state consistently frames flooding as an extrinsic problem stemming from natural forces, rather than acknowledging it as an intrinsic outcome of its own planning paradigms and interventions. To question the identification and framing of flooding as a problem and its intersections with other urban crises means considering the threatened livelihoods linked to altered social and environmental conditions that figure centrally in political ecology thinking (Bryant and Bailey, 1997). Feminist political ecologists further illustrates how situated material responses to everyday flood threats as well as organised practical resistance tactics emerge from everyday spaces (Henrique, 2023). Peter Marcuse's assertion that 'the city is the scale where questions of justice are felt concretely as part of everyday life' (Marcuse et al., 2009) underscores the need to examine how material practices shape lived experiences, especially during periods when multiple urban crises unfold simultaneously. In this paper, I employ 'material practices' as an analytical lens to integrate the aforementioned theoretical perspectives, enabling observation of how urban crises unfold simultaneously and how stormwater infrastructure impacts everyday life in Mumbai during flood events.

The BRIMSTOWAD masterplan and the transformation of stormwater infrastructure in Mumbai

The landscape of Mumbai has undergone extensive environmental transformation since the time it was acquired as 'Bombay island' (see Figure 1) in dowry by the English king Charles II, on his marriage to the Portuguese princess Catherine of Braganza in 1661 and subsequently leased to the East India Company (Dossal, 1996). In its growth as a metropolitan region, now spread across 4355 sq.km (see Figure 2), dealing with spatial water in all its hostile and distinct "natures"—which included coastal landscapes, tidal marshes, riparian areas, mangrove forests, and swamplands—was an inevitable task encountered in processes of reclaiming and expanding the colonial city (Indorewala & Wagh, 2022; Meera Kosambi, 1986). Most of the reclaimed lands in the city lie below the High Tide Line[3] whose outfall of stormwater is not naturally leading to the sea on the eastern and western shores (BMC, 2018; Dossal, 1996). Mastering stormwater drainage, therefore, has always been a prerequisite for making its urban landscape inhabitable, sanitary and healthy (Dossal, 1996; Indorewala et al., 2016).

3 The Town Hall Datum (THD), established at the historic Bombay Town Hall (now Asiatic Society) in Mumbai's Fort area, serves as the city's official vertical reference point for elevation measurements and is set at +3.658 meters above Mean Sea Level (MSL). The High Tide Line (HTL) is the highest elevation reached by seawater during spring tides In Mumbai (BMC, 2018).

Figure 1: The Bombay Group of Islands (Indorewala et al., 2016)

Figure 2: Map of Mumbai Metropolitan Region (MMR) (Indorewala et al., 2016)

Post the catastrophic 2005 mega flood, Mumbai's stormwater infrastructure has undergone significant transformation and expansion, radically reshaping the city's drainage patterns through engineered solutions for controlled water disposal. This comprehensive infrastructure is governed by the BRIMSTOWAD masterplan which regulates how rainwater percolates, accumulates, and ultimately drains across the urban landscape (Gupta, 2007). The Municipal Corporation of Greater Mumbai's (MCGM) Storm Water Drains (SWD) Department is responsible for the implementation of both the physical infrastructure and the operational practices that comprise this masterplan, from construction and maintenance to flood management protocols. The stormwater drainage system based on the BRIMSTOWAD masterplan is an integrated network of engineered and natural drainage pathways. The network comprises of constructed open/closed concrete drains which are in many places (particularly in parts of Greater Mumbai) connected to natural drains (nallhas, rivers, streams and creeks) for the purpose of channelling, discharging and releasing rainwater into the sea (BMC, 2018). It includes creating concrete embankments along the nallahs to contain outflows, and pumping stations near the mouth of estuaries to manage tidal backflow during heavy rains.

Despite significant public investment, Mumbai's BRIMSTOWAD masterplan has proven ineffective in flood prevention due to two fundamental shortcomings. The first lies in its outdated hydraulic design which was initially engineered to account for two events per year of 50mm/hour rainfall intensity, was recommended to account for 100mm/hr rainfall post the 2005 flood (Chitale, 2006). It, however, was not modified in plan and eventually revised slightly to accommodate 65mm/hour in few selected zones only (BMC, 2018; Chitale, 2006). This revision remains grossly inadequate, as historical rainfall data from the IMD for 1999-2004 demonstrates that peak intensities exceeded 72mm/hour rainfall 80% of the time, while contemporary climate extremes regularly surpass 100mm/hour rainfall (Gupta, 2007; *IMD*). The second, more fundamental flaw stems from its narrowly technocratic approach that conceptualises stormwater solely as excess to be disposed off, while completely disregarding its complex socio-ecological relationships with the city's landscapes and people (Chitale, 2006). This reductive engineering paradigm has produced multiple cascading failures: the concrete channelisation of natural drains and construction of embankments have displaced vulnerable informal settlements while protecting formal developments (Parthasarathy, 2009), degraded critical mangrove ecosystems and disrupted tidal flows in ways that ironically exacerbate flooding in certain suburban areas (Indorewala & Wagh, 2018), and institutionalised spatial inequities through disproportionate allocation of pumping stations to high real-estate neighborhoods in the south at the expense of northern suburbs dependent on gravity-based drainage. These systemic issues reveal the project's deeper contradiction where its intensive infrastructure conflicts with pressing needs for affordable housing and ecological conservation, while its implementation reflects and reinforces Mumbai's unequal political economy (Stecko & Barber, 2007). MMRDA's (Mumbai Metropolitan Region Development Authority) development of the Bandra Kurla Complex by landfilling 600 acres of the Mithi river (which flooded in 2005) is exemplary in this

case (Lewis, 2019). The resulting planning practices have not only proven exploitative in their execution but have also transformed flooding from a natural phenomenon into a techno-politically 'engineered' disaster.

Case study: Malad Wall Collapse, 2019

Mumbai recorded two extreme rainfall events on 29th June 2019 and 2nd July 2019 with the Santacruz observatory of the Indian Meteorological Department in the suburban city region recorded 234.8mm and 375.2mm of rain respectively, along with heavy showers observed on the night of 1st July 2019 as well[4] (*IMD*; "Monsoon Covers Ground," 2019) . At about 11.45pm on the night of 1st July, the 2.3km long (about 4-6m of varying height) periphery wall of the MCGM's Malad Hill Reservoir facility in Malad, Mumbai breached and collapsed at two points, in the adjoining settlements of Ambedkar Nagar and Pimpripada, a few hundred meters apart causing terrible devastation and loss of human life (Malad Wall Collapse, 2019). The wall collapse completely destroyed 140-160 houses in Ambedkar Nagar[5] and 65 houses in Pimpripada while flooding and damaging 80-95 houses in both areas. It resulted killing 31 people and leaving around 130 injured from about 86 families (Barnagarwala, 2019; Malad Wall Collapse, 2019; Marpakwar, 2021; Press Trust of India, 2019).

Figure 3: Photos of the uncollapsed wall (LEFT) and of the collapsed portions (MIDDLE and RIGHT) (Malad Wall Collapse, 2019)

Figure 4: Satellite imagery showing transect of the site with encircled locations of wall collapse

4 As per observations from the IMD, the Malad area in Mumbai received as much as 183 mm of rainfall in a short span of 3 hours between 10 pm on 30th June and 1pm on 1st July (IMD; Malad Wall Collapse, 2019).

5 As per survey conducted by Centre for Promoting Democracy (CPD) and Pani Haq Samiti (PHS) in July 2019 post the wall collapse event.

Methodology

This case study builds upon the observations and findings of the independent fact-finding committee's 2019 interim report titled 'Malad Wall Collapse: A state induced disaster' (Malad Wall Collapse, 2019). In this study, I employ an integrated methodological approach to examine the Malad wall collapse and its ongoing socio-spatial consequences. Through extensive fieldwork conducted during January-February 2025, I systematically documented the reservoir site and surrounding settlements using a transect-based spatial analysis framework. This approach enabled a critical examination of both the physical landscape of destruction and the lived experiences of affected communities, tracing how the disaster continues to shape everyday life along its path of devastation. The study combines archival investigation of historical news reports and relevant court cases with qualitative data gathered through semi-structured interviews and participatory walks along the transect with different actors including BMC engineers, municipal reservoir workers, and members of affected families. These techniques were used to corroborate and expand upon the fact-finding report. The transect-based spatial methodology functions as a critical analytical framework, bridging this study's theoretical foundations with empirical observations to systematically trace the interconnected relations of stormwater infrastructure to practices of housing and environmental regulation on site.

Consequences of 'constructed' presence and 'planned' absence of stormwater infrastructure

MCGM's Malad Hill Reservoir facility[6] is situated on the western edge of the Sanjay Gandhi National Park (SGNP) in Mumbai, spread across 46 acres—of which roughly half falls under forest land reservation—on a hilly terrain that's around 70-80m above mean sea level, with its boundary guarded on all sides by the high wall (Malad Wall Collapse, 2019). The observations from the fact-finding committee's interim report highlight significant deficiencies in the stormwater infrastructure, reveal a drainage system that is grossly inadequate in both design and maintenance inside the facility and completely absent in the adjoining settlements that lie downhill. My spatial documentation of the facility corroborates these observations, documenting a fragmented network of discontinuous drains and concrete culverts that remain obstructed by accumulated debris and unchecked vegetation growth. The facility's municipal workers interviewed on-site confirmed the absence of repair and maintenance efforts for the critical drainage infrastructure. Considering the topography of the site coupled with inefficient stormwater infrastructure inside the facility (see Figure 5), the boundary wall becomes a major obstruction to the natural drainage paths of rainwater that run downhill.

6 The facility constitutes of two water reservoir tanks, control rooms and housing for MCGM staff. Tank 1, which was renovated in 2017, has a capacity of 11 Million Gallon. Tank 2 is a smaller tank with a capacity of 4 Million Gallon, but remains under-utilised since it hasn't been repaired and is leaking from beneath due to its deteriorating condition (Data based on spatial documentation interviews of the facility's municipal workers and engineers conducted during field visit).

Figure 5: Satellite imagery of the site showing the boundary wall of the facility in red, overlaid with GIS based contour show direction of water flow (indicated with arrows), and natural drainage pathways in blue (Malad Wall Collapse, 2019)

The technical investigation committee (TIC), comprising of engineers and experts, constituted by the State to probe the event stated in its report that heavy rainfall coupled with holes in the wall blocked by the hutment dwellers resulted in the mishap (Ozarkar & Sharma, 2019). However, a closer inspection of the entire periphery wall through my spatial mapping—which is concurring with the investigations of the fact finding report—reveals that the wall itself is in fact technically flawed in its design and structure. It was constructed without any consideration for stormwater runoff, containing very few weep holes placed in a randomised manner scattered across some selective sections only. Unlike retaining walls, this wall was not built to sustain lateral pressures resulting from soil and rainwater accumulation (Malad Wall Collapse, 2019; Singh, 2019). This critical infrastructure led the adjoining housing tenements to be *walled against* a significant volume of water that had accumulated due to the heavy downpour of that night and the previous day. It was indeed built as *an infrastructure of containment, not protection* to shut out of sight and contain the adjoining dwellers who are perceived as "encroachers" by the state and judiciary, than protect them from landslides and flooding (Malad Wall Collapse, 2019). Except for the collapsed portions, the wall still stands the same way with no modifications or alterations made for drainage whatsoever even five years post the disaster. The Maharashtra State Government has in February 2025 approved a plan to build a protective wall along the entire periphery of the Sanjay Gandhi National Park to keep it from "encroachers" (Deshmukh, 2025). The building of such separation walls has, thus, become a normative planning practice in Mumbai's planning: containing people from "nature" by precariously walling them against its unstoppable forces.

Housing precarity and environmental regulation in Ambedkar Nagar & Primpripada

The areas of Ambedkar Nagar and Pimpripada abutting the boundary wall, lie downhill from the reservoir facility on a slope that's around 30-60m, and are a part of a much larger settlement that falls under the forest land of the Sanjay Gandhi National Park. As per environmental regulations, parts of the settlement that lie within the delimited extents of the forest land are not allowed to use permanent building materials to construct their tenements (Agarwal, 2002). Thus, the tenements closer to the wall have resorted to practices of constructing stone plinths out of loose random rubble and using skeletal bamboo frames covered with materials such as plastic/tarpauline sheets for their superstructure (see Figure 6 and Figure 7). These temporally fragile structures proved catastrophically inadequate when confronted with the force of the wall's collapse, which sent flood water and massive boulders cascading downhill.

The settlements have been denied and devoid of any formal infrastructure for managing stormwater drainage and depend almost entirely on ground water (sourced from an open well located downhill) for their domestic purposes. Following writ petitions and orders from the Bombay High Court in 1997, people living in this settlement—which is predominantly constituted by socio-economically marginalised groups of Dalits and

Muslims—were ought to be rehabilitated by the state government before evicting them from the forest land (Nivarra Hakk, 2000). Their rehabilitation has been pending ever since. However, the MCGM and forest department, in contempt of the court order, conducted forceful and violent demolitions in the settlement in 1999 and 2000 (Nivarra Hakk, 2000). Had the settlement residents been properly rehabilitated in compliance with court orders, their lives would not have been endangered on such hazardous terrain when the wall collapse in 2019. The resulting devastation was therefore not simply the consequence of rainfall-induced structural failure, but rather the direct outcome of deeply entrenched housing inequities and spatial injustice inflicted upon the urban poor belonging to marginalised communities who are forced to inhabit vulnerable and precarious conditions within the city.

Stormwater drainage at the intersection of flooding, housing, and environmental deregulation

The case of the Malad wall collapse event indicates a much deeper urban crisis that weaves together issues of stormwater drainage, housing, exclusionary forms of material infrastructures, and environmental conservation. The wall collapse event brought to the surface the overlapping epistemic injustices, connecting questions of drainage to housing precarity and environmental regulation which otherwise lay dormant yet very much present in the everyday lives of the Ambedkar Nagar and Pimpripada residents. The wall (and its partial collapse in time) symbolises, both materially and ideologically, the exclusive nature of environmental regulations aimed at conservation where the urban poor are singled out as "encroachers" on contested eco-sensitive lands, the SGNP in this case. While land disputes and the notion of 'encroachment' surrounding SGNP have been widely analysed within environmental debates (Bhide, 2009; Parthasarathy, 2011; Sen & Pattanaik, 2015), this paper employs the case of the 2019 wall collapse to illuminate one of the many critical dimensions of SGNP's complex environmental conflicts. The incident reveals the fundamental tension inherent in SGNP's dual identity as both a protected forest land and a transient (albeit at times violent) waterscape that amplifies risks for marginalised communities inhabiting its lands, peripheries, and fringes. State planning mandates protective measures such as boundary wall construction to safeguard forest lands, reinforced by environmental regulations that impose restrictions on building practices of the informal albeit legal settlements within these areas. However, the park's hydrological system, comprising of rivers, runoff channels, and hillslopes, functions as an active catchment zone (Mapping Aarey, 2019) by disproportionately endangering precariously housed residents abiding by the state's planning mandates. The fundamental paradox of this condition lies in the state's imposition of "forest land" zoning which does not consider the temporal nature of water that flows within this land. While the planning forcibly restricts residents to precarious, makeshift housing constructed with temporary materials, it simultaneously authorises the state to erect permanent concrete structures—which often fail to meet basic structural and environmental standards, as demonstrated by the Malad case—such as boundary walls, tunnels for highways, concretised link-roads, and metro sheds on the very same terrain as projects for economic development, often overlooking the implications of these on the forest's social-hydrology (Mapping Aarey, 2019; MMRDA, 2015; Sen & Nagendra, 2019; Surve, 2023). This contradiction reveals how conservation zoning operates as a material practice of spatial injustice. It criminalises legal informal settlements as "encroachments" while legitimising state infrastructure that exacerbates flood risks (in this case, boundary walls that obstruct natural drainage and intensify flood vulnerability). By framing the land as inviolable forest land yet buildable for state

projects, the policy perpetuates a double standard that perpetuates urban marginalisation under the guise of technical necessities for environmental protection.

The persistent question for housing, prior to and post the Malad wall collapse, exposes the systemic injustices at the heart of Mumbai's housing crisis. This case compels us to treat housing and spatial justice as non-negotiable parameters in stormwater infrastructure planning, especially in flood prone areas. The actions of residents in Ambedkar Nagar and Pimpripada, of building and occupying precarious homes since 1997, must be recognised as everyday practices by those most marginalised of coping with state planning practices that endanger their living environments. The exclusion of informal settlements from municipal stormwater drainage networks, the inadequate construction and maintenance of stormwater infrastructure, and the collapse of infrastructures during extreme rainfall events must be understood not as planning failures or oversights, but as intrinsic outcomes of Mumbai's technocratic planning paradigm (Indorewala, 2018). This system is principally rooted in valuing land solely for its economic potential and, thus, through its practices, systematically undermines its vital socio-ecological relationships with water systems and communities, inevitably producing disastrous environmental consequences for the city.

Conclusion

The inferences drawn from the ineffectiveness of the BRIMSTOWAD masterplan to prevent flooding combined with an analysis of the Malad wall collapse, demonstrates that Mumbai's chronic flooding problem is not a planning failure but rather the inevitable consequence of a technocratic planning system that subordinates socio-ecological considerations of water to the economic development of its land. The BRIMSTOWAD infrastructure as a techno-fix, designed to withstand only 50–65 mm/hr rainfall despite evidence of intensifying monsoons, reveals a deliberate disregard for both hydrological science and environmental justice. The stormwater drainage system's challenges and inadequacies—whether in excluding informal settlements, degrading natural drainage channels, or dysfunctions under climate extremes—are not technical miscalculations but logical outcomes of a planning paradigm that treats land as a commodity and all stormwater as disposable excess. The 2019 Malad wall collapse event, which killed 31 residents of an informal albeit legal settlement, exposes how issues of stormwater drainage are linked to inter-connected urban crises concerning housing and environmental regulation, thereby furthering the marginalisation of vulnerable communities. Such marginalisation and spatial vulnerability is not accidental but engineered. It is a direct result of planning that uses material practices of environmental regulation to displace and dispossess the urban poor. The boundary wall of the Malad facility shares both ideological and aesthetic similarities with the embankment walls of the BRIMSTOWAD project. Both structures serve a containment function. The BRIMSTOWAD's walls are designed to control and contain stormwater, while the Malad reservoir's periphery wall effectively confines adjacent informal settlements. Though their stated purposes differ, stormwater remains the common thread. It is the explicit target in BRIMSTOWAD's engineering, but implicitly present in the periphery infrastructure shaping the vulnerability of communities living near the reservoir facility.

The lived experiences and practices of those navigating waterlogged homes, inundated streets, and collapsing infrastructure reveal what official plans obscure, that flood risk is not natural but engineered. This paper has attempted to problematise flooding and related urban crises through the material practices that shape planning and the everyday in Mumbai. Reflecting on these practices would help us to understand—as Lefebvre puts it—'how people live or how badly they live, or how they do not live at all' (Lefebvre, 2014). The task ahead is not to "fix" flooding but to dismantle the systems that produce it.

Abstract
This study examines Climate Transition Strategies in medium-sized Italian cities (Bergamo, Brescia, Mantua), funded by Fondazione Cariplo. It investigates how urban nature is conceptualized and integrated, and the impact of these strategies on urban planning instruments. Despite varying visions – from human-centered 'oasis cities' to technical performance and integrated eco-climatic planning – direct actions across the CTS converge on (re)naturalization, (re)forestation, depaving, maintenance, and extension in urban spaces. A key finding is the significant influence of CTS on urban governance, integrating climate objectives into planning instruments. Competitive funding catalyses these experimental approaches in resource-constrained cities. The research highlights a shift towards integrating urban nature but notes challenges like fragmented actions and the need to assess long-term socio-ecological effectiveness and equitable benefit distribution.

Keywords: Climate Transition Strategies; Urban Nature; Medium-sized Cities; Climate Adaptation; Climate Mitigation

Introduction

Human activity is the primary driver of global warming and climate change (CC), significantly contributing to the increase in extreme weather events (Lynas et al., 2021; IPCC, 2023). Globally, 2023 was the hottest year since 1961, and in Europe it ranked as the second warmest on record (SNPA, 2024). Italy experienced comparable trends, with 2023 being its second hottest year on record and marked by significant deviations in rainfall patterns compared to historical norms (SNPA, 2024). Particularly in the northern regions of Italy, there has been an uninterrupted rise in average annual temperatures, coinciding with strong fluctuations in monthly precipitation (SNPA, 2024). Urban areas are amongst the most vulnerable to the impacts of CC, due to their high population density. The consequences of climate change for urban life are numerous. These include rising temperatures, worsening air quality and an increased risk of flooding or intense rainfall (OECD/EC, 2020). Consequently, there is an increasing need to develop effective strategies for climate mitigation and adaptation (Tang, 2024), as well as identifying mechanisms to finance the climate transition (WEF, 2025). A notable category of interventions involves Nature-based Solutions (NbS), which rely on natural processes to address specific challenges while delivering multiple co-benefits (Sowińska-Świerkosza & García, 2022). Despite the capacity of NbS to produce social, environmental, and economic value (Bockarjova et al., 2022), the concept of 'naturalness' has the poten tial to perpetuate a dichotomy between the natural and artificial, thereby diverting attention from their genuine functionality and effectiveness (Osaka et al., 2021).

Nature has played an integral role in shaping urban environments, particularly through the presence of natural green spaces. The discipline of urban planning has historically sought to reintroduce a natural environment into urban settings, thereby reflecting ongoing efforts to define the relationship between humans and green spaces. The role of nature has been subject to evolution since the late 19th century, as evidenced by the Barcelona Extension Plan (Urban, 2016), the Garden City movement (Howard, 1902), and more recent climate-focused projects. Early urban interventions were primarily concerned with public health and sanitation (Benevolo, 1971). In contrast, contemporary planning acknowledges the integration of cities with natural systems, with the objective of achieving goals such as biodiversity, climate regulation, stormwater management, and recreation. Recently, a growing number of European cities have adopted new planning approaches to support the climate transition. The overarching objective of these strategies is to rethink urban-nature relations and promote sustainable practices. Approximately 60% of Europe's population inhabits small to medium-sized cities (with 10,000–250,000 inhabitants) (Selada et al., 2010), which frequently encounter climate-related challenges with constrained financial

and human resources. For these cities, external funding – frequently obtained through competitive calls from public or private institutions – can provide vital support. Strategic plans that emerge from such funding are integrated into municipal planning frameworks with a view to promoting sustainability and climate resilience, while also outlining concrete actions. These strategies, particularly the ones originating from competitive funding programmes, frequently resort to experimental approaches (Broto and Bulkeley, 2013). Nevertheless, such approaches are not without critical issues (Caprotti and Cowley, 2017), and it becomes essential to evaluate both their social-ecological effectiveness and their influence on urban governance. The study draws on the concept of Social Nature (Castree and Braun, 2001) to investigate how different ideologies, imaginaries, and objectives shape the framing of nature. It highlights how climate strategies produce a 'socionature' (Swyngedouw, 1996) – a hybrid of social and ecological processes.

The present research focuses on the legacy of strategic climate plans, evaluating both the implementation outcomes and their impact on planning instruments. The present study explores varying interpretations of nature's role in Climate Transition Strategies developed under a shared funding framework and tailored to local contexts. The study considers the commodification of natural elements, their use in city branding, and their potential to redefine the relationship between people and the environment. Moreover, it explores the process through which global climate agendas are adapted to local contexts in order to facilitate the conservation, regeneration, and functional integration of nature in urban planning. The study is divided into three sections. The first section introduces the Climate Transition Strategies that have been promoted by Fondazione Cariplo. The second part of the study explores a selection of Climate Transition Strategies experiences enabled by this initiative, highlighting their visions and nature-oriented interventions. The third section of this study examines how these strategies have influenced urban planning instruments.

Climate transition strategies

The '*F2C - Fondazione Cariplo per il Clima*' project was initiated in 2019. The initiative has been promoted by Fondazione Cariplo (FC) and is in alignment with the European and national climate policies that gave rise to the European Green Deal (EC, 2019), the Next Generation EU and the National Recovery and Resilience Plan (PCM, 2021). The objective of the project is to implement CC mitigation and adaptation interventions within the Lombardy Region. Furthermore, the objective is to enhance the level of institutional and public understanding of CC. One of the F2C call is the call for ideas *Strategia Clima* [Climate Strategy]. The objective of this initiative is the realisation of Climate Transition Strategies (CTS), with the identification of a partnership necessarily composed of a lead municipal administration (with limits for the number of residents), an organisation managing a naturalistic area of high importance for the protection of biodiversity and a private non-profit organisation with experience in involving citizenship in environmental sustainability. In the context of this second project, Fondazione Cariplo is committed to providing technical assistance during the implementation phase of the CTS, as well as financing a share (up to 60%) of the expenditure related to each intervention.

The competitive call for ideas proposed by Fondazione Cariplo for the Climate Strategy Call for Ideas is composed of three phases (F2C, 2020): (i) Call for ideas: collection of project ideas related to the Climate Transition Strategy. In this phase, a high degree of detail is not required with regard to the proposals for action, but the application must mandatorily contain a number of well-defined areas (e.g. support to the revision of urban planning instruments of public bodies, adaptation and mitigation to CC). However, the necessity to influence public administration decision-making mechanisms from a policy and resource allocation perspective is emphasised. (ii) Provision of technical assistance for co-design: this is only available for ideas that have been selected during the initial phase. This phase is characterised by the elaboration of project ideas. The Fondazione Cariplo may provide direct support for the implementation of specific actions, prioritising those that have demonstrated effectiveness and can be implemented promptly (Quick win/No regret actions) and in social contexts where the consequences of CC are most pronounced. At the conclusion of the second phase, financial contributions are also determined. (iii) Effective implementation of interventions by the partnership. The terms of these agreements are to be defined in writing between the partners and Fondazione Cariplo.

The CTSs developed in this process must have two main objectives: (i) mitigation and adaptation to CC of vast

territorial areas, intervening on climate-altering emissions, impacts of extreme weather phenomena and increase in natural capital; (ii) intervention to improve public knowledge and awareness of CC, both by supporting scientific research and by promoting cultural and dissemination activities.

The territories and actions

The 2020 edition of the Climate Strategy encompasses four projects, each pertaining to a distinct Lombard territory. Of these four projects, three are the focus of this analysis: (i) 'Cli.C. Bergamo!', spearheaded by the Municipality of Bergamo in collaboration with the Parco Regionale dei Colli di Bergamo, Legambiente Lombardia, and ERSAF. The involvement of the Regional Park is instrumental in facilitating the project's extensive area of action. Within the designated area, encompassing a total of nine municipalities, the park's plan supersedes the urban planning instruments of the local authorities. This indirect influence enables the Cli.C. Bergamo! project to extend its intervention to areas beyond the municipal boundaries of Bergamo (Comune di Bergamo et al., 2020). (ii) 'Un Filo-Naturale', led by the Municipality of Brescia in partnership with Fondazione Centro Euro-Mediterraneo sui Cambiamenti Climatici (CMCC), AmbienteParco, Parco delle Colline di Brescia (Comune di Brescia et al., 2020); (iii) ACE3T - CLIMA, spearheaded by the Municipality of Mantua in collaboration with multiple municipalities, namely Curtatone, Marmirolo, Porto Mantovano, San Giorgio Bigarello, Parco del Mincio, Unione Colli Mantovani, and Alkémica Cooperativa Sociale (Comune di Mantova et al., 2020). The territorial extension of the intervention possibilities is variable for the three cases. Starting from the most limited, the Un Filo-Naturale project envisages interventions only within the municipality of Brescia. Conversely, the Cli.C. Bergamo! initiative delineates interventions within the lead municipality and, in a secondary manner, in the territory of nine other municipalities within the Regional Park. The final case, designated ACE3T - CLIMA, involves a total of six municipalities in addition to the primary municipality, thereby enabling direct intervention in the designated territory.

The three territories under consideration present different characteristics. The geographical area of Cli.C. Bergamo and Un Filo-Naturale are distinguished by their similarity in terms of urbanisation levels and topographical characteristics, specifically the presence of foothill zones. Conversely, the area of ACE3T - CLIMA pertains to a heavily irrigated and agricultural lowland context. The repercussions of CC accentuate phenomena deemed pivotal by the three projects: the hydraulic and flooding risk, and the escalation in temperature, in conjunction with the urban heat island phenomenon. However, the distinct local characteristics translate into further specific territorial criticalities. The first two territories highlight problems related to hydrogeological instability while the final territory is distinguished by diminished soil quality and reduced water availability.

The vision of each strategy is defined based on the territorial cognitive framework and the criticalities identified. The Cli.C. Bergamo! programme identifies five objectives: preventive adaptation and reactive adaptation to climate change; containment of the expansion of urbanised areas, including processes of depopulation and renaturalisation; strengthening of social cohesion for a new urban welfare; attribution of a relevant role to green areas and vegetation, including the creation of a green belt; and safeguard and enhancement of agricultural areas. Un Filo-Naturale, commencing from specific objectives, summarises them with three key words: oasis city (creating shade and coolness for human wellbeing, improving the urban microclimate and increasing urban biodiversity), sponge city (restoring space, time and quality to water) and city for people (with beautiful and liveable spaces guaranteeing rights such as health, slow mobility, meeting and inclusion). The vision of ACE3T-CLIMA is predicated on three fundamental pillars: firstly, blue permeability (the transformation of hydraulic risk into a resource, with concomitant improvements in safety, environmental quality and the adaptability of the territory to the effects of CC); secondly, green inclusion (the overcoming of the separation between natural and anthropic systems, with a view to favouring biodiversity, human wellbeing and the sustainability of productive and agricultural systems); and thirdly, resilience and decarbonisation of territorial systems (the energy efficiency which improves the quality of life and the sustainable management of resources from a fossil-free perspective)., The semantic structure of the strategies' objectives is different. Un Filo-Naturale employs a vision narrative, synthesising the advantages associated with the term 'city' and emphasising the robust 'urban' character of the strategy. ACE3T-CLIMA articulates the objectives by integrating them with the strategies of eco-climatic planning of the territory, thereby establishing a nexus between rural and urban contexts. It appears that Cli.C. Bergamo! employs a more technical approach, with a focus on the performance of the actions. The objectives of the vision are then translated into specific actions aimed at resolving the critical issues identified. All the actions, as explicitly requested by the call, fall into one of the following categories: governance actions/application for funding; support for the revision of urban planning tools; CC adaptation; CC mitigation; monitoring systems and

networks; capacity building and training of municipal technicians; territorial animation and communication.

The number of planned actions ranges from 20 in ACE3T - CLIMA to 30 in Un Filo-Naturale. Highlighting only the direct actions, that involve physical modification of the territory, Cli.C. Bergamo initiative entails 11 direct actions, constituting a proportion of the total 23 planned initiatives. All 11 of these direct actions pertain to mitigation or adaptation strategies. Un Filo-Naturale present only 11 direct actions, all in the adaptation category. In this STC, mitigation is achieved through actions that do not involve land modifications but are based on citizen participation and involvement. ACE3T - CLIMA incorporates a total of nine direct actions, exclusively those pertaining to CC adaptation. Despite the heterogeneity of strategies and the partiality of territorial criticalities, all direct actions can be ascribed to five families: (re)naturalisation, (re)forestation, depaving, maintenance and extension. Each action falls within a specific typology of space: wetlands, urban or suburban forests, green and blue infrastructure, urban parks, parking areas and draining plazas, water network, roof gardens, rain gardens, slow mobility paths.

The Influence of CSTs on Planning Instruments
The call expressly requires CTS to directly influence the planning instruments of the territories.

The CTS Cli.C. Bergamo! provides for four actions to 'review of urban planning instruments'. These four actions aim to address four CC mitigation objectives, two CC adaptation objectives, four governance objectives for the implementation of the CTS, and three objectives for participatory processes and co-design.

Action 1, 'mapping the climate risk index', has the following objectives: capacity building for public entities involved in the management, implementation and monitoring of the CTS; raising awareness of the impacts of CC among stakeholders and citizens. It involves correlating CC manifestations with the morphological and socio-economic characteristics of the territory in order to assess exposure and vulnerability. The mapping is carried out in stages: characterisation of the local climate through analysis of historical data series; investigation to characterise future climate scenarios; in-depth analysis of environmental, demographic and socio-economic matrices and the relationships between them to investigate the vulnerability and resilience of the territory; risk assessment consists of relating the potential direct and indirect impacts to the characteristics of the territory. The expected results include the creation of a Climate Risk Map to guide climate change adaptation and mitigation policies, the identification and study of the main climate-related threats and issues, and an analysis of the degree of exposure, vulnerability and adaptability of the territory.

Action 2, 'River contract for the Morla and its tributaries - how it flows between the hills and the city of Bergamo', will be described in detail below.

Action 3, 'Increasing resilience through planning choices in the new *Piano di Governo del Territorio*[1] (PGT)', has several objectives: disseminating CC mitigation policies in territorial governance choices; integrating CC adaptation and mitigation policies into urban choices and transformations; capacity building for public entities involved in the management, implementation and monitoring of the CTS. The Municipality of Bergamo is revising its PGT to respond to socio-economic and regulatory changes, with the aim of promoting sustainable and regenerative urban development. The new PGT pays particular attention to environmental and climate protection, integrating actions for climate change mitigation and adaptation, such as the enhancement of urban green spaces, sustainable water management and the limitation of land consumption. In this context, the CTS is a tool for guiding urban policies towards resilience, contributing to the definition of structural and non-structural interventions capable of reducing the city's environmental vulnerabilities. The CTS also supports the creation of new ecosystem services, urban forestry and renaturalisation, strengthening the integration between planning and sustainability. The expected results include the construction of a resilient city capable of coping with climate change and environmental risks in the long term. The development of organisational and management strategies geared towards prevention is envisaged, through both preventive adaptation tools – to reduce hazards and

1 The Piano di Governo del Territorio (PGT) is the overarching urban planning instrument to which all Lombardy municipalities are obliged to adhere in order to regulate land use, urban and territorial development, and environmental and landscape protection. The plan is composed of three primary documents: the Documento di Piano, which outlines the development strategies and general objectives; the Piano dei Servizi, which identifies the necessary equipment and public infrastructures; and the Piano delle Regole, which regulates the admissible uses and transformations of the territory.

vulnerabilities – and reactive tools to respond effectively to extreme events such as heat waves, droughts and floods.

Action 4 'from PAES to PAESC' involves the transition from the *Piano d'Azione per l'Energia Sostenibile*[2] (PAES) to the *Piano d'Azione per l'Energia Sostenibile e il Clima*[3] (PAESC). The objectives are manifold: dissemination of CC mitigation policies in land management decisions; reduction of climate-changing gas emissions through energy efficiency; integration of CC adaptation and mitigation policies into urban planning and transformation; capacity building for public entities involved in the management, implementation and monitoring of the CTS. The Municipality of Bergamo has begun developing its new PAESC. This process is part of the commitments made under the Covenant of Mayors, which Bergamo joined in 2009. After two monitoring cycles of the previous PAES, the municipality now intends to align itself with the new European targets: -55% CO$_2$ by 2030 and climate neutrality by 2050. The new SEAP will include mitigation actions to reduce emissions and adaptation actions to strengthen the city's resilience to climate change. The plan will be divided into three main parts: emissions inventory and risk analysis, decarbonisation plan and adaptation plan. The process will involve public participation, biennial monitoring and the sharing of good practices with other European cities through a network.

The CTS Un Filo-Naturale for the Brescia area provides for two actions to 'revise urban planning instruments', which aim to respond to one CC mitigation objective, one CC adaptation objective, two governance objectives for the implementation of the CTS, and one objective for participatory processes and co-design.

Action 1.1 of the CTS Un Filo-Naturale 'support for the revision of urban planning instruments' will be described in detail below.

Action 1.2 'analysis of local climate variability' has as its main objectives improving awareness of CC and capacity building for public bodies, citizens and stakeholders. The Municipality of Brescia wants to integrate the analysis of local climate variability into the process of revising urban planning tools. The aim is to identify the main past and future climate challenges to plan targeted adaptation measures. The analysis is based on internationally recognised climate indicators, calculated both from historical data (last 30 years) and future projections based on climate scenarios. This analysis makes it possible to define the current state of the climate and the potential risks arising from future changes, providing a scientific basis for planning local adaptation strategies and assessing climate risk. The expected result is the development and study of local climate variability.

ACE3T - CLIMA for the Mantua area provides for a single action of 'mainstreaming and revision of urban planning tools': action 2 'revision of urban planning instruments'. The objective of the action is to reorient the actions of municipalities in local and supralocal government decisions to include adaptation and mitigation to CC in urban planning instruments and processes. Some of these instruments are mandatory, others optional. The action plans to integrate the following tools with specific guidelines:

- *Piano Triennale delle Opere Pubbliche*[4]: definition of public intervention standards to contribute to resilience.
- *Regolamento del Verde Pubblico e Privato*[5]: identifying native plant species with high environmental

2 Piano d'Azione per l'Energia Sostenibile (PAES) is a strategic instrument developed by municipalities under the Covenant of Mayors, a European initiative focused on climate and energy. The SEAP delineates objectives and specific actions aimed at mitigating greenhouse gas emissions, encompassing initiatives pertaining to energy efficiency, renewable energy, and sustainable mobility.

3 Piano d'Azione per l'Energia Sostenibile e il Clima (PAESC), represents the evolution of the PAES and signifies the strategic instrument through which municipalities adhering to the new Covenant of Mayors commit themselves not only to reducing CO2 emissions, but also to addressing the impacts of climate change through adaptation measures. The strategy delineates an integrated approach to achieving European decarbonisation targets, promoting energy efficiency, the utilisation of renewable sources, and fortifying territorial resilience.

4 The Piano Triennale delle Opere Pubbliche is a planning document that every Italian municipality is required to draw up in order to plan, over a three-year time horizon, the implementation, maintenance and adaptation of public works of economic importance. It includes, for example, schools, roads, public buildings, sports facilities, road and environmental infrastructure.

5 The Regolamento del Verde Pubblico e Privato is a regulatory instrument adopted by municipalities for the purpose of protecting, managing and enhancing the public and private urban plant heritage. The document establishes criteria and procedures for the design, maintenance, felling and replacement of plants, with the overarching objectives of promoting biodiversity and

effectiveness; redeveloping public green spaces in relation to heat islands; considering CC in the design criteria for urban green spaces; promoting the adoption of municipal or inter-municipal green space plans.

- *Regolamento Edilizio*[6]: defining specific rules to increase adaptation and mitigation capacity in new construction and renovation projects and defining an index to increase the response to heat waves and urban flooding.
- *Documento di Piano*[7]: consider scenarios and critical issues arising from CC; integrate objectives and strategies with adaptation and mitigation elements and promote agriculture and rural land management, considering ecological networks, the promotion of biodiversity and the contribution of ecosystem services.
- *Piano delle Regole*[8]: promote urban regeneration by encouraging adaptation to CC; encourage environmental sustainability and urban resilience with new standards and criteria to minimise carbon emissions, improve drainage and the urban microclimate, create green infrastructure, mitigate heat islands; reduce hydraulic risk and de-impermeabilisation;

Action 2 of the CTS Cli.C. Bergamo! involves signing a River Contract (RC) for the Morla river basin, a 14 km watercourse considered to be Bergamo's river. From the start of its course within the city, the Morla is heavily artificialised. The RC is a voluntary planning instrument negotiated between several municipalities, which aims to protect water resources, improve their management and contribute to safeguarding against hydraulic risk. The RC can also help to integrate and guide local planning, while improving subordinate planning. The RC '*Il Morla e i suoi affluenti*' (The Morla and its tributaries) has the specific objective of restoring the watercourse and the surrounding area, both in terms of its naturalness and its historical and identity value. The stages indicated by the CTS for the implementation of the RC, which were then actually implemented, included: the drafting of a document of intent containing the reasons for the creation of the RC, its objectives and methodology; a fact-finding analysis of environmental, social and economic aspects; the mapping of potentially interested public and private entities and stakeholder; the implementation of participatory processes to share intentions among the entities and stakeholder; the development of a shared medium- to long-term strategic scenario; the definition of a three-year Action Programme, indicating objectives, actors (with obligations and commitments), timelines, implementation methods, and the necessary human and economic resources; the signing of the River Contract. Specifically, the Memorandum of Understanding was signed on 2 December 2022, while the actual River Contract was signed on 8 February 2024.

With regard to 2024, the first year of the RC, various interventions were carried out within the river basin: unsealing of a section of the stream; restoration of a drainage ditch; cleaning and redevelopment of the banks; conservation of tree vegetation; training meetings for technicians and professionals; development of a GIS database; updating of the areas of environmental enhancement within the PGT of the municipality of Bergamo. The year 2025 will be characterised by five themes: green space regulations, environmental compensation for investments and infrastructure, river routes, environmental education, and communication.

Action 1.1 of the CTS Un Filo-Naturale 'support for the revision of urban planning instruments' aims to update and integrate land management tools with objectives and actions strategically geared towards climate transition. The action therefore consists of updates and additions to reports, regulations, project guidelines, maps, procedures and regulations for planning tools that are currently in force or being implemented. The activities follow two coordinated lines: the first involves the introduction of new support tools to guide and prescribe interventions in the territory, improving resilience to climate change; the second line involves direct or indirect interventions

defining the responsibilities of citizens and entities in the care of green areas.

6 The Regolamento Edilizio constitutes a municipal regulatory instrument, the function of which is to govern the processes of construction, renovation and maintenance of buildings within the municipal territory. The overarching objective of the plan is to establish a set of rules that, if adhered to, will ensure safety, urban quality, environmental sustainability and respect for the local context. It is integrated with the PGT.

7 The Documento di Piano constitutes the strategic element of the PGT. It delineates the objectives of urban and territorial development for a medium-long term time span. It identifies the needs of the territory, guidelines for urban transformation, environmental, social and economic policies, and demographic and settlement forecasts.

8 The Piano delle Regole constitutes one of the three constituent components of the PGT. It is the regulatory component, the function of which is to regulate land use and the transformation of the existing territory. The document under consideration comprises the regulations that govern the construction and town planning interventions permitted within the various areas of the municipal territory. It identifies the agricultural areas, the landscape, historical or environmental assets to be protected, and the parts of the urban fabric where restructuring, replacement or building conservation is permitted.

on areas and buildings aimed at urban regeneration and the creation of interconnected green infrastructure. In detail, the CTS provides for interventions on specific urban planning instruments. Within the PGT, the main municipal-level tool is expected to:

- Introduce new annexes: climate variability analysis and municipal study for flood risk management.
- Updating documents and maps: urban redevelopment areas with direct and indirect interventions; areas for hanging gardens and green roofs; areas for tree planting and permeability; pilot interventions for water retention basins; areas for new woods and habitats in urban areas; retrofitting areas.
- Introducing a procedure for participatory processes in urban transformation interventions.

In addition to the PGT, the CTS also intends to intervene on other instruments such as the *Regolamento Edilizio*, the *Piano Urbano della Mobilità Sostenibile*[9] (PUMS), the PAESC, the *Piano Comunale del Verde*, and the Multi-Year Plan for the PLIS of the municipality of Brescia. New planning instruments are also planned: the de-paving implementation plan, the strategy for the spread of green roofs, the forestry action plan, and guidelines for the extension of the district cooling pilot project.

Worthy of note is the new municipal green plan, called the 'Green and Biodiversity Plan of the Municipality of Brescia'. The introduction presents the CTS and analyses of climate change scenarios. It highlights air pollution, heat islands and hydrogeological risk as specific vulnerabilities of the Brescia area. It then explores the benefits of ecosystem services such as carbon sequestration and the removal of air pollutants, temperature regulation, protection from hydrogeological risk, etc. Just as the CTS summarises the objectives in three visions for the city, this tool also has the same structure: the healthy city (inspired by the One Health principle), the spring city (to restore the central role of water), and the city for people (with public space and community at its heart). Finally, the plan's implementation tools include the NbS abacus, organised into three sections: the first section introduces the functions and benefits of NbS; the second relates NbS to the project areas of the city of Brescia, listing the appropriate NbS for each area; the last section brings together the NbS fact sheets, outlining guiding principles and ecosystem services.

Discussion

The present study investigates the role of urban nature within Climate Transition Strategies, which is funded by Fondazione Cariplo, in medium-sized Italian cities. The analytical framework utilised in this study focuses on the Climate Transition Strategies that have been developed by the municipalities of Bergamo, Brescia and Mantua. The primary objectives are twofold: firstly, to comprehend the manner in which diverse ideologies, imaginaries and objectives influence the conceptualisation and integration of nature within urban contexts; and secondly, to critically evaluate the impact of these strategies on urban planning instruments.

The semantic structures employed in the objectives of each strategy reveal distinct approaches to framing urban 'natures'. The 'Un Filo Naturale' project is an ambitious undertaking that aims to create an 'oasis city,' a 'sponge city,' and a 'city for people.' This vision, in which human society is placed at the centre, synthesises the benefits of urban nature with broader concepts of human well-being and liveability, positioning nature as an intrinsic component of an ideal urban environment. The 'ACE3T-CLIMA' initiative articulates its objectives through the integration of established ecoclimatic planning strategies for the territory, thereby establishing a nexus between rural and urban contexts through concepts such as 'blue permeability' and 'green inclusion'. The 'Cli.C. Bergamo!' project adopts a more technical approach, with a focus on the measurable performance of actions related to preventive and reactive adaptation or containment of urban sprawl. The manifestation of these disparate conceptualisations as discrete 'socionatures' (Swyngedouw, 1996) in action illuminates the multifaceted manner in which social and ecological processes are hybridised and negotiated within these climate strategies. The conceptualisation of nature, whether as a functional apparatus, a provider of ecosystem services or a source of human well-being, exerts a direct influence on the cultural approach to urban nature and the language employed to communicate its value.
Despite these divergences in vision, there is convergence regarding the direct actions proposed in the three CTS.

9 The Piano Urbano della Mobilità Sostenibile (PUMS) is a strategic planning instrument adopted by municipalities to design efficient, safe and environmentally friendly mobility systems. The objective of the initiative is to enhance the quality of life in urban areas by reducing pollution, traffic congestion and greenhouse gas emissions. It delineates integrated interventions to promote sustainable transport modes, including public transport, cycling and walking, shared mobility, and the utilisation of environmentally friendly vehicles.

These actions, which are designed to induce physical changes to the urban territory, can be categorised into five distinct families: (re)naturalisation, (re)forestation, depaving, maintenance and extension. These interventions target a variety of urban spaces, ranging from wetlands and urban forests to green and blue infrastructure and urban parks. The 'Cli.C. Bergamo!' initiative integrates climate mitigation and adaptation into direct actions, whilst 'Un Filo-Naturale' and 'ACE3T – CLIMA' focus their direct interventions on adaptation strategies. The mitigation objectives in 'Un Filo-Naturale' are chiefly pursued through initiatives centred on citizen participation and involvement. One of the key findings of this study is the influence of CTS on existing and developing urban planning instruments, demonstrating a systemic change in urban governance frameworks. In accordance with the stipulations of the call, all three projects under consideration have been designed to incorporate their respective climate objectives into the existing urban planning instruments.

The 'Cli.C. Bergamo!' project is an initiative that proposes a series of actions with the objective of revising urban planning tools. These include the creation of a detailed Climate Risk Map, the integration of climate policies into the TMP, and the adoption of a PAESC. The River Contract for the Morla basin in Bergamo serves as a case study in multi-municipal strategies for ecological restoration of natural watercourses, illustrating a direct and quantifiable impact on land management practices and environmental enhancement within the broader TMP framework. The contract under discussion is indicative of a shift towards collaborative governance models that transcend administrative boundaries, a key element for effective action against climate change. In a similar manner, the Brescia 'Un Filo-Naturale' project endeavours to modernise and amalgamate prevailing urban planning instruments. The development of a new 'Green and Biodiversity Plan', based on the visions of a 'healthy city', a 'spring city' and a 'city for people', together with the creation of an NbS abacus, represents an approach to integrating climate resilience directly within urban planning. This process underscores a transition from ad hoc projects to systematic policy integration.

The findings indicate that competitive funding programmes, such as those administered by Fondazione Cariplo, function as catalysts for medium-sized cities to adopt experimental approaches and integrate climate strategies into their spatial planning. This is of particular significance when considering the financial and human resource limitations experienced by these cities. This research study lends further credence to the integration of 'natural systems' in urban areas, a concept that has gained significant traction in contemporary planning discourse. However, this raises questions regarding the long-term sustainability and scalability of these experimental approaches, underlining the need to evaluate their socio-ecological effectiveness and their influence on urban governance (CIT). The potential for the commodification of natural elements in urban branding further underscores the necessity for a more profound and critical examination of how these emerging strategies are reshaping the relationship between urban populations and their environment. In addition, an evaluation of the potential equity concerns is necessary, as well as an assessment of whether the advantages derived from these 'greening' initiatives are distributed uniformly across all demographic groups within the urban population.

Conclusion

This study provided a comprehensive analysis of climate transition strategies in medium-sized Italian cities, revealing both promising progress and critical areas for improvement in local climate action. The results of the study indicate a paradigm shift in the way urban nature is conceptualised and integrated into planning. The cases of Bergamo, Brescia and Mantua exemplify different and functional approaches to exploiting NbS for climate change adaptation and mitigation, reflecting different narratives adapted to local specificities. Despite the integration of urban nature being substantial within planning instruments, the analysis also highlights certain challenges. A fundamental concern pertains to the absence of a systemic and strategic approach to climate action. The individual direct actions promoted by CTSs appear to be fragmented and independent, with no internal coordination or external alignment with other ongoing projects. This underscores the necessity for a systemic approach that acknowledges the variability of climate change effects, transitioning from isolated interventions to coordinated strategies.

A further distinction is to be drawn between the ways in which 'old' and 'new' nature are addressed. The concept of 'old nature' frequently serves as the focal point for conservation, control, exploitation, or removal interventions, largely attributable to the perceived risks associated with it. Conversely, the concept of 'new nature' (Tononi, 2025) is predominantly evaluated based on its immediate benefits for human well-being and the natural system. The incorporation of socio-nature mapping, encompassing elements such as wasteland, forgotten spaces,

and groundwater, could facilitate the development and implementation of more effective climate strategies. The strategy for planning tools demonstrates a commitment to institutionalising climate resilience, ensuring that these efforts become lasting urban development rather than 'experimental' phases (Broto and Bulkeley, 2013; Caprotti and Cowley, 2017). However, further investigation is required into the long-term socio-ecological effectiveness of these changes, in order to assess the impact on biodiversity, ecosystem service provision and the general well-being of urban populations. It is also necessary to investigate how these strategies can redefine the relationship between urban populations and their environment, fostering a sense of connectedness and responsibility. It is therefore essential to explore the distribution of environmental benefits across different socioeconomic groups and the potential of these initiatives to address existing urban inequalities.

Addressing these implications and conducting further comparative studies on different funding mechanisms and governance structures will facilitate the identification of best practices and improve the transferability of successful models. This, in turn, will promote a climate-resilient, nature-positive and socially just urban future.

Reintroduction of health impact assessment in Bulgarian city planning – why and how?

Angel Burov[1], Angel M. Dzhambov[2], Donka Dimitrova[3], Iana Markevych[4], Kostadin Kostadinov[5], Marco Helbich[6], Mark J Nieuwenhuijsen[7]

Abstract
Bulgaria has established practices in Strategic Environmental Assessment (SEA) and Environmental Impact Assessment (EIA), yet the integration of applied. Health Impact Assessment (HIA) research findings in the practice of urban planning, governance, and development is limited or absent. This study highlights the pressing need for reintroduction of HIA in the Bulgarian spatial planning system and proposes how that can be accomplished without excessive regulatory burden to city authorities, planning and design experts, (re)developers, and citizens. Drawing on local Bulgarian and international research experience with HIA-based urban planning, the present study conducts a comparative analysis of HIA regulations, provides an overview of health related SEA content, recent exposure studies for the 5 biggest cities in Bulgaria, and ultimately attempts to conceptually reframe HIA in the urban development practice.

Keywords: city planning; urban environment; health impact assessment; exposures; decision framework

Introduction

Urban environments shape human health through a range of direct and indirect pathways involving exposure to stressors, behavior modification, and salutogenic influences building resilience (Mueller et al., 2021). Compact and densely populated cities often amplify exposure to air pollutants, noise, artificial light at night, heat islands in summer seasons, and result in limited availability or inaccessible green space, exacerbating both physical and mental health disorders (Dyer et al., 2024). The means of production and consumption, shaped by political-economic systems of governance and spatial development configurations, influence air quality, the acoustics environment, energy dynamics, viewsheds, food availability, mobility modes, and physical activity among other characteristics of the living environment affecting health and quality of life (Barton & Grant, 2006; EEA, 2010; Krefis et al., 2018; Mouratidis, 2021). Historical waves of deindustrialization have left a legacy of unequal spatial development, often concentrating health risks in socioeconomically disadvantaged areas (Hajat, Hsia & O'Neil, 2015). Mixed use services oriented redevelopment and reindustrialization offer various opportunities for urban regeneration while technological and organisational advancements such as the smart city and circular economy concepts may optimize and prevent excessive energy and resource use. Nevertheless, all of these good intentions in cities' development may provoke new pressures and add specific adverse cumulative effects due to unbalanced patterns of spatial development relations and rebound effects (Parrique et al., 2019; Castro et al., 2022). The structural health-determining patterns and the future opportunities call for integrated public health-oriented urban design strategies that not only mitigate risks but also foster equity and resilience in the endless quest for sustainable cities.

Urbanization in Bulgaria is shaped by a post-socialist legacy, characterized by uneven development, deteriorating infrastructure, and persistent environmental issues. Many urban areas still bear the imprint of industrial pollution (e.g. Varnagglomeration, Burgas, Pernik) or newly emerging consumption externalities, especially in cities like Sofia and Plovdiv, where PM10 and PM2.5 levels regularly exceed the World Health Organization air quality guideline limits standards (European Environment Agency, 2023), while NO2 levels are often not in the spotlight that stay hidden from the official monitoring systems although there is confident evidence that it is an important issue (Popov & Hlebarov, 2021). This contributes to non-communicable disease respiratory and cardiovascular morbidity and mortality, disproportionately affecting mostly children and the elderly (Health Effects Institute, 2024). Despite its membership in the European Union and its current application for OECD accession, Bulgaria has recorded the highest mortality rate in the EU, with a crude death rate of 15.7-22.9 deaths per 1,000 inhabitants between 2019-2023 compared to the EU average of 10.4-11.9 (Eurostat, 2025). This reflects the combined impact of demographic shrinkage, population aging, chronic disease prevalence, underfunded health systems, and socioeconomic stress.

Health Impact Assessment (HIA) has emerged as a key tool for making health a visible and accountable component of urban planning and the parallel ex-ante and ex-post evaluation instruments (Mueller et al., 2021, 2023). The WHO's Healthy Cities movement provides a flagship guidance on the overall policy and tools, promoting governance

models that embed health into municipal decision-making via a series of indicators, such as health, health services, environment and socio-economic conditions oriented ones (Webster & Sanderson, 2012). HIA complements other legislatively established evaluation tools such as Strategic Environmental Assessment (SEA) and Environmental Impact Assessment (EIA), offering more detailed insight into local health status and projected outcomes. While SEA and EIA focus generally on environmental and ecological impacts, HIA places explicit emphasis on population health, wellbeing, and social equity and thus is helpful in bridging societal and environmental aspects with people in the focus. Incorporating high quality HIA into these broader environmental assessment frameworks at the strategic planning and the project level ensures that health benefits are not seen as a byproduct but a central consideration in the different scales of urban development policy and decision making.

Integrating HIA helps identify co-benefits and trade-offs early on in planning processes and drive and orient, inform or strongly support planning and decision-making approaches, alternatives and choices. The gradually improving local evidence and global understanding of health - urban environment relations make HIAs more relevant and with higher resolution thus increasingly helpful for the targeted design of urban level solutions.
The present study addresses two main points:

1) The pressing need for reintroduction of more advanced and robust HIA in the Bulgarian spatial planning system.
2) The feasible implementation of HIA without an excessive regulatory burden to city authorities, planning and design experts, (re)developers and citizens.

Materials and methods
Drawing on experience from one pilot (UBSP, 2025) and three research projects (CES, 2025; SU, 2025; MUP, 2025) as well as other related actual studies carried out by the authors, conducted in major Bulgarian cities, this paper proposes a framework for reintroducing and improving the quality of evidence-based HIA in the country. The study offers insights by drawing on three qualitative analysis approaches:

1. A comparative analysis of international regulations and the current state of HIA practices at the urban level in Bulgaria as well as stakeholder analysis and survey;
2. An overview of urban environment - public health interactions and exposure patterns across Bulgaria's five largest cities, with a particular focus on Sofia, highlighting some of the key urban exposures such as air, noise, and light pollution, alongside the characteristics of green spaces and their accessibility;
3. A conceptual reframing of approaches to address urban environmental pressures and develop balanced strategies for creating healthier urban environments in Bulgaria in the near future.

We first review existing international standards, EU regulations, and nationally adopted legislation regarding monitoring, screening, mapping, programming, and action planning in the urban environmental domain. The comparative analysis of international regulations and the current state of HIA practices at the urban level in Bulgaria covers WHO and selected national recommendations and their application, the EU acquis transposition in relations to SEA and EIA. Next a brief overview of the variety of procedural and content oriented norms in selected countries and the differences in capacity, that is scientific, professional, and political will for evidence-based decision making is presented as well as an overview of Bulgarian regulations and analyses of the SEA-related content of the general spatial development plans of the cities of Sofia, Plovdiv, Varna, Burgas and Ruse. As part of one of the studies on joint effects on urban health, a purposive sample of stakeholders using the Delphi method is compiled and surveyed. The initial iterative discussion process went through several stages of defining specific aspects of social or natural phenomena in the urban environment - health nexus, identifying individuals, groups or organizations affected and/or that may have an impact on the urban planning and management decisions and thus prioritizing participants to be invited. The output of the stakeholder analysis is represented as initial findings.

We then present an overview of the urban environment - public health relationship and discuss exposure patterns in Bulgaria's capital and other large cities. In particular, we draw on the projects mentioned above and represented in more depth later in the text with short 'nicknames' as follows:

1) **Urban Standard** or originally "Set an **Urban Standard** - Creation of a Standard for Evaluation and Monitoring of the Quality of the Urban Environment" (UBSP, 2025);
2) **URBiNAT** or originally "**URBiNAT** - Healthy corridors as drivers of social housing neighbourhoods for the co-creation of social, environmental and marketable NBS" (CES, 2025);
3) **Methodology for air and health assessment** or originally "Development of a **methodology for air** quality **and** human **health** risk **assessment** in urban areas";
4) **Joint effects** or originally "**Joint effects** of exposures to natural and built environments – informing healthy and sustainable urban development".

More information about the sets of methods and results are described and compared in 3.2. Additional references are included in terms of important screening studies in this knowledge base review - outlooks and compilations of the Health Effects Institute (2022, 2023), the EXPANSE, UBD Policy Horizon 2020 projects. The latter combines resources with the Methodology for air and health assessment and the Joint effects projects in order to bring the research experiences with Sofia to a higher level (Khomenko, 2025).

The exposures of interest here include air pollution, traffic noise, artificial light at night, greenery and urban health islands. Particular focus is on Sofia, the capital city of Bulgaria.
The conceptual reframing of HIA in Bulgarian urban planning practice is made on the basis of definitions and principles stemming from the outlined gaps and the compact review of the international regulations, national practice and stakeholders' survey, as well as the accumulated research evidence.

Results

3.1. A comparative analysis of regulations of health impact assessment practices at the urban level in the EU

The comparative analysis of regulations regarding HIA is represented by an unfolding matrix of procedural and substantive issues. The comparison includes neighboring countries of Bulgaria (Romania and Greece), countries of similar population size (Denmark, Ireland, Austria), and other influential or role model ones in the urban development domain (The Netherlands, Germany, France, Spain, Italy, Poland). As in most cases in Europe, HIAs are part of the SEA and EIA content, so an overview of the legislative framing of both is shown in Table 1.

Table 1 Types of national legislation transposing the SEA Directive in selected EU countries (based on EC, 2025)

Type of legislation	SEA legislation	Integrated legislation		
Country		Environmental code / protection act	EIA legislation	Sectoral legislation
Austria				Δ(federal level and in some provinces)
Bulgaria	Δ(by-law)	Δ	Δ(by-law)	
Denmark	Δ(SEA and EIA together)			
France		Δ		
Germany	Δ		Δ	Δ
Greece	Δ			
Ireland	Δ			

Italy		Δ		
The Netherlands			Δ	
Poland		Δ	Δ	Δ
Romania	Δ			
Spain	Δ(SEA and EIA together)			

The Environmental Protection Act (EPA) in Bulgaria regulates the obligation to carry out a strategic environmental assessment or as it is called "ecological assessment" of policies, plans and programs, and an environmental impact assessment (EIA) of investment design projects in order to prevent, reduce or compensate for harmful effects of planned activities on nature and human health. The SEA related ordinance (CMRB, 2020) further defines the procedures and criteria for carrying out EAs.

The main focus is on the systematic assessment of likely significant impacts, including the ones on human health.

Table 2 Comparative analysis of regulations of health impact assessment at the urban level in selected countries (EU, 2001; EC, 2019a,b; 2025)

Country and responsible regulative bodies	Key regulatory acts and complimentary documents	Themes - factors and indicators	Evaluation cycle steps and health considerations	Urban planning related requirements
European Union				
European Parliament Court of Justice of the European Union European Environmental Agency	Directives 2001/42/EC (SEA) and Directive 2011/92/EU (amended by 2014/52/EU) (EIA) as well as guidance documents	Biodiversity, population, human health, fauna, flora, soil, water, air, climatic factors, material assets, cultural heritage, landscape and the interrelationship between the factors	Screening, Scoping, Reporting, Consulting, Decision making, Monitoring Para 1, Annexe I (f) and II (2)	Health impacts considered as part of the assessment of significant environmental impacts of plans and programs via SEA and EIA
Bulgaria				

Ministry of Environment and Water Executive Environmental Executive Agency Regional Inspectorate of Environment and Water Regional Health Inspectorate	Environmental Protection Act (EPA), 2002 and later amendments; (SEA) Ordinance on the conditions and procedure for carrying out an environmental assessment of plans and programmes, 2004 and later amendments; (EIA) Ordinance on the conditions and procedures for carrying out environmental impact assessment, 2006	Components: atmospheric air, atmosphere, waters, soil, subsoil, landscape, natural sites, mineral diversity, biological diversity and its elements; Factors: natural and anthropogenic substances and processes; waste; risky energy sources - noise, vibrations, radiation, GMO (Art.4, EPA)	Screening, Scoping, Reporting (assessment of the alternatives through comparison of planning options with), Consulting (a prolonged Aarhus convention case for Bulgaria regarding both the information and environmental justice aspects (UNECE, 2025)), Decision making (elaboration of reasoning and criteria for selection of the best alternative), Monitoring (setting of indicators for post-approval monitoring and control of the implementation)	Urban planning not explicitly addressed, overall implications for spatial planning. The state of health affected by the state of environmental components, or via them by the factors, actions and measures (Art. 19, EPA); The report must assess impacts on health among the other aspects (Art. 86, para. 3, pt. 6, EPA) Considerations of the objectives, territorial scope, level of detail related to investments, location, characteristics, scale, and impacts of plans in general and general spatial development or detailed urban design plans in particular (Art. 81, para. 3 and Art. 85, para. 1&4, EPA; Art. 8a, para. 2 SEA Ordinance)
Other EU countries (Romania, Greece, Italy, Spain, France, Netherlands, Germany, Austria, Danmark, Ireland)				
Various, e.g. ministries (Greece), inspectorate (France), commission (Netherlands)	Single (e.g. Greece, Romania) to many acts, based on sectoral distribution of issues and/or hierarchy of acts (e.g. France), federal divisions of legal responsibilities (Germany, Austria)	Most notably air quality and noise, as well as a number of other themes similar to the ones described in the EU SEA and EIA directives and other specific themes highlighted in the national context	Adherent to the EU directives, including Screening, Scoping, Reporting, Consulting, Decision making, Monitoring Various guiding documents on separate steps of the process (e.g. Poland, Austria, Netherlands)	Additional procedural and content support such as urban planning guidance (e.g. France), GIS environmental sensitivity mapping portals and tools (e.g. Romania, Ireland)

Compared to other countries, Bulgaria has a well-developed legislative base, both SEA and EIA related, although more generic in terms of the HIA specific implications, methodological and technical and in the urban planning and geospatial field. The health protection is included in the EPA as well as in the Health Act, and there is synchronization in procedural terms but content of HIAs is not comprehensively addressed.

Content analysis of SEAs with focus on the HIA related content

Further on an exhaustive review of available health related assessments is presented drawing on the content of Strategic environmental assessments in the 5 biggest cities in Bulgaria.

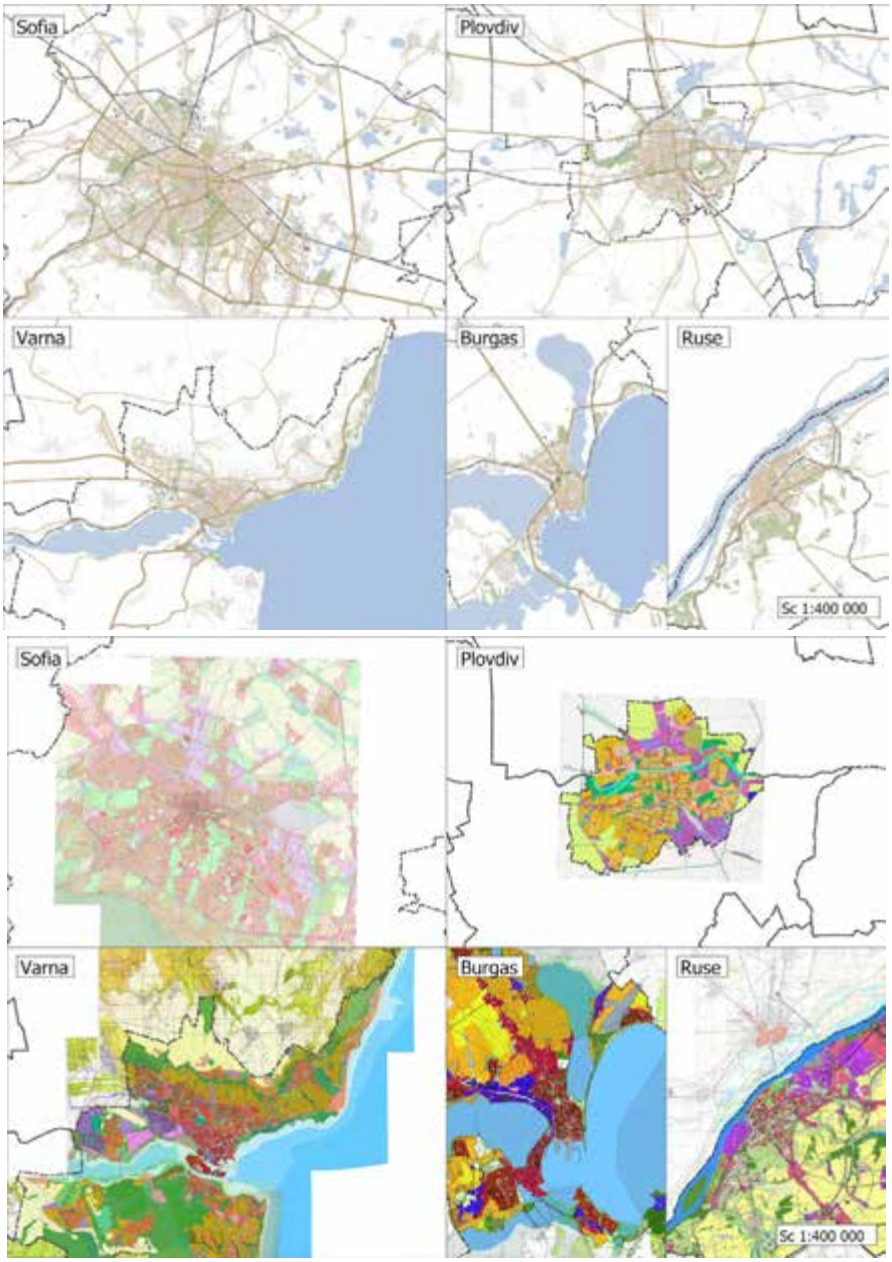

Figure 1 The 5 biggest cities (2023), their basic shape and the actual masterplans

The SEA content reviewed includes the available profiles in the official registry of the Ministry of Environment and Water (MEW). Additional sources like municipal portals are also used where older assessments are available, especially for the case of Sofia, whose spatial development plan and its SEA are preceding the creation of the registry (Sofiaplan, 2025). The selection of cities is based on their population size until 2023 when the last survey, part of the Joint effects project, was implemented.

Table 2 Review of SEA's health related content of the 5 biggest cities until 2023 in Bulgaria (Sofiaplan, 2025; MEW, 2025)

<table>
<tr><td>Health related content - quantity (number of mentions of the health word root) and quality (paragraphs with concentration of the root word)</td><td>Overall evaluation of the HIA aspects in terms of health data, statistics and geospatial data metrics used for impact assessment</td></tr>
<tr><td colspan="2">Sofia (SEA built upon preceding EIA but much lighter in tune with the SEA directive and national legislation) (Sofiaplan, 2025)</td></tr>
<tr><td>Quantity - 1 procedure, 269 mentions in Volume II of the SEA from 2008</td><td>Moderate amount of regional (equal to local level) health data used thanks to the overlapping of the regional district and the metropolitan municipality</td></tr>
<tr><td rowspan="2">Quality - pp. 556-559, 560-567, 573-600
describing conditions and state of health related factors; pp. 615-632 description of expected impacts mostly associated with climate, air quality and noise; 637-641 methodological description for the component and factor analyzes; annexes with prescription of mitigation and abatement measures</td><td>Health statistics are cited and descriptively analysed and projected by expert judgement on the basis of trends analyses and first tier modeling of components and factors</td></tr>
<tr><td>Geospatial data metrics are neither cited, analysed or applied due to lack of available data (though the preceding EIA of the draft version of the plan from 2002 included such a pilot interdisciplinary attempt thanks to intensive field work with district clinics and processing of analogous data)</td></tr>
<tr><td colspan="2">Plovdiv (SEAs) (MEW, 2025)</td></tr>
<tr><td>Quantity - 2 procedures, 41 mentions in the SEA from 2007, no health related SEA content from the amendment in 2020</td><td>Low amount of health data used</td></tr>
<tr><td rowspan="2">Quality - pp. 53-54 describing conditions and state of health related factors; pp. 72-74 prescribing mitigation measures against the expected impacts mostly associated with air quality, noise and water quality</td><td>Health statistics are neither cited nor analysed</td></tr>
<tr><td>No geospatial data metrics cited, analysed or applied</td></tr>
<tr><td colspan="2">Varna (SEA) (MEW, 2025)</td></tr>
<tr><td>Quantity - 1 procedure, 67 mentions in the SEA</td><td>Moderate amount of health data used</td></tr>
</table>

from 2009	
Quality - pp. 31-32 describing conditions and state of health related factors; pp. 60-65 prescribing mitigation measures against the expected impacts; pp. 65-85 prescribing mitigation measures against the expected impacts mostly associated with air quality, noise and water quality (incl. bathing waters)	Health statistics are cited and descriptively analysed
	No geospatial data metrics cited, analysed or applied
Burgas (SEAs) (MEW, 2025)	
Quantity - 6 procedures, 172 mentions in the last SEA from 2022, 84 mentions in the first SEA from 2007, the interim amendments of the plan are not directly related to health issues	Moderate amount of health data used
Quality - 2007 SEA, part 2 pp. 101-103 describing conditions and state of health related factors, part 3 with consistent methodology for multiple environmental issues; 2022 SEA of a partial amendment, pp. 34-40 and 96-100 describing conditions and state of health related factors	Health statistics are cited and analysed, interpretative and data based impact evaluation matrices is used
	Geospatial data metrics cited, analysed or applied through modeling of pollutants (e.g. atmospheric)
Ruse (SEA) (MEW, 2025)	
Quantity - 1 procedure, 150 mentions in the SEA from 2018	Low amount of health data used
	Health statistics are cited and analysed
Quality - distributed paragraphs across the descriptive and prescriptive parts	No geospatial data metrics cited, analysed or applied

The HIA related content is too general, except for Sofia and Burgas cities. Most of the initial plans were elaborated more than 15 years ago and the monitoring of their implementation is missing. Amendments are avoided due to procedural fears and the ones present avoid more thorough HIA, while consultations provide demand and proposals for more emphasis on the health effects.

Juxtaposing the regulative comparison and the content analysis we provide evidence that the health aspects are broadly mentioned in the Bulgarian legislation but the HIA guidance and planning and decision support tools are missing, while the content in the SEAs where such assessment usually has to take place is too vague and outdated. Much more is needed in order to address this pressing issue, given the exposure evidence and the related health risks in the Bulgarian cities and among its vulnerable population.

Stakeholder analysis

A purposive sample of stakeholders was surveyed to collect information on their self-assessments of awareness, interest, influence, knowledge of the major settlements; identification and prioritization of current issues of urban environment associated with health; as well as their opinions on the necessary actions/decisions; barriers and opportunities to overcome those, experience in evidence-based approaches and preferences as well as anticipated future problems and expected benefits for the urban quality of life. The initial consensus sample comprised 354 individuals associated with 136 organizations representing international, national and local institutions, political, governmental, business and non-governmental organizations, academia and professional communities, etc. invited to take part in the on-line survey. Results were obtained from 108 respondents from the 5 major cities in Bulgaria who were well familiar with the urban environment of more than one city – the highest rate being 79% (n=85) for Sofia, 48% (n=52) for Plovdiv, respectively 40% (n=43) for Burgas, 30% (n=32) for Varna and 13% (n=14) for Ruse overall comprising 32% (n=35) governmental/central authorities and national institutions or agencies, NGOs accounted for 19% (21), 16% (n=17) members of academia, researchers and experts, followed by business stakeholders 13% (n=14) and active citizens - 10% (n=11).

Respondents' professional roles are predominantly policy enforcement and planning ones and the scope of expertise is regionally and locally oriented for most of the half (fig. 1). Perceived ability to influence urban health decisions differed significantly and was highest for Sofia - 66% (n=61) while for Plovdiv and for Burgas it was respectively 25% (n=23) and 24% (n=22) and much lower for Varna - 10% (n=9), and Ruse at 8% (n=7), aligning with Sofia's role as a policy and decision-making hub.

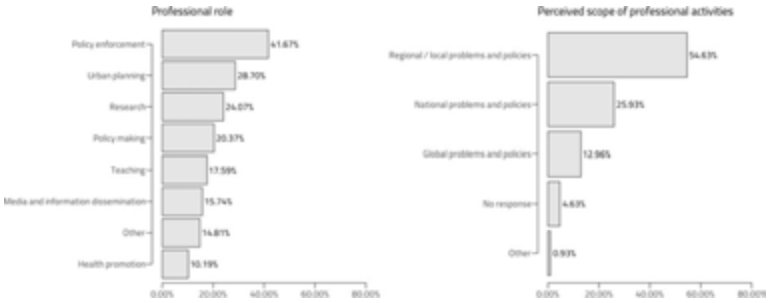

Figure 2 Professional role and activities of respondents

The priority challenges stated by the respondents are led by the urban air pollution, followed by issues related to the capacity and compactness of the city and the quality of green spaces, almost equally prioritized with the noise pollution (fig. 2).

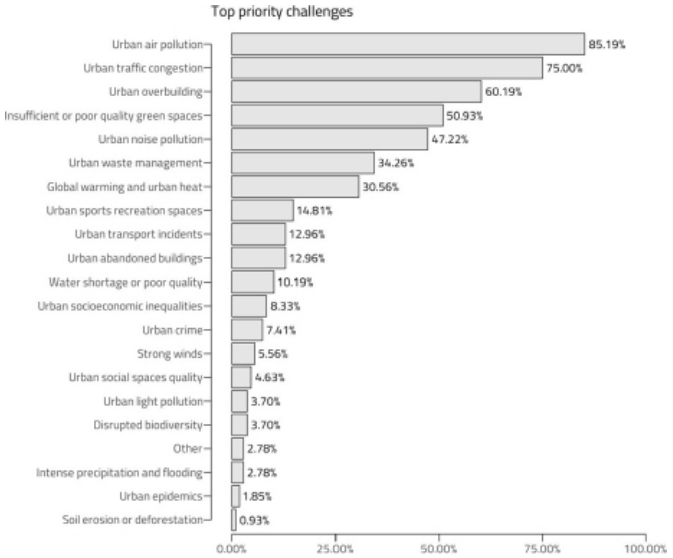

Figure 3 Priority challenges for health in the urban environment

Respondents awareness levels were high with urban environment issues having a profound personal significance for the stakeholders - 57% (n=61) reported being affected "very much" and in 39% (n=42) being "quite affected" and 44% (n=48) claiming expert knowledge of urban planning and evidence-based decision making supporting the idea of a well-informed respondent pool.

Policy preferences for tangible, high-impact interventions aligned closely with identified urban environment issues and policies targeting improvement of urban air quality were endorsed by 74% (n=80), followed by enhancing mobility and transport connectivity in 55% (n=59), improving green spaces quality and/or quantity in 42% (n=45).

Expected direct QoL benefits when effectively addressing urban challenges were mainly health related - improved public health indicators in 78% (n=83) associated with improved air quality, resulting in increased citizen satisfaction (77%, n=82) but also reduced noise levels (51%, n=54) and increased physical activity by 44% (n=47). Improved socioeconomic status and reduced social inequality ranked lower underscoring a primary focus on environmental and health outcomes.

Consistent with the self-evaluations of stakeholders' abilities to exercise influence were the reported barriers to sustainable urban development pointing poor coordination and alignment of decisions and policies as major challenge (44% n=47), along with conflict of business and public interests in 43% (n=46), as well as lack or insufficient political support in 39% (n=42), followed by poor or inadequate capacity and understanding of research evidence (38%, n=41), general public awareness (36%, n=39) and underfunding (35%, n=38) revealing major systemic governance and engagement challenges.

The prevailing opinion was that local authorities (90%, n=97) were the most effective agents in advancing sustainable urban development and health, along with communities (71%, n=77) while 48% (n=51) acknowledged the role of national and centralized policy decision making.

Overall results of the survey provided insight into deficiencies limiting effectiveness in urban health management and stakeholders' opinions favouring access to high-quality health-related research evidence to foster active engagement of both public and professional bodies thus providing rationale for validating the concept for reframing integrative HIA approach for sustainable urban development.

An overview of urban environment - public health interactions and exposure patterns across major Bulgarian cities

The overview of the interactions between urban environment and public health as well as the mapping and modeling of exposure patterns clarifies the current data and evidence base. This overview is focused on five of the largest cities, with a particular emphasis on Sofia. We highlight some of the key urban exposures such as air, noise, and light pollution, alongside the characteristics of green spaces and their accessibility.

One of the experiences drawn here together with others is the pilot project "Set an **Urban Standard** - Creation of a Standard for Evaluation and Monitoring of the Quality of the Urban Environment", funded by the "Europe" Program by Sofia municipality in 2017 in which the healthy urban environment was defined as one of the five major thematic spheres for high quality urban environment.

Another flagship experience reflected here, the project "**URBiNAT** - Healthy corridors as drivers of social housing neighbourhoods for the co-creation of social, environmental and marketable NBS" was funded by the EU Horizon 2020 program and provided ground from 2018 for natural experiments of healthy urban environment co-creative regeneration through nature based solutions in the form of green corridors, one of them implemented in Sofia by 2024.

A more focused and thorough approach in the project "Development of a **methodology for air** quality **and** human **health** risk **assessment** in urban areas" that is supported by the Bulgarian National Science Fund from 2021 onwards, helps to build the bridges between multiple disciplines in the sake of more robust air pollution modeling and assessment of its health impacts in terms of current status and future impacts from urban development alternatives.

The project "**Joint effects** of exposures to natural and built environments – informing healthy and sustainable urban development" as part of the "Strategic research and innovation program for the development of Medical University – Plovdiv" and as part of the Establishment of a network of research higher schools via the National plan for recovery and resilience is financed by the European Union – NextGenerationEU. It is a primary effort of all the authors of this paper to dive into the complex and intertwined urban environment - health relations in the major urban areas in Bulgaria.

Additional references made in terms of important screening studies in this knowledge base review are outlooks and compilations of the Health Effects Institute (2022, 2023), the EXPANSE, and UBD Policy Horizon 2020 projects. The latter combines resources with the Methodology for air and health assessment and the Joint effects projects in order to bring synergy in the research efforts for Sofia city.

Table 3 Overview of the HIA evidence for large cities in Bulgaria generated by selected research projects

Type of research / Characteristics	Previous local research - e.g. **'Urban standard'** project (Burov et al., 2023; UBSP, 2021)	Recent international urbanism, social sciences and other interdisciplinary research - e.g. **URBiNAT** project (Tasheva-Petrova et al., 2021; Cardinali, 2024a,b,c; Burov & Tasheva-Petrova, 2025)	Ongoing national multidisciplinary research - e.g. **Methodology for air and health assessment** project (Burov & Brezov, 2022; Brezov & Burov, 2023; Dzhambov et al., 2023; Velizarova et al., 2024; Dimitrova et al., 2025)	Ongoing epidemiological and multidisciplinary research - e.g. **Joint effects** project (Helbich et al., 2024a,b, 2025; Dzhambov et al, 2025a,b)	Recent and ongoing broader EU and comparative case studies epidemiological and multidisciplinary research - e.g. **UBD Policy** project (Iungman et al., 2024; Khomenko et al, 2025)

Studied interactions between urban environment and public health	Comprehensive demonstration in Sofia (several neighborhoods) Health as part of 5 strands of a 4 tiers taxonomy considering indicators representing components and factors for healthy urban environment at the lowest tier and at plot, street segment and quarter level	Co-creation action research in Sofia (Nadezhda district) as well as other EU cities Self-reported health before and after small physical and supportive participatory, social and solidarity nature based solutions (NBS) interventions along green healthy corridor in real scale	Multidisciplinary focus on air pollution as the major environment al risk factor along with other prominent health-relate d exposures in Sofia Dispersion modeling of air pollution and investigating health outcomes, scenario simulations at micro scale	In-depth and multilayered pictures of exposures of 5 biggest cities in Bulgaria Exposure-response functions, socio-economic and spatial disparities in health effects, studied at high resolution	Overall and multilayered picture linking multi city comparative analysis and several cities case studies, one of them Sofia, studied at high resolution neighborhoo d scale
Mapping and modeling and/or evaluation methods and techniques	Rapid assessment based on available data, information and knowledge	Mixed methods and acquisition of self-rated health data together with mapping and geospatial analysis	Focused multilevel air pollution and multi exposure modeling assessment filling gaps, cross-sectional survey for acquisition of self-reported health data	Integrated and focused various pollution and multi-exposure modeling assessment filling gaps, cross-sectional survey for acquisition of self-rated health data	Data science geospatial analysis, synthesis, case study multi-exposure investigation with specific sets of models adapted to every case study

Measured and modeled exposure patterns, thresholds, limits	Available secondary datasets collection, field surveys, geospatial analysis of air quality, noise, greenery, waste, light, water according to national regulations	Available secondary datasets collection, field surveys, behavioral mapping, ex-ante and ex-post cross sectional surveys, geospatial analysis, Structural Equation Modeling (SEM) and other mixed methods with foci on greenery and air quality (PM10, PM2.5, NO_2, and SO_2)	Own inventory, mapping, traffic, emission and dispersion models of air pollution: PM10, PM2.5, NO_2, etc. compared to national, EU and WHO thresholds. Additional co-exposure s such as: noise (road, rail and air traffic noise) from secondary sources; green space: access within 300m of residences.	Official noise measurements based land-use regression and explainable machine learning models compared to European Noise Directive maps with exposure-response curves assessed. Nighttime Light Pollution exposure based on VIIRS satellite data. Air Pollution based on own NO_2 measurements and EXPANSE air pollution data. Greenspace within buffers and via tree cover, NDVI and public spaces. Blue space within buffers.	Air pollution: PM2.5, NO_2) Noise: Road traffic noise levels range from 45-80 dB(A), exceeding WHO guidelines of 53 dB Lden and 45 dB Lnight. Green space: 77% of Sofia's population lacks sufficient greenspace access within 300m of residences. UHI: Average summer UHI effect of 2.5°C Temporal patterns: NO_2 peaks during rush hours (8 a.m. and 5-6 p.m.), with lower concentrations on weekends.
Health burden	Not explicitly addressed but with implicit references	Not explicitly addressed but with implicit references	To be addressed in the final round of well validated dispersion modeling	Health burden estimates of noise for the 5 big cities and others under consideration	Health burden estimates of Sofia with PM2.5, NO2, noise, green and UHI (Khomenko, 2025)
Health promotion, prevention and protection guidelines	Comparison s of (un) favourable exposure, particular urban development , planning and design recommendations, guiding and localisation of public space improvements	Air pollution mitigation by green corridors to improve air quality. Physical activity by accessible green spaces with sports facilities and walking paths. Community engagement by educational programs on environment al stewardship and healthy lifestyles	Measures like low emission zones (LEZ) and traffic reduction (20%) to significantly decrease pollution concentration levels in critical episodes. Integration of green wedges, cycling infrastructure, and transit-oriented development to reduce environmental stressors.	Upcoming set of recommendations based on the exposures and health effects found in each of the 5 cities	Policy briefs and scenarios to be developed as part of overall health promotion guidelines for Sofia

Concept for reintroduction of health impact assessment in Bulgarian cities

In order to enhance the general understanding of the healthy urban environment and its implications in the planning process and content a more holistic definition of its related qualities is needed in the primary EPA and/or in the Health Act along with more specific principles, requirements, capacity arrangements, etc. in a future edited version of the newly proposed by-law. Thus HIAs can become more clearly interpreted against the constitutional rights for healthy environment and wellbeing at a more collective level. Also, healthy aspects of urban planning, design and development can be more clearly treated in the judicial practice in this domain in order to resolve both types of cases under the umbrella of the civil and administrative law. Part of the small gaps can be filled by guidelines, standards and other supportive tools, but due to the contested nature of urban development neither laws nor guidelines are enough. Well targeted and well informed communication can be the key to reintroduction of health and HIAs in the urban arena of knowledge and action, as a cornerstone around the building of the very needed resilient and sustainable communities.

The conceptual model attempts to reframe and propose improvements of existing policies, regulations, tools, and measures. It further attempts to provide grounds for balancing trade-offs between urban development and health protection, by proposing a circular path to safeguarding the wellbeing of Bulgarian city dwellers (Fig. 4). The model is based on a set of definitions, principles and recommendations as follows:

A. Defining „healthy urban living environment“

At the level of the specific legislation - the Environmental protection and Health acts, the concept proposes a definition of “healthy urban living environment” in both legislative texts in order to serve as the basis for urban development policies and principles in this domain. The spirit of the definition proposed is embodied in the notion that “Healthy urban environments do not harm physical health and well-being and promote health-enhancing behaviors and resilience”. Additional proposal is to include in the definition the “Protective characteristics” that limit risk factors, reduce social inequalities, create access to green space and public spaces, support active travel, and promote sustainable resource use leading to overall satisfaction with environmental qualities”.

B. The concept for HIA reintroduction at the bylaw level implies adopting a set of principles:

- The use of sound scientific data and city specific knowledge building as a base;
- Formulation of health-based indicators adapted to the local environment;
- Targeted surveys and consultations with potentially influenced citizens and involved experts;
- Assessment of the needs of vulnerable groups and respect for socio-economic dimensions;
- Adherence to WHO, other international and EU guidelines
- Definition of national norms, thresholds for harmful and targets for protective urban environmental qualities.

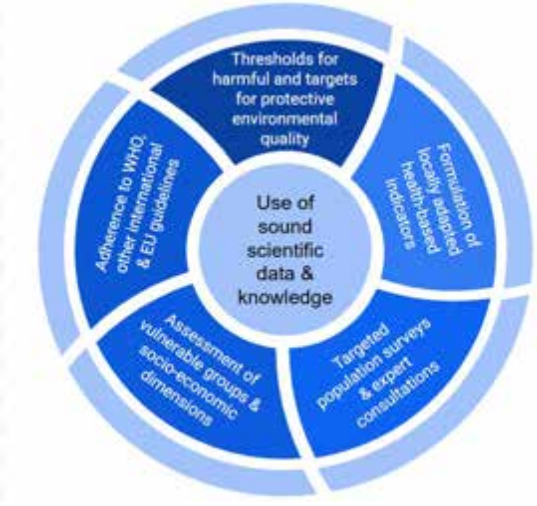

Figure 4 A circular path of HIA reintroduction principles

C. Furthermore, development of instructions is proposed, as well as methodological guidelines and technical standards based on scientific evidence and good practice.

Improved understanding of multidisciplinary issues and provision of references and resources for health protection is a more soft emphasis which could be implemented by the National Centre for Public Health and Analyses and the Regional Health Inspectorates in partnership with academia and professional organizations.

D. It is highly recommended that regulations and plans are updated regularly, and their implementation is monitored and controlled more closely.

Additional synchronisation of the HIA regulations with other environmental and development regulations and differentiation of the levels of complexity in the elaboration of spatial plans are also important aspects that can better direct the implementation of healthy urban planning and evaluation efforts at the appropriate level of initiative, mandate and competence.

Conclusion

Healthy urban planning should be both a goal ensuring the well-being and civilized continuity of urban life and a procedural mechanism driven by actual evidence and enhanced participatory governance. Advanced tools like geospatial analytics, mixed-method approaches, machine learning, and natural language processing enhance the capability of HIA to provide timely, context-sensitive insights and feedback loops, improving communication, saving time and providing precision of urban (re)development endeavors. Efficient procedures and equitable frameworks are essential for delivering health-promoting environments, particularly in post-transitional and contradictory contexts with many external and internal players like Bulgaria.

The proposed revitalized HIA agenda may support cities in staying livable and becoming more inclusive, resilient, and health-supportive spaces for current and future generations. Thus HIA can be a crucial instrument for avoiding the double spending of financial resources, time, energy and resource input as well as human efforts to overcome critical urban health issues while observing processes of urban decay.

Stimulating a wider and deeper discussion on the key principles for healthy and sustainable development of the urban living environment as well as the health support systems in decision making affecting urban development, planning and design is a necessity for Bulgaria. These decision making systems can benefit from a set of tools and interlinkages including qualitative and quantitative assessment of the expected impact, from planned development and regeneration, on public health in terms of morbidity, mortality and well-being, as well as associated socio-economic burden. Emerging platforms for sharing recent knowledge base and data spaces combining spatial data infrastructure and various services can help give confidence in HIA in times of multilevel challenges to our cities.

Abstract
Mountain territories provide essential ecosystem services (ES) to metropolitan areas, yet their contributions are often overlooked in spatial planning. This paper presents an updated application of the open-source SimulSoil plugin to model two key ES—Carbon Storage and Habitat Quality—in the Metropolitan City of Turin, a complex mountain-metropolitan system in northern Italy.

Using the high-resolution 2023 Land Cover Piemonte dataset, the models were applied across 11 Homogeneous Zones to map ES distribution and ecological asymmetries. Results show that mountain areas act as "ecological donors", offering critical services to densely populated urban zones.

This study demonstrates how spatially explicit ES analyses can support rebalancing-oriented governance. The updated models provide actionable knowledge for integrating ecological functions into territorial planning and reveal the need to address spatial imbalances and territorial justice.

Keywords: Metro-mountain Interdependencies, Ecosystem services, SimulSoil Modelling; Metropolitan governance, Spatial planning

1. Introduction

In recent years, ecosystem services (ES) integration into spatial planning has gained increasing attention among scholars and practitioners aiming to reorient territorial governance toward sustainability and climate resilience (Mosso, Nino and Salata 2025). Ecosystem services—broadly defined as the benefits humans obtain from nature—have emerged as a conceptual and operational framework for bridging ecological processes with human well-being (MEA, 2005; TEEB, 2010; (Egegard *et al.*, 2024). Despite this growing interest, the effective operationalisation of the ES paradigm in planning remains a significant challenge, especially in multi-scalar, ecologically diverse, and institutionally fragmented contexts such as metropolitan areas.

Urban and metropolitan areas are often perceived primarily as population, consumption, and economic activity centres. However many such areas—particularly across southern and alpine Europe—include extensive mountain systems within their territorial boundaries. While often peripheral in terms of infrastructure and political attention, these upland areas are critical suppliers of key ecosystem services such as carbon sequestration, biodiversity conservation, water regulation, and landscape stability. Recognising this role requires a conceptual shift in understanding metropolitan systems (Dematteis, 2018 and 2020): not as urban-centric spaces but as socio-ecological territories shaped by complex interdependencies between human settlements and natural ecosystems.

The Metropolitan City of Turin (CmTo) offers a compelling case for exploring this shift. Located in northwestern Italy, the CmTo encompasses 312 municipalities across a spatially diverse territory that extends from the densely

urbanised plain surrounding the city of Turin to the sparsely populated Alpine valleys to the west and north. This includes over 50% of its territory, classified as a mountain area. The institutional structure is based on 11 Homogeneous Zones (HZs), designed to facilitate territorial coordination, yet significant disparities in population, economic capacity, and ecological functionality remain.

Within this mountain-metropolitan system, the provisioning of ecosystem services is highly uneven. Mountainous municipalities contribute disproportionately to ecological regulation—through forested land, protected areas, and low-intensity land use—yet they often lack the institutional power and financial resources to influence metropolitan planning processes.

Conversely, lowland and urban municipalities concentrate demand for ES, infrastructure investment, and political representation while contributing relatively little to ecological functions. This asymmetry reflects a broader challenge in contemporary spatial planning: recognise and govern ecological interdependencies across heterogeneous territorial systems. The CmTo has taken up this challenge by basing the vision of its third Metropolitan Strategic Plan 2024-2026 on the this vision, incorporating elements from the Metropolitan Agenda for Sustainable Development and focusing on a new polycentric and "metromountain" development model. In this model, urban and mountain areas contribute to the competitiveness and attractiveness of the entire territorial ecosystem (Città metropolitana di Torino 2024).

One promising avenue lies in spatially explicit modelling tools that visualise ES flows and highlight ecological performance across territorial units.

This paper addresses this challenge by applying an updated version of the open-source SimulSoil plugin. Originally developed within the EU LIFE SAM4CP Project (http://www.SAM4CP.eu), SimulSoil integrates biophysical models from the InVEST software suite with locally adapted land use and ecological data (Barbieri&Giaimo, 2015; Giaimo&Barbieri, 2018; Giaimo, Barbieri&Salata, 2019). The project aimed to promote local-scale, sustainability-oriented models of land governance by providing tools to assess the costs and benefits of the free ecosystem services provided by soil; SimulSoil allows for the analysis of specific ecosystem services across planning-relevant spatial units, offering outputs compatible with strategic planning and governance frameworks.

We focus on two services: Carbon Storage and Sequestration (CS) and Habitat Quality (HQ) selected for their high relevance to climate and biodiversity goals, their mappability using available data, and their capacity to reflect underlying ecological conditions. CS and HQ serve as proxies for broader regulatory services and provide insight into the spatial logic of ecological provision in the CmTo.

Our objectives are threefold: i) to generate spatialised evidence of ES provision in the CmTo using updated and locally calibrated models; ii) to interpret the spatial patterns of CS and HQ across the 11 HZs and assess territorial imbalances in ES supply; iii) to reflect on how such evidence can inform rebalancing-oriented planning, particularly by recognising the role of mountain territories as ecological donors within the metropolitan system. The paper is structured as follows. Section 2 presents the regional context of the CmTo and discusses key socio-ecological characteristics of the HZs. Section 3 introduces the SimulSoil plugin, tracing its development and recent updates to data sources and model assumptions. Section 4 describes the methodology used to operationalise the InVEST Carbon Storage and Habitat Quality models within SimulSoil. Section 5 presents and interprets the modelling results, while Section 6 critically examines limitations of the approach and identifies potential avenues for integration into planning practice. The final section offers conclusions and policy recommendations.

This study makes three main contributions by applying updated ES models to a mountain-metropolitan case. First, it provides empirical evidence for the ecological centrality of upland territories within a metropolitan context. Second, it illustrates how open-source tools can be adapted and applied to produce planning-relevant outputs. Third, it contributes to debates on spatial justice by highlighting the need to account for territorial imbalances in ES supply and demand. Ultimately, we argue that ecosystem service modelling, when grounded in local data and critical territorial interpretation, can serve not only as a technical aid, but as a transformative planning lens—one capable of advancing ecological transition and promoting a more equitable distribution of responsibilities, resources, and recognition across metropolitan landscapes.

2. Case study: The Metropolitan City of Turin and Its Mountain-Metropolitan System

The Metropolitan City of Turin, located in the northwestern region of Piedmont, Italy, is a paradigmatic example of a mountain-metropolitan system where ecological, socio-economic, and institutional dynamics intersect. Established in 2015 as part of Italy's metropolitan reform (L. 56/2014), the CmTo replaced the former Province of Turin and is one of the ten metropolitan cities officially recognised by the Italian state. Its territory encompasses 312 municipalities, making it one of Europe's most fragmented metropolitan areas. This region's spatial heterogeneity poses challenges and opportunities for the governance of ecosystem services and territorial sustainability.

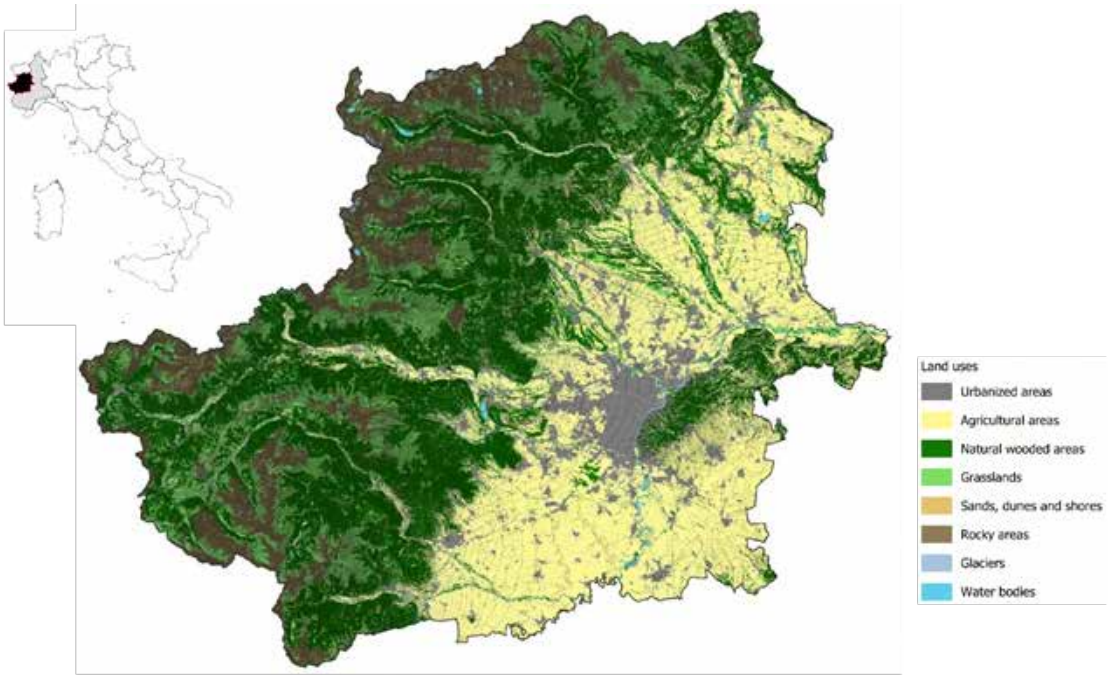

Figure 1 The Metropolitan City of Turin. Framing and Morphological-Settlement Structure (source: authors' elaboration)

Covering an area of approximately 6,800 square kilometres, the CmTo is geographically diverse and climatically varied. More than half of its territory is classified as mountain or upland area, with the western and northern parts defined by prominent alpine systems such as the Graian Alps, Cottian Alps, and the Lanzo, Susa, Chisone, and Pellice valleys. These mountain regions border France and include several national parks, protected areas, and Natura 2000 sites, collectively representing critical ecological infrastructure for carbon sequestration, biodiversity conservation, and climate regulation (Città metropolitana di Torino, 2021).

In contrast, the central and southeastern portions of the CmTo composed mainly of plains and hilly terrain, forming part of the upper Po Valley. This area hosts the urban core of Turin and its surrounding municipalities, where economic activities, transport infrastructures, and residential development are heavily concentrated. As such, the CmTo encapsulates a marked spatial asymmetry: mountainous zones are low-density, ecologically rich, and institutionally peripheral; lowland zones are high-density, socio-economically dominant, and ecologically stressed.

To foster more effective and participatory management of municipalities in metropolitan governance and government, the CmTo has adopted an internal subdivision into 11 Homogeneous Zones (HZs), each grouping municipalities with shared geographical and functional characteristics. This sub-metropolitan geography is not merely statistical but plays a role in policy coordination, funding allocation, and planning. For such reason it also serves as a practical framework for applying ecosystem service models and interpreting their results regarding planning relevance.

Figure 1 illustrates the spatial configuration of the CmTo and the major physical features of the area, including mountain ridgelines, river basins, and urban concentrations. The figure highlights the metropolitan region's concentric structure, with Turin's urbanised core surrounded by progressively more natural and mountainous belts. This spatial organisation is central to understanding the flows and gradients of ecosystem services across the territory.

Within this spatial framework, mountain territories' ecological functions are vital and under-recognised. Forests and semi-natural landscapes in the alpine valleys represent key carbon sinks and habitats of high ecological integrity. Due to limited land transformation, low-intensity agriculture, and restricted infrastructure development, these areas maintain high ecosystem service provision capacity, particularly in Carbon Storage and Habitat Quality. Simultaneously, they face socio-economic pressures such as population decline, ageing, service retrenchment, and low institutional capacity—factors that undermine their visibility and influence in metropolitan governance (Alberti et al., 2019).

Conversely, the lowland and peri-urban areas concentrate anthropogenic pressures, including land sealing, habitat fragmentation, pollution, and transportation emissions. Urban expansion into formerly agricultural land has reduced the plain's ecological connectivity, while the intensity of land use has diminished both carbon sequestration and habitat potential. While dominant in population and economic terms, these zones are ecologically dependent on the surrounding uplands for regulatory functions such as flood control, temperature moderation, and air quality improvement.

This functional asymmetry reinforces the concept of mountain municipalities as "ecological donors" in the metropolitan system, providing environmental benefits that are largely consumed elsewhere. Despite this role, ES-based reasoning is not yet institutionalised within the CmTo's planning practice. The General Metropolitan Territorial Plan (GMTP), though still in development, has only partially integrated ecological indicators, and coordination among HZs remains uneven. From a policy standpoint, the fragmentation of administrative competencies across municipalities creates obstacles to coordinated ES management. While the CmTo provides a metropolitan umbrella, actual planning competences are still largely exercised at the municipal level, with variable technical capacity and resources. This poses challenges for the integration of ES modelling tools, which require a shared vision, consistent data, and inter-institutional cooperation.

In this context, updating SimulSoil offers a valuable opportunity to visualise and quantify ecosystem services at the HZ level, providing empirical support for more equitable and sustainability-oriented planning strategies. The selection of Carbon Storage and Habitat Quality as focal ESs reflects their relevance to territorial resilience and the data availability within the regional land use framework.

The recent availability of the 2023 Land Cover Piemonte (LCP) dataset—developed by Regione Piemonte—has significantly improved the region's thematic resolution and reliability of land use information. This dataset enables a more accurate representation of forest types, agricultural mosaics, and anthropogenic land cover, essential for ES modelling. By integrating this dataset into the SimulSoil plugin, we achieve a more context-sensitive representation of ecological processes and service provision potential.

Moreover, using the HZs as the primary units of analysis allows for a better alignment between ES outputs and institutional planning scales. It helps overcome the disconnect between ecological data and planning implementation, a gap frequently highlighted in the literature on landscape governance (Primmer et al., 2015.

In sum, the Metropolitan City of Turin provides a relevant and rich case study for exploring ecosystem service dynamics in a mountain-metropolitan setting. Its territorial heterogeneity, administrative complexity, and ongoing planning reform processes make it an ideal laboratory for testing tools like SimulSoil. By linking spatialised ES modelling to institutional geography, this study aims to demonstrate how planning can move beyond urban-centric logic and embrace more ecological and equitable understandings of metropolitan space.

3. The Open Source SimulSoil Plugin: Origins and How to Update

SimulSoil is an open-source plugin for the QGIS (version 2.18.15) software, developed to support the qualitative and quantitative assessment of soil's ecosystem services. The tool aims to make mathematical and statistical models accessible to non-expert users by automating the complex calculation algorithms of the Integrated Valuation of Ecosystem Services and Trade-offs (InVEST) software.

SimulSoil provides access to repositories and databases that enable the mapping of the biophysical performance of soils at a spatial scale, as well as the identification of quantitative biophysical parameters that measure the potential of soils to deliver ecosystem services. It is achieved by relying on scientific literature and the availability of shared map bases. Additionally, the software enables the measurement of changes in ecosystem balance at the municipal scale through the simulation of alternative scenarios. The simulator was developed based on the assumption that constructing a cognitive framework for mapping ES would support more informed and shared decision-making processes regarding soil, spatial planning and management.

The tool includes eight ecosystem models selected by InVEST. This U.S.-based, open-source software uses computational models to map and assess ecosystem goods and services in biophysical and economic terms, quantifying their contribution to meeting essential human needs (Costanza *et al*., 1997; MEA, 2005). SimulSoil leverages QGIS capabilities for managing raster and vector data, integrating WMS/WFS services and using base maps (e.g. Google Maps, OpenStreetMap) to provide an intuitive, user-friendly interface. Its modular architecture and the open-source nature of the data facilitate adoption and continuous enrichment by a large, diverse user community.

SimulSoil aims to contribute developing methods and tools for integrating the ES paradigm into land-use governance activities by spatialising new knowledge on the distribution and flows of ecological and environmental performance. This methodology enables the development of a multi-scalar approach to be developed, allowing local applications to assess urban transformation scenarios and conduct spatial analyses to explore the complex interrelationships related to ecosystem flows, thus supporting decision-making processes (Corrado *et al*., 2019). It enables to prioritise scenarios in which investment in natural capital can balance human development and ecosystem conservation (Natural Capital Project, last accessed 27/05/2025).

The models produce map outputs in raster format with a pixel size of 5x5 metres, wich constitute valuable cognitive tools for studying the performance of ecosystems in soils.

At the local level, a significant potential application of the SimulSoil simulator lies in its use within the Strategic Environmental Assessment (SEA) process, a mandatory procedure for spatial planning. Analyses of ES associated with land use and land cover classes represent a concrete opportunity to quantify the impacts generated by ex-ante plan choices as well as using ES calculation models through SimulSoil allows alternative scenarios to be evaluated by modifying the cartographic input data that defines land uses and land cover.

At the scale of the metropolitan area, studying ecological and environmental performance supports spatial governance in distinct and evolving ways. For instance, studying ecological and environmental performance can address the need to consider and implement policies affecting the entire metropolitan area, which is characterised by significant morphological and settlement heterogeneity. In this context, SimulSoil is a valuable tool for analysing the exchanges and flows of ecosystem services between different spatial contexts, from the most peripheral municipalities to those close to the capital, highlighting the interdependent relationship between plains and mountains in particular. It allows to recognise the relationships between ecosystem demand and supply, identifying areas of provision and beneficiaries. Mountain territories play a strategic role in this system: they represent the entire metropolitan area's ecosystem pull, compensating for the impacts generated by the more densely urbanised lowland areas. Mountain areas provide essential regulatory services, demonstrating that ecosystem performance stems from spatial patterns generating a system of spatial interdependencies that are functional for the well-being of the entire metropolitan area.

Compared to the previous version of Simulsoil, which included eight ecosystem models, the ongoing update process aims to release a new version of the application consisting of five models: Carbon Sequestration (CS), Habitat Quality (HQ), Agricultural Production (CPR), Wood Production (TPR) and Sediment Retention (SDR). As these

ecosystem models all require Land Use Land Cover (LULC) mapping as their main input data, the update process began with revising this mapping. Additionally, the update to SimulSoil will enable it to be used with QGIS versions 3.0 and above, making it more accessible to users and allowing them to take full advantage of the latest software features.

With reference to mapping, the Piedmont Region periodically produces updates to this cartographic base under the name 'Land Cover Piemonte' (LCP). As SimulSoil was developed using the available LCP base dated 2010, one of the first activities conducted as part of its update was to check how to integrate the latest version of the LCP base 2023 and study their contents to ensure consistency with the previously used LCP base for automating SimulSoil's calculation models.

The LCP 2023 database contains more geometric and descriptive detail than its predecessor, moving from a four-level classification system with 74 classes to a five-level system with 99 classes. Due to this increased detail, we decided not to use the original input data from the SAM4CP project (2014–2018) directly, as this project relied on the 2010 LCP legend. A notable example of this change is the classification of urbanised areas intended for residential use. The 2010 LCP divided these into 8 classes based on building density criteria made explicit through qualifying adjectives (e.g. continuous and dense, medium dense, discontinuous and sparse). The 2023 version, on the other hand, adopts a classification based on zones that are differentiated through percentage thresholds of soil sealing (>80%, 50-80%, 30-50%, 10-30%, <10%) and a specific class for isolated residential areas. The improved detail of the 2023 map base allows for a clearer distinction between input values associated with LULC classes. Despite the advantages of geometric accuracy and descriptive detail, the new LCP base map has some critical structural issues. Notably, despite being derived from high-resolution sources such as the Piedmont Entities Spatial Reference Database (BDTRE), the mapping does not distinguish between buildings and contiguous spaces. This limits the ability to associate specific input values with certain land use types. Additionally, while the adopted LULC classification is inspired by Corine Land Cover (CLC), it introduces descriptive language that partially diverges from the 2010 version. This necessitates the reconstruction of input repertoires. (Giaimo, Pantaloni and Farina, 2025). The update also involved revising the reference geometries and enriching them with thematic information from various sources, such as the Forest Map, the Regional Landscape Plan, the Agriculture Census, Copernicus data, Piedmont Remote Sensing data and ISPRA land consumption data. We integrated all of this information into the parcels of the Mosaic Cadastral Survey. While this combination of sources enabled the creation of a more robust mapping base, it also necessitated substantial adaptation of the SimulSoil models in terms of content and data structure. In summary, adopting the new LCP base was a pivotal step in ensuring the continuity and reliability of the ecosystem service assessment models implemented in SimulSoil, though it did require significant work to harmonise and update the input data.

4. Methodology: updating the Habitat Quality and Carbon Storage and Sequestration models

This study employs two ecosystem service models—Habitat Quality (HQ) and Carbon Storage and Sequestration (CS)—from the InVEST software suite, integrated into the open-source SimulSoil simulator.

Carbon Storage and Sequestration refers to two distinct regulatory ES, which describe the processes by which carbon is sequestered and stored in soil, subsoil, and surface vegetation. These processes play a crucial role in balancing atmospheric greenhouse gases (Nowak&Crane, 2002). Specifically, the sequestration model quantifies the amount of carbon dioxide removed from the atmosphere by terrestrial ecosystems, while storage indicates the amount of carbon retained in organic form until the plant dies (Larcher, 1975). Therefore, Carbon Storage is linked to the entire life cycle of vegetation, whereas sequestration is generally assessed on an annual basis, corresponding to a single seasonal growth phase (McPherson&Simpson, 1999).

Habitat Quality is a life-supporting ecosystem service and a key indicator for assessing the ecological and environmental status of habitats (Assennato *et al.*, 2018). The ecosystem quality index reflects the extent to which biological and genetic diversity, and the evolutionary processes that underpin the regulatory, provisioning and cultural functions of ecosystems, are preserved. Assessing HQ at a local level is essential for understanding the ecological condition of urban areas and identifying critical areas and spaces with potential for increasing vegetation biodiversity. The latter is defined as the variability of all living organisms in terrestrial, aquatic, and marine ecosystems, as well as the ecological complexes of which they form part (ISPRA-CATAP, 2012). In the

literature, HQ is recognised as a key proxy value for representing regulatory ecosystem services. Assessing HQ in urban areas is particularly important because the interactions between living organisms and the physical environment generate functional relationships that determine the resilience of ecosystems, their conservation status and their ability to provide other ecosystem services (ISPRA-CATAP, 2012). This issue is becoming increasingly important in European metropolitan areas, where the ability to adapt to climate change is closely linked to the state of ecosystems and their biodiversity. Indeed, high biological diversity increases species' resilience to new environmental conditions induced by climate change (National Biodiversity Strategy, 2010).

In detail, the CS model proposed by the InVEST software and updated within the SimulSoil simulator provides quantitative estimates of the amount of carbon sequestered in soil. The model is based on associating predefined sequestration capacity values with LULC categories. Specifically, the model requires five types of input data in order to provide an output of the quantity of sequestered carbon expressed in tons/pixels. The first input is the map base, which spatially represents the different land uses and land covers. Four values representing the Carbon Storage capacity of the main reservoirs, namely litter, hypogean phytomass and epigeal phytomass, must be associated with the LULC classes. As the model is based on a direct association between these values and LULC classes, it can be considered static, as interactions between different habitats do not influence the output. Consequently, the output represents a strong simplification of the carbon cycle, as neither the plant component nor soil management is considered (Giaimo, Pantaloni and Farina, 2025): for example, agricultural processes that involve ploughing. Therefore, the model's goal is to provide shared and common parameters useful for recognising changes in LULC, rather than absolute data.

The HQ model is also based on LULC base mapping; each class is assumed to represent a different ecosystem. Unlike the CS model described above, the HQ output value calculation algorithm is more complex. The latter assesses the naturalness of land uses according to the spatial distribution of threats to them, such as infrastructure, agricultural areas and built-up areas, by cross-referencing LULC data with information on threats to habitats, including land-use changes, sealing, urbanisation, compaction, salinisation and invasive alien species, which lead to degradation, dystrophy, and the alteration of eco-biological processes. This results in a reduction in ecological resilience and ecosystem fragmentation (Seto *et al*., 2012; Romano&Zullo, 2014). The model operates dynamically, assessing interactions between different habitats and threats, which are also spatially defined within the range of LULC classes available. In detail, the input values needed by the model are seven as follows: the cartographic base of Land Use and Land Cover (on which habitats are defined); the level of naturalness, expressed by a 0-1 index, referred to each habitat; threat factors (LULC classes that determine threat to habitats); the sensitivity value of habitats to recognised threats (0-1 index); the weight associated with each threat (0-1 index); the maximum distance of interaction between threat and habitat (expressed in km); and the decay function of the threat factor in the interaction area (linear or exponential). These input values interact in a complex way to generate a parametric indicator associated with each pixel of the base map. This indicator has a value between 0 and 1 and provides a useful reference for identifying areas that are more or less prone to hosting biodiversity.

The CS model benefits from the higher quality of the updated map base in 2023, as its outputs depend on Carbon Storage values being directly associated with LCP classes. The research team chose to update the Carbon Storage values according to the new classification proposed in the LCP 2023, rather than changing the calculation algorithms proposed by the InVEST software on which Simul Soil relies. Therefore, the methodology adopted in the LIFE SAM4CP project was retraced and, where possible, the input values were updated through literature research. It should be noted that the 2023 LCP classification, particularly with regard to urbanised land, required a more substantial update to the input values concerning the storage data of the four carbon pools. Specifically, no useful bibliography could be found to define such biophysical values for urbanised territory. Consequently, a proxy storage value was adopted for the Meadows LULC class (ISPRA, 2024). This value was weighted by averaging the imperviousness threshold values derived from remote sensing data (Copernicus Sentinel-2), which define and differentiate the various urbanised classes. This is a significant revision, as in the previous version of SimulSoil, it was assumed that all urbanised land was incapable of storing carbon.

The data used to determine the carbon pools in agricultural and natural areas were searched in the bibliography. This update was based on the most recent national and regional databases, which allow Carbon Storage values to be associated with each LULC class.

As for CS, only the input data of HQ model were revised, without modifying the original algorithm. In fact, as previously described, the 2023 LULC base differs from the 2010 version in terms of both geometric accuracy and descriptive content. Consequently, the new LULC base was substituted for the one previously used by SimulSoil. The other input data required for statistical processing by the model were also revised, both to adapt to the new mapping base and to update them in light of new knowledge brought to light by the scientific literature.

5. Results and interpretation of the outcomes

The HQ and CS models produce raster maps which can be represented adopting a colour ramp, ranging from red to green, to display soil ecological and environmental performance levels. These maps therefore offer quantifiable, spatially explicit information, identifying areas, administrative boundaries, and minimum ecological and environmental units.

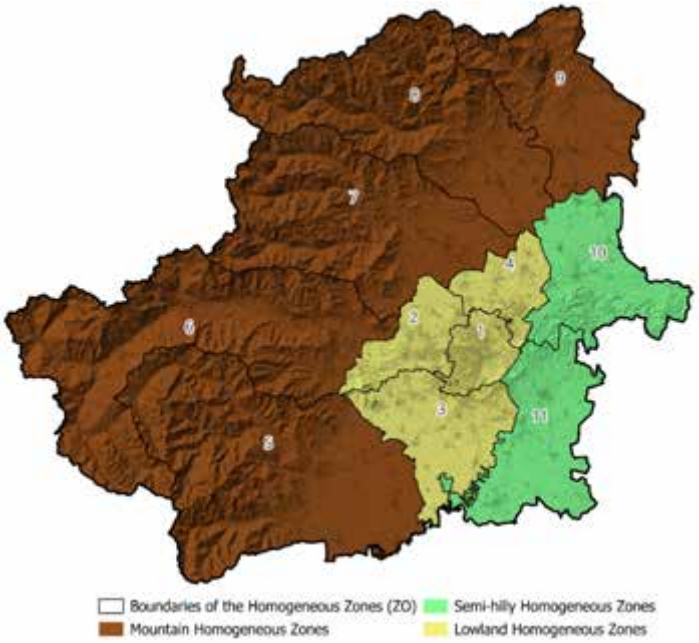

Figure 2 The 11 Homogeneous Zones. Morphological-settlement classification (source: author's elaboration).

Starting from these cartographic outputs, values expressing the average ecological-environmental performance of each OZ has been collected, both for CS and HQ ecosystem services. Doing that, the 11 OZ has been , divided into mountainous, hilly, and plain areas (Figure 2), and the mean ecological value has been compared with the one calculated considering the entire metropolitan territory.

The data illustrated in the two graphs (Figure 3) highlight that mountainous areas are the principal contributors to the ecosystem performance of the CmTo, with semi-hilly and lowland zones playing secondary roles. Among these zones, the highest value was observed in the one that includes the Turin Hill and a complex system of territorial parks and natural areas, with a relatively limited presence of heavily anthropised land uses and covers. In fact, comparing the biophysical values of HZ with those of CmTo helps us recognise which areas of the metropolitan territory contribute most to the territory's overall positive environmental performance. Furthermore, the positioning of the HZ values within the graphs shows that, although the same Land Use And Land Cover have a different contributing capacity in the provision of the two ecosystem services investigated, mountain territories constitute areas where the values recorded are always the highest, as they contain the largest amount of CmTo's natural capital.

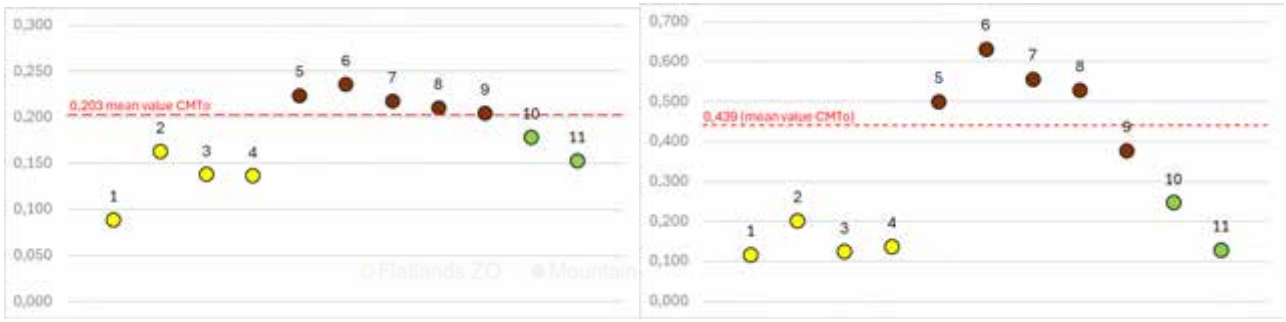

Figure 3 From left: average Habitat Quality value per Homogeneous Zone; average Carbon Sequestration value per homogeneous zone (authors' elaboration).

Considering that, the mountainous component of the metropolitan area plays an essential ecosystem role, providing most of the ecological and environmental benefits. However, this does not mean that areas in hilly or flat contexts cannot deliver significant ecological and environmental performance. Nevertheless, analysis at this scale suggests that anthropogenic pressures and the strong presence of urbanised soils in flat and hilly HZs lead to lower ecological and environmental performance being identified. A notable example is HZ number 11, which, despite including part of the Turin hills, exhibits ecosystem values comparable to those in the HZs of the flat terrain.

This example illustrates how both the morphological and settlement structure, as well as the spatial interaction between ecologically functional soils and anthropogenic pressures, shape the ecosystem values observed across the different Homogeneous Zones (HZs).

Importantly, the ecosystem values recorded in the hilly and lowland areas of the CmTo should not be interpreted solely as indicators of environmental degradation. Ecosystem service assessment requires a multi-scalar approach that allows for more nuanced interpretation of results. When analysed at a finer spatial scale, each HZ may reveal sub-areas with varying capacities to deliver ecosystem services.

In this light, the interpretation of biophysical data and maps can provide valuable insights for enhancing ecological connectivity or guiding the restoration of degraded areas.

The results of this study contribute to raising awareness of the critical role of ecosystem services in supporting sustainable metropolitan governance and planning. By applying updated biophysical models within the SimulSoil platform to the Metropolitan City of Turin, we have demonstrated how spatially explicit mapping and analyses of CS and HQ can generate valuable insights into ecological performance and territorial asymmetries. These insights are especially pertinent in a context such as the CmTo, where natural systems, demographic dynamics, and administrative fragmentation intersect in complex ways.

A key contribution of this research lies in its empirical demonstration of the functional dualism between mountainous and lowland areas in terms of ES provision and demand. The analysis shows that mountain territories act as ecological "donors" within the broader metropolitan system, supplying essential regulatory services that are largely consumed or degraded in more urbanised, lowland zones. This spatial imbalance has been acknowledged in the literature but is rarely documented through high-resolution, model-based evidence at the metropolitan scale. In this sense, the study bridges a gap between theoretical insights on territorial interdependencies and applied planning knowledge.

Moreover, the research adds methodological value by demonstrating how open-source tools such as SimulSoil, when appropriately updated and contextualised, can operationalise the ES paradigm in a practical and locally adapted way. While many studies rely on global or standardised model parameters, we show that region-specific data and assumptions can significantly enhance the relevance and credibility of outputs. This contributes to the ongoing debate on the scalability of ES modelling frameworks in diverse planning contexts.

Another important dimension is the articulation of the models with planning-relevant spatial units—namely, the 11 Homogeneous Zones (HZs) defined by the CmTo. By structuring the analysis according to these institutional geographies, we facilitate a potential alignment between ecological knowledge and decision-making boundaries. This is particularly relevant in metropolitan governance contexts marked by fragmentation and asymmetry, where the absence of shared spatial frames often undermines cooperation. Our results suggest that ES assessments can function not only as technical tools but also as discursive instruments for framing territorial challenges and negotiating shared priorities.

Nonetheless, the discussion of results also highlights certain challenges. The models employed, while useful for quantifying ecological functions, do not fully capture the socio-political realities that mediate ES access, governance, and valuation. As such, they must be interpreted as partial representations of complex socio-ecological systems. There is a risk that planners may overestimate the neutrality and objectivity of model outputs, or fail to integrate local knowledge and stakeholder perspectives into subsequent decision-making processes. For this reason, we stress the importance of combining model-based assessments with participatory approaches and qualitative investigations.

From a broader perspective, this study reinforces the relevance of ES-based planning in the face of global challenges such as climate change, biodiversity loss, and socio-territorial inequalities. Mountain regions, often peripheral in administrative and political terms, emerge here as central actors in ecological resilience and territorial sustainability. Recognising this role has profound implications for how resources, responsibilities, and planning competences are distributed across metropolitan systems.

This discussion underscores both the promise and the limits of ES modelling in metropolitan planning. The evidence presented here supports the call for more integrated, systemic, and evidence-based approaches, while also recognising that such transitions are not purely technical but institutional and political. The path forward will require not only better models but also new forms of governance, interdisciplinary collaboration, and shared ethical commitments to territorial equity and ecological integrity.

6. Limitations and potential of ES models and updating

Although the SimulSoil tool—based on updated InVEST models—represents a promising methodology for mapping and analysing ES in metropolitan contexts, it is important to acknowledge a number of limitations that constrain its current effectiveness and applicability. A critical appraisal of these issues is essential not only for scientific transparency but also to pave the way for future refinement and operational use of the tool in planning practice. A first limitation concerns the quality, classification criteria, and temporal resolution of the land use and land cover (LULC) datasets used as input. The 2023 LCP dataset represents a substantial improvement over previous versions, particularly in terms of thematic detail and spatial resolution. However, several issues persist. Certain land cover categories remain too generalised to capture the heterogeneity of real landscapes. For example, the classification of "forest" does not distinguish between mixed deciduous forests, coniferous stands, or agroforestry systems—each of which has different ecological functions and capacities for Carbon Storage or biodiversity support. Similarly, cropland areas are treated as homogeneous blocks, even though the ecological impact of monoculture maize fields differs markedly from that of organic or polyculture farming.

Moreover, the data used represent a static snapshot in time. The ES models assume that the landscape remains unchanged throughout the analytical period. This limitation may lead to distortions in dynamic contexts where land use is rapidly evolving—whether due to urbanisation, abandonment, natural succession, or policy-driven transformations (e.g., greening subsidies, forest incentives, agricultural zoning changes). As such, the outputs should be interpreted with caution when applied to medium- or long-term planning decisions.

Second, while the visual outputs of the models are spatially detailed and potentially useful for communication and decision-making, their uptake into planning and governance frameworks remains limited. Most municipal planning offices, particularly in smaller or mountainous areas, lack the technical skills, GIS infrastructure, or staff capacity needed to interpret and operationalise model results. Furthermore, the legal and procedural frameworks that govern spatial planning in many regions—including Piedmont—do not yet mandate or structurally integrate ES consideration. Without institutional anchoring, the models risk being perceived as optional or academic exercises, rather than as actionable tools.

Third, the models operate under assumptions that may not hold in every local context. For example, the InVEST Habitat Quality model assumes that all threats act linearly and that their impacts diminish with distance according to fixed decay functions. In complex urban-rural landscapes, these relationships may be more nuanced: some infrastructure corridors may have disproportionate ecological impacts due to edge effects or barrier functions, while others may support biodiversity if managed appropriately (e.g., green railway verges or low-traffic rural roads). Customising these decay functions and threat-response parameters requires detailed local knowledge and empirical data, which are not always available or incorporated.

Despite these limitations, the updated SimulSoil framework also exhibits substantial strengths and potential. From a technical standpoint, its open-source architecture allows for continuous improvement, localisation, and user-driven modification. The model is compatible with most GIS environments, can be run on ordinary hardware, and does not require proprietary software licenses—making it particularly suited for application in low-resource settings. The use of regionally specific data and parameterisation increases its contextual relevance, while its transparent structure enhances scientific credibility and reproducibility.

From a policy perspective, the tool offers several advantages. It enables planning authorities to move beyond abstract sustainability goals and base their decisions on spatially explicit evidence. For example, the model can be used to identify ES-rich zones that should be protected, or to detect ecological deficits in peri-urban areas where restoration is needed. It supports inter-municipal dialogue by offering a shared visual language and baseline for territorial coordination. Furthermore, by making the spatial interdependencies between upland ES providers and lowland beneficiaries visible, the model can support the development of compensation mechanisms, ecological fiscal transfers, or co-management agreements.

7. Conclusions

The results of this study confirm the strategic ecological role of mountain territories in the Metropolitan City of Turin, particularly in their capacity to provide Carbon Storage and habitat-related ecosystem services. The updated implementation of SimulSoil, based on high-resolution land cover data and spatially explicit modelling, has proven to be an effective tool for supporting evidence-based planning in complex metropolitan contexts.
The case study demonstrates that digital tools and open-access geospatial datasets can significantly improve the quality and accessibility of ecosystem service assessments. However, their integration into institutional planning processes remains limited. Bridging the gap between knowledge production and governance requires embedding these models into planning instruments through legislative frameworks, technical guidelines, and training for local authorities.

The ecosystem services paradigm offers a robust lens through which to understand ecological conditions and flows across heterogeneous territories. Importantly, this approach does not replace other forms of territorial analysis, but complements them by providing a shared methodological foundation based on data produced by institutional actors such as Regione Piemonte and the Metropolitan City of Turin. In this sense, the continued updating and application of SimulSoil is not only useful but necessary, ensuring that planning tools remain aligned with current land use dynamics and ecological knowledge.

Furthermore, this study shows that Homogeneous Zones (HZs) should not be interpreted as rigid ecological units, but rather as functional subdivisions that allow for tailored, site-specific planning responses. Their use supports a more integrated reading of metropolitan space, accounting for both ecological function and administrative relevance.

A key insight emerging from this work is the importance of spatial scale. Ecosystem service provision and demand are not evenly distributed, and assessments must be sensitive to variable geographies and territorial configurations. The revised models provide a framework for interpreting such patterns and for informing governance strategies aimed at improving ecological conditions and rebalancing flows between service providers and beneficiaries.

Ultimately, the application of SimulSoil in this context demonstrates the potential of ecosystem service modelling to enhance strategic planning. By offering spatially explicit, scientifically grounded information, this approach contributes to more sustainable, equitable, and context-sensitive territorial governance—particularly in metropolitan regions facing environmental and climatic transitions.

Acknowledgements
It should be noted that in October 2022, the Directorate-General for the Environment of the European Commission sent an official letter of appreciation to the Metropolitan City of Turin (CmTo) for the results achieved through the LIFE SAM4CP project, with particular reference to the SimulSoil tool. The Commission encouraged the continued use and promotion of the tools developed by the project, recognizing their value in supporting land-use planning and management.

In 2023, LIFE SAM4CP was included in the "Knowledge Platform" developed by the Department for Sustainable Development of the Italian Ministry for the Environment and Energy Security, as an example of good practice for the environment and climate, and as an experience to be widely disseminated at both national and local levels.

This paper presents part of the results of the assignment entrusted by the Metropolitan City of Turin to DIST–Politecnico di Torino for the update of SimulSoil. The work was coordinated by Carolina Giaimo (scientific supervisor). Specifically, Sections 1 and 7 are attributed to C. Giaimo; Sections 2, 3, and 4 to G.G. Pantaloni, F. Farina, and A. Nino in equal parts; Sections 5 and 6 were jointly written by all authors

Urbanization, Biodiversity, and Ecosystem Services in Norway: Challenges and Strategies for Sustainable Land Use

Anna Kaczorowska
Norwegian University of Science and Technology, Department of Arcitecture and Planning
anna.kaczorowska@ntnu.no

Abstract
Urban areas are complex systems where urbanization affects vegetation and land use, leading to biodiversity loss and fragmented green-blue spaces. Understanding urban biodiversity is essential for maintaining ecosystem services (ES), but assessing land-use changes remains difficult. There's growing interest in restoring and integrating nature into cities to support climate regulation, food production, recreation, health, and more. In Norway, "Area neutrality" (Arealnøytralitet) promotes a municipal land-use management system that prioritizes nature protection in urban development and extends the net-zero philosophy to nature loss. This article explores how urbanization in Norway impacts biodiversity and ES, and which planning tools can help bridge science and policy to address land-use and climate challenges. It emphasizes the need for local knowledge, citizen science, and policies to better integrate ES into urban planning.

Introduction

Nature is essential for human existence and good quality of life but is not often distributed equally across space and time and among different segments of society. There are often trade-offs in the production and use of nature's contributions (IPBES, 2019). The negative trends in biodiversity and ecosystem functions are projected to continue or worsen in many future scenarios in response to indirect drivers such as rapid human population growth, unsustainable production and consumption. According to Summary for policymakers of the global assessment report on biodiversity and ecosystem services of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES, 2019) societal goals, including those related to food, water, energy, health and human well-being for all, mitigating and adapting to climate change and conserving and sustainably using nature, can be achieved in sustainable pathways through the rapid and improved deployment of existing policy instruments and new initiatives that more effectively enlist individual and collective action for transformative change.

Biodiversity creates the unique variety of life on our planet that provides multiple benefits derived from ES, such as clean air and water, food, health and recreation. Nature is as important for our mental and physical wellbeing as it is for our society's ability to cope with global change, health threats and disasters (EC, 2020). Nature is in crisis. Anthropogenic land use, resource overuse, climate change, pollution, and invasive species have eroded biodiversity, pushing many species toward extinction. Wildlife populations have dropped 60% in the last four decades, with nature in steep decline globally. *Global Assessment Report on Biodiversity and Ecosystem Services* (IPBES, 2023) identified land-use change as the first direct driver of biodiversity loss for terrestrial and freshwater ecosystems, and sea-use change as the second direct driver for marine ecosystems.

Urban areas are dynamic and complex landscapes, where urbanization effects on vegetation are influenced by socio-ecological processes across multiple scales (Ernstson et al., 2008). Urban areas have become increasingly important for ecosystem services (ES) and biodiversity management as more than 50% of the world's population now lives in cities; a share that is estimated to reach 70% by 2050 (UN DESA, 2009). Under current processes of densification of urban areas, the alteration in land use is likely to be a major driver of changes in the distribution of ES (Eigenbrod et al., 2011). Sustainable urban development strives for an optimal relationship between built (grey) and green infrastructure. Increase of buildings, roads, and industrial areas often corresponds to the increase of impervious surfaces and decrease of green areas. The combined effect of increasing population and loss of permeable surfaces is likely to result in greater and more frequent floods and also loss of habitat for biodiversity due to fragmentation of natural habitats and drastic and persistent alteration of habitats (Ahrne et al., 2009). Further, the delivery of urban ecosystem services (ES) depends on the spatial structure of ecosystems (Alberti, 2005). The TEEB-Report for Cities (TEEB, 2010) suggests that ES could be used as a tool; thus, cities can make positive changes, saving municipal costs, strengthening local (green) economies, enhancing quality of life and securing livelihoods. There is renewed interest in reconnecting, restoring, and designing nature into the built environment to provide a wide suite of benefits for urban residents, infrastructure, and economies, which

include climate-change regulation, local food production, recreation, human health, and many other benefits. Many recent reports, (e.g.IPBES, 2023, the World Economic Forum,2022), have emphasized the importance of such an approach and encourage the implementation of nature-based solutions around the world. There is a need to develop place-based empirical knowledge, citizens' science and to define appropriate measures/policies for better integrating generation of ES into spatial planning (Kaczorowska et al., 2015).

Area neutrality

In Norway, "Area neutrality" (Arealnøytralitet) is promoted as a municipal land use management system that prioritizes the protection of nature in urban development (McCormack et al., 2022). This framework calls for first avoiding nature destruction, then reducing nature loss, and finally "replacing" natural lands that are developed for human use by restoring other areas. In effect, it extends the net-zero philosophy to the loss of nature.

Current research on nature and land use management emphasizes the need for holistic strategies that integrate ecological, social, and spatial planning considerations. This approach recognizes that biodiversity loss and ecosystem degradation are complex issues requiring collaboration across multiple fields, such as ecology, urban planning, environmental policy, and sociology as well as involving and mainstreaming to stakeholders at various levels. Institutional innovation can ensure more involving urban transformations (Nilssen & Hanssen, 2022). The complexity of today's societal challenges, such as political and economic instability, threat of war, climate change, loss of nature and alienation to nature, requires a greater ability for coherent thinking, reflection and a unified political direction. There is the importance of coordinating natural, technological, and socio-economic systems when designing, planning, and managing urban nature-based solutions to enable optimal social-ecological outcomes (McPaerson et al., 2022). Overall, interdisciplinary research underscores the need for comprehensive strategies where ecological preservation, policy design, and community development intersect to achieve sustainable land use and biodiversity conservation.

In the context of Norwegian urbanization, this paper presents how systems-based, interdisciplinary planning approaches—leveraging area neutrality, ecosystem services, and participatory methods—can bridge the science–policy gap to address land use, biodiversity loss, and climate adaptation.

Exploring Two Interpretative Models of Eco-cities in the United Arab Emirates: Masdar City and The Sustainable City Dubai

Marco Carlotti
Laboratoire Médiations, Sorbonne Université
marco.carlotti@etu.sorbonne-universite.fr

Abstract
Since the early 2000s, eco-cities have emerged as a key urban paradigm. As an umbrella concept, the eco-city encompasses diverse models aiming to address urban sustainability through environmental and socio-economic dimensions. However, a lack of consensus and context-sensitive variations has led to multiple "interpretative models." This paper explores two eco-city projects in the United Arab Emirates—Masdar City and The Sustainable City Dubai—revealing contrasting approaches shaped by local challenges such as oil dependency, car-centric urbanism, and extreme climate. Drawing on inductive research, the study highlights how differing visions—technology-driven versus community-centered—embody the flexible nature of the eco-city ideal. It contributes to understanding eco-cities as context-specific laboratories for sustainable urban futures.

Keywords: eco-city ; interpretative models ; UAE ; Masdar City ; The Sustainable City

1.Introduction

Phenomenon

Over the past two decades, we have witnessed a global proliferation of urban initiatives branded as "eco-cities", evolving in parallel with the rise of other future-oriented urban models such as smart cities and knowledge-based cities (Ingallina, 2019). Among these, the eco-city – or ecological city – has emerged as a key manifestation of sustainable urbanism, increasingly promoted by policymakers and planners – making it a new "paradigm" (Nguyen & Vu, 2023) or a "global phenomenon" (Joss, 2010, p. 242). In his global survey made in 2009, Joss (2010) identified 79 eco-city initiatives spanning various continents. This number has since increased to include new and ongoing projects, especially in Global South emerging countries such as Morocco (Zenata Eco-City) or Laos (Amata Smart & Eco City Natuey), to give few examples.

Literature review

The origins of ecological urban development projects can be traced back to the 1970s and 1980s, with the emergence of eco-neighbourhoods in countries of the Global North—particularly in Germany, the United Kingdom, and Scandinavia—largely initiated by grassroots associations. This phenomenon arose in response to global dynamics observed since the 1970s, a period marked by the rise of widespread *environmental consciousness*. This awareness was shaped by the growing visibility of ecological disasters through mass media, alongside the burgeoning body of scientific literature highlighting the human impact on the biosphere. One notable institutional milestone was the launch of UNESCO's *Man and the Biosphere* (MAB) Programme in 1971, aimed at understanding and managing the complex relationships between humans and natural ecosystems on a global scale. This initiative gave rise to one of the earliest known formulations of the eco-city concept, notably articulated by the Soviet sociologist Oleg Yanitsky, who defined it as "a human settlement of the future in which social and ecological processes are harmonized in the best possible way" (1982, p. 470). Over time, a growing number of international initiatives were launched in support of environmental protection, among which the publication of the *Limits to Growth* report in 1972 by the Club of Rome stands out as a major milestone. This report warned against the pursuit of unlimited economic growth in light of the planet's finite resources, thereby reinforcing the urgency of ecological considerations in urban and global policy frameworks.

Gradually, these small-scale European initiatives were paralleled by the emergence of large-scale urban development projects—designed to accommodate several thousand inhabitants—in the Global South. These projects aimed to address the urgent demand for housing while adhering to the principles of sustainable development, which had become a global paradigm following the publication of the Brundtland Report in 1987. Indeed, countries in the Global South are those experiencing the fastest demographic growth and are simultaneously the most exposed to the multifaceted impacts of climate change. These conditions characterise the Anthropocene—a new geological epoch in which human activity has become a dominant force disrupting ecological and planetary systems.

This shift marks a transition from the logic of eco-districts to that of eco-cities, a broader and more encompassing framework used to describe a diverse range of spatial interventions—from compact neighbourhoods to newly built megacities. Despite their differing scales and forms, these projects share a common objective: to ensure socio-ecological balance in an era of increasingly urgent climate warnings (Bibri, 2020; Joss, 2011).

In light of these challenges and the goals it sets out to achieve, the eco-city model is increasingly regarded as a meaningful response to the pressing issues of the 21st century. Urban areas are currently responsible for approximately 70% of global CO emissions associated with energy consumption (Dasgupta, Lall, & Wheeler, 2022), with transport alone accounting for one-fifth of total global emissions (Ritchie, 2020). These figures present a significant challenge for policymakers and urban practitioners, particularly given that the United Nations projects a global population of 9.7 billion by 2050, with two-thirds—over six billion people—expected to live in urban areas, compared to 4.61 billion in 2023 (World Bank, 2018). This demographic trajectory implies an intensification of urbanisation, primarily driven by rural-to-urban migration in developing countries.

To meet international climate mitigation targets—such as those outlined in the Paris Agreement—and to reduce the global carbon footprint, it is essential to address the urbanisation process itself, which has a direct and proven link to global warming (Helbling & Meierrieks, 2023).

Within this context, the development of more ecologically responsible cities—eco-cities—appears to be a relevant and timely strategy for tackling these multidimensional challenges. Such an approach aims to promote socio-ecological sustainability by striving for a balanced coexistence between human and non-human ecosystems. Cities of the future are thus expected to embody greater efficiency, sustainability, and resilience (Kohlhase, 2013).

Theoretical problem

These expectations have fostered a substantial body of literature surrounding the concept of the eco-city, particularly since the early 2000s. However, this literature remains characterised by conceptual ambiguity (Rapoport, 2014). Indeed, the concept is still polysemous, vague, and lacks a shared definition within the scientific corpus. This absence of consensus does not concern the ultimate goal of the eco-city—namely, sustainability in its broadest sense—but rather the means and forms through which it is to be achieved. Beneath the apparent unity of the term "eco-city," which functions as a catch-all expression, lie multiple divergent visions regarding how such projects are conceived and operationalised.

Within this conceptual vagueness, a comparative approach has frequently been favoured by scholars, who endeavour to assess projects against often technical and environmental criteria. Nevertheless, this comparative methodology can prove limiting, particularly in urban planning, given that urban projects are deeply embedded within the contexts in which they emerge—be they geographical, legal, socio-economic, or environmental. Consequently, it is challenging to compare projects located in different geographical settings and responding to diverse socio-political dynamics; moreover, the "urban project" is, by nature, bespoke (Ingallina, 2001).

It is therefore necessary to move beyond this comparative framework and adopt a more interpretative stance aimed at understanding the "meaning" attributed to the urban project. This approach seeks to elucidate the internal logics underpinning these projects and the spatial translations of these logics.

Research question

To better apprehend this diversity, this article proposes to investigate the interpretative frameworks at work within each project through the following question: What interpretative models of the eco-city can be identified through the analysis of eco-city projects? Furthermore, how do these models reveal differentiated visions of eco-sustainability?

Research motivation

This paper seeks to document the multiple interpretations attributed to the concept of the "eco-city," highlighting the intrinsically polysemous nature of the model. Aware of the absence of a single, unified definition, we argue that this lack of consensus should not be regarded as a weakness, but rather as a significant indicator of the plurality of approaches underpinning urban projects labelled as "eco-cities."

Accordingly, rather than aiming to establish a single definition of this urban model, the objective of this paper is to embrace this diversity and examine it through a "project-centred" reading employing an inductive methodology, detailed below.

On this basis, we explore how different eco-sustainable urban projects are shaped by varied project dynamics—ranging from the ideation phase through to operational implementation (Yanitsky, 1982). We thus introduce the notion of "interpretative models," understood as analytical constructs that capture the underlying logics of action, reference frameworks, and socio-spatial translations at work within projects designated as eco-cities. These models are not intended to constitute a fixed typology, but rather to reflect the diversity of visions and practices embedded within projects grouped under the eco-city label. Ultimately, we seek to understand how various actors conceive and operationalise the eco-city—despite their shared commitment to environmental sustainability—thereby revealing the multiplicity of urban projects encompassed by this designation.

Roadmap
The following section outlines the methodology of this research. Subsequently, two eco-cities developed in the United Arab Emirates are presented. The third section presents the conclusive findings emerging from the highlight of these two interpretative models.

Methodology

Research context
This paper presents preliminary findings from an ongoing doctoral thesis in urban planning, initiated in 2022, which investigates the "interpretative models" of eco-sustainable cities, collectively referred to under the umbrella term "eco-city" (Ingallina, 2019 ; Joss, 2010). This doctoral thesis adopts an international perspective, analysing urban projects located in three different countries: France, Morocco, and the United Arab Emirates. Within this framework, the present article focuses on two case studies in the UAE—Masdar City and The Sustainable City Dubai—which constitute the empirical field sites selected for this portion of the research.

Data collection and analysis
Within the framework of this inductive doctoral thesis, we employ the notion of the "urban project" (Ingallina, 2001) as an analytical lens through which to examine the cities under study. This choice is grounded in its capacity to systemically integrate the various constituent elements of the dynamics at play around the project, as well as the project itself. Unlike sectoral or thematic approaches, which are often compartmentalised, the urban project approach enables a comprehensive understanding of the complex relationships between territorial context, political ambitions, the processes of development and implementation, and the evolving trajectories within which these projects are located.

This article draws upon a body of empirical data collected between 2023 and 2025 as part of this research. To ensure a clear and structured analytical reading, we have deliberately chosen to organise the collected data into three categories: (i) the historical context of the project's emergence, (ii) its ambitions, and (iii) its spatial manifestations. These three interpretative keys guide the analysis of the two Emirati cities presented herein. For each category, we detail its scope and the types of data utilised to inform the analysis.

Historical context
Urban projects are embedded within specific historical and political contexts and are developed to provide a bespoke response tailored to the territory in which they are situated: "*The urban project is not simply the application of generic principles devised elsewhere to a particular place. It must emerge from local dynamics*" (Rémy, 1998). The motivations driving an urban project are manifold and stem from diverse political imperatives aimed at linking several themes: socio-economic transition, quality of life, strategic positioning, among others. Understanding this context allows for the identification of the political and strategic conditions underpinning these projects. This first axis employs a genealogical reading (Foucault, 1971) to uncover the processes leading to the formulation of the projects, incorporating planning documents, the strategic agendas of states or metropolitan authorities, and prior territorial transformations. This analysis is based on the examination of official documents, press sources, and interviews with key stakeholders.

Ambitions
Following the analysis of the historical conditions that gave rise to the project, attention is turned to the ambitions and objectives articulated through the urban project. This section draws on official documents (notably planning materials), interviews, and project websites.

Spatial translations
Finally, the stated ambitions and discourses must be confronted with the urban forms produced, the design choices made, and the concrete modes of implementation. This third axis examines the spatial translations of the project—that is, the manner in which the declared objectives are materialised within the urban fabric, infrastructure, morphology, and programming. This analysis relies on site observations, press coverage, official documentation, and interviews.

Case studies
For this article, we have chosen to focus on two urban projects located in the United Arab Emirates (UAE): Masdar City (Abu Dhabi) and The Sustainable City (Dubai). This selection is justified by the UAE's pioneering role in experimenting with so-called sustainable urban models in the Arabian Peninsula. As early as 2008, with the launch of Masdar City in Abu Dhabi, the UAE established itself as a key player in ecological urban transition, both in the Gulf region and globally. Indeed, the project represented the first eco-city to achieve tangible development following the abandonment of the world's first planned eco-city in Dongtan (China). Although still under construction, Masdar stands as the first large-scale attempt to realize an eco-city in a desert environment.

This project aligns with a broader national strategy aimed at supporting the country's energy transition—historically reliant on hydrocarbons—toward diversifying its energy sources by significantly increasing the share of renewables, primarily solar power, in its energy mix. It forms part of ambitious state-driven transformation plans, such as the Energy Strategy 2050 and the UAE Net Zero by 2050 Strategic Initiative, which position sustainability as a key pillar of the Emirates' long-term trajectory (United Arab Emirates, n.d.).

Beyond this pioneering role, the Emirati context also exhibits several characteristics that make it a relevant case study for analyzing eco-cities. The UAE serves as a veritable laboratory, as the country already faces constraints that the rest of the world is striving to mitigate or avoid. These include extreme environmental conditions – particularly its hyper-arid climate (Böer, 1997) – along with automobile dependency (Ochieng & Jama, 2015), urban sprawl (Elessawy, 2021), among other challenges.

Masdar City (Abu Dhabi)

Project's history
Abu Dhabi, the capital of the United Arab Emirates (UAE), has undergone profound urban transformation since the mid-20th century, triggered by the discovery of oil in 1958. In 1939, the settlement was a modest fishing village of approximately 10,000 inhabitants. The city's significant expansion began in the late 1960s under the leadership of Sheikh Zayed bin Sultan Al Nahyan. Upon becoming ruler of Abu Dhabi in 1966, and later founding the UAE in 1971, Sheikh Zayed initiated an ambitious modernization strategy through the creation of the Abu Dhabi Planning Council (Government of Abu Dhabi, n.d.). Breaking away from the austere policies of his predecessor Sheikh Shakhbut—who preferred to conserve oil revenues to maintain a tribal and Bedouin lifestyle—Sheikh Zayed reinvested oil wealth into public infrastructure. This included the rapid development of schools, hospitals, housing, and road networks, aimed at improving the quality of life for Emirati citizens (Davidson, 2010).

This moment marked Abu Dhabi's entry into modernity, characterized by a functionalist approach to urban planning (Bani Hashim, 2019). Under Sheikh Zayed's leadership, Abu Dhabi quickly transformed into a "boomtown", fuelled by successive waves of migrant labour necessary for large-scale construction efforts. These migratory flows were instrumental in the Emirate's rapid demographic growth. The first federal census in 1975 recorded a population of 211,812 across the Emirate, which would continue to expand rapidly in subsequent decades (UAE National Bureau of Statistics, n.d.).

To manage and anticipate this demographic surge, Abu Dhabi commissioned numerous master plans designed by international firms. These plans—closely supervised by Sheikh Zayed—sought to shape Abu Dhabi into a modern,

green city equipped with all essential infrastructures. At this stage, development efforts were overwhelmingly supported by oil revenues, as the emirate had not yet embarked on a transition toward a business-oriented economy.

The death of Sheikh Zayed in 2004 marked a significant turning point in the trajectory of Abu Dhabi. His successor, Sheikh Khalifa bin Zayed Al Nahyan, assumed leadership and ushered in a new development paradigm—one that was distinctly more business-oriented than oil-oriented. This shift in economic strategy, underpinned by efforts to reduce dependence on oil revenues, had far-reaching urban implications (Bani Hashim, 2019). In collaboration with Sheikh Mohammed bin Zayed, Crown Prince of Abu Dhabi from 2004, Sheikh Khalifa promoted economic diversification. This new strategic direction was formalised with the launch of the *Abu Dhabi Policy Agenda 2007–2008*, a foundational roadmap that defined the government's core priorities. The agenda aligned closely with Sheikh Khalifa's entrepreneurial vision to position Abu Dhabi as a robust and globally competitive economy. The ultimate objective was the establishment of a "sustainable knowledge-based economy", which entailed a dual ambition:

"*Sustainable here meant continual economic growth (as distinct from environmental sustainability), which in turn implied profit-making enterprises operating over the medium to long term. The emphasis on knowledge building meant high-skilled, high-wage rather than low-wage, low-productivity areas*" (Rossiter & Yates, 2025).

This vision became the foundational pillar for two subsequent strategic frameworks: the *Abu Dhabi Economic Vision 2030* and the *Abu Dhabi 2030 Urban Structure Framework Plan*. Together, these served as key policy instruments for aligning the Emirate's economic transformation with spatial and infrastructural development. The Urban Structure Framework Plan in particular articulated the principles and spatial strategies needed to position Abu Dhabi as a global economic hub by aligning its urban development with international standards (Samarrai, 2016, p. 112). The plan called for the enhancement of public spaces, improved mobility systems, and the strengthening of the city's global image to secure its success amid intensifying global urban competition.
As part of this broader diversification agenda, the Government of Abu Dhabi, through its majority ownership of Mubadala Development Company, launched the Masdar Initiative. Known as *Masdar* (meaning "source" in Arabic), the project embodied the Emirate's dual objectives: to foster new business ventures and to advance the transition away from oil through investment in clean technologies and alternative energy solutions. This strategic alignment of ecological innovation and economic diversification positioned Masdar as a flagship project in Abu Dhabi's entrepreneurial urban agenda.

The Masdar Initiative was founded with four primary objectives (Embassy of the UAE in Washington, 2009) :

- To help drive the economic diversification of Abu Dhabi;
- To maintain – and expand – Abu Dhabi's position in evolving global energy markets;
- To help Abu Dhabi become a developer of technology;
- To make a meaningful contribution to sustainable human development.

In this context, Masdar City was established as a demonstrator of these ambitions, embodying in its planning and development Abu Dhabi's broader diversification objectives. From 2014 onwards, the city became one of Masdar's four operational units: Masdar Capital, Masdar Clean Energy, Masdar Special Projects, and Masdar City (Griffiths & Sovacool, 2020).

Ambitions

Initial ambitions
Masdar City was conceived as a Special Economic Zone (SEZ), intended to serve as a commercially viable model for sustainable living. From the outset, its design was strategic: by offering the advantages of a free zone, the development aimed to attract international firms to Abu Dhabi. This economic incentive proved effective, drawing major companies such as Siemens and Saint-Gobain to establish a presence in the city. This approach aligned with Abu Dhabi's broader agenda of economic diversification, seeking to reduce reliance on oil revenues by fostering innovation-led sectors.

Beyond its economic ambitions, Masdar was also envisioned as a prototype for sustainable urban life in extreme desert conditions. The project thus combined environmental aspirations with a high-profile development strategy, seeking to demonstrate that sustainability could be both livable and profitable.

A cornerstone of Masdar's early phase was the creation of the Masdar Institute of Science and Technology, a graduate-level research university established in partnership with the Massachusetts Institute of Technology (MIT). The Institute not only brought the city's first residents—students—but also anchored Masdar in a research-driven, innovation-oriented trajectory. These students were envisioned as co-developers of the city's technological infrastructure, actively contributing to the advancement of solutions that would be deployed in Masdar itself.

In its initial configuration, Masdar operated as a Porterian cluster, concentrating government bodies, private enterprises, and academic institutions within a single geographic area to foster innovation and economic development. This strategic co-location laid the groundwork for what would later be conceptualized as a 'green knowledge-based city' (Ingallina, 2019; Carlotti & Alaoui Aziz, 2025), defined by the pursuit and deployment of eco-technological innovations (Ingallina, Park, & Carlotti, 2025).

A hallmark of the project was its bold ambition to become the world's first zero-carbon, zero-waste, and car-free city. This aspiration received widespread media attention, albeit often critical, particularly in light of the paradox that the initiative was spearheaded by a government whose economy remained heavily dependent on oil revenues—accounting for approximately 70% of GDP at the time.

To enhance the project's global visibility and symbolic value, Masdar engaged the renowned architecture firm Foster + Partners. The involvement of a starchitect reinforced the city's image as an iconic, high-tech experiment, positioned to elevate Abu Dhabi's standing on the international stage. This move echoed broader efforts by the emirate to diversify its global identity—not only economically but also culturally, architecturally, and environmentally—as evidenced by parallel initiatives like the Cultural District on Saadiyat Island.

Changing ambitions

Initially scheduled for completion in 2015, the Masdar City project experienced significant delays, particularly following the subprime mortgage crisis, which had substantial repercussions for the United Arab Emirates—Abu Dhabi included—notably in terms of the funding allocated to the project itself. This financial downturn compelled a strategic reorientation of Masdar City, prompting its leadership to broaden its vision beyond purely environmental goals to encompass economic sustainability, with an emphasis on the commercial viability of its operations as a means to ensure continued development. As noted by Masdar City officials:

"Abu Dhabi was not immune to the effect of this crisis. Under such an economic environment, a shift in the direction of Masdar City was about to take place. This shift marked a pivotal moment in Masdar City's evolution. Whereas the earlier focus was solely on environmental sustainability, the new focus was on economic sustainability in the form of commercial viability, but at the same time upholding environmental stewardship" (Masdar City, n.d. a).

The subprime mortgage crisis also had the effect of tempering the project's initial ambitions. Masdar City was compelled to soften its objectives, shifting from a 'zero-carbon' model—where no carbon dioxide emissions occur within the city's boundaries—to a 'net-zero carbon' model. This latter approach permits certain carbon emissions, provided that an equivalent amount is removed or offset, resulting in no net increase in atmospheric COΔ In an interview conducted with a Masdar City official, it was acknowledged that while the goal of achieving zero-carbon was unattainable at the time, it served more as a global message—an aspirational statement of ecological ambition underpinning the entire project:

[...]. *Also, you may have a brand that the big aspirations back then were net zero. This is something that, that most are called out in 2006, much to a lot of criticism and ridicule saying it's impossible and all that. And in many ways, in 2006, that was impossible. But we didn't set out to do what was possible in 2006. The goal was to have this as a kind of a driving factor to aim very high and actually push and develop the technologies within the city to achieve that. (interview, March 2024)*

Today, the project has refocused its efforts around the pursuit of net-zero carbon in alignment with the UAE's Net Zero 2050 Strategy, which targets net-zero emissions by mid-century across six key sectors: energy, industry, transport, buildings, waste, and agriculture. Masdar City now commits itself to the following targets (Masdar City, 2023):

- Reducing the energy use intensity (EUI) of its real estate portfolio by 45% by 2025, relative to the ASHRAE baseline;
- Achieving net-zero carbon emissions by 2050 across Scope 1, 2, and 3 emissions;
- Limiting the embodied carbon of concrete structures to less than 550 kgCOΔe/m² across all new developments;
- Diverting 80% of operational waste from landfills by 2030, across all waste streams.

Spatial translations

Masdar City is a planned urban development situated in the Emirate of Abu Dhabi, encompassing an area of 6 km². Conceived to host approximately 47,500 residents and accommodate 1,500 businesses—with an estimated 50,000 daily commuters—the project represents one of the most ambitious urban sustainability initiatives in the Middle East. According to the development programme, Masdar City will ultimately offer a total gross floor area of 3.7 million square metres, of which 57% is allocated to residential use, 38% to commercial activities, and 10% to community and retail functions. As of today, the city houses over 15,000 residents who both live and work within its limits, and it has established itself as a growing economic hub, hosting more than 1,000 local and international firms registered within the Masdar City Free Zone.

The master plan, designed by the British architectural practice Foster + Partners, is structured around a compact, pedestrian-oriented urban form intended to reduce energy consumption and encourage sustainable modes of mobility. Central to this design philosophy is the principle that all key services and amenities should be accessible within a maximum walking distance of 200 metres (Foster + Partners, n.d.). This contrasts markedly with the car-centric, low-density urbanism that characterises much of the Gulf region, and particularly Abu Dhabi.

Figure 1. *Masdar City master plan (Masdar City, n.d. c)*

Masdar's spatial logic draws heavily upon the morphological and climatic strategies of traditional Arab cities, particularly those of historic settlements such as medieval Cairo (Hassan, Lee, and Yoo, 2015). These influences are evident in the city's narrow, shaded streets, internal courtyards, and public plazas, all of which are employed to mitigate heat gain and enhance thermal comfort in the public realm. The compact urban fabric and building orientation optimise shading and natural ventilation, aligning with vernacular architectural practices adapted to arid environments.

Figure 2. From left to right: Masdar Park, Masdar Institute, and Masdar City Wind Tower *(personal pictures)*

Furthermore, the city's SE–NW grid alignment is strategically oriented to reduce exposure to the prevailing hot desert winds. This bioclimatic approach reflects a deliberate effort to integrate environmental responsiveness into the physical layout of the city.

Vehicular access to the inner city is strictly limited. Private cars are not permitted within the core of Masdar City, a policy designed to prioritise pedestrian circulation and reduce air and noise pollution. Instead, the city promotes sustainable mobility through a multimodal transport strategy that includes electric shuttles, autonomous vehicles, and extensive cycling and pedestrian infrastructure.

Key examples

Masdar City presents a paradigmatic shift in urban development models within the Gulf region through its explicit integration of cutting-edge technologies, high-performance architecture, and environmental design rooted in local climatic adaptation. Distinguished by a concentration of technologically advanced infrastructure and buildings, the city functions as a demonstrative site for green innovation and experimental sustainable urbanism (Pandita et al., 2024). Numerous scholarly works have analysed the performance metrics of individual buildings within Masdar, demonstrating the extent to which architectural prowess and engineering ingenuity have been mobilised to achieve ambitious energy efficiency goals (AbiSaad et al., 2014; Boyer et al., 2010).

One of the emblematic examples is the Masdar Institute of Science and Technology (now part of Khalifa University), the first completed building in the city, designed by Foster + Partners. The Institute is equipped with smart shading devices, passive design strategies, and a high-performance façade system that collectively reduce cooling loads by up to 70% compared to conventional buildings in the UAE. The integration of photovoltaic panels, wind towers, and optimised building orientation exemplifies the city's ambition to combine architectural excellence with energy consciousness. The Institute thus serves both as a research hub and as a living laboratory for sustainable architecture.

Another flagship development is the Siemens Middle East Headquarters, which achieved LEED Platinum certification and is often cited as one of the most energy-efficient office buildings in the region. The structure features a distinctive façading system that allows for natural daylighting while minimising heat gain, alongside advanced HVAC systems powered in part by renewable energy sources. With an Energy Use Intensity (EUI) far below regional averages, the building symbolises the operational translation of net-zero objectives at the individual parcel scale.

Other large-scale projects have been implemented or are currently planned:

Table 1. *Selected High-Performance Developments in Masdar City (made by the authors, with sources on this table)*

Project	Masdar City Square	The Link	Net-Zero Energy Mosque
Expected Completion	Scheduled for 2025	Scheduled for 2025	Completed (Date not specified)
Primary Function	Cluster of 7 commercial buildings	Mixed-use development (offices, residential areas, co-working spaces, recreational activities, visitor center, multi-use hall)	Religious facility
Sustainability Certifications (targeted)	• Targeting LEED Platinum, WELL Gold • Estidama 4 Pearl PBRS • Zero Energy certification	• LEED Platinum • WELL Gold • Estidama 4 Pearl, • Parksmart Silver for sustainable mobility integration	Targeting Estidama 4 Pearl Rating
Energy Strategies and Technologies	• Extensive photovoltaic panel installations designed to meet 100% of the project's annual energy needs • Shaded walkways to reduce solar gain	• 131% estimated annual savings • 40% light power reduction • Net-zero energy Co-Lab Building powered entirely by renewable sources, incorporating advanced HVAC systems, real-time energy monitoring, and high-efficiency appliances	• 35% reduction in energy consumption relative to conventional mosques • 1,590 m² of photovoltaic panels integrated into the roof system so it can produce 100% of the energy it needs over the course of a year • 55% reduction internal water consumption • 100% of its recycled water used to irrigate outside gardens

The Sustainable City (Dubai)

Project's history

Dubai, the largest city in the United Arab Emirates (UAE), has progressively positioned itself as a global city through a rapid and ambitious process of urban transformation. Originally a modest fishing and pearling settlement, Dubai experienced limited economic activity until the decline of the pearl industry in the 1930s. Over the course of the twentieth century, however, the city underwent dramatic changes following the discovery of oil in 1966.

Under the visionary leadership of Sheikh Rashid bin Saeed Al Maktoum, the city invested its initial oil revenues in foundational infrastructure—constructing ports, airports, road networks, and basic utilities to modernise its urban fabric.

Yet it was from the 1990s onward that Dubai's trajectory took a decisive turn, as the Al Maktoum ruling dynasty actively pursued a strategy of economic diversification to reduce dependency on finite hydrocarbon resources. This vision gave rise to a globalised urban identity rooted in leisure, finance, commerce, and large-scale real estate development (Pagès-El Karoui, 2021). Landmark projects such as the Burj Al Arab (1999), the Palm Jumeirah (early 2000s), and the Burj Khalifa (2010) not only redefined the city's skyline, but also projected an image of Dubai as a global city.

As part of this internationalisation and diversification agenda, Dubai enacted *Law No. 7 of 2002* (the Dubai Property Ownership Law), enabling foreign nationals to acquire freehold property in specific areas. Within this regulatory framework, two entrepreneurs founded Diamond Developers in 2003. Between 2004 and 2013, the company engaged in conventional real estate ventures aligned with the prevailing urban logic of the time. These included the Marina Diamond towers, situated near the Palm Jumeirah, and the Diamond Views residential complexes in Jumeirah Village Circle—a popular, family-oriented district that appealed particularly to an international clientele seeking affordable and secure housing within the emirate.

However, the 2008 global financial crisis—driven by the collapse of subprime mortgage markets—prompted a strategic reorientation for the company. In an environment of investor mistrust and depreciating property values, sustainable real estate products were perceived as less volatile and more resilient in times of economic downturn, according to one manager in an interview. It was within this context that the founders of Diamond Developers identified an opportunity to innovate. Moving beyond superficial 'green' add-ons such as photovoltaic panels, they embraced a more holistic understanding of sustainability, one which integrates environmental responsibility, social cohesion, and economic viability. As one of the firm's urban planners explained in an interview, the objective was not simply to construct energy-efficient buildings, but to design entire communities aligned with long-term socio-ecological values.

Ambitions

According to an interview conducted with one of Diamond Developers' urban planners, the company's ambition in the aftermath of the 2008 financial crisis was to demonstrate that an alternative, more resilient model of urban development could indeed be viable. Rather than pursuing high-risk speculative ventures, the objective was to secure a stable return on investment by appealing to prospective homeowners seeking assets perceived as economically low-risk—namely, properties grounded in sustainability principles. Diamond Developers thus adopted a cost-efficiency-driven approach, selecting technologies with a proven track record, such as photovoltaic solar panels. These technologies, while environmentally beneficial, were above all seen as reassuring features for buyers: durable, reliable, and capable of substantially reducing long-term utility costs.

The project's development was therefore underpinned by a strategic philosophy based on six interconnected domains: Food, Energy, Water, Products, Mobilities, and Waste. These six pillars formed the conceptual backbone of the master plan (see after), establishing the foundation for a self-sufficient urban model that contrasted sharply with the typical, resource-intensive developments seen elsewhere in Dubai. By integrating pragmatic solutions into each of these domains, the developers sought to achieve a high degree of sustainability that could respond effectively to the city's harsh climatic and environmental conditions.

Spatial translations

General presentation

TSC Dubai represents the first fully operational sustainable urban community in the Middle East (The Sustainable City Dubai, n.d.). Developed by Diamond Developers, construction began in 2014, with the first residents moving in by 2015. Located on a 46-hectare site (113 acres) and comprising 500 residential villas designed to accommodate approximately 3,000 inhabitants, the project amounted to an investment of USD 354 million.

The master plan is structured around six pillars—Food, Energy, Water, Products, Mobility, and Waste—that articulate the project's holistic approach to sustainability. Central to the design is a "green spine", a linear, pedestrian-friendly corridor running through the development. This spine, accessible to all residents within a five-minute walk, incorporates biodomes, recreational facilities (e.g. swimming pools, sports fields), and community gardens. The biodomes are designed to meet 100% of the residents' caloric needs by supplying free, locally grown fruits and vegetables. The residential clusters—five in total—are oriented northward to maximise thermal massing and reduce heat gain, enhancing passive cooling strategies. Each villa is equipped with rooftop photovoltaic panels, and the cumulative solar infrastructure enables the community to generate 150% of its total energy demand. Internal combustion engine vehicles are banned from the site; mobility within the city is exclusively ensured through electric buggies and soft modes of transport. TSC also adheres to the principles of the "15-minute city", whereby all daily services—including shops, clinics, schools, and a central market square—are within a 15-minute walking radius from any residence.

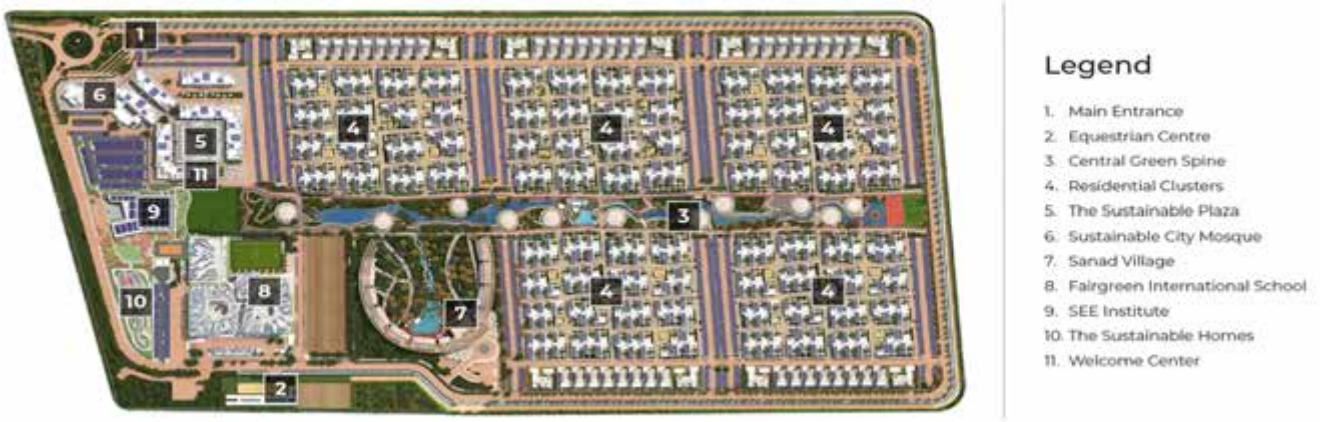

Figure 3. *The Sustainable City Master Plan (The Sustainable City, n.d.)*

Figure 4. From left to right: the farm ; one biodome ; villa *(personal pictures)*

Key benefits
The developers of TSC Dubai have based the city's development on 6 pillars:

Table 2. *The Six Sustainability Pillars of The Sustainable City Dubai (made by the author)*

Pillars	Implemented Solutions	Expected Benefits
Food	• Biodome greenhouses • Community-based urban agriculture using hydroponics	• Enhanced food security • Reduction in greenhouse gas emissions • Nutritional education
Energy	• Rooftop photovoltaic panels • Passive energy-efficient building design	• 100% renewable energy supply • Reduced utility costs • Lower carbon footprint
Water	• Greywater recycling systems • Measures to reduce water consumption	• Minimised water waste
Products	• Use of sustainable and recycled materials • Low-carbon architecture • Promotion of local supply chains	• Waste reduction • Strengthened local economy • Reduced ecological footprint
Mobility	• Electric vehicles only • Pedestrian and cycling infrastructure (20-minute city model)	• Zero local emissions • Improved public health • Reduced noise and traffic congestion
Waste	• On-site composting systems	• Decreased landfill waste • Organic waste valorisation • Support for circular economy

Findings
Despite being developed within the same national context and underpinned by overarching sustainability goals, Masdar City and TSC Dubai illustrate two markedly different interpretations of the eco-city paradigm, even if they take place in the same Gulf context. Two core findings emerge from this comparative analysis:

(i) Each city articulates a distinct conceptualisation of the eco-city model partly based on governance and actor rationalities;
(ii) And each follows a different operational logic—community-based adaptability in one case, and technological disruption in the other—while both ultimately converge towards similar sustainable development objectives.

Two eco-city types in the UAE
As previously discussed, the eco-city model is inherently protean and subject to diverse interpretations. In the context of the United Arab Emirates, Masdar City and The Sustainable City (TSC) Dubai offer compelling illustrations of this plurality by embodying two contrasting visions of what is often framed as the "city of the future." Like all urban projects, these initiatives are deeply shaped by their historical and geographical contexts—in this case, the unique political economy and developmental trajectory of the UAE. Each project has generated singular responses to the challenges of sustainable urbanism, reflecting the situated nature of their emergence. Their respective trajectories—sometimes diverging, sometimes complementary—can be largely attributed to distinct governance logics and actor rationalities, which significantly influence the projects' underlying philosophies, spatial configurations, and operational frameworks.

Masdar City, for its part, represents a complex and long-term endeavour embedded within a state-led strategic vision. Initiated by Masdar in close partnership with the Government of Abu Dhabi, the city is conceived as the physical manifestation of the Emirate's broader economic diversification agenda, particularly its efforts to pivot away from oil dependence through investments in renewable energy and ecological transition. As previously outlined, this agenda is closely linked to the production of new and bold urban landmarks—such as the Cultural District on Saadiyat Island—designed to brand Abu Dhabi as a global centre for business, leisure, and culture. Within this broader assemblage, Masdar City operates as a new pillar of Abu Dhabi's soft power strategy, projecting an image of environmental consciousness and technological sophistication. This strategy has become particularly visible at the national level, notably during the UAE's hosting of COP28 in Dubai in 2023, where Masdar City was prominently featured and promoted as a national showcase of sustainability.

In this context, Masdar aligns with and extends ambitious national and regional strategic visions. It stands out not only for its philosophical ambition but also for its formal innovation, displaying an architectural futurism emblematic of the UAE's broader approach to urban spectacle, often mobilising renowned starchitects to underscore the project's boldness. As such, Masdar City functions as what Arab (2007) describes as an "operational vector of metropolitan ambitions and urban policies," articulated within larger territorial development frameworks. Its public-private governance configuration further distinguishes it from other eco-city models such as TSC Dubai. Crucially, Masdar's trajectory has been subject to external contingencies—most notably the slowdown following the 2008 global financial crisis—demonstrating the project's need to adopt a more adaptive and phased implementation strategy.

On the other side, The Sustainable City Dubai is a private development by a private developer that took the subprimes crisis as a springboard to promote a more sustainable vision of urban planning in the Dubai context. By being a private-led project, the city is exclusively relying on the developer ambitions which should be market-aligned to sustain a demand. This city fits into what Arab (2007) defines as a Type B project—primarily private-sector-driven, contained within a delimited area, and usually delivered over a relatively short timeframe.

A high-tech disruptive model vs. a modular community-based model

Masdar City: A disruptive high-tech urban model
Masdar City forms an emblematic disruptive urban project—one that seeks to redefine the very boundaries of sustainable design through the integration of cutting-edge technologies, renewable energy systems, and experimental urban form. This ambition is clearly expressed in publications such as *The Future of Energy* (World Future Energy Summit, 2025), where the city is variously marketed and described as a "global model", "greenprint", "sustainable energy-efficient urban space", and "global laboratory" (pp. 14–21). These varied designations reflect the project's experimental and future-oriented character, marking it as a high-tech flagship of eco-urbanism.

The Sustainable City Dubai: A modular, Scalable and replicable model
By contrast, The Sustainable City offers a more grounded and pragmatic model of eco-urbanism—one that prioritises the implementation of proven, low-risk solutions over the development of novel high-tech innovations. Rather than investing in experimental technologies with high costs and uncertain returns, TSC focuses on practices that have already demonstrated effectiveness, thereby fostering buyer confidence and limiting financial and technical risk. Visually and spatially, the development adopts what could be described as a 'conventional' urban morphology, yet it is optimised to deliver tangible socio-ecological benefits.

These benefits manifest, first and foremost, in the creation of a vibrant community, centred around recreational and communal facilities—such as farms, swimming pools, playgrounds, and a local marketplace. This configuration fosters social interaction, especially through the self-sufficient nature of the development, which reduces the need for residents to leave the city for daily necessities. This dynamic was particularly evident during our field observations, where residents' daily routines were interwoven with informal encounters and collective activities. Secondly, TSC's planning principles demonstrate a clear commitment to environmental sustainability—both through the integration of extensive green spaces and the use of photovoltaic solar panels to power the neighbourhood.

What is particularly distinctive about TSC, in contrast to Masdar City, is its character as a replicable urban prototype. It functions as a scalable and modular template for sustainable development, with clear and measurable outcomes that facilitate adaptation across different contexts. Its design logic can be easily transferred to new sites, with flexibility for local adjustments depending on land characteristics, territorial specificities, and regulatory frameworks. Having acquired significant experience and credibility with its first operation in Dubai—which achieved full occupancy—Diamond Developers have been able to replicate and extend the model with greater ease and reduced risk. This modular quality proves to be a strategic asset: as the developers themselves claim, "*The Sustainable City is a resilient, scalable, and replicable working model*" (The Sustainable City, n.d.).

This approach significantly reduces the time required for both conceptualisation and implementation in subsequent projects. It allows for both upscaling and contextual adaptation, enabling each new iteration to refine and build upon the previous version. Such a logic is currently evident in the developer's expansion projects in Sharjah, Abu Dhabi, and particularly Oman, where the core layout—comprising public plazas, leisure centres, and equestrian facilities—is maintained while incorporating substantial improvements. This replicability and modularity stand in marked contrast to a complex urban experiment like Masdar City, which must navigate a distinct set of constraints and respond to broader state-driven strategic imperatives.

Abstract
The contribution investigates the key-role of coastal cultural heritage in a strategic approach to address environmental and climatic vulnerabilities in mid-Adriatic coastal areas. The research hypothesis that coastal heritage can act as resilience factor is considered and tested within the framework of the PRIN 2022 COSTA | Med project. Focusing on two case studies along the mid-Adriatic coast of Abruzzo (Pineto-Silvi and Fossacesia-Vasto), it explores the potential of heritage as environmental infrastructure to support adaptive strategies against climate risks. Through a research-by-design approach, the paper combines vulnerability mapping with design strategies, highlighting the regenerative capacity of existing and latent heritage assets. The study aims to outline planning agendas that integrate ecosystem services, socio-spatial dynamics, and infrastructure transformations, fostering resilience in complex land-sea interfaces.

Keywords: Land-sea, coastal heritage, environmental infrastructure, vulnerability mapping, design strategies.

1 | Introduction

Coastal territories represent a particularly intricate and vulnerable interface between socio-ecological systems (Adger et al., 2005). Significant anthropogenic transformations, climate pressures and cultural stratification are found in this variable-width strip, generating unprecedented challenges for the governance of coastal space (Hoegh-Guldberg et al., 2019). Land-sea interfaces, characterised by intense human occupation and high environmental variability, offer favourable conditions for experimenting with systemic approaches in response to the effects of ongoing climate change. In this framework, Mediterranean coastal areas are particularly vulnerable to a range of environmental challenges, including erosion, hydro-geomorphological fragility, excessive soil sealing, sea level rise, saltwater intrusion, increased surface and water temperatures, loss of biodiversity, marine pollution from plastics, chemicals and eutrophication, extreme weather events, flooding, and subsidence. These issues are further compounded by the presence of a significant concentration of cultural heritage values (Reimann et al., 2018; Bonazza et al., 2018). It is therefore well established in the relevant literature that the analysis of risks associated with climate change cannot be limited to the observation of physical processes alone but must also consider the interactions between the natural and anthropogenic environments (Bruno et al. 2016). This necessitates a departure from conventional risk mapping, which is predominantly relying on the superimposition of layers of information. In lieu of this, there is a requirement for alternative models that can reflect the conditions of vulnerability which emerge from the interaction between environmental pressures and the specific characteristics of places (Turner et al., 2003). In the context of land-sea interface, the risk levels at the "friction points" between anthropogenic uses and naturalistic and ecological values are of particular relevance. In such contexts, systemic assessment becomes crucial for interpreting the dynamics at play and guiding integrated planning processes.

The contemporary urgency of mitigation and adaptation has contributed to a gradual shift in focus from sectoral approaches to systemic perspectives able to address the complexity of territorial interactions (O'Brien and Sygna, 2013). This paradigm change is of particular significance in coastal areas, where the accelerated pace of transformation necessitates active and coordinated responses in terms of integrating environmental and cultural protection. From this standpoint, cultural heritage can only be recognised in its evolutionary dimension, generated and renewed by those who care for it and nourished through continuous interactions with society (Magnaghi, 2020), thus overcoming the static approach that considers it exclusively in reference to its monuments. A systematic analysis of these values necessitates the incorporation of at least two primary categories. The first of these is manifest heritage, which is represented by real estate and tangible cultural assets, protected areas and landscape values. These are bound, protected and recognised not only by the community but also by law. The second component encompasses latent heritage, comprising cultural practices, traditional knowledge systems, human and animal migration patterns that have historically characterised these regions, and maritime

uses. It also incorporates virtuous approaches that have emerged through the historical interplay between human societies and their environments (Lenzerini, 2011). This dual focus enables the identification of heritage resources, including those that are not formally recognised, but which have significant potential to contribute to the resilience of coastal contexts. In recent years, several studies have emphasised the value of Mediterranean identity heritage as a key component of integrated coastal zone management systems (Daire et al., 2012; Khakzad et al., 2015). However, most approaches are anchored in risk mitigation strategies that treat cultural heritage as a vulnerable asset to be protected, rather than as an active infrastructure for territorial adaptation (Fatorić and Seekamp, 2017).

The present paper illustrates the line of research that falls within this framework. It recognises the potential of systemic analysis – both of heritage values and associated risks – alongside the identification of design and transformation strategies. These strategies aim to enable interventions on both tangible and intangible heritage that actively contribute to reducing the vulnerability of coastal areas. The themes mentioned are at the centre of the applied research conducted in recent years by the Department of Architecture of Pescara on the Adriatic coast[1], and in particular the ongoing research project PRIN 2022 – *COSTA | Med: Catching Opportunities for Strategic Transformation and Adaptation of Mediterranean Coasts*[2] – dedicated to the development of methodologies for the analysis of coastal areas to support strategic transformation and adaptation to climate change in the Mediterranean. The research activity in Pescara focuses on experimenting with innovative ways of recognising and enhancing coastal cultural heritage as a strategic tool for observing coastal transformations and designing degrees of resilience. The central Adriatic coastline of Abruzzo has been identified as a case study of particular interest, with reference to two specific contexts that are distinguished by the specificity of their urbanisation processes and socio-economic and cultural dynamics. However, these contexts are united by the relevance and density of existing heritage values.

The research addresses several key issues, including multiscale mapping of vulnerability levels, identification of the tangible and intangible heritage values that characterise the study areas, and exploration of design scenarios and approaches for risk reduction. Accordingly, particular attention is paid to the ways in which coastal heritage interacts with risk levels, with the aim of guiding the integrated design and planning of coastal areas, providing guidelines that can be transferred and scaled to other Mediterranean coasts.

The contribution specifically focuses on the analysis of selected Adriatic coastal stretches as case studies, and on conceptual reflections regarding the definition of heritage as a resilience factor for reducing vulnerability, with particular attention to design approaches aimed at restoring environmental connectivity.

2 | Territorial Context and Case Studies

2.1 The linear Adriatic city: a fragile and stratified settlement system

The Abruzzo coastal area constitutes a component of the extensive system of the so-termed linear Adriatic city, a settlement pattern spread across the regions of Emilia-Romagna, Marche and Abruzzo, extending into a portion of Puglia. This dense and stratified urban-infrastructural continuum is characterised by the pervasiveness of urbanisation processes and the pressure they exert along land-sea spaces. The coexistence of high building density, linear infrastructure and tourist flows has resulted in a particular configuration of the territory that has attracted considerable critical attention within the relevant disciplinary field. This critical attention began with the definition of the 'medium-Adriatic city' as the result of post-war transformations linked to the construction of the railway line and State Road 16 (Bianchetti, 2011).

The intricacies of this territorial system are not solely attributable to anthropogenic influences, but also to substantial morphological, landscape, socio-economic, and cultural factors. The proximity of anthropogenic and natural landscapes, coupled with the historical interactions between land and sea, has contributed to the definition of settlement patterns along the coast, thereby fuelling the relational dimension of the cultural heritage of these places.

1 The comparative research propositions guiding the reflections of the PRIN COSTA | Med research are the outcome of activities carried out in recent years within the framework of teaching (master's theses), doctoral research, and university third mission initiatives, conducted in the Department of Architecture, coordinated by prof. Matteo di Venosa.

2 More information is given in the Acknowledgements section; further details are available at: https://costamed.uniroma3.it/

However, this relational richness is now confronted with growing environmental pressures manifested through land consumption, the reconversion of tourism and production systems, and the effects of the climate crisis.

The result is a fragile geography where multiple critical conditions converge (including the aforementioned coastal erosion, hydrogeological risk, flooding, ecosystem fragility, etc.) associated with seasonal anthropogenic pressure and building densification (Zullo et al., 2015). Linear urbanisation processes have increased soil sealing, resulting in a progressive disconnection between coastal and inland hill ecosystems, thereby interrupting important environmental flows and compromising the resilience of the entire territorial system (Ricci, 2018). ISPRA data (2024) confirm that land consumption rates along the Abruzzo coastline remain at significant levels, contributing to increased territorial vulnerability to extreme weather events.

The intersection of urbanisation dynamics and environmental vulnerability thus engenders a particularly intricate management and planning scenario (di Venosa, 2023), rendering the Adriatic case study emblematic for the examination of settlement dynamics and the manifold levels of risk that typify Italian coastal landscapes. In this context of widespread fragility, the PRIN 2022 *COSTA | Med* research identifies two contexts representative of the morphological and settlement characteristics and environmental issues found along the Abruzzo coast: the Silvi-Pineto context (C1) in the north and the Fossacesia-Vasto stretch, known as the Trabocchi Coast (C2) in the south. The density of heritage values they share, together with the different spatial configurations, recent transformations, and evolutionary potential expressed by the selected contexts, provides a complex picture of the challenges and opportunities within the land-sea interface.

The contexts mentioned represent two distinct models of coastal urbanisation: the first characterized by continuous development and high levels of artificialisation, the second distinguished by an alternation of fragmented built environments and preserved natural areas. This divergence is evident not only in the spatial layout but also in the types of cultural heritage present and in the adaptive strategies developed over time by local communities. As highlighted in studies on cultural landscapes, such settlement patterns give rise to differing forms of vulnerability and resilience, thereby requiring differentiated management approaches (Antrop, 2005).

2.2 The Silvi-Pineto system: urban continuity and ecological fragility

The Silvi-Pineto context (C1), which is bordered by the Vomano river to the north and the Saline river to the south is characterised by an almost uninterrupted coastal urban continuity (Figure 1). The littoral system under examination is a narrow, compact strip consisting of a succession of parallel lines extending from the water towards the mainland. These include the sea defences at Silvi, the shoreline, the Abruzzo section of the Adriatic Cycle Route, the railway corridor, the SS16 state road and the A14 Bologna-Taranto motorway. The most significant physical and perceptual barrier is the Adriatic railway, which separates the historic town of Silvi, located on a hill, from the waterfront settlement. This reflects a pattern typical of many municipalities in Abruzzo, where the main urban nucleus is distinct from the marina, with a relatively differentiated development of the built environment. The urban fabric of Silvi Marina, which alternates with the infrastructure system, has become denser especially since the 1960s. This phenomenon can be attributed to the predominantly flat terrain and early development linked to tourism and seaside resort growth. This has led to a high degree of seasonal specialisation. This spatial expansion has resulted in a progressive loss of functional and visual connections with the hinterland, a condition exacerbated by the construction of north-south infrastructure corridors, which have disrupted the continuity of ecological networks. This territorial fragmentation has contributed to the formation of a spatial system marked, ultimately, by multiple disconnections: between the sea and the hills, between the historical core and coastal development, and between ecological and anthropic systems.

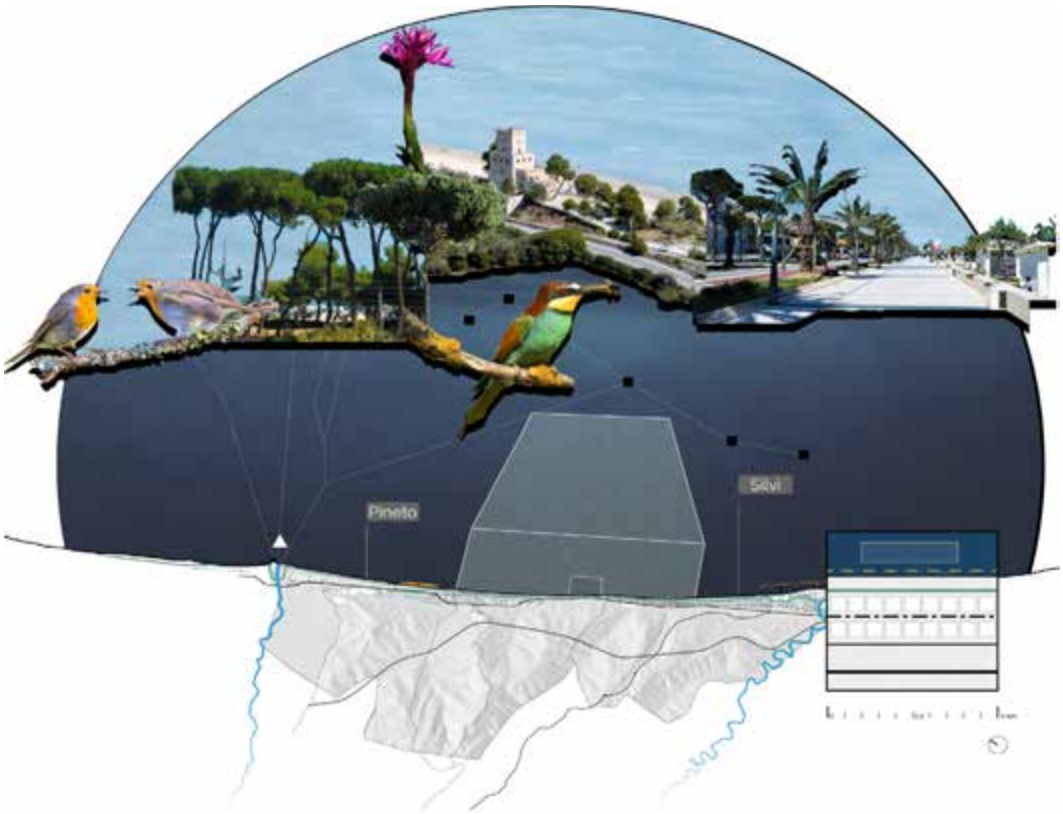

Figure 1: The Silvi-Pineto context (C1). The image illustrates the continuous urbanisation along the narrow coastal strip, punctuated by infrastructure systems and key heritage features: coastal pine forests, the Torre del Cerrano Marine Protected Area, the seafront promenade, and selected elements of local flora and fauna.

The pressure of construction, the functional rigidity of the urban system and the scarcity of open spaces render these areas more vulnerable to current climate dynamics. ISPRA data (2021) indicates that a considerable number of coastal segments between Silvi and Pineto are experiencing structural retreat, resulting in a substantial loss of natural sediments and, consequently, a compromise to the morphological resilience of the coastline. Furthermore, the rigid defence measures adopted in recent decades, such as groynes and breakwaters, have often proved ineffective or even counterproductive in the medium term, with a negative effect on the landscape and the coastal hydrodynamic balance (CIESM, 2012).

Despite the critical issues outlined above, the C1 context evinces elements of historical, landscape and naturalistic value of considerable interest, four of which are particularly noteworthy.

The first is the Torre del Cerrano Marine Protected Area (MPA), one of the few MPAs along the central Adriatic coast, which was established to protect a complex and interdependent ecological system comprising dunes, the coastal zone and the open sea (Ministero dell'Ambiente, 2009). Within the reserve, which covers approximately 37 square kilometres, the Torre del Cerrano plays a central role: an ancient coastal tower dating back to the viceregal era (1568), which has now been transformed into a narrative device illustrating the relationship between land and sea. The Museo del Mare (Sea Museum), located within the tower, features an exhibition dedicated to the Adriatic ecosystem, which progresses from the depths of the seabed to the sea surface, thereby facilitating a vertical and immersive interpretation of the underwater and coastal landscape, articulated across the various floors of the building. This symbolic narrative serves to reinforce the link between cultural heritage, historical memory and ecological perception, thereby positioning the Tower as a physical and conceptual hinge between the terrestrial and marine environments (AMP Torre del Cerrano, 2023).

The second is the system of coastal pine forests dating back to the 19th century, including the Catucci and Filiani Pine Forests. These vegetative formations, originally planted to stabilise the coastal dunes, have now become

significant reservoirs of biodiversity and ecological corridors within the urban landscape (Stanisci et al., 2014). The third comprises the remains of historic agricultural and industrial buildings, some of which have been partially incorporated into urban development. These bear witness to the functional relationships between the coast and hinterland prior to the rise of tourism.

Finally, the fourth consists of a few 20th-century accommodation facilities and traces of social tourism associated with Italy's "holiday culture", including examples of notable architectural quality (Fiadino and Zucconi, 2020).

In recent years, the area has been a fertile ground for experimenting with climate adaptation strategies and coastal regeneration processes, thanks to the implementation of co-management programmes and European projects. The participation of the Torre del Cerrano Marine Protected Area in the MPA NETWORKS project has strengthened the collaborative dimension of local governance, contributing to the adoption of integrated and multi-level approaches to planning (MedPAN, 2020). These initiatives proffer an alternative interpretation of coastal vulnerability, transcending a purely physical and morphological assessment in favour of a more systemic vision.

This approach is exemplified by the planning and management initiatives undertaken by the Municipality of Pineto in recent years. Through integrated policies focused on sustainable tourism, slow mobility, and the enhancement of coastal pine forests, the area has consolidated its role as a laboratory for innovation at the intersection of environmental conservation and local development. The establishment of the Zone 30 coastal area along the Teramo coast – which stretches from Martinsicuro to Silvi, constituting the largest initiative of its kind at national level – is an example of this (Eco dalle Città, 2023).

2.3 The Trabocchi Coast: intermittent landscapes and vulnerability in transformation

The second study context (C2) corresponds to the southern coastal stretch that includes the municipalities of Fossacesia, Torino di Sangro, Casalbordino and Vasto, part of the so-called Trabocchi Coast (Figure 2). In contradistinction to the Silvi-Pineto coastal system, this context exhibits a discontinuous settlement pattern, characterised by alternating promontories, coves and small coastal plains, where natural features still maintain a significant territorial presence.

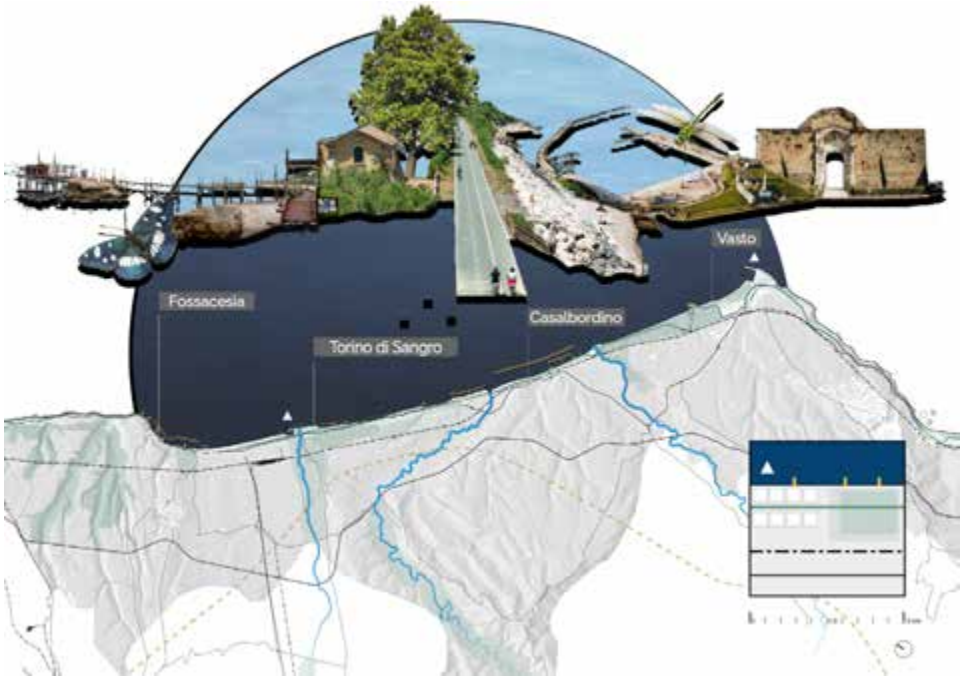

Figure 2: The Trabocchi Coast context (C2). The image highlights the coexistence of fragmented built environments and extensive preserved natural areas. Key features include: the trabocchi fishing structures, the *Via Verde* with its disused railway stations, the port of Vasto and historical traces, along with elements of flora and fauna typical of the Special Conservation Areas of this stretch.

Here, the orography of the terrain has historically influenced the processes of anthropisation, leading to a lower degree of building pressure and a greater preservation of environmental values in comparison to the northern section of the Abruzzo coast. This is evidenced by the fact that significant parts of the coastal area maintain a high degree of natural characteristics (Stanisci et al., 2014).

Indeed, this particular stretch is distinguished by intermittent natural "episodes" of high value, which are interspersed with infrastructure, industrial areas and seasonal settlements. From north to south, Special Conservation Areas (Habitat Directive 92/43/EEC) have been designated, including the Lecceta di Torino di Sangro, Punta Aderci - Punta Penna, and Marina di Vasto, in addition to two regional nature reserves. However, the restrictions and legal protection measures have not been sufficient to prevent actions with a significant environmental impact, such as the creation of the industrial area of the Port of Vasto or the post-war coastal settlements, sometimes built within 300 metres of the coastline, where building is strictly prohibited according to the Code of Cultural Heritage and Landscape (2004).

In addition to its rich natural heritage, the regional identity of the area is characterised by the distinctive trabocco system, which consists of ancient fishing machines built on stilts. This unique cultural heritage has recently become the focus of tourism and identity enhancement processes (Barone, Marino and Pignatelli, 1999). These structures are an emblematic example of anthropic adaptation to the morphological and hydrodynamic conditions of the coast, bearing witness to a history of symbiosis between humankind and the marine environment through construction techniques handed down through generations. The trabocchi are an embodiment of a living heritage that extends beyond their monumental value, representing a synthesis of technical and cultural expertise that has enabled local communities to devise adaptive strategies in a changing and occasionally hostile coastal environment (Cuzzucoli Crucitti, 2018).

In fact, the Trabocchi Coast is increasingly vulnerable due to the interaction between morphogenetic processes and anthropogenic pressures, particularly in river mouth areas. The most recent data demonstrate an intensification of coastal erosion and hydrogeological risk, with numerous stretches of the coastline being classified as "highly vulnerable" (ISPRA, 2022a). The risk of flooding and landslides is increasing, both in terms of extent and frequency of events, with a progressive expansion of the areas at risk compared to previous surveys (ISPRA, 2022b; ISPRA, 2023a). The area surrounding the mouth of the Sangro River has already been identified as one of the Italian coastal zones most exposed to flood risk by 2100 in the absence of adequate adaptation measures (ENEA, 2018). In recent years, this area has shown growing signs of criticality, particularly due to the increasing frequency and intensity of extreme weather events recorded over the past five years (ISPRA, 2023b).

The C2 context has gained increasing relevance due to recent territorial transformations, particularly the decommissioning of the Adriatic railway line and its conversion into a coastal cycle and pedestrian path. The *Via Verde of Trabocchi Coast* project, launched in 2009 and largely completed by 2020, has redefined the relationship between accessibility and the coastal landscape, offering new perspectives for the appreciation and enhancement of local natural and cultural heritage (Agenzia per la Coesione Territoriale, 2020). The repurposing of the railway corridor has created an opportunity to rethink the interplay between infrastructure and landscape, promoting a model of soft mobility aimed at valorising environmental resources and enhancing territorial resilience – although the latter still struggles to find effective implementation. Moreover, the increased tourist appeal generated by the new infrastructure has accelerated certain dynamics of change that require careful monitoring in terms of environmental impact and human pressure. The growing demand for tourism-related services and facilities along the route risks compromising the very landscape qualities that constitute its main attraction, introducing further elements of vulnerability into an already ecologically sensitive setting. In this light, the *Via Verde* may be understood not only as a sustainable mobility corridor, but also as a strategic infrastructure equipped to reconnect fragmented ecological networks and supporting adaptation strategies. However, to fully realise this potential, it is vital to move beyond conventional sector-based planning approaches and embrace integrated strategies that address the ecological, cultural, and socio-economic complexities of the coastal landscape (Clemente and Nanni, 2024).

In the preparatory studies for the coastal risk assessment of Abruzzo (AnCoRa Research, 2017)[3], the exposure analysis considered demographic data, building density, infrastructure, and the presence of environmental and cultural assets. However, in the final evaluation concerning the Trabocchi Coast – the region's most naturalistic stretch – these aspects were often secondary to geomorphological vulnerability alone. This methodological imbalance serves to confirm the necessity for integrated approaches to risk assessment, able to capture vulnerability as a combination of sensitivity and adaptive capacity (IPCC AR5, 2014), proposing reading categories suitable for restoring the complexity of local contexts.

3 | Heritage as environmental infrastructure

3.1 Two coastal landscapes, a common challenge

In both contexts (C1-C2), the conflictual relationship between processes of anthropisation and environmental values clearly emerges, exacerbated by the transformations associated with ongoing climate change. The land-sea interface is configured as a space of tension and opportunity, where critical issues related to environmental emergencies intersect with the potential for transformation and regeneration of the settlement system (Manigrasso, 2023).

The presence of significant heritage elements offers an opportunity to rethink adaptation strategies from an integrated cultural perspective, where the memory of place and the transmission of traditional practices become resources for imagining resilient futures.

In this regard, the selected case studies provide a significant experimental setting in which to test innovative design approaches, grounded in the recognition of heritage value as a strategic lever for reducing coastal vulnerability.

The *design testing phase* carried out in the described contexts, as part of the research undertaken, represents a significant methodological step aligned with the *research by design* approach. This phase aims to identify recurring conditions and design guidelines that can be transferred and scaled to other areas, while maintaining close attention to the specific characteristics of each site and its territorial and community vocations. The experimental phase, developed through educational initiatives, applied research activities, and meetings with experts and stakeholders, highlights the value of design as an exploratory investigative tool. It allows for the description of the conditions and resources that can be activated within a given territory (Marchigiani, 2022), functioning as a cognitive practice in which hypotheses, intuitions, and interpretations are tested and brought into tension (Pasqui, 2017). In line with these considerations, within the framework of the PRIN research project, scenarios and design guidelines were derived through an inductive approach from the experimental activities (see note 1), abstracting the outcomes and emphasizing strategic approaches that are particularly relevant in relation to the evolving dynamics and risk conditions of the coastal contexts under investigation.

3.2 Environmental infrastructure: reconnecting ecological and cultural matrices

With reference to the multiplicity of interactions between risk levels and coastal cultural heritage, as well as to the richness of landscape and natural values found along the examined coastal stretches, this contribution aims to highlight the significant role that design strategies can play in supporting and promoting natural regeneration, restoration, and the enhancement of ecological networks, starting from the reconnection of existing environmental matrices. The literature concerning the definitions and terminology of green infrastructures identifies a key aspect in overcoming the notion of infrastructure or network as a mere sum of elements or parts, which, in order to provide benefits, must be adequately connected. This is not merely a matter of physical-functional connection, but of strengthening and enhancing the networks and the services they can provide (EEA, 2011). The advantages associated with the "stitching together" and "recomposition" of ecological matrices and networks underline the importance of moving beyond sectoral approaches that limit the scope of action to isolated interventions, without recognizing their strategic and structural impacts on ecosystem and territorial balances (Sargolini, 2009).

3 In 2017 AnCoRa research project (Risk Analysis of the Coastal Area of the Abruzzo Region) was developed as part of an agreement between the Abruzzo Region and Univaq - DICEAA. The results are available online at: https://www.regione.abruzzo.it/content/analisi-e-documenti-propedeutici/

Therefore, the conceptual and operational background is broader than the framework defined by the narrative of landscape ecology, which focuses on the functioning of environmental systems and emphasizes the description of natural processes while continuing to implicitly separate "natural" from "cultural" heritage (Cevasco, 2007). From the perspective adopted here, natural and human-made ecosystems cannot be understood as separate components; the benefits associated with the functioning of continuous ecological matrices and capillary environmental networks should not be assessed solely in terms of human needs or advantages. Although ecosystem services, as defined by the Millennium Ecosystem Assessment (2005), are anthropocentrically interpreted as the benefits humans derive from ecosystems, it is now clear that they serve as an interpretive tool for understanding the relationships between natural processes and the uses and activities of society (Franchina, 2018).

These very ecosystem services underpin the definition of green infrastructures, conceived as a key system for interpreting the health and well-being of ecosystem components (water, soil, organisms). Accordingly, this contribution adopts a definition of green infrastructure as a system of elements and parts capable of creating conditions and enabling opportunities – an "assemblage" whose functions may vary, but whose entirety can become structure, support, and a base for implementation. In this view, green infrastructures are understood not only as environmental networks, but also as carriers of identity, historical-cultural connections that underscore slow processes of decoding and interpreting places. This perspective informs the research reflections aimed at addressing the fragmentation of environmental matrices, whose spatial configuration in Adriatic coastal systems is associated both with natural edges – currently discontinuous – running longitudinally along the waterline, and with a dispersed distribution linked to interstitial spaces within the linear urban fabric.

Considering heritage as environmental infrastructure – as a strategic approach to reducing vulnerability – brings to the forefront of contemporary planning debate and tools the role of soil itself, which is currently described and indexed in terms of uses that increase its profitability or productive capacities. This is consistent with the territorialist definition of heritage adopted in this research, which goes beyond a merely conservative vision. It recognizes the processual and incremental dimension of heritage, encompassing the identity features of landscapes and grounded in the dynamic interactions between local communities and the "natural" heritage (Magnaghi, 2020). It is not only a matter of material elements and sites, but also of traditions and collective imaginaries of coastal communities. This approach shifts the focus to relational spaces – buffer zones where overlapping and transitions of land-sea uses occur – thus variably defining the range of influence of land-sea interactions.

The heritage dimension is therefore expressed in land-use practices, in the innovation of architectural and urban solutions, as well as in the transformations of production systems in response to diverse environmental conditions. Reactivating these mechanisms through design means recovering adaptive approaches that are still traceable in some indigenous contexts, where social, cultural, and productive dimensions are deeply integrated into ecological practices of natural resource management and use.

However, exploring the potential of heritage as an infrastructure capable of mitigating vulnerability in a complex system such as the coastal one requires that communities once again be placed at the center of territorial transformation processes – as active agents in the very processes of patrimonialisation. Enhancing heritage as infrastructure, in fact, requires the active contribution of communities that resume responsibility for the care of the territories they inhabit through practices of management and maintenance. This is not only about caring for soil as a functional base of the natural and built environment, but also about recovering and transmitting the relationship with the land on which cities are established and continue to evolve (Pileri, 2015). This is the core of what cultural heritage represents: the progressive accumulation of material and immaterial sediments, nourished by continuous exchange with society, which shares its value and transmits it to future generations.

4 | Conclusions

The research presented in this contribution highlights the strategic potential of coastal cultural heritage in supporting adaptive responses to climate and environmental risks within the complex land-sea interface of the mid-Adriatic. By adopting a research-by-design approach and focusing on the coastal systems of Silvi-Pineto and the Trabocchi Coast, the study aims to demonstrate how heritage – both manifest and latent – can be reinterpreted as an active infrastructure, capable of informing and guiding resilience-oriented territorial strategies.

The comparative analysis of the two case studies reveals that heritage values, far from being static or merely preservable assets, constitute dynamic resources embedded in socio-ecological processes. These resources offer interpretive and operational frameworks to reconfigure spatial fragmentation, support ecological connectivity, and strengthen local adaptive capacity. In this regard, the reconceptualisation of green infrastructure as a system of relations – ecological, cultural, and infrastructural – emerges as a critical perspective for moving beyond sectoral planning logics and embracing a more integrated, place-based approach.

Importantly, the study underscores the role of communities as co-producers of resilience. The transition from a protection-oriented vision of cultural heritage to one that frames it as a living infrastructure requires both a conceptual shift and the reactivation of social processes of care, maintenance, and transmission.

The research outputs derived from the design testing phase contribute to formulating transferable planning agendas and strategic design guidelines, which may inform other Adriatic coastal territories experiencing similar dynamics of pressure and change. Ultimately, the integration of heritage and environmental infrastructure perspectives fosters a more nuanced understanding of vulnerability, not as a static condition but as a relational state shaped by history, identity, and the capacity to adapt. In a context marked by accelerating climatic change and territorial fragility, this approach offers a valuable contribution to the development of adaptive planning paradigms, capable of sustaining the ecological and cultural integrity of coastal landscapes over time.

Acknowledgements

The ongoing PRIN research – mentioned in the contribution – is conducted by the Research Unit of "RomaTre" University (national coordinator Prof. Maria Grazia Cianci) and the Research Unit of "G. d'Annunzio" University of Chieti-Pescara (coordinator Prof. Matteo di Venosa). The authors are involved in Pescara Research Unit (UdR Pescara), which include: prof. Track 6

URBAN CULTURES AND LIVED HERITAGE

Reimagining Postgrowth Urbanism: Adaptive Reuse of Industrial Heritage for Sustainable Futures

Asma Mehan
Architectural Humanities and Urbanism Lab (AHU_Lab),
Huckabee College of Architecture, Texas Tech University, USA
E-mail: asma.mehan@ttu.edu

Abstract
Amid escalating planetary crises, postgrowth urbanism emerges as a critical paradigm shift, challenging traditional planning models by prioritizing ecological balance, social equity, and community well-being over relentless economic expansion. This paper investigates the adaptive reuse of industrial heritage as a transformative tool for advancing sustainable urban futures. Focusing on regions shaped by extractive industries, such as West Texas and the MENA region, the study examines how these legacy sites can be reimagined to address today's environmental, social, and cultural challenges.

Keywords: postgrowth urbanism, adaptive reuse, industrial heritage, resilience, sustainable development

1.Introduction

The escalating environmental crises and socio-economic inequalities of the 21st century have prompted a critical reevaluation of traditional urban development paradigms. Conventional growth-centric models, which prioritize economic expansion often at the expense of ecological and social well-being, are increasingly being challenged. In response, the concept of postgrowth urbanism has emerged, advocating for urban development strategies that emphasize ecological balance, social equity, and community resilience over relentless economic growth (Eizenberg & Jabareen, 2017).

Within this paradigm shift, the adaptive reuse of industrial heritage sites presents a compelling strategy for sustainable urban transformation. Industrial heritage, encompassing defunct factories, warehouses, and other industrial infrastructures, often occupies significant urban spaces. Repurposing these sites not only preserves cultural and historical values but also mitigates the environmental impacts associated with new constructions (Mehan & Stuckemeyer, 2023). Moreover, adaptive reuse can catalyze community engagement, foster local economies, and contribute to the creation of inclusive urban environments.

This paper explores the potential of adaptive reuse of industrial heritage within the framework of postgrowth urbanism. Focusing on regions shaped by extractive industries, such as West Texas and the MENA region, the study examines how these legacy sites can be reimagined to address contemporary environmental, social, and cultural challenges. Through a comparative analysis of exemplary adaptive reuse initiatives, the research aims to identify actionable strategies that bridge the gap between theoretical aspirations and practical implementation, fostering a more inclusive and resilient urban future.

The urgency of reimagining urban development models is underscored by the increasing frequency and intensity of climate-related disasters, resource depletion, and social unrest. Traditional urban planning approaches, rooted in the pursuit of economic growth, have often failed to address these multifaceted challenges adequately. Postgrowth urbanism offers an alternative framework that prioritizes sustainability, equity, and resilience, aligning urban development with the ecological limits of the planet and the well-being of its inhabitants (Raco & Street, 2012).

Adaptive reuse of industrial heritage aligns seamlessly with the principles of postgrowth urbanism. By repurposing existing structures, cities can reduce the environmental impact of new construction, preserve cultural heritage, and revitalize communities. This approach not only conserves resources but also fosters a sense of place and identity, contributing to social cohesion and community empowerment (Barthel-Bouchier, 2013).

The transformation of industrial sites into functional spaces for contemporary use also presents opportunities for economic diversification. By integrating green industries, cultural institutions, and community services into these repurposed spaces, cities can stimulate local economies and create employment opportunities that align

with sustainable development goals (Mehan, 2022). However, the implementation of adaptive reuse projects is not without challenges. Structural issues, regulatory constraints, and financial limitations can hinder the successful transformation of industrial heritage sites. Addressing these obstacles requires innovative policy frameworks, interdisciplinary collaboration, and community engagement to ensure that adaptive reuse initiatives are both feasible and beneficial (Mehan & Mostafavi, 2024).

This study aims to contribute to the discourse on sustainable urban development by examining the intersection of postgrowth urbanism and adaptive reuse of industrial heritage. Through a comparative analysis of case studies from West Texas and the MENA region, the research seeks to identify best practices, challenges, and strategies for leveraging industrial heritage in the pursuit of inclusive, resilient, and sustainable urban futures.

2. Literature Review

2.1 Postgrowth Urbanism: A Paradigm Shift

Postgrowth urbanism represents a transformative approach to urban development, challenging the traditional emphasis on economic growth as the primary indicator of progress. Instead, it advocates for development models that prioritize ecological sustainability, social equity, and community well-being (Raco & Street, 2012). This paradigm shift is rooted in the recognition that perpetual economic expansion is incompatible with the finite nature of planetary resources and the need for equitable social structures.

Adaptive reuse significantly contributes to environmental sustainability by minimizing the need for new construction materials and reducing demolition waste. By repurposing existing structures, cities can lower carbon emissions associated with building processes and conserve natural resources. This approach aligns with circular economy principles, emphasizing the reuse and longevity of materials. Moreover, adaptive reuse projects often incorporate energy-efficient systems and sustainable design elements, further enhancing their environmental performance. For instance, the integration of green roofs, solar panels, and natural ventilation systems in repurposed buildings can lead to substantial energy savings and reduced urban heat island effects. These environmental benefits underscore the role of adaptive reuse as a practical strategy for cities aiming to achieve sustainability goals and mitigate climate change impacts.

The principles of postgrowth urbanism align with the concepts of degrowth and steady-state economies, which call for the downscaling of production and consumption to achieve ecological sustainability and social equity (Barthel-Bouchier, 2013). In the urban context, this translates to planning and development strategies that focus on resource efficiency, community resilience, and the preservation of cultural and natural assets (Kozlowski et al., 2020).

The implementation of postgrowth urbanism requires a reorientation of urban planning practices to prioritize long-term sustainability over short-term economic gains. This involves integrating environmental considerations into land-use planning, promoting mixed-use developments, and enhancing public transportation systems to reduce carbon emissions and improve quality of life (Eizenberg & Jabareen, 2017). Furthermore, postgrowth urbanism emphasizes the importance of participatory governance and community engagement in the planning process. By involving residents in decision-making, cities can ensure that development projects reflect the needs and values of the community, fostering a sense of ownership and accountability (Mehan, 2024a; 2024b).

Adaptive reuse projects have the potential to strengthen social cohesion by providing spaces that reflect and serve the needs of diverse communities. Repurposed industrial sites can be transformed into community centers, cultural venues, or affordable housing, addressing local needs and fostering a sense of belonging. Engaging community members in the planning and design processes ensures that the outcomes resonate with local identities and aspirations. Such participatory approaches can build trust, empower residents, and promote social equity. Moreover, preserving historical structures through adaptive reuse can reinforce community narratives and collective memory, contributing to a shared sense of history and place. These social dimensions highlight the importance of inclusive strategies in adaptive reuse initiatives.

The successful implementation of adaptive reuse projects relies on supportive policy frameworks and effective governance structures. Governments can facilitate adaptive reuse by offering incentives such as tax credits, grants, or streamlined permitting processes. Establishing clear guidelines and standards for the preservation

and modification of historic structures ensures that adaptive reuse projects maintain architectural integrity while meeting contemporary needs. Interdisciplinary collaboration among urban planners, architects, policymakers, and community stakeholders is crucial for addressing the complex challenges associated with adaptive reuse. By fostering a regulatory environment that encourages innovation and sustainability, policymakers can unlock the full potential of adaptive reuse as a tool for sustainable urban development.

2.2 Adaptive Reuse of Industrial Heritage: Definitions and Benefits

Adaptive reuse refers to the process of repurposing existing buildings for new uses while retaining their historic features. In the context of industrial heritage, this involves transforming obsolete industrial structures into functional spaces that serve contemporary needs, such as cultural centers, residential units, or commercial establishments. This approach offers multiple benefits, including the conservation of cultural heritage, reduction of construction waste, and revitalization of urban areas (Mehan, 2024c). Moreover, adaptive reuse contributes to environmental sustainability by minimizing the need for new construction materials and reducing urban sprawl. It also fosters social sustainability by preserving the historical identity of communities and providing spaces that can accommodate diverse social activities (Mehan, 2020).

Beyond environmental considerations, adaptive reuse serves as a catalyst for economic revitalization in urban areas. Transforming obsolete industrial sites into functional spaces can attract investment, stimulate local economies, and create job opportunities. These projects often become hubs for innovation, entrepreneurship, and cultural activities, drawing both residents and tourists. The revitalization of such sites can lead to increased property values and enhanced tax revenues for municipalities. However, it's essential to implement policies that ensure the economic benefits of adaptive reuse are equitably distributed, preventing displacement and promoting inclusive growth. By fostering economic development while preserving cultural heritage, adaptive reuse projects can contribute to resilient and vibrant urban communities.

Economic benefits of adaptive reuse include cost savings on construction, increased property values, and the attraction of tourism and investment. By revitalizing underutilized spaces, cities can stimulate local economies and create employment opportunities in construction, design, and cultural sectors (Mehan & Mostafavi, 2024). Adaptive reuse projects also serve as catalysts for community development, providing venues for social interaction, education, and cultural expression. These spaces can enhance social cohesion and contribute to the overall well-being of residents (Barthel-Bouchier, 2013).

2.3 Challenges in Adaptive Reuse of Industrial Heritage

Despite its benefits, adaptive reuse of industrial heritage faces several challenges. These include structural and environmental issues, such as contamination and degradation of materials, as well as regulatory and financial barriers. The complexity of retrofitting old structures to meet modern building codes and standards can also pose significant obstacles (Mostafavi et al., 2024). Furthermore, the success of adaptive reuse projects often depends on effective stakeholder engagement and community participation. Without inclusive planning processes, such projects risk marginalizing local communities or failing to meet their needs, thereby undermining the social sustainability objectives of postgrowth urbanism (Eizenberg & Jabareen, 2017).

Financial constraints can also impede adaptive reuse initiatives, as the costs associated with renovation and compliance with regulations may exceed those of new construction. Securing funding and investment for such projects requires innovative financing models and public-private partnerships (Mehan, 2022). Regulatory frameworks may not always support adaptive reuse, with zoning laws and building codes often favoring new developments. Reforming these regulations to accommodate the unique requirements of adaptive reuse is essential for the successful implementation of such projects (Barthel-Bouchier, 2013).

2.4 Integrating Adaptive Reuse into Postgrowth Urbanism

Integrating adaptive reuse into postgrowth urbanism requires a holistic approach that considers environmental, social, and economic dimensions. This involves developing flexible policy frameworks that support adaptive reuse initiatives, providing financial incentives, and fostering interdisciplinary collaborations among architects, planners, policymakers, and community members (Barthel-Bouchier, 2013).

Successful examples of adaptive reuse within postgrowth urbanism demonstrate the potential of this approach to create resilient and inclusive urban environments. These cases highlight the importance of context-specific strategies that respect the historical and cultural significance of industrial heritage while adapting to contemporary urban needs (Mehan & Stuckemeyer, 2023). Furthermore, integrating adaptive reuse into urban planning can contribute to the achievement of broader sustainability goals, such as reducing greenhouse gas emissions, conserving resources, and promoting social equity. By aligning adaptive reuse projects with these objectives, cities can enhance their resilience and adaptability in the face of environmental and socio-economic challenges (Raco & Street, 2012). In conclusion, the adaptive reuse of industrial heritage offers a viable and sustainable strategy for urban development within the framework of postgrowth urbanism. By addressing the challenges and leveraging the benefits associated with this approach, cities can transform obsolete industrial sites into vibrant, inclusive, and resilient urban contexts.

3. Methodology

This study employs a qualitative, comparative case study approach to investigate the adaptive reuse of industrial heritage sites within the context of postgrowth urbanism. The research focuses on two distinct regions: West Texas in the United States and the Middle East and North Africa (MENA) region. These areas were selected due to their rich industrial histories and ongoing efforts to repurpose obsolete industrial infrastructures for sustainable urban development.

Data collection involved a comprehensive review of academic literature, policy documents, and project reports related to adaptive reuse and postgrowth urbanism. Additionally, site visits and semi-structured interviews with stakeholders, including urban planners, architects, and community members, provided insights into the practical challenges and successes of adaptive reuse projects.

The analysis framework is grounded in the principles of postgrowth urbanism, emphasizing ecological sustainability, social equity, and community engagement. Each case study was evaluated based on criteria such as environmental impact, economic viability, cultural preservation, and community involvement.

By comparing cases from different geographical and cultural contexts, the study aims to identify common strategies and unique adaptations that contribute to the successful integration of adaptive reuse within postgrowth urban development models.

4. Case Studies

4.1 West Texas: The Transformation of the Seaholm Power Plant, Austin

The Seaholm Power Plant, originally constructed in 1951, is a notable example of Art Moderne architecture and served as Austin's primary power source until its decommissioning in 1989. Recognizing the site's historical significance and potential for urban revitalization, the City of Austin initiated a comprehensive redevelopment plan in the early 2000s. The adaptive reuse project, completed in 2016, transformed the decommissioned power plant into a vibrant mixed-use development encompassing residential units, office spaces, retail establishments, and public green spaces. This redevelopment not only preserved the industrial character of the original structure but also integrated modern sustainable design elements, such as a 325,000-gallon rainwater harvesting system for landscape irrigation.

A significant aspect of the Seaholm redevelopment was its emphasis on community engagement and public accessibility. The project included the creation of open public spaces and pedestrian pathways that connect the development to the adjacent Lady Bird Lake and downtown Austin. By fostering walkability and providing communal areas, the redevelopment aligns with postgrowth urbanism principles that prioritize ecological balance and community well-being over relentless economic expansion. Furthermore, the Seaholm Power Plant redevelopment serves as a catalyst for sustainable urban development in Austin. The project is part of the Seaholm EcoDistrict, one of ten projects in North America participating in the EcoDistricts Pilot Program, which aims to create sustainable and resilient neighborhoods. By integrating adaptive reuse with sustainable urban planning, the Seaholm redevelopment exemplifies how industrial heritage can be leveraged to foster inclusive and regenerative urban spaces.

The success of the Seaholm project has inspired similar adaptive reuse initiatives in Austin and beyond, demonstrating the potential of such projects to contribute to urban revitalization, heritage preservation, and sustainable development. By reimagining obsolete industrial sites as vibrant, multifunctional urban spaces, cities can address contemporary challenges related to sustainability, community engagement, and economic diversification.

Caption: The Seaholm Power Plant, a decommissioned Art Moderne-style facility in Austin, Texas, has been transformed into a vibrant mixed-use development. This adaptive reuse project integrates residential units, office spaces, and retail establishments while preserving the industrial character of the original structure. The redevelopment emphasizes sustainability through features like a 325,000-gallon rainwater harvesting system and contributes to the revitalization of Austin's downtown area. Source: Guide to Austin Architecture. Seaholm Power Plant Redevelopment

4.2 MENA Region: The Revitalization of the Gasworks in Cairo, Egypt

In Cairo, Egypt, the adaptive reuse of a former gasworks facility into a cultural and community center exemplifies the potential of industrial heritage transformation in the MENA region. The project involved the restoration of historic industrial buildings and the introduction of new public spaces for art exhibitions, workshops, and community events. This initiative not only preserved the architectural integrity of the industrial site but also provided much-needed cultural infrastructure in a densely populated urban area. The project demonstrates how adaptive reuse can address urban challenges such as the scarcity of public spaces and the need for cultural amenities, contributing to the social sustainability goals of postgrowth urbanism.

A key component of the Cairo gasworks redevelopment was its focus on community involvement and cultural engagement. By transforming the industrial site into a hub for artistic and educational activities, the project

fostered a sense of ownership and pride among residents. This participatory approach aligns with postgrowth urbanism principles that emphasize inclusivity, social equity, and community-driven development.

The adaptive reuse project also incorporated sustainable design strategies to enhance environmental performance and resilience. Efforts included the implementation of energy-efficient systems, the use of locally sourced materials, and the integration of green spaces within the urban fabric. These measures contribute to the broader goals of environmental sustainability and climate adaptation in urban redevelopment projects.

The revitalization of the Cairo gasworks serves as a model for similar initiatives in the MENA region, highlighting the potential of adaptive reuse to address urban challenges while preserving cultural heritage. By reimagining industrial sites as vibrant community spaces, cities can promote sustainable development, enhance social cohesion, and celebrate their unique historical identities.

Image 2: Adaptive Reuse Project in Historic Cairo, Egypt

Caption: In Historic Cairo, Egypt, adaptive reuse initiatives have revitalized former industrial sites into cultural and community centers. These projects involve restoring historic buildings and introducing public spaces for art exhibitions, workshops, and community events. By preserving architectural integrity and providing much-needed cultural infrastructure, such initiatives address urban challenges and contribute to the social sustainability goals of postgrowth urbanism. Source: Zawya. How adaptive reuse transforms communities

4.3 Comparative Analysis

Both the Seaholm Power Plant in Austin and the Gasworks in Cairo exemplify the transformative potential of adaptive reuse in urban settings. While differing in context and execution, these projects share common goals of preserving industrial heritage, fostering community engagement, and promoting sustainable development.

In Austin, the Seaholm Power Plant's redevelopment into a mixed-use complex has revitalized a once-dormant area, integrating residential, commercial, and public spaces. This project not only preserves the architectural integrity of the original structure but also incorporates sustainable design elements, such as a 325,000-gallon rainwater harvesting system for landscape irrigation. The success of this redevelopment has spurred further

investment and development in the surrounding Seaholm EcoDistrict, reinforcing the city's commitment to sustainable urban growth.

Conversely, the adaptive reuse of the Gasworks in Cairo focuses on cultural preservation and community development in a context where public spaces are scarce. The transformation of this industrial site into a cultural and community center addresses the need for accessible public spaces and cultural amenities in a densely populated urban area. By restoring historic industrial buildings and introducing spaces for art exhibitions, workshops, and community events, the project contributes to the social sustainability goals of postgrowth urbanism.

Despite their differing approaches, both projects underscore the importance of context-sensitive strategies in adaptive reuse. They demonstrate how industrial heritage can be leveraged to meet contemporary urban challenges, whether through economic revitalization and sustainable development, as seen in Austin, or through cultural preservation and community engagement, as exemplified in Cairo. These case studies highlight the versatility of adaptive reuse as a tool for creating inclusive, sustainable, and resilient urban environments.

2 School of Architecture and Urban Planning, Tongji University, Shanghai, China, tjupchenchen@tongji.edu.cn

Abstract
As the process of globalisation accelerates, cultural diversity is receiving unprecedented attention. As the international community continues to explore sustainable development models for traditional communities, the value of culture in shaping local identities, transforming resource values and enhancing economic competitiveness has become increasingly important. Peasant Life in China: A Field Study of Country Life in the Yangtze Valley opens a window for the international community to understand the Chinese countryside, and the history and cultural resources of the classic case study of Kaixingong Village in the new era. In the context of the new era, the cultural resources of Kaixiangong Village have undoubtedly become an excellent example for exploring the transformation mechanism and sustainable development path of rural cultural resources. Borrowing Bourdieu's concept of cultural capital, the study chooses a village in Suzhou, China Kaixingong Village, and explores the ways and mechanisms of transforming rural cultural resources into cultural capital through field surveys, semi-structured interviews and questionnaires. The study finds that: 1) The transformation of cultural resources involves the synergy of the government special team, the village committee and the enterprise group. The rural governance structure under the scale reorganisation promotes the development of rural regionalisation and the overall planning of cultural resources. 2) The village committee plays the role of coordinating all parties in the process of transforming cultural resources, making use of the social base of rural acquaintances, storing villagers' unused houses, and overlaying the policy benefits to guarantee the group's market operation in the countryside. 3) The group and the village enterprise, as the terminal of transforming cultural resources, maximise the economic value of cultural resources through rural operation. Maximise the economic and social benefits of cultural resources, transform them into value-added cultural capital, and give them capital attributes. At the same time, the passive impact on villagers during the transformation of cultural resources requires the establishment of an effective communication mechanism in the subsequent development of the village to ensure the sharing of benefits and sustainability. The study aims to accurately analyse the capitalization mechanism of rural cultural resources, deeply explore the positive role of rural historical and cultural potentials in contemporary socio-economic development, further expand the application dimension and feasible path of cultural capital in rural revitalization practice, and contribute innovative and referential Chinese wisdom and solutions to the effective development and utilization of global rural cultural resources.

Key words :cultural capital Kaixiangong Village Peasant Life in China Government special team

1. Introduction

Since 2000, culture and heritage have been recognised as the fourth pillar of sustainable development in European and international policy research. The rise of culture as a solution to urban social and economic 'diseases' has received unprecedented attention(Sabatini, 2019, Dinardi, 2015). However, research on culture-led development strategies has focussed mainly on large cities and metropolitan areas, with less attention paid to villages and small towns(Bell and Jayne, 2010, Lysgård, 2019). So far, the link between rural development and culture has been dominated by tourism, which may have exacerbated existing problems while promoting economic development(Ghahramani et al., 2020). Cultural policy in the countryside is limited and related to the urban culturally dominated policy discourse(Lysgård, 2016). Despite this lack of attention, cultural resources can be a valuable driver of revitalisation in rural areas and a major contributor to social cohesion and civic engagement(Thurley et al., 2015). In rural areas, culture mainly refers to landscape management and conservation, traditional social practices, customs and lifestyles, etc. Established research narratives on rural culture also mainly refer to natural capital and tourism-related benefits, neglecting other rural resources and capital(Egusquiza et al., 2021).

Indeed, culture shapes access to other forms of capital and is itself an indispensable form of capital(Daskon and McGregor, 2012). We believe that rural areas will benefit from culture-led revitalisation opportunities, and that traditional or vernacular culture has been recognised as a key resource and an important variable in the survival and sustainability of villages. Rural villages beyond culture itself and heritage-related tourism can access additional resources by utilising the power of higher levels of government and business, but the transformation of cultural resources driven by different agents has rarely been studied. To address the existing research limitations, this study uses Bourdieu's concept of cultural capital, aiming to understand the ways of accumulation of

cultural resources in the countryside, the transformation pathways and the impact of cultural capital on rural development. A rural village in Suzhou, China is empirically selected to explore the process of realising rural cultural capital and the key elements involved in the process. The main contribution of the study is the introduction of a new transformation theory model that describes the transformation mechanism of cultural resources. The study aims to contribute to the study of rural cultural capital by furthering the understanding of rural cultural values and the factors that may influence participants' cultural capital.

2. Literature review

2.1 Capitalisation of cultural resources

Culture is a highly ambiguous concept that is difficult to define. Broadly speaking, culture can be divided into three categories: material, institutional and spiritual. Generally speaking, the capitalisation of cultural resources refers to the transformation of all kinds of industrially exploitable cultural resources owned by a society into value-added cultural capital with the goal of maximising economic and social benefits, and endowing them with the attribute of capital. Resources, as the sum of all means of production that can promote the progress of the cultural cause, play an important role in cultural identity, power cohesion and economic competition, and prompt the corresponding cultural capital to participate in cultural production activities, thus generating new cultural resources(Ma et al., 2021). Resources are not capital in themselves, but only have potential value before they are transformed. Moreover, not all cultural resources can be transformed into cultural capital, only those that can be developed under the existing conditions and have market potential can be transformed into capital. Therefore, Bourdieu believes that cultural resources and cultural capital have a dependent relationship, and cultural capital is the cultural resources that are activated and utilized. Sotheby's believes that cultural resources are the cultural products of labour value accumulation, and only the cultural commodities that can be circulated and generate new benefits in consumption can be called cultural capital, and they tacitly agree that cultural products are the basis of cultural capital, which raises the starting point of classification of cultural resources. Therefore, the essence of capitalisation of cultural resources is the process of activation and utilisation of static cultural resources, which is also the essence of cultural capital.

In rural areas, the material dimension of cultural resources is embodied in the products that people create and their longstanding ways of producing them, including the specific tools, processes and technologies used to produce goods. The institutional dimension consists of the moral and ceremonial norms established over time to maintain stability and social order in rural societies. The spiritual dimension reflects the shared psychological structure and emotional response patterns, often expressed in villagers' personalities, values and outlook on life(Daskon and McGregor, 2012). Cultural resources provide opportunities for other forms of capital to be shaped in the process of capitalisation, as assets that represent the strengths or weaknesses of actors, such as natural, physical and financial capital, and profoundly influence villagers' upgrading decisions and standards of living(Lewis, 2005). There is a consensus among researchers that cultural resources must undergo a series of developmental transformations and market operations before they can finally be transformed into chemical capital. However, for the capitalisation process of cultural resources, or the transformation mechanism of cultural resources, more studies focus on the cross-section results of cultural resources into cultural capital. Fewer studies have explored the capitalisation process and effectiveness of cultural resources from the time series dimension.

2.2 Cultural capital and rural development

When cultural resources are transformed into cultural capital, they become a kind of assets that can be transferred from one generation to another in the social field over time. The concept of cultural capital we are discussing nowadays is mostly derived from Bourdieu's theory of cultural capital, in which he believes that cultural capital is the appropriation of certain cultural resources by actors, including their dress and behaviour, aesthetic preferences, cultural qualities, educational diplomas, and so on(Apple et al., 2009). Cultural capital is the accumulation of the value of cultural labour in the field of production, which can evolve into a class structure of continuous intervention, the capital power of resource distribution, and is expressed as a method and adaptive capacity, which provides human society with the possibility of using and transforming the natural environment(Berkes and Folke, 1992). Correspondingly, cultural capital possesses three forms: concrete, physical and institutionalised. Concrete cultural capital is dependent on the inherent cultural skills and cultivation of individuals; physical cultural capital is the form of material presentation under the action of subjective initiative; and institutionalised capital is the form of officially sanctioned institutionalisation. The three forms of existence complement and influence each other, and play the roles of regulating, structuring and safeguarding in the 'field' on which the

theory of cultural capital is based. cultural capital theory has developed the following characteristics under the continuous expansion of researchers: 1) cultural capital (1) Cultural capital can bring economic value, which is in essence a kind of 'attention economy'. (2) With the help of certain real carriers, cultural capital has the form of materialisation. (3) Cultural capital can be accumulated through time, which needs to be inherited by people. (4) Cultural capital can be accumulated and reproduced. Cultural capital can be accumulated and reproduced, and its essence is the continuous expansion of the value system.

Bourdieu leaves a lot of space for the study of cultural capital, which is both determined by the social structure and reproduced through the continuous practice of the subject, and the concept of cultural capital can be interpreted in the broader social context of the city and even the countryside. The countryside can be regarded as 'a history of accumulation', or even a way of existence in which culture and capital are organically combined. This gives rise to the concept of rural cultural capital, which is an umbrella term for those historical or contemporary, traditional or modern, material or immaterial, dynamic or static, tangible or intangible rural production and lifestyles that have been created under the dual role of agricultural and industrial civilisations. Rural cultural capital is based on in-depth excavation of rural cultural resources, through a variety of ways to carry out the optimal allocation of resources and effective operation, so as to promote the progress of cultural productivity, and achieve the maximisation of the economic and social benefits of cultural capital. In the process of transforming such resources into capital, a benign interactive cultural construction can be formed, which becomes the productivity and competitive advantage of the countryside and drives the development of rural industries(Daskon and McGregor, 2012). Through the intensive use of cultural resources in the countryside, it can optimise the industrial structure of the countryside, change the mode of economic development and promote the development of the tertiary industry. At the same time, it can also bring back the labour force, adjust the population structure, and revitalize the countryside(Radcliffe and Laurie, 2006). Some studies have extensively discussed the impact of rural cultural capital on rural livelihoods(Ma et al., 2021), or linked rural cultural capital with rural tourism and cultural festivals, and discussed the relationship between culture and labour, resources and social capital(Rossetti and Quinn, 2021). However, these studies are more at the level of phenomenon association, and have not explored in depth the transformation process, mode and conditions of cultural resources, and lack of application-oriented transformation strategies. This study focuses on the transformation mechanism of cultural resources, and explores the impact of cultural resources on rural governance structure and spatial planning, so as to realise the transformation into economic benefits. The integration process of cultural resources, the way they are transformed into cultural capital, and the key details of the transformation will be fully investigated.

3. Research design

3.1 Case study

A village in Suzhou, China, Kaixiangong Village, one of the representative economically developed areas in Southern Jiangsu Province, was selected for the study, Figure 1. Kaixiangong Village consists of five natural villages: Kaixiangong, Lotus Bay, Xicaotian, Tianzixuwei, and Sifangxuwei. The village area has a total area of 4.5 square kilometres, with 25 villagers' groups, 752 households, a resident population of 3,020, 2,965 acres of arable land, 45 acres of mulberry land, 2,920 acres of paddy and mulberry land converted into fish ponds, and 1,400 acres of water surface in the outer swings.

The accumulation of cultural resources in Kaixiangong Village comes from Mr Fei Xiaotong's Peasant Life in China, which analyses the economic system, social structure and cultural ecology of Kaixiangong Village in depth, and constructs a complete and academically valuable narrative framework for the village. This is not only an objective record of Kaixiangong Village's specific stage of development, but also gives authority and uniqueness to the village's cultural resources, constituting the core and dominant part of Kaixiangong Village's accumulation of cultural resources.1938, when Fei Xiaotong was studying at the University of London in England, he relied on a study of the village's economic system, social structure, and cultural ecology. In 1938, while studying at the University of London, Fei Xiaotong wrote his doctoral thesis, Peasant Life in China, based on his research in Kaixiangong Village, which documented the process of rural industry in China, and he visited Kaixiangong Village a total of 26 times. Since then, Kaixiangong Village has become a research base for the international sociological community to study the Chinese countryside and establish long-term academic ties.

Figure 1 Location map of Kaixiangong Village
Source: Self-drawn

3.2 Research method

In order to fully discuss the transformation mechanism of Kaixiangong Village cultural resources, this study adopts a combination of quantitative and qualitative research methods. A one-week field survey of the village was conducted in July 2023, with short semi-structured governmental, village committee, enterprise group leaders, and villagers field interviews (N=20). The interviews were semi-structured and included open-ended questions that allowed respondents to answer questions in their own way, independent of the researcher. All interviews were transcribed verbatim and thematic analysis techniques were used to identify key themes and conceptual issues. Secondly, questionnaires were administered to the villagers and 150 valid questionnaires were collected. In addition, Kaixiangong Village's planning atlas related to cultural resources, statistical data, and information about development projects by outside companies were collected. Although, a case study can never form a generalisable sample, this study can be partially replicated and can shape the design of future studies.

4. Capitalisation of cultural resources

4.1 Accumulation of cultural resources

The study systematically combed and statistically analysed the specific content of Mr Fei Xiaotong's 26 visits to Kaixiangong Village, Figure 2, quantifying the material, spiritual and institutional levels of cultural resources respectively. We divided the sequence of visits into three stages, the first stage is from the 1st visit to the 9th visit (1935-1985), which is mainly the accumulation of cultural resources in the material level. The second stage is

from the 10th visit to the 19th visit (1985-1996), in which the accumulation of cultural resources shifted from the material level to the spiritual and institutional levels, and the accumulation of cultural resources was relatively balanced in the three levels. In the third stage, from the 20th visit to the 26th visit (1996-2002), the accumulation of cultural resources was mainly at the spiritual level, with the material level decreasing and the institutional level increasing.

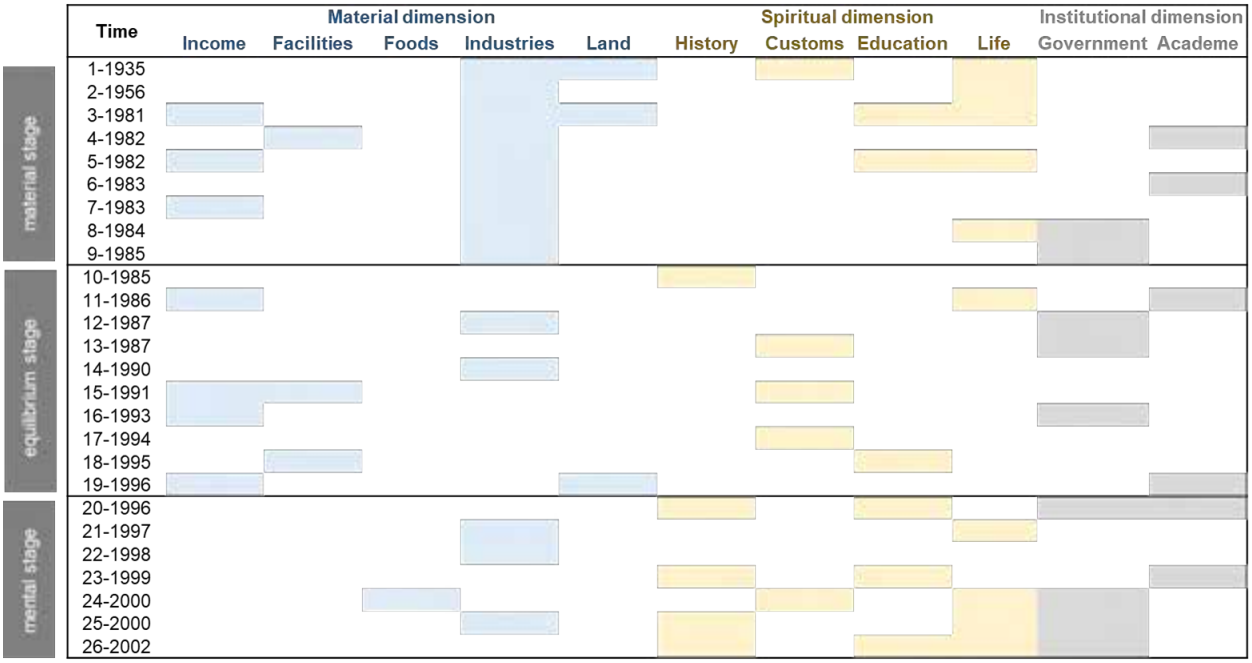

Figure. 2 A compendium of Fei Xiaotong's 26 visits
Source: Self-drawn

We further screened the content frequency of the 26 visits to the countryside to determine the main content of each stage of the visit, in order to identify the process of accumulation of elements of cultural resources, and to provide a basis for the subsequent transformation of resources, Figure 3. In the material stage, industrial labour and land use, as the main accumulation of cultural resources at the material level, not only create the material products needed for life and satisfy the basic needs of rural residents through specific production and practical activities and the development of land space, but also lay a solid material foundation for subsequent academic research, and their embedded economic value and physical presence form the material foundation of cultural resources. The economic value and physical existence of these products constitute the core elements of the material foundation of cultural resources in the countryside. In the equilibrium stage, economic income and infrastructure at the material level, local customs at the spiritual level, and academic research at the institutional level mutually empower each other, and the optimisation and upgrading of economic income and infrastructure provide material support and dissemination platforms for the inheritance and display of local customs, while the unique local customs attract more attention and feed the economic development. Meanwhile, academic research at the institutional level provides theoretical basis and scientific guidance for the first two, ensuring that cultural resources in the countryside achieve all-round, sustainable and balanced development in the process of accumulation, and jointly promoting the advancement of rural cultural capital to a higher level. In the mental stage, the focus of cultural resources accumulation is shifted to the spiritual level of historical accumulation and cultural education. Deep historical deposits have injected rich connotations into rural culture, while cultural education plays a key role in the process of inheriting and promoting these cultural elements. This process not only promotes intergovernmental exchanges at the institutional level and the deepening of academic research, providing policy support and theoretical guidance for the development and utilisation of cultural resources in the countryside, but also, with the help of various channels of communication, vigorously promotes the widespread dissemination of rural cuisine at the material level and enhances the overall influence of rural culture.

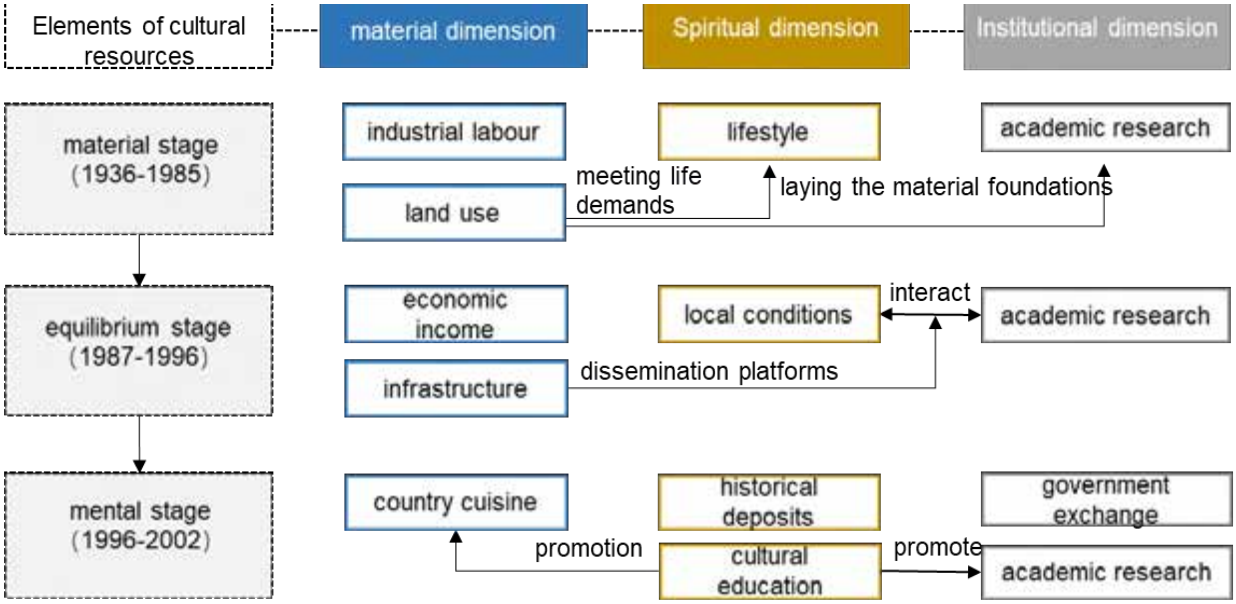

Figure 3 Cultural resources element accumulation
Source: Self-drawn

4.2 Transformation of cultural resources

4.2.1 Transformation path 1: government special team under scale reorganisation

The uniqueness of China's villages lies in the vertical depth and grassroots intervention of the governance system. Unlike the bottom-up governance model in Western countries, Chinese villages are governed by an informal administrative body, the village committee, which is an extension of state power and is indispensable for most village development, capital introduction, and project attraction, but when the influence of the village extends beyond its boundaries and attracts cross-regional investment, large-scale project resources or complex policy coordination needs, the limited resources and coordination capacity of the village committee alone are often insufficient to cope with the situation. However, when the influence of the village extends beyond the village, attracting cross-regional investment intentions, large-scale project resources, or facing complex policy coordination needs, it is often difficult to cope with the limited resources and coordination capacity of the village committee alone, and a cross-scale reorganisation of the government special team becomes a necessary and efficient response. In Kaixiangong Village's cultural resources capitalisation process, a government special team was set up to coordinate the development of the hyper-village, and work with the village committee to promote the transformation of cultural resources and the dissemination of the 'Jiang Village' IP, Figure 4. In addition to the valuable academic cultural resources left behind by Mr Fei Xiaotong for Kaixiangong Village, in the context of China's rural revitalisation strategy, Suzhou City has established the 'China Jiang Village' rural revitalisation demonstration zone in 2020, which is officially recognised at the municipal level. Institutionalisation. In the same year, Wujiang District, a subordinate district of Suzhou, built a project command department for Kaixiangong Village, and started to organise government personnel across administrative scales to form a special team. The mayor of Wujiang District acted as the head of the command department, linking up various departments of agriculture and rural areas at the district level, and correspondingly, Qidu Township set up a special comprehensive rural upgrading task force and deployed township staff to work in the village, which has been in place since then.

The establishment of the government special team in Kaixiangong Village has led to a systematic transformation of the village, laying the institutional foundation for the creation of the 'Jiang Village' cultural brand. On the one hand, the special team continues to promote the excavation of village culture, and on the other hand, it works with the village committee to assist in village planning and the development of introduced projects. As Director Shen of the government special team said:

'At the beginning of the establishment of the task force, the overall planning of the village was to build a cultural development corridor centred on Kaixiangong Village, and around Kaixiangong Village North, Kaixiangong Village South and Lotus Bay Village, we built the Jiang Village 1936 North Garden, Taihu Crab Garden, Jiang Village 1936

South Garden, and Jiang Village 1936 Landscape Mulberry Field. Now all of them, except the North Garden, have been completed and are open for business.'

At this point, cultural resources have been transformed into institutionalised capital. The cultural capital of Kaixiangong Village exists in an 'institutionalised state' in the form of social identity, which is officially recognised, legal and socially accepted. Kaixiangong Village's cultural resources, both material and spiritual, are preserved, inherited and disseminated more widely through the vehicle of the government special team.

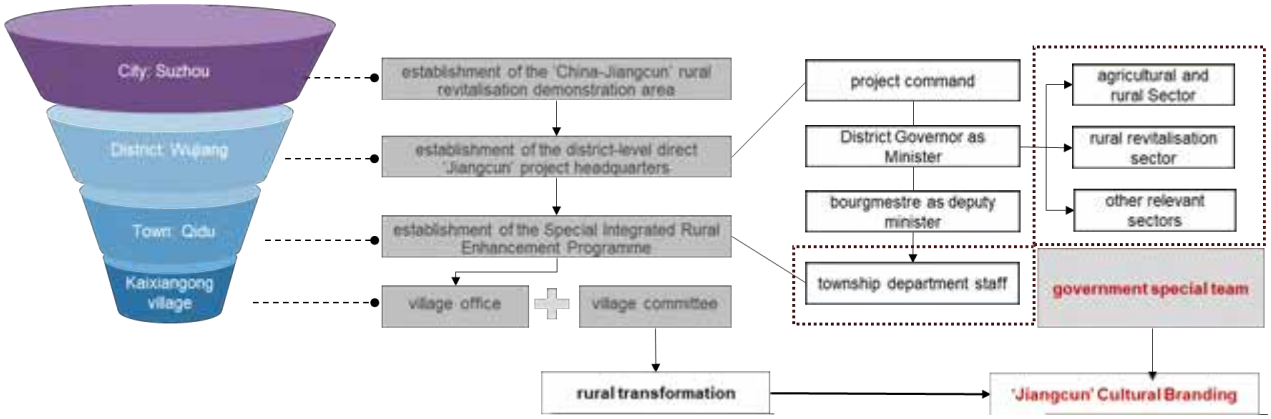

Figure 4 Institutions under scale reorganisation cultural capital
Source: Self-drawn

4.2.2 Transformation Path 2: Internal and External Symbiosis of Rural Public Cultural Space

The co-governance between the government special team and the village committee has led to the materialisation of Kaixiangong Village cultural resources, creating new values in the production field through the introduction of projects, promoting the reproduction of cultural space, and storing it in an 'objective state' in the concrete material. Through the investment and introduction of projects, new values are created in the production field, and the reproduction of cultural space is promoted, which is stored in the concrete material in an 'objective state'. In order to revitalise and utilise cultural resources, a series of rural public cultural spaces have been created, Figure 5, and with the development of urbanisation and rural revitalisation, rural operating companies with cultural service skills have become the dominant factor in intervening in the development of the countryside, and the traditional endogenous space and the new exogenous and modern space have appeared to be mixed and symbiotic. In Kaixiangong Village, we see two different paths of cultural resources being transformed into public space under the intervention of capital. Firstly, there is the entry of the village sage enterprises. Kaixiangong Village's Shanshui Mulberry Field, South Park Carnival and Taihu Crab Bank are all invested by the village sages, who have returned to their hometowns with their deep feelings for their hometowns and their familiar industrial fields, and have given back to their hometowns through their practical actions. Compared with foreign enterprises, the sages deeply understand the value of their hometown culture, show a high degree of cultural identity and cultural self-awareness, and integrate regional cultural characteristics into industrial development, which not only promotes local economic growth, but also promotes the inheritance and innovation of rural culture. As the director of government special team, Mr Miao, said:

'In the beginning, we also negotiated co-operation with larger foreign companies and groups, but their understanding of the culture of Jiang Village was not that deep. Instead, my local entrepreneurs were able to sense what we wanted, what we wanted to do for the villagers, what we wanted to do for this village.'

Secondly, in order to further expand the influence of the 'Jiang Village' cultural brand, the village has introduced a village operation company (Blue City Group), which cooperates with the government in rural revitalisation projects. For example, Kaixiangong Village's Jiang Village Hall, Market, Council Chamber and Cultural Gallery are all public cultural spaces funded by the company during its operation of the village. Compared to the direct economic benefits generated by the mulberry fields, crab gardens and carnivals, the functional attributes of these public spaces are more integrated into the lives of the villagers and attract foreign tourists to learn about village culture. Integration of fragmented cultural resources and further formation of cultural capital will lead to the development of diversified industries.

4.2.3 Transformative pathway 3: Participatory research and learning activities

In the process of capitalising cultural resources, in addition to institutionalised and materialised forms of storage, Kaixiangong Village also has an educational and cultural dissemination value of study activities. This includes village social surveys and academic exchanges between scholars from home and abroad at the beginning, as well as a wide range of research experiences for students at the present time. The unique cultural features and connotations of the villages, such as historical deposits, local customs and lifestyles, have been internalised over time into the unique spiritual qualities of Kaixiangong Village. Research activities have expanded the scope of dissemination of this cultural capital, and its audience has shifted from scholars to a wider public. The participatory nature of this spiritual transformation of cultural resources is very important. Therefore, the promotion of research activities and the target groups are the main considerations for Kaixiangong Village in shaping its cultural capital. Through research and interviews, our research team concluded that study activities are mainly classified into task-type, spontaneous-type, and education-type, Figure 6. Specifically, task-type study activities are usually carried out by government staff as the main body to carry out collective activities, mainly to learn from the village's governance model of multi-party participation, the government's experience of linking social capital and villagers' assets for economic development, and the experience of tapping into the countryside cultural resources to create a village cultural brand. Resources to create a rural cultural brand model. Spontaneous research activities refer to the researchers' independent decision to go to the countryside for research based on their own research interests and research directions. Their research includes the social structure change, economic transformation, and cultural inheritance of Kaixiangong Village. Through interviews, observations, questionnaires, etc., they dig into the first-hand data, and dedicate themselves to contributing innovative results to the field of academic research. Educational study activities are agricultural experience activities organised for primary and secondary school students to participate in, based on the rural agricultural production environment, integrating agricultural knowledge learning and practical experience in depth. Through field visits to farmland, participation in agricultural operations, observation of the growth process of crops and other forms, primary school students are guided to broaden their horizons of knowledge in real agricultural scenes, and to understand the basic process and importance of agricultural production.

The interactive process of research activities further promotes the capitalisation of cultural resources and gives participants unique cultural capital experiences, for example, participants can buy cultural goods, develop skills and learn about local cultural history. Of course, there are scholars who believe that people participate in study activities just for fun, not for the development of cultural capital in villages. However, from the actual development of Kaixiangong Village, the high frequency of study activities has been effective in spreading culture. Participants have attracted more social resources to invest in them, further helping the village to carry out more cultural projects, so that the culture of the Jiang Village can be cohesive in Kaixiangong Village, which is worth preserving and passing on, and sharing with a wider range of people and regions.

5. Discussion and conclusions

5.1 Mechanisms for the formation of cultural capital

The analysis of the research results shows that the process of cultural resources capitalisation is complex, and the relationships between different subjects are intertwined, and they play different roles and have their own interests in the process of cultural resources capitalisation. Therefore, this study provides a conceptual model of cultural capital development and related dominant actors, Figure 7, which includes the direction and interrelationships of different actors in the process of cultural resources transformation, as well as the forms of cultural capital that are formed under the role of these actors. Firstly, the transformation of cultural resources involves the synergy of government special team, village committee and enterprise group. In the case of Kaixiangong Village, cultural resources were the first to be officially recognised, and the legitimacy of the social identity was the strategic basis for a series of business projects. The reorganisation of the village governance structure has facilitated the regionalisation of the village and the development of the cultural concept of 'Extensive Jiang Village', which has facilitated the overall planning of Cultural resources. The government's function is to attract investment and bring in external resources and capital. Secondly, village committee plays the role of coordinating all parties in the process of transforming cultural resources, making use of the social basis of village acquaintances, storing the idle houses of villagers, and overlaying policy preferences to guarantee the market operation of the group's enterprises. In addition, the group and the village committee, as the end point of cultural resources transformation, maximise cultural resources and social benefits through village operations, transform them into value-added cultural capital and give them capital attributes.

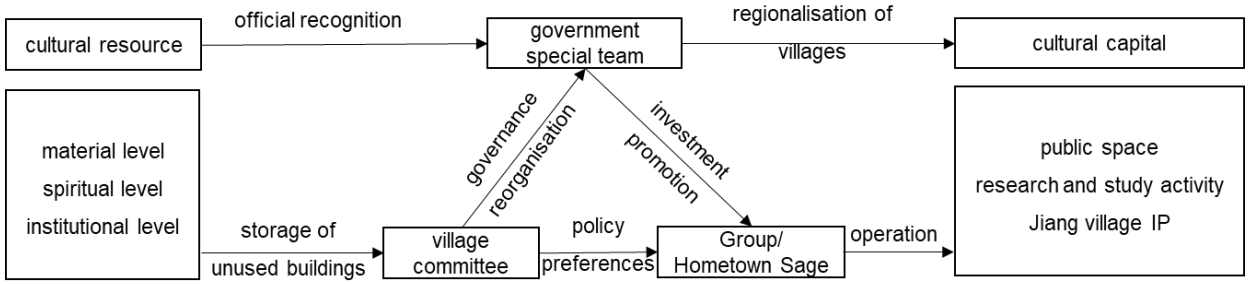

Figure 7 Cultural resources transformation mechanism
Source: Self-drawn

5.2 Response of villagers to passive participation

In the case of Kaixiangong Village, we see that the government, village committees and enterprises are actively involved in the dissemination, transformation and transmission of cultural resources in the villages, but the villagers living in the villages are involved in a passive way. In our research questionnaire, we found the unequal distribution of benefits in the relative deprivation theory and the information asymmetry in the knowledge gap hypothesis. More than 24% of the villagers are indifferent to the development of the cultural industry in the countryside, and 27% of the villagers think that the current public cultural space attracts insufficient and does not have a positive impact on their lives. This shows that the value-added of cultural capital has not yet fairly benefited all villagers, and villagers fail to get direct economic and social benefits from it, then their interest and support for these changes will be reduced. Second, villagers only see the external changes in the villages superficially, and differences in access to information further widen the knowledge gap between different groups. Villagers do not understand the specific process and long-term significance of the transformation from cultural resources to cultural capital, and therefore cannot feel the positive impact of this transformation.

The reason for this is the lack of participation in the project and the lack of sustainability, which leads to the perception of group differences in the process of transforming cultural resources. This also requires that the government, enterprises and village committees pay more attention to the actual needs and opinions of the villagers in the subsequent development of the countryside, and promote the active participation and support of the villagers through the establishment of an effective communication mechanism, ensuring the sharing of benefits and respecting and integrating the local cultural characteristics, as well as the provision of the necessary education and training. In addition, the government and village committees need to pay more attention to the actual needs and opinions of villagers by establishing effective communication mechanisms, ensuring benefit sharing and respect for and integration of local cultural characteristics, and providing the necessary education and training, so as to promote villagers' active participation and support. At the same time, there is a need to formulate long-term plans to ensure that the process of transforming cultural resources into cultural capital is sustainable and can bring about substantial improvements.

5.3 Conclusion and prospect

The main purpose of this study is to further understand the transformation paths and mechanisms of rural cultural resources, which provides theoretical explanations and case sharing for the study of the adaptive use of rural cultural resources. Based on a study of a rural village in Suzhou, China, a new theoretical model of cultural capital is proposed, including the relaxation of the accumulation of cultural resources, transformation pathways and impacts. The study reveals three forms of cultural capital storage in villages, the interactions between different actors and the passive responses of villagers. The study highlights the dominant role of the scale-restructured village governance structure in the formation of cultural capital, the coordinating role played by village committees in the process of resource transformation, and the value-added role in the operation of group enterprises.

Clearly, this is an exploratory study and conclusions relying on one case alone are not broadly generalisable. Rural culture is significantly territorial, and future research could carry out a larger survey of villages. Attention should also be paid to how rural cultural capital can be beneficial to participants on an individual level.

The inheritance mechanism of rural living heritage in China based on the model of "rural governance - policy supply - protective activation"

Sijie Liu
Affiliation: college of architecture and urban planning, Tongji university
Email:2310335@tongji.edu.cn

Abstract
This paper studies the triadic dialectics of "rural governance - policy supply - protection and activation", builds a theoretical influence model of the three, and puts forward the views that rural governance is the tool, policy supply is the guarantee, protection and activation is the purpose.

Taking rural governance as the starting point, this paper analyzes the protection and utilization of cultural heritage in the process of rural evolution in Zhongshan under the influence of policy supply since 2018. It also proposes five suggestions for establishing the mechanism: improve the regional resource survey mechanism, strengthen the design of top-level protection and activation policies, enhance the Role of Village Collectives through Governance-Oriented Mechanisms, improve the dynamic protection-update feedback mechanism, establish a supervision and inspection mechanism.

Keywords: rural governance; policy supply; protection and activation; rural lived heritage

The countryside is an important space for carrying the culture[1] and an indispensable part of heritage protection[2]. However, since the reform and opening up in 1978, rapid urbanization has had a significant impact on China's rural areas. Rural heritage generally faces two major situations. First, urbanization in some areas is based on the annexation of rural areas, and many traditional villages have been completely demolished. Second, there is a large loss of population, the backwardness of village infrastructure, and serious damage to rural buildings and landscapes. Rural heritage protection is urgent. For a long time, China's rural heritage protection has been a continuation of urban policies (such as demarcating protected areas and listing cultural relics/historical buildings), which has played a good role in single-point static protection of heritage, but has insufficient dynamic activation of the entire region. From the endogenous characteristics of Chinese villages, it is a highly autonomous clan society and is independent of the "central-provincial-municipal-county" administrative agencies. This determines that the protection and renewal of villages needs to rely on rural governance. However, as a strong government society, China's rural self-revitalization ability is not strong, and the protection and utilization of rural cultural heritage cannot be separated from policy supply.

Therefore, it is particularly important to achieve dynamic protection of rural heritage through comprehensive policy supply and rural governance tailored to local conditions. It is necessary to systematically sort out the relationship between "rural governance-policy supply- protective activation ", re-understand the connotation and characteristics of rural governance, and then think about the impact of policy supply on the protection of rural living heritage.

1. Research review

1.1 Rural lived heritage related research

The New Oxford Dictionary's definition of heritage includes "unspoilt countryside" . The Venice Charter of 1964 points out that "rural setting" is also a monument that bears witness to history. The Charter on the Built Vernacular Heritage of 1999 points out that rural heritage plays an important role in human emotions and pride. It is informal, orderly and has use value, the focus of life in an era and a record of social history. The Guidelines for the Protection of Chinese Cultural Relics and Historic Sites proposes hat historical and cultural villages and cultural landscapes are still closely connected with contemporary life, reflecting specific cultural significance and possessing "living characteristics".

Foreign scholars have long recognized that rural heritage includes all tangible and intangible systems and spaces[3], and is the product of the coupling of people, society and ecosystems[4][5]. The authenticity and effectiveness of rural heritage protection are closely related to local policies[6]. Establishing a good relationship with local residents is conducive to the protection of rural cultural heritage[7]. In summary, the protection of rural heritage deeply depends on policy support and rural governance.

Chinese scholars' understanding of the living characteristics of rural heritage involves aspects such as rural historical stratification[8], rural landscape[9], and living traditions[10]. They also start from multiple dimensions such as architecture, geography, economics, sociology, and management to study topics such as traditional dwellings[11], rural cultural heritage systems[12], rural heritage protection paths[13], and rural heritage landscapes[14]. It can be seen that the protection and inheritance of rural living heritage has received more and more attention from Chinese scholars, and has become an important supplement to the research on urban and rural heritage.

1.2 Rural governance related research

Mr. Fei Hsiao-Tung mentioned in "Rural China" that the origin of Chinese society is rural, and the rural society regulates everyone's behavior through close and long-term common life. "Governance" has been running through the entire process of rural development since ancient times. The research on rural governance is mainly divided into two aspects. On the one hand, scholars have realized that under the background of rapid urbanization, the social structure of villages has become increasingly atomized, the ability of rural governance has gradually weakened[15], the lack of villagers' subjectivity has led to governance difficulties[16], and it is difficult for a single government to meet the diversified needs of public goods[17]. On the other hand, scholars have also proposed that the action strategies and governance capabilities of village communities play a key role in rural construction and protection[18]. Rural governance is needed to achieve coordination of village affairs and build consensus[19], promote rural protection and development[20], and then play a role in promoting policy transmission, industrial development, cultural protection, and common prosperity for rural revitalization[21].

1.3 Rural policy related research

There are relatively few studies on rural policy mechanisms. Scholars point out that the flexibility of public goods supply policies, the organizational mobilization capabilities centered on village cadres, and the group governance capabilities constitute the policy organizations and social foundations for activating autonomy[22]. The establishment of policy supply mechanisms such as village creation and financial incentives plays a certain role in mobilizing village enthusiasm and social participation[23]. However, in the traditional rural policy system, villages lack the autonomy to make project decisions, supervise and evaluate, and use funds. Rural grassroots organizations lack the necessary financial resources, and their space and autonomy for action are limited[24]. Strengthening the design and research of policy mechanisms plays an important role in ensuring the implementation of plans[25].

1.4 Summary of research review

Overall, rural governance, policy supply, and rural living heritage are attracting more and more attention from scholars, but existing research focuses on a single content, and there is little research on the relationship between the three. There is insufficient research on how policy supply affects the protection of rural living heritage and what role governance plays in it.

2. Research framework

2.1 Research on the Institutional Framework for Rural Heritage Protection in China

Heritage protection in China has always been directly affected by policy system, and can be roughly divided into three stages. The first stage was the "cultural relics protection unit" period, which was mainly single-point protection. The second stage was the "historical and cultural city" period (1982 to present). The third stage was the "whole-region heritage protection" period (2003 to present). Up to now, relevant ministries and commissions have successively launched historical and cultural villages (a total of 487 from 2003 to 2014), the list of traditional Chinese villages (a total of 8,155 from 2012 to 2014), and provinces and cities have successively issued policy documents to protect rural heritage. It can be seen that China's rural heritage has gradually received attention from the central and local governments. In 2025, the CPC Central Committee and the State Council's "Notice on Strengthening the Protection of Cultural Heritage" clearly stated that "in the process of urbanization, we must effectively protect the historical and cultural environment, and make outstanding vernacular architecture and other cultural heritage an important part of the urbanization development strategy."

At present, the framework of China's rural living heritage protection and inheritance system mainly includes three aspects: legal documents, top-level policies, and listing certification. First, legal documents, including "the Cultural Relics Protection Law" and "the Regulations on the Protection of Historical and Cultural Cities, Towns and Villages", stipulate that local governments at or above the county level must provide necessary financial support for the protection of historical and cultural villages, propose development intensity and construction

control requirements based on the traditional pattern and historical style of the village, and formulate a phased implementation plan for the protection plan. The second is the listing certification, which mainly clarifies the protection requirements through the list of famous historical and cultural towns and villages in China, the list of traditional Chinese villages, the list of cultural relics protection units and the list of historical buildings issued by the Ministry of Housing and Urban-Rural Development, the Ministry of Culture and Tourism, the Ministry of Finance, etc. The third is the top-level policy. Since 1978, a total of 26 "Central Document No. 1" (1982-1986, 2004-2024) have mentioned the issue of rural development and protection. The programmatic documents issued by the State Council in recent years, such as the "Rural Comprehensive Revitalization Plan (2024-2027)", have also put forward new requirements for the protection and inheritance of traditional villages and the cultural empowerment of rural development.

It can be seen that most rural protection policies are issued by the central government and its ministries, as local governments just play a supporting role. The top-down policy mechanism has played an important role in the protection of rural living heritage, but the content is mostly directional guidance, and there is often a big gap between policies and implementation[12]. The national-level protection system can only play a bottom-line protection role for villages with listed identities, while a large number of rural cultural heritage with protection value but not included in the protection system are facing the risk of demolition. This requires, on the one hand, strengthening the vertical extension of the mechanism, paying more attention to local policy, strengthening control, and focusing on implementation. On the other hand, strengthening the horizontal expansion of the mechanism, promoting the continuation of the use function, cultural expression, social connection, and management and care of rural cultural heritage, and truly realizing the "living up" of heritage.

2.2 Connotation of rural governance in China

In recent years, with the decentralization of power and the influx of capital into villages, rural interest groups have become more diverse, and the rural self-organization governance system that has lasted for thousands of years has been impacted. The key role of rural governance in the protection of living heritage is reflected in some fields. First, it is the participation of multiple subjects. The government's public power guarantees the bottom line of heritage protection and seeks a balance between heritage protection and revitalization. The village collective strengthens the cultural identity and internal integration of the village through the guidance of local sages, forms a "community of thought", builds a "protective wall" of collective consciousness, and promotes the implementation of protection measures. Corporate investment in the social field is an important supplement to rural governance and an important support for the revitalization of rural heritage, as the villagers are the real users and conservators of rural heritage. Second, there is continuous collaboration throughout the protection process. Heritage protection and revitalization is not a single physical space repair, but a whole process of planning, construction, management, and operation. Third, the whole work is dynamic and sustainable. The complexity of rural population, industry, and economy determines that the protection and revitalization of rural heritage is a dynamic process, which must be promoted continuously and effectively. This requires exploring village development empowerment, operation transactions, and income distribution mechanisms on the basis of protection and revitalization to stimulate the "self-generating" ability of villages.

2.3 Construction of theoretical model based on institutional perspective

Mr. Hok-Lin Leung proposed in "Policy Planning and Evaluation Methods" that policies are achieved through a series of means, and the policy process includes "value selection-determination of goals-clarification of means-policy results". It is generally believed that the government formulates policies based on public value, and its implementation requires the use of governance tools that take into account both policy attributes and social attributes, and ultimately improves the policy implementation path through policy results. There is often a certain deviation between the protection of rural heritage with long-term value and the short-term economic interests of the village collective, which leads to the implementation of policies must rely on the power of rural governance. Therefore, the efficient unification of policy, governance, and protection has become the key to rural development.

Therefore, firstly, this paper proposes to construct a theoretical model of "rural governance-policy supply-protection and activation" from the perspective of theoretical understanding. Policy is a means to actively mobilize various resources, promote rural heritage protection, and achieve institutional and mechanism innovation; governance is a capability, which is an important driving force behind the effectiveness of heritage protection and

an important angle for evaluating whether policy supply is effective; rural heritage protection and activation is a carrier, an object of observation and an object of action. Ultimately, the three interact with each other to promote the sustainable protection and utilization of rural living heritage (Figure 1).

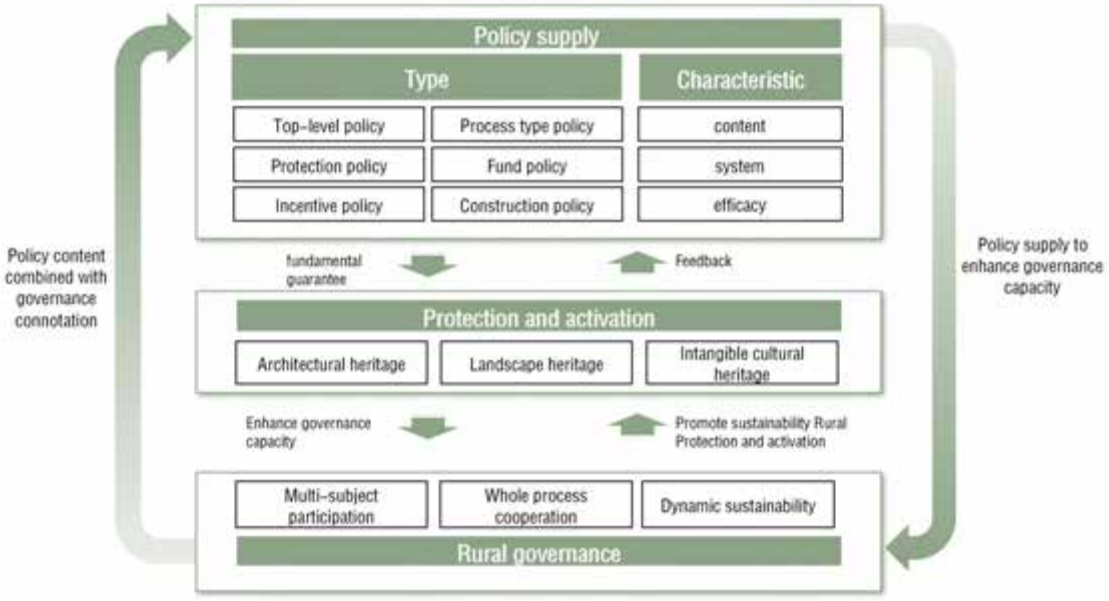

Figure 1: Dialectical relationship of "policy supply - rural governance - rural construction"
Picture source: self-drawn by the author

Secondly, we respond to the theory from the perspective of case practice. We explore the impact of policy supply on the protection and revitalization of a traditional Chinese village since 2018 , study the role of rural governance in protection and revitalization, and propose suggestions on how to accurately match policies and promote efficient governance in the protection and revitalization of rural living heritage.

3. The practice of rural living heritage inheritance in Yungmark Village, Zhongshan City

Established in the Southern Song Dynasty, Zhongshan's villages have gathered a large number of buildings that combine Chinese and Western styles, nurtured Mr. Sun Yat-sen and many celebrities, and witnessed half of China's modern history. Among 900 villages, more than 300 have typical cultural values, and have formed a rural heritage circle around Wugui Mountain in space (Figure 2). The historical and cultural value of Yungmark Village includes: Yungmark is the hometown of Zheng Guanying, the "first person to open his eyes to the world" in the late Qing Dynasty. Yungmark is the place where Deng Xiaoping proposed " never walk backwards " during his southern patrol, an important witness to reform and opening up, and the first village in mainland China to open up to the outside world. Yungmark is a window for Sino-Western exchanges, a typical hometown of overseas Chinese, and rich in historical and cultural relics. Yungmark is the geographical center of Zhongshan, Zhuhai and Macau, and a strategic place for ancient transportation and coastal defense.

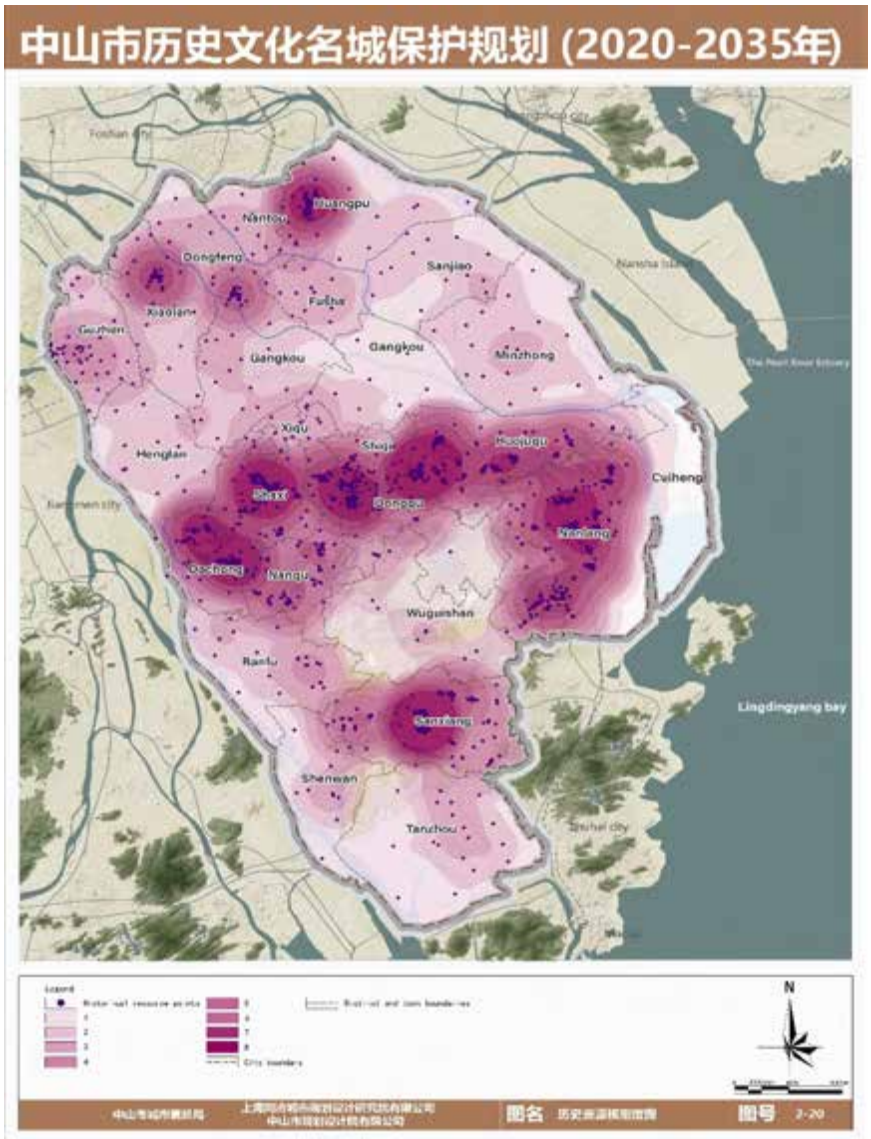

Figure 2: Distribution map of historical resources in Zhongshan City
Picture source: self-drawn by the author

3.1 Types, effectiveness and problems of policy supply

3.1.1 The type of policy supply

Since 2018, Zhongshan City has successively published dozens of policies related to rural revitalization and protection, which can be divided into seven categories (Table 1). Top-level design policies clarify the outline of rural revitalization and lay the foundation for the promulgation of subsequent detailed policies. Protection policies clarify that urban-rural renewal must carry out historical and cultural protection evaluations and strengthen financial subsidies for the protection and repair of historical buildings. Process policies simplify the process of small construction projects, promoting the rapid implementation of protection and repair projects with a total investment of less than 2 million yuan, as well as single projects with an investment of less than 1 million yuan. Funding policies focus on the management of special funds, and propose the scope of fund use, project reserves, fund allocation, use management, project acceptance, performance evaluation and other contents, which are the core policies to ensure the implementation of protection and revitalization projects. Incentive policies include city leaders taking charge, evaluation of human settlement environment improvement, etc., which mobilize the collective will of villages through a healthy competition mechanism. Construction policies ensure that rural architectural styles and forms are appropriate through guidelines, positive and negative lists, etc. Talent policies mainly strengthen the management of craftsmen who repair traditional buildings.

	"2023 Zhongshan City Rural Craftsmen Professional Title Evaluation Reform Implementation Plan" (Zhong Ren She Fa [2023] No. 49)

3.1.2 The characteristics of policy supply

In terms of content, the first is administrative guidance. The 2021 "Zhongshan City Leaders' Contact with Characteristic and High-quality Demonstration Village Creation Work Plan" clearly states that characteristic and excellent villages are contacted by city leaders. Under the influence of administrative effectiveness, the villages have formed comparative advantages in heritage protection, financial rewards and subsidies, etc. The second is healthy competition, policy supply tends to villages with good basic conditions and strong willingness to revitalize. Strong villages will first invest funds to carry out ancestral hall repairs, cultural building conservation, etc. to express their own willingness and organizational capabilities. Townships are more willing to recommend villages with strong initiative and high execution to strive for funds. The third is third-party evaluation. Starting from 2022, the Municipal Agriculture and Rural Affairs Bureau will entrust a third-party organization to randomly select villages and communities to conduct rural beauty index evaluation every year, and reward and subsidize the top 8 townships in the monthly evaluation to promote healthy competition in village construction. The fourth is to implement supervision, establish a rural environmental improvement inspection mechanism, report on villages with poor assessment results, and provide additional financial rewards for villages with outstanding achievements.

In terms of system, policy supply is continuously upgraded throughout the life cycle of rural construction, including encouraging the transition from "individual village heritage protection" to "rural heritage belt conservation". Emphasis is placed on correcting the implementation effect, and the "Zhongshan City 2019-2021 Beautiful Rural Construction Project Positive and Negative List" and "Zhongshan City's "Ten Dos and Ten Don'ts" for Rural Construction"" are promulgated to strengthen the management of design units and construction units, and clarify the contents of the positive and negative lists such as protection and repair, protection technology, and farmhouse style control.

In terms of effectiveness, high-effectiveness policies include financial subsidies, process simplification, leadership appointments, protection policies, etc. Medium-effectiveness policies include assessment, fund management, positive and negative lists, etc., which cannot play a decisive role, but have a certain promotion effect on rural construction. Low-effectiveness policies are mainly special policies and talent policies. This type of policy is difficult to directly affect the village level, takes a long time to be effective, and has a low degree of impact.

3.1.3 The problem of Policy supply

On the one hand, rural construction is mainly funded by government investment, and policy supply focuses on the improvement of public space and the protection and repair of public buildings. However, there are insufficient policies on how to mobilize villagers to carry out the renovation of their own traditional buildings, and the operation of houses after repair is insufficient. On the other hand, with the government's continued investment but low returns, Zhongshan City requires that rural construction and heritage protection should focus on self-balancing funds. This has led to the fact that although most villages are facing problems such as imperfect infrastructure, poor architectural style, and heritage in urgent need of rescue repairs, it is difficult for people's livelihood investment to directly generate economic benefits, so the funds for rural revitalization have been greatly reduced, which has also affected the confidence of social capital to be injected into the countryside, resulting in insufficient motivation for rural construction and protection.

3.2 The influence of policy supply on the lived heritage in Yungmark Village

Funding policies are the basis for the protection and revitalization of rural heritage. From 2018 to 2021, Yungmark Village received 55 million yuan in central special funds, 30 million yuan in municipal funds, 15 million yuan in town fiscal funds, 3.6 million yuan in village collective funds, and 650,000 yuan in donations from local elites and villagers, making it the most funded village in the city, and directly promoting the implementation of hundreds of small projects.

Protection policies have laid the foundation for rural heritage protection. Under the guidance of the "Zhongshan City Sanxiang Town Yungmark Village Traditional Village Protection and Development Plan", it is proposed to protect the "mountain-village-field" pattern in an integrated manner to maintain the natural and cultural heritage of the village. In the village, an overall protection framework of "cultural relics (20) + historical buildings (14) + traditional style buildings (16) + historical streets (55) + environmental elements (ancient trees, ancient wells, ancient roads, ancient springs, etc.)" is constructed.

Process policies have improved the efficiency of heritage protection and repair. Based on the simplification of rural small-scale project processes, Yungmark Village has repaired two cultural relics protection units represented by Zheng Guanying's former residence, and Dongxuan Zhenggong ancestral hall, three general immovable cultural relics, five historical buildings, and 40 traditional buildings. It has also rectified more than 40 inharmonious buildings around cultural relics and historical buildings, renovated 17 historical lanes, improved six public spaces represented by Yungmark Art Square, built a new tourist parking lot, and rectified two water systems, Zhongzhu Sewage Channel and Qianyang River (Figure 3). As they felt the benefits brought by the improvement of the implantation of business functions, some villagers began to change their mindsets and agreed to renovate their houses, which in turn pushed governments to increase investment in rural construction. Eventually, the village collective invested in Zhongshan Yonghui Cultural Tourism Investment Co., Ltd. and Zhongshan Yonghe Cultural Tourism Development Co., Ltd., promoting the entry of social capital and forming a virtuous circle.

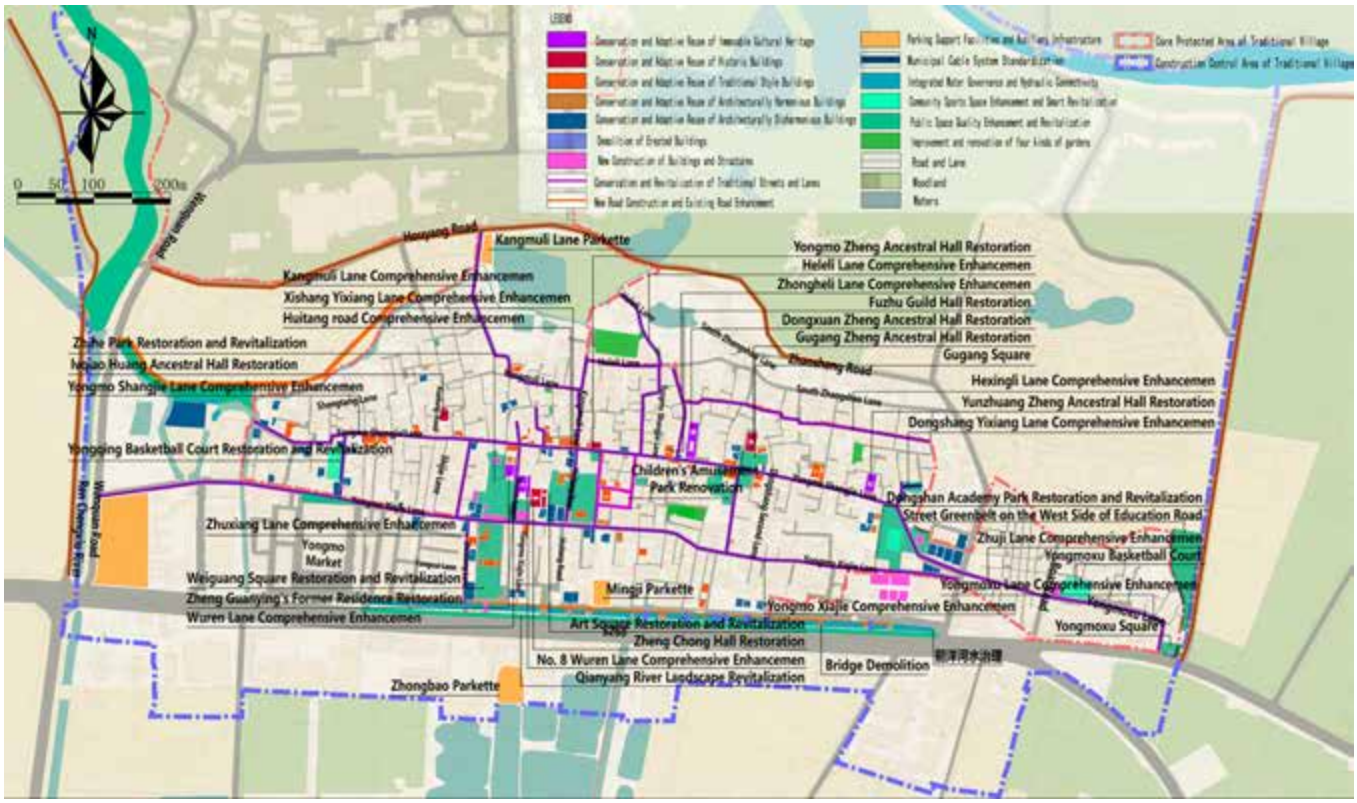

Figure 3: Distribution map of construction Project in Yongmo Village
Picture source: self-drawn by the author

Incentive policies played a guarantee role. Through the appointment of the then municipal party secretary and the appointment of the leaders of the municipal/town agriculture and rural bureau as the village's first secretary, Yungmark Village opened up a communication channel directly from the village to the municipal level, effectively ensuring the implementation of funds and the advancement of project review.

3.3 The effect of protection and inheritance of lived heritage in Yungmark Village under rural governance

3.3.1 Multi-subject participation: to achieve multiple governance of "co-consultation, co-operation, co-management"

"Co-consultation" is to build a village-level discussion platform for the government, village committee, enterprises, designers, villagers and other parties. Through a multi-party co-discussion meeting, the protection and renovated project will not be started until the villagers all agree. "Co-operation" is to encourage social groups to participate in the promotion and operation of Yungmark. Since 2018, Yungmark Village has held more than 200 art performances, Cantonese opera cultural evenings, etc., vigorously promoting the cultural card of village. "Co-management" is to implement rural house style control for buildings that have not been included in the protection system, and put forward the five styles of rural house style guidelines to provide design guidance for

villagers to renovate their houses by themselves (Figure 4). The mechanism has greatly promoted the continuation of the "use function-cultural expression-community connection" of living heritage.

Figure 4: The five styles of rural house design style guidelines
Picture source: self-drawn by the author

Continuation of the use function: the renovation of the Yungmark ancestral hall is a typical case. Before the renovation, the ancestral hall had been vacant and abandoned, and part of it was demolished and occupied by villagers. Whether from the perspective of heritage or life, the function and space conversion should be given priority. To this end, the renovation took the following measures: 1) The village collective negotiated with the villagers who occupied the ancestral hall to demolish the houses and formulated a proper resettlement plan. 2) Encourage villagers to donate money to achieve "self-repair of the ancestral hall ", which guaranteed the funding needs. 3) According to historical photos, the ancestral hall was repaired to reproduce the damaged and covered historical information to continue the original function, continue the functional positioning of the ancestral hall as a public space in the village, and transform it into a cultural space that is currently lacking in rural areas (Figure 5).

Figure 5: Before-and-after comparison pictures of the Yungmark ancestral hall 's renovation
Picture source: Photographed by the author

Continuation of cultural expression: The changes in heritage include tangible and intangible parts. The former is the material space, and the latter is festivals, customs, and beliefs. The two are interdependent as a unified whole. The renovation of the surrounding area of Zheng Guanying's former residence well presents the process of cultural transformation and derivation: with the concept of "amber", the historical deposits of each stage are protected, including the restoration of the private school (Xiaoxi Zhenggong ancestral hall) based on the old photos provided by the villagers in 1980, and the preservation of some of the interior walls and corridors of the Yungmark Primary School classroom. The memory of the old and middle generations is continued (Figure 6).

Figure 6: Before-and-after comparison pictures of the renovation
of the surrounding area of Zheng Guanying's former residence
Picture source: Photographed by the author

Community connection and continuation: The Nara Authenticity Document states that the responsibility and management of heritage should belong to the heritage community. The residents of the heritage site and their communities are both creators and users of heritage. The restoration of the Fengshui Pond in front of the Overseas Chinese Building embodies this spirit. The vacant land on the south side of the Overseas Chinese Building was originally planned to be transformed into a village square, but during the construction process, the surrounding villagers proposed to change the design based on their childhood photos and memories of the "pond" and "pondside granite". In the end, the design party, the construction party, and the village collective adjusted the plan on site to restore the old pond environment and realize the connection between the site and the villagers' memories (Figure 7).

Figure 7: Before-and-after comparison pictures of the restoration of the Fengshui Pond
Picture source: Photographed by the author

3.3.2 Whole process coordination: "planning-design-construction-operation" overall coordination
The rural revitalization chain is improved through four steps. At the planning level, the short-term and long-term implementation plans for the protection and revitalization of village heritage are clarified from the perspective of the entire region and all time periods, the bottom line of protection is formulated, and the recent project library is delineated. At the design level, the villagers are encouraged to design together, and designs are carried out for the urgent problems of the villagers. At the construction level, the design party and the construction party visit local old craftsmen and use traditional craftsmanship to repair the ancient village. At the operation level, it is to mobilize the villagers to combine self-operation with the introduction of social capital. At present, the repaired traditional style buildings have introduced rural operation formats such as "Winter Melon Pastry", "Macau Bakery", and "Yungmark Pub ".

3.3.3 Dynamic sustainability: Improving the value realization mechanism of rural heritage resources
The residential houses, ancestral halls, streets, squares, and farmlands formed by the spontaneous growth of villages are important components of rural heritage resources. The positive cycle of "rural heritage → rural assets → rural capital → rural funds → reintegration of rural heritage" promotes the dynamic sustainability and spiral rise of rural heritage protection. However, as a highly autonomous self-growing settlement, the property rights of houses in the village are mostly dispersed among the villagers, which makes it particularly difficult to transform rural heritage into rural assets. The degree of realization is highly related to the collective willingness and governance capacity of the village collective. In the practice of Yungmark Village, the village collective first counted the "rural resource list", including village collective properties, long-term rented private houses, overseas Chinese houses that can be managed, and farmlands that can be operated. Secondly, the village head led the team to carry out house collection and storage. This process involves multiple aspects such as ownership determination, transfer of use rights, resale of operating rights, and agreement on income rights. In the end, nearly 40 dilapidated houses and ownerless houses were collected and stored. The rural heritage resources collected within a certain period of time were packaged again, and rural assets were formed through joint ventures/self-operation. The capital income generated after the capital entered the market was reinvested in the next round of resource integration. This cycle process ensures the asset appreciation of rural heritage and obtains the support of villagers.

4. Relevant suggestions on improving the protection and inheritance mechanism of China's rural living heritage
4.1 Improve the regional resource survey mechanism
At present, rural heritage listed in the framework of historical and cultural villages, traditional villages, cultural relics protection units, and historical buildings is strictly protected by law, but there are still a large number of rural heritages with typical value not included in the list. Take Zhongshan City as an example. Among the 300 villages with protection value, there is only one national historical and cultural village and seven national traditional villages. This has led to the possibility that other villages may be demolished during the urbanization process due to the lack of a protection system.

First, the survey mechanism needs to be improved. Through the joint efforts of multiple departments, use remote sensing, drones and other technologies to form a digital record chassis to take stock of the village's architectural style, property ownership, and intangible cultural heritage. Secondly, the property rights mechanism also needs to be improved. Villages with better property rights collection are similar to "rural clean land", which makes it easier to carry out asset confirmation, transfer of operating rights and income distribution, and reach a consensus. It is necessary to strengthen the relevant policies on property rights collection and land preparation, and provide policy guarantees for the participation of multiple subjects. Finally, the survey conclusions will be used as an important reference for the revision of the protection plan, and according to the principle of "protecting everything that should be protected", the work from resource surveys to resource protection will be effectively promoted.

4.2 strengthen the design of top-level protection and activation policies

On the one hand, firstly strengthen the bottom line protection. Under the institutional framework of "historical and cultural city-historical and cultural town-historical and cultural village", add the "Historical village" level, including villages that do not meet the conditions for inclusion in the historical and cultural village but have relatively rich heritage into the "traditional village". The protection and development of " Historical village" should formulate special contents for historical and cultural protection, delineate historical and cultural protection lines, and clarify positive and negative lists. In recent years, Zhongshan City has promulgated 79 traditional villages, promoting the protection of rural areas throughout the city at the overall level. Secondly, Improve the listing mechanism, promote the implementation of the "rural traditional architecture" system, and "rural traditional architecture" will be listed by the village collective to protect the village from the bottom up. Taking Yungmark Village as an example, a total of 52 traditional buildings in Yungmark Village have been listed, and has promoted the formation of village cultural cognition community.

On the other hand, strengthening heritage revitalization requires vigorously promoting the supply of rural operation policies, stimulating multiple participating entities to jointly operate rural heritage through a diversified policy package, and improving the construction of rural asset operation mechanisms. From the experience of Yungmark Village, although state-owned enterprises have carried out rural heritage operations, the operating quota accounts for a relatively low proportion of the overall asset, and rural operations are difficult to become a key area of concern for state-owned enterprises. Instead, they are more about completing administrative tasks in accordance with municipal requirements, which leads to insufficient innovation in rural operations, insufficient flexibility, and difficulty in making dynamic adjustments to the operation content according to actual conditions. Although villagers actively participate, their operational capabilities are not strong, their sensitivity to the market is not high, and there is a lack of preferential policy support to encourage private capital investment. In addition, the policy mechanism for investment promotion and operation is not sound. Public welfare projects such as the Zheng Guanying Life and History Museum invested by the government are operating well, but there is no clear business access list and attraction mechanism for the architectural heritage that is rented out to the public, making overall operation difficult.

4.3 Enhance the Role of Village Collectives through Governance-Oriented Mechanisms

First, reconstruct the dominant position of village collectives. Strengthen the organizational capacity of village collectives in heritage protection, such as establishing a compilation team led by the collective, organizing villagers to participate in the compilation of oral history and the collection of old objects, and activating the enthusiasm of villagers to participate in governance. Clarify the legal responsibilities and rights of village collectives in heritage protection, such as giving village collectives the right to supervise the repair of traditional buildings, and requiring them to cooperate with the government to complete the heritage census and registration, forming a power and responsibility system of "government guidance and village collective implementation".

Second, formulate protective village rules and regulations, incorporate heritage protection into the framework of villagers' self-governance. Taking Yungmark Village as an example, the government timely incorporated the village appearance management requirements into the village rules and regulations, and regulated the control of building height and volume, maintenance of public facilities and green environment, protection of natural resources and cultural heritage, control of building style and parking management, etc., to improve the self-supervision and self-management level of villagers' self-built houses.

Third, realize the multi-governance of city-town-village planners-public. incorporate village collectives into the assessment system for protection effectiveness, evaluate their organizational capabilities, villagers' participation and other indicators through third-party institutions, and link the results with policy support.

4.4 Improve the dynamic protection-update feedback mechanism

The inheritance and development of rural living heritage is a continuous evolutionary process, which requires policies to respond to actual rural problems and stage goals in a timely manner and establish a dynamic response mechanism. A policy evaluation action group should be established to track the entire process of policy implementation, build a rural construction implementation indicator system, and conduct policy implementation evaluations at half-yearly time nodes. Provide timely feedback on areas where policy implementation effects are not as expected or even have negative effects, and formulate the direction of policy adjustments. For policies with good feedback, trace the specific paths of policies to promote rural construction, explore whether they have universal value and the possibility of being promoted to more villages. Key issues should be discussed through villager discussions, expert consultations, and other methods to explore solutions and fill policy gaps in key and difficult areas.

It is also necessary to realize that the inheritance and development of rural living heritage is not a campaign-style behavior that can be achieved overnight, and policy supply must be consistent and sustainable. The effectiveness of policy supply cannot be measured solely by investment returns. Rural protection and development is a long-term incubation process that needs to respect its objective laws. Rural policy supply should also play a long-term leading, corrective and supervisory role.

4.5 Establish a supervision and inspection mechanism

Firstly, emphasize the self-supervision of the village collective and villagers. The village collective assumes the daily supervision responsibility, organizes villagers to participate in heritage protection inspections, coordinates conflicts of interest among multiple parties, and improves the self-supervision and self-management level of villagers' self-built houses.

Secondly, improve the incentive and accountability mechanism. Responsibility binding: link the supervision results with the performance evaluation of village cadres, and clarify the statutory responsibilities of the village collective in heritage protection. Villager participation incentives: encourage villagers to actively participate in supervision through the points system, honorary awards, etc., and enhance their subject awareness. The third is to improve the supervision methods and technical means. Digital monitoring: Use remote sensing, drones and other technologies to establish a digital monitoring platform to record the status of heritage protection in real time.

5. Conclusion

Based on the inheritance of rural living heritage, this paper constructs a theoretical model of "rural governance-policy supply- protective activation ", and conducts an empirical study using Yungmark Village in Zhongshan City as an example. The study found that the protection and revitalization of rural heritage is driven by both the external influence of policy supply and the internal role of rural governance. The integration of rural heritage protection and revitalization into the rural governance helps the effective implementation of policies. First, as a top-down intervention, policy supply is prone to "failure" when facing villages with endogenous logic and governance order. It is necessary to fully respect the contractual spirit and clan ties of Chinese villages, consider the important role of collective economic organization relations in rural governance, give play to the core role of village collectives in rural building property rights identification, village rules and regulations, and building repair coordination, and formulate policies from the perspective of activating the endogenous organizational strength of villages. Secondly, protective activation is a dynamic maintenance process, which requires multiple dimensions such as improving the heritage survey mechanism, improving the protection mechanism, and establishing a supervision and inspection mechanism to achieve heritage protection throughout the life cycle.

Compared with cultural relics and historical sites, China's research and practice on the protection of rural living heritage is still in its infancy. The key lies in how to coordinate the collaborative relationship between the government, village collectives, and villagers in heritage protection. Limited by the research object, this article focuses on the practical content of the protection of the material space of Yungmark Village. Further follow-up

observation is needed on how to further enhance the social autonomy of villagers and form sustainable heritage management. At the same time, given the significant differences in heritage characteristics and protection conditions in various parts of China, existing protection experience and methods may not be applicable to other regions. Therefore, how to establish an effective demonstration promotion mechanism and form a heritage protection system suitable for China's national conditions needs further discussion. observation is needed on how to further enhance the social autonomy of villagers and form sustainable heritage management. At the same time, given the significant differences in heritage characteristics and protection conditions in various parts of China, existing protection experience and methods may not be applicable to other regions. Therefore, how to establish an effective demonstration promotion mechanism and form a heritage protection system suitable for China's national conditions needs further discussion.

GLOSSARY OF TERMS

The following is a list of terminologies and their meanings used for this research, which stem from my mother tongue, Urdu.

Abbu- father
Bazaar - marketplace
Biryani - local Pakistani food
Behn-chara – sisterhood
Chacha - uncle
Chitai – floor mat
Chut – rooftop
Dhaba – informally built tea stall/shop
Gaon - village
Ham saygi- neighbourly relations
Islamabadi – belonging to the city of Islamabad
Jirga – elderly tribal group
Katchi gali – unbuilt footpaths
Mohalla – neighbourhood, community
Mohalla Dari – neighbourly relations, communal ties
Nalkiyan – thread reels
Pashtun/Pathan – people from the province of Khyber Pakhtoon Khawa in Pakistan
Purdah – privacy maintained by Muslim women
Punjabi – people from the province of Punjab in Pakistan
Quran Khwani- a Muslim traditional ceremony marking the completion of the recitation of the Holy Quran.
Saalan – curry
Sehn – courtyard
Urdu Speaking – people from the province of Sindh in Pakistan.
Ziddi – to be stubborn

Abstract
This research conceptualizes the "Modern Mohalla" in a post-independence Pakistan to explore the interrelatedness of feminist 'Mohalla-Making practices' and formal urban planning in Islamabad's G-9/2 Government Housing Quarters. The study investigates the lived experiences of subaltern women through a critical ethnographic methodology, including interviews and visual translations of spatial practices. The research addresses the systemic exclusion of women from the design process of Islamabad and the Government Housing quarters, feminist spatial discourse, and archival data about feminist lived experiences. By engaging with Doxiadis' theory of Ekistics, the study further interrogates its potential alignment with feminist Mohalla-making practices. Ultimately, the research aims to develop a historiographical feminist dialogue that highlights unacknowledged female communal networks within a socially stratified and patriarchal urban context.

Keywords: Informality, Modern Mohalla, Mohalla-making practices, feminist spatial practices.

Introduction

At the turn of the mid-20th century in Pakistan, in between the post-war era of 1965 and the two-decade-long rush of the Great Partition, which occurred in 1947, Islamabad came into being as a modern bespoke metropolitan city designed by a foreign architect, Doxiadis. Planned, seemingly clean, and equipped with an organized infrastructure and abundant recurring green spaces amidst a strictly orthogonal street grid, Islamabad post-independence was designed on the concept that symbolized unfettered growth. As Hull (2012) explains, while designing the communal structure of Islamabad, Doxiadis believed in the homogenizing of neighbourhoods

based on their income brackets, thereby employing a bureaucratic approach of socially stratifying the city. This research examines how this approach has impacted the socio-cultural construct of neighbourhoods in Islamabad today by exploring the community's spatial practices within a socially stratified Class-IV low-income[1] 'Modern Mohalla' in the Government Housing Quarters of G-9/2, Islamabad. It seeks to investigate this theme by identifying and studying female lived experiences and their informal 'Ziddi' socio-spatial appropriations in this neighbourhood.

As this research is grounded in the absence of female representation in a communal structure, it examines the lack of designed feminist spaces within a Mohalla of Islamabad that have inevitably given an impetus to 'radical' Mohalla-making practices as recorded via the oral testimonies of the female participants as a part of the research methodology. Introvert spaces that are reflective of the Islamic cultural construct of feminist spaces in a Mohalla, since the time of the Mughals within the subcontinent, in the form of interior courtyards, rooftops, and balconies, are studied as unrealized spaces of the Modern Mohalla. Therefore, addressing this absence of feminist spaces and their reclamation by establishing a deeper ethnographic dialogue with the 'other', as Madison (2020) suggests, the concealed spaces of feminist appropriation that are being explored in this research are imperative to comprehend the complex socio-spatial structure of the Mohalla. The research further grounds itself in De Certeau's (1984) theory of 'strategies', which is associated with Doxiadis' role as the omniscient master planner of Islamabad's communities versus the innate 'tactics' developed as a response by the female residents of the Modern Mohalla. This research seeks to explore this hypothesis while reflecting on the oral testimonies of the female participants as a part of the research methodology.

When one explores Islamabad's existing literature and archival history to address this research inquiry, one notices a glaring gap in the documentation of its people's rich and complex lived histories, particularly women, and their relation with the built environment through their communal practices. Historians and academics like Doxiadis, Daeschel (2015), and Hull (2012) have focused on Islamabad's urban design and policymaking, often highlighting statistical aspects of the city's master planning process. Other scholars, such as Moffat (2024), examine housing communities like Anguri Bagh in Lahore but overlook the female lived experience. Similarly, female author Moatasim (2023) discusses informal slum settlements in Islamabad but fails to capture the role of women in shaping these informal urban spaces, particularly concerning their communal norms. This research fills in this gap by aiming to highlight and call out the paradoxical situation where female representation and their lived experiences in these important informal urban spaces are completely hidden in formalized modernist settlements. By revealing the informal feminist spatial practices of the women in the 'Modern Mohalla' of G-9/2 as an acknowledgment of the female presence in Islamabad's communal structure, which is otherwise buried beneath the profession of their spouses, this research aims to highlight and record the unrecorded qualitative aspect of the female contribution to the community's socio-spatial relationships as a part of the Mohalla culture.

Furthermore, this research examines how Doxiadis' urban planning for Islamabad, specifically in the Modern Mohalla of G-9/2, manifests in the neighbourhood. While the city is considered well-planned, the study reveals that true community diversity is only evident through the women's oral histories. It questions the impact of Doxiadis' design on fostering mixed communities and explores how women's roles in the Mohalla contribute to feminist practices in a patriarchal context. This study, due to time constraints, will not be studying Islamabad as a whole but will focus on one 'Modern Mohalla'/neighbourhood in G-9/2 to investigate how Doxiadis' designs are manifested at that level. It also explores the Modern Mohalla's untold realities by examining its historical formation in the South Asian context by linking Doxiadis' Ekistics theory to the communal structure in G-9/2. It highlights gaps in feminist representation in the original planning and how women's lack of participation has influenced informal Mohalla-making practices. Analysing these practices through Hook's (2021) 'Homeplace' theory, this study looks at how women celebrate 'Behen-chara' (sisterhood) while reinforcing their roles in a patriarchal society. The research also views these feminist practices as a post-colonial space for marginalized women, aiming to bring attention to their previously overlooked lives within the Modern Mohalla's socio-urban fabric.

As its research methodology, this research engages with an ethnically diverse set of women living in the Government Housing Quarters of G-9/2 via interviews to develop a critical ethnography of their lived histories

1 Doxiadis classifies this neighbourhood as Community Class IV. A systemic classification of communities was established for Islamabad where 20,000 to 40,000 people of the same income bracket in the government sector dwell together.

as drawings supported by calligraphic commemorations of their oral testimonies. By applying Tayob's (2018) methodology of drawing as a research tool to study and portray subaltern feminist Mohalla-making practices, this methodological approach seeks to respect their privacy and maintain their anonymity, which is an integral part of their Islamic culture. The oral testimony of the female participants is collected, which informs this research inquiry of how the historical socio-spatial values are at risk of being lost and can be recovered by deciphering their Mohalla-making practices. Drawing as a tool for ethnographic research is used to shed light on the absence of female subaltern representation within the archival and critical historiographical forefront of Islamabad. This methodological approach illustrates the role of women, namely **Umaima and Laiba[2],** in this Modern Mohalla as historical actors, communal leaders, and autonomous social visionaries. Drawing as a research tool in this research paper foregrounds the participants' privacy under Glissant's theory of opacity, whereby the documentation of feminist lived experiences does not need to be seen via the Western lens of explicit transparency.

The History Of Mohallas And Their Rite Of Passage Into Islamabad

This section discusses the intersectionality between Mohallas and modernist planning principles in post-independence Islamabad. It underlines the historiographical context of the Mohalla in the context of South Asia and proceeds to examine how Mohallas exist today in Islamabad as an innate means of informal spatial appropriations within a modernist built environment. To trace the Mohalla's rite of passage into the planned city of Islamabad as a socio-spatial concept, understanding its relationship with Rawalpindi is integral, as they are like 'two peas in an urban pod'. This chapter explores the intersectionality between Islamabad and Rawalpindi and how the latter acts as a permeable membrane for the conceptual diffusion of a Mohalla as a spatial practice in Islamabad's modernist neighbourhood structure.

The concept of the Mohalla, a community space rooted in Pakistani culture, has persisted since before the 1947 Partition and remains a significant socio-spatial practice. It originated from Muslim immigrants who carried these traditions to Pakistan, reflecting a shared history with pre-partition India. Historically, Mohallas evolved through different regimes, including the Mughal and Colonial eras, shaping subaltern communities' social, cultural, and economic dynamics. Originally autonomous, family-centred, and grounded in Islamic practices, Mohallas now appear as 'cloaked' neighbourhoods in modern cities. They balance private family life and the public sphere, with a focus on social celebrations and communal activities, especially observed during the Delhi Sultanate. The legacy of Mohallas is seen as a form of traditional social cohesion across generations. In Islamabad, the influence of modern planning as implemented by Doxiadis reshaped the Mohalla structure via informal Mohalla-like spaces, persisting particularly among migrants from Rawalpindi. This research explores whether these spaces are a result of deliberate urban planning or a continuation of historical socio-spatial practices. Existing literature about post-independence Islamabad conceptually situates the rite of passage of Mohallas into Islamabad by analysing its complex relationship with Rawalpindi (Figure 1), a much older and colonized city by the British. When designing Islamabad, Doxiadis' initial study about the science of the human settlement in Islamabad can be argued to have been from a broader perspective, where Hull (2012) explains he was required to treat Islamabad and Rawalpindi as a dual force that progressed simultaneously. However, the reality was far from different as Islamabad was designed and actualized in complete isolation from Rawalpindi for not only making administration and surveillance convenient but, also formulating a city that had a tailored, modernist, and socio-economic hierarchal approach regarding its master planning and was thus not similar in its outlook to the dense and complex layout of Rawalpindi. Daeschel (2013) expands on this further by explaining that Islamabad was conceived as a prototype of a subjective 'vernacular modernism' through a Westernized lens, whereby the previously discussed Islamic identity of its residents was sidelined. Thus, this resulted in spaces that locals were not acquainted with, and so they appropriated them as per their needs. For Doxiadis, this was an innate quality that could be preserved by the community members autonomously on a micro-level, which is the argument this research paper seeks to make through the feminist Mohalla-making practices and spatial appropriations in the Government Housing community of G-9/2.

2 All names of participants for this research have been anonymized.

Figure 1. View of the Mohalla settlement around the main Murree Road in Rawalpindi. Source: Pindi Heritage Tours

As shown in the archival images below (Figures 2 and 3) Daechsel (2013), concerning the Master plan of Islamabad, writes about how it was intended to project a dynamic growth amidst three distinct areas demarcated in the city i.e. 'the new capital' which was roughly triangular and sat at the base of the iconic Margalla Hills, the Capital Park area which runs north-east to the main Islamabad-Rawalpindi Highway also demarcating the southern end of Islamabad and thirdly planning its expansion alongside Rawalpindi. However, Daechsel (2013) argues that this expansion was not thought of in terms of how it could be a complementary relationship between both cities, therefore revealing a displacement of the socio-spatial practices that reflect the city's modernized communal structure intermixed with their informal practices. Islamabad's physical and historical connection with Rawalpindi is relevant to mention as it conceptually grounds Mohallas and their spatial translation into the socio-cultural fabric of the neighbourhoods designed in Islamabad through the practices of its residents. Accordingly, it is important to question how the Mohalla culture was appropriated into the modernist city through the residents' practices. Even if one assumes that Doxiadis recognized the intricate relationship between Islamabad and Rawalpindi's shared socio-cultural heritage, the absence of implementing it within the actualized master plan of Islamabad is observed through the informal feminist spatial practices revealed further.

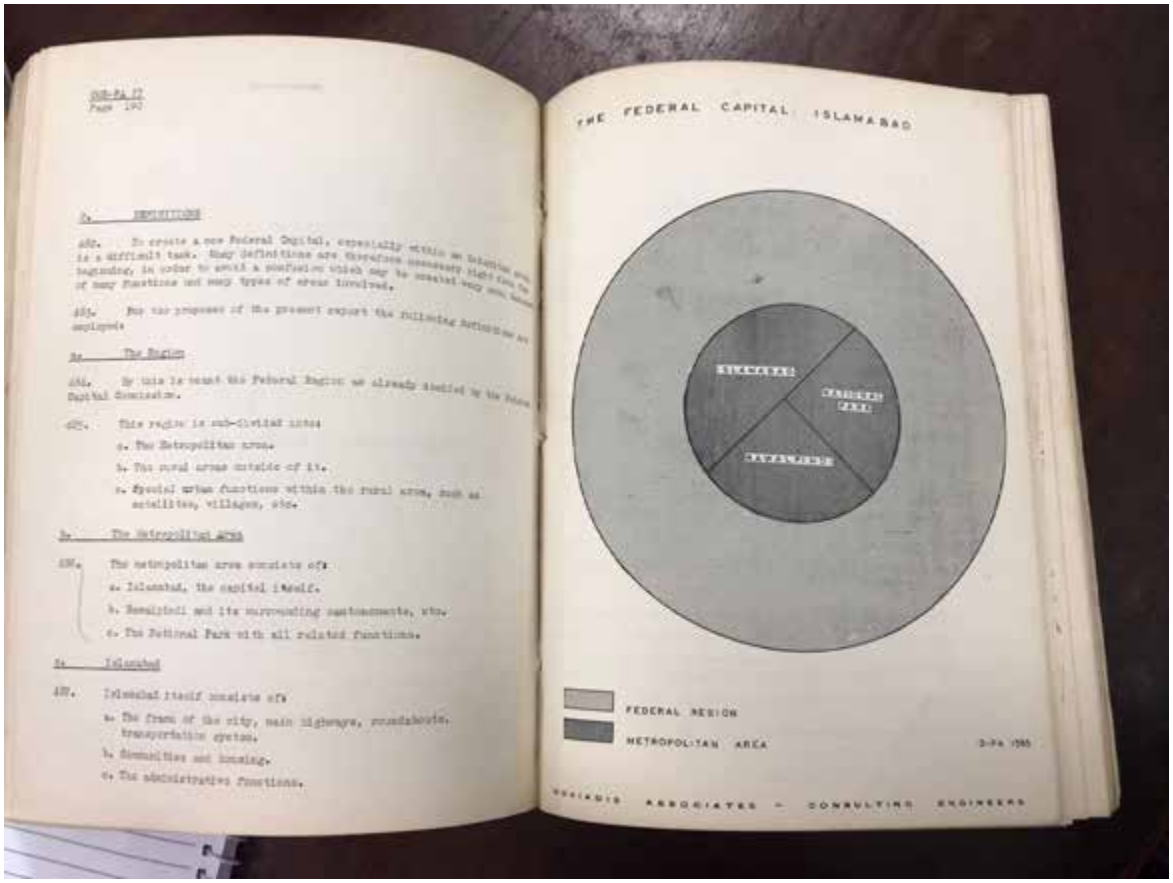

Figure 3: This image is from my visit to the Capital Development Authority Library's informal archives, which exist in the basement of the Water and Tax Revenue building in Islamabad. As the diagram in this image shows (RHS), Islamabad was meant to be conceived as a whole with Islamabad and Rawalpindi in geographical proximity, but was never actualized. Source: Doxiadis Associates Reports Developed for Islamabad Master Planning Project: DOX-PA 77, pp.190-191.

Despite this strategic separation, the idea of a Mohalla has been carried forward to Islamabad by the residents of Rawalpindi and other rural regions of the country who have migrated to Islamabad. As they keep commuting to Rawalpindi to purchase goods and visit families settled there, the socio-spatial practices are migrating between the two cities through the movement of the people. Doxiadis organized each residential sector with a sense of hierarchy in Islamabad, as illustrated in Figure 4 below, showcasing a strict modernist iron grid in which the communities were allocated based on their income and profession, of about 20,000 to 40,000 people. This modular and utilitarian design was focused on achieving quick and better visual results, not resembling the informality of a Mohalla, especially those of Rawalpindi, that the state leaders felt necessary to exhibit for the Western Powers who had invested in this project, namely the USAID and the Ford Foundation (Daeschel, 2013). In contrast, the so-called 'Ballet of the Street', which Jacobs describes as the surfacing of ethnically vibrant communities in homogenous neighbourhoods, is now observed within the spatial zoning of Islamabad, thereby anchoring the stark visual differences within the formal and informal urban spaces that are a by-product of complex unplanned communal structures of its people.

Figure 5: Elevation of the Government Building Blocks from the courtyard. Source: Author

The Government Housing Quarters were one of the first building typologies within Islamabad that were proposed by the Capital Development Authority to be built separately from the surrounding residential zones of their respective sectors[3]. The government housing quarters in G-9/2 were constructed in the early 80s, a little after Islamabad was established. With sixteen of these apartment blocks in the vicinity, they house a hundred living quarters each, where six to ten family members reside in one living quarter on average. The Government Housing Quarters in G-9/2 portray a socially stratified community of low-income families of government servants who reside here based on their income bracket (Community Class IV[4]) as predetermined by Doxiadis via his spatial zoning for the city. This planned stratification, as explained by Yanagisawa and Funo (2018), is reflective of the historical practice of formulating the social structure of the Mohalla based on the caste of its residents, an administrative practice originating from the Delhi Sultanate. Similarly, this is also observed as a modernist urban principle of social planning pertinent within the Mohalla of G-9/2, whereby the creation of a community, as Moatasim (2023) explains, is accomplished via the spatial bundling of low-grade government servants in a mid-rise vertical building exclusively. The socio-economic indicator of the residents in a vertical settlement here is being given precedence as a factor in establishing a neighbourhood demographic rather than dealing with intermixed communities based on their religion or ethnicity. As Daeschel (2013) explains, the insulation of the government servants from the wider society, despite being an issue that had been present since the colonial regime and even in Rawalpindi, posed itself as a newfound socio-spatial issue for Doxiadis. To avoid this issue, lower-income families were mainly housed in the rectilinear G sectors of Islamabad due to their proximity to their workplaces (industrial and government workers). It can be suggested that this was done to preserve the social stratification and keep at bay the potential ties of kinship between neighbourhoods that could otherwise consequentially threaten the social and bureaucratic hierarchies (Hull, 2012) that Doxiadis was asked to maintain categorically while designing Islamabad independently from Rawalpindi, as discussed earlier. The Government

3 The whole metropolitan area is subdivided into sectors, called Communities Class V, each for about 20,000-40,000 people and each according to the income group it will serve. The sub-division of the metropolitan area into sectors resulted from the adoption of a pattern of principal roads placed 2,200 yards apart in both- directions.

4 Each sector in Islamabad is named after an alphabet with subsequent subsectors denoted by numerals. So for Sector G, subsequent sectors are G-9/2 onwards.

Housing Quarters in G-9/2 on the surface level appear as the act of 'ghettoising of civil servants' in a designed colony of Islamabad. On the contrary, this act of 'ghettoisation' has further sparked an informal Mohalla-esque character that seems to remain imbibed inherently within the practices of the women of these government quarters in G-9/2 and is thus further explored through the documentation of female lived experiences.

Radical Rooftops

This section, through the lived experiences of the female participants, explores how their Mohalla-making reveals informal socio-spatial relations in a modernist housing community that has not been documented before. Their oral testimonies depict the rich and paradoxically heterogeneous nature of the communal fabric within the formal modernist built environment they reside in. As a post-colonial city planned on modernist design principles that did not aim to spatially replicate the essence of a Mohalla within its master plan or modernist housing complexes realized later, the memories and oral histories of the female participants in this research being collected seek to substantiate the argument that a Mohalla is indeed an intrinsic socio-spatial propeller of cultural relations in the modern-day neighbourhood of Islamabad.

Figure 6: A Kameez, which Umaima has tailored and brought to the interview. Source: Author

' I stitch for the women here... I also have clients from Rawalpindi, my previous home... Sania's *Libas*...I made it for her.'

Umaima is the Mohalla seamstress. She has the gift of creating a tangible product, i.e., Libas (Figure 6), that marks the intangible heritage of the shalwar kameez, the national Pakistani dress. As a housewife with a family of five living in a two-bedroom apartment, she migrated from Rawalpindi to these government living quarters with her husband.

'...Rawalpindi was nice... but too busy... people were too nosy. I like it here...'

For Umaima, migrating from Rawalpindi to Islamabad has been a breath of fresh air. She feels content with the order that the Mohalla brings to her lifestyle. The complexity of the Mohalla in Rawalpindi, where she resided previously, was far too overwhelming for her.

'...it is easy, commuting by foot instead of hiring a taxi for menial everyday tasks such as purchasing groceries

or buying my *'nalkiyan'* (stitching supplies) from the *'Bazaar'*.. it is across the block, so it is convenient for me...'.

She recalls the richness of the Mohallas of Rawalpindi. Still, she feels more secure in a modernist environment with infrastructure. She has created an introverted yet unconventional feminist node on her building's rooftop, which she can visit anytime without being questioned.

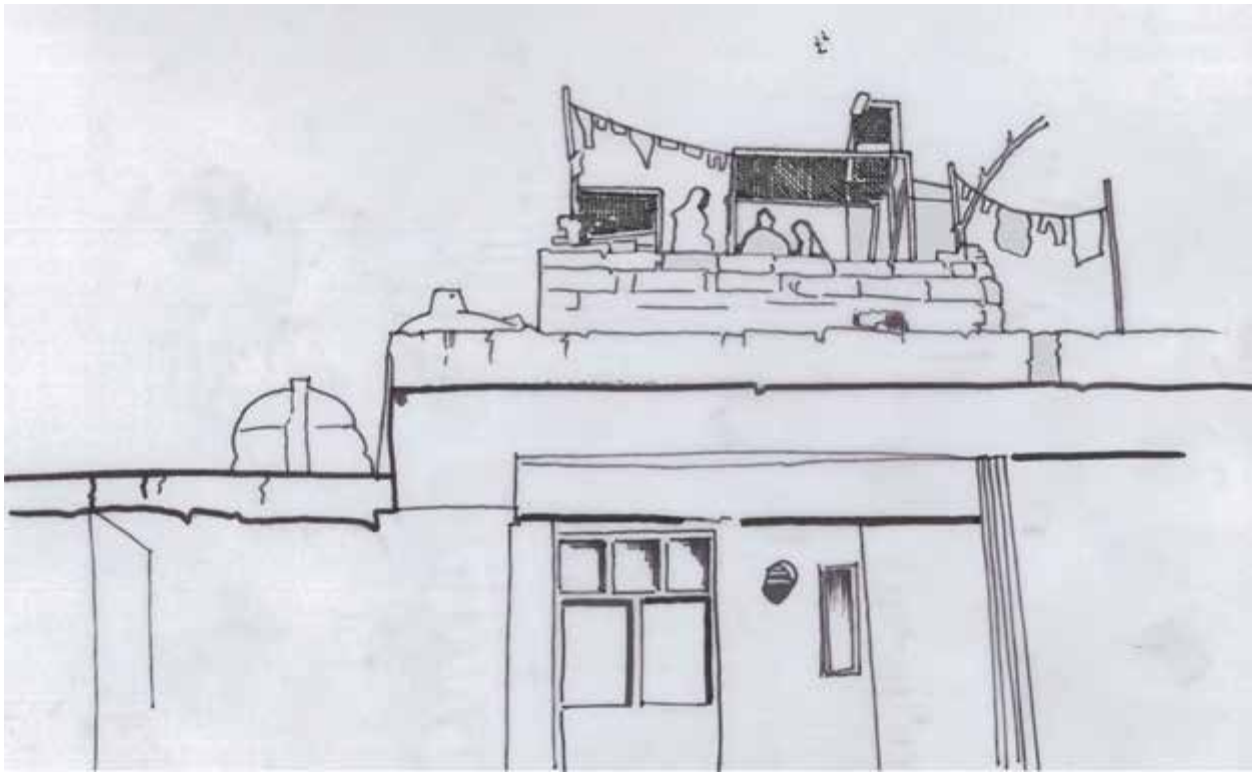

Figure 7: A platform for a 'stickier' social practice in the Mohalla. Source: Author

'...we cannot go freely in public spaces... rooftop was left... so I use the stepladder... my husband doesn't even have a problem...my friends and I get together and go...'

The symbolic approach towards the 'Chut' (rooftop) as communal spaces in Mohallas has been present in the subcontinental region during the Mughal and Colonial periods and also post-partition (1947 onward) in Rawalpindi where rooftops (Yanagisawa and Funo, 2018) were understood to be spaces of congregation that supported commotion, community, and privacy for women.

'...The rooftop for this building block serves the sixteen families who live here, but also draws in women from neighbouring building blocks...'

However, regarding the Government Housing Quarters of G-9/2, rooftops were not designed as inhabitable social spaces, let alone as spaces for women. Due to its concealed accessibility, which is only viable from inside the building via a flimsy stepladder, it gives the women of the Mohalla the freedom to socialize without the 'male gaze', much to the consent of their husbands. Again, one observes the female struggle to secure a space to freely socialize as a radical exercise of feminist communal appropriation, reeling in Hook's (2021) argument of women redefining the domestic realm as an act of social emancipation, yet decrying that this is an act of forced labour for them.

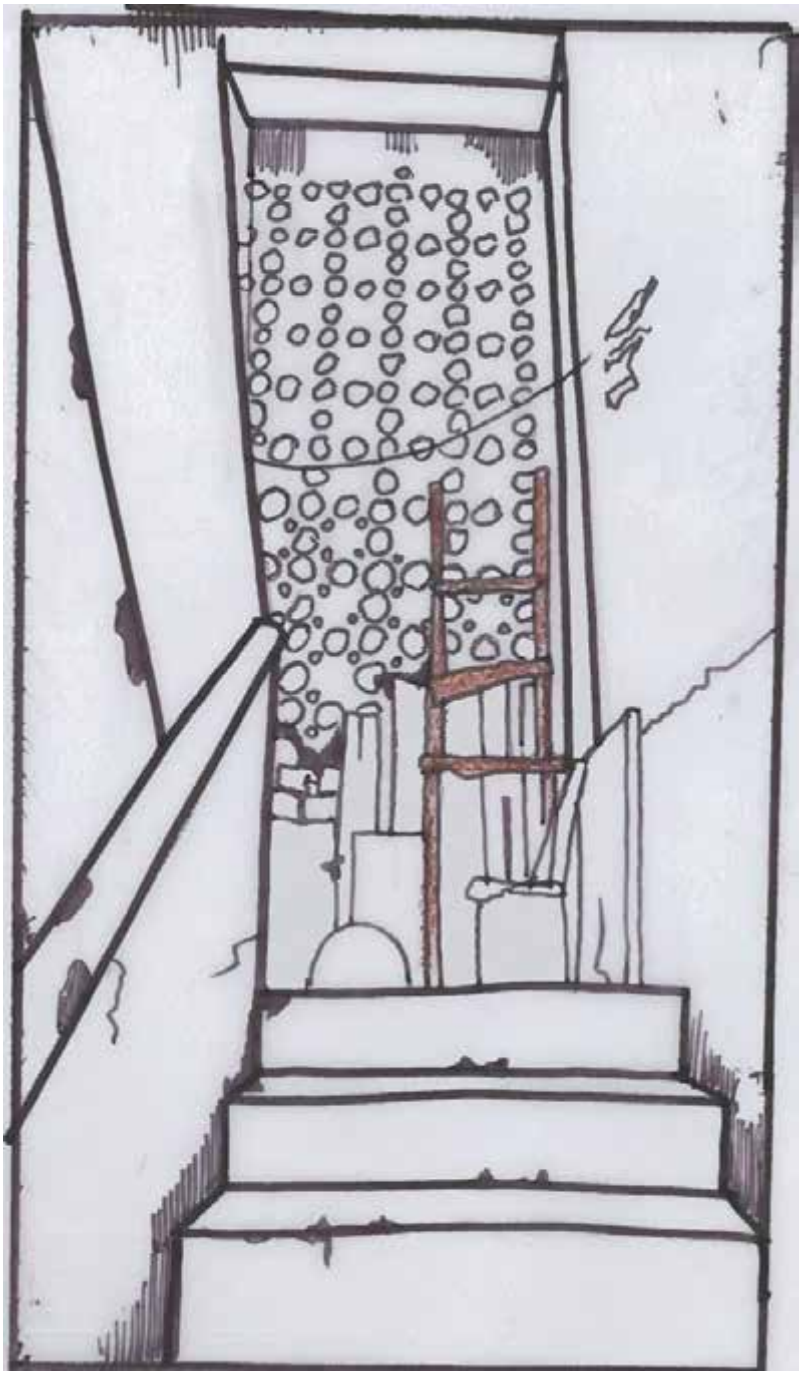

Figure 8: The stepladder used by the women to access the rooftop from inside the building block. This stepladder demonstrates that the roof was not meant to be used in the first place. Source: Author

'...We, the women, gather here in the warm summer evenings and crisp winter mornings... talk about our daily routines, cut vegetables, and babysit... we also have a Quran Khwani[5] here...'.

The association Umaima and her cohort of women living in this neighbourhood have developed with the rooftop while maintaining a sense of purdah through a vertically detached means of communal bonding can be seen as an attempt to reinvent the idea of a Mohalla from Rawalpindi via rooftops, a recurring theme in the majority of the oral testimonies collected. As Gosh (2014) suggests in her scholarly work regarding vertical communities, this

5 A local celebration where people of the Mohalla gather to celebrate a child completion's of reciting the Muslim's book i.e. the Holy Quran.

indicates how the Mohalla found its way conceptually into the communal fabric via a collective social practice in newfound spaces, thereby developing a feminist 'stickier dependence' (Gosh, 2014). As shown in Figure 7, the rooftop has been collectively transformed by Umaima and the women of the Mohalla as a usable space, which otherwise was an abandoned building cover.

'We- the women living in this block- get together every month and clean the entire rooftop together... I consider it an exercise for myself...women living on the ground and first floors socialize on the ground level, whereas women living on the second-floor level and above usually visit the rooftops...'

This phenomenon of feminist salvation of rooftops as an act of Mohalla-Making has further enhanced the dynamic and fluid nature of the everyday lives of the women within a Modern Mohalla spatially. This has birthed a unique solidarity among them as the communal exercise of having to clean the rooftop together, lay down a 'Chitai'(mat) to sit on, and then use it to cut vegetables or even counsel each other commemorates the act of coming together in a unique space that is solely for women.

Dissecting Umaima's oral testimony alongside Doxiadis' ideology behind communal arrangements of neighbourhoods in Islamabad, rooftops as feminized nodes in Mohallas are a reflection of the architect/planners 'gaze' that applied aerial visual decoding as a design tool to understand the local culture, as mentioned by Daeschel (2015). As a triptych of vantage points, i.e., De Certeau, Doxiadis, and Umaima, one observes that the authoritative figure envisaging everything from an aerial view can ultimately be challenged through subaltern feminist Mohalla-making practices, even unintentionally. Daeschel (2015) mentions how Doxiadis' surface-level approach to understanding the vernacular cultural context of Islamabad gets lost in translation. This is because, as an architect for a post-colonial city who came across as a 'gora sahab', i.e., white man, Doxiadis, as a Westernized Pakistani planner, planning from above, physically and metaphorically (Figure 9), was seldom challenged by the local Pakistani. Can one suggest that the unforeseen feminist spatial appropriation of rooftops symbolizes a shift in the power dynamic between the makers of 'strategies' and enactors of 'tactics' as an act of feminine spatial resistance?

What is important to acknowledge here is that this unique shift in the standardized relationship between strategies and tactics as defined by De Certeau (1984) has transformed into a radical perspective where women of an Islamabadi Mohalla manage their way up to the rooftops, unintentionally, as the Mohalla-makers of 'strategies' within a community where female appropriation of spaces was not even acknowledged as a part of the overall communal structure. It is an ironic yet critical feminist action to document as it redresses the image of female subaltern identity within the built environment of Islamabad. This intersectionality between the repression and expression of Islamabad's inhabitants and their communal structure today not only transforms the modernist design principles employed by the master planners and architects but also creates diverging poles of interpretation of feminist lived experiences.

FEBRUARY 6, 1955

FROM DACCA TO LAHORE

Dacca-Delhi

At 9 o'clock in the morning I leave by Orient Airways for Lahore via Delhi.

During the first 15 minutes we fly continuously over extended hills where settlements are build on the top of small or big areas. On their slopes there are gardens covered with high types of vegetation, bushes, etc. There are also some trees.

In between these islands there are light green fields with very clearly cut divisions between them. Here and there there are beds crossing these fields to different directions and in between these small hills, in the deepest line of the landscape, there are rivers and small canals with water still in them.

Fifteen minutes later we fly over the landscape in which there are no more settlements on islands, probably no hills at all and all settlements are linear and full of trees. In between these settlements there are fields without any trees at all or with some few trees.

At exactly 30 minutes we fly over the Ganges full of sand-covered banks and relatively low-level of water.

Past the Ganges, the landscape remains the same as before. There are only linear settlements again, many rivers completely dry at this time of the year and no trees at all outside of the settlements and the immediate surrounding of the ponds. These ponds are of irregular shapes and very seldom rectangular.

Figure 9: The romance of aerial surveillance. Aerial topography was sketched and interpreted by Doxiadis in his diary en route from Dacca to Lahore. Seen as a planning 'strategy' used by Doxiadis, this is from one of his diary entries, which demonstrates how he addressed the challenge of master planning in Islamabad from a literal aerial view. Courtyards And Feminized Aerial Occupation

This section discusses the Mohalla's most obvious spatial feature, i.e., 'Sehn' (courtyards), due to its massive scale, amidst an aerial entanglement of washing lines. Courtyards, which have been a symbolic architectural element for Muslim neighbourhoods, in the context of the site, were not intentionally designed for Mohalla-making in

this neighbourhood of G-9/2. They were pieces of barren land connecting the building blocks. Through the lived experiences being studied in this section, one observes how the practice of feminist Mohalla-making redefines the modernist and homogenous socio-spatial construct as well.

The courtyards, or 'Sehn', in the government living quarters of G-9/2 (Figure 10) are key architectural features, historically central to Muslim design for their space, ventilation, and ability to create introverted environments, particularly for women. Each residential block, housing sixteen families, is linked by a large courtyard, serving as a communal area for various activities like weddings, funerals, cooking, and laundry. While courtyards traditionally offer privacy, in this case, they transform into extroverted public spaces, reflecting an unconventional approach to Mohalla-making that encourages communal interaction across blocks.

Figure 10: Aerial view of the Mohalla in sector G-9/2, Islamabad, with courtyards in between housing blocks. Rectangles shown in the middle represent the courtyards in between the housing blocks. Source: Google Maps

Figure 11: The Washing Line Phenomenon of the Modern Mohalla, i.e., the pulley system. Source: Author

Laiba, a Pashtun woman, and her family of six moved to the government quarters from Kohat, Peshawar, when her husband secured a job as a driver for the Capital Development Authority in Islamabad.

'...back in the village, there were open spaces, and the houses were very spacious. My home is much smaller here...'

Her migration to the city has been for the sake of the three holy necessities that she deems as 'electricity, gas,

and water'. She enjoys the richness of this Modern Mohalla with its infrastructure, which was absent back in Kohat. Laiba's chronicle commences with her narration regarding the aerial reclamation of space via 'washing line clusters' and the formation of micro communal friendships based on this. ,

'...These washing lines in the Mohalla are spaces of interaction for us... It is our routine in the morning, after our husband leaves for work, we used to go down to the courtyards... women who put their clothes in the same area... children go to school...we run the machine...also have to put clothes out to dry today...'

The drying of laundry itself is an act of Mohalla-making by the women, illustrating the rich ethnic blend of its residents, where women of all ethnicities congregate to dry their laundry based on which floor they reside on. What adds to the character of this social space within the Mohalla is the authority that different residents from the surrounding blocks exert on the courtyards surrounding the building blocks concerning drying their laundry.

'...We leave our kids with each other and ask for *saalan* (food) from each other.. we cook for each other.. we clean each other's homes (shared spaces like the central staircase and main entrance of the building)...also look out for each other's laundry, we don't fight for space on the washing lines. We don't throw away other neighbours' clothes to dry our own...sometimes it is a problem, so my husband made this for me...'

For Laiba, living on the second floor is problematic. She mentions that the families living on the ground floor feel more entitled to use the space for their laundry compared to the other residents residing on the upper levels. Due to this conflict, many families, like Laiba's and Umaima's, have installed a pulley system from their living room window where they hang their washing lines thereby introducing an alternative 'modern' practice of drying laundry in the Mohalla that transcends the traditional drying occurring at ground level in the courtyards and relieves the 'laundry load' on ground level.

'...my husband does not like me putting our family's clothes on public display in the courtyard downstairs, so he fixed this pulley from my living room window... See, I will show you... Now I hang my clothes here and we do not need to wait for other families like we did before on the ground...'

Umaima's narrative concerning the aerial retrieval of space to avoid conflict with other residents of the Mohalla shows a means of facilitating socio-spatial hierarchies through the Sehn, which is translated as a feminist socio-spatial agency that can assimilate into the aerial space as well.

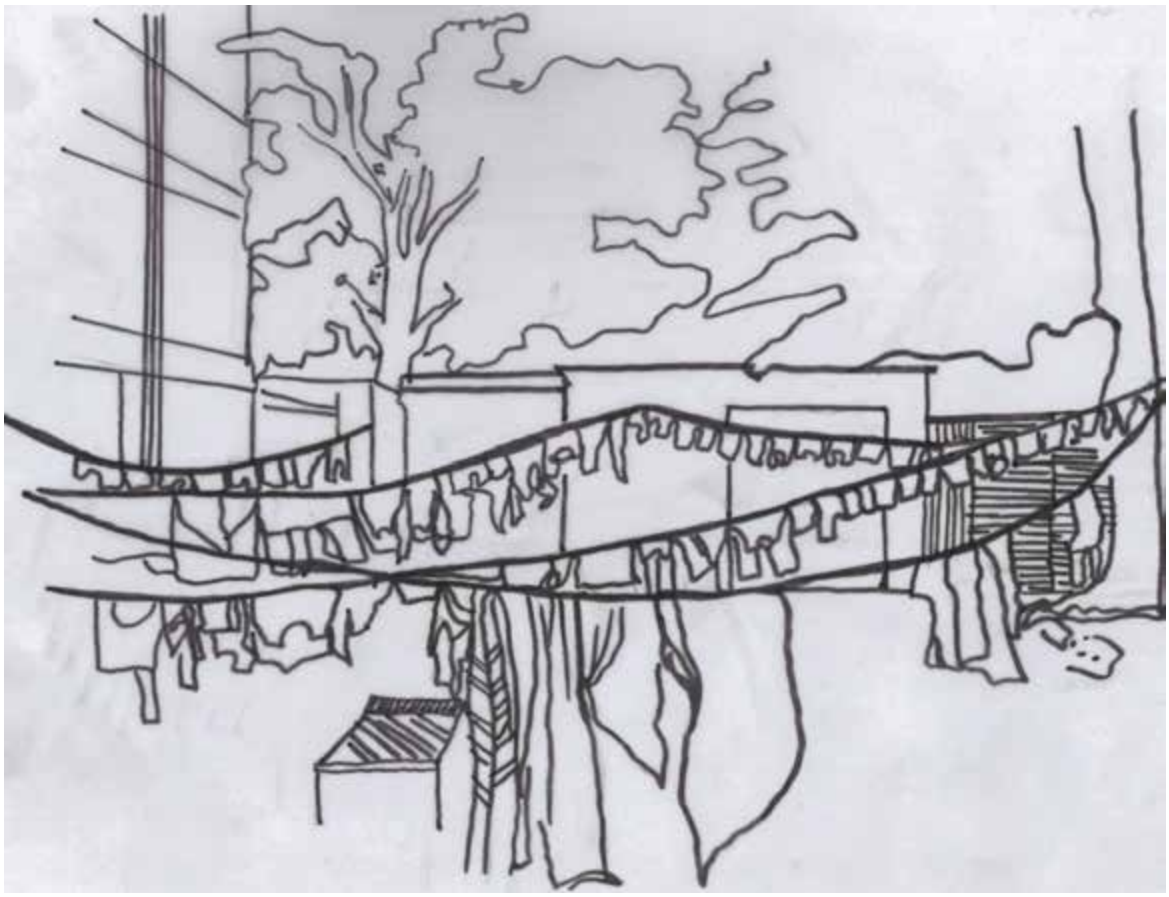

Figure 12: Drying laundry on ground level (in the courtyard) is a Mohalla-making practice versus the aerial pulley system that is illustrated in Figure 10. Source: Author

'...we usually go here (as written in Figure 13)**, to the playground... my kids enjoy it. We go there in the evenings as it is summer now... we go early morning in the winter...'**

As a woman of Pushtun descent, Laiba explains that her Mohalla-making activities vary distinctly from women of different ethnicities around her. Pashtun women are expected to be introverted, and the men expect their women to observe purdah and avoid public spaces of gathering. However, in Laiba's case, the aforementioned unique situation is observed by her interaction in the public realm within the Modern Mohalla of G-9/2, which is ironically propelled by her youngest children, a set of twins, who regularly visit Mohalla Park, i.e., the courtyard readapted into a playground. It must be noted that the adaptation of the courtyard into a playground was not a part of the original design plan for the housing block.

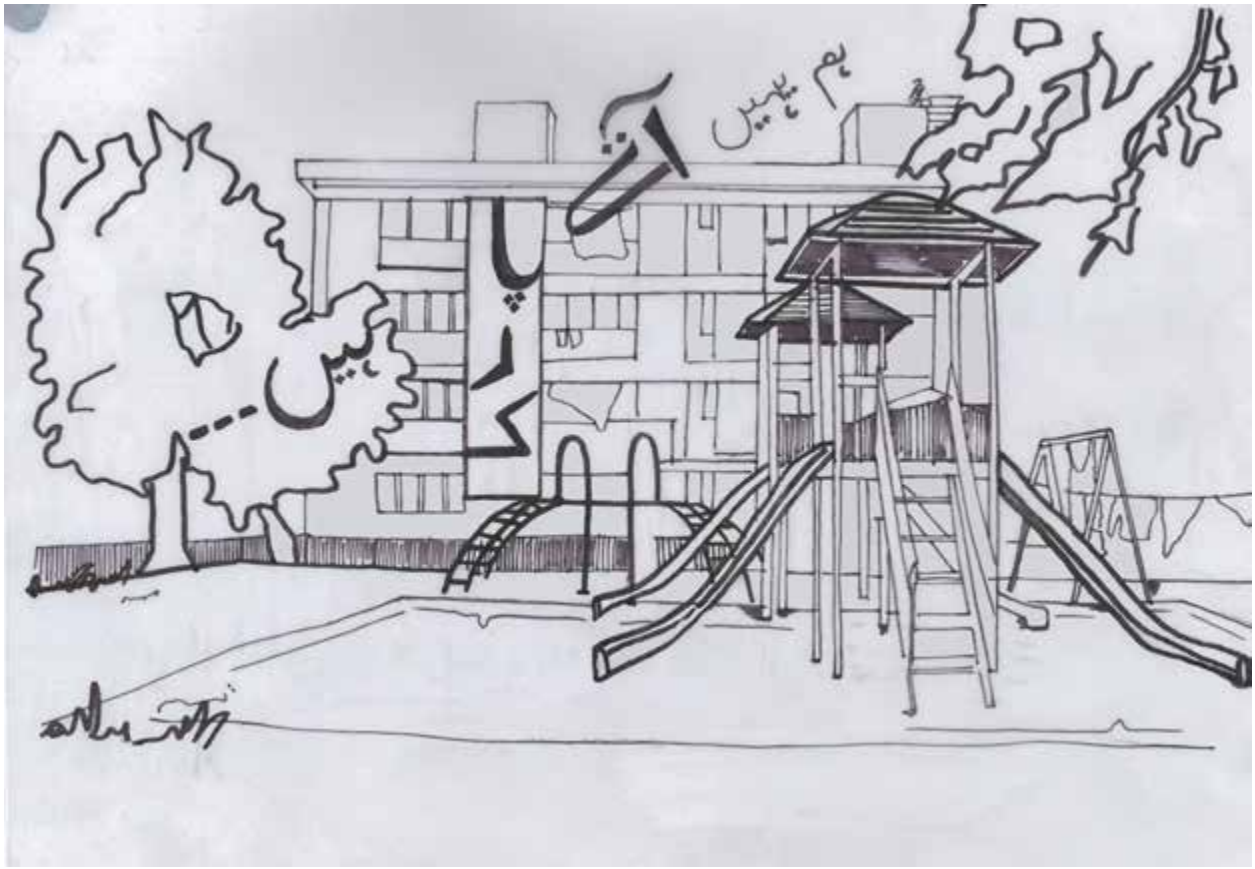

Figure 13: The transformative nature of the Mohalla courtyard, now a playground, serves as a means of social interaction for the Mohalla mothers.

Laiba visualizes a Mohalla as a playground where mothers of the community, together with their children, can socialize freely. In contrast to the women who socialize on the rooftop, Laiba and her cohort of women do not visit the rooftops because their husbands do not see the space for women as 'socially appropriate' i.e., they prefer their women to be using conventional spaces for communal gatherings, the idea of a rooftop is strange to them.

'...it is preferable to see children playing in the park on a ground level where they can also be seen from their kitchen or living room windows...'

'...This is where we come, the park is within walking distance from my house... only takes us five minutes... it has fences around so it is safe for children to play while we talk...'

Questioning how efficiently the park is designed and to what extent it satisfies the needs of its users, it is important to point out that it is not a green space. It comprises some playground items fixed onto a barren courtyard inside a sand pit lined with bricks. The park is more of an informal playground that serves as a recreational facility for the women and children of the Modern Mohalla. As discussed further, parks are a design element of the original communal structure that Doxiadis planned in his archival illustration (Figure 15), however, Laiba's testimony illustrates this space as an afterthought brought to the forefront through the feminist appropriation of courtyards as play areas for their young rather than the design process itself.

Laiba defines the idea of a Mohalla as an 'act (s) of caring' that she appropriates to a play area, as that is where she embodies the concept as a tangible space. Facilitating her children's and her social needs through a playground is an act of Mohalla-making that can be carried through for generations. As shown in the written calligraphic image of Figure 13, 'this is where we come', courtyards, despite their extroverted nature, are seen as spaces used by women like Laiba, who otherwise belong to an introverted culture where using public spaces for Pashtun

women is not the norm. Therefore, Laiba's Mohalla-making is seen as a socially reformative act where women like her can identify and meet their communal needs by informally establishing newfound Mohalla-making traditions in a modernist urban setting.

By reflecting on the oral testimonies of Umaima and Laiba, the theme of socio-spatial interrelatedness becomes more apparent as the idea of a Modern Mohalla and its physical manifestation via their unconventional practices of Mohalla-making can be traced to their consistent intangible communal practices linked to their lifestyles before migrating to Islamabad from Rawalpindi and Peshawar, respectively. As such, a trajectory of concepts regarding traditional spatial formations is seen in a modernist built environment, a requirement that Doxiadis blanketed under the homogenous zoning as a part of his master planning exercise. This is further explored in the next section, where Doxiadis' theory of Ekistics is studied as a facilitator for feminist Mohalla-making in Islamabad.

Islamabad And Ekistics: How Does Ekistics Facilitate Mohalla-Making?
This section investigates Doxiadis' theory of Ekistics and how it impacts the structure of a community in Islamabad and ultimately Mohalla-making. It addresses the research inquiry of how the Mohalla-making practices of women are facilitated by Doxiadis' illustration of a communal structure. Viewing this research inquiry through a post-independence lens and Doxiadis' theory of Ekistics, questions whether female representation was a consideration during the design process of Islamabad's neighbourhoods and whether feminist spaces were conceived as a part of the overall communal structure of Islamabad and the site of study in particular.

Doxiadis defines Ekistics as the understanding of social interaction between and within human groups and societies. Doxiadis uses his science of human settlements to develop a coherent social structure of how neighbourhoods should be designed in Islamabad, thereby shaping their future social practices. Concerning the layout of communal structures, Doxiadis grounds his theory of Ekistics on the following units, which are sourced from his archival works (Doxiadis, 1972): Nature, which is the site on which settlements are built, Man who creates and inhabits them, Society which is formed within them via people and whose social Networks allow people to grow, and lastly Shells which are translated as the built environment housing the other three elements (man, society, and networks). By connecting these units as building blocks of a community, this research examines how they collectively impact the structure of a neighbourhood in Islamabad and consequently the Mohalla-making practices of the women in the Modern Mohalla of G-9/2.

The structure of a community is integral to understanding the investigation of the Modern Mohalla. As a living quarter that is a modernist vertical building, it is not a customary building typology for its inhabitants, who have migrated from non-modern communities to the city for a better lifestyle. Yet their communal practices permeate the modernist built form and birth new informal spatial appropriations as studied via the feminist oral traditions and drawings. Islamabad was a culmination of Doxiadis' vision for a city that operated on multiple fronts, which he believed made a city embody the principles of autonomous growth (Kreutzmann, 2013) while catering to the daily needs of its residents. However, it was not realized particularly via a feminist lens of utility. The entire process of Doxiadis' appointment and the master planning of Islamabad was seen as a bureaucratic strategy that Moatasim (2023) explains envisioned the city according to the modernist ideals of its administrators and patrons rather than its people's intangible or gendered cultural practices. Most academics who have written about Islamabad from a post-independence lens omit the qualitative aspect of documenting the lived experiences and feminine participation as a part of Islamabad's inception because there wasn't any to document in the first place. The female presence as a part of this research is felt as an 'otherly' subject, which Madison (2020) describes, with which a critical dialogue has yet to be made. This 'otherly' characteristic is deeply felt because even more than seventy years after Islamabad's birth, there is no archival record of feminist representation regarding community planning and dwelling design as a part of Islamabad's establishment.

One focuses on the archival evidence of Doxiadis' work titled The Human Community Project (Doxiadis, 1965), a project launched in 1961 in Athens, ironically coinciding with Islamabad's creation, to study the human community level and prescription of relevant communities at a local district level per their social needs as an attempt to situate an informed strategic decision regarding community design. However, despite having a systemic observational technique, one notices the lack of its implementation within the design of Islamabad, especially during its preliminary stages when Doxiadis was attempting to understand the social structure of Islamabad. For whatever reason, this may not have been executed, had The Human Community Project been used

as a participatory socio-spatial tool to understand the sensitive social structure of the neighbourhood culture in Islamabad, their presence today would be mainstream and more cognizant of women's spatial practices on an urban level.

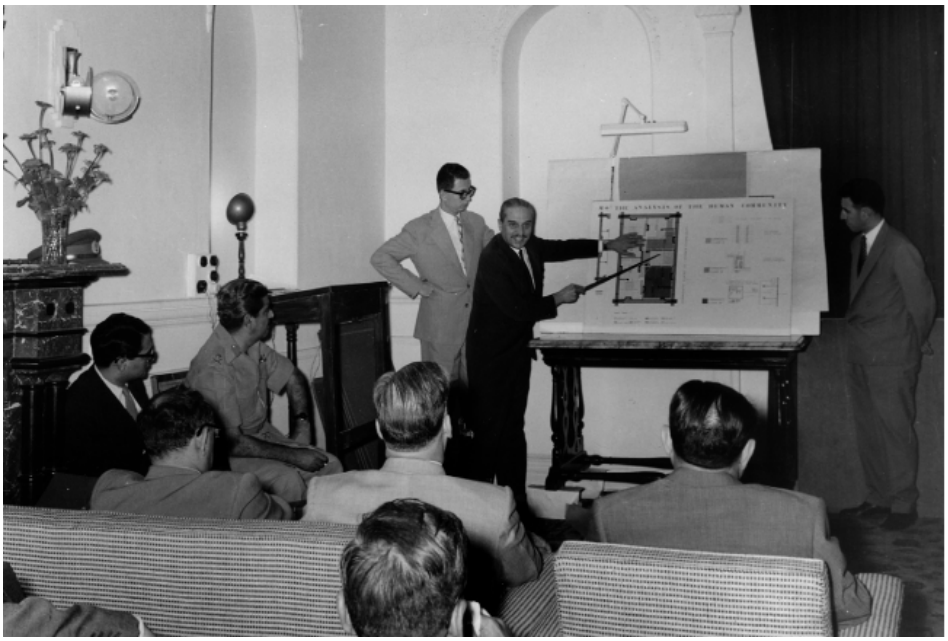

Figure 14: Two images show only male representation during Islamabad's design process. The first image shows Doxiadis presenting aspects of his master plan for Islamabad to the Capital Development Authority, Rawalpindi, in May 1961. A lack of female representation in the meeting is observed. Source: CADA: Photographs No. 30917. The second image shows a meeting in Athens between Doxiadis and General Azam Khan who was Doxiadis; the most powerful supporter in Pakistan and influenced his success in securing Islamabad as a design project. Source: CADA: Archive Files 28557.

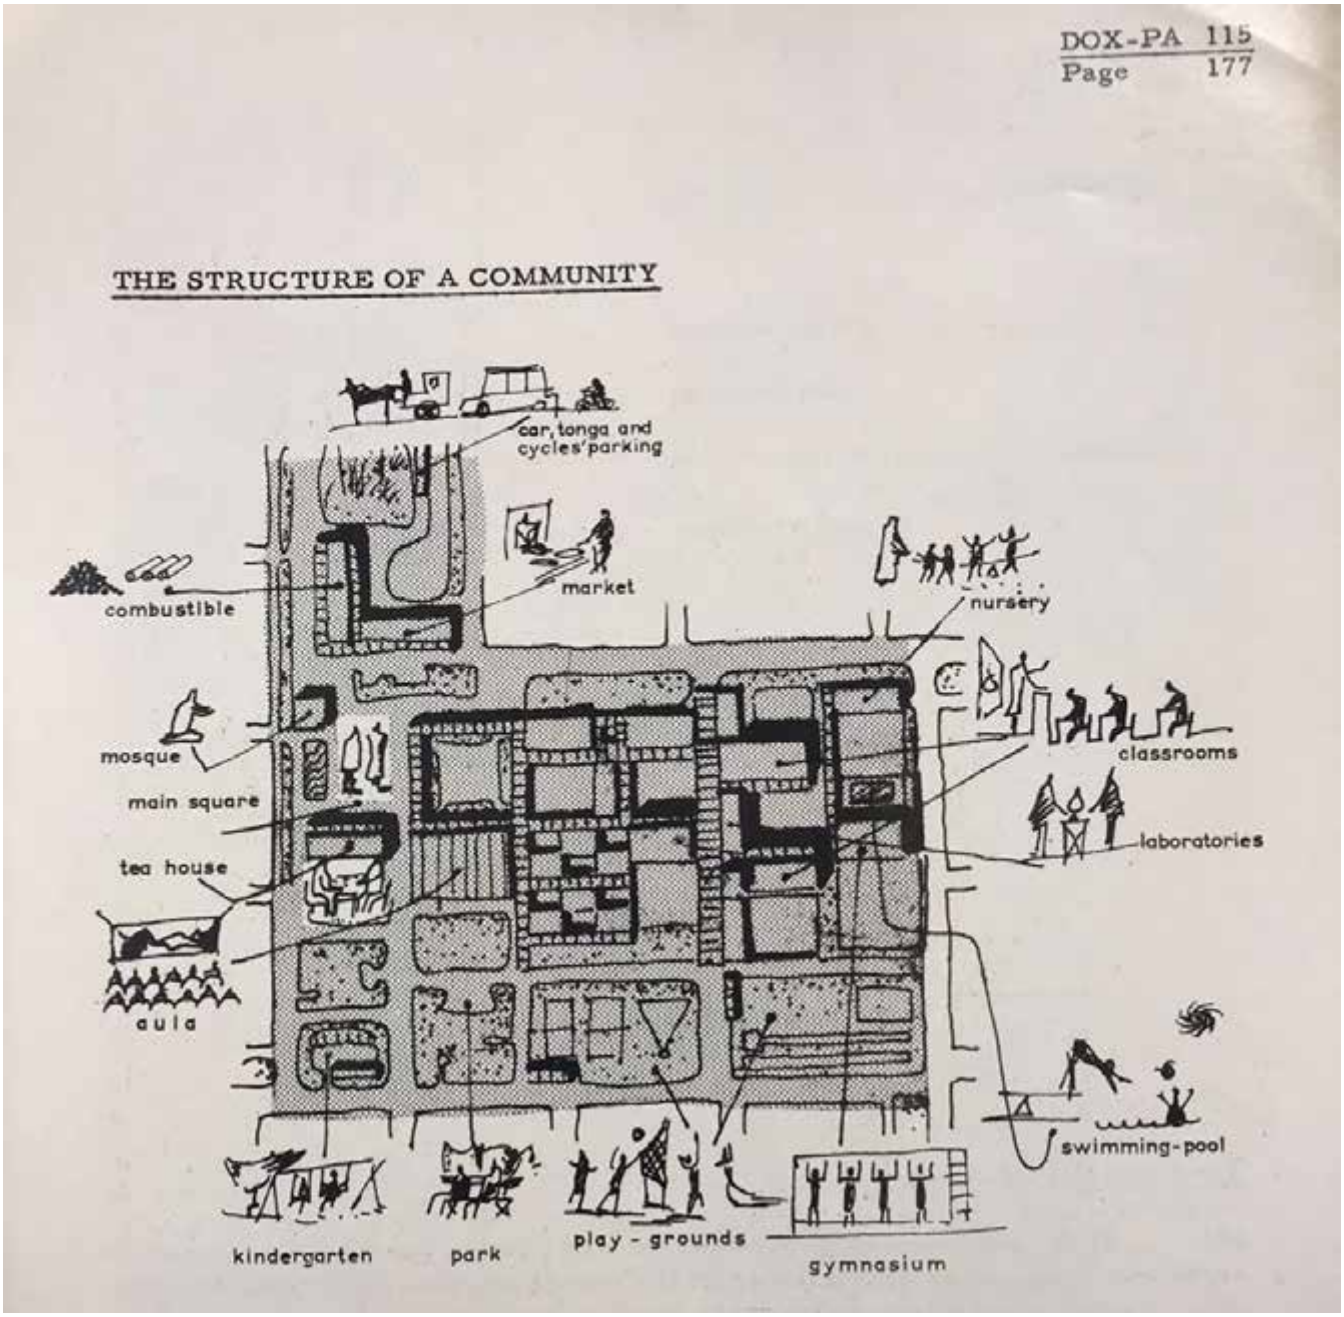

Figure 15: The structure of a community, illustrated by Doxiadis. Source: Capital Development Authority, Islamabad. Doxiadis and Associates- DOX-PA 115.

Stitching together Doxiadis' theory of Ekistics with his illustration of a communal structure, as a modernist master planner (Figure 15), each spatial relation reflects his vernacular interpretations. The spatial typologies assigned by Doxiadis have been translated and transformed by the inhabitants as per their lifestyles, driven by their traditions today. Once again, we notice that this illustration (Figure 15) depicts the socio-spatial relations of a neighbourhood from an aerial view, a recurring theme in Doxiadis' planning approach. When this 'strategy' of Doxiadis is observed via my site visit, on a street level, and through the feminist lens of lived experiences, the Mohalla-making 'tactics' of the residents are noticeably different. For instance, spaces demarcated as 'tea-house' exist informally as 'dhabas'(pop-up tea stalls), cobblers, or fruit vendors, as shown in Figure 16. Can one suggest that Ekistics envisioned Mohalla-making for the locals from a top-down approach? If so, this research argues that this top-down approach is contested through the feminist re-appropriations of his canonized theory of human settlements, another act of feminine resilience that can be connected with Hooks' (2021) proposition of

women doing the work only because they are expected to do so to create alternatives for themselves when none are available. This is explored further via Figure 17, which is seen again but from a feminist lens of occupying communal spaces.

Figure 16: Local fruit vendor's informal stall in the Government Housing Modern Mohalla. These spaces are primarily used by men.

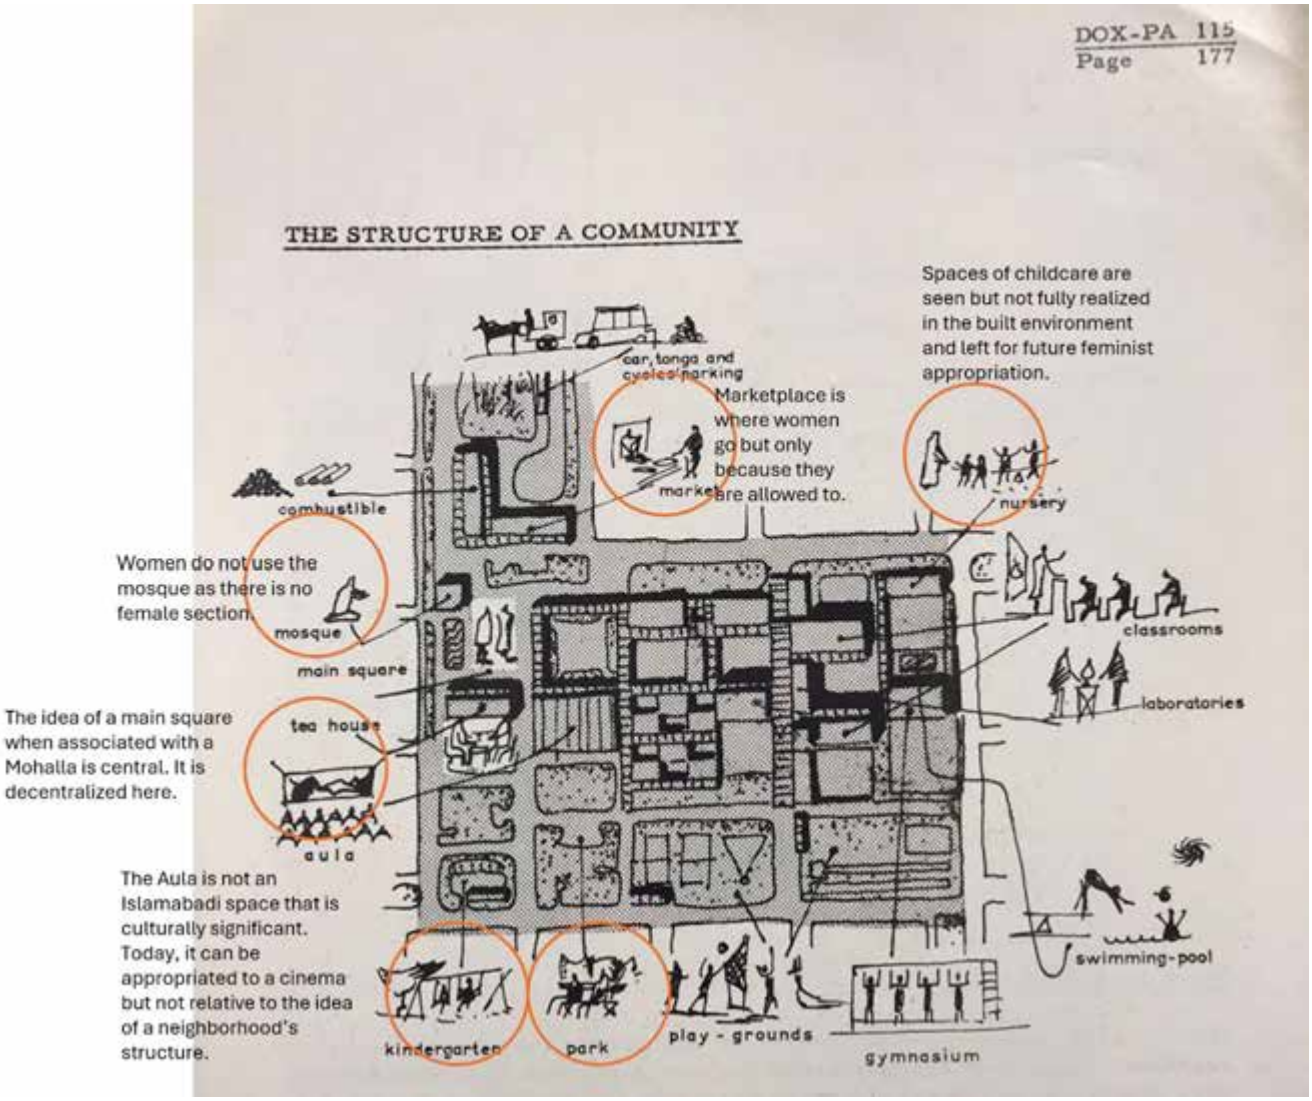

Figure 17: The structure of a community designed by Doxiadis revisited via a feminist lens of Mohalla-making practices.

The extroverted nature of the spaces shown in Figure 15 highlights a disconnect between Doxiadis' urban planning approach and the introverted, culturally specific needs of the community in Islamabad, particularly for women. Doxiadis' designs, such as the 'Aula' (a modern screening area or swimming pool), reflect a Westernized, extroverted vision, which does not align with the introverted Mohalla culture, particularly in terms of feminist spaces and the concept of 'purdah' (female segregation). The absence of women in the planning process of the 1960s and their lack of representation in public and communal spaces (such as mosques) is noted as a significant issue in Doxiadis' illustrations. This research, therefore, explores unique spatial appropriations of retaining privacy by women for women. It focuses on how women navigate and appropriate space to maintain privacy, via oral testimonies revealing that the practical realities of vernacular socio-spatial practices differ from Doxiadis' vision, emphasizing a need for more context-sensitive urban design that acknowledges these socio-cultural nuances.

Conclusion

This interdisciplinary research explores the lived experiences of women in the Modern Mohalla of G-9/2, Islamabad, emphasizing their "Ziddi feminist Mohalla-making practices". The study frames the Modern Mohalla as a space of urban informality where women actively redefine their socio-spatial roles within a post-independence, modernist Islamabad. It portrays the women being studied as independent, radical agents of change, whose contributions to community-building extend beyond traditional roles tied to their spouses' income, asserting their presence in a space that was never designed with them in mind. With my interpretation of a Mohalla's socio-spatial

construct as shown in Figure 18, one of the findings is how the communal life in a Modern Mohalla indicates an unconsciously conceived feminist prototype of dynamic cultural customs as a collective response to the modernist planning principles implemented by Doxiadis. This study is unique because it highlights a paradoxical situation of the qualitative lived experiences of the women as residents of formal settlements practicing informal urban practices. The collected feminist lived experiences in the Modern Mohalla are an unintentional antithesis of the communal structural stratification for government servants that Doxiadis designed, since feminist spaces were not realized as a part of his study, to begin with.

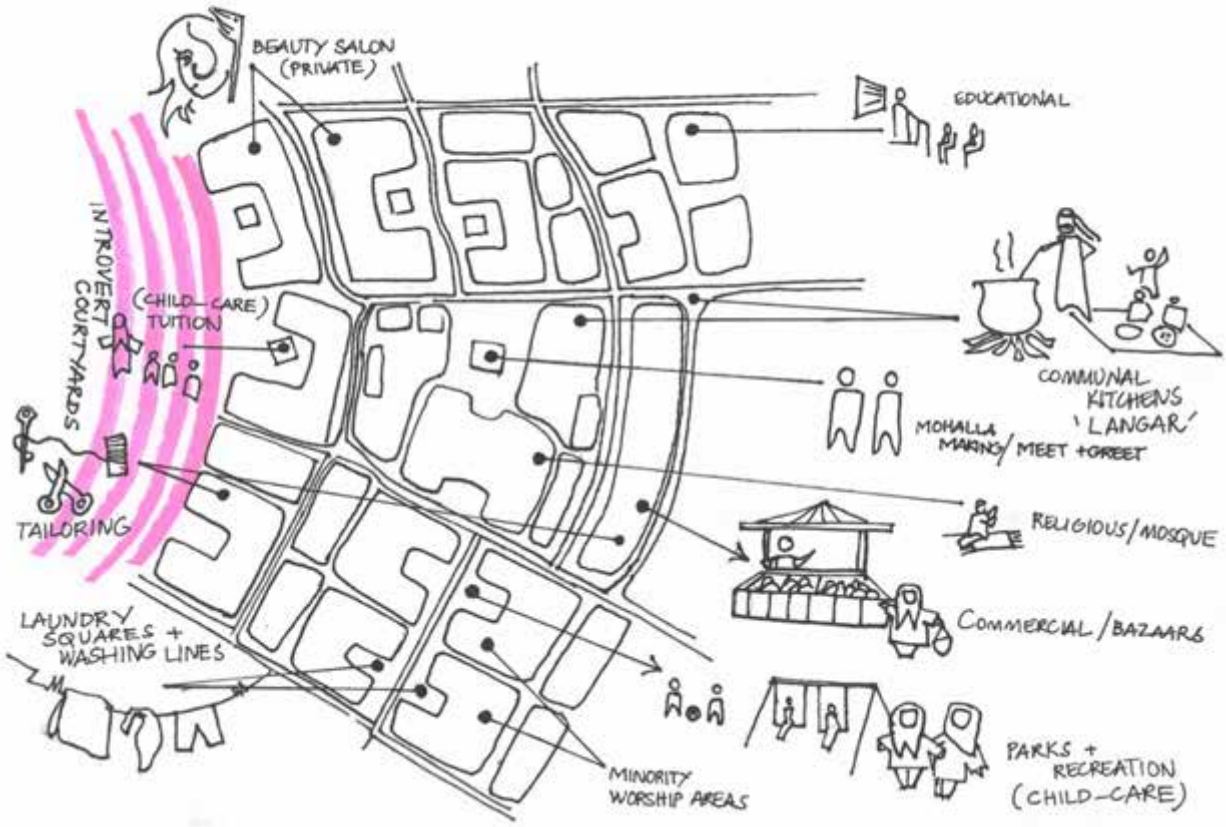

Figure 18: An interpretation of how a Modern Mohalla could be structured if it were seen via a feminist lens of participatory engagement after my site visit. The intersectionality between the formal nature of the built environment and the informal nature of the feminist Mohalla-making practices thrives through a dense interrelated network of streets and buildings as an ephemeral concept of socio-spatial relations.

The approach shown in Figure 17 challenges the rigid, ungendered zoning proposed by Doxiadis, which treats public spaces (market, mosque, square) as functional areas that do not limit women's social interaction. Instead, by reimagining the neighbourhood as a complex web of historical, socio-cultural, and feminist influences, blending private and public spaces, the study envisions a more emancipated communal structure. The Modern Mohalla manifests itself as a hub of intangible socio-spatial relationships passed down through generations, evolving within a modernist framework. As a female Islamabadi researcher focusing on the feminist lived experiences of the Government Housing Quarter of G-9/2, this research explores my role in uncovering and documenting their often-overlooked stories to address their "triple absence" in critical feminist socio-spatial discourse within Islamabad's neighbourhoods. Writing about the architectural history of my hometown as a Pakistani woman is itself a radical act, as it advocates for incorporating feminist spaces into urban design, something that has not been previously considered. By examining the complex Mohalla-making practices, the study allows the researcher and audience to engage with the once-overlooked experiences of these communities. It opens the door to further inquiry, questioning "What more is there to know?" about Modern Mohallas in Islamabad, especially with the low-income government servants and their ghettoised communal structures influenced by feminist practices that

remain largely unexplored.

Abstract
Under the guidance of Sustainable Development Goals, Olympic legacy is defined as the long-term benefits of major sporting events for residents and cities. As a key component of event legacies, large-scale sports architecture(stadium) has become a significant urban research topic. Capital sports architecture serves as a carrier of national identity, embodying symbolic urban imagery and enriching urban cultural landscapes. This study employs longitudinal and comparative analyses to examine the evolution of Beijing's stadiums over the past 70 years, systematically exploring their construction context, design concepts, architectural features and public activities. The findings aim to summarise trends, provide insights for stadium development, and promote sustainable growth. These outcomes ensure that these iconic venues continue to represent national identity and connect the past, present, and future.

Keywords: Beijing; Sports architecture heritage; national image; urban development; comparative study

Under the guidance of the goal of Sustainable Development Goals, Olympic legacy is defined as the long-term benefits that the Olympic Games or major sports events bring to residents and cities(Han & Xie, 2020). Effective reuse of 'Olympic legacy' has become a critical focus for modern Olympic Games. Therefore, the construction, development and reuse of 'Olympic legacy' represented by large-scale sports buildings has become an important research topic in global academic circles and planning practices. Stadiums are the most important type of sports buildings and a key urban landmark. Stadiums are one of the places where national and city sports events and activities are held. National and world-class high-level games and events, such as the Olympic Games, National Games, World Cup, etc., have great international influence and are the medium for the country to enhance its international image. Because of its natural functionality, agglomeration and openness, the stadium is not only the venue for these competitive sports, but also the venue for the opening ceremony and other events, and more importantly, the venue for some commemorative meetings, cultural performances and other national celebrations. The capital stadium, more important, as a national and international activities held in the place, is to show the strength of the country, reflecting the dignity of the country's important window, excellent stadiums on the development of the city has a positive role in promoting. The stadium architecture is also the expression of the image of the capital and the image of the country, so it is of great research value to analyze the architectural development changes, style concept changes, and urban spatial relations of the capital stadium.

1. Status of research and scope of content

1.1 Status of research

Currently, the research on Beijing stadiums focuses on the construction and use of stadiums: function and utilization, building structure and construction, building form and external spatial relationship, energy consumption analysis and optimization; and the cultural level: protection of sports heritage buildings, sports buildings and humanities analysis, most of which are focused on the consideration of single buildings or stadiums, and less on the study of 'capital city' within the scope of the stadiums. There are few studies on the stadiums within the scope of 'capital city', and there are few comparisons of the changes of the capital city stadiums in both vertical and horizontal dimensions, and fewer of them focus on the correlation between the stadiums and the image of the country.

1.2 Content and scope of the study

Stadium for all kinds of games sports buildings, according to the 'Architectural Design Sourcebook 6 (third edition)' interpretation, the stadium is able to outdoor track and field and soccer and other sports buildings, can also be called track and field or integrated stadium, which is mainly by the field area (including track and field and soccer field), grandstand area, auxiliary rooms and facilities and other parts of the composition(Architectural Society of China, 2017). According to the China provisions of the 'Sports Building Design Code' (JGJ 31-2003), the stadium's official competition venues should include a 400m perimetre of the standard circular track for track and field events, a standard soccer field and various field events. Specialised soccer stadiums can also have only standard soccer fields without a loop track and field events. According to the code, stadiums with more than 60,000 seats

are considered mega, 40,000 to 60,000 seats are considered large, and 30,000 to 40,000 seats are considered medium.

As the capital stadium with a certain influence that can show the dignity of the country is inevitably large, high level and wide range of services, so the important stadiums in Beijing involved in the study are the Xiannongtan Stadium, Workers Stadium, Olympic Sports Centre Stadium, National Stadium and the new Workers Stadium (a professional soccer stadium). Small stadiums such as college stadiums or non-special grade and Grade A stadiums are not included in the scope of this study.

2. Reviewing the 70-Year evolution of stadiums in Beijing

Modern sports architecture and culture originated from the Greek Olympic, and the prototypes of modern sports stadiums also came from the stadiums and colosseums of ancient Greece and Rome. Modern sports in China began with the sports of Westerners in the concession and trading ports, and Western sports buildings under the colonial regime began to be constructed in China(Hou, 2020). Under the passive importation of the West and the active fusion of the local community, modern stadiums modeled on Western modern venues were gradually built.

The earliest formal stadiums in Beijing were the Huiwen Shuyuan Stadium and the Xiehe Shuyuan Stadium(Hui, 2023). According to the time division, the construction of major stadiums in Beijing can be roughly divided into 5 Stages, corresponding to the background characteristics and urban development needs of different eras, namely, the Early Development stage (EDS)(1936-1958), the Construction Start-up stage (CSS) (1959-1978), the Asian Games stage (AGS) (1979-1990), the Olympic Games stage (OGS) (1991-2008), and the Post-Summer Olympics Stage (PSOS) (2009-present). which has lasted for more than 70 years since Beijing became the capital of new China.

Figure 1: Study cases and location relationships

2.1 Early Development stage (1936-1958)

The main stadium of this Stage was the Xiannongtan Stadium, built in 1937 and originally called the 'Peking Public Stadium'. In 1936, in preparation for the 19th North China Games (not held), the design of the Xiannongtan Stadium in Beijing was completed by Guan Songsheng of the Kwan, Chu and Yang Architects & Engineers (KCYAE). Since there was no precedent to follow from the traditional building activities in China, domestic sports buildings of this stage were often modeled directly on modern Western venues. Before taking over the public stadium in Peking, KCYAE had already had experience in building stadiums, therefore, the design is inherited from the Nanjing Central Stadium, under the core of the 'Western Stadium', set up the enclosed grandstand, the long axis of the stadium conforms to the axis of the Xiannongtan (Agricultural god temple), set up an end gate tower as the entrance on the north side, and the exterior design is integrated into the palace form, so as to achieve the integration of the traditional Chinese architectural style.

Stadium was equipped with a 400m runway, with a capacity of 4,000 spectators, and is the only large-scale public stadium in Beijing before and after the liberation. After the peaceful liberation of Peking, Stadium took over many political and cultural events. The 28th anniversary of the founding of the Communist Party of China and the Beijing Municipal People's Sports Congress were held here. In the 1950s, Stadium was expanded twice, increasing the number of spectators to nearly 30,000(Shaoyi, 2004). Prior to the construction of the Workers Stadium, almost all of China's major competitions were held at the Xiannongtan Stadium, which was nominally the 'National Stadium'.

Figure 2: Xiannongtan Stadium Design

Figure 3: Aerial view of the stadium

2.2 Construction Start-up Stage (1959-1978)

The main stadiums built during this stage were the Workers Stadium and the renovation of the Xiannongtan Stadium. The main construction opportunity was the First National Games (1959).

In the early years of the founding of the PRC, Beijing was very short of stadiums, and there were no large stadiums except for the Xiannongtan Stadium mentioned above. As the capital city, Beijing often hosted visits by foreign athletes, and due to the lack of relevant facilities, the venues for various competitions were very simple, which did not match the temperament of the capital city of new China. Taking the opportunity of the 10th anniversary of the founding of the People's Republic of China and the first National Games in 1959, one of the '10 major projects of the National Day', the Workers Stadium, was completed in the eastern suburb. The Workers Stadium has a geometrically regular group layout, with the stadium at its core. The Workers Stadium north-south length of 282m, east-west length of 208m. ring depth of 40m for the grandstand, the ring for the competition venue. The grandstand is divided into two levels, the highest place in the ground above 22m(Youming, 1959). The total area is 80,000 m^2 and can accommodate 80,000 spectators. The whole building adopts the whole cast reinforced concrete frame orange structure.

The facade of the building is treated under the guidance of the architectural policy of 'applicable, economical, and pay attention to the aesthetics under the possible conditions', with generous, open and bright large glass windows together with the light and powerful columns(Beijing Municipal Planning Bureau Design Institute Sports Farm Design Team, 1959), the design is simple, with the practical characteristics of socialist architecture, and the window patterns on the outer wall of the stadium are the traditional Chinese style. 13 sculptures of workers and athletes are arranged around the building, which is very characteristic of the times. The Workers Stadium became the de facto national stadium, taking over from the Xiannongtan Stadium, which hosted the first National Games in the year of its completion, and later hosted many important competitions; in the 1960s it became a 'political stadium'(Dongming, 2008), with more functions such as parades and rallies.

Figure 4: Opening Ceremony of the First National Games

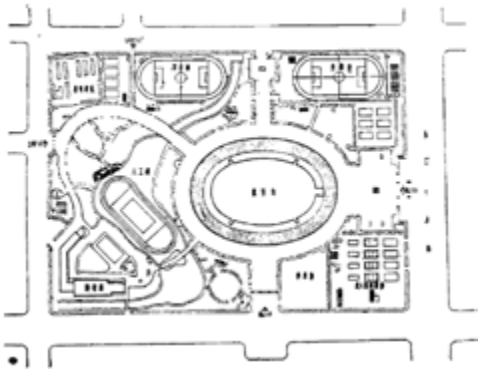

Figure 5: Site-plan of Workers Stadium

2.3 Asian Games Stage (1979-1990)

The main stadiums built during this Stage were the Olympic Sports Centre Stadium, as well as the reconstruction of the Workers Stadium and the restoration of the original site of the Xiannongtan Stadium. The construction opportunity of this Stage was the 11th Asian Games (1990).

The Asian Games was the first large-scale comprehensive international games held in China, and it was also an important opportunity for China to show its dignity and image to the outside world. To host the Games, a new National Olympic Sports Centre was chosen to be built in the northern suburbs of Beijing. The National Olympic Sports Centre was planned and designed as an integrated whole, with a total of three large sports buildings, 'one stadium and two gymnasiums', for which Ma Guoxin was the chief architect. In this area, the northern part of the building is used as the first phase of the venue to serve the Asian Games, and the overall planning takes grid and curve as the design elements, and draws on the group combination treatment of Beijing's traditional city to form the overall design, and the centre is planned to open to the public as a sports park after the games. The centre is planned to be opened as a sports park for all after the games. The stadium of the Olympic Sports Centre is located on the main east-west axis, with a floor area of 30,000 m^2, a design capacity of 20,000 people, and reserves in the north and south, and is planned to be converted into a football stadium with a capacity of 40,000 people in the later stage. The podium is located in the West Stand and has a technical special box. The top of the west stand has a 20m wide, 100m long overhanging translucent canopy(Ma, 1990).

Since 1986, the first large-scale renovation of the Workers Stadium was carried out in preparation for the 1990 Asian Games. The Workers Stadium had been damaged by 30 years of wind and rain. The stadium was reinforced, a torch platform was added, the comfort of the seats in the stands was improved (reduced in number), and the top was covered with a large canopy, with the canopies of the east and west stands cantilevering inwards by up to 18 m. The restored Workers Stadium successfully hosted the opening ceremony and matches of the 11th Asian Games, and celebrations for the return of Hong Kong to China and other festivities. At the same time, in order to meet the Asian Games, Xiannongtan Stadium was demolished and rebuilt in 1986, and the new Xiannongtan Stadium became a 30,000-seat modern stadium in line with the modern track and field and football stadiums(Beijing No.2 Municipal Engineering Company, No.1 Team of No.2 Work Area, 1985).

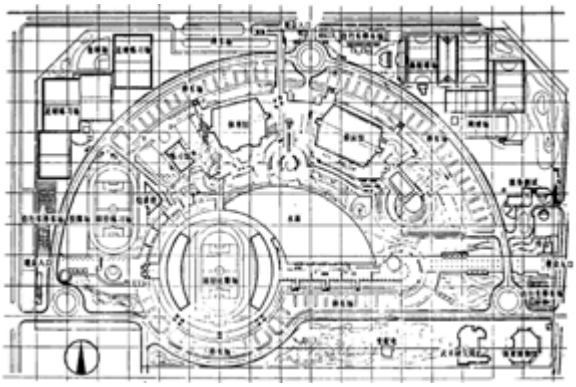

Figure 6: Site-plan of Beijing Olympic Sports Centre

Figure 7: Beijing Olympic Sports Centre Stadium

2.4 Olympic Games Stage (1991-2008)

The main stadiums built during this Stage were the National Stadium and the renovation of the Olympic Sports Centre Stadium and the Workers Stadium. The opportunities for construction were the 21st World University Games (2001) and the 29th Beijing Olympics (2008). Since Beijing lost the bid for the 2000 Olympics, it retreated to bid for the Universiade, but the main target event for this stage was the Olympics, so this stage is categorised as the Olympics phase.

The China National Stadium (Bird's Nest), designed by the China Academy of Architectural Design Institute (CAADI) in conjunction with Herzog & de Meuron, was the main venue for the 2008 Beijing Olympic Games. After the completion of the stadium, it officially succeeded the Workers Stadium as the National Stadium. The shape of the stadium is an ellipse with a north-south length of 333 m and an east-west width of 298 m, with a maximum height of 69 m and a minimum height of 40 m; the middle opening has a north-south length of 182 m and an east-west width of 124 m. The main steel structure forms an integral giant large-span, crosswise rotating braided structure, and the stadium grandstand is a bowl-shaped structure supported by a reinforced concrete frame(Li, 2008) . The National Stadium is a design from the inside out, where the structure is the appearance, forming a woven structure like the 'Bird's Nest', a perfect unity of structure and appearance due to function.

Figure 8: Floor plan of the China National Stadium

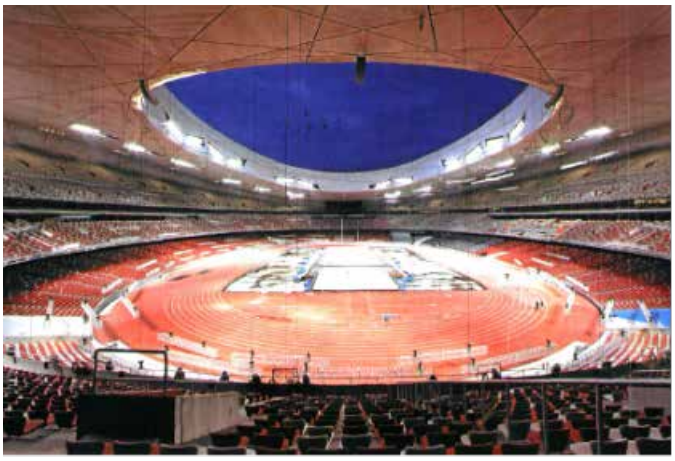

Figure 9: Inside China National Stadium

Figure 10: Site-plan of the China National Stadium

Meanwhile, the Workers Stadium also saw two important renovations during this stage. In 2000, the Stadium was renovated for the second time to meet the Universiade. The stadium was partially reinforced, with the construction of high-standard lounges and a press centre. In 2006, the third renovation of the Workers Stadium was carried out. The most significant change in its appearance was the installation of the overhead light frame cable structure. After a comprehensive renovation of the Workers Stadium, can accommodate 62,000 spectators, the field facilities fully meet the technical standards of the Olympic Games football match requirements. The Olympic Sports Centre Stadium has also undergone related alterations, removing the ring road, reconstructing the east and west awnings and expanding its capacity to 40,000 while reinforcing the structure to meet the requirements of the Olympic Games.

2.5 Post-Summer Olympics Stage (2009-present)

The main stadiums built during this stage were the restoration of the Workers Stadium (New Workers Stadium) and the renovation of the National Stadium. The construction opportunities are diverse, mainly for the Beijing 2022 Winter Olympics and the AFC Asian Cup.

The Workers Stadium has undergone four renovations, reaching its design life of 50 years after the Olympics, and was partially renovated in 2010, transforming it from a comprehensive stadium into a professional football stadium. However, as an important stadium building in Beijing, its external environment as a whole presents a messy and disordered, therefore, in order to make effective use of the stadium, coinciding with China's opportunity to host the 2023 Asian Cup (Stadium was originally scheduled to serve as the main venue for the Asian Cup, but was abandoned due to an epidemic), under the basic principle of 'three constant' -- the elliptical shape remains unchanged, the facade form remains basically unchanged, and the style remains basically unchanged, the way of dismantling and reconstructing was finally determined, and the concept of 'traditional appearance, modern arena' was put forward. Workers Stadium ushered in the opportunity of nirvana rebirth(Du song & Wang, 2023).

Figure 11: New Workers Stadium

Figure 12: Inside New Workers Stadium

With a floor area of 380,500 m^2 and 68,000 seats, the new stadium meets the highest standards of FIFA, with the pitch sunk to 11m below ground to form a sunken professional football stadium. The 4-tier grandstand is designed and integrated into 2 tiers on the north side to create a 15,000-seat super grandstand for home fans. The first row of spectator seats is only 8.5m away from the lawn to enhance the sense of intimacy. The sports reconstruction retains the original architectural style as much as possible(Sheng et al., 2021), such as restoring the original eaves and ring bands and other architectural features. For special historical memory construction, such as the old gymnasium outer wall window patterns, reliefs and peripheral sculptures, etc., three-dimensional laser scanning technology and 3D printing technology are also used to repair and reproduce(Wang et al., 2023). Up to now, the new Workers stadium has been put into use for more than two years, as the home stadium of Beijing Guoan in the Chinese Football Super League.

In the design of the space around the stadium, the sparse urban space form of 1959 is restored, a large area of greenery is added, and the water space is upgraded and improved to provide the public with a high-standard space for sports activities. The underground space introduces the concept of integrated operation of underground and business, and actively creates the Greater Sanlitun Business Circle in the form of 'TOD+Block+Mall', providing the city with a new integrated space for sports, culture and business(Du S. et al., 2023).

In the post-summer Olympic Stage, the National Stadium also hosted the 2015 World Athletics Championships, and in 2019, for the opening and closing ceremonies of the Beijing Winter Olympic Games, the National Stadium followed the 'green, sharing, open, clean' concept of running the Olympic Games, the main energy-saving performance of the building to regulate the transformation to meet the sustainable development needs. After the renovation, the 'Bird's Nest' officially opened a new mode of energy saving, low carbon and intelligent service. After the renovation, a large-scale cultural performance to celebrate the 100th anniversary of the founding of the Communist Party of China was held in the National Stadium.

Figure 13 Opening Ceremony of the Beijing Winter Olympics

Figure 14 Large-scale Cultural Performance to Celebrate the 100th Anniversary of the Founding of the Communist Party of China

Table 1: Summary of Beijing Stadiums by Stage

Name	Year	Location	Seating Capacity	Purpose	Architectural Features	Main Activities
Early Development Stage						
Xiannongtan Stadium	1938	Urban South (Xiannongtan)	4,000	The 19th North China Games*	Traditional Chinese Style	Celebrations for the 28th Anniversary of the Founding of the Communist Party of China, etc.
Construction Start-up Stage						
Workers Stadium	1959	Eastern Suburb (Sanlitun)	80,000	The 1st National Games	Socialist Characteristics, Simple and Plain	The 1st to 4th National Games, Mass Political Gatherings, etc.
Asian Games Stage						
Olympic Sports Centre Stadium	1989	Northern Suburb (Beitu Cheng)	20,000	The 11th Asian Games	Modernist Architecture	The 11th Asian Games
Workers Stadium (Renovated)	1986	-	70,000	The 11th Asian Games	Reinforcement, Modern Renovation, Addition of Torch	Main Venue for the 11th Asian Games, Celebration of Hong Kong's Return, etc.
Xian Nong Tan Stadium (Reconstructed)	1986	-	30,000	The 11th Asian Games	Modernist Architecture	Asian Games Events, Jia-A League Matches
Olympics Games Stage						
National Stadium	2008	Urban Nouth (Olympic Park)	80,000 (11,000 temporary)	The 29th Summer Olympics	Technology, Oriental Aesthetics, Olympic Spirit	Opening and Closing Ceremonies of Beijing Olympics and Competitions
Workers Stadium (2nd Renovation)	2000	-	70,000	The 21st Universiade	Reinforcement, Addition of Restrooms and Press Centers	Opening and Closing Ceremonies of Beijing Universiade and Competitions.
Workers Stadium (3rd Renovation)	2006	-	62,000	The 29th Summer Olympics	Reinforcement, Meeting Requirements for Olympic Football Matches	Football Matches of Beijing Olympics, CSL Matches, etc.
Olympic Sports Centre Stadium (Renovated)	2007	-	40,000	The 29th Summer Olympics	Addition of Stands, Renovation of Canopies, etc.	Related Competitions of Beijing Olympics
Post-Summer Olympics Stage						
New Workers Stadium	2023	Original Site	68,000	2023 AFC Asian Cup*	three constant Principles, Integration of Technology and Culture	Opening Ceremony of the 2023 CSL, Chinese Football Super League
National Stadium (Renovated)	2021	-	-	The 2022 Winter Olympics	Green and Low Carbon Sustainable Development	Opening and Closing Ceremonies of the Winter Olympics, etc.

Note: * indicates not held

3. The wave of stadium construction orientated to tournament celebrations: from the region to the world

The development of the stadiums in the capital of China was orientated towards celebrations, with the construction and renewal of the stadiums being associated with major sporting events. After 1978, the stage of stadium construction was even divided on the basis of the dates of sports events. The construction of stadiums in most foreign capitals is also similar to this, with the Olympic Games, the World Cup and other opportunities for stadium construction. China's special characteristics are: the level of the event is gradually increased, the scope of influence of the event is gradually increased, and the importance of the event is gradually enhanced. We have experienced a progressive trajectory in stadium development, evolving from domestic regional games to national-level competitions, followed by Asian-level multisport events, and ultimately culminating in world-class comprehensive games. This progression has also expanded to encompass a wide range of global-scale sporting and cultural activities.

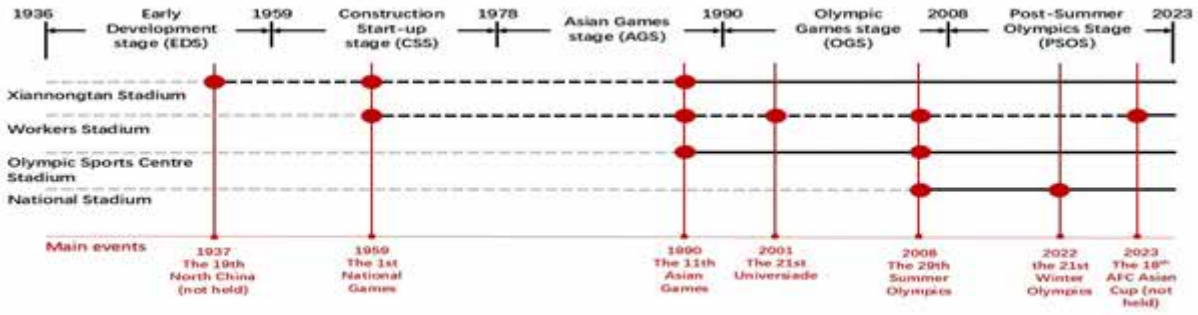

Figure 15: The Development of Capital Stadium Construction under the Orientation of Tournament Celebration

Before the founding of new China, China's social instability, economic foundation is weak, but also unable to hold international events, so this Stage of the country's cities in the construction of the opportunity are all the local games, such as the North China Games. North China Games is also China's modern sports history of the greatest influence, the longest duration of the regional games, held a total of 18 sessions, and then cancelled due to the outbreak of the WWII. For a period of time after the founding of New China, the construction of sports buildings in the capital city was also dominated by simple venues, with a number of simple stadiums built in urban areas in combination with parks and green spaces, and the main events were held in the Xiannongtan Stadium. 1952, after participating in the Finnish Olympic Games for the first time, decision-makers realised that sports performance was related to international status, and therefore vigorously promoted sports during the 'First Five-Year Plan'. During the 'First Five-Year Plan', the construction of sports buildings was vigorously promoted, and after the Great Leap Forward, the Workers Stadium was built to celebrate the 10th anniversary of the National Day of New China and to welcome the first National Games. At this time the country has been on track after ten years of construction, the overall national strength has been improved, the construction of stadiums, held the National Games is a new China's national strength show. There were 24 friendly countries participating in the National Games, which was an expression of the image of the new China and a manifestation of the dignity of the country.

After the reform and opening up in 1978, China sought to organise comprehensive international sports competitions to reflect China's new image and provide new opportunities for international exchanges and economic development. In 1984, Beijing started to organise the 11th Asian Games in 1990, with 'based on the Asian Games, with an eye on the Olympics' as the main construction goal for this Stage, and through this organisation, the Workers Stadium reached the level of advanced stadiums at that time, and new buildings such as the Olympic Sports Centre were built with an eye on the Olympics. Through this preparation, the Workers Stadium Stadium also reached the level of advanced stadiums at that time, and the Olympic Sports Centre and other buildings were newly built 'with an eye to the Olympics', which made the number and level of Beijing's sports facilities greatly improved. After the Asian Games, Beijing declared for the 2000 Olympic Games, but unfortunately failed. In order to gain practical experience in organising international high-level sports events, and to lay a good foundation for further bidding for the Olympic Games(Hou, 2020), Beijing hosted the 21st Universiade, which was the first time that China held a world-class comprehensive sports event, and took this opportunity to upgrade and update the sports buildings in Beijing.

In 2001, Beijing's bid for the Olympic Games was successful, and the related sports stadiums were gradually put on the agenda. By 2008, China had been reforming and opening up for 30 years, and its comprehensive national power had been greatly enhanced. The Bird's Nest, as a unique and unprecedented landmark building, was a renewal of China's image and a demonstration of its national power in the new millennium. After the Olympic Games, Beijing stepped into the Stage of transformation and operation to protect and make use of the Olympic legacy. After the Olympic Games, in addition to hosting the Winter Olympics, the country is seeking the comprehensive development of all kinds of sports events, and hopes to host major events such as the Asian Cup and the World Cup, etc. At this time, the renewal of the capital city's sports buildings is to take these

activities as an opportunity for the balanced, dynamic, highly efficient use of the construction and management of sustainable development.

4. Changes in Architectural Style and Philosophy in the Context of the Times: From Western Learning to Parallel Development

Since the beginning of the last century, the capital stadium has been influenced by the sports, styles, concepts and cultures of different eras in the course of a century, showing colourful and varied changes. Similarly, the social background of China as well as sports and architectural undertakings have gone through different stages of development since the modern times, which have also shaped the soil of the development of the capital stadium. From the background of different Stages, we compare the architecture of the capital stadium with that of foreign countries in the same Stage, and explore the causes of the changes in the architectural style and concept of the capital stadium.

4.1 Early Development Stage: Study of the West and Formal Collage

In this stage, China was in a stage of transformation of the social system under the external war and internal revolution, and the main sports and architectural undertakings were also dominated by the activities of Westerners. Therefore, the stadium construction in China was still in the process of learning from the West and imitating the Western sports architecture, and after absorbing a certain amount of Western experience, it was gradually tracing the traditional Chinese form from the style. A stadium from the same Stage as the Xiannongtan Stadium was the Olympiastadion (Reichssportfeld) in Berlin, Germany, in 1936.

Berlin was again awarded the right to host the Olympic Games in 1931, and the German government decided to remodel the stadium in Charlottenburg, west of Berlin, as the main venue. The Olympiastadion was completed in 1936 with an east-west layout and a double-decker grandstand that could accommodate 110,000 spectators. The stadium was built in expensive materials such as granite, and its form is predominantly Fascist, with a symmetrical layout, soaring vertical rows, and dehumanising superscales to create a solemn atmosphere. The two stadiums are similar in form, controlled by axes and ceremonial at the ends, but the Xiannongtan Stadium is too small, with a capacity of only 4,000 spectators in the early days. Considering the social turmoil and weak industrial economy at that time, the stadiums were out of reach of the West in terms of both the scale of the stadium buildings and the creation of spatial order, and were in the position of learners.

Figure 16: Olympiastadion

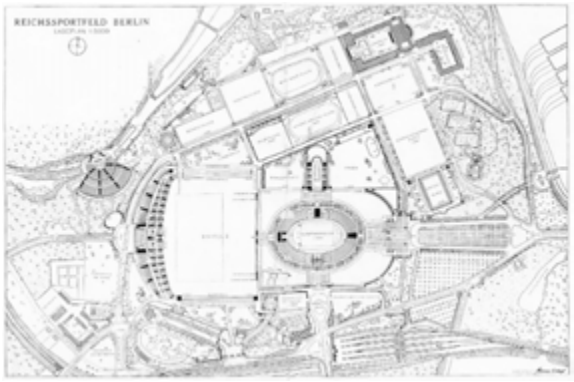

Figure 17: Site-plan of Olympiastadion

4.2 Construction Start-up stage: Soviet Influence and Simplicity and Economy

In the beginning of the construction stage, from 1949 to the Reform and Opening Up, China basically followed a foreign policy of 'alliance with the Soviet Union and opposition to the America', and basically drew its modern architectural nourishment from the Soviet Union. In the early 1950s, the Soviet Union began to provide large-scale construction assistance to China, and the architectural creations were deeply influenced by the Soviet Union ideology, and 'socialist content and national form' became the supreme guidance in architectural creations. After the Great Leap Forward, economic savings itself became a necessary requirement for architectural construction, and reflection on national forms also became the mainstream architectural thinking, at this time, the designers

could not take the 'capitalist' road of modernist architecture, so they could only weaken the attention to architectural forms as much as possible, and reduce the architectural features in form.

The Soviet Union was also in the midst of the Khrushchev era, and after 1955, the Soviet Architectural Society under Stalin was abolished, abandoning the 'Stalinist' aesthetic and replacing it with an architectural style aimed at pursuing high efficiency and economic benefits. The Central Lenin Stadium, built before the Workers Stadium, bears a strong resemblance to it. Built in 1956, Luzhniki Stadium (Стадион 'Лужники'), known as the Central Lenin Stadium before the collapse of the Soviet Union, is located on the banks of the Moscow River in the south-west of the city, and was the national stadium of the Soviet Union (also Russia), as well as the largest stadium, which was constructed for the purpose of hosting the Spartak Games of the Soviet People in 1956. Built under the direction of Alexander Vlasov, it has a total of 80,000 seats. The stadium's architectural style is simple and frugal, and it has undergone a number of alterations and extensions in later years.

The two buildings, the Workers Stadium and the Luzhniki Stadium, are similar in form and volume, and show the same architectural style and compositional features, and the buildings of the capital city in this Stage were deeply influenced by the Soviet architectural style. Among them, the biggest difference between the Workers Stadium in terms of elevation is that the Luzhniki Stadium emphasises vertical composition, with robust and powerful columns with vertical bar windows and designed with curved porticos, while the columns of the Workers Stadium are thinner, and the horizontal bar windows emphasise the horizontal composition in a more minimalist way. The completion of the Labour Stadium not only demonstrates that China has the ability to build mega stadiums after 10 years of development, but also assumes more political meanings, its name is closely related to the historical position of the working class and the main theme of the times, which emphasises the development of the country's national strength and the awakening of the country's will, and at the same time, swears to the independence of the country from the cultural and spiritual level.

Figure 18: Central Lenin Stadium

Figure 19: Site-plan of Stadium

4.3 Asian Games stage: Catching up with the West and Connecting with the World

After the reform and opening up in 1978. Lifting the political burden, sports architecture began to get rid of the limitations of national sentiment, the formal thinking of sports architecture quickly turned to modernism, and domestic sports architecture designers began to learn from the experience of advanced Western venues. Under the background of internal reform and opening up to the outside world, Chinese sports architecture also began to connect and catch up with advanced western sports architecture. In this Stage, the planning of a large sports centre appeared for the first time in the capital. The overall planning of the Olympic Sports Centre is people-oriented, and it is the first large-scale sports park in China to achieve the separation of pedestrian and vehicular traffic and a barrier-free environment for the whole field(Ma, 1990). In terms of building technology, the Olympic Sports Centre stadium is the first in China to adopt the canopy technology of steel pipe space mesh shell.

A similar foreign building to this phase is the Stadium of France (Stade de France), built in 1998. Located in the north of Paris, the Stadium of France is the national stadium of France and the home of the national football

team, and was built for the 1998 FIFA World Cup with a seating capacity of 80,000 people. The design idea is 'open, transparent and fluid', and its architectural image consists of a vertical facade and a horizontal ring (roof) suspended above the stadium. The curved steps give the building a sense of movement, while the roof discs 'floating' above the city symbolise the dexterity of movement(Hu & Zhang, 1998). The Stade de France was characterised by 'high technology', with its suspended circular roof and mobile stands being the most advanced designs of the time. Comparing with the high technology, high efficiency, adaptable and changeable development direction of Stadium of France in the same Stage, although some new technical means have been applied in the Olympic Sports Centre Stadium, it is still in a catching-up stage compared with it in all aspects.

4.4 Olympic Games stage: Parallelism and Cultural Expression

After the new millennium, China's political situation has stabilised, its economic level has greatly improved, and the society has developed in a comprehensive and harmonious manner; sports architecture has also faced multiple development opportunities and has developed rapidly. International competitions for sports buildings have provided opportunities for foreign design organisations, and a large number of advanced design ideas and technologies have been conveniently introduced into China, directly promoting the progress and development of Chinese architectural design. The National Stadium, as a co-operation work between a foreign firm and a Chinese design institute, not only reaches the world advanced level in overall planning, structural technology and functional layout, but also contains 'the oriental aesthetic thought of order and introspection' and 'the perfection of a single object'. It combines Chinese oriental aesthetics and humanistic style with contemporary art and Olympic sportsmanship(Li, 2008).The design of sound, light, heat and drainage fully embodies the concept of Green Olympics.

The London Olympic Stadium ('London Bowl'), which was completed 4 years later, has a different architectural character from the 'Bird's Nest'. Located in the Stratford district of East London, the stadium is designed for 80,000 people. Since the London Olympics began with the themes of 'sustainability' and 'economy', the concept of 'sustainability' has been incorporated into the design, with the stadium being constructed as a lightweight frame with a steel composite base. The main structure of the stadium is a lightweight frame, with a basic steel hybrid structure forming the main body of the stadium. Plans to demolish the upper levels after the games to reduce the size of the stadium to a permanent 25,000-seat venue did not materialise and the stadium is now used as the home of West Ham United of the Premier League. Compared to the two stadiums, the 'Bird's Nest' focuses more on appearance and practicality, and is a display of national culture, national image and national strength. As London itself has large stadiums such as Wembley Stadium, the 'London Bowl' focuses more on practicality and economy. The difference between the two venues is a reflection of the economic and cultural background of the two countries.

Figure 20: Stadium of France

Figure 21: London Olympic Stadium

4.5 Post-Summer Olympics Stage: Cultural Confidence and Low Carbon Sustainability

In the post-Olympic era, China's economic development has undergone a historic and substantial change, entering

the stage of 'adjustment, optimisation and upgrading', and industrialisation, specialisation, and a balanced focus on competitive and popular sports have driven the development of the sports industry. In the construction industry, the design and construction of buildings return to the rational road, iconic no longer become the only pursuit, green ecological and sustainable construction has become an important way out of the development. In the context of cultural self-confidence and national rejuvenation, cultural heritage, respect for tradition and integration of science and technology became the mainstream of design in this Stage.

The capital stadium in this Stage is represented by the New Workers Stadium. As a professional football stadium, the new stadium has a high degree of integration of technology and culture, reproducing the simple appearance of the old stadium with the technique of fair-faced concrete. The canopy adopts the creative concept of 'national prosperity and people's peace, gold purlins', and uses the rib-supported single-layer arched shell structural system to present the classic composition of "'San Jiao Liu Wan' (Three Crossings and Six Rays) decorative motif" window lattice(Sheng et al., 2021). The canopy also integrates the functions of sun shading, lighting, siphon drainage, snow melting, photovoltaic power generation and acoustic noise reduction, which maximally realises the sustainable concept of the whole life cycle to reduce the energy consumption of the building and practice the concept of green and low-carbon.

A similar project from the same Stage was the Santiago Bernabeu Stadium (Estadio Santiago Bernabéu) in Madrid, Spain. Located in the north of Madrid, the stadium is an iconic landmark in Madrid and is one of the home stadiums of Real Madrid FC and the Spanish national team. The stadium has a capacity of 81,000 people. Due to new demands for use, the stadium, built in 1947, will be remodeled in 2020, using high-tech elements to create a new experience for fans(Gmp Architects, 2024). The renovation project will cover the building's unified image with a softly curved surface formed by metal louvres, and a translucent curtain wall that connects the inner and outer scenes, enriching the view of spectators and pedestrians, and giving a unique spatial quality to the public environment around the stadium. At the same time, the design takes into full consideration of the surrounding urban space, and will include additional viewing corridors, movable roofs, commercial complexes and other service facilities. A sense of technology, integration with the urban space, humanised experience, and the addition of commercial operations characterise the stadium's architectural design in this new era.

On the basis of 'sustainability', the New Workers Stadium actively integrates into the city, and adopts the concept of integrating metro and commercial operations in the underground space for operation and maintenance, which is very similar to the design concepts of technology, commerce, humanity, and localisation of Madrid's Bernabeu Stadium, but with more respect for tradition and cultural expression.

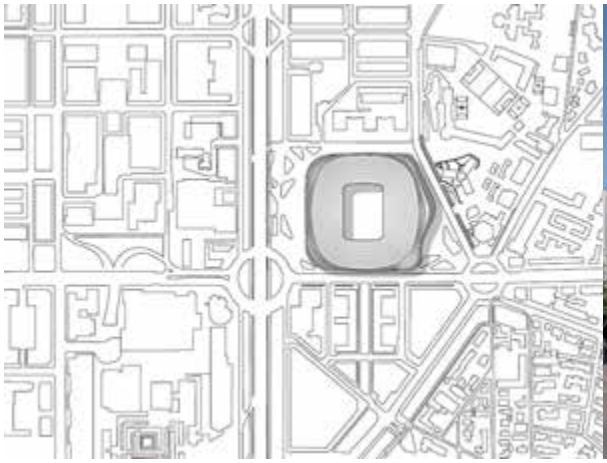

Figure 22: Site-plan of Bernabeu Stadium

Figure 23: Bernabeu Stadium

In conclusion, within the broader historical and cultural context, the stylistic evolution of China's capital stadiums has undergone a complex trajectory, transitioning from an initial phase of Western influence and appropriation, through a Stage marked by eclectic formal collages and Soviet-inspired models, towards a convergence

with international architectural trends. This developmental path ultimately culminated in a dynamic shift characterised by growing cultural confidence, alongside an increasing emphasis on low-carbon and sustainable design principles.

Table 2: Comparison of Capital Stadium buildings from different stages

Stage	New Building	Time	Scale/Capacity	Architectural Features
1 EDS	Xian Nong Tan Stadium	1936	Medium /30,000	Traditional Chinese style, modern sports
2 CSS	Workers Stadium	1959	Mega /80,000	"Soviet-style", frugal and economical
3 AGS	Olympic Sports Centre	1986	Large/40,000	Modernist architecture, new structural systems
4 OGS	National Stadium	2007	Mega /80,000	Technology, Oriental aesthetics, Olympic spirit
5 PSOS	New Workers Stadium	2023	Mega /68,000	Fusion of technology and culture, sustainability

Table 3 Comparison of backgrounds from different stages

Stage	Social	Architectural	Political	Economic
1 EDS	Transformation of social systems amidst external wars and internal revolutions	Western-dominated activities, beginning of modern architecture	Internal and external turmoil	Low level
2 CSS	Exploration of socio-political structures centred on political forms	Establishment of architectural systems, influenced by the Soviet Union and politics	Internal exploration	Low level
3 AGS	Economic reform and opening up with a focus on economic development and societal progress	Flourishing architectural theories and technological advancements	Stability	Initial development
4 OGS	Economic advancement and societal openness under globalisation influences	New developments in architectural theory, industry liberalisation and institutionalisation	Openness	Rapid development
5 PSOS	Emphasis on economic quality and low-carbon humanism post-rapid development	Continuous advancement in building science and technology, embracing new urban design concepts	Inclusiveness	Quality development

Table 4: Comparison of other countries' stadiums in different stages

Stage	Other Country Stadium	Time	Scale/Capacity	Architectural Features
1 EDS	Germany - Berlin Olympic Stadium	1936	Mega /110,000	Super-scale, solemn
2 CSS	Soviet Union - Luzhniki Stadium	1956	Mega /80,000	Frugal and economical

Stage	Other Country Stadium	Time	Scale/Capacity	Architectural Features
3 AGS	France - Stade de France	1998	Mega /80,000	High-tech, adaptable
4 OGS	United Kingdom - London Olympic Stadium	2012	Mega /80,000	Sustainable, economical
5 PSOS	Spain - Santiago Bernabeu Stadium	2024	Mega /81,000	Technological, humanised

5. The Changing Relationship between Stadium Architecture and the City: Connecting History, Present and Future

5.1 Trend towards the convergence of stadium siting

In the site selection of the stadium building in the capital, it presents the characteristics of siting in the peri-urban area of the city boundary and moving outward with the development of the city. In 1936, the vicinity of Xiannongtan was a peri-urban area, and the stadium was 3.8 km away from Tiananmen Square(city centre); by the end of the 1950s, the urban area of Beijing was gradually expanded, and Youth Lake in the eastern suburb was chosen as the site of the Workers Stadium, which was 4.8 km away from Tiananmen Square, and the site of the Olympic Stadium Centre in the 1980s was even further to the north, which was 8.4 km away from the Tiananmen Square; after the new millennium, due to the development of the city, the construction of a mega stadium was not suitable for the south side of the Olympic Stadium Centre. After the new millennium, due to urban development, it was not suitable to build a mega-stadium on the south side of the Olympic Stadium, so the National Stadium was even further north, with a distance of 9.5 km from the centre; in the post-Olympic era, the city has reached its limit of development, and the location of the Workers Stadium has changed from a suburban area to the core area of the city, so the restoration of the stadium will enable it to be better integrated into the city to serve it. Compared with other national stadiums, Berlin Olympic Stadium is the furthest away from the city centre, located 11 km to the west, while Madrid Bernabeu Stadium is the closest, only 4.2 km away, and most of the other stadiums are between 6 and 8 km away. It can be seen that the sites of the capital stadiums, after moving outwards to their limits, will gradually stop moving and will instead be invested in the renewal of the existing stadiums, forming a spatial core that is constantly integrated into the city.

5.2 Trend towards composite stadium functions

In the overall planning of the Capital Stadium, it can be seen that the overall presentation of the small venues to large single venues, to sports centres, sports parks and then to urban parks, culture, tourism and business integration space of the development of the transformation, which reflects the capital stadium venues layout more intensive and organic, venues function gradually composite integration, the construction of more flexible mode of operation, the public participation continues to enhance the characteristics of the stadium.

In terms of venue categories, it can be seen that integrated stadiums such as the Bird's Nest, London Bowl, Luzhniki Stadium and other integrated stadiums are often used as one of the buildings of the sports centre, forming a cluster effect with other venues to better serve large-scale integrated tournaments, while professional football stadiums such as the New Workers Stadium, Stade de France and Bernabeu Stadium are mostly operated and maintained as independent stadiums in the city's core area, which are also more flexible in terms of the number of events and activities held in the stadiums. This is also more in line with its main activities such as football tournaments. The introduction of commercial, leisure, cultural and tourism businesses in the New Workers Stadium and the new Bernabeu has enabled the stadium to become a city landmark, cultural and sports business card, and a centre of vitality. The attention to urban spatial integration and infrastructure compensation will further drive the overall improvement of the surrounding environment, making the stadium a sports complex in the city, and contributing to the new pattern of 'stadium-region' integrated and linked development in the city.

5.3 Trend towards the adaptive reuse of sports architectural heritage

Major stadiums in capital cities, as events or Olympic legacies, are not only static buildings but also dynamic cultural vehicles. In response to the multiple challenges of tourism, gentrification and climate change, the capacity of the stadiums should be continuously upgraded in order to redefine their social function and cultural

significance. In this regard, it is important to enhance the sustainability of the building, for example, by retrofitting it with a new energy recovery system, enhancing the connectivity of the urban space, for example, by optimising public transport connections, increasing public participation, for example, by utilising NGOs to organise events and implementing a policy of free admission, integrating the land around the building, integrating the renovation and development of the building, revitalising the space, utilising the intensity of the use of the venue by means of an innovative investment and financing model, and enhancing its spatial relevance to the urban environment. And enhance the spatial correlation with the urban environment. This will strengthen their role in improving the quality of life of urban residents and stimulating urban vitality.

6. Conclusion

Beijing stadium architecture, especially the national stadium, is the window and embodiment of the national image and national culture. This paper takes vertical and horizontal comparison as the main vein to analyse the construction background, building scale, construction concept and architectural image of the capital stadium architecture in different periods. At the same time, it also compares the stadiums of other countries in the same period horizontally, explores the unique temporal characteristics behind the stadiums, sums up their architectural features and concepts, and finally concludes that 'The wave of stadium construction orientated to tournament celebrations: from the region to the world' and 'Changes in Architectural Style and Philosophy in the Context of the Times: From Western Learning to Parallel Development'. It provides new ideas for the construction of stadiums in the capital city and other cities and the display of national dignity. We also summarise the urban development characteristics of stadiums in terms of their relationship with the city, and propose optimisation strategies that not only enhance public participation and promote the synergistic and sustainable development of architecture and urban space, but also ensure that these iconic stadiums continue to play a key role as important carriers of the national image, connecting history, the present and the future.

Abstract
Incremental historic urban district renovation has emerged as a political consensus and trendy research field in China. However, intertwined challenges have made sustainable incremental renovation an increasingly demanding job. Evaluating incremental HUD renovation and exploring the potentials and limitations of such incremental approaches have become key topics in contemporary research. This paper proposes a theoretical and technical framework to evaluate HUD renovation processes and results regarding sustainability principles. With this framework, the paper evaluates the DSN quarter in Old Peking—one of the most representative cases of incremental urban renewal in China. Based on this evaluation, the paper identifies the key strengths, potentials and challenges of this emerging pattern, offering learnings towards sustainability for historic urban districts in and beyond Beijing Hutong.

Key words: Incremental historic urban district renovation; Beijing Hutong; evaluation; sustainability

1. Introduction

Incremental renovation, an urban renovation/redevelopment/renewal approach that "does not resort to wholesale demolition" and occurs without large-scale displacement (Shih, 2017; Wu, Zhang and Liu, 2022)derived from and defined by local entrepreneurial governance. However, changing state politics, in particular national political mandates, has not been adequately addressed. Through examining variegated practices, this paper understands how the changing national political context affects or redefines local redevelopment projects. These cases reflect local responses to the national campaigns for rural vitalisation and "Beautiful China", heritage preservation and "incremental regeneration" (weigaizao, has been long considered as a scholarly consensus among urban planners and scholars in China as well as a recommendation for historic urban district (HUD) renewal. Wu Liangyong, one of the most influential figures in this discourse, created "organic renewal theory") based on the Ju'er Hutong renovation project in the inner Peking. Wu advocated for a metabolic renovation process to achieve "sustainable development," applying different policies – such as conservation, demolition, etc. -- depending on the physical quality and the cultural significance of individual courtyards in HUDs. (Wu, 1994, pp. 63–69) Since the turn of 21st century, as China joined the WTO in 2000 and successfully bid for hosting the 2008 Olympics in 2001, the country has been further engaged in world industrial division and cultural exchange. Heritage conservation and cultural branding have been increasingly vital in the context of inner city renovation in China's urban development, especially in major metropolitan areas such as central Beijing (Tang and Zhang, 2021). In response, a growing number of scholars and local citizens have criticized the large-scale HUD demolition and replacement, once the "mainstream" mode of redevelopment since the late 20th century, for their adverse effects on urban conservation and social justice. (Fang, 2000) However, "dull-dozer redevelopment" remained to be in dominance in the 2000s driven by profit-oriented objectives under the joint control of local governments and real estate developers.

Incremental renovation became a widely-accepted political consensus (Ni, Zhang and Huang, 2017) and a popular trend (Wu, Zhang and Liu, 2022)derived from and defined by local entrepreneurial governance. However, changing state politics, in particular national political mandates, has not been adequately addressed. Through examining variegated practices, this paper understands how the changing national political context affects or redefines local redevelopment projects. These cases reflect local responses to the national campaigns for rural vitalisation and "Beautiful China", heritage preservation and "incremental regeneration" (weigaizao in China in the early 2010s, especially in HUD renewals. The shift was largely driven by central government's strong will and commitment (Wu and Zhang, 2022) to heritage conservation and community construction as deepening the "all-round reform." (China Daily, 2013) In addition to the top-down effort, the growing instability of the financial mechanisms underpinning large-scale "bulldozer" redevelopment programs further accelerated the transition toward incremental approaches in the late 2010s. Compared to bulldozer redevelopment, incremental HUD renovation with limited demolition and replacement, has been widely considered to be more sustainable

regarding economic, social, and cultural dimensions. It can contribute to preserving the spatial framework of the old city, the texture of the historic district, traditional architecture, traditional craftsmanship and customs, etc. (Ni, Zhang and Huang, 2017; Chen, 2021, p. 152; Wu, Zhang and Liu, 2022)derived from and defined by local entrepreneurial governance. However, changing state politics, in particular national political mandates, has not been adequately addressed. Through examining variegated practices, this paper understands how the changing national political context affects or redefines local redevelopment projects. These cases reflect local responses to the national campaigns for rural vitalisation and "Beautiful China", heritage preservation and "incremental regeneration" (weigaizao. It can also help to maintain local social network and collective memory, enhancing residents' sense of community belonging. (Chen, 2021, pp. 156–161; Wu, Zhang and Liu, 2022)"publisher":"China Architecture & Building Press","publisher-place":"Beijing","title":" (The Research of Protection Renewal and Regeneration of Historic District: The Case of Three Blocks and Seven Alleys Historic District in Fuzhou Moreover, incremental renovation allows for "flexible social capital investment influx" and helps to "avoid market risk" (Fang, 2000; Chen, 2021, pp. 165–166), making it a resilient strategy for sustainable urban regeneration.

This study focuses on incremental renovation in Chinese HUD renovation by raising up the following research questions: Can the incremental HUD renovation modes in China align with sustainability principles? What are the potentials and limits of the current incremental approaches? By evaluating a typical Beijing Hutong case -- Dongsinan (DSN) renovation -- against a sustainability-based framework, the study will offer reflections and recommendations on incremental HUD renovation practices in China. Section 2 will develop an evaluation framework grounded in sustainable principles. Section 3 will introduce the case site, outline the major challenges of Hutong development and conservation, and introduce the data collection methods. Section 4 will present the evaluation results, while Section 5 will provide reflections and discussions informed by the findings especially on the potentials and limits of the current incremental renovation mode.

2. Sustainability principles in incremental HUD renovation

2.1 Literature review on sustainability

"Sustainability" has emerged as a prominent global discourse in the 21st century. (Li, 2025) The concept highlights integrity across multiple dimensions, encompassing environment, social development, economy, and culture. (Strezov, Evans and Evans, 2017; Sabatini, 2019; Zhao, Zhao and Hui, 2021; Najjar, 2022; Li, 2025)comprising Change in Wealth Index (CWI It also features both intergenerational and intragenerational "justice" among diverse actors. (Neugebauer, 2014, pp. 69–74) As urban heritage has been recognized among "central components" towards sustainable urban development (UNESCO, 2016, p. 22), understanding and interpreting "sustainability" principles in the HUD renovation contexts provide a basis for evaluating renovation cases and generating learnings from past experiences.

"Sustainability" in the HUD renovation refers to both sustainable processes and sustainable results. (Li, 2025) With regard to sustainable HUD renovation processes in response to the increasingly complex and intertwined challenges with uncertainties, a body of literature highlights the importance of a strategic approach. Such an approach highlights both integrity -- integrative vision, inclusive participation, and integrative governance and institution design – as well as adaptiveness, which requires both consistency and flexibility in the course of time and varying scenarios. An integrated and adaptive strategic thinking, offering "a set of concepts, procedures, and tools" towards fixed objectives or open visions (Wiechmann, 2007), can contribute to organising thinking, setting direction, focusing on effort, defining organization, providing consistency, and reducing ambiguity. (Mintzberg, Ahlstrand and Lampel, 2005, pp. 15–17) It can play a crucial role in addressing the complexities and uncertainties in HUD renovation. Carter and Roberts (2017, p. 50) identified a set of key features of a sustainable strategic approach drawing on extensive theoretical research on urban issues. They highlighted the importance of recognizing the inherent complexities involved, maintaining consistency of objectives under a long-term vision, and facilitating broad-based participation of both "bottom-up" and "top-down" interests throughout the entire process. They also underscored strategic adaptiveness, highlighting the need for creating a self-sustaining system open to ongoing adjustment and refinement, alongside regularly monitoring and evaluation. Other key principles included building consensus creation under a shared strategic vision as well as ensuring transparency in information dissemination. The HUL Guidebook (WHITRAP et al., 2016, p. 13) outlines a six-step methodology for strategy development, highlighting comprehensive survey and mapping, participatory planning for consensus building, integrated value and vulnerability assessment, action prioritization, and partnership establishment.

As HUD renovation has been increasingly incremental and emergent, strategic approaches are required to incorporate "embedded flexibility" (Van Karnenbeek and Janssen-Jansen, 2018) in response to the complex urban systems. Since the renovation results may be "provisional and contingent," (Dovey, 2014) in recent decades emphasis has been turned to institutional design—or "the rules of the games" (North, 1990)—by a number of scholars, including D.A. Jelincic and Y. Mansfeld (2019) and Dovey (2014). In addition, an adaptive development model featuring "gradual adjustment of routines as a reaction to the dynamic environment" grow out of "collective learning" has been proposed in addition to the traditional linear, fully-formulated, and "from ends to means" strategy model (Wiechmann, 2007).

As for sustainable results, the expected and un-expected outputs, outcomes, and impacts of HUD renovation actions should be taken into account. A comprehensive understanding of sustainability in HUD renovations requires the integration of multiple dimensions—typically environmental, economic, social, and cultural. Scholars have developed a variety of multicriteria assessment methods and indicator systems to evaluate sustainability, either holistically (Neugebauer, 2014; Kou et al., 2018; Lin et al., 2021) or from specific disciplinary perspectives. There is also a growing body of literature on Impact Assessment (IA), such as Heritage Impact Assessment (Ashrafi, Neugebauer and Kloos, 2022), Environmental Impact Assessment (Glasson and Therivel, 2013), and Social Impact Assessment (Sairinen and Kumpulainen, 2006; Yung, Chan and Xu, 2014, 2015), providing detailed discussions and criteria for different (potential) impacts of the renovation efforts in ex-ante and/or ex-post contexts. All these studies contributes to a comprehensive understanding of how to describe, assess, and evaluate the multifaceted outcomes of HUD renovation projects.

2.2Incremental HUD renovation evaluation framework on sustainability

Based on the literature view on "sustainability," the study proposes an evaluation framework of both sustainable HUD renovation process and results. In evaluating the renovation process, sustainability is interpreted through four key dimensions: integrated vision, justice, adaptiveness, and robust institutional support. An integrated vision involves both integrative value interpretation and comprehensive strategic objective or direction setting. Justice mainly refers to the fair participation among different actors, especially the local communities and the experts since in China the party-state can always be in a dominant position in HUD related issues. Adaptiveness should also be highlighted in an incremental and emergent process in the course of time. Last but not least, robust institution design, or game rules design, such as resource allocation and negotiation system, can be essential for guiding ongoing, open-ended renovation efforts and achieving long-term strategic goals. With regard to the outcomes, a comprehensive assessment should consider the impacts across environmental, economic, social, and cultural dimensions. Figure 1 and Figure 2 list the key evaluation criteria derived from the literature, which will subsequently be applied to the case of the DSN Hutong renovation by evaluating to what extent the DSN case is in line with sustainability.

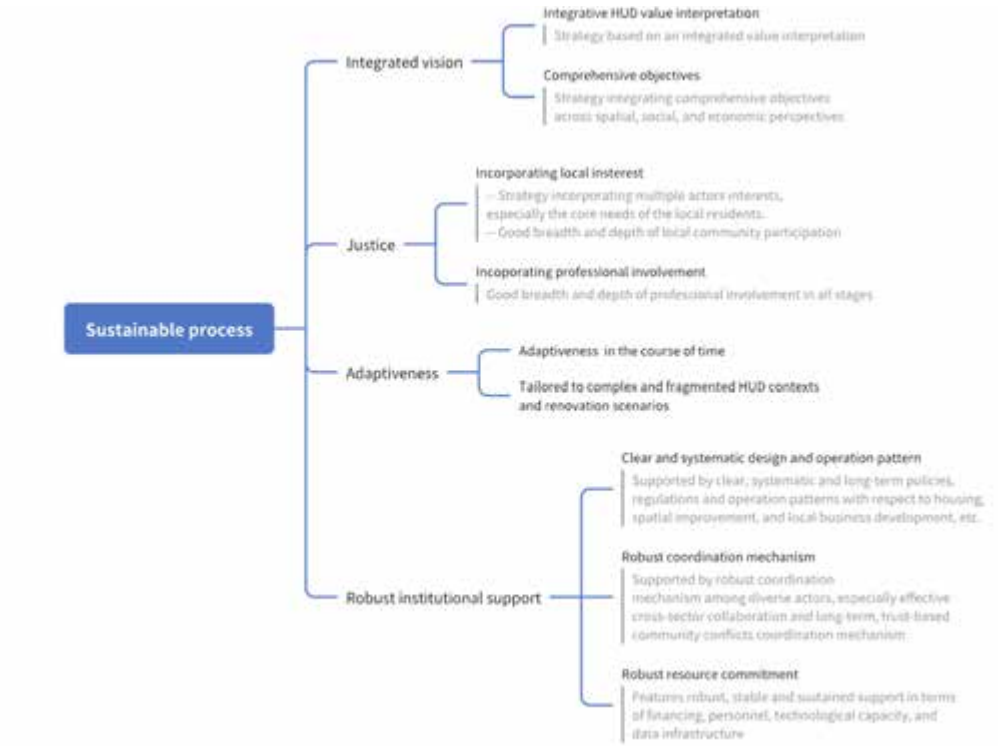

Figure 1: Criteria for sustainable processes (key reference: (Carter and Roberts, 2017; Li, 2025))

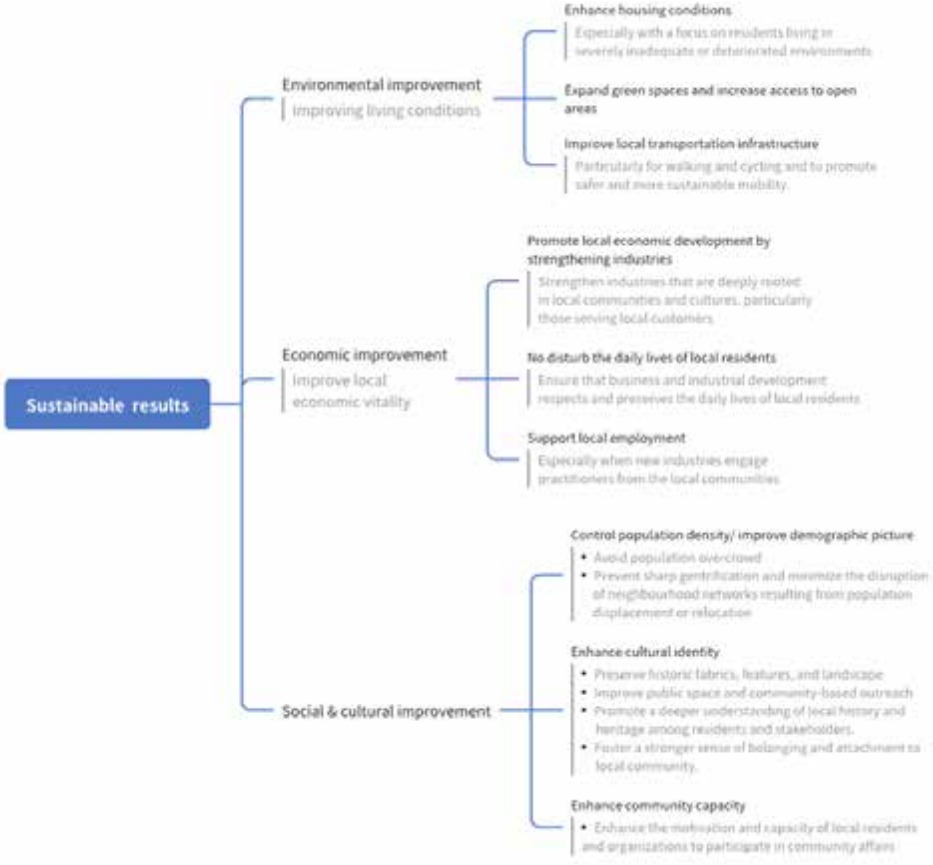

Figure 2: Criteria for sustainable results (key reference: (Neugebauer, 2014; Shi, Bian and Ge, 2015; Lin et al., 2021; Li, 2025))

3. Case study: DSN Quarter in Beijing Hutong

3.1 Key challenges for Hutong renovation

Beijing Hutong quarters are typically residential and commercial-residential HUDs in China, located in the central area of the city. These quarters feature a traditional spatial pattern of Hutong (narrow alleys) – siheyuan (courtyard houses). A Hutong (alley) refers to a narrow alley lined by the exterior facades of courtyard residences, while siheyuan, also known as a Chinese quadrangle, typically consists of inner yard enclosed by one-story houses. Historically, a single Siheyuan was often inhabited by an extended family; however, in contemporary times, these courtyards are usually shared by multiple households. Beijing Hutong quarters possess significant historical, social, and economic value. They exemplify traditional Chinese urban planning principles and embody the cultural philosophy of rites and order. However, in the recent decades, Beijing Hutong and its associated renovation efforts have faced a range of complex and pressing challenges.

Figure 3: Beijing Hutong (DSN Quarter), photoed in Nov 2023 (left) and June 2024 (right)

First, the Hutong quarters suffer from population-space conflicts. Accommodating a large population within spatially constrained environment has resulted in the limited living space, informal self-built additions within the yards, and encroachment on public and semi-public areas[1] with their personal items, which further undermines the historical spatial pattern and landscape, adds to the difficulties in improving local residents' living conditions, and may even exacerbate tensions among residents when competing for limited shared space. (BUT Research Team on Dashilar, 2019) Second, the Hutong quarters feature spatial and social fragmentation. There can be considerable differences among different courtyards in terms of property right management, courtyard neighbourhood relations, and households' willingness to engage in relocation or renovation processes in Hutong Quarters. (Shi, 2022, pp. 159–184) Therefore, a uniform approach or "one-size-fits-all" policy is unlikely to be effective. Renovation efforts need to take into account the diverse preferences and conditions of individual households featuring flexible and context-sensitive strategies tailored to different scenarios.

Third, the Hutong quarters remain insufficiently robust in terms of grassroots management. As the Danwei-allotment system in the planned economy time collapsed in the late 20th century, an institutional vacuum emerged regarding the grassroots management. Though local Neighbourhood Committees,[2] Street Offices[3], and certain

1 The "semi-public" space here mainly refers to the yard space inside the courtyards, usually shared by multiple families.

2 Neighbourhood Committee is the fundamental local-based organization in urban China featuring a dual character of both residents' self-governance organization at the grassroots level and quasi-state administrative agency.

3 Street Offices, or "街道办" in Chinese, is the administrative agency of the district-level governments. They are always the lowest formal state governance agency in urban China.

local community organizations have taken on responsibilities in local management, grassroots management are still suffering from unclear delineations of rights and obligations among different actors, limited local resources and power, and authority fragmentation among sectors. The weak local management institution construction has posed challenges for effective community participation and interdisciplinary collaboration in HUD renovation processes.

Last but not the least, local Hutong communities have limited capacity for sustainable product production and consumption. It can be difficult for local residents, especially the underprivileged, to "generate their own blood." In addition, due to the increasingly stringent control of commercial and tourism developments in HUDs in Beijing (BMBCT, 2021), the "rent gap" (Smith, 1979) in these areas has been reduced, limiting opportunities for economic revitalization and capital inflow into the Hutong quarter.

3.2 DSN Renovation

DSN Hutong quarter is located in the Dongcheng District of Central Beijing. It retains a historical spatial pattern of Hutong alley-courtyard, though now a single courtyard has often been shared by multiple families. Since the early 20th century, the quarter has attracted a number of educational and administrative institutions and has become a favoured residential and gathering place for prominent figures in literature, education, and modern science. (BMCPNR, 2021) The quarter spans around 1,24 km^2 and holds around 40, 000 long-term residents. (Chen, 2020, p. 29) Like many other Peking Hutong quarters or HUDs in China, DSN quarter faces intricated challenges towards sustainable development.

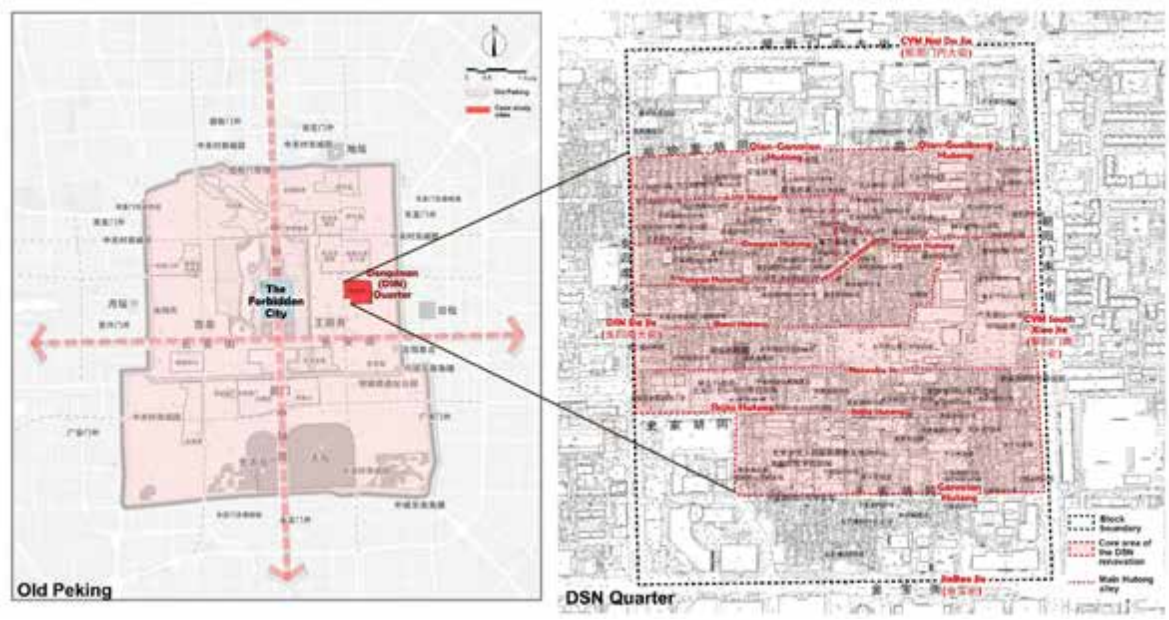

Figure 4: DSN quarter (base map of the left: (BMCPNR, 2018); base map of the right(BMCPNR, 2021))

DSN renovation is one of the most representative incremental HUD renovations in China. Initiated in 2010, it remains an ongoing process till today. Instead of following a linear trajectory, DSN renovation features open-ended development towards comprehensive community building and renovation. The renovation can be categorized into three phases: an incubation phase (2010–2013), characterized by tentative strategy-making through community workshops and the pilot renovation of Shijia Hutong Museum (SHM); a phase of institutional development (2014–2018), focused on community-based institutional construction and renovation efforts led by the Shijia Hutong Style and Feature Conservation Association (SHSFCA)[4], a local organization established in 2014; and a phase of comprehensive exploration (2018–present), marked by the development of long-term responsible planner cooperation and the creation of a collaborative management platform, known as "DSN Platform" for short, DSN renovation come to a new period, featuring multiple series of cooperative across the Quarter.

4 SHSFCA is composed of local residents, property-right danwei, local party state members, experts from universities and planning institutes. (Feng et al., 2020, p. 3)

Up till now, DSN renovation has accumulated experience in developing local organization institution and has established several renovation patterns for incremental spatial improvements exemplified by round-by-round residential courtyard improvement, historic courtyard rehabilitation, and micro-public space renovation. Additionally, it also highlights cultural outreach and capacity building.

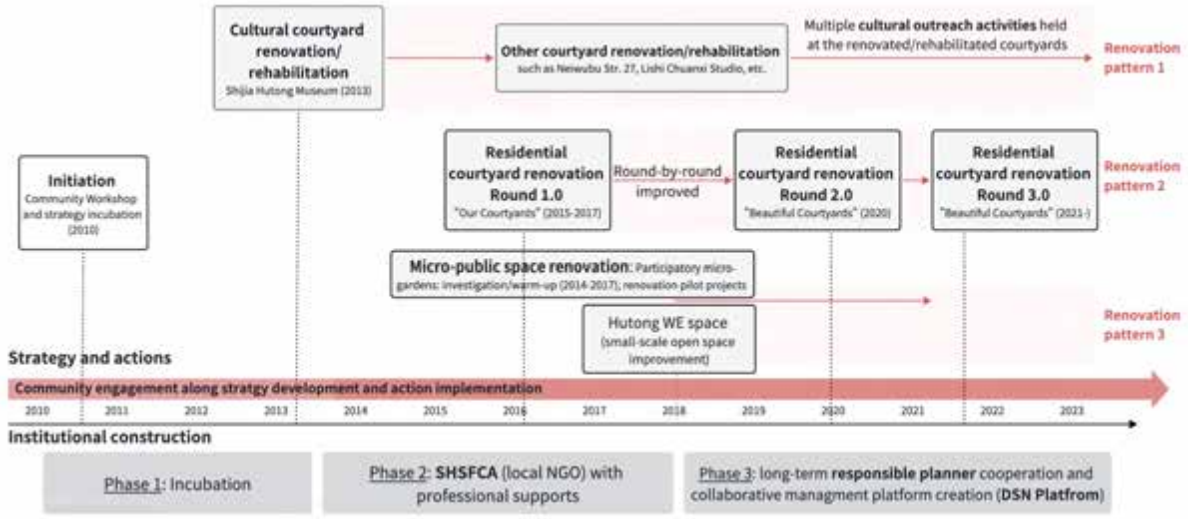

Figure 5: DSN renovation procedure (Li, 2025)

3.3 Data Collection

In order to assess and evaluate DSN renovation processes and results against sustainability, data were collected through three primary methods: (1) literature review; (2) direct field observation in the field trip; and (3) semi-structured interviews.

The literature review draws upon a wide range of sources, including governmental notices and documents, academic publications (books, journal articles, theses, etc.), community bulletins, newspapers, and official media outputs. Field observations were conducted during site visits to the DSN Quarter in November 2023 and June 2024, covering most of the public spaces within the HUD. During these visits, careful measures were taken to minimize the influence of the researcher's presence on the observed environment. Semi-structured interviews were conducted from November 2023 to June 2024 with a range of key stakeholders, including experts directly involved in the renovation process, members of local Neighbourhood Committees (NCs) representing the resident communities, and representatives of NGOs and guest performers engaged in community outreach. All interviewees were informed of the study's purpose in advance, and notes or audio recordings were made with their prior consent.

4. Results

Based on the literature review, field observations, and interviews, the study presents preliminary evaluation results referring to the framework and criteria on sustainable HUD renovation processes and results.

Table 1: Process evaluation of the DSN case

Criteria		Assessment and Evaluation
Integrated vision	Integrative HUD value interpretation	Mostly in conformity (For) The strategy is grounded in an integrated HUD value interpretation, especially the social and cultural values. (Against) However, there is still a long way to go to create "value consensus" and clear bottom lines among different actors.
	Comprehensive objectives	Fully in conformity (For) The strategy addresses multiple objectives regarding spatial, social and cultural perspective with a long-term vision.
Justice	Incorporating local interest	Partly in conformity (For) The renovation is relatively open to local residents engagement, especially compared with the non-incremental HUD renovation cases in China. (Against) The strategy can be limited regarding housing condition improvement, which is the residents' primary concern (Shi, 2022, p. 226) Resident participation mainly stay in the level of tokenism according the citizen participation ladder (Arnstein, 1969) and still limited in terms of genuine decision-making power.
	Incorporating professional involvement	Mostly in conformity (For) The renovation features "responsible planners" system and exhibits good depth and spectrum of professional participation in the entire process. (Against) The power and working scope of the responsible planners can be depended on the altitude of local street office.
Adaptiveness	Adaptiveness with consistency in the course of time: Tailored to diverse and complex renovation scenarios	Mostly in conformity (For) The strategy adopts an incremental, step-by-step approach, allowing for continuous adaptation based on feedback, thus balancing consistency with flexibility over time. The strategy features small steps at a time and tailored to the fragmented HUD courtyard contexts. The strategy features wide-range cooperation with third parties, enhancing its ability to respond effectively to different scenarios when coming across various challenges. (Against) Many of the incremental operation patterns remain experimental and vulnerable to uncertainties.

Robust institution support	Clear and systematic design and operation pattern	Partly in conformity (For) The renovation provides valuable explorations on institutional infrastructure design and game rules making regarding incremental small-scale actions supported by the local-based collaborative platform, exemplified by the round-by-round courtyard renovation pattern. (Against) Limited regulations and operation patterns have been developed regarding population and housing management and housing condition improvement, which is the core challenge and concern of the local community. The courtyard renovation operation pattern has still suffered from high transaction costs and lack of long-term maintenance
	Robust coordination mechanism	Partly in conformity (For) Creating the collaborative platform contributes to inter-sectoral and interdisciplinary cooperation, though the impacts have been gradual rather than transformative. Facilitating small-scale cooperation and consensus building in community activities or renovation actions as well as utilizing endogenous interpersonal structure and leadership to contribute to long-term trust-based community conflicts coordination mechanism. (Against) The coordination mechanism is not robust enough in the face of serious disputes, especially those involving core interests or occurring in courtyards without strong endogenous leadership.
	Robust resource commitment	Partly in conformity (For) Instead of relying solely on local government, the renovation draws on multiple resource sources and creates its resource pool to support renovation and community building. (Against) Current resource commitment are not stable and robust enough to provide continuous support for a broad range of initiatives.

Table 2: Result evaluation of the DSN case

Criteria		Assessment and Evaluation
Environmental improvement	Improving living conditions	Partly in conformity (For) Spatial improvements have been made in several courtyards through cultural outreach rehabilitation and round-by-round residential yard enhancement. Spatial improvements have been made regarding creating small public space and green space (Against) Only a limited number of courtyards have undergone renovation. No or limited improvement in housing conditions, (semi-)public space encroachment, and local walking, cycling, and parking system
Economic improvement	Improve local economic vitality	Partly in conformity (For) DSN has attracted a few self-sustainable organizations providing cultural and welfare-related services to local residents (Against) Limited improvements on local employment. An increasing influx of tourists has begun to disturb the everyday life of the local community

Social and cultural improvement	Control population density and improve demographic picture	No or limited in conformity No specific strategies or actions—either direct or indirect—addressing population density have been identified in the renovation plans
	Enhance cultural identity	Fully in conformity (For) Historic fabric and landscape conservation and rich community-based outreach activities have enhanced local heritage understanding and cultural identity.
	Enhance community capacity	Partly in conformity (For) Community activities and thematic seminars have created opportunities for some Hutong residents to develop a more open and proactive attitude toward local participation. The development of trust and emotional connections among local residents, on-site professionals, and NGO workers—alongside the accumulation of professional experience—has contributed to strengthening local community capacity. (Against) The depth and the scope of community participation as well as the capacity of local residents require further improvement.

5. Discussions

The evaluation results of the DSN renovation highlight both its potential and its challenges in terms of sustainability. One key advantage is that incremental HUD renovation like the DSN case allows for a long-term, gradually-improving strategy, fostering institutional design and the development of an operational model that balances consistency and adaptability. This approach is particularly valuable in addressing the growing complexities and uncertainties of current HUD renovation and instrumental in evolving institutional procedures from an experimental, easily initiated, and community-inclusive phase into a well-structured, mature framework. For instance, in the DSN case, the operational model for residential courtyard renovations has undergone three rounds of refinement. Improvements have been made regarding the establishment of the "pilot courtyard pool," courtyard selection processes, collaborative design, and renovation plan confirmation, and the early experimental efforts of the Round 1.0 courtyard renovation in 2015–2016 have gradually evolved into a more structured and well-designed series by Round 3.0 in 2021. Furthermore, the DSN renovation case also suggests that in order to guarantee the long-term strategy with consistency, adaptiveness, integrity, it is important for the local authorities and professionals stay in an open mind and provide long-term commitment, as well as to create long-term local-based collaborative institutions alongside professional support systems.

In addition, the DSN case also indicates the great potential in social capital accumulation in the incremental HUD renovation process, which will reduce transaction cost in the negotiation and cooperation and benefit long-term spatial improvement and community capacity building. "Social capital" refers to resources embedded in "social network accessed and used by actor for actions" (Lin, 2001, p. 25) or "the good will that is engendered by the fabric of social relations and that can be mobilized to facilitate actions." (Adler and Kwon, 2002, p. 23) The DSN case indicates that long-term local-based cooperation can enhance trust and emotional connection between the local residents and the community urban planners or the NGO workers and facilitate smoother collaboration. Moreover, it is also an important learning that we should not neglect endogenous structure and leadership shaped by the kinship, prestige, tenancy relationship, and long-term gaming among residents themselves. Supporting individuals with endogenous leadership roles can be important in facilitating cooperation and decision-making within the local community.

Apart from the advantages and potentials, incremental HUD renovation, as demonstrated in the DSN case study, also reveals limitations. In particular, this approach struggles to address situations involving severe conflicts of interest or the absence of endogenous leadership. In addition, the current DSN renovation does not touch one of the primary concerns of local residents: housing condition improvement. Critical issues such as expanding residential space and upgrading basic amenities (such as the kitchen facilities) remain insufficiently addressed, especially for underprivileged groups living in substandard conditions. Instead, it focuses more on semi-public and public spaces, such as shared courtyards and the open green space. Therefore, the DSN renovation falls short of tackling one of the fundamental challenges of sustainable HUD development -- managing population pressure within limited space – and results in limited explorations regarding the housing policy studies, property right clarification, etc. It also means that the derivative issues of population-space conflicts -- such as the self-additions in the courtyards spoiling the historical landscape and the encroachment into the public areas, courtyards neighbours conflicts on using the limited shared space, etc. -- can hardly be adequately assessed. Further explorations are still required with respect to a more holistic and resident-centred approach and taking population pressure management and housing policy improvement into consideration, supported by strengthened resource support and institutional frameworks.

Based on the above discussion, Table 3 summarises the potential advantages and limits of incremental renovation models, as exemplified by the DSN case. In further cases, the table may serve as a useful tool for determining whether the incremental renovation approach is appropriate for specific contexts. It is also important to note that the analysis in Table 3 is situated within the specific context of China and may not be directly applicable to other settings. In the future, the incremental approach requires further enhancements on improving its local-based capacity in addressing more challenging residents concerns with party-state and third-party supports as well as community capacity building, especially with respect to population density control and housing conditions improvement.

Table 3 Limits and potentials of incremental renovation models exemplified by the DSN case

Well-suited to these conditions	Inappropriate for these conditions
- Not suffering from severe population pressure or critical housing condition issues	- Suffering from severe population pressure or critical housing condition issues
- Featuring a certain degree of endogenous structure and emotional connection accumulation that favouring negotiation within the local community	- Featuring a poor degree of endogenous structure and emotional connection accumulation that favouring negotiation within the local community
- Featuring a relatively strong potential for long-term collaborations with local experts and emotional connection	- Featuring a poor potential for long-term collaborations with local experts and emotional connection
- Facing limited political pressure to produce immediate, visible, and remarkable results	- Facing great political pressure to produce immediate, visible, and remarkable results

6. Conclusion

This study investigates the current exploration of incremental HUD renovation with a particular focus on its current strengths and weaknesses on sustainability. It develops a comprehensive evaluation framework on both sustainable HUD renovation processes and results based on literature review and applies this framework to assess and evaluate one of China's most representative cases—the DSN Quarter renovation in Beijing's Huong.

The case study and evaluation indicate the dual nature of incremental renovation at current stage in China: on one hand, it allows a long-term, gradually-improving strategy with consistency and adaptability and it demonstrates the potential for social capital accumulation, thereby reducing transaction costs in negotiation and collaboration over time. One the other hand, the findings also underscore existing challenges. Specifically, further exploration is needed to advance a more holistic and resident-centred approach that integrates population pressure management and housing policy reform. These insights may contribute to enhancing the sustainability of future incremental HUD renovation efforts.

Abstract
This paper investigates the transformative potential of urban planning by presenting the process through which a comprehensive Views and Vistas Analysis for Valletta World Heritage City was drawn up. The theoretical background is presented through key themes related to Urban Cultures and Lived Heritage. We explore how space is a relational concept and present a critical understanding of the changing gaze in its regard to the city. The methodology for the analysis is then presented, this based on identifying key visual elements within the city, assessing their aesthetic and symbolic importance, determining optimal viewing positions and analysing the visual composition of the views. The analysis resulted in a set of key principles for good governance in the interpretation and application of Maltese spatial planning policy.

Keywords: Community, Ritual, Spatiality, Views, Visual Integrity

Lived Heritage through the Changing Gaze: A Views and Vistas Analysis for Valletta

1. Introduction

Valletta was conceived by the Knights of St John as a Renaissance city with the rather grandiose duty of serving as a 'bulwark of Christendom'. Striking while the iron is hot, as the saying goes, the Grandmaster appealed to the Pope to fund a new city in Malta following the Knights' successful survival of the Great Siege in 1656. Faith and military prowess thus intertwined, Valletta was inaugurated as Malta's capital city in 1571 and has remained so to this day. It was inscribed on the UNESCO World Heritage List in 1980 under criteria (i) and (vi) and is currently the subject of several studies being undertaken to draw up a Management Plan for the city. A Views and Vistas Analysis has thus been completed and submitted to the World Heritage Committee (MHAL, 2023), the methodology for which is described in this paper. The Analysis underscores the significance of visual perception within the historical and cultural fabric of Valletta, a point echoed by the reflections of Italian author Italo Calvino. He observed that the eye is perhaps the most existential organ of the body and hence the most important one (Calvino, 2010).

Calvino's observation was particularly inspired by the existential philosophy of Martin Heidegger so preponderant at the time, who in his 1927 magnum opus 'Being and Time' dwelt considerably upon the 'throwness' of Being, and hence the 'situatedness' of existence (Heidegger, 1962). According to Heidegger, there is little that has to do with choice when it comes to our existence; we find ourselves 'thrown' in the world, and the world is always a situation that has already been worked out. One could say that we are not only born in a determined time and space, but, perhaps more important, we are also 'born in language'. By language it is understood a system of signs and signification, of symbols and their meaning, of an ordering of the world that provides us with an understanding of it. This paper shall delve into such an understanding of Valletta by taking a theoretical and practical journey through the assignment of significance and meaning to our changing gaze of the city.

2. A Theoretical Lens on Views and Vistas

To continue upon Calvino's astute observation, the eye is not merely a biological organ but is also a linguistic (and thus an existential) phenomenon. Through the gaze, the act of seeing, we understand where we stand in the world, because the eye is never a naked organ, but an organ dressed in the livery of meaning. The act of seeing is not a natural act but an educated (or informed) act; we learn how to see, what to see and where to put that which is being seen within the order of meaning.

This has a profound impact on our understanding of space. Space is therefore always relational to our gaze. We never look at space with a naked, neutral eye. Ours is an informed eye, and therefore even before the act of

seeing we already have expectations, assumptions, values that will impact what we see and how we will relate to it. To a certain extent we see what we prepare ourselves to see and overlook pretty much else. This explains why, for example, many tourists experience heightened emotions in front of such monuments as the Great Pyramid of Giza, but then those emotions are significantly less strong in front of, say, the step pyramid in Saqqara projected by Imhotep – ignoring the fact that the quantum leap in the structuring of burial mounds occurred in Saqqara rather than in Giza. The tourist, whose gaze had already been armed by the expectation of wonder and grandeur, finding himself standing in front of the Great Pyramid, is further awed by sheer size, and therefore, the already informed eye not only finds confirmation of its expectations but the relationship in size experienced first-hand only fuels further the sense of awe and wonder.

The impact of a foreign set of eyes can also work the other way round. An expectant pair of eyes, on the lookout for things of interest, can also serve to open the eyes that have got used to the gaze to see new things. In the Maltese experience, it was the eyes of the foreigner that first noticed the strange formation of boulders on land used by the locals for foraging. Once the area around them was excavated these boulders proved to be the remaining menhir of stone age temples now recognised as World Heritage Sites. In the historical field, travel diaries left us accounts written through foreign eyes of customs, fashions, monuments, that many times their authors misunderstood – precisely because theirs was a foreign gaze – but which in the long run left us with precious details that did not necessarily hold the same value or importance with the locals.

For the purpose of our journey to understand the changing gaze vis-à-vis Valletta, this theoretical standpoint implicates that any analysis of views and vistas will always depart from an already informed eye. In the case of Valletta, the inward views and vistas (looking from outside viewing points towards Valletta) were influenced by three different gazes, which in themselves are not mutually exclusive: a) the 'local' gaze; b) the 'touristic' gaze; and c) the 'technical' gaze. What we are calling 'the local gaze' is influenced by the symbolic meaning that Valletta has for the Maltese people. Given that such symbolic meaning changes over time, it is significant to point out that there was a resurgence as to the value of Valletta, not merely as a capital - political - administrative city but as an architectural, cultural and social phenomenon, during the past twenty years in Malta. During the 1980s and especially the 1990s, the local gaze was more directed towards more modern areas and developments as the country was experiencing an unprecedented wave of modernisation and economic expansion. Valletta was a remnant of a decaying past, eyed with a sense of detachment, as the new high-rises in Sliema and St Julians' most prominently provided a view towards a prosperous future to a fast growing, considerably affluent middle-class. Valletta was rediscovered by the Maltese when that same growing economy brought towards the island archipelago wealthy European foreign executives whose 'foreign eyes' saw an opportunity to invest in elegant baroque palaces either as their private residences, offices or the hospitality industry. Restoration – including a widespread rehabilitation programme by the Maltese Government prior to Valletta becoming European Capital for Culture in 2018 – and commercial development, especially in the food and beverage sector, together with more cultural activities taking place within the city walls, made the Maltese fall back in love with their capital city.

The 'touristic gaze' is based on the narrative by which Valletta is 'sold' to the tourist that visits Malta. It is what one could alternatively call 'the iconic gaze'. The most prominent of these is the view of Valletta from across Marsamxetto Harbour, with prominence given to the skyline marked by the spire of the Anglican Proto-Cathedral of St Paul and the massive cupola of the Carmelite Church constructed in 1955. It is quite ironic that the most prominent elements of this most iconic view are the two elements appearing to sit on the original bastions built by the Knights of St John that were not in the 'ideal' original plan of the city and were not built by the Knights. On the other side, the viewpoints from Cottonera, exalt the beauty of the Grand Harbour, and bring to prominence the garden element of Valletta, since both Barrakka Gardens are on the eastern side of the city.

Perhaps the viewpoint that remains closest to the original intended gaze of Valletta is the one from the sea where at the tip of the peninsula rests Fort St Elmo. The Knights of St John were profoundly aware of the visual impact that Valletta was intended to leave upon anyone approaching it from the sea. It was not just a military statement. The imposing fortifications, St Elmo at the forefront curtained by multiple layers of bastions, was not just meant to send a message of military might to an approaching enemy. They were also the Order's calling card – a symbol of affluence, modernism, and cultural refinement. In an age where wars are fought by drones and digital technology, this is the least obvious gaze to the uninformed eyes and the details that make up the big picture tend to escape the attention not just of the tourist but sometimes to the modern planner too.

The 'technical gaze' of the expert is informed by the study of the historical development of Valletta. It is a gaze that must often find balance between the 'ideal' city and the 'real' one. The Knights themselves had to veer from their 'ideal' plans for the city for various reasons, perhaps the most notorious being the Manderaggio, where originally they planned to have an enclosed bay for their galleys but due to difficulties during excavations they had to abandon their plans and the empty quarry ended up taken over first by workers migrating from the countryside and then eventually degenerating into a slum area, until it was finally cleared and new housing units were constructed in the 1950s. During the late baroque period the Knights further altered the original plans for the city to make way for new developments along the fashion of the times. The British period also brought about various changes, especially after the devastations of the Second World War. Other significant changes happened following Malta's independence in 1964, the last most significant one being the construction of a new Parliament and City Gate in 2015. Although elements of the 'ideal' city remain, sometimes masked behind alterations from later periods, these 'traces' (as Walter Benjamin would call them) are not enough to construct a credible narrative of the actual city.

The 'real' city is a lived city, that has undergone numerous transformations, some of them at the hands of political-administrative authorities, but other mutations are simply the result of the local community's lived experience. On the eastern side of Valletta, to take an example that divides expert opinion, on the coastline, against the walls of the city, over a period of time certainly dating back to the nineteenth century several boathouses were constructed by the locals. These had (and still have, at least a number of them) the function of housing the boats of Valletta fishermen. However, they are also used during the summer months for recreational purposes, where the owners host their families and friends when they want to spend a day by the sea or have an evening barbeque. The question facing experts is: should the 'real' city, that includes these inelegant constructions that hide a good part of the walls on that side, make way for the 'ideal' city to stand out? Or should the 'real' city prevail, and the routine that has shaped the livelihood of those families be considered as part of a lay ritual that has become endemic to the city itself?

Here we would like to make a small digression in favour of a certain historical consideration. We would like to argue against a static view of history in favour of a dynamic understanding of history as a state of becoming (Deleuze and Guattari, 1977). History is a continuous process and today, as we stand here, history is still being written. There is never a final history. If for planning or conservation purposes we understand history as 'what it was' or 'how it was originally conceived', in order words if we seek comfort in the 'ideal' city, we overlook the lived experience of the city. The city is not a plan designed on paper, and it is beyond the physical or monumental dimension. It is a human and humanised space, and beyond its physical it also has a meta-physical, symbolic dimension (Lowenthal, 1998). The experience of living in the city means that the communities that somehow meet within the city alter not just its physical dimension but also its symbolic qualities. Living also entails adaptability. For example, considering the challenges posed by climate change in our age, to what extent should the implementation of rooftop gardens and further greening be prioritised in Valletta, even though this might bring some changes to the idealised views of the city? Would the benefits that urban greening can bring to the air and sea quality, as well as the reduction of temperature, benefit the conservation and preservation of the city in the long run?

When it comes to the outward views and vistas (from Valletta looking out or within Valletta itself) the three gazes used for the inwards views and vistas still hold. However, in addition, one has also to consider the Valletta community more closely. It has been estimated that over 55,000 people cross the streets of Valletta every day. The include employees (especially in the public sector), tourists, shoppers and customers, service providers and school children. On special occasions such as public events of a religious and cultural nature, most notably carnival, Good Friday, New Year's Eve celebrations, concerts and political mass events, this number increases exponentially. In comparison, the community of Valletta residents is small, close to six thousand souls. It is a small population, mostly living in the lower part of Valletta, and ageing. They are increasingly besieged by tourism, commercial development, and a sense of alienation even from basic services. Their gaze has progressively become more nostalgic and what used to be a very worldly population (as a port city Valletta, together with Cottonera, used to be the cradle of Maltese intelligentsia and enlightenment) has become with the steady dwindling of its numbers more inward looking and pessimistic.

The element of nostalgia, with its characteristic element of remembering only selective fragments that create

a romanticised ideal narrative, now characterises the symbolic value of different areas in the city. Thus, Strada Stretta, a narrow street that cuts across Valletta from north to south and which used to be known by sailors across the Mediterranean as The Gut for the poverty, crime, prostitution and sordid entertainment that characterised it, has been sanitised and idealised as an emblem of a presumed golden age for Valletta. This narrative is often used to contrast with modern entertainment outlets that operate nowadays in the same street, even though in reality there is no comparison to the squalor of the past. These narratives attached to different locations, idealised as they might be, are also a community's way of resistance at the face of extinction. In fact, during the past few years, the Valletta community has become more sensitive and more vocal with regards to certain public occasions, such as religious rituals and festivities, as a way to reclaim – even if only for the duration of the event – public spaces that they feel were stolen from them especially by the commercial community. In the gaze of the Valletta community, therefore, the presence of churches, places where the community gathers – or used to gather – local shops owned by Valletta residents, informal meeting spaces along the waterfront, and other places that hold a historical significance to the history of the city as home to the local community hold paramount importance. One might even argue that for the Valletta community, its interest lies almost exclusively within the city walls and their gaze rarely ventures outside – to what surrounds the city. This is often in contrast with the attitude of the general Maltese gaze, which looks at Valletta mostly from the outside, and is more concerned about the impact of outside elements upon the city, than it looks at Valletta from the inside. Perhaps this is the case because their trips to Valletta are usually motivated by something other than Valletta itself and therefore in their gaze Valletta never really emerges from being in the background.

As fundamental as the gaze of the Valletta community is for an adequate understanding of the city, one must not forget that Valletta is also the capital city of Malta and therefore certain of its elements hold national symbolic importance. If one had to trace a line from the Mall in Floriana to Fort St Elmo on the northernmost tip of the Valletta shoreline, it is one long road going from the monument for Independence, to the monument for the Eucharistic Congress of 1913, to the Triton Fountain, to City Gate and all down Republic Street (previously known during the British Period as Kingsway) it is all one road to the sea at the horizon, mostly pedestrian. It is for the Maltese people a national symbol, a place where lay rituals are held, where all important Events of State pass including State Funerals and the first public outing of prime ministers and Presidents of the Republic. In Republic Street is also the former palace of the Grand Masters, now the palace of the President of the Republic of Malta, fronting St George's Square, the former piazza d'armi where the most important public and State events are held.

Just before St George's Square is Republic Square, however the Maltese still know it as Pjazza Regina (the Queen's Square), because of the statue of Queen Victoria that still dominates this public space. The presence of the statue in the square, right in front of the National Library, has long been the subject of controversy within the context of post-colonial debate, since it is often regarded as an imposition of British colonial authority. Some argue that it should be removed, but till now a consensus still has not been reached, largely the result of divergent views about colonialism and its impact on the Maltese islands. The same square, the space of which is nowadays divided between umbrellas, tables and chairs from different food and beverage outlets, used to house two historic cafeterias – Cordina, which is still running, and Premier, which has been turned into the offices of the Valletta Local Council. The former Premier site still forms part of the nostalgic gaze in Valletta because of its past ties to the Maltese Jazz golden age during the first half of the twentieth century and later in the late 1960s and 1970s in association with the Maltese literary movement called Moviment Qawmien Letterarju.

The act of seeing in fact, is not always the act of seeing 'what is there', but seeing 'what was there', or even 'what could have been there', and this alters the symbolic value what is being seen. We often find ourselves in a place that elicits memories and consequently the value we attribute to that place is intrinsically linked to those memories and similarly could be said to aspirations that we might have had for that place and did not materialise. As in the case with Premier, the gaze towards the past, towards 'what has been', tends to shape the gaze of the present, with nostalgia and possibly even resentment, for those who still hold memories from when Premier still existed. The Valletta community can provide many other examples of artisan workshops, the homes of notorious citizens, and community spaces that nowadays have either been completely transformed or are no longer existent. In contrast with the narrative about Strait Street, these have not become subject to a narrative of resistance perhaps because their existence was never in itself transgressive enough to become a symbol of defiance. One can sense this element of resistance even in the pride that some Valletta residents take in identifying themselves as coming from certain areas that were held in ill repute in the past, such the Mandraġġ, Kamrata or Diju Balli.

For younger generations these considerations have no value, and for them, Pjazza Regina is a square like any other, which in summer provides the perfect spot to quench your thirst whilst watching the world go by like a true flaneur. Indeed, side streets, especially those narrow staired streets that were traditionally given lesser importance – many of which used to be characterised by empty buildings in a bad state of conservation, have since been rediscovered by commercial outlets, especially in the food and beverage sector, become meeting spaces for younger generations and flourishing even touristically. Their quaintness, enhanced by street decorations, and often by their views of the port, have made them much sought after not just for entertainment but also as a visual spectacle in themselves. A look at social media would immediately indicate that they are amongst the most photographed by tourists visiting Malta. Looking outwards from the streets of Valletta, on the eastern side the views are dominated by the sight of the port waters and Cottonera on the other side including Fort St Angelo and the Drydocks, depending on from which side street you are viewing from. For the Maltese gaze, looking westwards is where perhaps the most controversial views are. The westwards outwards gaze from Valletta is characterised by the high rise buildings in Sliema and Gżira. This is, in our opinion, a perfect example of a conflicted gaze.

On the one hand, the Sliema-Gżira development is very much symbolic of economic affluence and success within the context of a globalised free-market economy. It is aggressive and dominating, aesthetically rooted in global-capitalist urban aesthetics very much removed from the Mediterranean characteristics that even British colonialist architecture and spatial dynamics had incorporated within its style. The Sliema-Gżira area is home to a multi-national, multi-ethnic population, mostly working within the offices and establishments of trans-national corporations that made the same area their regional hub. For this reason, that same economic success and expansion can be considered equally symbolic of a loss of national identity by some, an imposing reminder of the might of corporate power and money. The preservation of the views and vistas to and from Valletta, alongside the World Heritage Status of the city, often becomes a political argument tainted with a blend of nationalist-nostalgic discourse whereby Valletta becomes a symbol of national identity and (misunderstood) authenticity juxtaposed with the unrestrained development and greed symbolised by nearby mega-developments on either side of the peninsula. Such arguments often pose Valletta as an 'idealised' city neglecting the complex realities of the lived city. It is indeed the minority view that the Sliema-Gżira developments and those at Xgħajra need not be necessarily alien to Valletta despite the obvious visual difference that characterise them. Such differences can in fact be interpreted as two different facades of modern Malta, at once rooted in its long history but also moving forward with the modern world.

3. Methodological Considerations of the Views and Vistas Analysis

The way in which the Views and Vistas Analysis of Valletta unfolded is one typical of spatial planning policy - the rationality of logic pitting itself against the vagrancies of politics. These two contending bedfellows define the process that was undertaken to understand the context of the policy, to carry out the analysis, and to ratify the measures that were eventually recommended. Over the course of several years and numerous collaborations, a multidisciplinary team of heritage professionals strove to understand the meaning of a World Heritage context, the responsibilities that the designation entailed, and the considerations related to the development control of tall buildings within this context. Malta has a strong regulatory background, with several targeted policies in place for the safeguarding of strategic views to and from Valletta. A significant weakness lies however in the application of such policies, when faced with development pressure and land-based commitments for the construction of major development projects and tall buildings, as shall be discussed.

An easy trap to fall into is to consider Valletta only within the immediate context of the Grand Harbour, or even within the national context of the Maltese Islands. As a World Heritage Site, matters of international significance come into play, based on the criteria for which the city is inscribed onto the World Heritage List, and specifically its Outstanding Universal Value (OUV). Another key consideration was obsolescence, used here as a term to define the relevance of the city, both in the physical sense - its morphology and building typologies, and in the socio-economic sense – its administrative and commercial role. In this, heritage policy plays a crucial role, both from a national and international perspective. These matters guided the identification of the view value during the analytical stage of the Views and Vistas Analysis. To define such a view value however, a meticulous process of investigation was embarked upon. To begin with, the Operational Guidelines for the Implementation of the World Heritage Convention (UNESCO, 2021) were thoroughly consulted, to understand the requirements of the World Heritage Committee and therefore, the remit of such a study. The Recommendation on the Historic

Urban Landscape was an influential reference, stating that "the urban area [is] understood as the result of a historic layering of cultural and natural values and attributes, extending beyond the notion of 'historic centre' or 'ensemble' to include the broader urban context and its geographical setting" (UNESCO, 2011). This definition allowed us to consider the city in its totality, both tangible and intangible, as opposed to the more traditional understanding of the city as a receptacle for monuments large and small.

The team was now well-set to place heritage value at the centre of the study and could continue shaping the methodology. To assist, best practice methodologies were identified, searching specifically for similar studies on World Heritage Sites which are Mediterranean cities, towns or historic centres in a dense urban context, located in proximity to a port or riverside. Ratified UNESCO Management Plans were helpful in this regard, that recently drawn up for the Historic Centre of Florence World Heritage Site (Municipality of Florence, 2022) standing out amongst the many relevant case studies from Albania, Croatia, France, Greece, Italy, Morocco, Portugal and Spain. Though some of these case studies did not offer much in terms of a methodology for the assessment of views and vistas, they all have a defined buffer zone which was studied for its relationship to the OUV of the World Heritage Site to which it appertains. This served to forge a strong link between the assessment of the view values for different strategic viewpoints to and from Valletta, and the delineation of a proposed buffer zone for the city, in line with the requirements of the World Heritage Committee for each inscribed site. Since Valletta is the core of Malta's Principal Urban Area (PUA), as defined in the Strategic Plan for Environment and Development (SPED) (MEPA, 2015), ratifying such a buffer zone has historically been a policy minefield. Development pressures abound within an urban context that is one of the densest globally, with high rise buildings and mega-projects taking centre stage in the drive to modernise Malta's economic model. Nevertheless, Valletta's peninsular topography and the historic cities of the Cottonera to the south-east have protected the city somewhat from such development within its immediate environs, despite the density of the urban environment. The environs to the north-west are however another matter entirely, as shall be discussed.

A seven-point methodology was subsequently devised for the Views and Vistas Analysis and the eventual delineation of the proposed buffer zone for Valletta, as follows:

1.Understand the SOUV for Valletta and extract key view-based indicators.
2.Identify the features of Valletta that have visual amenity, based on the key indicators.
3.Discuss the visual and symbolic merit of the features identified.
4.Define viewing positions from which visual assessments of the features can be made effectively.
5.Analyse important visual compositional characteristics of the views from these viewpoints.
6.Summarise the compositional attributes of the background, middleground and foreground.
7.Outline measures for protecting the visual integrity of the features from the viewpoints.

Once these methods were successfully implemented, a visual sphere of influence around Valletta was defined, within which the proposed buffer zone was to be delineated. This served as a springboard for discussion as to where the actual regulatory boundary was to be placed, since it shall become an important spatial planning policy tool to be used in development control mechanisms for the region. Prior to undertaking this exercise however, an assessment of the relevant local spatial planning policies and guidance documents was necessary to understand the protective measures already in force. There are several strong measures in favour of protecting the OUV of Valletta, specifically targeted to the retention of the skyline and views towards the city. The challenge was therefore to understand why such measures were not being as effective as one would expect them to, considering their status within the hierarchy of spatial planning policy for the Islands.

Let us therefore delve briefly into which the relevant policies for the purposes of the Views and Vistas Analysis are. From an internal perspective, the most pertinent documents are the Resolutions on the Conservation of Smaller Historic Towns, 1975 (ICOMOS, 1975), the Xi'an Declaration on the Conservation of the Setting of Heritage Structures, Sites and Areas, 2005 (ICOMOS, 2005), and the Australia ICOMOS Charter for the Conservation of Places of Cultural Significance, 2013 (The Burra Charter) (ICOMOS, 2013). Cumulatively, these documents make the case for a sensitive approach to development both within the heritage site and within its setting or visual sphere of influence, as we have chosen to call it. They repeatedly mention the cultural significance of a heritage site and the need to respect both tangible features and intangible aspects of the site, the latter including views and other sensory indicators that contribute an integral part of the heritage value of the World Heritage property.

Nationally, the SPED sets out policies for cultural landscapes in Thematic Objective 8, referring to the need for "Re-appraising the value of the character, amenity and distinctiveness of designated areas and sites for their built heritage value" (MEPA, 2015). Valletta is recognised a cultural landscape since it is a designated Urban Conservation Area (UCA), as ratified in the Grand Harbour Local Plan 2002 (Government of Malta, 2002). The city thus benefits also from the protection of other SPED policies, specifically Urban Objective 2, which mentions "a context driven approach to the control of building heights within Urban Conservation Areas" and that "[d] evelopment within historic sites is to be carried out in such a manner as to ensure that the historic sites' skyline is not adversely affected."

Furthermore, the Grand Harbour Local Plan 2002 designates an Area of High Landscape Value (AHLV) which encompasses the Grand Harbour Fortifications, of which Valletta forms part; and the North Harbour Local Plan 2006 (Government of Malta, 2006) designates Strategic View Corridors (NHSE07), with the aim to protect "the settings of key landscapes, landmark buildings, Urban Conservation Areas and the Valletta World Heritage Site." Considering guidance documents which form part of Malta's hierarchy of plans, we find the Development Control Design Policy, Guidance and Standards, 2015 (DC15) (Malta Environment and Planning Authority, 2015), the Planning Authority Circular 3/20 - Assessing and Determining development Applications in the Setting of Scheduled Buildings and Monuments, 2020 (Planning Authority, 2020), the Planning Policy Guide on the Use and Applicability of the Floor Area Ratio, 2014 (FAR) (Malta Environment and Planning Authority, 2014b), the Height Limitation Adjustment Policy for Hotels, 2014 (Malta Environment and Planning Authority, 2014a) and the Height Limitation Adjustment Policy for Retirement Homes, 2017 (Planning Authority, 2017). These numerous documents set out an agenda for sensitivity towards heritage contexts, including key considerations related to the visual impact of development on rooftops and at exposed rides within and in the context of heritage sites, the appropriateness of increased height for specific types of development, and crucially the siting of tall buildings in relation to the impact of such landmarks on views to and from heritage sites.

Once the policy context was sufficiently understood, a photographic analysis was carried out to serve as a visual baseline for determining the view value of each strategic viewshed. The take-off points for a series of photographs were carefully chosen to represent ubiquitous views of the city, and from the city, therefore including belvedere along the imposing Grand Harbour fortifications and picturesque waterfronts on either side of the Valletta peninsula. Within the city, the photographic take-off points highlighted the undulating streets parallel to the main thoroughfare, Republic Street, and public spaces off this street. The views were characterised based on a methodology developed by DEGW to assess London's Skyline, Views and High Buildings (DEGW, 2002), defining each Viewing Experience as a sum of the Viewing Place and View Type. Three viewing places were identified for Valletta and its environs – the High Point, the Open Space and the Axial Route. The viewing types were consequently characterised as a Panorama, a Contained Prospect and a Linear View respectively. The sum of these definitions thus led to three Viewing Experiences, namely:

1. A wide view looking towards or outwards from the city.
2. A broad view with a clearly defined edge.
3. An unfolding, changing view along major routes.

In parallel, a formula for defining a set of View Enhancement Criteria was developed, based on the sum of the View Value, the Compositional Quality and the Landmark Impact. Having set out these parameters to frame the analysis of the views, each was critically described in terms of the composition quality of the background, middleground and foreground features that are visible at the time of the study and making sure to describe the landmark impact of key features. Subsequently, a technical analysis for each view could be carried out, focussing on a detailed description of each View Experience in relation to its perceived visual and symbolic value, and the ultimate delineation of a set of View Enhancement Criteria based on the preservation and enhancement of the views to and from the city. The exercise culminated in a set of guiding principles for the protection of views to and from Valletta (MHAL, 2023).

4. Deconstructing the Changing Gaze in Valletta's Visual Narrative

A more detailed description of the view value is warranted here, since this sets the scene for a later outline of the ensuing guiding principles. The view value can be described under three headings, firstly considering the foundational aspects of Valletta that can still be appreciated, thereby referring to the criteria under which

the city is inscribed on the World Heritage List – "an ideal creation of the late Renaissance" that "is irrevocably affiliated with the history of the military and charitable Order of the Knights of St John of Jerusalem" (UNESCO, 2023). Secondly, we consider the defining characteristics of the fortified city itself, rising high above flanking harbours. Finally, we consider the dense urban context that characterises the setting of the city on either side of the peninsula.

To begin with, let us recall that the first impression of many visitors to Valletta prior to mass air travel was by sea, arriving at one of the city's heavily fortified maritime gates and walking up St John Street towards the eponymous Co-Cathedral with its distinctive twin belfries. This route is visible today by following a dip in the saddleback skyline of the city when viewed from across the Grand Harbour. Thus, although the visual landscape of Valletta and its approaches has changed drastically, there is much charm in its skyline, and in the strong line of fortification walls of the city. This places much value on keeping the waterfronts free of unsympathetic accretions at the base of the fortifications, and the same goes for the spaces above the numerous bastions and curtain walls, all of which warrant ongoing restoration to ensure their continued appreciation within and around the World Heritage Site.

Within the city, the undulating streets lead the eye along a picturesque route lined by honey-coloured stone façades that often culminates in the blue waters of the two harbours and beyond. Unsympathetic rooftop development can easily mar the uniqueness value of these streets by failing to mirror the topography at street level. Such development also has an impact on the aesthetic value of the city's skyline, since it can obscure the view of key monuments that attest to its history, both from its early years such as the various belfries and cupolas of Baroque churches, and from later alterations such as the definitive cupola of the church of Our Lady of Mount Carmel and the spire of St Paul's Anglican Cathedral. From beyond the city walls, one can appreciate the mammoth undertaking that the entire system of harbour fortifications once was, as well as the impact of many centuries of development that the harbour region attracted. The still visible gap between the Valletta and Floriana land-fronts attests to this continuous change and provides a visual clue as to the boundary of the World Heritage Site. Around both harbours, the fortifications that line the foreshore in an almost unbroken line are a visually appealing reminder of the military nature of Valletta in its earliest attestation, and proof of the heritage value that countless generations have imbued these sites with. As a culminating observation that attests to the Islands' scale, the Mdina promontory rises in the far distance view viewed from many places around the harbour cities, another valuable visual cue attesting to the relationship between the former and current capital cities of Malta.

A series of guiding principles has ensued from the detailed consideration of the view values pertaining to Valletta, with the foremost referring to the need to responsible governance in applying spatial planning policy, harking back to the point made earlier about planning as both a rational endeavour and a political practice. Note however that although several relevant policies for the safeguarding of the views exist, they are not universally applied when deciding upon whether to grant or refuse applications for development permission that may have an adverse impact of the World Heritage Site. Considering the principles that apply to the foreground views, these pertain primarily to the immediate visual experience of Valletta, when it comes to applying appropriate textures, materials, colours and even forms. Here we observe the jarring effect of large, glazed areas, exposed party walls created by developments higher than their context, and the cumulative impact of rooftop extensions within the city. Visual clutter too plays a part, this including redundant wiring and signage, as well as paraphernalia erected for outdoor catering areas.

Continuing to the middleground views, the principles focus on fostering urban attractiveness within and around the city, and especially within the proposed buffer zone. Good design takes centre stage when considering appropriate building height, form and rooftop design, recognising that the overall massing of new developments significantly influences views to and from Valletta. Recalling the OUV of the city, the morphological characteristics of the grid-iron plan and the topographical characteristics of the undulating streets must be respected during redevelopment projects, as this will protect the visual dominance of existing landmarks that are a key aspect of the iconic skyline of the city. This applies also to development that may obstruct seascape views from within Valletta, a picturesque feature that evokes memories of a time when this city was the maritime hub of the Mediterranean. As guiding principles for background views, the analysis proves that tall buildings visible from Valletta must showcase sensitive architectural techniques that allow them to meet the sky gracefully, such as

tapering upper levels or incorporating translucent elements to create a smoother visual transition, drawing inspiration from both exemplary modern designs and the traditional Maltese skyline adorned with church spires and cupolas. Protected viewshed gain much significance here, since they serve to outline locations where tall buildings are acceptable or otherwise and emphasise the importance of determining a height envelope within the visual sphere of influence of Valletta to enable development control to serve as a protective measure for the visual and symbolic value of the city.

The synthesis of the visual sphere of influence into a proposed buffer zone for Valletta was heavily prejudiced by the consideration of previously made land commitments and the vested interests of influential lobby groups. The blue waters of the Mediterranean Sea lapping at the albeit heavily contested foreshore of the Valletta peninsula, act as perhaps the strongest deterrent to overdevelopment in the immediate vicinity of the World Heritage Site. An initial proposal for the buffer zone, submitted to the World Heritage Committee for consideration, incorporates Marsamxetto Harbour and the Grand Harbour, the latter with its many creeks on either side of the Ricasoli, Kalkara and Cottonera peninsulas. The entire urban area within this zone is incorporated into the proposed buffer zone, as is Floriana, Manoel Island and Fort Tigne. These are all historic places that have been intimately tied to the history and development of Valletta over the centuries and are therefore well-suited to be offered the additional protection that the buffer zone may provide.

5. Conclusions

To conclude, through the analysis of views and vistas in and around Valletta, we have sought to highlight the critical importance of visual perception in understanding and safeguarding the city's lived heritage, within the scope of its significance as a World Heritage Site. The analysis forms a key component of the city's Management Plan, which though yet to be ratified, considers Valletta's urban fabric and its susceptibility to change. Through the reflections of thinkers such as Calvino and Heidegger, we have accentuated the importance of the gaze in shaping our experience and understanding of place, specifically heritage places that are fundamentally imbued with values both tangible and intangible. Therefore, we posit that the way we see and interpret Valletta is deeply intertwined with its historical and cultural significance in a fluid and dynamic manner that requires ongoing valorisation.

The proposed buffer zone emerges as a crucial policy mechanism for safeguarding Valletta's visual integrity in the light of its position within Malta's dense conurbation. Here, the city's visual landscape is pitted against land commitments and vested interests that pose a threat to strategic views to and from Valletta, thus potentially undermining the experience of the city for those who look upon it. The maritime boundary of the natural harbours at either flank of the peninsula on which it is built provide an inherent protection that sets the city at a distance for its built environs, however short this may be. Thus, the Views and Vistas Analysis aids in the strategic implementation of essential steps that are required to ensure that Valletta's visual and symbolic value endure for future generations to appreciate, recognising the profound connection between lived heritage and the ever-evolving gaze.

Measuring Cultural Participation: A Comprehensive Study in Kayseri

Özlem Tepeli Türel
Erciyes University
ozlemtepeli@erciyes.edu.tr

Ahmet Türel
Abdullah Gul University
ahmet.turel@agu.edu.tr

Abstract
This study investigates cultural participation in Kayseri, a secondary city in Türkiye with rich historical heritage yet persistently low levels of cultural engagement. Drawing on a quantitative survey conducted with 166 residents, the research identifies key barriers to participation, including socio-economic constraints, limited accessibility, and low awareness of cultural opportunities. The study is situated within the theoretical frameworks of cultural capital and socio-spatial inequality, emphasizing how demographic and geographic factors shape engagement with cultural life. The findings point to uneven distribution of cultural resources and highlight the need for localized, inclusive policy interventions. By offering data-driven insights into cultural behavior and access patterns, the study aims to inform municipal and institutional strategies and contribute to broader efforts for equitable cultural development in non-metropolitan urban contexts.

Keywords: cultural participation, access to culture, cultural policies, cultural capital, arts and culture

1. Introduction

Cultural participation has increasingly become a critical domain for examining spatial, social, and policy-related dimensions of urban life. As cities attempt to promote inclusive development, the question of who participates in cultural life—and who is excluded—remains a persistent challenge. Particularly in the context of secondary cities with rich cultural heritage but low levels of cultural engagement, such as Kayseri, Turkey, understanding the dynamics of cultural participation is essential for designing more equitable and responsive urban cultural policies.

Kayseri, a historically significant city located in central Anatolia, possesses a wealth of tangible and intangible cultural assets. Despite this potential, cultural participation rates remain considerably low, and access to cultural resources is unevenly distributed across socio-economic and spatial lines. The lack of comprehensive, data-driven assessments of cultural participation in such cities limits the capacity of local stakeholders—municipalities, cultural institutions, and civil society organizations—to develop inclusive strategies that ensure broader cultural access and engagement.

In Türkiye, regional disparities in cultural engagement remain a persistent issue. While metropolitan areas such as Istanbul, Ankara, and Izmir have experienced diversification in cultural offerings and the emergence of participatory policy frameworks, mid-sized cities like Kayseri often struggle to establish sustainable cultural ecosystems. Limited institutional support, insufficient cultural infrastructure, and a lack of locally grounded cultural policies contribute to these persistent gaps. As a result, secondary cities remain peripheral in the national cultural landscape, despite their significant historical and demographic presence.

This study aims to fill this empirical and policy gap by conducting a comprehensive analysis of the cultural participation landscape in Kayseri. The research investigates who participates in cultural life, what barriers inhibit participation, and how strategies can be developed to foster inclusive and equitable access to arts and culture. By addressing both the structural inequalities embedded in cultural participation and the experiential realities of local residents, this research contributes to a more nuanced understanding of culture-led urban development.

The study is framed within broader theoretical and policy debates on cultural capital (Bourdieu, 1984), socio-spatial inequalities in cultural access (DiMaggio & Useem, 1978; Stevenson et al., 2017), and participatory cultural governance (UNESCO, 2012). It responds to recent calls in European and Turkish literature for more localized, bottom-up assessments of cultural engagement, especially in regions outside major metropolitan centers.

2. Theoretical Framework

Cultural participation is increasingly understood as a multi-layered phenomenon shaped by intersecting social, spatial, and institutional dynamics. Rooted in classical sociological traditions yet evolving through contemporary critiques and policy discourses, scholarly debates on cultural participation interrogate not only who participates in cultural life, but also how, why, and under what conditions such engagement occurs—or fails to occur. A foundational reference point remains Pierre Bourdieu's conceptualization of cultural capital, wherein cultural consumption is understood as a form of distinction that reflects and reproduces social inequalities (Bourdieu, 1984). In this framework, participation in "legitimate" cultural forms—such as museums, concerts, or theatre—is closely aligned with educational attainment, occupational prestige, and class-based dispositions acquired through socialization. DiMaggio and Useem (1978) further argue that educational systems and cultural institutions contribute to this stratification by privileging certain tastes and competencies, rendering high culture more accessible to dominant groups while alienating others.

Yet, Bourdieu's determinism has been critically revisited in light of empirical research suggesting more fluid and hybrid modes of cultural consumption. The "cultural omnivore" thesis posits that high-status individuals increasingly engage with diverse forms of both highbrow and popular culture, reflecting an eclecticism that transcends rigid class boundaries (Peterson and Kern, 1996). Studies from Flanders support this view, revealing new consumption clusters that blend traditional and contemporary cultural preferences (Vander Stichele and Laermans, 2006). These findings underscore the need for analytical approaches that accommodate evolving patterns of engagement shaped not only by class, but also by generation, urban context, and cultural hybridity (Bennett et al., 2009).

At the same time, critical policy scholars have drawn attention to the structural barriers that inhibit participation, especially in secondary cities or marginalized communities. European cultural policy often constructs non-participation as a "problem" to be solved, legitimizing top-down strategies that fail to address deeper socio-economic exclusions (Stevenson et al., 2017). The cultural sector's tendency to promote narratives of success while ignoring systemic failures has also been critiqued, with calls for more reflexive and inclusive models of cultural governance (Jancovich and Stevenson, 2023). These critiques resonate in the context of cities like Kayseri, where formal cultural policies often lack embeddedness in everyday lived experiences, and where community needs and alternative cultural expressions remain underrecognized (Finkel et al., 2019).

Feminist and relational approaches further underscore the importance of intersectionality and social networks in shaping cultural access. Cultural participation—particularly among women—is strongly influenced by the diversity and density of social ties, with exclusion often emerging from time poverty, caregiving responsibilities, or absence of supportive networks (Kane, 2004; Chan et al., 2008). These insights complicate traditional models and call for an understanding of participation that is attuned to both structural and interpersonal constraints.

Building on this relational turn, the concept of "classed cognition" has been proposed to describe how cultural policy initiatives often fail to recognize the ways in which class-based experiences and perceptions mediate engagement (Roaldsnes, 2025). When participation is framed as a universally attainable goal, cognitive and affective exclusions shaped by classed experiences are often overlooked. Cultural institutions are thus urged to shift from instrumental rationality to more dialogical, value-centered models of cultural legitimacy (Holden, 2006).

In parallel, the contribution of cultural participation to subjective well-being and quality of life has attracted growing attention. Regular engagement in cultural activities can enhance emotional resilience, life satisfaction, and social cohesion, although these outcomes depend on the accessibility, form, and frequency of participation (Reyes-Martínez et al., 2020; Galloway, 2006). Galloway cautions against reductive, instrumentalist interpretations and instead advocates for frameworks that capture the experiential and symbolic dimensions of cultural life, particularly in urban contexts marked by uneven access and identity-based exclusions (Grogan, 2021).

Globally, the measurement of cultural participation has been systematized through UNESCO's Framework for Cultural Statistics, which defines participation as encompassing attendance, creation, access, and digital engagement (UNESCO, 2009; 2012). This approach views participation as both a right and a public good, essential for inclusive development and cultural sustainability. However, critics highlight the limits of universal metrics and emphasize the importance of contextually grounded indicators that reflect diverse cultural practices and

infrastructural conditions (Tomka, 2013; Schuster, 2007). Recent scholarship further stresses that digital divides—often shaped by socio-cultural rather than merely technological gaps—have become increasingly significant in determining access to cultural participation (Selwyn, 2004; Heikkilä and Sassi, 2021).

Altogether, this theoretical framework positions cultural participation as a site where social stratification, institutional design, symbolic boundaries, and subjective meaning converge. By drawing on classical theory, post-Bourdieusian perspectives, policy critiques, and international frameworks, the study constructs a conceptual foundation capable of interrogating the uneven landscape of cultural engagement in Kayseri and advancing grounded insights for equitable cultural policy-making. Culture must be read as "a web of significance" through which social life is interpreted and made meaningful (Geertz, 1973).

3. Methodology

This study employs a quantitative, exploratory research design to investigate the patterns, motivations, and barriers of cultural participation among residents of Kayseri, Türkiye. Developed as a pilot study within the scope of a scientific research project funded by Erciyes University, the research constitutes a preliminary empirical inquiry into cultural participation in mid-sized Anatolian cities. The study aims to test the local applicability of UNESCO's (2012) cultural participation framework and generate baseline insights for future, more comprehensive investigations.

The survey consisted of 38 structured questions divided into four thematic sections:

• Demographics:

Age, gender, education level, household income, employment status, and neighborhood.

• Cultural Participation Behavior:
- Frequency of engagement with cultural activities (e.g., theater, museum, festivals, concerts)
- Preferred cultural formats (physical attendance vs. digital participation)
- Frequency of participation (never, rarely, occasionally, frequently)

• Barriers to Participation:

Participants were asked to evaluate potential obstacles such as:

- Economic factors (ticket prices, transportation costs),
- Physical and spatial barriers (venue accessibility, distance),
- Informational barriers (lack of knowledge about events),
- Sociocultural reasons (lack of interest, cultural mismatch).

• Perceptions and Attitudes:
- The perceived importance of cultural life,
- Role of the municipality in promoting culture,
- Suggestions for improving access and relevance of cultural services.

All questions were either multiple-choice, Likert-type scale (1–5), or single-answer categorical variables.

Data collection took place between March and May 2025 using both digital and paper-based formats to ensure inclusivity. Approximately 60% of the responses were gathered via Google Forms, while the remaining 40% were collected in-person in locations such as university campuses, community centers, and public squares. The sampling strategy was non-probabilistic and purposive, designed to reach individuals from different age groups, income brackets, and neighborhoods across Kayseri. This dual-mode approach helped include digitally marginalized or older populations who are often underrepresented in online surveys.

The final dataset comprised responses from 166 participants. Descriptive statistical methods were employed to analyze the data, including frequency distributions, percentages, and mean scores. Cross-tabulation techniques

were used to explore relationships between cultural participation levels and demographic indicators such as age, gender, education level, and income. Data analysis was conducted using Microsoft Excel and SPSS, and analytical categories were structured in alignment with UNESCO's typology of "active," "occasional," and "non-participant" cultural users.

As a pilot study, the research is subject to limitations, particularly concerning the representativeness of the sample and the generalizability of the findings. While the study offers valuable initial insights, the conclusions should be interpreted as indicative rather than definitive. These results are intended to inform the design of future studies utilizing probabilistic sampling methods and more robust inferential statistical techniques.

All participation was voluntary and anonymous. Prior to survey administration, respondents were briefed about the purpose of the research, and verbal consent was obtained. The study was conducted in accordance with the ethical protocols of Erciyes University, ensuring confidentiality and the responsible handling of data throughout the research process.

4. Findings

This section presents the core empirical findings of the study, organized thematically to reflect the main dimensions explored through the survey. These include the sociodemographic characteristics of participants, patterns of offline and digital cultural engagement, perceived barriers to participation, attitudes toward cultural life, improvement expectations regarding municipal cultural services, and everyday conceptions of "culture." The analysis integrates both descriptive statistics and thematic coding to highlight how structural factors, personal dispositions, and spatial conditions intersect in shaping cultural participation in a mid-sized Anatolian city.

4.1. Socio-Demographic Profile of Respondents

The survey collected responses from 166 participants residing in Kayseri. Of these, 51.8% identified as female and 48.2% as male, indicating a relatively balanced gender distribution. In terms of age, the 25–34 age group constituted the largest share of respondents, followed by the 35–44 and 18–24 cohorts. Participants aged 45 and above were less represented, suggesting a skew toward younger, working-age adults in the overall sample. Table 1 provides a comprehensive overview of the percentage distribution of respondents across gender, age, education level, employment status, and monthly income brackets, offering a demographic snapshot that contextualizes the cultural participation patterns explored in this study.

Table 1. Sociodemographic profile of respondents (%)

Gender (%)	F (51.8)	M (48.2)				
Age (%)	18-24 (17.5)	25-34 (41)	35-44 (20.5)	45-54 (12)	55-64 (5.4)	65+ (3.6)
Education Level (%)	Prim. (9.6)	Sec. (22.9)	BA (53)	MA (13.9)	PhD (0.6)	
Employment Status (%)	Public (19.3)	Private (28.9)	Self-employed (6)	Student (18.7)	Unemployed (23.1)	Retired (3)
Monthly Income (TRY, %)	0-20.000 (34.3)	20.001-40.000 (22.3)	40.001-60.000 (14.5)	60.001+ (13.3)	Prefer not to say (15.7)	

In terms of educational attainment, the majority of respondents held bachelor's degrees (53%), followed by secondary education (22.9%), master's degrees (13.9%), and primary education (9.6%), while less than 1% reported holding a doctoral degree. This indicates a participant pool that is largely composed of individuals with tertiary-level qualifications, with approximately 67% holding at least a bachelor's degree.

Regarding employment status, the largest group of respondents were employed in the private sector (28.9%), followed by individuals who reported being unemployed (22.9%), working in the public sector (19.3%), and students (18.7%). A smaller portion identified as self-employed (6%), retired (3%), or homemakers (1%), indicating a diverse labor force composition within the sample. In terms of monthly income levels, 34.3% of participants reported earning between 0–20,000 TRY, followed by 22.3% in the 20,001–40,000 TRY range, and 14.5% between 40,001–60,000 TRY. Notably, 13.3% reported earning above 60,000 TRY, while 15.7% preferred not to disclose their income. These figures reflect a concentration in lower- to mid-income brackets, with a significant number of respondents indicating financial constraints that may affect their access to cultural activities.

4.2. Patterns of Cultural Participation

4.2.1. Offline Participation: Frequency and Preferences

Respondents reported relatively low-to-moderate engagement with cultural events in the past year. 40.4% attended 1–2 events, and 24.1% attended 3–5 events, while only 15.7% reported participating in more than five events (Figure 1). This suggests a modest but non-negligible level of cultural engagement.

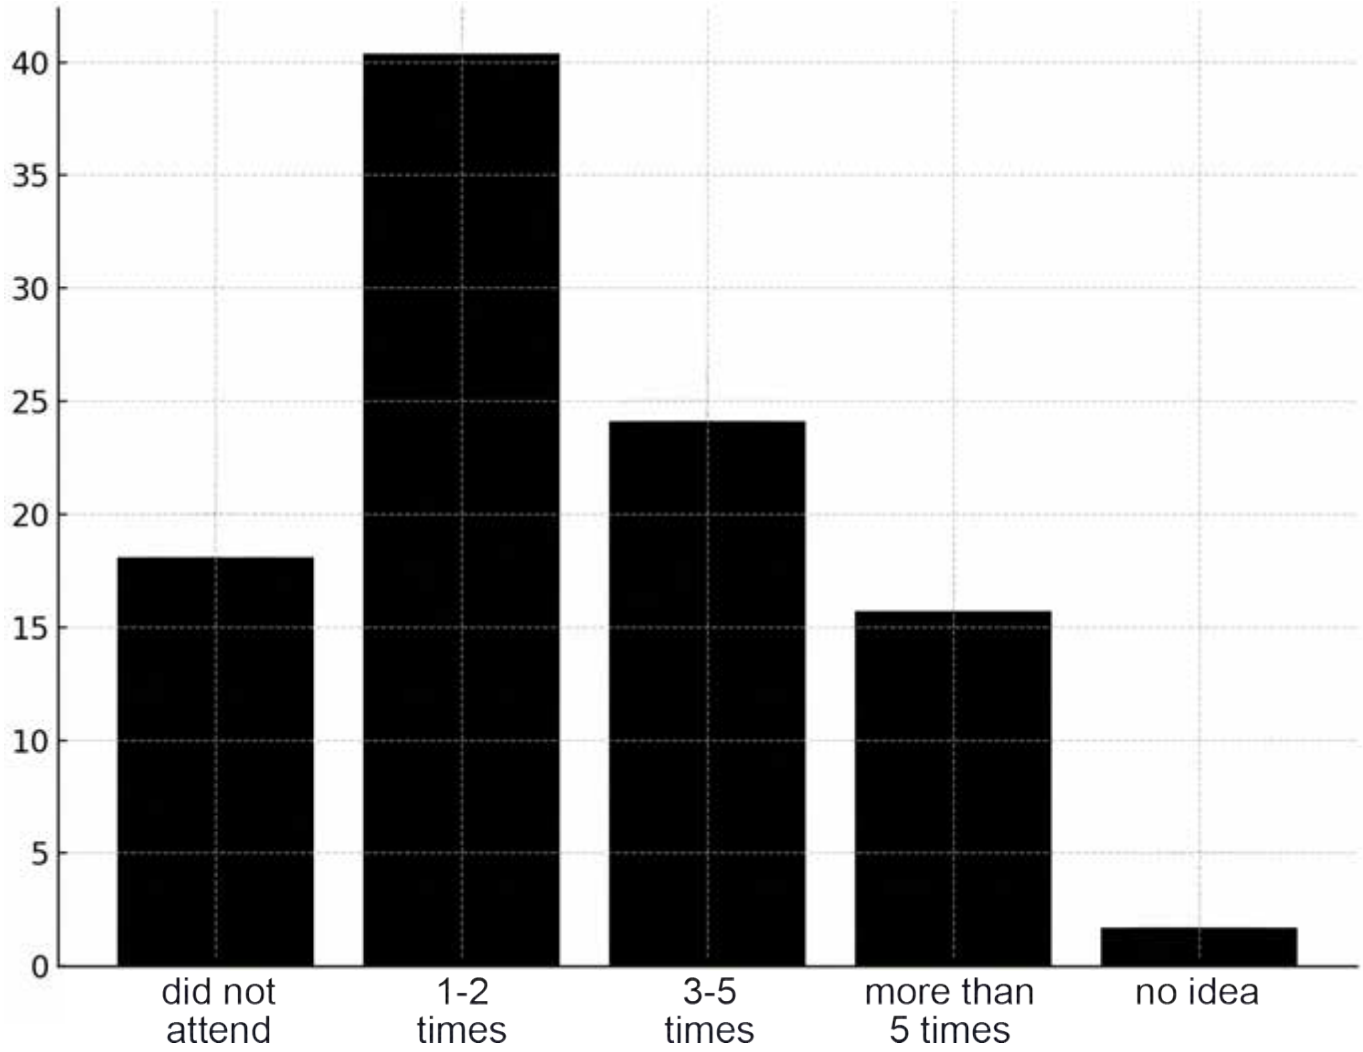

Figure 1. Frequency of cultural participation in the past year (%).

Figure 2 illustrates the distribution of respondents' most recent cultural event participation, grouped into broader thematic categories. The most commonly attended events were concerts and musical performances, followed by cinema and film-related activities. Theater and performative arts also had a notable share, reflecting continued interest in live artistic expression. Museum visits, exhibitions, and literary events constituted a smaller but significant portion. The "Other" category includes responses such as traditional ceremonies, religious gatherings, local fairs, educational panels, and family-oriented social events. This diversity suggests that while mainstream cultural formats dominate participation, respondents also engage with a wide range of community-based and informal cultural expressions, highlighting the importance of recognizing alternative forms of cultural engagement in policy and planning frameworks.

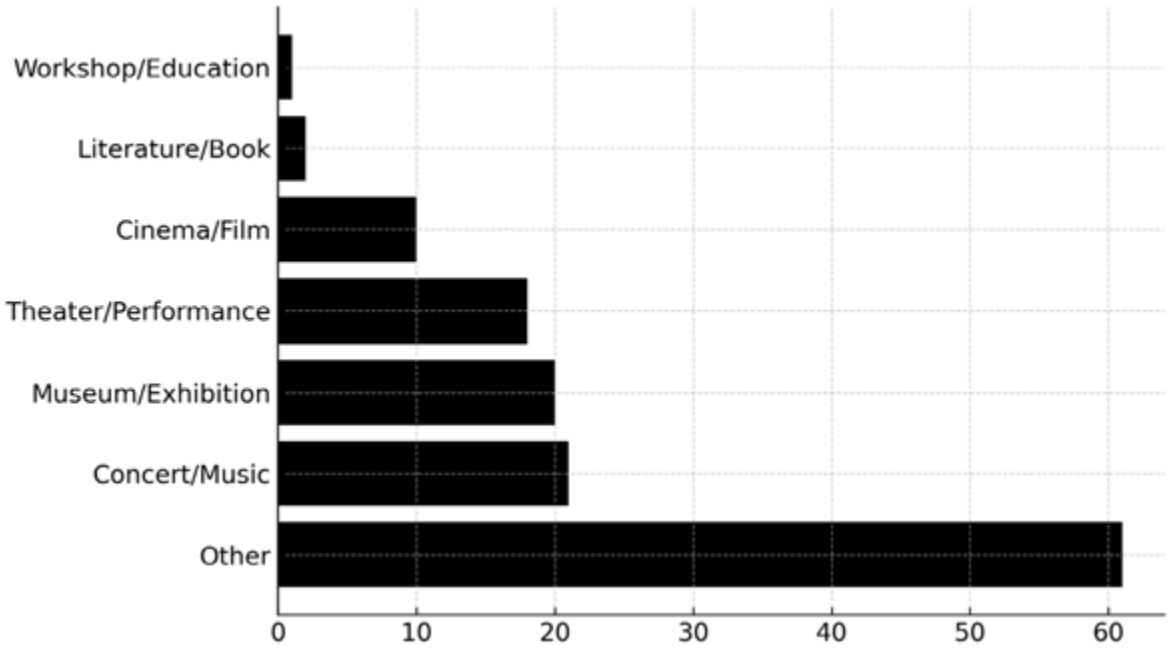

Figure 2. Types of most recently attended cultural events (%).

Based on the data visualized in Figure 3, respondents demonstrated a clear preference for certain cultural formats they would like to see more frequently organized by local authorities. Music and performing arts ranked highest, selected by 71.1% of respondents, followed by historical and cultural excursions (59%), and visual arts and exhibitions (42.8%). Workshops and educational activities also garnered significant support (41.6%), indicating a strong public interest in participatory and skill-based formats.

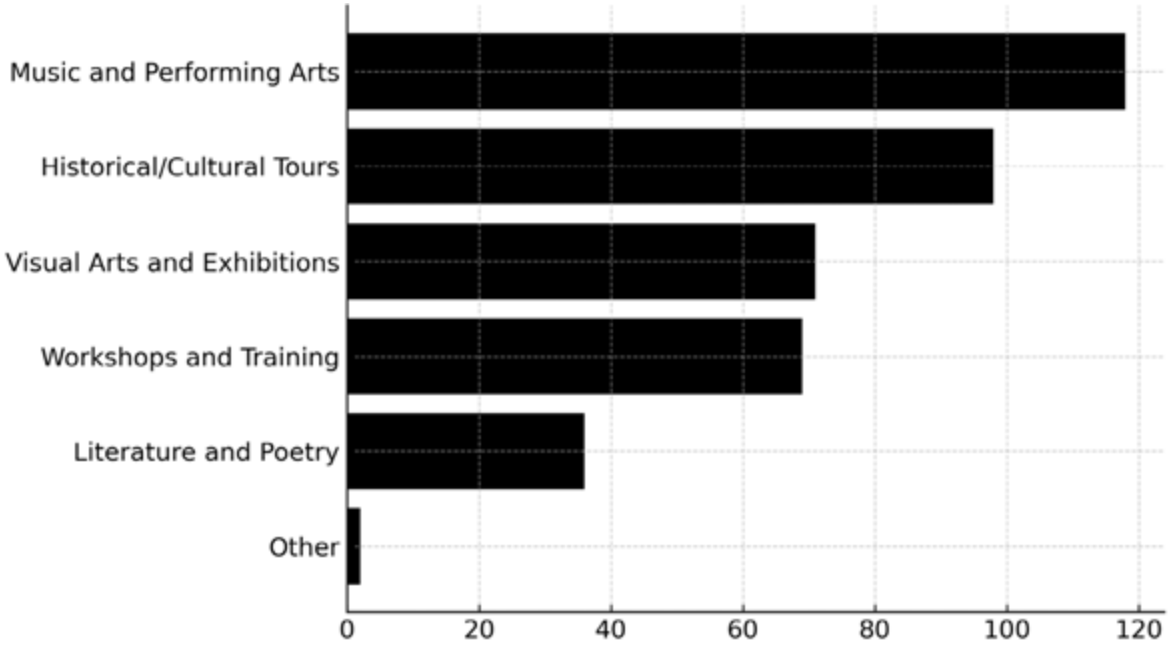

Figure 3. Preferred cultural event formats desired from local authorities (%).

Although mentioned less frequently, literature and poetry events (21.7%) still reflect a notable cultural demand among a segment of the population. These preferences suggest that residents of Kayseri expect municipalities

to go beyond conventional event programming and adopt a more proactive and inclusive cultural strategy. The results support the broader argument that diversifying and expanding cultural offerings—especially through accessible and experiential formats—can act as a catalyst for deeper and more widespread cultural participation.

4.2.2. Digital Participation: Platform Use and Activity Types

Survey findings reveal that digital cultural participation is highly shaped by platform preferences and content accessibility. As shown in the first chart, a substantial majority of respondents (77.7%) reported using social media platforms (e.g., Facebook, Instagram, Twitter) to engage with cultural content. In contrast, culture-specific applications such as YouTube, Netflix, or Spotify were used by 27.7%, and only 9% reported engaging with cultural events through online platforms like Zoom or Teams. Additionally, 15.7% indicated that they do not use any digital platforms for cultural participation, suggesting the presence of a digitally disengaged segment.

When asked about the types of digital cultural events they had attended, the most common response was online education and workshops (43.8%), followed by online theater/cinema screenings (32.8%), digital exhibitions or virtual museum visits (20.4%), and online concerts (16.1%). These preferences indicate a tendency toward more structured or performative formats, though overall participation rates remain modest.

The third chart, which illustrates the frequency of participation across five types of online activities over the past year, shows a clear variation in engagement. Film and series streaming stood out as the most frequent activity, with a large number of participants reporting 10 or more viewings. However, participation in online education, e-book reading, and virtual museum tours was considerably lower. In each of these categories, the most frequent response was no participation at all, indicating limited uptake of more cognitively or culturally intensive formats.

Overall, the findings suggest that digital engagement is widespread primarily through social media and entertainment platforms, while educational and heritage-related content remains underutilized. These patterns point to gaps not only in digital access but also in content relevance and awareness. Enhancing digital cultural participation will require targeted communication strategies and inclusive programming that reflect the diverse needs and digital habits of the local population.

4.3. Barriers to Cultural Participation

The survey findings confirm that a significant portion of respondents face obstacles to full cultural engagement. While nearly half (48%) stated they cannot participate in cultural activities as much as they would like, an even higher proportion (68%) reported that there are specific cultural events they wanted to attend but were ultimately unable to. These responses underline the presence of a consistent gap between cultural interest and realized participation.

When asked to elaborate on the reasons behind their inability to attend cultural events, respondents identified a diverse set of barriers (Figure 8). The most frequently cited issue was lack of time, selected by 52.6% of participants, followed closely by economic limitations (40.1%) and the absence of such events in Kayseri (40.9%). This indicates that both structural deficits in event availability and personal constraints significantly shape participation patterns.

Additional barriers included a lack of events suitable for families (10.9%), insufficient awareness or communication about events (22.6%), and the inadequacy of event content with respect to quality or relevance (24.8%). Social constraints also emerged: 8% reported not having someone to attend with. Practical challenges like difficulty in accessing tickets (5.8%), transportation problems, and family responsibilities—such as recent parenthood—were cited by a smaller but important portion of respondents.

These results reaffirm that cultural non-participation in Kayseri is shaped not merely by individual disinterest but by overlapping constraints across time, cost, access, relevance, and social support. Addressing these complex layers will require coordinated efforts to enhance both the infrastructure and inclusivity of the cultural environment.

4.4. Attitudes Toward Cultural Engagement

Although actual levels of participation in cultural activities remain relatively modest, respondents' attitudinal profiles reveal a more complex and hopeful picture. As illustrated in Figure 4, a majority of participants (57.2%) regard cultural activities as either "important" or "very important" in their daily lives. This normative appreciation is further supported by the fact that nearly three-quarters (74.7%) have attended at least one free cultural event—an encouraging indicator of public interest, even when structural limitations exist.

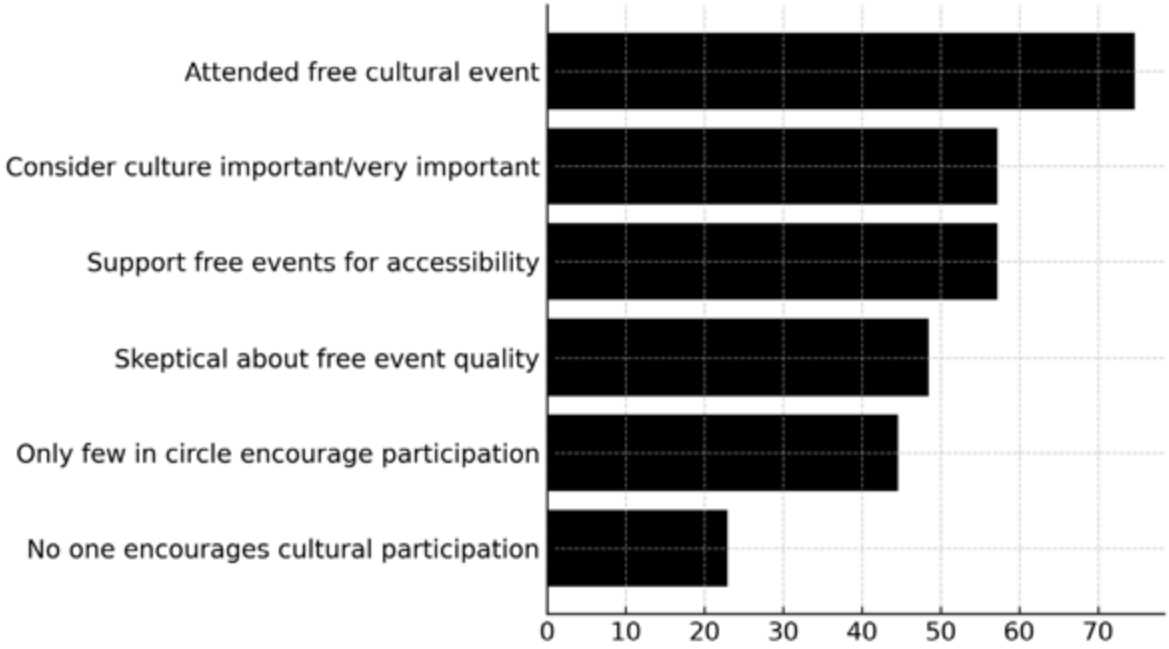

Figure 4. Key indicators of cultural engagement attitudes (%).

However, the presence of such interest does not automatically translate into widespread participation. The same figure shows that 48.5% of respondents expressed skepticism about the quality of free cultural programming, suggesting a perceived trade-off between accessibility and content richness. Additionally, 57.2% agreed that free events play a vital role in broadening access to culture, yet this support was tempered by ambivalence regarding their qualitative merit.

Social dynamics also appear to influence participation: while only a minority (13.9%) reported having a highly encouraging peer network, a significant portion (44.6%) noted that only a few people in their social circles support or promote cultural engagement. Meanwhile, 22.9% stated they lack any such supportive network entirely. This indicates that social encouragement remains unevenly distributed and may act as a hidden barrier, particularly among younger or more isolated individuals.

Taken together, these findings suggest that while cultural value orientations are largely positive, their impact is moderated by perceptions of quality, affordability, and social support. Strategic interventions should therefore go beyond merely increasing event quantity or lowering costs—they must also address content curation and community-building to convert positive attitudes into active participation.

4.5. Expectations for Cultural Development in Kayseri

When asked about their expectations for the improvement of cultural activities in Kayseri, respondents highlighted several priority areas (Figure 5). The most frequently expressed expectation was the diversification of event types, with a clear demand for a broader range of cultural programming that appeals to different age groups, interests, and artistic forms. This was closely followed by the need for enhanced communication and promotional strategies to ensure that cultural opportunities are widely known and accessible. Respondents also emphasized the importance of lowering ticket prices or expanding the availability of free events, reflecting economic concerns as a major constraint to participation.

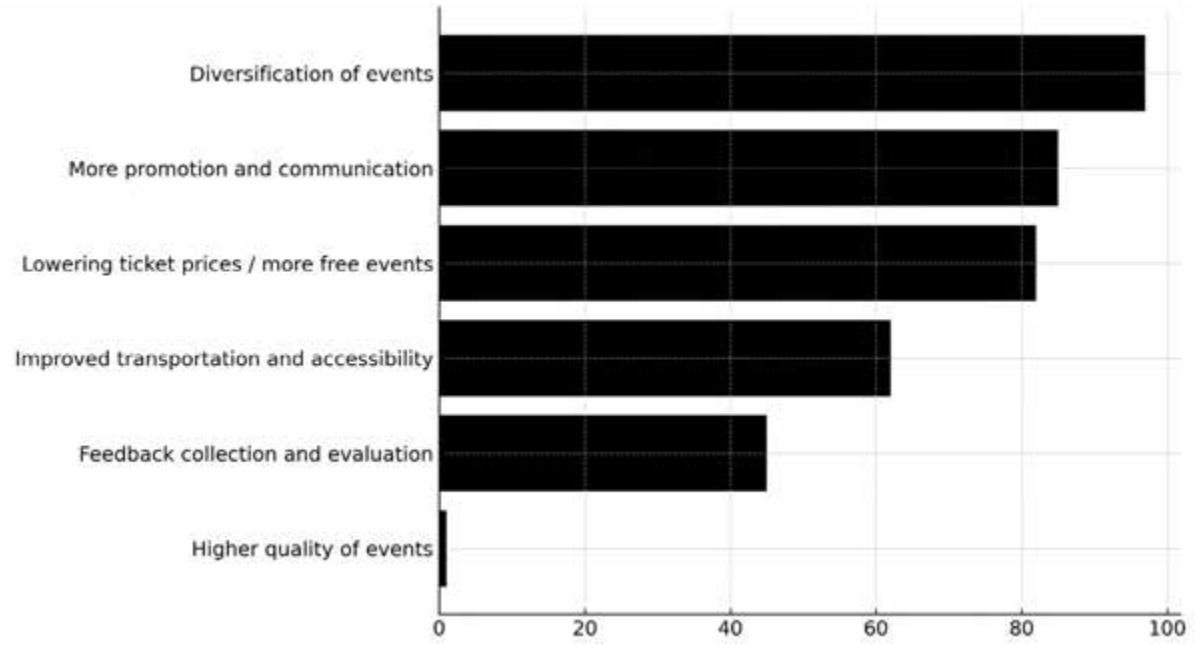

Figure 5. Public Expectations for Improving Cultural Life in Kayseri (%).

Transportation and spatial accessibility also emerged as key themes, with participants calling for easier access to venues and improved mobility, particularly for those living in outlying areas. In addition, a significant portion of respondents expressed a desire for their feedback to be considered in the planning and evaluation of cultural activities, indicating a preference for more participatory and responsive cultural governance practices.

These expectations signal a strong public demand for a more inclusive and responsive cultural ecosystem in Kayseri. Participants envision cultural services that are not only affordable and accessible but also better tailored to community interests. As such, policy responses should aim to diversify programming, enhance outreach, reduce financial barriers, and integrate resident feedback into cultural planning and delivery. Taken together, these improvements could contribute to a more vibrant and equitable cultural life across the city.

4.6. Perceptions and Meanings of Culture

In addition to measuring participation behavior, the survey asked respondents an open-ended question: "What comes to mind when you hear the word 'culture'?" Thematic analysis of these responses—coded and aggregated from 166 participants—offers insight into how individuals conceptualize culture in their everyday lives. The results reflect a rich and multidimensional understanding of culture that goes beyond institutional or elite associations.

The most frequently mentioned concept was "gelenek" (tradition), followed by "sanat" (art), "tarih" (history), "yemek" (food), and "müze" (museum). This distribution indicates that participants associate culture both with intangible heritage and artistic expression, as well as with material spaces and everyday practices. Notably, food and museums serve as symbolic anchors, connecting the personal and the institutional dimensions of cultural memory. These associations align with UNESCO's (2003) expanded definition of culture as encompassing "ways of living together, value systems, traditions, and beliefs", alongside creative and artistic output.

The prominence of tradition and history points to a conception of culture that is grounded in continuity and collective memory. At the same time, art and museum-related references indicate that respondents also perceive culture as something cultivated and displayed—tied to aesthetics, curation, and public representation. The mention of food reveals the extent to which culture is also seen as embodied and experiential, embedded in daily life rather than restricted to high-cultural institutions. These findings resonate with anthropological perspectives that frame culture as a "web of meaning" (Geertz, 1973) and with contemporary sociological accounts that

emphasize culture as both structure and practice (Swidler, 1986).

Importantly, the variety of associations suggests that respondents do not view culture as static or monolithic, but rather as plural, layered, and context-dependent. This is consistent with studies highlighting the increasingly hybrid and localized definitions of culture emerging in non-metropolitan urban contexts (Moulin, 2021). In the context of Kayseri, the data points to a public imaginary where culture is simultaneously communal and curated, lived and learned—a framework that offers fertile ground for inclusive, place-based cultural policy development.

Digital Cultural Participation by Age and Income The analysis of average participation frequencies in digital cultural activities across age and income groups reveals distinct generational and socio-economic divides. Younger participants, particularly those aged 18–24 and 25–34, exhibit the highest engagement across nearly all digital cultural forms, especially in film and series streaming and online education. Conversely, engagement levels decline steadily with age, with respondents aged 45 and above reporting significantly lower frequencies of participation—particularly in e-book reading and virtual museum tours.

Income-based variations further underscore disparities in cultural access. Respondents in higher income brackets (e.g., 40,001–60,000 TRY and above) tend to engage more frequently in diverse online cultural formats. Notably, those earning below 20,000 TRY still demonstrate high engagement in film/TV streaming, likely due to the relative affordability and accessibility of such platforms. Participants who opted not to disclose their income generally exhibited lower participation levels, especially in educational and literary content.

These findings point to both generational and economic factors shaping patterns of digital cultural consumption. They also suggest that streaming services may play a crucial compensatory role for lower-income groups, while digital educational and heritage-oriented offerings remain underutilized among older and economically disadvantaged populations.

4.7. Perceptions of Kayseri's Cultural Capacity

In addition to behavioral patterns and barriers, the survey included specific items aimed at gauging how residents perceive the city's overall cultural infrastructure and institutional responsiveness. The results, summarized in Figure 6, reveal a generally critical but nuanced public assessment.

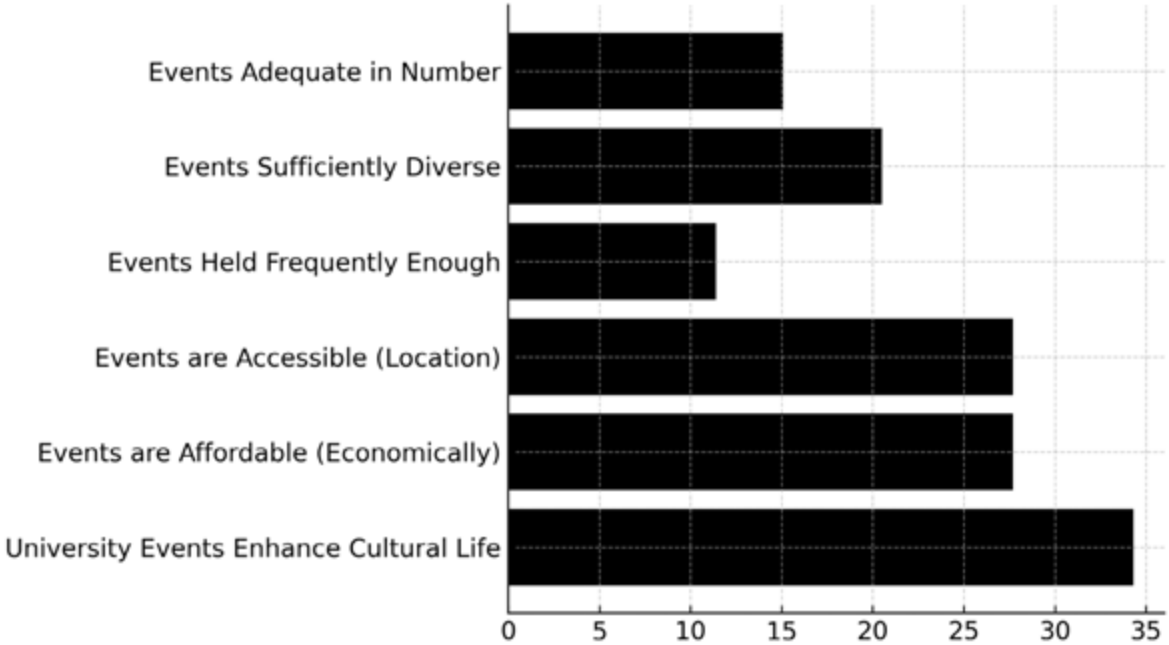

Figure 6. Overall perceptions of cultural infrastructure and participation opportunities in Kayseri (%).

Only 15.1% of respondents believe that cultural events in Kayseri are adequate in number, and an even lower share (11.4%) think they are held frequently enough. This highlights a perceived scarcity in both volume and continuity

of cultural offerings. Diversity also appears to be lacking, with just 20.5% agreeing that events reflect a sufficient range of interests and formats.

More encouraging responses were recorded for spatial and economic accessibility: 27.7% of participants found event locations to be reasonably accessible, and an equal percentage stated that cultural events are economically affordable. These figures suggest that while physical and financial access remains a challenge for many, there is a partial recognition of ongoing municipal efforts in these areas.

Notably, the most positive result emerged in relation to universities: 34.3% of respondents agreed that university-led cultural activities contribute meaningfully to the city's cultural life. This points to the prominent role higher education institutions may play in compensating for broader gaps in public cultural provision.

Together, these findings indicate that Kayseri's cultural ecosystem is perceived as limited in diversity, frequency, and scale, yet with modest successes in affordability and location, and with universities emerging as key cultural actors. These perceptions underscore the need for coordinated municipal-university partnerships and expanded efforts in event programming, frequency, and outreach to enhance cultural vitality across the city.

5. Discussion

The findings of this study reveal a persistent pattern of uneven cultural participation in Kayseri, driven primarily by socio-economic, spatial, and informational barriers. These results corroborate long standing theoretical arguments emphasizing the role of cultural capital, educational attainment, and social positioning in shaping access to cultural life (Bourdieu, 1984; DiMaggio, 1982). Despite Kayseri's wealth of cultural heritage and infrastructure, participation remains limited, particularly among lower-income groups, women, and youth with limited exposure to institutionalized culture. The survey results indicate that affordability, awareness, and accessibility are the most frequently cited barriers—each mapping onto broader structural dynamics that inhibit inclusion.

These empirical patterns resonate with recent critiques of cultural policy discourse in Europe, which problematize non-participation without sufficiently addressing the socio-structural conditions that produce it (Stevenson et al., 2017; Jancovich & Stevenson, 2023). In the context of Kayseri, the absence of participatory planning mechanisms and the dominance of top-down cultural programming result in a limited responsiveness to local needs. This reinforces symbolic boundaries and maintains a disconnection between formal cultural institutions and the everyday cultural practices of residents.

Moreover, the findings reveal that cultural participation in Kayseri is not merely a matter of personal interest but is closely tied to place-based factors such as proximity to venues, urban transport connectivity, and neighborhood-level social networks. These insights align with intersectional and network-based approaches, which highlight the role of relational infrastructures in enabling or constraining cultural engagement (Kane, 2004). In this light, cultural participation must be understood not only as an outcome of individual choice, but also as a relational and spatial practice embedded within urban inequalities.

The results also raise critical questions about the universality of cultural metrics. While this study draws upon UNESCO's Framework for Cultural Statistics (2012) to guide the design and interpretation of survey instruments, the application of such frameworks in secondary cities like Kayseri reveals key limitations. Standardized indicators may obscure context-specific dynamics and overlook alternative, informal, or non-institutional forms of cultural expression that are vital to local identities. In line with Roaldsnes (2025), this study underscores the need to attend to the spatial-temporal embeddedness of participation—how seasonal rhythms, municipal planning calendars, and local traditions mediate cultural engagement in context-specific ways.

These findings collectively indicate that increasing cultural participation in Kayseri will require multi-level interventions that not only address structural barriers, but also recognize and integrate local cultural practices. This necessitates a shift in cultural policy toward inclusive, participatory planning that reflects the lived realities of diverse populations in secondary cities.

This study provides a comprehensive exploration of cultural participation patterns in Kayseri, a city that possesses significant cultural heritage yet continues to exhibit relatively low engagement levels. The findings confirm that while many residents value culture and express a desire to participate, structural and symbolic barriers often inhibit their ability to do so. This phenomenon echoes broader scholarly debates on cultural inequality, wherein participation is shaped not solely by individual preferences but by socio-economic, spatial, and informational asymmetries (Bourdieu, 1984; DiMaggio & Useem, 1978).

One of the study's most striking revelations lies in the discrepancy between attitudinal support for culture and actual engagement. Despite nearly two-thirds of respondents deeming culture "important" or "very important," only a minority regularly attend cultural events. This gap reinforces prior claims that positive dispositions alone do not guarantee participation in the absence of enabling conditions (Miles & Sullivan, 2012). Instead, our data suggest that participation is mediated by an ecology of access, where economic hardship, time poverty, limited spatial mobility, and informational deficits intersect.

The strong presence of economic and temporal constraints—identified as the most significant barriers—resonates with cultural access literature that foregrounds cost and time as recurrent inhibitors (Chan et al., 2008; Stevenson, 2013). In the Kayseri context, ticket prices, transportation costs, and competing responsibilities among working-age adults represent core challenges. Moreover, the urban geography of cultural provision remains highly centralized, limiting access for residents in peripheral districts—an issue corroborated in spatial justice and cultural planning literature (Grogan, 2021; Finkel et al., 2019).

The findings also point to substantial informational and social barriers. The prevalence of late or inadequate announcements, limited outreach through digital or local channels, and a lack of event diversity reflect an ongoing misalignment between supply and demand. This is consistent with Holden's (2006) argument that cultural institutions must evolve from traditional producer-consumer models toward dialogic, audience-responsive frameworks. Furthermore, the lack of a supportive peer environment for cultural engagement—reported by nearly half of the respondents—suggests that cultural participation is not only an individual act but a socially embedded practice, often shaped by networks of encouragement and belonging (Bennett et al., 2009).

The digital dimension of cultural engagement in Kayseri also reveals significant disparities. While social media use for cultural content is high, more substantive formats such as online workshops or virtual museum visits remain underutilized. Age and income were found to be major predictors of digital participation, confirming findings in other studies highlighting the digital divide in cultural access (Selwyn, 2004; Heikkilä & Sassi, 2021). These disparities underscore the need for inclusive digital strategies that move beyond passive content delivery to foster interactive and meaningful online experiences.

Finally, respondents' open-ended definitions of culture demonstrate a pluralistic and hybrid understanding that encompasses both tangible heritage and lived practices—aligning with UNESCO's broader definition of culture (2003) and anthropological perspectives that frame it as a "web of meaning" (Geertz, 1973). The prominence of food, tradition, art, and museums as cultural referents suggests that policies should not limit themselves to high-cultural institutions but instead embrace everyday and community-based expressions.

6. Conclusion and Policy Recommendations

This study offers a comprehensive analysis of the structural and experiential dimensions of cultural participation in Kayseri. Through the use of a standardized survey grounded in UNESCO's (2012) methodology, the research identifies both the scope and limitations of cultural engagement in a historically rich yet under-researched secondary city. The findings underscore that cultural participation is not evenly distributed across the urban population and is shaped by a complex interplay of economic, educational, spatial, and symbolic barriers (Bourdieu, 1984; DiMaggio, 1982).

Despite Kayseri's wealth of tangible and intangible cultural assets, participation remains limited, particularly among lower-income groups, women, and youth. Barriers such as affordability, lack of awareness, and restricted physical access align with broader structural conditions, highlighting the embedded nature of cultural exclusion. These findings resonate with critiques of European cultural policy discourses that often individualize non-participation while neglecting systemic inequalities (Stevenson et al., 2017; Jancovich & Stevenson, 2023).

In response, this study proposes a series of policy recommendations aimed at fostering a more inclusive and equitable cultural environment:

• Adopt Participatory Cultural Planning Cultural institutions and local authorities must adopt participatory mechanisms that actively involve underrepresented groups in decision-making processes. This includes co-designing cultural programs with local residents and diversifying content to reflect plural identities, needs, and interests.
• Develop Targeted Outreach and Awareness Strategies Informational gaps should be addressed through strategic communication efforts, particularly in peripheral neighborhoods. These efforts must be complemented by improved transportation infrastructure and the establishment of decentralized cultural hubs embedded in residential areas.
• Recognize Informal and Everyday Cultural Practices Cultural policy in Kayseri should shift from a supply-driven model toward a needs-based, place-sensitive approach that acknowledges informal and everyday cultural practices as legitimate forms of participation. This reframing requires the integration of cultural access into broader urban and social policy frameworks, linking it to education, mobility, and social cohesion.
• Adapt Standardized Metrics to Local Contexts While UNESCO's cultural statistics framework offers a valuable starting point, its application in secondary cities like Kayseri reveals limitations. Standardized indicators may obscure local dynamics and overlook non-institutionalized forms of expression vital to community identities. In line with Roaldsnes (2025), the study calls for the development of culturally sensitive, spatially embedded, and temporally attuned metrics that reflect local patterns of engagement.
• Expand Research Methodologies Future research should complement quantitative surveys with qualitative methods such as interviews, focus groups, or ethnographic observation to capture the lived experiences and cultural meanings of participation. Longitudinal and comparative studies across cities in Türkiye would further enrich the evidence base for inclusive cultural policy-making.

By shedding light on the local dynamics of cultural participation, this study not only contributes to academic debates on culture-led urban development but also provides actionable insights for policymakers, planners, and cultural actors. Advancing inclusive cultural governance in secondary cities like Kayseri demands both structural reform and a reconceptualization of participation that values diversity, everyday practices, and the co-production of cultural life.

While future research should expand the empirical base through longitudinal and comparative studies, this investigation provides a foundational step toward rethinking cultural participation in Türkiye's secondary cities. By positioning cultural engagement as both a right and a process, policymakers can begin to build more just, inclusive, and resilient cultural ecosystems.

Metropolitan Cities as Living Monuments: Resilient Territories between Culture, Justice and Innovation

Antonella Contin
Affiliation: Politecnico di Milano
Email:antonella.contin@polimi.it

Abstract
The text redefines the concept of the monument within metropolitan conservation, shifting from a static object to an active, antifragile device that generates values and behaviours over time. Conservation becomes a dynamic design process aligned with societal sustainability and evolving heritage, rather than mere material preservation. At the metropolitan scale, cities are seen as living monuments—relational infrastructures fostering cultural continuity and innovation. They catalyse social and environmental transformation, translating local knowledge into adaptive strategies. Case studies introduce the idea of eco-centrality as a node of territorial resilience, where new forms of living, producing, and governing emerge. These places integrate sustainability, spatial justice, and care for the commons, offering a forward-looking model of urban development rooted in cultural vitality and collective agency.

Keywords: Antifragile heritage; Metropolitan resilience; Eco-centrality

Heritage as an engine for localising the SDGs: culture, metropolitan policies and sustainable connections

The territorialisation of the Sustainable Development Goals (SDGs), known as 'localisation of the SDGs' (Senatore, Bellabarba, 2021), is a key element in implementing a sustainable development strategy. This approach is based on multi-level governance and the involvement of territories, civil society, and non-state actors in the policy cycle, from planning to monitoring and evaluation.

There are four vectors of sustainability: planning and design for sustainability, policy coherence, culture and participation in sustainable development.

In particular, culture promotes training, information, and communication to strengthen governance and encourage population involvement. It also develops the capacity to closely observe contextual factors to identify what needs exploration in order to improve the quality of life for metropolitan populations.

In our research at the MSLab of the Politecnico di Milano, we asked ourselves whether humanity's quality of life remains the central reference for any consideration. Our reflection runs through the transformation of cities driven by emancipated and multi-ethnic societies shaped by technological progress.

Indeed, with the evolution of technology, geopolitical changes, and the expansion of cities into rural areas, there is a need to integrate non-linear urban realities by merging elements of ultra-modernity with fragments of neo-archaism. Modern metropolises, once deeply connected to the bodies of their inhabitants and urban spaces, now struggle to re-establish this relationship. Critical issues arise, such as the integration of historic and peripheral areas into the urban fabric and the need to design policies for metropolitan spaces that can engage with the local physical context, which has shifted in scale while maintaining its own identity to avoid producing a generic city (Koolhas, 1995). Areas emerging from the destruction of war or natural disasters deserve special attention.

Our research focuses on implementing a strategic framework to guide the transformations necessary to overcome the negative impacts of the metropolitan scale. Furthermore, in line with the new European Green Deal, we emphasise the central role of sustainability in evaluating metropolitan-scale policies that require introducing the cultural component of local populations.

In this context, ecological and social transitions are intertwined in an integrated and cooperative transformation process. The final objective is to present examples of local cultural resistance actions that influence decision-making processes at the metropolitan scale for the development of inclusive public spaces and new metropolitan typologies, with a specific focus on metropolises' grey-green infrastructure and its impact on the individual and collective behaviour of 'conservative' and 'futurist' inhabitants.

The link between the localisation of the SDGs and culture underlines the crucial role of territories and their knowledge in promoting metropolitan sustainable development projects and policy coherence. Integrating the 2030 Agenda into horizontal metropolitan and vertical local planning processes relies on the meaningful engagement of various metropolitan and local agents.

A combination of culture and civil society movements is essential. Artistic practices can create a discontinuity with the past through an emotional rupture. However, this remains momentary and didactic if the wedge of mobilisation does not widen and if we stay anchored to a vision of art limited to individual emotion. Instead, they must be capable of leaving a mark of permanent value, contributing to constructing a collective landscape, producing a shared experience, and defining and recognising a community.

Millions of people, frightened and distressed by a significant rise in inequality, must be provided with a convincing alternative: a radical realignment of public governance to the collective interest and the right to their own 'lifestyle'. We would like to present proposals and experiments on this approach formulated by the MSLab of the Politecnico di Milano, particularly in Latin America.
That requires efforts to change the prevailing common sense, i.e. the mental predispositions, beliefs and attitudes that guide our decisions. Once again, science, history, knowledge, and local culture, which exist in the ashes, show us the way. We need a combination of two ingredients: culture and civil movements.

The new idea of a monument
According to the Venice Charter (ICOMOS, 1964), the notion of monument includes the architectural work and the urban/landscape environment.

I would replace this definition with that of a monument as an architectural sign that establishes a virtuous behaviour that is valid for a period of time (Choay, 1992).

That means that any significance of value we attach to an architectural fact is not linked to a 'then', but because it is recognised as valid today as it was then.

Thus, we can point to a value of time that does not focus on permanence but on duration, that is, on that which persists because it has determined lasting relationships with the context to which it belongs.

The relationship between past and present makes the past meaningful insofar as it can activate the reasons for today, and conservation is authentic if, after conservation, society can remain alive. With the extinction of society and, consequently, of subjective time, there is no longer any meaning or value in conservation; therefore, we can define that the sustainability of action is linked to its strong relationship with the survival of human society. Sustainability, thus, must be considered in the light of a temporality understood in its variance that requires an understanding of the meaning of the common sense, and of the accidental event that breaks into the metaphysical dimension of principles. The question is the value relationship between what we now consider eternal and accidental, temporary and consumable.

The theme of consumption encourages us to reflect on the relationship between human beings and nature, which has been profoundly transformed. This transformation carries philosophical, ethical, and practical implications that have shaped our understanding of the natural world and our role within it. It is linked to three interdependent concepts: freedom, constraint, and the secularisation of nature.

If we consider the metropolitan dimension, we can argue that the 'metropolitan commons'- that which today's generation must preserve for future generations as the mark of cultural value to leave as a testimony to its understanding of the world of this era and its society- is precisely what we can still call the cultural landscape, within which nature also lies, since it is no longer possible to distinguish human history and its preservation from that of the planet. Dipesh Chakrabarty, in his The Climate of History: Four Theses (2009), leads us to look at the entanglement between culture and nature as an extreme attempt in the age of the Anthropocene to save the planet.The concept of entanglement, also proposed by the New European Bauhaus, is the eye of the storm from which to understand the current condition and to comprehend what the culture of nature means today, i.e. the entanglement between culture, technology, and the biosphere that is the unprecedented phenomenon of the current era.

That is where the discussion on the monument comes in. In our Western tradition, the monument serves as the warning that each generation entrusts to the next. But can every warning become a monument? No. A monument becomes a monument only when it elevates itself to a universal rule, a shared obligation, a secular sacred that binds all. In this sense, the monument is metaphysical sacredness made immanent.

This translation of the sacred into immanence is realised in heritage: a heritage that cannot exist only as a warning but takes shape in the collective expectation of leaving a mark of value to future generations, consolidating itself through law and intention.

Today, what gives the warning the status of the monument stems from an inverse process compared to the past, when the sacred deity sanctioned the law. Today, sustainable human behaviour towards nature has become a necessity, a spontaneous form of self-confinement. It is the detachment from the idea of a religious metaphysics, a vital and unavoidable act, to be handed down to those who will come after us as a universal condition and rule, binding for the very survival of humanity.

If heritage is not only a legacy of the past but also an engine of change, a hope, it is a strategic resource for shaping sustainable urban futures. As cities work to localise the Sustainable Development Goals (SDGs), cultural and natural heritage becomes crucial to integrate policies across sectors, linking water, agriculture, food, mobility and social equity.

Heritage, serving as a bridge between tradition and innovation, conservation and transformation, underlies the New Urban Agenda's emphasis on strengthening the links between city and country through the definition of Urban-Rural Linkage Patterns, which are an integral and fundamental part of the new metropolitan landscapes (Contin,2021).

Achieving the sustainability goals of our metropolitan cities enshrined in SDG 11 requires moving beyond isolated interventions to integrated metropolitan policies that address climate adaptation, resource efficiency and social inclusiveness while strengthening local identity. European frameworks such as the Green Deal (European Commission, 2019) and the Digital Agenda (European Commission, 2010) emphasise the alignment of heritage with green and digital transitions. However, systemic change requires adaptive governance and flexible institutions that respond dynamically to evolving challenges.

Metropolitan landscapes are complex ecosystems in which heritage plays a vital role in maintaining regional equilibrium; incorporating heritage into planning processes is key to addressing socio-economic inequalities and environmental degradation. The Mombasa Swahilipot Hub (https://www.swahilipothub.co.ke/) demonstrates how youth culture, digital innovation and heritage entrepreneurship can challenge traditional patterns of preservation, transforming metropolitan heritage into a catalyst for economic growth and highlighting the need for strategies that integrate heritage into spatial development.

Even more, the Quintuple Helix Model (Contin, Sona, Pesci, Porreca, Pandolfi, Yang, Koike, 2025, p.253) includes the environment among the stakeholders and offers a governance framework that balances economic, environmental, and social factors. This approach is particularly strategic in conflict-affected areas, such as Gaza.

War erodes the protection of human rights and leads to the destruction of cultural heritage.

War is abhorrent because it also erases the complexity and dynamism of cultural heritage. It erases the multiplicity of human existence, cultural spaces, and shared meanings. It erases the possibility of crossing cultural boundaries and learning from others who appear different. UNESCO should have the courage to declare that the war in Gaza is destroying people's right to their Memory and History.

Our study of the autumn semester 2024/2025 at the Politecnico di Milano was based on research and academic collaboration between the GLA programme, Birzeit University, An Najah National University and Gaza students enrolled in the online educational programme at the aforementioned Palestinian institutions, AUB in Lebanon and the Politecnico di Milano. The semester's intervention took place in the Gaza Strip, Palestine, focusing on the landscape of emergencies in the territories in transition. Students and teachers explored the concept of landscape in conflict and related planning for socio-environmental justice in a war-torn territory, Gaza, Palestine.

Landscape results from a dynamic interaction between a community and its environment, demonstrating how landscape architecture can foster socio-environmental justice by linking heritage conservation to resilience and recovery efforts.

This is why we have argued that urban resilience is no longer about survival but about anti-fragility. We use crises as opportunities to rethink governance and planning. This approach encourages urban planners, architects, and politicians to see heritage as an active force in transitions towards sustainability.

Urban planning in fragmented territories such as the Gaza Strip and the West Bank is not only a response to systemic oppression but also a profound act of resistance and resilience. Our Master Studio Project demonstrated that by integrating nature- and culture-based solutions through metropolitan mapping (Contin, Galiulo, 2022) and participatory design interventions, it is possible to reimagine urban landscapes as spaces of equity, connectedness and sustainability.

The case studies and strategies presented, such as the reconversion of fragmented empty spaces into agricultural networks and rehabilitating coastal areas in Gaza to foster shared spaces that promote cultural identity, emphasise the transformative potential of urban design in addressing human and ecological needs. These projects exemplify how participatory design processes can counter systemic fragmentation by promoting ownership, solidarity, and collective action. These efforts align with the philosophy of 'Sumud', which embodies perseverance in the face of adversity, sustaining cultural memory and ecological balance (Massad, El-Astal, and Thabet, 2018).

Mapping the damage, segregation, and ecological disruption within Gaza highlights the critical role of cartography as a tool to visualise spatial injustice and imagine alternative futures. By exposing the mechanisms of fragmentation and proposing integrative strategies, the maps presented in this study allow us to transform boundaries into opportunities, gaps into centres and blockages into avenues for collaboration and restoration.

Ultimately, the projects emphasise that resilient urban planning must go beyond survival to envision hopeful, inclusive, and decolonial futures. They invite architects, planners, landscape architects, and policymakers to fuse local culture with global solidarity, creating spaces that resist erasure and support justice, sustainability, and equity. By bridging gaps between people, places, and ecosystems, design becomes a catalyst for healing fragmented territories, promoting lasting coexistence, and building infrastructures of resistance.

Finally, the Heritopolis Society (https://heritopolis.org/), a UN-Habitat initiative within the Korean Ministry of Culture, positions itself at the intersection of cultural identity, adaptive management and policy innovation, promoting cross-sectoral metropolitan connections.

By linking research and practice, as well as past and future, we aim to implement the habitat's local and sustainable cultural landscape. We consider heritage a fundamental pillar for localising the SDGs (Sustainable Development Goals) and constructing more just, resilient, and inclusive metropolitan territories, integrating other knowledge of local communities (Hale, Lynn Stephen, 2014) in current metropolitan projects and policies. It is time to move beyond static notions of heritage. Blood and territorial identity must be dismantled if we are to reconcile conflicts, thereby transforming the identity value of heritage to embrace a new, albeit ancient, idea of democracy.

The metropolis as heritage

The heritage debate revolves around two crucial issues: determining which heritage elements should be permanent and balancing conservation with community growth.

We argue that the definition of cultural heritage is inherently subjective. Traditions play a crucial role in maintaining heritage, but events such as the COVID-19 pandemic have demonstrated how disruptions can alter perceptions of time and cultural continuity. Furthermore, we suggest shifting the focus to fringe events and alternative manifestations to revitalise heritage, emphasising the need for individuals to actively engage with cultural heritage as creators and users, shaping cultural appropriation.

The modern debate recognises the challenge of maintaining cultural heritage while allowing communities to evolve. A successful balance preserves key cultural elements such as street layouts and commercial activities. It also means emphasising the importance of branding cities while permitting the creative reinterpretation of historical heritage. Expanding the definition of heritage includes emerging technologies and creative expressions, arguing that heritage should not be confined to traditional monuments but evolve alongside societal changes.

For this, we must emphasise the transformative role of technology in discovering new aspects of cultural heritage (iHERITAGE, or the 'UNESCO Mediterranean ICT Platform for Cultural Heritage'). Digital tools can redefine the way we perceive cities and experience urban culture. However, we must emphasise the importance of responsible digital information management as it significantly influences our understanding of heritage. Future challenges include integrating technological advances to enhance cultural appreciation without diluting its authenticity (Buragohain, Meng, Deng, et al. 2024).

If we interpret heritage as an infrastructure capable of transporting values/resources, we highlight its dynamic nature. Traditions and recognisable elements ensure continuity, but the anti-fragile approach (Blečic, Cecchini, 2019) makes it sustainable in a changing urban context. The key lies in fostering participation, welcoming creative and counter-thinking reinterpretations, and harnessing technology to enrich the cultural experience, without sacrificing responsible preservation practices.

Our field of research is the Metropolis of the Second Modernity. In the ecological era (Khan, Vandevyvere, & Allacker, 2013), we need to focus on the paradigm of anti-fragility (Taleb, 2014) and de-risking that concerns contingent, fluid, and emergent structures and relations. The metropolis, therefore, in its dimension of bioregion (Barbanente, Fanfani, 2023), represents a 'different nature', a worldview in which nature overflows through its categories and touches culture (and vice versa) and in which human beings do not possess external characteristics that guarantee them a privileged viewpoint on things.

The Metropolis of the Second Modernity must be rethought from the demand for sustainability as a place where the soil, transformed with low environmental impact, becomes a critical node in the metropolitan processes that drive development and determine anthropological, social, technological, economic and managerial mutations. The consumption of energy, materials and, above all, soil must, therefore, be understood as the consumption of a rare commodity within a metabolic approach that calls into question a generational responsibility. For the new generations, it is a matter of building a life-cycle project that puts ecological issues at the centre. We must, in fact, consider the impact of metropolitanisation as a generational threshold: a transition that, in a short time, has

radically altered the lifestyle of local communities.

The coexistence of different places and their communities is typical in metropolitan societies.

The need to consider the metropolis as a cultural issue stems from the fear of losing due to the immeasurable size of the city today, our understanding and control of the spaces we inhabit, and the certainty of our social identities. This anxiety makes the conservative perspective on change extreme and exclusive, even though change is an undeniable reality. The issue of radicalised identities can lead to indifference to the dangers of obsolescence or disinvestment, and conflict intensifies with the rapidity of change. Conversely, there is hope for the future, but sometimes, an uncritical belief in its benefits often overshadows the past as we strive to look only ahead.

In this scenario, various cases of inequality and vulnerability are attributed to the inability to recognise and appreciate the value of cultures other than one's own and the consequent failure to include these cultures in a new metropolitan cosmopolitan culture; the loss of the plurality of different cultures and knowledge results in a resultant monotony of values, with risks of homogenisation and uniformity.

Cultural identity risks becoming a failed project if not conceived as a system of different resources. Moreover, it would be necessary to govern the dynamic transitions of processes and epistemologies, turning them into resources for designing new territories and lifestyles.

The metropolitan structure is based on a systemic approach: the metropolitan scale was chosen as the privileged dimension to observe, with greater precision, the gaps in local knowledge, particularly concerning the know-how of the territorialisation of the twin transitions and their impact on the SDGs.

The Metropolis of the Second Modernity is a system of places constituting its region, an alliance of multiple decision-makers and heterogeneous populations.

In the opening of a path of convergence between macro and micro scales, local intelligence intertwines with global dynamics, becoming a strategic axis.

Recognising the local languages of common sense and the earthworks that inhabit metropolitan areas is necessary. From these elements, we must be able to extract systemic resources that are treated as invariant data on a metropolitan and national scale.

Only then will a metropolitan architecture project be able to return these enhanced values to the territory, strengthening its local identity through conscious regeneration processes.

Resilient territories: Dialogues between city and country
In the past, in many culturally relevant areas, the lack of infrastructure drastically compromised the quality of village life, leading to the exodus of younger generations and triggering a demographic decline that reduced the availability of local labour.

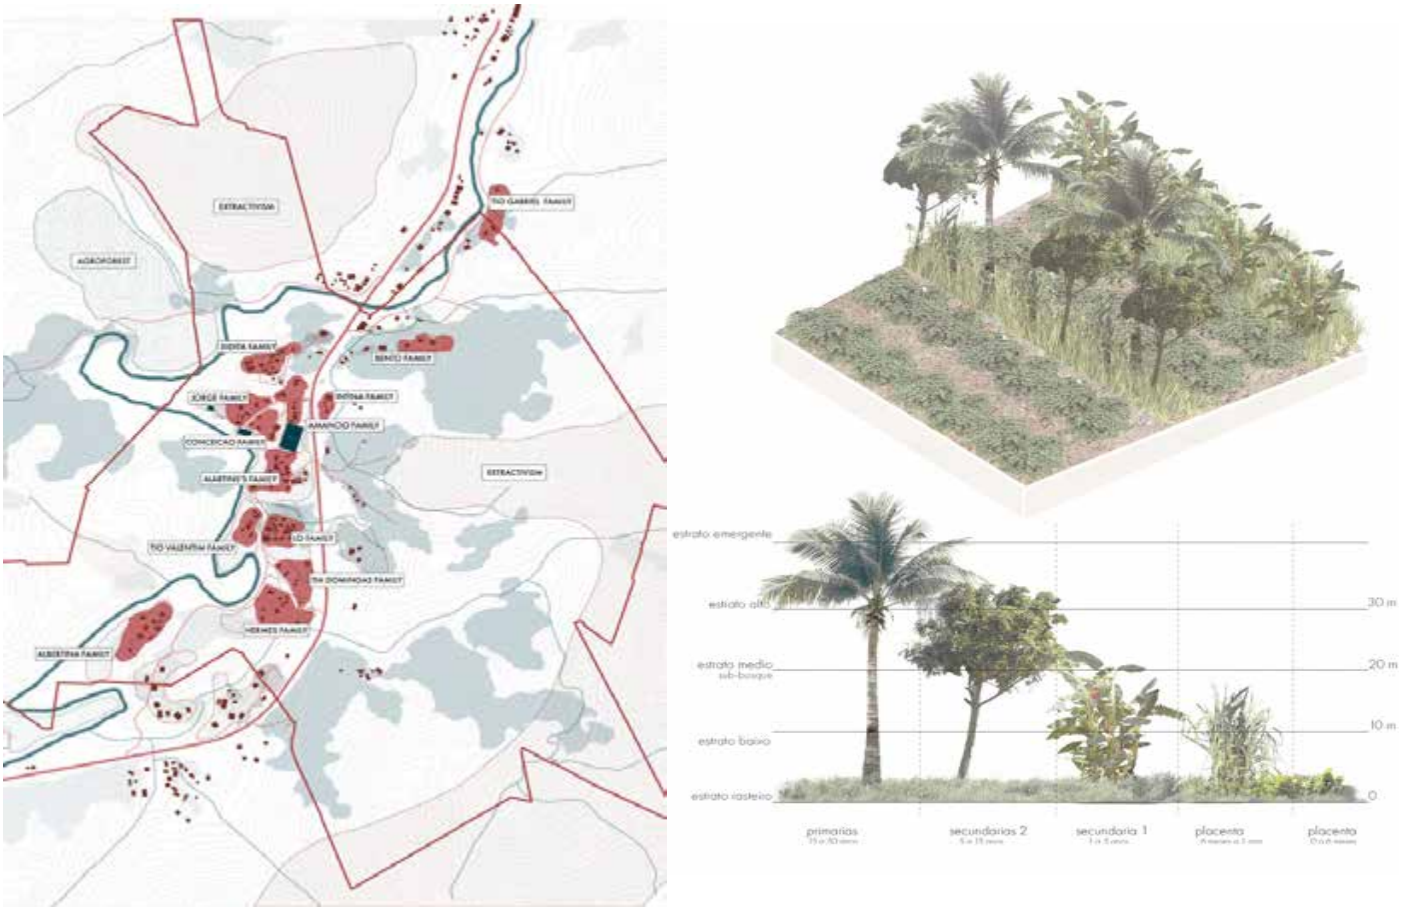

Figure 3. The perimeter of the Quilombo defined by the Palmares Foundation encompasses the areas of 13 family plots, and Agroforest type. Credit. MSLab & Erika Nataly Amidati e Francesca Cisaria.

Today, in those same areas, the increasing influx of tourists has generated a progressive shift from the traditional agricultural economy to the tourism industry, narrowing the range of employment opportunities and reducing the diversity of jobs available.

This shift manifests itself on spatial, economic and socio-cultural levels.

However, alongside these material transformations, there have also been intangible losses: local knowledge - the legacy of practices and skills linked to the land - has gradually been supplanted by a tourist economy that, while bringing new flows, has eroded the fabric of the local economy and disarticulated traditional social structures.

Of course, geography is also instrumental in shaping the divisions between rural and urban areas. Topographical features, including mountains and rivers, as well as policies and regulations, have played a role in the clear separation of areas. This zoning has profoundly influenced the population, and its effects are visible in various places, from economic disparities to social differences.

The fragmentation of rural and urban areas results from a combination of geography, politics, and history, and its effects are still lasting and significant.

In the project Paraty-Quilombo do Campinho (Contin, 2025), we investigate how local knowledge and cultural landscapes can become active agents of change in the face of the most pressing global challenges: climate

change, inequality, and poverty. We propose that new ecocentres, through the strength of their living culture, can play a central role in building resilient and antifragile communities capable of adapting, transforming and thriving in contexts of uncertainty and pressure.

Protecting the natural reserve is crucial for preserving the region's biodiversity. Some areas have been safeguarded to maintain the delicate ecological balance and ensure the continuity of native species. The reserve served as an ecological and cultural barrier at one time, establishing clear boundaries between valleys and fostering settlement agglomerations with distinct morphologies and identities.

In our intervention, we recognised the existence and value of traditional villages, working to enhance the quality of public spaces within a broader heritage conservation project. The objective was to find a balance between the needs of the local populations and the need to protect the fragility of their cultural landscape. We thus decided to activate agroforestry processes in the capoeira areas that had remained inactive due to the cyclical nature of production. In some of these spaces, agroforestry has hosted an experiment in urban-rural linkage: housing units built according to local indigenous techniques have sprung up, revealing new ways of living integrated into the ecological cycle.

In parallel, we proposed revising the UNESCO boundary for the protected area: indigenous building expansion was pushing dangerously towards the Atlantic forest. The design hypothesis was to extend the boundary through reforestation to agroforestry. This strategy, inspired by the theories of David Gouverneur (2015), generated more collective spaces in an ecologically sensitive area and helped turn the Quilombos into active custodians of natural and cultural heritage. Attractive activities and welfare nuclei have accompanied this - true stem cells of the project - that testify to the institutions' presence, care and shared responsibility.

Thus, more living and usable spaces within a protected area can be a driving force for improving the inhabitants' quality of life and offering new opportunities for truly sustainable development and participatory heritage protection.

The gap between urban and rural areas remains significant and requires new strategies of connection and cooperation. Our research in Guadalajara (Mexico) aims to explore metropolitan dynamics capable of building an urban-rural continuum through a multi-scalar approach that enhances the role of small and medium-sized cities and rural service centres, generating new models of connection and complementarity between territories.

At the core of the analysis is the strengthening of local agricultural identity, integrated into the Guadalajara metropolitan region's green and grey infrastructure systems. In this context, rethinking food systems and prioritising environmental care in public policies are strategic tools to address complex challenges related to employment, mobility, access to services, poverty and social cohesion.

Since the second half of the 20th century, the development of the State of Jalisco has been intensely concentrated in the Guadalajara metropolitan area, which is now home to approximately 60 per cent of the State's population. This trend reflects a global process of urbanisation, which risks widening the gap between rural areas, which are often disadvantaged in terms of quality of life and opportunities.

Today, the relationship between cities and the country is no longer defined by clear boundaries. Daily interactions, the mobility of people and goods and functional interdependencies shape new relational geographies. Increasingly interconnected cities operate as nodes of complex networks embedded in specific ecological and spatial contexts.

Figure 4. Eco-centrality and Settlement Concept. Acatlan de Juarez - Guadalajara (Messico). Credit: MSLab & Valerio Rigamonti.

In this scenario, rapid urbanisation requires a rethinking of metropolitan governance. Urban dynamics now go beyond traditional administrative boundaries and require holistic strategies that integrate planning, sustainability and inclusion. It is within this framework that the role of Acatlán de Juárez emerges.

Officially integrated into the Guadalajara Metropolitan Area in 2019, Acatlán - although not yet physically connected to the consolidated urban fabric - acts as an intermediate city, facilitating dialogue between urban and rural contexts along a strategic axis for regional balance. Its location and potential make it a key node for experimenting with innovative models of territorial interaction, promoting a balance between development and cohesion. The MSLab project investigates the potential of an urban-rural connection, already observed in Far Eastern contexts, by importing and reinterpreting the concept of the Desakota region (McGee, 1991). In metropolitan environments characterised by rapid urbanisation - driven by industrial expansion and population pressure- the landscape has fragmented into a constellation of urban, peri-urban, and rural areas, often disjointed. The concept of Desakota, a fusion of Desa (village) and Kota (city), accurately represents this intermediate and blurred condition: a hybrid space where agricultural, residential, and productive elements coexist, forming a complex and interdependent territory. Starting from McGee's analysis and observing the evolutionary dynamics at work in the Guadalajara metropolitan region, the project proposes a systemic approach that activates synergies between rural and urban areas through a network of metabolic relationships. The system is considered a connective tissue in which integrating green and grey infrastructures becomes a fundamental lever to build a resilient, adaptive and learning metropolitan model.

Through a new infrastructural and landscape gradient, the project fosters an urban-rural connection that recognises and enhances the specific identity of each territorial fragment. This strategy mends existing discontinuities and activates a new morphogenetic layer in the metropolis's DNA, creating a capillary weave of coexistence and transformation. Local nodes thus become catalytic devices, generators of meaning and form, capable of triggering systemic regeneration dynamics throughout the entire metropolitan structure.

A theory for metropolitan city culture and a cartographic tool to explore the local sustainable habitat.
Context matters and, in the end, context always wins. That is ultimately the true definition of sustainable culture.

To discuss culture seriously, we must first clarify its operational meaning: culture is the living link between what we know and how we know it. It is knowledge that becomes action. It is not an abstract concept but a reality that guides choices and defines priorities.

We also need a clear definition of the objective. However, targets - especially those with high abstraction - often lose their meaning precisely because they are taken out of context. Take, for example, SDG 11, the urban goal: Where is poverty? Where is inequality? Where is productivity? These are key words for understanding the urban environment, yet they do not appear. We can talk about cities without addressing the issues that define them.

What are we trying to improve with SDG 11 if we examine it from the perspective of the role of local culture in the sustainability of metropolitan landscapes? Does it make sense to discuss urban heritage without recognising that this heritage is embedded in contexts marked by deep inequalities, widespread poverty, low productivity, and high unemployment? It is one thing to speak about urban heritage in a poor African country and quite another in Italy: possibilities change, priorities shift, and the meaning of intervention evolves.

We cannot monitor changes in territory without considering the local economy, ecology, cultures (both formal and informal), institutions, and hierarchies. The local context is always interconnected. Without a theory of the city and an understanding of how urban space is constructed and transformed, we cannot grasp metropolitan culture, let alone comprehend how human behaviour influences urban spaces.

It must be stated emphatically to address a culture-related urban objective. Otherwise, the fundamental questions remain unanswered: How can we improve the living conditions of the majority of urban residents? How can we prevent poverty and inequality from increasing while tourism productivity grows for the few?

These are not abstract considerations; they are concrete problems affecting millions and billions of people. Urban policies must begin by analysing territories, vulnerabilities, and the relationships between local and metropolitan scales. Furthermore, they must adopt a less simplistic and less linear vision.

The World Bank speaks of 'global knowledge, local results. ' However, the most crucial issue is the lack of local knowledge. Knowledge from the territories recognises specificities and lends meaning to action.

Even the word 'commitment', often used in the SDGs, remains empty if it is not based on a vision. Without an urban theory, the mechanisms of cause and effect cannot be explained. There is no social justice. There is no ethics. It is just a list of good intentions, but without the why.

The New Urban Agenda must serve this purpose: to build a vision, choose priorities, and use vulnerabilities as starting points for conscious, concrete, and coherent action.

We cannot solve problems without understanding the conditions that created them. For this, we need a comprehensive, integrated vision. Once again, we must start from the context.

The context influenced the tools, but the tools also reinforced the definitions of the contexts.

The master plan served as the context. Everything that was 'outside the plan' was truly outside and not taken into account. In many urban areas, what was outside the plan was, by definition, illegal and, therefore, subject to demolition by public authorities.

Policies and regulations guide urban behaviour, allocating resources through projects and strategic investment plans. In recent years, there has been a progressive shift of focus towards expected outcomes - what must necessarily be - under the assumption that those involved adhere, almost by nature, to codes of behaviour in design, construction, and use. The central question, therefore, revolves around identifying which rules can steer urban actors in specific directions and what the enabling conditions are for the emergence of that collective intelligence capable of recognising the metropolitan common good as a shared value and resource. That intelligence is necessary to achieve results that are not only formal but also transformative.

However, this is where the limitations of policy instruments emerge: the lack of institutional capacity to effectively implement policies, resulting in a disconnect between strategy and execution. In particular, market-oriented policies—especially in their application to the tourism sector—represent a crucial variant of this scenario. The issue lies not only in directing the actions of individual actors but also in attempting to shape the systemic

behaviour of society, intervening in common sense, shared representations, desires, and value mechanisms, both individual and collective.

In this framework, context refers to the dynamic set of spaces, sites, flows, and interactions between agents, which define the balance between supply, demand, and price. The instruments of stimulus packages - first and foremost, government spending - fit into this logic as typically Keynesian devices for stimulating the production of goods and services, injecting liquidity, and sustaining consumption (Keynes, 1936).The speed of public spending directly affects the pace of the creation of new demand and, thus, the trajectory of economic recovery. Nevertheless, how does this mechanism relate to the operating culture (Salazar, 2023)? How can the economy generate truly widespread forms of prosperity? What values and contradictions does the tourism industry generate for the world culture (Shepherd, 2002)?

The metropolitan architecture projects (Contin, 2015) were designed to translate, through principles of sustainability and interscalarity, the physical objectives of the plan into constructed forms: housing, infrastructure, and social services. The possibility was tested that values and resources linked to operational culture could act as active tools against poverty, inequality and low productivity, improving the quality of life. As a spatial and non-verbal narrative, Metropolitan Cartography (Contin, Galiulo, 2020) recognises and names these values, identifying them as resources to be translated into factual indicators capable of nourishing transformative and measurable processes in the dimension of urban reality.

In this context, the metropolitan architecture project (Contin, 2015) assumes a strategic role: it is configured as a tool to physically formalise values and resources from the operational culture, not as a theoretical abstraction, but as a set of living practices, behavioural codes, and local languages. Through these spatial devices, an accurate collective intelligence capable of recognising the metropolitan common good can be activated beyond institutional rigidities and the limits of normative planning. As a non-verbal narrative, metropolitan cartography makes it possible to identify and translate into measurable indicators those shared values that escape the logic of standardisation and rent. It does not merely represent the territory but traverses it, codifies it, and returns it as a relational space where culture becomes infrastructure and is no longer just symbolic heritage. In this perspective, urban planning must open up to the plurality of languages, recognising in situated behaviour and local practices - even where written law is absent - a generative heritage capable of guiding development, even in opposition to dominant economic interests.

Conclusions and openings: The reactivation of the 'culture of care'; the role of cultural and creative industries in promoting knowledge and education; why conserve?
The proposed project represents an innovative theory for the culture of the Metropolitan City, centred around a large-scale cultural enhancement strategy that focuses on creating an integrated model for utilising cultural heritage. This model, characterised by its unique dimensions and functions, aims to enrich local communities' knowledge and attract interest from non-regional audiences by leveraging the region's significant cultural, natural, and environmental heritage.

The proposal is based on a visionary project that sets the territory in motion, creating a connection between a physical path and an imaginary one: a transgenerational strategic plan project capable of promoting innovative functions for a green and digital economy that can attract new categories of entrepreneurs and users into the territorial system.

A vision that serves as a framework for the new common and public space of relations, acting as a figurative cornerstone and a tool for constructing a memorable yet everyday image to recognise the identity of the new agro-urban reality. This reality recovers knowledge of the environment through innovative mapping methodologies and modern communication technologies that refunctionalize industrial archaeology. It also reactivates the urban fabric by replacing certain features while respecting specific dimensional and formal considerations. However, it must identify a strategic cultural reason for its preservation.

It is necessary to consider supply chains that create a new economic dimension around which to 'do agriculture' and 'do handicrafts', starting from the understanding of the territory as a resource and analysing the data constructed by the citizens themselves. Synergy will be the keyword: between municipalities and their territories,

between hoteliers and tourists passing through, and between hoteliers, entrepreneurs, and schools.

Starting from a project as an engine for the renewed hydration of cultural energies within the identified urban system, a project that recognises its value concerning the three ecosystem services of supply, regulation, and culture (which are crucial today in light of the recent flooding phenomena), we aim to list areas and themes that can be subjects of a process of innovation and social evolution:

1. Urban-rural areas: The sociology of agriculture and the urban park;
2. Built city: mapping and diagnostics, common and public spaces (the sponge of the urban fabric), green areas reclaimed from built-up areas, the relationship between land use and water system management (the city as a source of quality water);
3. Neighbourhoods: maintenance, development and transformation. The recovery plan and innovative solutions;
4. New citizenships: cultural start-ups, inclusion (second-generation migrants), diffuse tourism.

The project identifies two approaches: one is based on molecular re-appropriation of the territory, promoting local values to create relationships between territory and settlement; the other aims to work on the nodes of interchange between regions and cities, viewing territories as archipelagos and networks of sustainable activities, with cities seen as systems composed of a web of networks and nodes, understood as dynamic and interconnected networks of relationships (Castells, 1996) that connect urban and rural actors, facilitating the exchange of knowledge, cultural practices, and forms of resistance (Srinivasan, 2017).

This network is expressed through social, economic, and cultural connections beyond classical spatial separations, generating a mutual and sustainable interaction between city and countryside (Ananthasubramaniam et al., 2022). The active nodes of this network - the hinge points - function as connection (web) hubs: points of tension and contact that, as in a web, spread and multiply these relations in the territories, traversing what Shane (2005) calls body of space, those 'spaces in between' dense with potential, friction, and transformation (see: https://www.myvillages.org/index.php).

By fostering the sustainability of agricultural areas through the creation of synergistic production circuits (agriculture, production-transformation of natural resources in a sustainable manner), a new model of territorial system is established that views agriculture as 'the other part of the city, but city', integrating it through the introduction of new functions and a new concept of supra-municipal public space.

To counter the dissipation of our heritage, which the new urban scale could induce, we need to refine the concept of sustainability: how is regeneration sustainable? We aim to honour the identity dimension of the context, where stagnation presently prevails instead of development. Agriculture is essential for the city, contributing to sustainability like a spring by safeguarding water and alternative energies linked to local waterways and the surrounding context. It is vital to envision supply chains that create a new economic dimension centred on 'doing agriculture' and 'doing handicrafts'. Synergy will be the key term for the project's structural component, while communication will be the second key term.

A pilot project, *City of Muses*. The arts of the city and metropolitan landscapes
In his text, The Image of the City, Kevin Lynch (1960) explicitly aims to control the production of the urban image by elaborating a visual plan for the city, promoting a reordering of public mental images of the urban environment to foster greater integration of citizens with their places of residence and work. Lynch's approach seeks to reveal a possible order beneath the chaotic appearances of the urban landscape, emphasising it through increased figurability, i.e., the individuality and visual evidence of forms.

Lynch's project, which we would like to support, aims for an urban figurability of the metropolitan dimension that is intended to manifest in a visual plan not confined to the aesthetic realm but also focused on the well-being and psychological safety of urban users. This state of 'feeling adequate' is closely associated with the ability to orient oneself: figurability is, therefore, the clarity of visual matrices.

The intention is to design a shared public mental image of the city and its metropolitan landscapes through the recognition of the profound identity of the selected places: a portrait that combines spatiality and the arts,

particularly music and images. In this context, the architectural project becomes a salient expression of the city, contributing decisively to its mental image.

The proposal - as already outlined by Tschumi in 1981 - is understood here as a network of stem cells or connection nodes (web) scattered throughout the new metropolitan landscapes. It aims to initiate a reflection on the relationships between architecture, cities, landscapes, and the arts, establishing a dialogue between architectural and urban design, technologies, and art. The ultimate goal is to enhance the quality of urban space, providing art with significant opportunities to communicate rhythms, sounds, sociality, and well-being. In particular, we intend to explore the relationship between art and urban space concerning the redevelopment of places through traditional and innovative devices activated by 'ephemeral architectures' capable of introducing an augmented sensorial experience in public areas through music and images.

The project supports a vision of the analysis, interpretation, and design of metropolitan urban interiors through forms that cannot be traced back to Euclidean geometry, capable of generating spatiality through the support of music and images. The aim is to envision structures that can be realised with inexpensive, durable, and sustainable materials. Among the areas of research explored is the use of 3d printing and solar concentrators (Müller, Zastrow, 2015), with the intention of developing a system that can be modelled during assembly using parametric digital tools. Experimentation also involves interactive technologies in design, architecture, and robotics, utilising physical computing systems, which are understood as environments capable of perceiving and reacting to stimuli from the surrounding environment.

If the project anticipates the subsequent deconstruction of the installations, it is configured as a permanent transformative action of the public space, which is enhanced both in the collective imagination and in the virtual dimension created ad hoc. The latter, reconstructed using sophisticated software and archived online, will host all data related to the places, allowing the installations to be revived and reapplied elsewhere.

A metropolitan urbanity project is outlined through a series of installations that experiment with innovative materials, augmented reality, and responsive interactions. Utilising new technologies opens up a new way to map the city, allowing urban values to be communicated on a different level. The installations interpret space in relation to sound, light, and sustainability, establishing profound connections with historical places and urban art, which are rediscovered and recognised through a spatiality where music, images, and narratives merge. The intention is to trace an itinerary capable of rewriting the narrative of the city and its suburbs, guiding citizens and users to discover an unprecedented historical and future heritage.

The elliptical itinerary will have a beating heart. It will construct a new narrative of the city that accounts for its past, recent history, and urban, rural, and natural contexts, laying the foundations for future perspectives that enhance a new metropolitan identity. Each landscape will tell its own story and serve as a treasure chest to be discovered, engaging in dialogue with other places through diffuse installations. With its scenic effects, technology will connect citizens with music, the city, its networks, and its forgotten or hidden landscapes.

The operation not only connects the mother city with its most precious objects, but also acts in the opposite direction by bringing the city into other hinge points of the metropolitan landscapes. The images, photographs, and videos of the places and their history conveyed by the installations will construct a new urbanity as part of the metropolitan landscapes. Just as in ancient times, large-scale event apparatuses were built to embellish the city, today, the urban landscape will be broken down into its most beautiful parts and distributed in forgotten places.

The route will be accessible both physically and through a dedicated mobile application. New technologies prove to be fundamental in creating innovative landscape settings that encompass historical, agricultural, and natural heritage. Responsive technologies are transformed into educational and informational tools capable of transmitting and archiving multimedia content. The reactivated places once again communicate the strong message of the city of the past, projecting it into the future.

The project aims to reinterpret the metropolitan city, fostering a new territorial awareness and a strong cultural identity for a sustainable future. It also seeks to integrate the cultural sector with tourism, research, innovation,

and education, identifying key locations for valorisation, cultural animation, dissemination, and training activities.

The interaction between new technologies and regenerated public spaces represents an opportunity to connect the metropolitan city's most prestigious institutions in an articulated system of places, knowledge, and visions capable of regaining an authoritative position in the global city network.

The metropolitan city of the second modernity is configured as an integral fusion of biosphere, water, and soil, which we call the critical zone (Latour, 2004). It requires regenerative agricultural techniques and a profound synergy between culture and science. This intertwining - the entanglement - strengthens the resilience of the natural system and places society at the centre of protecting this fragile but potential heritage.

In the Urban-Rural Linkage Patterns project, the network of hotspots- junction points, such as the metro-world web- functionally and symbolically interconnected, becomes a design element and socio-spatial device. These can activate resources and build ecological narratives and forms of environmental governance. In this context, we propose constructing an abacus of patterns of network hotspots, which will be included as recognisable elements in the metropolitan structural plan, along with defining information layers to create localised maps using open-source data.

The project is configured as a precise cultural enhancement strategy through an innovative and integrated model of heritage use. It is aimed at both the local public and external users, attracted by the widespread cultural, natural, and environmental excellence. The expected repercussions on the territory are multiple: a greater dissemination of knowledge of the heritage, an improvement in the quality of life, an increase in tourist flows and employment opportunities, as well as an enhancement of the image and local development. The project actively involves the local population, especially young people, through workshops and educational activities, while externally targeting users interested in exclusive, innovative and immersive cultural experiences. The ultimate goal is to expand the use of immersive virtual reality, moving it from mere entertainment to a cultural and academic sphere, opening the doors of museums and historical sites to the world in an accessible, detailed, interactive and deeply personal experience.

Through an application, each citizen will be able to experience and relive these spaces, creating individual mental maps and forging a new relationship with the city and its landscapes. This will be supported by effective, engaging communication that can reactivate the lost urban narrative. The City of Muses is not just a project: it is a system, a generator of art, innovation, economy, and future.

Study on evaluation of liveliness level and promotion strategy for Intangible Cultural Heritage in Qinghai Province

Zhe Wang
Affiliation:Xi'an University of Architecture and Technology,Xi'an,China
Email:1979901178@qq.com

Abstract
The shift towards living heritage protection necessitates robust evaluation systems. This study constructs a quantitative assessment model using the Analytic Hierarchy Process (AHP), integrating four dimensions: carrier transmission, policy support, social engagement, and production efficacy. Empirical analysis of Qinghai Province reveals: (1) moderate overall vitality with marked internal disparities; (2) hierarchical dimension performance—carrier transmission excels while policy support lags; (3) traditional crafts and folk customs demonstrate stronger vitality through effective dissemination, contrasting with marginalised traditional sports. Proposed strategies encompass liveliness inventory management, spatial carrier development, and 'Integrating Intangible Cultural Heritage' integration strategies. The model transcends conventional qualitative paradigms, providing a theoretical-practical framework for optimising living heritage mechanisms.

Keywords: Intangible Cultural Heritage; Liveliness level; Evaluation system; Promotion strategy

0. Introduction

Under the background of the transformation of world cultural heritage protection from "emergency preservation" to "liveliness inheritance", the protection concept of intangible cultural heritage (hereinafter referred to as "ICH") has changed, gradually shifting from "cultural remnants" to "liveliness" protection. The Convention for the Safeguarding of the ICH, officially adopted by the 32nd session of the UNESCO General Conference, clearly states that "safeguarding" refers to all measures aimed at ensuring the viability of ICH, including its identification, documentation, research, preservation, protection, promotion, transmission (especially through formal and non-formal education), and revitalization. The protection of ICH should focus on its "liveliness inheritance process" rather than merely preserving it as a static cultural specimen. However, current ICH protection practices generally face two major problems: the contradiction between cultural authenticity and modern adaptability, and the dilemma of ambiguous protection subjects and insufficient inheritance motivation. How to scientifically assess the liveliness survival level of ICH and formulate precise improvement strategies has become a focus of both academic and policy circles.

As a convergence point of diverse cultures on the Qinghai-Tibet Plateau, Qinghai Province possesses six representative works of human ICH, including the Thangka Art and the Epic of King Gesar, as well as over a hundred national and provincial-level ICH projects. Its ICH is characterized by ethnic diversity, ecological vulnerability, and the threat of extinction. Despite the government's efforts in strengthening protection through legislation and establishing protected areas in recent years, some ICH still face the crisis of "museumization" due to issues such as inheritance gaps, limited dissemination, and lagging industrialization.

Against this backdrop, constructing a quantitative evaluation model to analyze the liveliness state of ICH, identify its development shortcomings, and propose differentiated strategies not only provides a theoretical tool for regional ICH protection but also has practical significance for maintaining cultural ecological balance and promoting sustainable development in ethnic areas. This study, through literature analysis and the Delphi method, deconstructs the "Four Forces Model" of ICH liveliness state (inheritance force, dissemination force, innovation force, and vitality force), aiming to provide a scientific basis for the protection and development of ICH in Qinghai Province.

1. Research Progress and Theoretical Framework

1.1 Review of Domestic and Foreign Research on the liveliness Protection of ICH

After the United Nations Educational, Scientific and Cultural Organization (UNESCO) proposed the concept of "all living cultures" in 1994, the term officially entered policy documents. The release of the Convention on the Protection and Promotion of the Diversity of Cultural Expressions in 2005 marked that "liveliness" has become a key theme in the field of cultural heritage protection and a central goal of cultural heritage protection actions. In 2009, the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM)

systematically proposed the “Living Heritage Approach” (LHA), emphasizing the liveliness continuation of the cultural value of heritage.

Abroad,(Jia, L. ,2024) related research focuses on the following aspects: In terms of legal guarantee systems, the European Union established a hierarchical protection system through the European Heritage Law, incorporating the protection of ICH into a unified legal framework and strengthening the enforcement effect through regional collaboration. France’s Heritage Protection Law pioneered the concept of “cultural space”, combining the material carriers of ICH with liveliness practices, promoting adaptive protection by law for liveliness inheritance. Japan’s Cultural Properties Protection Law established the “Living National Treasure” certification system, encouraging inheritors to participate in liveliness practices. In terms of community participation models, Mexico’s “Day of the Dead” festival achieved the liveliness renewal of ICH through community self-organization, and its experience was summarized as a three-stage model of “festival empowerment - skill regeneration - economic feedback”. (Table 1)

Table 1 Topics and Contents of Overseas Research on ICH

Research Topic	Author	Year	Research Content
Sustainable Development of ICH	Giliberto	2020	How cultural heritage projects implemented in the MENA region promote environmental sustainability through ecotourism and sustainable agriculture.
Community Participation in ICH Research	Sheila Watson	2010	Community-led conservation measures tend to be more sustainable, and ICH projects can better reflect the uniqueness and diversity of local culture.
Cultural Landscape Heritage and ICH	Daniel	2013	The relationship between cultural landscapes and local identity, how local cultures are preserved and displayed through heritage landscapes in the context of globalization.
Digital Research on ICH	Bonacchi	2019	Through digital museums, virtual exhibitions, etc., the display and dissemination of ICH have become more convenient and extensive.

In the domestic academic circle, there has been a consensus that ICH is regarded as a living culture with its own liveliness attributes. Based on this, the calls for and academic exploration of liveliness protection have been deepening. (Qi,Q.F. ,2009) clearly proposed the viewpoint that the fundamental purpose of protecting ICH is to preserve the "living inheritance". He believed that all protection methods conducive to the preservation of the living inheritance of ICH are reasonable. (Liao W.J. ,2013) argued that ICH has both cultural value and market value, and the transformation from recognition to practical implementation of living protection is a necessary issue for the inheritance and industrial development of ICH. (Qi A.M. ,2017) constructed an institutional system for the liveliness protection of inheritance schools, and institutionalized the concept of liveliness protection of ICH. (Huang Z.Z. ,2024) proposed that "livelinessization" is a practical path connecting the historical value of ICH with current needs, emphasizing the need to highlight the people-oriented, contemporary, and national nature of ICH through liveliness protection, and avoiding it from becoming static exhibits. Current research mainly focuses on external factors of living inheritance and protection, such as government management, market operation, legislative guarantee, school education, and ecological museum construction.

1.2 The Essence of the Liveliness level of ICH

The concept of "living attitude of ICH" refers to the comprehensive degree at which a specific ICH maintains its vitality during the liveliness process of inheritance through the maintenance of its essence, adaptation to the environment, and transformation of value. The living space centered on ICH and serving as its carrier is linked by the inheritors, connecting the physical and spiritual spaces where the heritage exists. The embodied knowledge, experience, skills, and folk beliefs formed in this way are perfected through the inheritance mechanism in

contextualized teaching and practice, and are continuously refined into a shareable knowledge form in the process of practical application, thereby enabling the knowledge and culture related to ICH to be recognized and orderly inherited, and reflecting the vitality of ICH.

This paper studies its connotation and includes four core dimensions: the degree of carrier inheritance centered on ICH, manifested as the completeness of the inheritance lineage and the intergenerational continuity of skills and knowledge; the policy support degree based on systems, covering the levels of legal protection, the intensity of financial investment, and the effectiveness of restoration of inheritance space; the social exchange degree driven by interaction, manifested as the breadth of public participation, the depth of media dissemination, and the intensity of cultural identification; the production adaptation degree oriented by innovation, reflecting the conversion efficiency and market vitality of ICH resources into the modern economic system. The characteristics of the "living attitude of ICH" can be perceived from aspects such as carrier characteristics, expression form characteristics, cultural characteristics, and activation characteristics. An example analysis using six projects from the Representative List of the ICH of Humanity of Qinghai Province is provided, as shown in the Table 2.

Table 2 The characteristics of the Liveliness level of ICH

Name	Carrier Feature	Form Feature	Activation Feature	Illustration
Thogon Art	With Tangka, murals, sculptures, etc. as carriers	integrating Tibetan Buddhist culture and folk art elements, featuring bright colors and rigorous composition.	Business value	
Flowers	Presented through folk song performances	The melody is high-pitched and melodious, the lyrics are simple and natural.	Video and audio	
Gesar	Presented through epic singing	It is of a grand scale, with a rigorous structure, vivid language, and rich imagination.	IP development	
Tibetan Opera	Presented through theatrical performances	It integrates various art forms such as music, dance, and performance.	Festival format	
Chinese Shadow Puppetry	Presented through the use of carved human silhouettes made of animal skins or paper	During the performance, the silhouettes are projected onto the screen using light, accompanied by singing and music.	Cultural performance	
Tibetan Medicine Bath Therapy	It uses natural minerals and plant medicines as the bathing agents	It acts on the human body through methods such as soaking and fumigation.	Health preservation concept	

2. Construction of the Evaluation Model for ICH Liveliness level

2.1 Evaluation Method

This study adopts a combination of the Delphi method and the Analytic Hierarchy Process to construct the evaluation model for ICH live attitude. The Delphi method conducts multi-round anonymous expert consultations to screen and revise the rationality of the evaluation indicators for the live activation of ICH, ensuring the scientificity and authority of the indicator system; the Analytic Hierarchy Process constructs a hierarchical indicator structure,

constructs a judgment matrix, and conducts consistency tests to quantify the relative importance of each indicator, ultimately determining the weight distribution. The combination of these two methods avoids the one-sidedness of subjective experience judgment and realizes the collaborative optimization of qualitative analysis and quantitative calculation, providing methodological support for the liveliness evaluation of ICH Liveliness level.

2.2 Selection of Evaluation Indicators

When constructing the evaluation model for the live attitude of ICH, the scientific selection of the indicator system should be based on the liveliness essence of live inheritance, follow the core principle of "ensuring the vitality of ICH" in the Convention for the Safeguarding of the ICH, and respond to the practical needs of sustainable governance of cultural space in the context of China's new urbanization. This study constructs an evaluation framework from four dimensions: carrier inheritance degree, policy support degree, social exchange degree, and production efficiency degree, forming a multi-dimensional coupled and positively and negatively balanced indicator system. Finally, 4 criteria, 12 subcategories, and 28 minor categories are selected to construct the evaluation indicator system for the Liveliness level of ICH, as shown in the Table.3below.

Table 3 Evaluation Index System and Weights for the Liveliness level of ICH

Target Layer	Criterion Layer	Weight	Sub-criterion Layer	Weight	Indicator Layer	Weight	Nature
Innovative Liveliness level Evaluation Index System A	Carrier inheritance degree B1	0.5340	Inheritance Holder Scale C1	0.2453	Heritage Holder LevelD1	0.0238	Positive
					Number of Heritage Holders D2	0.0571	Positive
					Age of Heritage Holders D3	0.1643	Positive
			Project scale C2	0.0787	Project Category D4	0.0245	Positive
					Project LevelD5	0.0176	Positive
					Project Quantity D6	0.0366	Positive
			Inheritance risk coefficient C3	0.2100	Natural Reduction Rate of Heritage Holders D7	0.1343	Negative
					Inaction of Heritage Holders D8	0.0377	Negative
					Risk of Skill Distortion D9	0.0381	Negative

Policy Support degree B2	0.1872	Policy and Regulation C4	0.0967	Number of Policies D10	0.0239	Positive
				Policy Implementation Rate D11	0.0728	Positive
		Capital investment C5	0.0689	Investment Amount D12	0.0363	Positive
				Reward Mechanism D13	0.0326	Positive
		Policy implementation deviation C6	0.0216	Incidence of Violations D14	0.0042	Negative
				Impact of Violations D15	0.0174	Negative
Social exchange degree B3	0.2176	Activity scale C7	0.0966	Activity Frequency D16	0.0142	Positive
				School Education D17	0.0718	Positive
				Number of Participants D18	0.0106	Positive
		Media Index C8	0.0287	Number of Propagations D19	0.0123	Positive
				Search Popularity D20	0.0164	Positive
		Social Identity Crisis C9	0.0924	Cognitive Deviation Index D21	0.0680	Negative
				Cultural Heritage D22	0.0244	Negative

Production efficiency degree B4	0.0612	Tourism Development C10	0.0262	Proportion of ICH Tourism Income D23	0.0056	Positive
				Tourist Experience Conversion Rate D24	0.0206	Positive
		Production efficiency C11	0.0207	ICH Cultural Products D25	0.0050	Positive
				ICH Employment D26	0.0157	Positive
		Developed overload C12	0.0142	Expansion Degree of Homogeneous Production D27	0.0099	Negative
				Invasion Index of Heritage Holding Scenarios D28	0.0044	Negative

Due to significant differences in the units and magnitudes of the evaluation indicators (for example, the number of inheritors is an absolute value, and the policy implementation rate is a percentage), the incomparability needs to be eliminated through normalization. This paper uses the range method to standardize the original data.

Positive indicators (the larger the value, the better):

$$I_{ijk} = \frac{X - X_{\min}}{X_{\max} - X_{\min}}$$

Negative indicators (the smaller the value, the better):

$$I_{ijk} = \frac{X_{\max} - X}{X_{\max} - X_{\min}}$$

2.3 Determine the weights of evaluation indicators

Inviting 10 experts in the field of ICH protection (including cultural policy researchers and project managers of ICH) and ICH inheritors to form an expert group, based on the hierarchical structure of the "Evaluation Index System for the Live Attitude of ICH" shown in the figure, construct a judgment matrix, and conduct pairwise comparisons of the evaluation indicators belonging to the same criterion level. Using the Saaty 1-9 scale method to quantify the expert judgments. That is, the ratio of the importance of the i-th indicator to the j-th indicator under the same indicator level can be expressed as aij. Generally, it is assigned a value using a 1-9 proportion scale. When aij is assigned 1, 3, 5, 7, or 9, it indicates that the importance of the two indicators compared pairwise is equally important, slightly important, relatively important, very important, or absolutely important. When aij is assigned 2, 4, 6, or 8, it indicates that the importance of the two indicators compared pairwise is between the adjacent important scales. Using software such as Spssau and Yaahp to analyze it, the matrix score results of each expert are obtained respectively. The consistency ratio CI of the judgment matrices of all experts is all <0.1. The results of the expert scoring matrices that pass the consistency test are geometrically averaged to obtain the mean

judgment matrix, and then the weights of each indicator are calculated, as shown in Table 3.

2.4 Define the comprehensive evaluation criteria

In order to evaluate the live attitude of ICH as a whole, it is necessary to calculate the total of each indicator of the live attitude of ICH. This paper selects the multi-objective comprehensive evaluation method and constructs the comprehensive evaluation function of the live attitude of ICH, the mathematical formula is:

$$M = \sum_{i=1}^{n} \left(\sum_{j=1}^{n} I_j \times R_j \right) \times W_i \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \quad (1)$$

In the formula, M represents the total score of the live attitude evaluation of ICH; Ij represents the score of the individual indicator j of the live attitude of ICH; Rj represents the weight of the individual indicator j of the live attitude of ICH; Wi represents the weight of the evaluation criterion.

Based on the comprehensive evaluation score of ICH, ICH is classified into five levels: extremely poor live attitude, poor live attitude, average live attitude, good live attitude, and excellent live attitude (Table 4).

Table 4 Evaluation Criteria for the Liveliness level of ICH

Evaluation index	<0.20	0.20-0.40	0.40-0.60	0.60-0.80	>0.80
Evaluation criterion	Range	Poor	Average	Better	Good

3. Empirical Analysis on the Evaluation of ICH Approaches in Qinghai Province

3.1 Case Selection and Data Sources

Based on the statistics from the five batches of the "National ICH Representative Projects List" published by the State Council from 2006 to 2021, Qinghai Province currently has 88 national-level ICHs, covering ten major categories such as folk literature, traditional music, traditional dance, traditional drama, folk art, traditional sports and games, traditional art, traditional skills, traditional medicine, and folk customs(Table 5) .From 2006 to 2023, Qinghai Province has announced 335 provincial-level ICH items. Among them, national-level ones are mainly traditional music, while provincial-level ones are mainly traditional skills. From the spatial distribution of each city and prefecture in Qinghai Province, the spatial distribution characteristics of ICH representative projects are as follows: They are mainly concentrated in Xining City, Haidong City, and Yushu Tibetan Autonomous Prefecture, accounting for nearly 60% of the total number of projects, forming a core distribution area; while Hainan Tibetan Autonomous Prefecture and Guoluo Tibetan Autonomous Prefecture have the fewest distribution numbers, accounting for about 10%, forming a low-density area(Figure 1).

Table 5 Statistics of Representative ICH Projects in Qinghai Province

Category	Number of National-level Projects (items)	Number of Provincial-level Projects (items)	Number of UNESCO Representative List of the ICH of Humanity Projects (items)	Total
Folk literature	9	39	1	49
Traditional music	15	32	1	48
Traditional dance	9	31	——	40
Traditional drama	3	12	2	17
Traditional sports, games and acrobatics	3	17	——	20
Traditional craftsmanship	11	90	——	101
Traditional medicine	6	17	1	24

Folk customs	17	61	——	78
Oral art	4	10	——	14
Traditional fine arts	11	26	1	38
In total	88	335	6	429

(Note: National-level includes 6 projects listed in the UNESCO Representative List of the ICH of Humanity)

At the same time, Qinghai Province has 88 national-level representative inheritors and 343 provincial-level representative inheritors. There are 3 national-level cultural ecological protection (experimental) zones (Hotong Culture, Gesar Culture (Goluo), and Tibetan Culture (Yushu)) and 3 provincial-level cultural ecological protection (experimental) zones (Tu Ethnic Group (Huzhu), De Du Mongolian (Haixi), and Xunhua Salar Ethnic Group) for ICH. 33 ICH (Qingxiu) employment workshops, 5 national-level ICH production protection demonstration bases, 7 provincial-level ICH production protection demonstration bases, and 27 provincial-level ICH inheritance bases have been established.

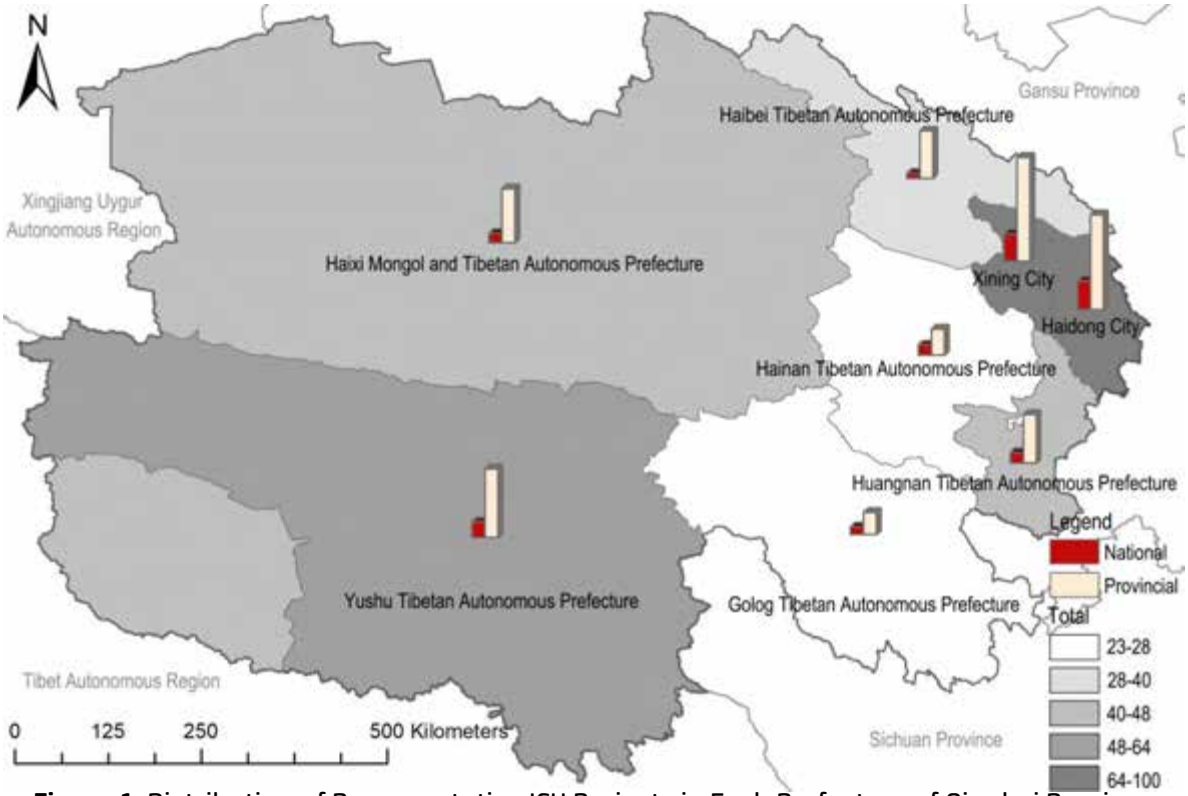

Figure 1: Distribution of Representative ICH Projects in Each Prefecture of Qinghai Province

This research was based on the "Qinghai Province ICH List", "Qinghai Province Cultural Statistical Yearbook (2018-2024)", the list of ICH representative projects, information on inheritors, and policy texts such as the "Qinghai Province ICH Regulations". It integrated the data on cultural heritage protection funds investment from 2018 to 2024, quantified policy support indicators. Through on-site research from July to August in 2024, interviews with inheritors of 6 ICH representative projects such as Hotong Art and Gesar Epic were conducted to record the frequency of skill transmission and innovative practices. Participatory observation methods were used to collect audience interaction data from 15 ICH performance activities such as the Tarsar Monastery Butter Sculpture Exhibition and the Yushu Horse Racing Festival. Data on the degree of social exchange was derived from the dissemination data of topics related to "Qinghai ICH" on platforms such as Douyin and Weibo from 2018 to 2024, and public awareness and consumption behavior were analyzed. Data on the degree of production efficiency was quantified through the sales revenue of ICH workshops, the scale of employees, and product development

cases (such as Snow Leopard Culture).

3.2 Evaluation Results

After comprehensive calculation, the overall score of the ICH (ICH) in its living form in Qinghai Province is 0.44. According to the living attitude grading standard (0-1 range, divided into five levels: extremely poor, poor, average, good, and excellent), the overall score falls within the critical range between "poor" (0.3 - 0.4) and "average" (0.4 - 0.5), indicating that the current overall living inheritance of ICH in Qinghai Province is in the transitional stage from a low level to a medium level.

From the perspective of the living attitude scores of various categories of ICH in Qinghai Province, the living attitude of traditional skills (0.75), folk customs (0.70), and traditional fine arts (0.60) are at a good level, with leading scores and obvious advantages in living attitude; the living attitude of traditional dance (0.46) and traditional music (0.45) are at a general level, and there is still room for improvement in the living inheritance ability; the living attitude of traditional medicine (0.38), traditional drama (0.37), folk art (0.29), and folk literature (0.23) are at a poor level, with low scores and facing a systemic inheritance crisis; the living attitude of traditional sports, games, and acrobatics (0.17) is at an extremely poor level, and is at risk of breaking the living inheritance.

Based on the scores of the four criteria(Figure 2), in terms of the degree of inheritance of the carriers, traditional skills received the highest score, benefiting from the dual promotion of the ICH workshops (such as the Silver and Copperware Making Training Institute) and the construction of digital archives; traditional drama received the lowest score, due to the lack of training venues (such as the Qinghai Pingxian Opera, with only 2 fixed performance venues remaining). In terms of policy support, traditional skills received the highest score,reflecting the tilt of policy resources (such as the provincial ICH special funds accounted for 42% from 2021 to 2023); traditional sports, games and acrobatics received the lowest score,lacking special support policies (accounting for only 3.5% of the total funds) and regular management mechanisms. In terms of social exchange, folk customs received the highest score,achieving high-frequency public participation through festival activities (such as the Tarsar Temple Lantern Festival, the Hotong June Festival); traditional medicine received the lowest score,limited by the single market-oriented channel (over 90% relying on local clinics for sales) and weak dissemination. In terms of production efficiency,folk customs received the highest score, as the cultural tourism integration projects (such as the Tujia Ethnic Folk Tourism) brought economic benefits; traditional medicine received the lowest score, with a low degree of industrialization (no large-scale production enterprises) and a lack of innovative products (only 3 patent registrations).

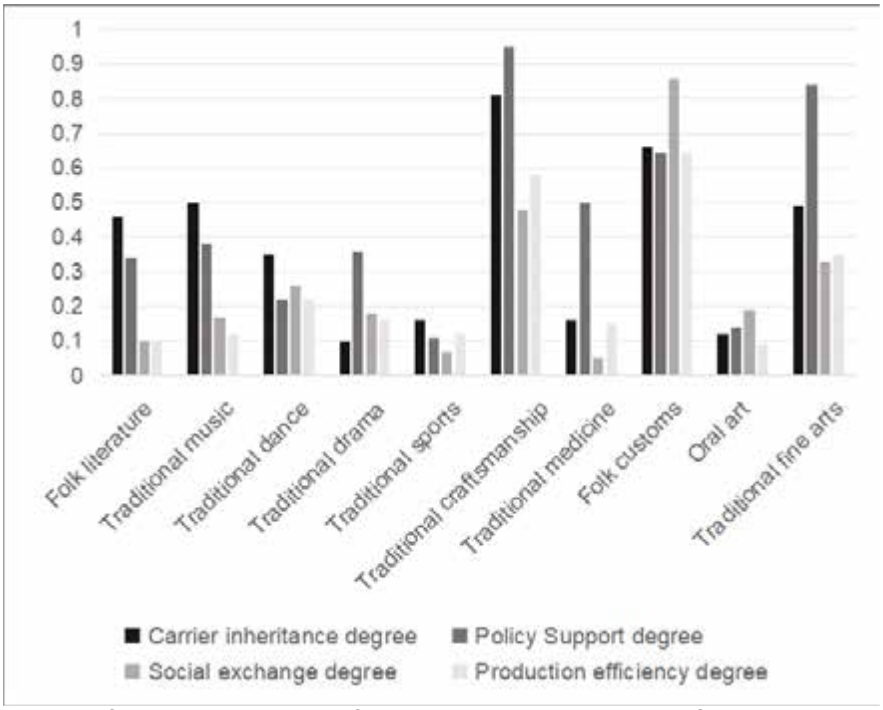

Figure 2 Score of the criterion layer for the top ten categories of ICH in Qinghai Province

3.3 Result Analysis

Traditional skills, folk customs and traditional art, positive driving forces from policy support and industrialization; The number and level of inheritors show a good active attitude. Traditional skills (such as Huangzhong Silver and Copper Ware, Jiaoya Tibetan Blanket) and folk customs (such as Hotong June Festival, Tu Ethnicity Naonong Festival) are the benchmark areas for the protection of ICH in Qinghai. The policy support is strong, the industrialization level is high, and the social participation is extensive. Traditional skills achieve economic transformation through the development of cultural and creative products (such as snow leopard-themed leather embroidery, Qing embroidery pendants) and large-scale production, while traditional art relies on the high-end art market of Hotong Thangka and pile embroidery to form a stable industrial chain. At the same time, the model of ICH workshops drives employment for farmers and herdsmen, and the production efficiency is good.

Traditional dance and traditional music, coexistence of cultural tourism integration and inheritance bottlenecks; Traditional dance and music face problems such as aging of inheritors and insufficient participation from young groups, and the coverage of digital recording is low. Policy resources are concentrated on handicrafts, while non-performance art ICHs lack special support. For example, the construction of traditional drama training venues lags behind, and traditional dance and music attract tourists through scenic area performances (such as the ICH performances in Taichang Ancient City), but there are insufficient regular activities and rely on short-term festival exposure. Cultural tourism integration brings economic benefits, but the industrialization path of traditional dance and music is single and relies on ticket revenue, with low added value.

Traditional medicine, traditional drama, folk art, and folk literature are facing a crisis in systematic inheritance; the digital protection of traditional medicine and folk literature is weak. For instance, the Tibetan medicinal bath method only has basic archives but lacks a platform for liveliness display. There are insufficient venues for traditional drama transmission, and the genre of folk art relies on oral transmission, which makes it prone to loss due to the absence of a continuous line of inheritors. The policy coverage is uneven; traditional medicine and drama have not been included in the key support list, and the investment is insufficient. The marketization ability is weak; traditional medicine lacks e-commerce channels; folk literature, due to the lack of innovative expression (such as adaptation to short videos), is difficult to attract young people. The commercialization path of the genre of folk art is single (such as tea house performances), and the income is unstable.

Traditional sports, games, and acrobatics are on the verge of losing their liveliness inheritance; there are no venues for transmission (the number of folk art troupes is decreasing year by year), and they lack special support and have not been included in the mainstream promotion system of national fitness. The activities are mostly carried out based on festivals for short periods and have insufficient regular participation; the commercialization path is single (such as the archery association relying on a small group of enthusiasts), and the market appeal is low. The economic transformation ability is weak, and there is a lack of cultural and creative development (such as no social fire theme study tours), making it difficult to form a scale effect(Table 6).

Table 6 Analysis of Live Evaluation Data for the Top Ten Categories of ICH

Liveliness level score	Reason analysis	Indicator analysis
0.6-0.8	Driving Factors and Advantages	Key Support
Traditional craftsmanship	Outstanding production efficiency: mature industrialization	the proportion of ICH creative products in D25 accounts for 35%
	Precise policy support: 40% of the national-level production-oriented protection demonstration bases	annual average growth rate of fiscal input: 18% (D12)
Folk customs	Vigorous social exchanges: Frequent festival activities	The frequency of D16 activities is the highest in the province
	High degree of cultural and tourism integration: The Na Ton Festival and the June Festival will become cultural and tourism IPs	The revenue from D23 tourism accounts for 28%
Traditional fine arts	The intergenerational transmission is relatively balanced: 25% of the inheritors are young people	The average age of the D3 inheritors is 50 years old
	Digital dissemination leads the way: Digital Tibetan painting collections reach over 10 million yuan in transaction volume	D20 search popularity grows by an average of 45% annually
0.4-0.6	Bottleneck issues and potential	Main problem areas
Traditional dance	Performance scene contraction: Traditional ritual spaces have decreased by 70%	D18 Annual participation rate has dropped by 12%
	Insufficient innovation: Dance choreography homogeneity rate exceeds 60%	D27 Homogenization expansion degree is 0.58
Traditional music	Audience aging: The proportion of listeners over 60 years old is 65%	D21 Cognitive deviation index is 0.42
	Single dissemination form: Digital music works account for less than 10%	D19 New media dissemination accounts for 8%
0.2-0.4	System crisis and root causes	Intuitive risks
Traditional medicine	Inheritance Gap: Only 6 national-level inheritors, with an average age of 68 years old	D7 Natural Decrease Rate: 7% (the highest in the province)
	Policy Support Mismatch: Funds are biased towards tourism development, and the integration rate of the medical system is less than 5%	D13 Reward Mechanism Coverage Rate: Only 12%
traditional drama	Loss of Young Audience: The audience under 35 years old accounts for less than 15%	D16 Annual Average Decrease in Activity Frequency: 20%
	Digital Absence: Online performances account for less than 5%	D19 Digital Communication Investment Ratio: 3%
folk art	Lack of Training Funds: County-level inheritors' subsidies coverage rate is 10%	D14 Violation Rate: 22% (the problem of fund misappropriation is prominent)
	Disappearance of Performance Venues: Traditional tea houses have decreased by 70%	D28 Scene Occupation Index: 0.65
folk literature	Oral Inheritance Crisis: There are only 5 young inheritors of the Gesar Epic	D9 Risk Level of Skill Distortion: 4.2 (evaluated by experts)
	Insufficient Modern Transformation: Lack of IP development and digital narrative	D25 Cultural and Creative Industry Output Ratio: Less than 1%
<0.2	At risk of breaking and analysis	Core weakness
Traditional sports, games, and acrobatics	The traditional scenes are disappearing: traditional events such as horse racing and archery have decreased by 90%	D2 inheritors is only 23 (the lowest in the province)
	Policy neglect: There is no dedicated protection fund or event planning	The penetration rate of D17 school education is 0%

Meanwhile, the status of ICH preservation in each prefecture of Qinghai Province was statistically analyzed (Table 7), and spatial visualization was conducted (Figure 3) to facilitate the formulation of targeted strategies based on the prefectures. Among them, the ICH preservation status in Xining City, Huangnan Prefecture and Haidong Prefecture was at a good level, while that in Haibei Prefecture, Yushu Prefecture was at a medium level, and that in Hainan Prefecture, Haixi Prefecture and Guoluo Prefecture was at a poor level.

Table 7 Evaluation of the living attitudes of ICH in each prefecture of Qinghai Province

Ranking	Provinces /Counties	Carrier inheritance degree	Policy Support degree	Social exchange degree	Production efficiency degree	Overall score	Liveliness level
1st	Xining City	0.82	0.78	0.75	0.68	0.79	Better
2nd	Huangnan Prefecture	0.76	0.65	0.70	0.55	0.72	Better
3rd	Haidong City	0.68	0.60	0.65	0.50	0.65	Better
4th	Haibei Prefecture	0.53	0.48	0.56	0.26	0.54	Generally
5th	Yushu Prefecture	0.55	0.45	0.60	0.30	0.53	Generally
6th	Hainan Prefecture	0.40	0.35	0.38	0.15	0.38	Poor
7th	Haixi Prefecture	0.38	0.30	0.35	0.20	0.34	Poor
8th	Goluo Prefecture	0.25	0.20	0.28	0.10	0.24	Poor

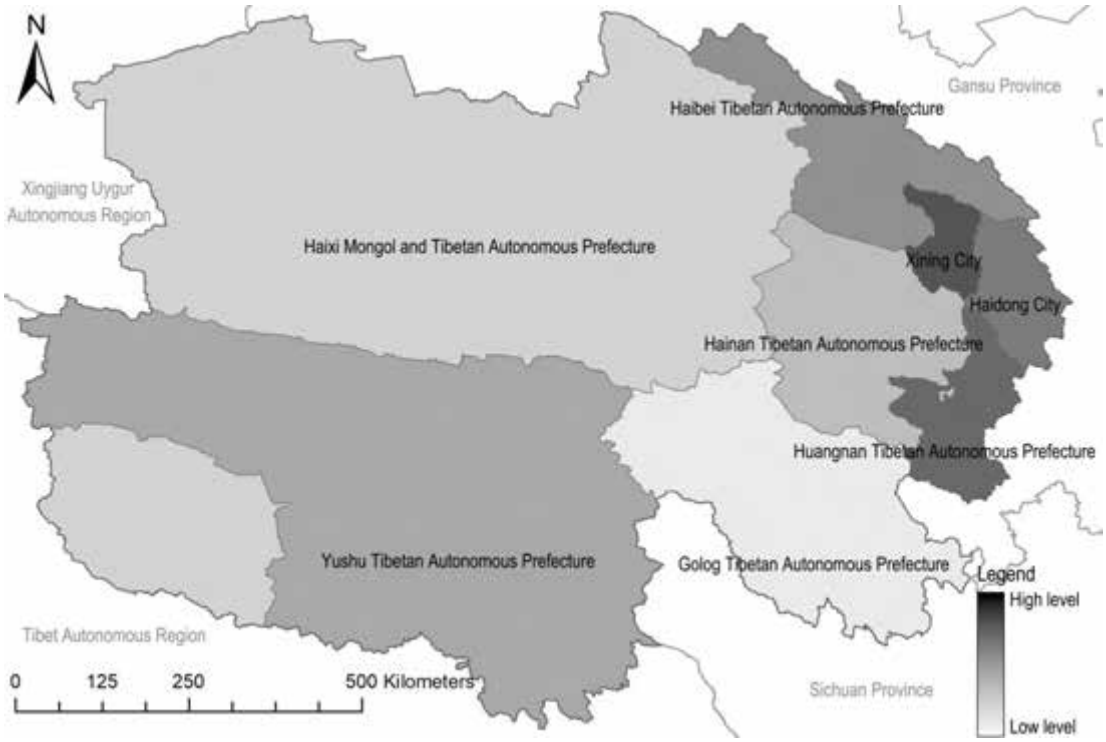

Figure 3 The spatial distribution of the ICH across various cities and counties

4. **Strategies for Enhancing the liveliness Transmission of ICH in Qinghai**

4.1 liveliness Addition Mechanism

Although Qinghai Province has established a four-level ICH list system at the national, provincial, municipal (city), and county (district) levels, the current list management still has several prominent problems such as high data isolation, insufficient public participation, and lagging liveliness updates. The national and provincial lists are generally announced by government documents, making it difficult for the public to obtain comprehensive data on ICH in Qinghai. The public has a low level of awareness of basic information such as the categories of ICH projects and the distribution of projects by cities and counties. The subjective initiative for bottom-up addition is weak. At the same time, the protection measures for the list have long relied on static management and failed to achieve liveliness adjustment based on the evaluation results of the living attitude (such as the disappearance of inheritors or the extinction of the environment). As a result, some endangered projects are difficult to be promptly included in the key protection category. Therefore, it is urgent to establish a "data-driven, public participation, and hierarchical response" liveliness addition mechanism.

In response to the relatively fixed protection situation of existing ICH projects and the lack of a digital and public platform for liveliness addition(Song, J.H. ,2015). The Qinghai Provincial Department of Culture and Tourism can collaborate with the Qinghai ICH Protection and Smartization Center and the digital management platform "Qinghai ICH Map" jointly created by Baidu. This platform integrates the data resources of the four-level list in the province, publicly displays core information such as the map of ICH projects, the distribution of inheritors, and training venues, and opens functional modules for public application, evaluation, and supervision. By real-time access to liveliness evaluation indicators (such as the frequency of D16 activities, D25 cultural product output), the platform can automatically identify low-living attitude projects (if the rate of inheritance of the Lozhou Gezarsa Epic is 7%) and endangered categories (such as traditional sports, games, and acrobatics ICH in Haixi Prefecture <0.2), triggering warnings and promoting the management department to initiate emergency addition procedures according to risk levels.

4.2Construction of ICH Spaces

There is an imbalance in regional development in the construction of ICH spaces in Qinghai Province. Currently, the three national-level cultural ecological protection areas (Thorgon Culture, Gesar Culture, and Tibetan Culture) and the three provincial-level protection areas (Tuo Ethnic Group, De Du Mongolian, and Xunhua Salar Ethnic Group) are concentrated in the eastern regions such as Huangnan and Yushu. Meanwhile, the 72 production-based bases (including 5 national-level, 7 provincial-level demonstration bases, and 33 Qingxiang embroidery workshops) also exhibit a "dense in the east and sparse in the west" pattern, resulting in weak capacity for the liveliness transformation of ICH spaces in the western regions such as Haixi and Guoluo.

At the level of cultural ecological protection areas, (Dai, X. ,2020)we can leverage the advantage of the Thorgon Cultural Ecological Zone (in Huangnan Prefecture) in the abalone painting industry cluster to collaborate with 33 Qingxiang embroidery workshops to create a "ICH production - cultural tourism experience" complex. By adopting the "front store-back workshop + e-commerce live streaming" model (Dai Xin, 2020), we can enhance the efficiency of the production-based bases and promote an annual output value exceeding 800 million yuan. In response to the shrinking inheritance scenarios in the Gesar Cultural Ecological Zone (in Aba Prefecture), we can rely on 27 provincial-level inheritance bases to build a digital narration center, restore traditional ritual spaces such as horse racing and shooting festivals, and cover low-density areas with "village-based mobile workshops" to alleviate the crisis of spatial discontinuity. At the same time, we can upgrade the 5 Qingxiang embroidery workshops in the Tuo Ethnic Cultural Ecological Zone (in Huzhu County) into a "ICH study and tourism + folk customs tourism" hub, design the chain of "homestay experience - festival performance - handmade creation", and strengthen the degree of cultural and tourism integration (D23 indicator).

4.3 "Integrating ICH"

The integration of "ICH" in Qinghai Province should be based on the regional resource endowment and the differences in the attitude towards life. It needs to break through the current bottlenecks such as "domination by cultural and tourism integration, with insufficient penetration in other fields" and "single high-scoring regional models and ambiguous low-scoring regional paths". Combining with the research by Chen Wei and Yang Lianjiao (2020) on the spatial differentiation characteristics of ICH in Qinghai, the ICH across the province presents a spatial differentiation pattern of "eastern cultural and tourism type, central production type, and western ecological

type". It is necessary to construct a "tailored to local conditions, integrating ICH" integration system based on the different attitude levels of different prefectures and cities (Xining, Huangnan, Hedong are "better", Hainan, Haixi, and Guoluo are "poor") and the characteristics of ICH categories.

High-scoring areas (Xining, Huangnan, Haidong): Centered on “ICH (ICH) + tourism”, extend the chains of “ICH + cultural creation” and “ICH + technology”. Xining City, leveraging the ICH clusters such as Hotong Tangka and Huangzhong Silver and Copper Ware (with an annual output value of over 1 billion yuan), promotes the linkage of “ICH workshops, theme scenic areas, and city IPs”, drawing on the “urban ICH complex” model (Chen Wei et al., 2020), to create immersive ICH districts (such as Tangka Digital Art Museum), develop digital cultural products like “ICH limited edition boxes” and “Yuanzuo Collection”, and increase the proportion of D25 cultural industry output to 40%; Huangnan Prefecture, relying on the Hotong Cultural Ecological Protection Area, deepens the integration of “ICH + festivals”, embedding folk activities such as the June Festival and Tibetan Opera Performances into the Qinghai Lake tourism route, and designing an “ICH Experience Points System” (tourists can exchange cultural products by participating in training activities), enhancing social exchange rate (the annual average increase in activity frequency is 15%); Haidong Prefecture, leveraging the folk customs of the Tu ethnic group, promotes “ICH + study tours”, building an ICH study camp in Huzhu County,and jointly developing “ICH handicraft courses” with the Qingxi Embroidery Workshop,attracting young audience (the proportion of participants under 35 years old has increased to 50%).

Low-scoring areas (Hainan,Haixi,Guoluo): Taking “ICH + ecology” and “ICH + medical care” as breakthrough points,activate marginalized ICH categories. Hainan Prefecture,addressing the low attitude towards traditional medicine (score 0.38) and the singleity of market channels,promotes “ICH + health care”,introducing business models such as hot spring therapy and medicinal bath experiences at the Tibetan Medicine Heritage Base (such as Guinan County Tibetan Hospital),developing “Tibetan Medicine Health Tourism Packages”,and promoting the integration rate of the medical system (from <5% to 20%);Haixi Prefecture,relying on the De'udu Mongolian Cultural Ecological Protection Area,pilots “ICH + ecological compensation”, integrating Mongolian epic training and traditional horse racing activities into the national park system, extracting 3 yuan of ecological funds for each ICH experience by tourists.

5. Conclusions and Outlook

This study focused on the liveliness inheritance of ICH in Qinghai Province. Addressing the common issue in current ICH protection, which is "emphasizing static preservation while neglecting liveliness development", a liveliness evaluation index system based on the Analytic Hierarchy Process (AHP) was constructed. This system quantitatively assessed the liveliness level of ICH projects from four dimensions: carrier inheritance degree, policy support degree, social exchange degree, and production efficiency degree. The scientificity and applicability of this system were verified by taking Qinghai Province as an example. The research results showed that the comprehensive score of ICH livelinesss in Qinghai Province was 0.44, indicating that it was in the transitional stage from a low level to a medium level. However, there were significant differences among different categories and regions: traditional skills, folk customs, etc., scored ahead due to their advantages in industrialization and cultural tourism integration (0.6 - 0.75), while traditional medicine, folk arts, etc., fell into a systemic crisis due to the lack of inheritance continuity and policy support (scores < 0.4). Based on this, the study proposed strategies such as liveliness supplementation mechanism, spatial network reconstruction, and "ICH +" integration, aiming to promote ICH protection from "passive rescue" to "active adaptation" through digital platforms, resource elasticity allocation, and cross-border collaboration. This study hopes to promote the return of ICH protection from "cultural specimens" to "life practice", injecting vitality into the creative transformation and sustainable development of outstanding traditional cultures worldwide.

The Mountain of Gargano
Where the Sacred Dwells in the Forms of the Earth

Giuseppe Fraddosio
Università degli Studi di Bari "Aldo Moro"
giuseppe.fraddosio@uniba.it

Abstract
The Gargano promontory in southern Italy constitutes a sacred landscape where archaic, arcane, sacred, and daimonic dimensions converge within a living geography of pilgrimage and revelation. This study examines key sanctuaries as spatial archetypes that articulate the dialogue between architecture, ritual, and terrain. Through archival research, cartographic analysis, and field surveys, it explores how sacralisation has shaped both physical forms and cultural practices. The sanctuaries emerge as infrastructures of meaning, sustaining territorial identity while facing challenges such as environmental degradation and overtourism. The paper proposes an integrated strategy of active conservation; where walking, ritual, and silence reactivate sacred presence. Ultimately, the sacred mountain is presented as a regenerative palimpsest: a landscape where spiritual heritage and ecological care entwine in a dynamic equilibrium between memory and transformation.

The Archaic, the Arcane, the Sacred, the Daimonic

"And he said, Draw not nigh hither: put off thy shoes from off thy feet, for the place whereon thou standest is holy ground"[1]

A fruitful path toward a conscious and profound appropriation of architecture and place restores meaning to its condition of necessity, refocusing on the generative elements of place by drawing on multiple, mutually enriching modes of thought. This stance, simultaneously hermeneutic and metaphorical, celebrates rootedness, continuity, resistance, and persistence. It nurtures a vital tension: a disposition and aspiration that reach beyond form, uncover the root embedded in things, and invite continual renewal.

Grasping the richness of this critical posture requires a transdisciplinary itinerary that honours the term in its most precise sense while exploring the diverse meanings it gathers across the fields in which the concept finds application. Archaic, Arcane, Sacred, and Daimonic flow through mythic imagination as four interlaced forces. In the pages that follow, each lemma reveals its linguistic root at the moment of emergence, allowing word history and conceptual movement to rise together, like breath animating meaning.

The pulse of the archaic refers to a primordial layer of human experience and culture – the ancient, foundational mode of thought and world creation. In a philosophical sense, it evokes the original archē or "beginning", the creative depth from which later symbols and institutions emerge. Mythically, the archaic resonates with ancestral gods and the primal Cosmos: it is the time of gods and heroes when the structures of reality were first cast in archetypal form. In this view, natural phenomena and social norms are not mere accidents but sacred patterns inherited from the "time before time." As Mircea Eliade observed, "for archaic man, reality is a function of the imitation of a celestial archetype[2]": to know a thing's origin is to grasp its essence. Thus, the archaic dimension emphasises origin and power in beginnings – a world where knowing the origin of a river, a ritual, or a clan name confers magical competence.

Practically, the archaic resides in cultural memory; it endures in myths, symbols, and landscape names that connect us to a mythic past. Hesiod invokes Gaia and Ouranos. It also underpins a mythopoetic mode of thinking in which ancestral spirits animate the world, linking one's existence to primordial mysteries. In Aboriginal Australian traditions, sacred landscapes are crossed by "songlines"[3]—paths sung by ancestral beings that shape the land and its meaning. In Japan, Mount Fuji is a sacred presence, honoured as a living spirit or kami. In symbolic geography, an archaic sensibility may emerge in reverence for prehistoric sites or in the concept of "deep time," whereby a sacred mountain or river is perceived as an unbroken thread linking present-day people to primordial events. The Ganges River, for instance, is both a river and a goddess. It connects today's people with ancient, divine origins. Mountains carry this weight of memory. Mount Sinai is the place of divine law in Jewish tradition,

1 Ex 3:5
2 (Eliade, 1949)
3 (Chatwin, 1988)

and Mount Hira in Islam is where the Prophet received the first revelation. These places remain spiritually active, not merely historical. By turning to the archaic, cultures affirm a link to a sacred beginning[4]. The Palatine Hill in Rome, where Romulus is said to have founded the city, has retained its sacred role even in later centuries. These spaces hold meaning because they are seen not just as old but as originating—they give shape to time and belief.

The arcane denotes the mysterious and hidden aspects of reality – secret knowledge, esoteric practices, and the concealed logic of the cosmos. Its root, from Latin arcanus (hidden), suggests what is closed or kept from ordinary sight. In intellectual terms, the arcane refers to wisdom or traditions accessible only to initiates, such as the hidden symbolism of temple rites, alchemical formulas, or secret texts. Culturally, arcane knowledge is often woven into rituals, mysteries, or mythic lore, promising insights, or powers beyond the common understanding.

The arcane dimension imbues certain landscapes and rituals with a potent sense of enigma. It neither conceals arbitrarily nor mystifies for effect; instead, it withholds meaning in a manner that demands interpretative patience, symbolic literacy, and spiritual receptivity. In this way, it stands in contrast to profane clarity: the arcane is not merely hidden—it is hidden to be revealed, but only to those adequately prepared to receive it. Landscape features such as caves, labyrinths, or remote peaks frequently become vessels of arcane power precisely because they defy immediacy; they necessitate passage, descent, or ritualised approach. A case in point is the adyton of the Delphic temple[5], where the Pythia, seated above a chasm, pronounced her ambiguous oracles under the influence of sacred vapours. The oracular cave functions as both a literal fissure and a metaphysical one—a breach in rational knowing through which divine utterance filters. Similarly, the Buddhist monument of Borobudur in Java presents a mandalic labyrinth that encodes spiritual ascent in stone. Pilgrims progress through levels of iconography and architectural symbolism, not towards spectacle, but towards a central void—a sunyata that is both physical and ontological. The arcane is not confined to architecture.

The ritual of the whirling dervishes, for example, exemplifies an embodied arcane practice. Their movement traces a cosmology of inward return, where the body becomes a compass and gesture a theological glyph. This arcane grammar of movement mirrors another site of veiled revelation: Plato's cave, whose darkness shelters not ignorance but latency. The shadow-world requires a conversion of vision, not the abandonment of place but its transfiguration through ascent. Initiatory traditions heighten the arcane by codifying silence. The difficulty of access, the echoing darkness, and the visceral imagery combine to form a space where myth, matter, and motion converge. Here, the arcane is not a category of thought but a mode of presence: an atmosphere wherein the visible and the invisible coil around one another.

In each case, the arcane enriches cultural geography not through abstraction, but through embodied difficulty: meaning is earned. This mode of symbolic withholding opens up space for imagination, mythic elaboration, and sacred secrecy to function as formative forces. The landscape becomes not merely a backdrop, but an interlocutor—silent, yes, but suggestive; opaque, but resonant. In this tension between what is shown and what is withheld, the arcane offers not obscurity, but depth.

The sacred designates that which is elevated and set apart, a domain marked by divine or numinous presence. It evokes notions of sanctity, reverence, and ultimate significance. In religious traditions, the sacred emerges in specific spaces—such as temples, groves, and mountains—as well as in designated times, including festivals and mythic epochs, and in beings that carry a transcendent dimension, including gods and saints. Rudolf Otto's seminal analysis defines the core of sacred experience as the numinous, an encounter with the Holy that transcends rational comprehension. He characterises this experience as mysterium tremendum et fascinans: a wholly other mystery that provokes awe and trembling while simultaneously drawing the individual into a state of wonder. The tremendum evokes a majestic dread and overwhelming intensity, while the fascinans conveys grace, attraction, and the marvellous (mirum), which together generate a condition of profound spiritual receptivity.[6]

Mircea Eliade advances this phenomenological understanding through the concept of hierophany, the manifestation of the sacred within the fabric of the ordinary. For Eliade, the sacred serves as the ontological foundation of meaning in space, time, and human orientation. In The Sacred and the Profane, he affirms that the sacred

4 (Ravasi, 2001)
5 (Kerényi, 2015)
6 (Otto, 2020)

"manifests itself as a reality of a wholly different order from 'natural' realities"[7]. Such a manifestation opens a fissure in the continuity of profane space and introduces an axis around which experience may be ordered. Stones, rivers, trees, or mountains can emerge as axis mundi, vertical connectors through which the divine engages and reconfigures the human world.

Rather than inventing sacred space[8], homo religiosus[9] identifies it—recognising its pre-existing power and ritually reaffirming its role as a cosmic centre. Sacred geography takes shape through the resonance of mythic origin. The mountain summit, for instance, assumes meaning not only through its elevation but also by its symbolic link between heaven and earth. It replays the act of creation, becoming a condensed image of cosmogony. The sacred mountain thus functions both as a symbol and as a generative medium of revelation. While the profane may unfold as a dispersed or disoriented field, sacred space concentrates presence, renews orientation, and intensifies awareness. The sacred affirms an experience of the real that remains deeply rooted in the origin and animated by presence.

Eliade emphasises the significance of ritual repetition and reactualisation in religious life. Rites do not merely refer back to a mythic past; they re-enact the original event, collapsing ordinary chronology into the primordial illud tempus—the time of beginnings. This cyclical orientation revitalises the sense of the mirum, enabling lived experiences of sacred time. Religious festivals, pilgrimages, and architectural structures contribute to this rhythm. They offer not representation, but the incarnation of sacred presence. As Eliade puts it, "religious man feels the need to live in a sacred time and in a sacred space," thereby re-establishing contact with origins and reinforcing his existential stability.

The sacred affirms a condition that both elevates and deepens human experience. It inspires reverence for divine majesty and reveals the gracious allure of the Holy. Sacred places—mountains, temples, sanctuaries—draw their power from this dual intensity: they awaken awe and cultivate devotion. Their atmosphere unites proximity and transcendence in a manner that roots human presence while opening it towards the beyond. This convergence endows sacred geography with formative power, enabling it to organise perception and facilitate transformation.

Every sacred encounter manifests as an event of revelation, a moment when the world becomes transparent to a deeper order. When a pilgrim ascends a mountain and feels a surge of sanctity, this experience signifies more than emotional elevation—it initiates a hierophanic breakthrough. The mountain transforms into a liturgical site, where presence deepens and silence speaks. Otto's mirum captures the aesthetic wonder of such encounters[10], where the divine does not merely overwhelm but also radiates beauty in strangeness. Eliade reinforces this vision by affirming that this beauty belongs intrinsically to the sacred order itself: "the sacred is saturated with Being"

To witness it is to enter a field where meaning is unveiled rather than invented, and where reality becomes luminous with presence.

What Socrates himself said about his daimonion, the "inner voice" that gave him advice, we do not know[11]. The daimonic pertains to the realm of daimons or spirits—beings that bridge the human and divine, inspiring, or compelling us. In Greek thought, a daimon (as Plato taught) is a guiding spirit or intermediary; modern psychology (via Jung) redefined it as a numinous psychic force. Jung described the daimon as an "autonomous psychic content"—a kind of inner presence that has its own momentum, "something alien from the unconscious... an archetype or numinous imperative" with authority beyond our intellect. He likened it to a god within us, giving creative energy or demanding action: "There lives a creative being inside all of us," he noted, that will give no peace unless he is obeyed. This daimonic influence is neutral: it can drive outstanding achievements or cause inner turmoil, depending on its alignment with the conscious will.

7 (Eliade, 2013)
8 (Dematteis, 1994, p. 31)
9 (Eliade, 2013)
10 (Otto, 2020, p. 40)
11 (Luck, 2006, p. 233)

Mythologically, the daimonic finds vivid expression in figures like Pan – the horned, goat-legged god of rustic nature – and in angels or celestial messengers. Pan embodies the wild, instinctual side of the daimonic. He is "the goat-God," a personification of untamed nature with "hairy, phallic, roaming and goatish" energy. Modern interpreters (Hillman among them) point out that Pan was demonised as the Christian Devil, but originally he symbolised the raw, life-affirming force of nature. In this way, Pan represents the earthy daimonic – the instinctual libido, creativity, and passion that possess us if we neglect them. Conversely, the angelic side of the daimonic represents the luminous guiding spirit – the Platonic "daemon" of destiny or the guardian angel of some traditions. Angels, angels' apparitions, and other bright daemons signify the daimonic as inspiration and moral illumination.

Thus, we may say that the daimonic is the mediating breath between the mortal and the immortal: it can manifest in dark, bestial form (Pan, daemonic possession) or angelic, visionary form. In both cases, it works beneath or within the self to call forth transformations. Jung and Hillman emphasise that personal destiny or creative vocation is guided by such a daimonic presence – an unconscious genius or archetype urging one towards fulfilment. In every age, the daimonic has been illustrated by figures who hover at the boundary of the human and the divine, reminding us that the psyche is enlivened by spiritual forces beyond ordinary reasoning.

According to the opening words of the chronography of being, God "created the heavens and the earth"[12], and this division of all of creation has always been regarded as foundational. Likewise, in the profession of faith, we call upon God as "the Creator of all things visible and invisible"[13], the maker of what can be seen and, equally, of what cannot. These two realms—the visible and the invisible—indeed touch, yet their difference is so profound that one cannot help but question the nature of the boundary where they meet: a threshold that both separates and unites them. How should this be understood?[14] It may be that the sacred mountain softens the threshold, offering a place where distance gives way to nearness, and the intangible begins to take form—where the mystery of the unseen quietly emerges within the contours of the world.

A sacred mountain is an archetypal locus where the archaic, arcane, sacred, and daimonic converge. Mountains have been universally regarded as natural pillars or axis mundi, connecting Earth and sky[15]. (fig.1) As Edwin Bernbaum notes, the highest sites "form natural links between heaven and earth, the sacred and the profane." In other words, peaks serve as natural thrones for the gods and stages for revelation. When the transcendent momentarily touches our world ("hierophany"), it often occurs on a mountain that acts as "an absolute fixed point, a centre" in the homogeneous expanse of profane space. At such sites, all four dimensions can unfold: the archaic echoes in the primaeval rock and legendary origins of the place; the arcane dwells in hidden grottoes or concealed pathways; the sacred manifests in visions of the divine; and the daimonic appears through spirit-figures or the mountain's own numinous presence.

Consider Mount Sinai, where Moses received the Law. In Exodus, the peak is enveloped by storm, fire, and cloud – theophany at its most dramatic. Smoke and flame streak across Sinai's summit as the divine hierofany unveils itself. Here, the sacred is explicit: the trembling, silent presence of God is both "terrifying and wonderful," matching Otto's tremendum et fascinans. Sinai also embodies the archaic (it is perceived as ancient earth consecrated by God's words) and the daimonic (the divine commandment is delivered by a transcendent spirit in the storm). Its height and isolation designate it as a liminal centre of the world, fulfilling Eliade's notion of sacred space as a fixed point in the cosmos.

Mount Olympus in Greek imagination embodies a profound convergence. As the legendary abode of Zeus and the gods, Olympus represents sacred geography. Heroes and mortals who ascended or glimpsed Olympus confronted both the divine and the daemonic: gods in council, nymphs, and Pan in hidden woods, oracles in caves. A mortal's journey up Olympus would carry the archaic aura of Homeric myth (the age of heroes) and the arcane mystery of pagan ritual (sacred groves and unknown rites). Even today, climbers on Olympus can discover wild, uncanny places (e.g., the Cave of the Sleeping Nymphs) that preserve a sense of secret power.

12 Gn, 1, 1
13 Col, 1, 16
14 [Trad. by Author] (Florenskij, 2024, p. 1)
15 Cfr. (Daumal, 2020)

In the Christian East, Mount Athos – literally "Holy Mountain" – exemplifies these dimensions through monastic life. Athos has been continuously inhabited by monks since the Byzantine era, making it a lasting channel of sacred tradition. The archaic reverence is found in the strict traditions and ancient chants still preserved; the arcane in the disciplined, hermetic practices of hesychasm (inner prayer) and its cloistered terrain. Pilgrims who ascend its slopes speak of an intense presence, as though the entire mountain is imbued with the prayer and asceticism of centuries. Athos serves as both a geographic promontory and an imaginal high point where earth and heaven converge in liturgy.

On the Italian side of the Adriatic, Monte Sant'Angelo (Mount Gargano) epitomises the convergence of the daimonic and the sacred (fig.2). In late antiquity, the Archangel Michael appeared repeatedly on this mountain's windswept summit, instructing that a grotto there be a place of Christian worship. These angelic visions made the site a significant pilgrimage centre. The rocky cave beneath the peak became a physical symbol of arcane depth – the hidden cave of revelation – while the archangel's fiery sword rendered the peak itself the axis mundi of Western Christendom for a time. It stands today as a reminder that even in the Christian era, the daimonic (angels, visions) and archaic magic (mountain cult, sanctuary) coexist in the sacred landscape.

Sacred mountains are both geological forms and living symbols. Climbing a mountain has always represented a symbolic ascent —a movement from the human realm toward the divine. As one ascends, the four dimensions interact with each other. One might find oneself re-enacting an archaic myth (hearing echoes of the hero's journey), decoding arcane omens (unfamiliar flora, mysterious lights), and experiencing a cleansing of the profane through awe. The summit ceremony – whether a priest's liturgy, a tribal dance, or a solitary prayer – becomes a theophany in miniature, a moment when the sacred cleaves through space. In that instant, Pan and angel alike seem near: the wild life-force of Earth and the luminous grace of heaven unite.

Thus, in the mythopoetic geography of the sacred mountain, the archaic endurance of Earth's origins, the arcane secrets hidden in stone and sky, the overwhelming sacred presence of the divine, and the daimonic guardians of fate all converge. On such peaks, earth and heaven kiss, and the four dimensions – archaic, arcane, sacred, and daimonic – are felt as one.

The Geographies of Hierophany in the Sacred Landscape of the Gargano

The Gargano massif, in Apulia, emerges as a geographical structure of extraordinary symbolic intensity, whose relationship with the plain — understood both as the land of the Capitanata and the Adriatic Sea — expresses a profound spatial dichotomy, reflecting the opposition between two domains of differing ontological order. Here, hierophany — literally "manifestation of the sacred" — is embodied in caves, on summits, in forests and across liminal thresholds, delineating a topography that articulates a hierarchy of places capable of transcending the horizontal continuity of plains and waters (fig.3). While the plain and the sea appear as open and undifferentiated spaces, the mountain rises with vertical force, dominating the landscape through a system of reciprocal visibility and positioning itself to be recognised as an axis mundi, a symbolic and spiritual pivot of the world. Within this scenario, Mircea Eliade's distinction between the sacred and the profane becomes manifest: the sacred bursts into the fabric of the landscape, punctuates it, interrupts it, leaving signs and revelations that alter its continuity. Similarly, Rudolf Otto's concept of the numinous conveys the emotional ambivalence these places evoke: trembling and wonder, distance, and desire. One of the earliest ways in which human beings began to understand the relationship between the sphere in which they moved and far more extended horizons was, in fact, through an essentially visual approach to geography[16]. In the Gargano, as in many Mediterranean landscapes, pilgrimage routes — including the Via Francigena — trace a rhythm of sacred manifestations, structuring space through deeply significant places. Such places are elective, sites chosen by culture and faith to host the presence of the divine.

In the Mediterranean, the richness of rocky outcrops and hydrographic channels along the coastline — that is, the morphological fragmentation of geographic contexts — has favoured the formation of perceptual fields, punc-

16 [Trad. by Author] The reference here is to the "chain of fires" bridging the physical and symbolic distance between Troy and Mycenae in Aeschylus's Agamemnon, as studied by Tracy and cited in (Horden & Purcell, 2000, pp. 119-120)

tuated by visual and symbolic landmarks. This condition has fostered a diffuse character of visibility[17], grounded in both the forms of the land and a network of reciprocal observation, which constitutes one of the fundamental traits of sacred manifestations and settlement patterns in the Gargano.

Indeed, starting from the natural condition, humans progressively visualised[18] these elective places, commenting on and reinterpreting the physical forms of the landscape through the construction of increasingly complex artificial structures. Earth metaphors and archaic imagery reveal the sacred dimension of sites such as Santa Maria di Stignano, San Matteo, San Michele Arcangelo at Monte Sant'Angelo, the Santissima Trinità on Monte Sacro, and Santa Maria di Pulsano, interpreted through mythopoetic spatial categories such as the cave, the summit, the forest, and liminal landscapes.

These sacred places embody archetypal meanings and foster a profound dialogue with the natural and cultural context that surrounds them. Within them, one encounters a deep-seated tension between panoramic elevation and primordial terror, between vision and vertigo, between "panorama" and "panic" — a contrast that becomes inscribed in the very body of the sacred mountain, shaping its most intimate and enduring symbolic experience. Otherwise, Nature has no language or signs but simply 'is'. Nature is an essence to which we attribute feelings that exist solely within us. Architecture, on the other hand, is language; it is a convention of signs. However, Cave Architecture imposes linguistic connotations on Nature; geological formations and landforms are selected as existing forms of Architecture and become part of a project. The material: spatial continuity between the cavern and its lithic matrix thus proposes the ambiguity between inside and outside, between Architecture and non-architecture, between Nature and artefacts, between language and essence. Hermitic monasteries are an extraordinary example of how Architecture can create relationships with the forms of the land on which it is grafted. In these places, the discrepancy is attenuated, leaving free space for communication and interpretation of forms. The relationship between interior and exterior becomes the focal point of this dichotomy, which confronts Architecture with a dilemma: to oppose the land or conform to its form, adapting to it. The Nature-Architecture theme develops in the monastic context in three distinct variants: development orthogonal to the terrain; polar development of secondary modules; development parallel to the ground. This image refers to an "uninterrupted body of myths"[19].

The possibility of identifying places with a strong symbolic value - true topoi of the sacred landscape - depends on an intense interpretative operation, activated in the representation and design, of the multiple units that make up the mountain landscape. In this process, iconemes[20], elementary signs of spatial perception, play a key role. they orient the gaze, structure the vision and allow an overall cognitive grasp of an intrinsically hybrid and heterogeneous environment, such as that of the mountains. in this sense: the anacrusis, the meander, the daimon, the echo and the counterpoint, (fig.4) help to describe the forms and metaphors of the interactions between Architectures and Earth.

Anacrusis and Meander

The pilgrim's journey to the mountain begins in the valleys below – the liminal, in-between land where the earth constricts and guides the way. Two convents near San Marco in Lamis exemplify this anacrusis and meander before the ascent of the mountain.

The origin of the magnificent Church of Saint Mary in the Valley of Stignano is recorded in the divine book of God, aimed at the salvation of humanity, who should seek Him through the Blessed Virgin Mary, His glorious Mother.
A 19th-century manuscript on the sanctuary's history starts with these words, and similarly, I would like to clarify that this is not meant to be an anonymous historical account. Instead, it serves as a journey through the events and devotions of the men and women who have traversed this valley for centuries, where the Supreme and Good God, alongside His Mother, narrates the "History of Salvation."
The Gargano's history is marked by the lack of historical documents, leading to the rise of many sacred and profane legends over the centuries. These tales include stories of kings and queens, sailors and pirates, disreputable

17 (Horden & Purcell, 2000, pp. 118-134)
18 (Norberg-Schulz, 1981, p. 17)
19 [Trad. by Autor] (Hillman, 1972)
20 (Turri, 2023, p. 19)

women, dragons, devils, brigands, witches, sorcerers, hidden treasures, hermits, monks, wandering shepherds, sprites, and various other figures from the rich imagination of the people. However, among the "creators" of these legends are some pseudo-scholars who, from the slightest evidence, think they can discern "lu trajòne"[21] oblivious to the fact that illusions and mirages can mislead them. With these fantasies, they seek to reconstruct history as if it were merely about "the deeds of men."

The Valley of Stignano is among the most legend-filled and evocative places in the Gargano. One such tale holds that Saint Francis of Assisi, en route to the cave of the Archangel Michael, passed through the Valley of Stignano and was enraptured by the beauty of the landscape and the kindness of its people. It is said that, in gratitude for the charity he received from the inhabitants—and even from the animals, who brought him food—he blessed the fruits of this valley. Though clearly a legend, it is important to recall that Stignano is a land of blessings as well as of legends, and also of sorrowful and dramatic events.

The convent of Stignano (fig.5) is located at the entrance to the broad valley that opens to the north-east of the great Tavoliere plain, where the road begins to climb; the sanctuary stands as the northern gateway to the sacred territory of the Gargano. Some have proposed that this was the path of the Via Sacra Langobardorum, or the Way of the Angel, or more precisely, the Via Francesca or Via Peregrinorum. However, I shall not dwell on the route of the road, leaving to future studies the investigation of the possible pilgrim paths to the Gargano.

From this natural threshold, one enters the Gargano Sanctuary, the very heart of the sacred mountain, making a stop at this sanctuary imbued with the deepest Marian and Franciscan spirituality.

The entire Tavoliere plain and the mountainous zone of the Gargano have been inhabited since prehistoric times. There is extensive evidence of human presence dating back to the Palaeolithic and Neolithic periods. The whole piedmont and lowland area was cultivated in the ancient Daunian period, throughout the era of Magna Graecia, and during the Roman age. The numerous archaeological sites, settlements, and tombs provide ample confirmation of this.

The Valley of Stignano is a vital part of the enduring human journey. Serving as a prelude (anacrusis) to the sacred path, it represents the instant when pilgrims bid farewell to the ordinary plains: the land constricts, and the soul is urged to look within.

The valley stretches from San Matteo to Stignano is known as Valle la Iana.

"This name appears as such in the Tavolario Pugliese... and in the public land registries, it is still referred to as Ponte di Iana, or, more precisely, as Ponte di Giano (Bridge of Janus)..."[22]

Ciavarella, meanwhile, notes:

Via Iana, which branches from Vico della Pace and leads to Via Lungo Iana, is a street name that originated in 1907, formerly known as Vico 1 Santa Chiara. Via Lungo Iana (which runs from Via Roma to Piazza Gramsci) also received its name in 1907. The name is thought to be derived from Giano (Janus), leading to the entire ravine of San Marco, situated between the convents of San Matteo and Stignano, being referred to as Valle la Iana; Torrente Iana, the small stream that flows down from the cliffs of the Difesa di San Matteo into the settlement below; and Ponte di Iana, the bridge that was once built at the location where the road Ponte le Grazie would later be constructed."[23]

Thus, the valley begins not with a declaration but with a constriction — a folding of the land that draws the pilgrim inward. It's not a threshold one crosses but rather a space into which one is gradually received, as the plains recede and the earth's contours tighten into significance. The Valle la Iana, named in honour of Janus, the god of dual faces and sacred passages, stretches between Stignano and San Matteo like an antechamber shaped by time and reverence. The earth does not immediately reveal its sacredness; it demands approach, attunement — a descent that, in reality, prepares one to ascend.

21 F. P. Borazio, Lu trajòne, poem in the Sammarche vernacular
22 [trad. by author] (Giuliani, 1846, p. 6)
23 [trad. by author] (Ciavarella, 1982)

The sacred begins softly, in quietude. The Stignano sanctuary, nestled against the valley's side, does not elevate but instead envelops. Its flatness signifies not a lack of height, but a liturgical calm — a gesture of gathering, a maternal embrace. The church remains still, surrounded by trees, as if the forest itself has learned to pray. There is no grand reveal here; the sacred surfaces through the earth's natural rhythm, where the land curves to create space for worship. The structure wraps around, its energy centripetal — a basin of memory, shelter, and blessing.

The Sanctuary of St. Matteo (fig.6) is perched on its small peak at the foot of Monte Celano (871 m). The first Benedictine foundations were developed here in the 11th century, becoming a centre for pilgrims on their way to the Gargano[24]. Topographically, San Matteo is located on a knoll emerging from a mixed oak and hornbeam forest (the Bosco Difesa). The meandering condition alludes to the winding pilgrimage path leading there, or perhaps to the meandering river shape of the valley. To arrive at St Matthew's is to follow the bend in the valley: to stop on a ledge of land that, at the same time, offers a view of the town and the passage. The sanctuary of St Matthew is a ledge, marking the passage. St Matthew's could be said to be the first 'peak' of the Gargano pilgrimage, albeit on a modest scale: a promontory reflecting the pilgrim's path from below. a constructed 'peak' that completes the natural knoll.

The entire valley serves as an anacrusis — it's not yet the mountain's peak, but already hints at it. The pilgrim cannot yet see the sanctuary of the Archangel, yet the mountain is weaving its language into the landscape's gestures. A fold, a rise, a ledge, a curve: these are the expressions the earth communicates through stone and shadow, and the pilgrim learns to interpret them with their steps.

Sound quiets in this place. The bells do not chime but float away. Silence is not merely an absence; it takes form, resembling the pause before a prayer, like the instant when a breath is held right before it transforms into a chant. This is not mere location; it is a liturgy made of stone. The landscape is not merely traversed but engaged with as a text. The sacred does not come from above; it lies dormant in the earth, waiting to be stirred by the one who walks through it. There exists a particular geography of silence in this place: as one steps into the valley's confined walls, sound ceases.

Cave and Daimon

At the summit of the promontory rests Monte Sant'Angelo, crowned by the Sanctuary of San Michele. This Romanesque basilica encloses the renowned Grotta di San Michele, a natural cave long revered as a sacred site (fig.7). According to legend, around the year 490, Bishop Lorenzo of Sipontum witnessed flaming apparitions of the Archangel Michael on this very rock[25], commanding that the grotto be consecrated to Christ and Michael. Yet the rocky cave and its subsequent chapels do not invite vertical ascent but rather a descent—a stooping of the body and spirit—as pilgrims enter the womb of the mountain. This subterranean space functions simultaneously as womb and tomb, a threshold between realms, charged with symbolic ambivalence and eschatological weight. The tangible darkness, the dripping stone, the echoing ventilation: all contribute to a vastness that overwhelms the senses—a felt tremendum. And yet, locals say that no winter storm ever disturbs its entrance, suggesting a protective, even maternal, aura. It is here, in this mineral hollow, that the Gargano daimon resides: not only the Archangel Michael, but also the latent spirits and healing forces that animated the mountain long before Christianity.

Indeed, the cave, one of the most ancient and sacred forms of natural architecture, embodies dual principles of concealment and emergence, evoking powerful imagery across cultures and cosmogonies. Functioning as both womb, symbolising genesis and gestation, and tomb, marking withdrawal and finality, it serves as a primordial site for transformation—where birth and death, vision, and silence, converge. In Greek mythology, caves were revered as the cradles of gods: sites of incubation, refuge, and revelation. In Eastern traditions, they function as thresholds towards inner enlightenment. Described by some as "a uterine space of regeneration," the cave

24 (Villani, 2023)

25 AA.VV., Il Santuario di San Michele sul Gargano dal VI al IX secolo. Contributo alla storia della Langobardia meridionale, edited by C. Cadetti and G. Otranto, Bari 1980; hereinafter referred to as 'Atti Monte Santangelo'. The volume contains essays by a group of scholars from the Institute of Ancient Christian Literature of the University of Bari (C. Colafemmina, C. D'Angela and M. Salvatore, in addition to the editors) who worked on the monument in close collaboration with scholars from other universities: M.G. Arcamone, M. Cagiano de Azevedo, C.A. Mastrelli, A. Quacquarelli.

offers a distinct spatial condition: rather than raising the gaze upwards toward celestial light, it draws the self downwards, into the hidden depths of being.

At Monte Sant'Angelo, this archetype finds its fullest theological expression. The sanctuary is believed to have been revealed rather than built, underscoring the precedence of divine presence over human intervention. Bishop Maiorano, upon witnessing the miracle, chose not to consecrate the grotto, deeming it already sanctified by the Archangel's epiphany. This refusal articulates a profound conception of non-mediated sacredness: a holiness that emerges from the land, not from ecclesiastical rites. Here, sanctity is inherent—ontological—rather than conferred. The descent into the cave becomes a katabatic liturgy, a ritual of immersion into the earth's psyche and one's own unconscious, evoking what Mircea Eliade called "the chthonic mode of the sacred": a form of holiness rooted in instinct, earth, and the raw vitality of life.

This sensibility finds symbolic resonance in the figure of Pan, the archaic nature-daemon whose presence intensifies the perception of the landscape, transforming it from a neutral background into a psychological mirror of human desire, terror, and wonder. The grotto becomes not only a setting for religious action but also a topography of the soul, wherein the sacred does not descend from above but erupts from within—from rock, root, and echo. "The sacred," Eliade writes, "reveals itself as phàinesthai": a coming-into-appearance that precedes rational understanding, causing a trembling of perception, a reverence for being itself.

The Apparitio Sancti Michaelis[26] in Monte Gargano, the foundational text of the site's cult, situates the sanctuary within its topographical and spiritual context. After anchoring the city of Siponto within its landscape, it recounts three emblematic apparitions of the Archangel, including the vision in which Michael prophesies the victory of the Beneventans and Sipontines—Lombard groups—over the Byzantine Neapolitans. The text subsequently shifts from visionary narration to a detailed natural description, portraying the rocky sanctuary, its surrounding environment, and the early practices of pilgrimage, devotion, and miracle-working (fig.8).

At the time of its historical emergence, the cult of Michael showcased a fundamentally therapeutic and naturalistic character. The Apparitio recalls that the Archangel healed fevers through a miraculous water (stilla) that sprang directly from the rock within the cave[27]. This healing force, inseparable from the materiality of the place, resonates with earlier mythological traditions: the site was previously linked to iatric-divinatory figures such as Calchas and Podalirius, whose presence prefigures Michael's functions. Thus, the sanctuary inherited not only its physical location but also a deeper archetypal role as a site of visionary incubation and bodily healing.

The presence of elemental forces—water, stone, forest, altitude—converges to create a landscape infused with sacral density. These features define the symbolic grammar of sacred space in the Gargano throughout the Middle Ages, shaping liturgical imagination and practices. The cave, referred to in medieval sources as both crypta and domus angulosa, remains irregular and tactile: walls protrude with jagged edges; the ceiling varies dramatically in height; the floor descends in stages, guiding the body through spatial modulation. Outside, the dogwood forest (cornea silva) encircles the summit, sheltering the sanctuary before it opens onto a vast plateau.

For the medieval pilgrim, the experience is not only topographical but also existential. The act of entering the cave serves as an initiation. In Greek, daimon refers to a guiding spirit[28] or genius loci[29]. Michael, in this context, becomes both guardian and revealer, governing not from above but from within. Inscriptions within the cave suggest a practice of incubatio—sleeping in the sacred space to receive dreams and prophecies—echoing ancient rites that were later reinterpreted in Christian terms. The votive tablets and banners preserved in the sanctuary reflect centuries of pilgrimage and protection, extending from battlefields to the thresholds of death.

Within the grotto, even sound behaves differently: footsteps echo like liturgical bells; prayers are absorbed into the stone with muted resonance. As one moves inward, the light grows dimmer, and silence acquires texture.

28 (Richer, 1989)

29 (Norberg-Schulz, 1981)

Then, at the threshold, a sudden opening reveals the Gargano ridge sloping towards the sea, evoking a sacred panorama—not an image, but an event of perception. The cave of Monte Sant'Angelo does not merely contain the sacred. It is the sacred, in its most primordial, unmediated form: an archetypal hierotopy[30], a cleft in the world through which the supernatural discloses itself—not in spite of the earth, but through it.

Counterpoint

Opposite the Carbonara Valley, in relation to the Sanctuary of San Michele, lies the Abbey in Monte Sacro (Mattinata), the ruins of which indicate an even older sacred heritage. At its peak are the remnants of a Benedictine abbey dedicated to the Holy Trinity, founded in the 11th century. However, archaeology and legend suggest this was once Monte Dodoneo – a mountain associated with Zeus Dodoneus. Giuseppe Piemontese notes that a temple of "Giove Dodoneo" stood here until the 5th century, echoing the cult of the Dodona oracle. An ancient inscription remarked "to Janus or to the door," but the name Dodoneus truly originates from Dodona in Epirus. Bishop Lorenzo, the same bishop who built the church at Monte Sant'Angelo, is reputed to have diminished the pagan oracle and consecrated the site to the Trinity. From that moment on, it was known as Monte Sacro, "the sacred mountain par excellence" of that area. Ongoing archaeology around the abbey continues to reveal Hellenistic temple foundations (fig.9).

The body of the building itself is entrusted with the task of meeting life and interacting with its manifold forms and infinite expressions. In order to define the meaning of this art of building, Bernard refers to two decisive and precise terms: rigour and dispossession. Building is essential, but not exhibiting, because the true construction must, paradoxically, be invisible. It is no coincidence. At the same time, in the clearing in which it usually stands, the ensemble of the abbey is like the soul of the land, of a body that would have remained dead without the effort of the men that arose it from its torpor. «As in the soul, in fact, maintained by all the humours that flow through the human body – and it, in turn, entrusts to the body warmth and life – in the dwelling – wher e in an e fervescence of light the riches, still dark, that the stimulated earth produces are consumed – resides the motor of every action»; through memory, reason, will.[31]

In Gargano's thematic geography, Santissima Trinità serves as a counterpoint to San Michele. While St. Michael's location is described as "high, fast, glorious" (a soaring beacon), the site of Monte Sacro is more stately, solstitial, and perhaps more connected to the earth. Both locations are significant for gods associated with thunder and sky (Zeus and Michael) on parallel ridges, apparent to each other and to pilgrims traversing the gulf. The ancients were aware of their relationship: Mattinata's carbonate spring (the Altheno river) noted by Strabo in the context of the Podalirius cult, flows from the base of Monte Sacro. Thus, Podalirius's healing waters were located at Monte Sacro's foot, while Calcante's oracle resided atop Monte Sant'Angelo. Christianity intertwined these sites by erecting Michael's church on the summit and the Trinity church (which continues the legacy of Jupiter) on the adjacent peak.

Now a dilapidated convent, Monte Sacro vividly embodies Otto's notion of the numinous. Visitors report feeling "caught up in the mystery" of walls that have become "prey to the assaults of the vegetation." The remaining arches and cells are "gripped by giant ivy," haunted by "the spirits of the forest" – as nature reclaims the sacred space. An unsettling aura pervades the site, as the legend of a treasure-guarding demon "does not seem so unfounded." In these instances, Monte Sacro unmistakably feels "wholly other" and profoundly awe-inspiring – a true "mysterium tremendum et fascinans," both daunting in its power and captivating in its beauty.

The mountain insists on the liveliness of nature: the forest reappropriates stone and altar, allowing ethos and environment to merge. The image takes us back to the original condition, to nature 'within.' Every ivy-covered arch and every fallen pillar resonates with an archaic, numinous quality. In the desolate splendour of Monte Sacro, the sacred, the demonic and the arcane intertwine in the lived landscape, leaving the visitor with a sense of wonder at the ancient mystery of the place. Monte Sacro remains a place of arcane wonder, where the archaic and the numinous converge in tangible form. A place where Homer[32] would say the Nymphs live, "personifications of those filaments and banks of mist suspended over the valleys, the mundane walls and springs, veiling

32 Odissea, VI, 123.

the waters and dancing above them"[33].

The Echo: Forest Hermitages of Santa Maria di Pulsano

Descending again towards the foothills of the Gargano, the landscape wrinkles - the southern terraces - where silence and echoes of solitude, of the monastic desert, prevail. Perched on a rocky spur dominating the coast between Monte Sant'Angelo and Mattinata is the Abbey of Santa Maria di Pulsano[34], founded in the 6th century (according to tradition by Pope St Gregory) and re-established in the 12th century by St John of Pulsano. Here the echo manifests itself both acoustically and spiritually. Rocky spurs envelop the abbey complex; small hermitages cling to the cliffs below, where monks once led a composite life[35]. Human existence is realised only in the composite life, that is, in the cooperation of the active life with the contemplative life (fig.10). As St. Gregory teaches:

"when a good program of life involves a transition from the active to the contemplative life, then it is often helpful for the soul to return to the contemplative life to the active, causing the flame of contemplation kindled in the heart to give all its perfection to industriousness thus the active life must lead us to contemplation, but contemplation [...] must lead us back to action"[36].

The landscape visible from Pulsano is not a passive view but rather a visual architecture that establishes the way of looking at and inhabiting space. The panorama generates orientation, establishing both a vertical and a horizontal axis: the former connects the cave to the vault of heaven, while the latter links the hermitage to the sea and the plain below. The place does not merely open itself to view; it demands a conscious gaze that permits it to be traversed by light and time. Here, what Gernot Böhme calls the "aesthetic atmosphere" is activated—namely, an affective quality of the landscape that shapes perception and establishes an existential dimension.

The landscape extends beyond mere visual observation; it encompasses light, sound, air, and the body's position. The monastic liturgies performed within the abbey found their spatial counterpart in the landscape: every canonical hour and chant coincided with shifts in the coastal light, breezes from the gulf, and a deepening silence. As a result, the landscape is shaped into an expansive liturgical space, where heaven and earth engage in the rite, positioning man not as a mere observer but as an active participant in this sacred tableau.

The expanse of the panorama induces a feeling of internal growth akin to what James Hillman[37], a perceptual broadening that links the individual to the entirety. The Gargano landscape, viewed from Pulsano, conjures the essence of Pan not in its frightening aspect, but in its rich, natural, and inherent quality. This vision transforms into a tangible experience, enhancing the connection with the world and granting access to an ancient form of knowledge that integrates humans with their surroundings, creating a unified living web.

Thus incarnates the geography of silence. It contrasts vividly with the grand panorama it overlooks: here is both altar and amphitheatre for contemplation. Modern commentators note how a visitor "stops and gazes at the boundless horizon, moved by the signs of the distant, tenacious Christian tradition of Santa Maria di Pulsano." It is this echo of history – a thousand years of solitary prayer inscribed on stone – that gives Pulsano its mythopoetic charge. As at Stignano, the site is an "elective place": not for crowds, but chosen by pilgrims seeking interiority.

34 (Cavallini, 1999)

35 Human existence is realised only in the composite life, that is, in the cooperation of the activa life with the contemplative life. As St. Gregory teaches: "when a good program of life involves a transition from the active to the contemplative life, then it is often helpful for the soul to return to the contemplative life to the active, causing the flame of contemplation kindled in the heart to give all its perfection to industriousness thus the active life must lead us to contemplation, but contemplation […] must lead us back to action". [Trad by Author] (Han, 2023, pp. 113-114)

36 Alois M. Haas, Die Beurteilung der Vita contemplativa und activa in der Dominikenermystik des 14. Jahrhudnderts, in B. Vickers (Hrsg.), Arbeit Musse Meditation, Verlag der Fachvereine, Zurich 1985, pp. 109-131

37 "Panic is no longer seen as a physiological defense mechanism or an inadequate reaction or abaissement du niveau mental, but would instead be seen as the right response to the numinous. precipitous flight becomes a breach out of protected safety into the 'mysterious wild regions of elemental existence.' Panic will always exist because it is rooted in human nature as such so even to govern it says Brinkmann will need to follow a mythological ritual procedure of gestures and music." [Trad. by Autor] (Hillman, 1972, pp. 68-69)

Calvino, valuing lightness, would point out how here the world is rendered thin – one is suspended between sky and rock. In Otto's terms, the place is no less tremendum, for the soul feels the scale of eternity in the "smisurato orizzonte" (boundless horizon) and the weight of solitude. In short, Pulsano is the echo chamber of the Gargano, where the sacred reverberates in empty space as much as it did in carved chapel walls (fig.11).

An Active Conservation of the Sacred Landscape

A sacred landscape needs to be reactivated, reinhabited, and maintained through ritual. Its sacredness exists in the stone, gestures, silences, and rhythms. A landscape is considered sacred not when it is merely observed, but when it is practised[38].

In this way, conservation is viewed not as an act of immobilisation but as a continuity: a sacred ecology of care. To maintain sacred sites, it is essential to provide attention that rejuvenates gestures, upholds rhythms, and nurtures our presence in relation to the land's shape and time. Monte Sant'Angelo exemplifies this principle by maintaining form alongside liturgical gestures, where structure is inextricably tied to spiritual orientation. Its strength is rooted in the lasting connection between sacred vision and the ritual path. The divine is etched into the physical space and the temporal layers of the land—its accumulated expressions of gesture and devotion.

Central to this valorisation is the practice of walking. Pilgrimage, understood as embodied liturgy, reactivates terrain as a revelation space. The Cammino di San Michele retraces an arc from Mont Saint-Michel to Jerusalem through Monte Sant'Angelo, linking sacred sites across time and geography.[39] This gesture aligns with the ethics of slow tourism: decentralisation, ecological awareness, and temporal openness. Micro-sites such as Santa Maria di Pulsano, Santa Maria di Merino, and the eremitic clearings of the Foresta Umbra become nodal points in a sacred network. The landscape re-emerges as a reticulum—an interconnected web of presences held by pilgrimage and prayer.

Valorisation, however, risks degradation when it shifts to consumption. "The sacred cannot be consumed; it demands a pact." The landscape is thus man-made. In the Gargano region, this results from prioritising the infinite over the finite[40] - While the effects of an urbanised landscape are clear, they require our focus eyes[41].This principle underscores the importance of sacred maintenance through acts of discretion and reverence. Voice, gesture, and rite must be preserved before presenting the artefact. Infrastructures remain discreet, and access flows are ritualised. The grotto is not simply a scenography; it retains its voice.

Equally important is the revitalisation of place through everyday actions. Ancient mule paths are restored, and dry-stone terraces are revitalised using agroecological methods. Forest trails are ceremonially cleared again. These actions do not merely enhance the sacred; they uphold its rhythm. They embody forma del patto—acts that reaffirm the bond between the land and those who inhabit it. The Eremo di Pulsano illustrates this approach. Reoccupied by a lay monastic community, it combines ascetic living, spiritual sharing, and landscape care. Pilgrims experience a renewed presence instead of a mere static heritage. Its architecture comes alive. What happens here is not a programme—it is a rite: a commitment to the space and its sacred evolution.

At the core of this philosophy lies a dialectic: the sacred landscape flourishes through responsiveness to rhythm rather than being tethered to rigid form. Sacred landscapes embody layers of time, serving as venues where various durations coalesce. Rather than imposing design, architecture should be attuned to the cycles of seasons, rituals, and the paths taken by pilgrims. Engaging with such an environment invites collaboration in its revelation. Projects ought to resemble liturgies rather than mere products, concentrating on the place instead of superimposing a design. To appreciate Monte Sant'Angelo is to engage in its continual manifestation of the divine—by hearing the whispers of its stones, respecting the patterns of approach, and nurturing the echoes of revelation[42].

(Re)Production of Urban Space through Cultural Events: Legacy of the Bergama Festival

Neslişah Kesici, Nilgün Çolpan Erkan
Affiliation: Yildiz Technical University
Email: nkesici@yildiz.edu.tr

Abstract
This study explores how planned events temporarily reshape public spaces while permanently transforming their form, function, and meaning. Focusing on the Bergama Festival, it examines the shift from a region-wide celebration across the Bakırçay Basin to a city-centred event held in modern and historical public spaces. The research primarily relies on archival analysis of past events and the spatial mapping of these findings to trace the transformation of public spaces. While the festival enhances cultural vitality and public engagement, its increasing commercialisation and spatial compression risk marginalizing residents and diminishing inclusivity. By analysing the socio-spatial dynamics of event spaces, the study contributes to debates on public space, cultural heritage, and urban equity, offering insights for planners and policymakers to create more inclusive and resilient urban environments.

1.Cultural Events as Urban Agents: Rethinking Festivals in the Public Space

Cultural events, particularly festivals, have increasingly come to be understood as significant urban agents that contribute to the social, spatial, and symbolic reproduction of public space. Drawing on Habermas's (1989) concept of the public sphere, planned cultural events can be seen as arenas where individuals express opinions, engage in dialogue, and contribute to the construction of public discourse and communal life. However, the extent to which these events strengthen the public sphere depends on their underlying intentions whether they cultivate civic engagement or serve primarily commercial or entertainment-driven goals.

From a sociological perspective, Castells (2000) identifies public spaces as contested terrains where collective identities are formed and negotiated. In this context, festivals and other cultural events provide crucial platforms for these expressions. Similarly, Bourdieu (1990) emphasizes that the organization and experience of planned events reflect cultural practices and underlying power relations, revealing how spatial transformations are shaped by, and in turn shape, social dynamics.

The performative aspect of public events is further illuminated by Goffman's (1959) concept of the "presentation of self," which highlights how individuals use events to navigate and negotiate public identities. Massey's (1991) work on the "global sense of place" complements this view by challenging static definitions of place, instead emphasizing the interplay of global processes, local dynamics, and personal experiences in shaping public space. From this perspective, events are not merely activities situated in space but symbolic expressions that actively transform it (Sennett, 2017).

Lefebvre's (1991) spatial triad, conceived, lived, and perceived space, provides a critical theoretical framework for understanding the multifaceted role of events in urban life. Within this framework, events are understood as "celebrated moments of time and space" that shape and mediate the relationship between society and the urban realm (Elden, 2004). Festivals thus serve as temporal articulations of the spatial dialectic, making visible both the physical and symbolic layers of public life.

In recent decades, there has been a growing shift from enclosed venues to open public spaces as preferred locations for cultural events. Richards and Wilson (2004) argue that the private sector increasingly uses public space as a stage for promoting events, while local governments utilize festivals as tools to "stage the city" in global inter-urban competition (Colomb, 2012). Smith (2016), however, pushes this discourse further by advocating for event planning that reflects the dynamics of the city and its inhabitants a transformation from the notion of "city as stage" to "city as staged."

Jakob's definition of a planned event as the "deliberate organization of an elevated emotional and aesthetic experience" underscores the aesthetic and affective dimensions of public events. Stevens (2007) views such events as choreographed moments that enrich the streetscape, while Montgomery's (1998) Form-Activity-Meaning (FAM) model provides a concrete framework for assessing their impact. According to this model, festivals and similar events activate public space through diverse uses, enhance social interaction, and create meaningful, memorable experiences. However, the commercialization or imposition of such events can alienate

users and diminish the inclusiveness and democratic potential of public space.

Urban thinkers such as Jane Jacobs and Jan Gehl offer valuable insights into how cultural events can align with principles of vibrant and inclusive public space. Jacobs advocates for diverse, people-oriented spaces where social life can flourish. Within this framework, events such as street festivals and community markets can transform underutilized areas into active hubs of social life, exemplifying Jacobs' notion of "eyes on the street." Gehl's distinction between necessary, optional, and social activities similarly helps articulate how planned events can enrich public life by intersecting with different types of spatial engagement.

Crucially, the management and governance of public space are vital in supporting or undermining the success of cultural events. Carmona (2010) emphasizes the importance of designing accessible, active, and socially engaging spaces. Effective event planning must not only address physical design but also ensure that public spaces remain open, inclusive, and meaningful in both everyday use and during special occasions.

Finally, Smith (2016) categorizes the transformative impacts of festivals into three spatial dimensions. First, formal and monumental public squares can be animated and democratized through participatory cultural events. Second, parks often subject to restrictive control can be temporarily reactivated as open, communal spaces. Third, by closing streets to vehicular traffic, festivals reclaim urban space from privatization and consumerism, fostering communal experiences and spatial justice.

Taken together, these perspectives demonstrate that cultural events when thoughtfully conceived and inclusively implemented are not merely spectacles but critical instruments in the social production and transformation of public space. Through their temporal nature and symbolic richness, they hold the potential to sustain urban vitality, foster civic identity, and reinforce the democratic life of cities.

2.Layers of Heritage and Change: Tracing the Historical Trajectory of the Bergama Festival

The Bergama Kermesi, Turkey's one of the first local festival held continuously for 89 years and initiated under Atatürk's leadership with the aim of promoting local values, has been selected as the field site for this study due to its diverse and multi-dimensional character. The festival comprises a variety of events, including cultural and artistic performances as well as sports activities, taking place across the city's public open spaces over the course of a week. The kermes supports Bergama's international visibility and tourism, fosters the marketing of local products and economic revitalization, and facilitates encounters between villagers and townspeople, locals and tourists, and citizens and artists

With its rich historical, cultural, and natural assets, Bergama was inscribed on the UNESCO World Heritage List in 2014 under the title "Pergamon and its Multi-Layered Cultural Landscape." In addition to its tangible heritage, comprising successive layers from the Hellenistic, Roman, Byzantine, and Ottoman periods, Bergama's intangible cultural heritage has also been formally recognized and registered in line with UNESCO's principles. A prominent example is the Bergama Festival (Bergama Kermesi), held annually since 1937 in response to Mustafa Kemal Atatürk's directive: "An opportunity should be provided to promote this exceptional corner of our country through a fair or festival for its people.". As one of the oldest festivals in Turkey, the Bergama Festival now in its 89th edition, represents a vital expression of the city's living heritage.

Today, the term kermes, used to describe this week-long local festival, refers, according to the Turkish Language Association (TDK), not only to festivities, holidays, and fairs, but also to collective events organized for the public good, such as communal efforts and fundraising events. In its first 15 years, the Bergama Kermesi was organized entirely by civic initiative, specifically by the "Bergama'yı Sevenler Derneği" Later on, the responsibility for organization and funding was assumed by the Bergama Municipality, with contributions from the public, the district governorate, and the Bergama Foundation for Culture and Arts (BERKSAV) (Eriş, 2011).

The poster archive offers a valuable clue for understanding the shifting approach to how the Bergama Festival has been presented over time (see Figure 1). In its early years, graphic designs prominently featured traditional folk dances and the city's rich historical heritage. However, these representations gradually faded into the background. Notably, following the rise of neoliberal influences in the post-1980s period, the poster for the 54th festival included the logo of a global beverage company that sponsored the event, a clear indication of commercialization. In the

posters from the 2010s onward, elements of Bergama's local identity are largely absent. Instead, the focus shifts to promotional images of performing artists scheduled to give concerts during the festival. This transformation in the visual language of the posters alone reveals that the festival, originally intended to highlight local values and represent the place, has increasingly been compelled to forfeit its authenticity in the face of global dynamics, evolving into an event more focused on chasing popularity than celebrating local heritage.

Figure 1: Posters of the Bergama Festival from 1938 to 2024

This situation demonstrates that the event has gradually shed its original character of representing, promoting, and reproducing the space. Instead, it has assumed a new role that contributes to the consumption of space. Rather than fostering new cultural expressions or sharing what is unique to Bergama, the festival increasingly mirrors mainstream popular culture. In doing so, it drifts away from its initial function as a platform for the articulation of local identity, becoming a stage where imitation replaces authenticity and commodification overshadows cultural rootedness.

Cultural policies in Turkey have undergone significant transformations since the early Republican period. With the establishment of community centres "Halkevi" in 1932, cultural activities such as theatre, music, literature, and folk dance were institutionalized, positioning "Halkevi" as central venues for local festivals and artistic expression. The transition to a multi-party-political system in 1950 led to a partial decentralization of cultural initiatives, encouraging private sector involvement. In 1958, the closure of Halkevleri marked a turning point, as municipalities and private actors took over the organization of public cultural events. During the 1960s and 1970s, rapid urbanization and cultural pluralism saw the diversification of events in major cities, while popular culture flourished in informal settlements.

The 1980 military coup brought increased censorship and repression in the arts. Between 1983 and 2000, neoliberal policies contributed to the commercialization of cultural events, with international festivals emerging in big cities. The 1990s witnessed the rise of global cultural forms in Turkey, including music festivals, independent theatres, and biennials. In the 2000s, metropolitan municipalities like Istanbul and Ankara began to exert greater influence over cultural policy. By the 2010s, cultural events held in public spaces were increasingly shaped by security, profit-driven motives, and urban transformation agendas. The 2013 Gezi Park protests underscored the central role of public space in cultural production, sparking alternative forms of cultural expression. However, growing concerns include the homogenization of event programming and venues, the suppression of spatial diversity, overcapacity, and cultural degradation.

The Bergama Festival, with its nearly nine-decade history, stands as a unique cultural formation that encapsulates the evolving dynamics of Turkey's cultural policies, urban transformations, and local identity politics. Initially conceived as a celebration of Bergama's rich cultural heritage and a civic act of local representation, the festival once offered a platform for promoting both tangible and intangible assets of the city. However, as revealed through the changing actors, aesthetics, and spatial strategies of the event, the Bergama Festival has undergone a significant transformation from a place-based, community-oriented expression of heritage to a commodified spectacle shaped by neoliberal imperatives. While it continues to attract attention as a cultural attraction,

the shift toward a popularity-driven and commercially influenced format undermines its potential to act as a generator of cultural continuity and urban meaning. This transformation signals not only a detachment from the festival's founding ethos but also a broader struggle for authenticity, inclusivity, and cultural memory in the face of global and local pressures. Understanding this trajectory is vital not only for reclaiming the cultural integrity of the Bergama Festival but also for informing more equitable and place-sensitive cultural policy frameworks that prioritize collective memory, local participation, and spatial justice.

3.Shrinking the Festive Geography: From the Bakırçay Basin to the City Core

Located in the northern part of İzmir Province, Bergama has long held a central role as a cultural and commercial hub in Western Anatolia (see Figure 2). As the modern inheritor of ancient Pergamon, the town's unique archaeological wealth, layered historical fabric, and diverse natural landscapes have positioned it as a key tourism destination within the region. This potential has been further amplified since Bergama's inscription on the UNESCO World Heritage List, which has brought greater national and international recognition. In this context, the Bergama Festival (Bergama Kermesi), held annually since 1937, plays a critical role in both the promotion of the city's tangible and intangible cultural heritage and the active reproduction of urban life. Serving as a bridge between past and present, the festival not only invites residents and visitors to engage with the city's legacy but also transforms Bergama into a space of collective celebration and memory.

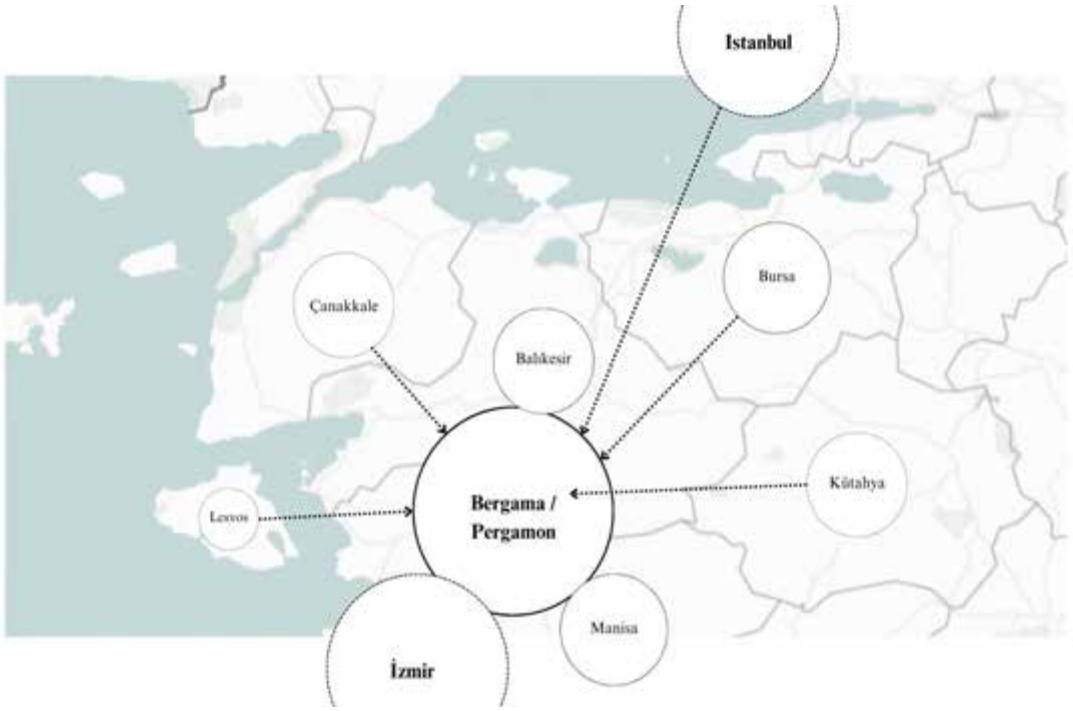

Figure 2: Bergama's regional position with surrounding settlements

In its foundational years, the festival was envisioned as an event that connected the urban and rural, drawing on the full geography of the Bakırçay Basin, from the coastal settlements of Çandarlı and Dikili to the forested heights of the Kozak Plateau and the agricultural plains of Göçbeyli and Kınık (see Figure 3). Through this expansive geography, the festival embraced a diverse array of local identities and practices. Seaside festivities along the Aegean coast, sports competitions in the forests, and folkloric performances, particularly the traditional "Bengi" dances of the plain villages collectively reflected the rich and pluralistic cultural identity of the wider basin. In this sense, the festival functioned as a powerful agent of territorial representation, producing a spatial narrative that connected nature, history, and cultural expression across multiple settlements.

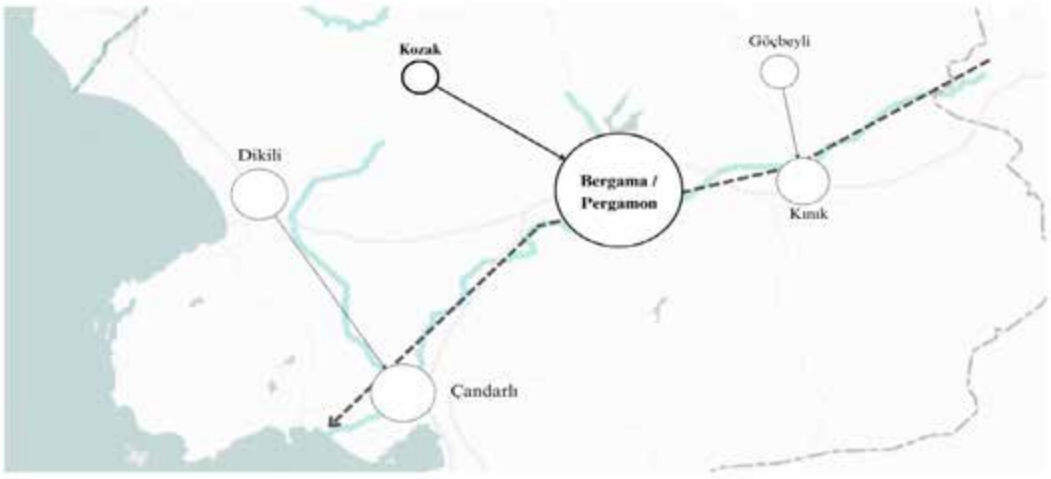

Figure 3: The geography of the festival spread in the Bakırçay Basin

However, over time, structural shifts in administrative boundaries and governance frameworks have significantly reshaped this geography. With the transition of Bergama into a district of the İzmir Metropolitan Municipality and the redefinition of local government jurisdictions, the festival's spatial scope has gradually narrowed. Practical considerations such as transportation, security, visibility, and institutional control have contributed to the centralization of festival activities within the historic core of the city. As a result, key venues now include symbolic urban spaces such as Cumhuriyet Square, Atatürk Boulevard, and historical sites like the Red Basilica, Asklepieion, and the Arasta district. While these locations lend prestige and cultural depth to the event, they also signal a marked shift: from a basin-wide, inclusive celebration of shared rural-urban identity to a centralized, curated spectacle within the city's core.

The only remaining trace of the festival's once expansive geography lies in the final-day celebrations held in the Kozak Plateau, a symbolic gesture toward its rural roots. Yet even this tradition faces the risk of becoming a ritualized performance rather than a genuine extension of the festival's original ethos.

The contraction of the festival's geography mirrors broader trends in urban governance, cultural commodification, and spatial politics. What was once a decentralized celebration fostering territorial belonging and collective identity across the Bakırçay Basin has been reconfigured into a more controlled, urban-centred event. While this shift may offer advantages in terms of visibility and logistical management, it raises critical questions about authenticity, inclusivity, and the politics of cultural representation. As public events become increasingly embedded in strategies of city branding and tourism promotion, there is a growing need to revisit the spatial logic of festivals like the Bergama Kermesi, not merely as performances in space, but as active instruments in the production of space, identity, and memory.

4.The Power of Bergama Festival to (Re)produce Urban Space

Public festivals have long been recognized as influential tools in shaping the spatial, social, and symbolic dimensions of cities. In this context, the Bergama Festival (Bergama Kermesi) offers a compelling case for understanding how recurring cultural events can participate in the (re)production of urban space. Since its inception in 1937, the festival has not only functioned as a celebratory ritual rooted in local heritage but has also played an active role in redefining the spatial narratives and practices within the city. Through its varied programming, from parades and performances to exhibitions and street activities, the festival temporarily transforms Bergama's urban fabric, reactivating public spaces, reassigning symbolic meanings to historical sites, and creating new rhythms of urban life. More than a reflection of cultural identity, the Bergama Festival becomes an agent in the production of space, mobilizing collective memory, political narratives, and everyday encounters.

Although the festival has become largely confined to the city centre, limited to its historical and modern public spaces, it retains significant power to (re)produce urban space. This potential is most evident in the spatial

diversity of event venues, which collectively form a unique urban event landscape. The festival activates a wide range of spatial typologies, including historical sites, parks, squares, streets, public buildings, and natural areas (see Figure 4). While central squares serve as stages for concerts and large public gatherings, parades and ceremonial processions animate the main boulevard, creating temporary flows of movement and spectatorship. Elevated parks located on the city's dominant hills provide scenic vantage points, transforming into collective viewing platforms that extend the experiential field of the events. At the same time, Bergama's layered historical environment, comprising archaeological landmarks and cultural heritage sites, offers an evocative backdrop, enriching the festival's spatial atmosphere and reinforcing the symbolic connection between past and present. Thus, the festival reclaims, reconfigures, and reinvests meaning into these spaces, temporarily reshaping the city's spatial rhythms and enhancing its public life.

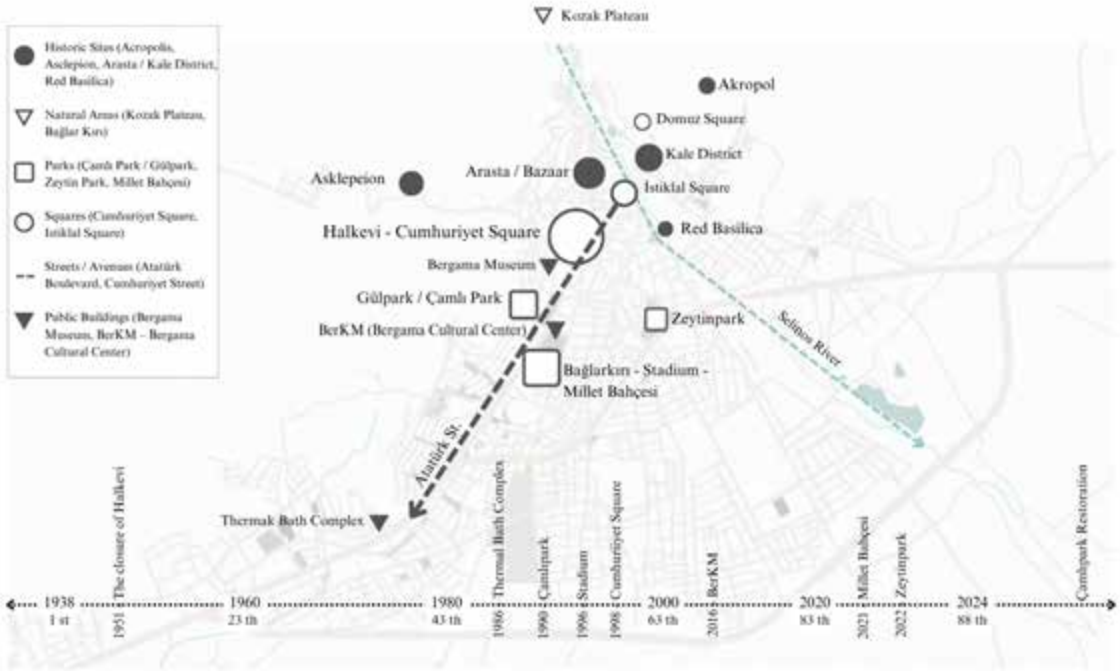

Figure 4: Distribution of the Bergama Festival across different urban space typologies

This spatial reconfiguration is most clearly embodied in Cumhuriyet Square, which has become the epicentre of the festival's urban imprint. Originally the garden of the Halkevi (Community House), the square has undergone multiple transformations aligned with broader political and cultural shifts in Turkey. While its earliest traces go back to the early Republican period, shaped by ideals of Westernisation and civic identity, the space has been continuously redefined through successive interventions. The most decisive transformation took place in 1998, when celebrated architect Cengiz Bektaş redesigned the square with a vision centred on spatial experience and collective memory, explicitly to accommodate festival activities. Since then, Cumhuriyet Square has functioned as the primary venue for major performances, including folk-dance shows, opening ceremonies, award distributions, and especially evening concerts that draw large crowds. During the most recent edition of the festival (2–8 September 2024), this site hosted the highest concentration of events, temporarily reshaping both the functional logic and symbolic meaning of the space.

In addition to the square, various public spaces, such as Atatürk Street, Arasta, and Çamlı Park, are temporarily defunctionalized during the festival, as their everyday uses are suspended in favour of programmed activities. The transformation also extends to historically and culturally significant sites such as the Acropolis, Asklepeion, Red Basilica (Kızıl Avlu), and the ancient theatre, whose accessibility is reconfigured to allow large-scale gatherings, performances, and public engagement. While this strategy increases the visibility of Bergama's cultural assets and expands the festival's experiential landscape, it also risks overexposure and commodification. Particularly since the 2000s, neoliberal influences have prompted a gradual shift in festival content, increasingly favouring

popular cultural acts to attract broader and often external audiences. This trend has amplified the appeal of the festival but has simultaneously narrowed its connection to local cultural practices and community identities. As a result, the festival becomes more consumption-oriented, and urban spaces, particularly central ones, are pushed to accommodate excessive demands, which may displace everyday users, diminish local belonging, and alienate long-term residents from their own city spaces.

In recent years, a growing institutional fragmentation has begun to constrain the symbolic impact and spatial potential of the Bergama Festival. While the event itself is organized and embraced by the local municipality, many of the city's most significant historical sites such as the Asklepeion and the Acropolis are managed by the central government through the Ministry of Culture. This divide has led to a disconnection between the festival and these emblematic locations, reducing the festival's ability to activate historically and spatially meaningful venues. This is particularly striking given that both the Asklepeion and the Acropolis include amphitheatres, making them naturally suited for performances and collective gatherings.

In addition to this institutional tension, evolving spatial interventions in the city have also influenced the festival's capacity to reproduce urban space. A key example is the area known as Bağlarkırı, which in the early years of the festival served as a major venue and host site. Over time, Bağlarkırı was transformed first into a stadium and later into a "Millet Bahçesi", thereby losing its function as a festive space. This shift illustrates how urban development decisions can sever historical continuities in public event geographies. Nevertheless, the city has also seen the emergence of new public venues that are being integrated into the festival landscape, such as Zeytinpark and the Bergama Cultural Centre (BerKM). These additions suggest that while certain traditional spaces are lost or repurposed, new possibilities for cultural expression and spatial activation are still being created. This tension between spatial loss and renewal encapsulates the broader challenge of sustaining the festival's urban role in a rapidly changing cultural and political environment.

Public space emerges as a dual entity within this context. On the one hand, festivals enliven and democratize urban environments, offering opportunities for collective memory, cultural performance, and temporal reappropriation. On the other, they intensify spatial pressure, potentially marginalizing everyday users and transforming public domains into semi-exclusive eventscape. The Bergama Festival thus represents both an opportunity and a challenge in terms of urban policy: it revitalizes and redefines space yet simultaneously contributes to spatial inequalities. This study contributes to broader debates on urban space and cultural event policy by critically examining the mechanisms through which festivals shape the physical and symbolic dimensions of cities. By highlighting the spatial consequences of shifting festival geographies, it offers insights for planners and policymakers seeking to balance visibility, accessibility, and inclusivity in the use of public space, especially in heritage-rich, yet socioeconomically fragile, urban settings like Bergama.

Heritage Perception and Identity Construction Among Residents in Industrial Community Transformation: A Case Study of National Creative Park, Nanjing, China

Wenjing Dong, Zimeng Kong, Yanhui Wang
Southeast University
Melodydongwj@163.com

Abstract
In the context of China's deindustrialization, the redevelopment of industrial heritage sites has become central to urban transformation strategies. This study examines the regeneration of Nanjing National Creative Park (NCP), tracing its evolution from a major Qing-era factory to its closure in 2011 and subsequent conversion into a creative industry park. Using a qualitative approach, the research analyzes dominant narratives over different historical periods. In addition, in-depth interviews were conducted with various community residents to assess heritage perception and identity construction. The findings formed an unofficial "community narrative." This study reveals the dynamic interaction between dominant narratives and community narratives in the redevelopment of Chinese industrial heritage sites. It highlights the complexity of local residents' perceptions and argues that these perspectives should be incorporated into the framework of industrial heritage conservation. Moreover, the study emphasizes the importance of considering community voices in ensuring the sustainable development of heritage sites.

Keywords: Industrial Heritage; Dominant Narratives; Community Narratives; Urban regeneration; Place identity

1 Introduction

1.1 State-led redevelopment of industrial heritage sites

Post-industrialization and urban regeneration have become key global trends in urban governance and spatial transformation. While sharing similar drivers, their mechanisms and narrative practices differ significantly across contexts (Harvey, 2007). Industrial heritage has emerged as a site of cultural narration and identity construction. In China, as the world's largest manufacturing nation, post-industrial redevelopment is shaped by a unique socialist governance model and land regime. Under this context, state-led redevelopment and cultural re-narration have reshaped industrial heritage. Sites like Nanjing's National Creative Park (NCP) have been reframed through discourses of "creative industry parks" in planning texts, policy discourse, and curated exhibitions. Unlike the overt political expressions of working-class resistance in the West, China's former industrial community residents often respond to dramatic spatial and social restructuring through subtle, depoliticized forms of "silent resistance" and negotiated identity (Zhao and Nichols, 1996; Bray, 2005).

1.2 Industrial Heritage Communities under Divergent Policy and Cultural Contexts

In recent years, researchers have begun to highlight the "north–south divide" in China's industrial heritage landscapes. Similar to well-studied cases like Germany's Ruhr Valley, northern Chinese cities (e.g. Shenyang, Tianjin) typically exhibit single-industry clustered communities, where heritage regeneration primarily focuses on addressing systemic community decline (Zhang et al., 2023). In contrast, cities like Nanjing feature small-scale industrial sites embedded within existing neighborhoods, where heritage overlaps heavily with residential life. Here, urban regeneration is entangled with multiple pressures—historic preservation, industrial restructuring, and everyday livelihoods. Spatially and socially, such mixed-use heritage areas differ significantly from traditional "industrial satellite towns," which were once highly unified in terms of work and living arrangements.

In these hybrid heritage districts, residents are not limited to former industrial workers, but may include indigenous households, relocated residents, tenants, and homebuyers. This "internal heterogeneity" challenges the conventional class-based frameworks of identity and calls for analytical tools based on narrative negotiation. Studying the regeneration processes in these areas can therefore enrich our understanding of how identities are shaped across diverse social groups.

This paper applies critical discourse analysis (Fairclough, 1995), three-level positioning framework (Bamberg, 1997), and narrative structural approach (Riessman, 2008) to analyze how different types of residents engage with policy discourse, spatial change, and cultural reinterpretation. It examines how narrative positions are chosen, senses of belonging evaluated, and social roles reconstructed. Responding to the emerging academic focus on narrative governance, this study argues for pluralistic and dialogic mechanisms in heritage-led urban regeneration, providing insights into more inclusive approaches to community renewal.

Specifically, it addresses the following questions: In the face of transformation, how do residents from different backgrounds within hybrid industrial communities perceive their neighborhoods and construct their identities? Under the control of China's socialist institutional system, how can industrial heritage sites undergo a social transformation from "industrial relics" to cohesive "heritage communities" in the process of deindustrialisation?

2 Literature Review

2.1 Narrative Contestation in Post-Industrial Urban Regeneration

In the context of post-industrial urban regeneration, the reproduction of space is frequently accompanied by struggles and negotiations among narratives. Urban space becomes a site of multi-actor narrative competition (Jensen, 2007). Amid industrial transformation, heritage reuse, and community renewal, governments, developers, indigenous residents, and cultural actors engage in discursive battles over how the city should be remembered, represented, and envisioned for the future (Raco & Henderson, 2009). Such contestation reflects conflicts over historical legitimacy, cultural identity, and social spatial justice, often involving the restructuring of power and the marginalization of alternative knowledge systems (Lees, 2008).

Mainstream narratives, underpinned by policy language, development strategies, and capital logic, dominate through urban branding, spatial aesthetics, and elite discourse production (Balibrea, 2001). However, these narratives frequently neglect or marginalize the voices of vulnerable communities, particularly in terms of their sense of loss and displacement, resulting in what Lees (2008) terms "narrative silencing." The emotional energy and historical significance embedded in post-industrial ruins are often sanitized or instrumentalized under official discourse (Emery, 2019).

In response, residents, local actors, and critical scholars have developed "counter-narratives" that challenge elite representations and reassert local history and identity (Till, 2005). These alternative narratives are grounded in memory, affective landscapes, and lived experience, emphasizing locality and a "sense of historical presence." In China's socialist and post-socialist context, narrative contestation exhibits unique characteristics. First, the regeneration process is highly centralized, with limited community participation. Second, the functional and symbolic values of industrial heritage are explicitly embedded within national economic development agendas (Sun & Chen, 2023).

Narratives are not static but continuously negotiated through multi-actor interaction. Fairclough (1995) highlights the process of "selective recontextualization," where dominant narratives absorb, alter, or discipline individual voices—a phenomenon especially pronounced in post-industrial heritage settings. Thus, narrative contestation in post-industrial urban regeneration concerns not only cultural reproduction but also has profound implications for identity formation, spatial belonging, and civic participation.

2.2 Identity in Heritage Discourse

The reconfiguration of heritage spaces not only reshapes urban landscapes but also directly impacts residents' identities and sense of place (van Knippenberg & Boonstra, 2024). Studies indicate that functional changes in space often accompany symbolic reconstructions. For instance, transforming former labor sites into commodified exhibition spaces or art districts can impose a certain cultural narrative, leading residents to adopt new "identity frameworks" associated with the redefined "locality" (Mathur, 2014).

Residents' identities in industrial heritage spaces are often shaped by both official mainstream narratives and grassroots local discourses. Mainstream narratives, through institutional frameworks, planning contexts, and cultural reinterpretations, often shape residents' identities based on institutionalized discourses rather than personal experiences or grassroots collective memories. Zhang et al. (2023) argue that local identity has been "cultural symbolized" by dominant discourses, reducing it to an object of passive reception. In contrast, community narratives are articulated through personal and collective experiences and memories.

Preece (2020) introduces the concept of "biographies of belonging," highlighting how individuals in working-class communities construct identities through emotional and experiential connections to local spaces. These narratives not only reflect personal self-understanding but also maintain the historical continuity and collective memory of communities. Such participation is crucial for forming a sense of spatial belonging (Jones & Leech, 2015). For example, community-led redevelopment models are more likely to preserve residents' familiarity

and intimacy with spaces, thereby enhancing their sense of belonging. Conversely, neglecting or marginalizing residents' narratives can exacerbate their sense of spatial alienation (Preece, 2020).

While existing research acknowledges the importance of incorporating residents' narratives into industrial heritage renewal processes, discussions have primarily focused on the emotional memories and historical experiences of the working class. However, industrial heritage communities often have diverse demographic structures. The perceptions and emotional attachments of other types of residents to heritage renewal have been marginalized in current research. Moreover, existing literature has yet to reveal how narratives serve as mediating forces in shaping place perceptions and community identities amidst the interplay of multicultural and social structures.

3. Study Area

The Nanjing Creative Park (NCP), located in the heart of Qinhuai District, Nanjing, occupies a site historically used by two significant institutions: the Jiangnan Mint (formerly responsible for coin casting during the Qing Dynasty) and later the Nanjing No. 2 Machine Tool Plant, a major manufacturing base in the early industrialization of the People's Republic of China. In response to national deindustrialization policies, the site has undergone a series of transitions, including factory relocation, property restructuring, industrial heritage designation, and both park and community redevelopment. Its role has shifted from a self-contained industrial unit to a mixed-use urban precinct (Fig. 1, Fig. 2). Although now positioned as a creative industry park, NCP is spatially and socially interwoven with adjacent residential neighborhoods, making it a key case for understanding policy-driven transformation and community integration.

Figure.1. A photograph of a public space in this residential community), photo by Wenjing Dong

Figure.2. A photograph of houses in this residential community (Lai Feng Xin Cun), photo by Wenjing Dong

Surrounding areas such as Lai Feng Li, Ling Jiao Shi, and Lai Feng Xin Cun, many former workers and their families, who represent important community voices in this research (Fig. 3). Following the closure of the factory, these residents experienced institutional detachment, employment insecurity, and identity dislocation. Conversely, the commercialization has created new interactions for residents with no prior connection to the industrial past. The NCP thus exemplifies the dynamic interplay between dominant state narratives and plural community discourses in the context of heritage-led urban regeneration.

Figure.3. Location of NCP community, author self-painted.

4. Methodology

4.1 Research Design

This qualitative study investigates narrative construction and identity formation in the redevelopment of NCP. Two stages were conducted: (1) critical discourse analysis of policy texts, and (2) narrative analysis of resident interviews, aiming to explore the interaction of spatial discourse, place attachment, and identity.

4.2 Data Collection

Two datasets were used: (1) 10+ planning documents, exhibition texts, and media sources (1900s–2024), capturing official narratives of transformation; (2) 32 semi-structured interviews (Sept 2024–Jan 2025) with residents categorized as "old" and "new". "Old residents" include former No. 2 Machine Tool Plant workers and their family members ("worker group" and "worker family group"), as well as long-term dwellers with no direct factory affiliation—such as original inhabitants, relocated households, and residents assigned housing from other work units ("other old residents"). "New residents" refer to homebuyers and renters who moved in after the park's redevelopment. Interviews focused on memory, experience, attachment, and heritage perception. All were anonymized and transcribed.

4.3 Data Analysis

Official texts were analyzed via Fairclough's (1995) CDA model to uncover discursive mechanisms legitimizing redevelopment. This involved examining language use, discourse production, and the underlying ideologies. Special attention was given to keywords such as "industrial revitalization" and "heritage activation" to uncover how official narratives construct heritage discourse. Resident narratives followed Bamberg's (1997) identity positioning framework and Riessman's (2008) narrative structuring, examining how individuals negotiate identity and space in response to policy and change.

By comparing the structures and strategies of two narrative logics, this study aims to present a tension-filled context of industrial heritage redevelopment, revealing how personal memory and policy planning intersect, conflict, and negotiate within local narratives.

5 Official Narratives: Functional Transformation and Discursive Reconstruction

5.1 Functional Narratives in Spatial Transformation

The origin of Nanjing Creative Park (NCP) is closely tied to state-led policies. Initially established in the early 20th century as the Jiangnan Mint under the Qing court, the site was later transformed into the Nanjing No.2 Machine Tool Plant after the founding of the People's Republic of China (Xu, 2012) (Fig. 4, Fig. 5). In 2012, under the "retreat of secondary industry and advancement of tertiary industry" strategy, the plant began its industrial transformation. By December 2013, under the guidance of the Nanjing Industrial Heritage Protection Plan, the site was redeveloped into a national innovation and entrepreneurship hub (Li & Chen, 2022).

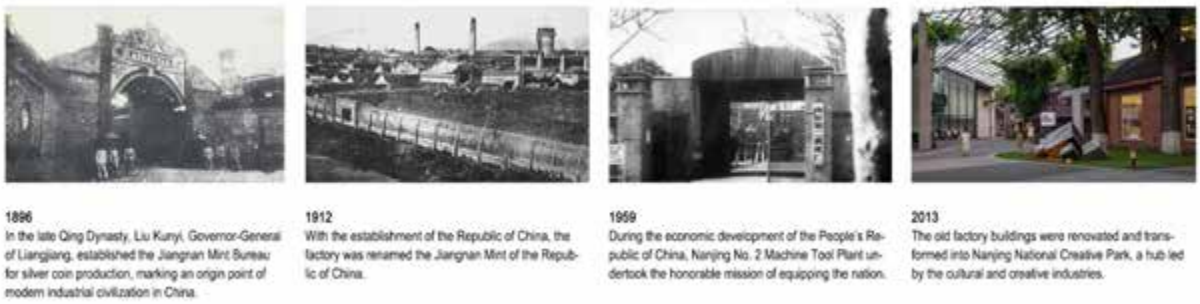

Figure.4. NCP during the different historical stages, author self-painted.

Figure.5. The spatial extent of NCP, author self-painted.

Currently, guided by the strategic goals of constructing a "national all-area tourism demonstration zone," building an "innovation-driven city," and promoting "high-quality development," NCP has become a key node in the spatial restructuring of Qin Huai District (Qin Huai District Development and Reform Commission, 2019). According to the mid-term evaluation report of the 13th Five-Year Plan, the old southern city area has been designated a national cultural demonstration zone (Qinhuai District Government, 2018). In this narrative of "all-area tourism," industrial heritage sites like NCP are framed as cultural and tourism assets.

Multiple policy documents indicate that the NCP's identity has undergone a shift from "industrial relic" to a hub for "cultural and creative industries" and the "digital economy." In this transformation, the park is no longer regarded solely as a historical site but reimagined as a complex industrial space symbolizing innovation and integration (Qinhuai District Government, 2019a).

The official narrative strongly emphasizes NCP's economic function, especially its roles in cultural industries and tourism. On one hand, the park is promoted as a cultural IP incubator and a key site for implementing the "Ten Measures for Cross-border E-commerce in Qin Huai." On the other hand, it is integrated into tourism strategies like "Night Stay in Qin Huai," aimed at fusing industry and tourism consumption experiences (Qin Huai

District Government, 2019b). This narrative logic reflects a systemic embedding of the "production–exhibition–consumption" chain into the traditional industrial community.

5.2 Shifting Policy Subjects and the Redistribution of Discursive Power

An analysis of policy texts across different historical periods reveals a significant shift in the subject of NCP's official narrative from the "working class" to "enterprises," "investors," "park managers," and "tourists." This semantic shift reframes the park not as a site of industrial production, but as a spatial tool for project implementation, resource aggregation, and productivity enhancement. For instance, the Qin Huai District Bureau of Commerce (2025) emphasizes supporting enterprises' global expansion and building a cross-border export ecosystem, highlighting a "park–enterprise–government" cooperation model. Similarly, the Qin Huai District Government (2019a) stresses the creation of a full industrial chain for IP development, with the operative subjects being park operators and tenants. This discursive strategy restructures the actor network of the park and reallocates discursive power to new entrants.

Driven by these dominant narratives, NCP has redefined its institutional identity. First, it is positioned as a key platform for cultural display, technological innovation, and industrial upgrading, and as a model for policy implementation. Second, while policies highlight the roles of government and enterprises, local residents are largely absent from these texts, with little attention to their emotional needs, lifestyle shifts, or identity struggles. Third, policies do not offer pathways for former residents to engage with or reestablish roles in the transformed park. Thus, while the official narrative facilitates spatial and functional renewal, it simultaneously neglects the reconstruction of local identity and community continuity, transforming the park from a "social space" into a purely "functional space."

5.3 Fractures Within the Dominant Narrative

The official narrative, which centers on an integrated framework of "technology, culture, tourism, consumption," has effectively repositioned NCP within Nanjing's high-quality development discourse. However, this narrative model also exposes certain limitations, particularly its unidirectionality and closure. While emphasizing "innovation driven" development and a "showcase city" image, it tends to overlook the social fractures and cultural exclusions that may arise during redevelopment. The de-contextualization of daily life, the fading of historical memory, and the weakening of place-based identity present latent challenges behind the polished official discourse. This analysis provides a critical foundation for subsequent examinations of community narratives and lays the groundwork for exploring the dynamic between policy frameworks and lived experience.

6 Community Narratives and Place Identity in Industrial Heritage Redevelopment

6.1 Emotional Narratives and Identity Reconstruction among Former Workers

Interviews with former workers revealed diverse and emotionally charged narratives. These accounts not only addressed physical spatial changes but also reflected nostalgia for industrial identity, cognitive dissonance toward urban transformation, and emotional responses to shifting social status.

Some retired workers retained strong place attachment. Long-term residents of former factory housing described frequent visits to the site (Fig. 6), calling it a place "with feelings," often using collective terms like "we workers" to affirm historical bonds—demonstrating group cohesion. Such narratives carried implicit loss. When discussing deindustrialization and relocation, one respondent expressed alignment with official discourse: "National policy comes first," indicating both trust and resignation. When asked whether the redevelopment had affected his life, one respondent replied, "Now it's the young people in there," and "preserving the site allows us to reminisce," acknowledging the historical retreat of the worker community. He also noted that the redeveloped NCP "can boost consumption," suggesting not hostility but an attempt to understand its economic rationale. These responses represent a "compliant-adjustive identity," shaped by dominant narratives of reform and development.

Figure.6. A photograph of the former factory housing (Lai Feng Li), photo by Wenjing Dong

Others, especially laid-off workers, expressed sharper criticism. One respondent explicitly rejected the redevelopment: "It was not good! Workers were laid off with nothing to eat," signaling forced identity loss and resistance to mainstream discourse. These "protest narratives" reveal emotional rupture and identity crisis among marginalized groups.

Some older workers exhibited silent acceptance. One elder noted, "We're too old to go there," showing emotional distance and disengagement. This "withdrawal narrative" reflects the exclusion of elderly residents from heritage reuse processes.

In sum, worker narratives are emotionally complex and heterogeneous, combining memory, belonging, grievance, and disengagement, offering insight into contested identity reconstruction.

6.2 Domestic Narratives and Collective Belonging among Workers' Families

Elderly women, particularly as wives or mothers of former workers, expressed strong place attachment despite not working in the factory themselves. Their narratives reflect a shared memory of household life under the "work-unit system" (housing, employment, and welfare were tightly bound to one's workplace). and highlight a gendered experience of spatial cohabitation. As one group of elderly women noted, "This whole row was factory's dormitories," constructing a sense of spatial belonging through the nested relationship of house and family. Although most had not worked in the factory themselves, phrases like "our husbands and sons were in the plant" enabled indirect identity formation and reinforced their narrative legitimacy as members of worker families.

Compared to workers, these family members tended to view redevelopment more positively. One respondent commented, "The renovation is nice; I go for walks in the evening," and participates in volunteer activities. Their narratives focus on everyday spatial use and temporal rhythms rather than political loss or class identity, representing a pragmatic, life-oriented mode of storytelling.

6.3 Marginalised Narratives and Functionalist Tendencies among Other Old Residents

An analysis of narratives from "other old residents", including original inhabitants, relocated households, residents assigned housing through other work units, and those who moved in through marriage, reveals a pattern of structural marginalization, especially when compared to the identity-secure and memory-rich narratives of former factory workers. Although these individuals have lived long-term in the area surrounding the original factory, their lack of affiliation with the "work-unit system" has largely excluded them from dominant historical narratives and cultural identity frameworks. Many respondents clearly distanced themselves from the factory's legacy, stating "I wasn't part of the factory" or "it has nothing to do with us." While some acknowledged the reputation of NCP as a "good unit," their accounts emphasized practical belonging, such as "we've lived here for a long time" or "we're used to it", but without emotional or historical resonance. As institutional "outsiders"

inhabiting shared spaces, they experience a tension between spatial inclusion and narrative exclusion. These non-worker residents tend to frame their narratives around everyday concerns such as convenience, social ties, and housing stability. Their recognition of NCP reflects a utilitarian orientation.

Their narratives often focused on everyday concerns like convenience, housing stability, and neighborhood ties, reflecting a utilitarian mode of place identification. Many expressed functional approval of the redevelopment, noting the area's walkability, food options, and livability, while deliberately withholding affective attachment.

Some, however, voiced strong disaffection. One resident, resettled in the 1990s, strongly rejected any association with community life, describing the area as "dirty," "expensive," and "annoying," and dismissing both the present and historical identity of the NCP. She expressed no sense of belonging: "I don't join activities" "I don't like living here". This group, resettled through policy-driven arrangements, remains excluded from prevailing community narratives, revealing a structural contradiction: spatial embeddedness without socio-cultural inclusion.

In sum, this group experiences dual marginalization, which excluded from both institutional memory and cultural representation, highlighting the need for inclusive heritage regeneration that embraces diverse social identities and lived experiences.

6.4 Instrumental Narratives and Cultural Reception among New Residents

Within the newly formed community structure following NCP's transformation, new residents constitute a key variable in identity dynamics. Their sense of place attachment often increases significantly with the length of residence. Younger tenants with shorter residency often display an instrumental narrative orientation, viewing the site primarily in terms of amenities like dining or leisure, showing little emotional connection or historical awareness.

Longer-term homeowner residents, though lacking direct historical involvement, gradually establish a connection to the site through everyday use and begin to develop interest in its history and culture. Those with even longer residence accumulate a strong sense of belonging through daily engagement. One interviewee, for instance, demonstrated a shift from functional engagement to cultural reflection by actively discussing the relationship between industrial heritage preservation and public education, suggesting that new residents can become potential agents in the transmission of industrial heritage.

Narratively, this group tends to follow a trajectory of "relocation, engagement, usage, and understanding," with role positioning evolving from "user" to "identifier." While situated on the cultural periphery of NCP's legacy, they possess strong potential for discursive integration. Though new residents are not directly involved in memory construction, they are actively shaping the contemporary meanings of industrial heritage.

7 Discussion

7.1 Selective Interaction Between Dominant and Community Narratives

During the redevelopment of NCP, dominant narratives have been actively constructed through policy documents, media representation, and exhibition spaces, emphasizing themes such as "industrial heritage renewal" and the clustering of "cultural and creative industries." These future-oriented discourses serve to reframe the post-industrial transformation in a positive light. In contrast, community residents' memories of the former factory, their attachment to the work-unit system, and their experiences of cultural disconnection and identity marginalization throughout the redevelopment process form an unofficial counter-discourse. Rather than directly opposing the official narrative, these local stories engage in an "interactive dynamic". Policymakers have selectively incorporated elements of community narratives, particularly those with positive emotional value, into heritage and tourism storytelling. However, this selective integration tends to marginalize expressions of loss, skepticism, and resistance, constituting what can be described as a state-led "curated fusion." In the Chinese socialist context, where the working class is valorized in official ideology, the identity of working-class residents is shaped differently depending on whether it is viewed through the lens of political propaganda or social reality (Xin & Xiaofan, 2020). While individuals may outwardly conform to dominant narratives, they also demonstrate active support for aspects that align with their class interests. This reflects a characteristic interplay between dominant and individual narratives in socialist systems, where conformity coexists with pragmatic negotiation.

7.2 The Complexity of Community Narratives and Narrative Aphasia

Former workers of the No. 2 Machine Tool Plant often articulate emotions marked by a mixture of pride and sorrow. Their narratives reflect both a sense of dignity rooted in their industrial past and grief over its loss. Family members of workers, particularly women in domestic roles, focus their narratives on the everyday spatial transformations, expressing a strong attachment to the worker community. Other long-term residents, such as original inhabitants or resettled households, have undergone a shift in identity from peripheral observers to engaged participants, due to the influence of industrial heritage discourse. In contrast, new residents primarily engage with the community through ownership or economic interest, reflecting a more instrumental orientation in their narratives.

A significant number of residents exhibit what may be termed "narrative aphasia" in the face of media interviews or official surveys. This silence does not stem from an inability to speak, but from a lack of appropriate discursive space within the dominant narrative. Some former residents expressed sentiments like "no one listens when we speak" or "we don't understand what is written," revealing a broader "loss of narrative agency." In other words, residents lack the authority to define or reinterpret the place they inhabit.

This discursive marginalization is rooted in structural constraints. Many residents share the belief that they have no control over their living environment. Although many are dissatisfied with their conditions, few are willing to voice complaints or seek change. A key reason lies in property rights: residents often possess only the right to renovate their interior living spaces, while control over streets and public infrastructure remains with government authorities. Another contributing factor is the enduring influence of collectivist ideology. As former dominant actors in the community, the working class and their families have long internalized a trust in and compliance with state policies, much like their acquiescence during deindustrialization. Meanwhile, other residents, marginalized for nearly 80 years, lack both the power and the confidence to articulate their concerns.

This exclusion from discourse is not merely an individual issue but a reflection of how narrative positions are stripped away through interactions with dominant discourses. These fragmented and non-mainstream narratives reveal the deep entanglement of historical trauma, identity anxiety, and cultural discontinuity.

7.3 Integrating Individual Narratives into Dominant Discourse to Enhance Community Belonging

Although the dominant narrative of NCP emphasizes "historical and cultural regeneration," it remains largely focused on the visual reproduction of space (Fig. 7), with limited incorporation of residents' collective memory. While some industrial artifacts have been preserved, the individual voices of the working class have been intentionally overlooked. This "depersonalized" approach to heritage transformation has led to a sense of disconnection and weakened identity attachment.

Figure.7. Factory structures preserved within NCP, photo by Wenjing Dong

Systematically incorporating individual narratives into dominant discourse constitutes a form of cultural justice. Resident narratives should not merely serve as resources for cultural tourism but ought to be embedded within spatial redevelopment, policy formulation, and participatory governance. Such integration can disrupt the unidirectional narrative dynamic of "government planning—resident compliance," and instead foster a co-creative, co-governed, and co-shared model of spatial governance. Moreover, narrative pluralism may alleviate intra-community tensions, strengthen social cohesion, and promote the transformation of industrial heritage sites into inclusive "heritage communities."

8 Conclusion

This study focuses on the narrative practices surrounding the transformation of NCP within the broader context of urban regeneration and industrial heritage redevelopment. Employing an interpretive qualitative approach, it uncovers the dynamic interaction between official narratives and individual community accounts, and explores how local identities are continuously negotiated and reconstructed through spatial restructuring and cultural reproduction.

Findings reveal that individual narratives are selectively excluded from official discourse. Both long-term and recent residents exhibit complex emotions regarding identity positioning and place attachment. This divergence highlights the heterogeneity of narrative positions and the risks of narrative silencing faced by marginalized groups within institutionalized discourses.

The study argues that incorporating diverse personal narratives into mainstream heritage discourse enriches cultural meaning and enhances community belonging and intergenerational continuity. It calls for a more inclusive "narrative governance" framework in heritage-led urban regeneration. Theoretically, the research extends the application of narrative identity theory to post-industrial spatial contexts, demonstrating that identity is actively constructed through individual responses to space and policy. Practically, it advocates for dialogic planning processes that recognize resident experiences as a source of heritage value. Furthermore, studying mixed-type industrial heritage can offer globally relevant perspectives, especially for cities undergoing industrial restructuring, demographic shifts, and cultural hybridity.

It is important to note that the study is based on a single case, which limits the generalizability of its conclusions. Future research could benefit from cross-regional comparisons to explore how residents engage with industrial heritage spaces in varied socio-spatial contexts. Additionally, integrating spatial analysis and participatory ethnography would further illuminate the mediating role of narrative in urban heritage landscape reconstruction.

Abstract
The Duku Heritage Corridor is known as "China's Most Beautiful Highway",represents the the essence of the Tianshan World Heritage Scenic Byway. The 14th Five-Year cultural development Plan from China's central govemment emphasizes the importance of systematically protecting and utilizing historical and cultural heritage. Cultural adaptability plays an important role in achieving this balance by fostering harmony between cultural heritage and ecosystems. Through the creation of adaptive landscapes, integrating "ecological restoration - health restoration - cultural restoration - economic restoration", it is possible to ensure both preservation and sustainable use of heritage corridors.The Duku Heritage Corridor erves as a valuable case study for exploring how these principles can be implemented effectively.By analysing the "production space", "living space",and "ecological space" along the corridor, the research provides insights into how these spaces can coexist and support each other. The findings inform the development of a culturally adaptive management model that can guide route planning, infrastructure design, and conservation strategies. Ultimately, the proposed model offers a comprehensive framework for understanding the unique cultural and natural heritage of the Duku Heritage Corridor.

Keywords: Heritage ecosystems; Duku heritage corridors; multiple values; cultural adaptation mechanisms; digital management

1 Introduction

Since the promotion of the strategy of 'Tourism Development of Xinjiang' and the implementation of the project of 'Culture Runs Xinjiang', the regional government has made every effort to promote the development of Xinjiang's tourism industry. 2019, in order to promote the vigorous development of the new industry pattern of 'Transportation + Tourism In 2019, in order to promote the 'transport + tourism' new mode of vigorous development, the implementation of the regional party committee '1 + 3 + 3 + reform and opening up' for the precise poverty alleviation, rural revitalisation and vigorously develop the tourism industry deployment of the 'traffic and tourism exemplary project', in response to the traffic and transport In 2024, General Secretary Xi made an important instruction on tourism work, stressing that efforts should be made to improve the modern tourism system and accelerate the construction of a strong tourism country, promote the high-quality development of tourism to make a steady progress [1], shape the tourism with the culture, highlight the culture with the tourism, and protect the cultural heritage and ecological resources. By promoting the construction of 'full-time' tourism along the Dokku route and driving the development of the regional economy, it will help multi-ethnic areas to fight poverty.

Fig. 1 The Duku Heritage Ecosystem

The Dushanzi-Kuche Highway starts in the Dushanzi district of Karamay City in the north and connects with the city of Kuche in the Aksu region in the south, crossing the Tianshan Mountains in the north and south, with a total length of 561 kilometres. More than half of this part of the road crosses high mountains and canyons, connecting many ethnic minority areas; snow-capped mountains, canyons, lakes and grasslands cover nearly all of Xinjiang's topographical features. The Duku Heritage Corridor, a landmark natural-cultural landscape route in Xinjiang, is taken as the object of study to address the practical issues of strengthening infrastructure construction along the route, upgrading the quality of services, enhancing regional cooperation in the heritage corridor, and focusing on the sustainable development of the heritage ecosystem.

Emphasis is placed on the construction of ecological protection zones and cultural heritage protection zones [2], the use of big data, cloud computing, artificial intelligence and other modern information technologies to promote intelligent tourism, enhance the intelligent level of culturally-adapted management and services, strengthen tourism safety management, enhance security and emergency response systems, and undertake the mission of the times to promote the cultural adaptability of the Duku heritage ecosystem.(Fig. 1).

2 Related concepts

2.1 Adaptation of heritage ecosystems

In 2025, the Gunma Declaration introduced the concept of 'heritage ecosystems' [3], which aims to deepen the understanding of heritage by emphasising the interconnections between tangible and intangible, cultural and natural heritage. Adaptive heritage ecosystems emphasise the ability to respond to environmental change and the ability of ecosystems to repair and renew themselves. Through the creation of adaptive landscapes, integrating 'ecological restoration - health restoration - cultural restoration - economic restoration', it is possible to ensure the conservation and sustainable use of heritage corridors. Cultural adaptation of heritage ecosystems plays an important role in achieving a balance between cultural heritage and ecosystems by fostering harmony between them. Cultural adaptation of heritage ecosystems emphasises the integration of cultural heritage into modern life and sustainable development in a dynamic and changing social environment through living heritage, community participation, value transformation and institutional innovation, while maintaining its originality.

Adaptability requires the integration of heritage into modern life to avoid becoming 'museum specimens', and emphasises the need to maintain the authenticity and original protection of core cultural values of heritage in the process of adaptation. Cultural adaptation relies on the subjective status of the heritage-holding community, such as community empowerment. The right to information, participation and benefit-sharing of indigenous people in heritage management is clarified. Holistic conservation and systematic management break through the single heritage ontology and focus on the synergy of cultural ecosystems, whose adaptability ultimately serves cultural continuity and identity construction. Therefore, the cultural adaptability of the heritage ecosystem is essentially the resilience of guarding the cultural genes in the midst of changes: it is necessary to abide by the bottom line of originality and innovate the inheritance path; it relies on the endogenous dynamics of the community as well as the exogenous support of the system and science and technology. The ultimate goal is to make cultural heritage a 'living tradition' through dynamic balancing, so as to continuously nourish the national spirit and modern civilisation.

2.2 Discriminating between resilience and adaptability

The Duku Highway Cultural Landscape Corridor is a major transport route connecting the north and south of the Tianshan Mountains, and its mode of protection should be resilience and sustainable management. The word 'resilience' (resilience), meaning 'recovery to the original state' is divided into three dimensions, namely: resistance (Resistance), recovery (Recovery) and evolution (Renewal). The main purpose of the project is to assess the cultural landscape of Duku. The main focus is on the adaptation of living conservation, the stabilisation of holistic conservation, and the promotion of regenerative conservation of the Duku cultural landscape corridor. Fabrizio Aimar explored the possibilities of cultural landscape resilience in his book Cultural Landscape Resilience: a Perspective on UNESCO World Heritage Sites, where the study emphasised the necessity of building an integrated management system and a heritage space that is more capable of responding to continuous change, and proposed the need to build an integrated management system and a heritage space that is more capable of responding to continuous change, as well as to build an integrated management system, and proposes a resilience management model with multidimensional synergistic enhancements [4].

Therefore, in the context of the Dokku Heritage Corridor, cultural adaptability is reflected in the 'adaptability' of communities and herders along the route to respond to external changes in the tourism economy brought about by the opening of the highway, and to take the initiative to adjust their economic models, such as the operation of B&Bs, service modes, or forms of cultural display; and cultural resilience emphasises the 'ability to maintain and rebuild' the ecological outlook of these communities after experiencing the impacts, Cultural resilience [5], on the other hand, emphasises the ability of these communities to maintain their core values such as ecological outlook, identity, traditional festivals or key rituals, and social structures to resist dissolution, maintain stability and achieve innovative inheritance after experiencing impacts . In short, adaptability is about 'how to change flexibly in order to adapt to new environments', while resilience is about 'how to protect and revitalise the core in the face of change'.

3 Adaptive mechanisms for the Duku Heritage Corridor

3.1 Mechanism for the Integration of Tourism

With the continuous promotion of the strategy of 'Tourism to Develop Xinjiang' and the in-depth implementation of the project of 'Culture to Run Xinjiang', the regional government is making every effort to promote the rapid development of tourism in Xinjiang. Since 2019, the regional party committee has put forward the '1+3+3+Reform and Opening Up' work deployment, aiming to promote poverty alleviation and rural revitalisation as well as the further development of tourism through the development of tourism. In order to implement this deployment and promote the development of the new industry of 'transport + tourism', the regional government has launched the 'Transport and Tourism Exemplary Project'. The project aims to respond to the support of transport to the development of culture and tourism [6], and at the same time expects the development of culture and tourism to feed back to transport, so as to achieve the positive interaction and common prosperity of the two. As an important corridor connecting the northern and southern parts of the Tianshan Mountains in Xinjiang, the Duku Heritage Corridor, with its unique geographical location and spectacular natural scenery, has become a typical example of the deep integration of transport and tourism. It has become a typical representative of promoting the deep integration of transport and tourism.

3.2 Mechanism of cultural and tourism integration

The cultural and tourism integration value of the Duku Heritage Corridor mainly consists of 'minority cultural value + tourism' and 'red cultural value + tourism', which fully embodies the functional value of guaranteeing ancient social and economic development, contemporary military defence and cultural exchange. The history of Duku Highway can be traced back to the ancient Mengkede Road at K625 Road Marker, as the predecessor of Ili section of the original Duku Highway, there are still traces of the national defence and war preparation highway that had been constructed in April 1964, when Chairman Mao issued the instruction of 'activating the Tianshan Mountain', and the road, which started from Dushanzi in the north and went to Kuche in the south, was completed and opened to traffic in September 1983, in order to communicate with the traffic along the north and south of the border. In order to communicate with the north and south of the border and increase the unity of the various ethnic groups along the route, during the many years of arduous road construction, 168 PLA soldiers were killed in avalanches [7], mudslides and other causes, and were buried in the Chorma Martyrs' Cemetery along the route, and a Dokoukou Highway Museum was built to commemorate this epic piece of road-building culture (Fig. 2).

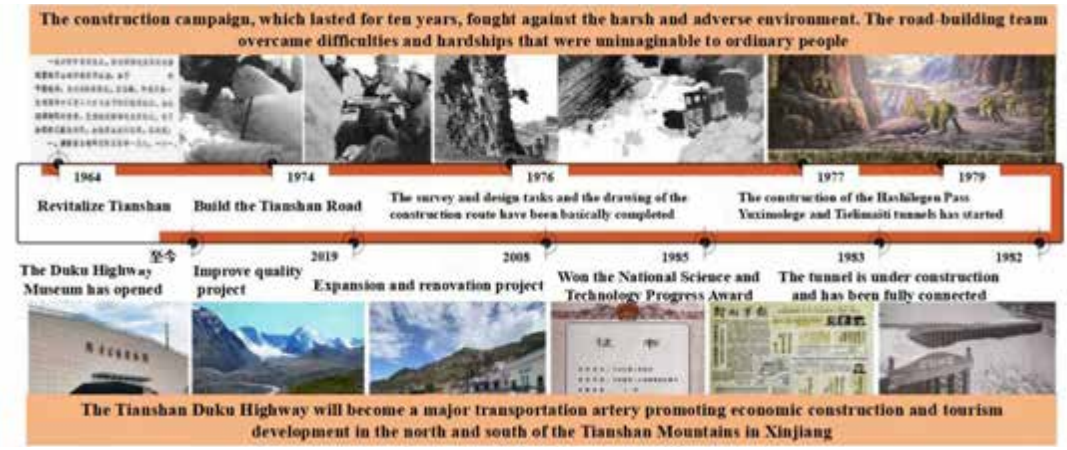

Fig. 2 History of the Duku Highway

In addition, Duku Cultural Landscape Corridor presents the most significant minority cultures as Donggui culture, Guzi culture, monuments, Ovoo, grottoes, murals and other cultural relics witnessing the diversity of roadside culture, while shouldering the responsibility of protecting, managing and demonstrating the use of the roadside cultural relics of the times.

3.3 Mechanism of production and tourism integration

The value of industry-tourism integration of the Duku Heritage Corridor lies in the sustainability of resource protection and management along the route, which improves the regeneration of the heritage sites, nature reserves, characteristic landscape nodes and parking spots in the road area, thus enhancing the effectiveness of the production space along the route. The translation value of its production and tourism integration value consists of the resource utilisation value and the socio-economic value brought by tourism, which can be broken down into the tourism resource value and the industrial resource value [8].

Duku Highway also has a very high value of tourism resources, and the natural and humanistic scenic spots along the way, such as Narathi Grassland Scenic Area, Jorma Scenic Area, Big and Small Dragon Pools, Bayinbruk Grassland and so on, have attracted many tourists from home and abroad for sightseeing and travelling, which brings the social and economic value and the popularity of the transport-tourism linkage. Duku Highway along the rich industrial resources, including tourism, including animal husbandry, mineral resources, water conservancy and hydropower resources, emerging industries and other industrial resources value, while the industry empowers the protective development of resources along the Duku Highway to promote the maximisation of socio-economic value, and together to create the 'Corridor Economy' of the value of the integration of the industry and tourism.(Fig. 3).

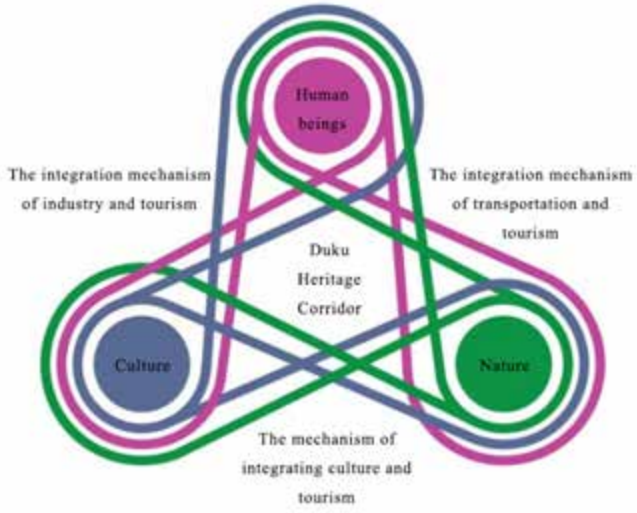

Fig. 3 Adaptive mechanisms for the Duku Heritage Corridor

4 Heritage Ecosystem Utilisation Pathways in the Duku Heritage Corridor

4.1 Zoning protection for ecological restoration-healthy recovery

The Duku Heritage Corridor Plan divides the Duku Highway into six regions based on the principles of resource similarity, cultural uniqueness, and regional coordination, including the Kuiduwu Area, the Qorma-Tangbra Area, the Nalati-Gongnaix Area, the Bayinbruk-Bayin Goleng Area, the Dalongchi -Yanshigou Area, and Baicheng County-Kuche County Area.

(1) Rational development of regional tourism resources

Tourism resources such as landforms, forests, scenic spots, water conservancy, humanities, wetlands, etc., should be reasonably developed and used, and all kinds of material and non-material resources with tourism and sightseeing value should be reasonably developed and utilised and perpetually used. Develop red tourism resources rich in local characteristics.

(2) Drive the tourism service industry, catering and accommodation industry, tourism equipment and other industries

Invest and operate in scenic spots, develop speciality tourism commodities, and turn local specialties into tourism commodities; use intangible cultural heritage as a carrier to develop a strong experience, entertainment and playability.

(3) Create a favourable atmosphere conducive to private tourism investment

Vigorously publicise national policies and the State Council's preferential policies and initiatives on encouraging, supporting and attracting the development of private capital, and vigorously promote and publicise the positive role and contribution of private capital in increasing the supply of tourism, meeting the needs of tourists, optimising the industrial structure, and enhancing the strength of economic development.

(4) Developing various types of tourism products along the route

Cultivate eco-tourism, forest tourism, trade tourism, study tourism and other tourism products according to local conditions, cultivate tourism products such as 'Nongjiale' and leisure farms, and actively cultivate leisure and tourism tourism products. Within the scope of the Duku Scenic Byway, except for the ecological conservation area, scenic restoration area and scenic excursion area, all other areas are the development control area. Within the development control area, the original land use pattern can be retained, and locally suitable tourism facilities and projects can be arranged for the orderly production, operation and management of the area; however, the scale and intensity of all facilities should be controlled, and be compatible with the environmental carrying capacity of the scenic area, and the three-level protection is implemented [9].

Through the zoning protection of the Duku scenic area, it forms a regional cycle of development and promotes regional tourism development, and has a positive demonstration and promotion effect on the construction of the Duku National Park Road.

Fig. 4 General road map of the Duku Highway
Photo credit: Author's own drawing

4.2 Segmental revitalisation of health restoration and cultural restoration
Through the G217 Dushanzi to Kuqa section of the highway 'traffic + tourism' service quality improvement project, a tourism corridor from the icebergs to the grassland is formed, displaying the natural landscape, history and culture and ethnic customs.(Fig. 4).

Create a high-quality demonstration highway with national influence, a model in Xinjiang and an industry leader in the integration of 'traffic+tourism'; create a world natural cultural heritage tourism highway (because of the Bayinbruk natural cultural heritage along the route, it is recommended to build a world natural heritage scenic road), the first red tourism highway to show the spirit of road building (because of the Qorma martyrs along the route), and the first red tourism highway to show the spirit of road building (because of the Qorma martyrs along the route). (because of the combination of five scenic spots: the scenic beauty of Tianshan Mountain, the scenic beauty of rivers and lakes, the scenic beauty of the countryside, the scenic beauty of canyons, and the scenic beauty of Yadan, Xinjiang's first tourism highway is proposed), the cultural card of showcasing the regional flavour of the Dukui Highway, and the provision of a smooth, safe, comfortable and beautiful driving environment and infrastructure (Tab. 1).

Tab. 1 Cultural Interpretation of Overall Line Sections

county and city	Pre-designed points for road space	Road elevation	cultural interpretation	Heritage ecosystem use pathways
Dushanzi District (starting point)		H0.75 km	The Red Heritage	Realising the integration of transport and tourism + cultural tourism

Wusu city in Xinjiang		H3 km	Geology Expo	Realising the integration of transport and tourism + cultural tourism
Nilka County		H2.26km	The Red Heritage	Realising the integration of transport and tourism + cultural tourism
Xinyuan county		H1.8km	natural landscape	Realising the integration of transport and tourism + agri-tourism
Hejing County		H2.25km	(Natural Landscape) Donggui Culture	Realising the integration of transport and tourism + agri-tourism
Baicheng County		H1.025km	Geology Expo	Realising the integration of transport and tourism + cultural tourism
Kucha City (end point)		H1.05km	(Geological Expo) Guzi Culture	Realising the integration of transport and tourism + cultural tourism

4.3 Multi-point enhancement of cultural and economic recovery

The Duku Highway connects many ethnic minority settlements and always puts the improvement of highway safety in the first place. In the near future, it mainly improves the safety and accessibility of the Duku Highway, and focuses on the treatment of road diseases that can be implemented at present and have an important impact on the improvement of the access conditions; it also strengthens the function of tourism services, and improves the sightseeing stops, signage systems, service areas, parking areas and other ancillary service facilities in suitable areas along the route; and it also improves the road appearance and the road environment to beautify the highway tourism environment. Improve the road appearance and road environment, and beautify the highway tourism environment. The medium- and long-term goals can be summarised as strengthening itself, promoting integration and leaving interfaces [10]. On the basis of guaranteeing the safe passage of highways and upgrading the quality of road surfaces, we will focus on the development of traffic+tourism integration into the industrial system, actively create the form of traffic+tourism industry, and build a high-quality highway for the integration

and development of 'traffic+tourism'.

5 Conclusions and Implications

5.1 Rationalisation of thematic mountain landscapes for travelling through the seasons

Due to the special climatic conditions and unique topography, four-season access to the Duku Highway is not yet possible. AI can process and analyse a large amount of environmental monitoring data, such as temperature, humidity, light, etc., so as to detect potential risk factors in time and prevent the risk of damage to the Duku Heritage Corridor. By analysing and monitoring data through machine learning algorithms, AI can predict the maintenance needs of heritage corridors and help managers plan maintenance work in advance to extend the life of the heritage. The term 'Digital Intelligent Conservation' [11].usually has two meanings: one is to make physical conservation more scientific through digital technology and intelligent management, such as better detection of diseases, more accurate identification of roadblocks and deformation of roadbeds, etc.; and the other refers to the fact that we use modern digital intelligence technology to digitise the heritage corridor itself and even the road environment and the view-scope landscape in a complete and holistic manner. Secondly, through modern digital intelligence technology, we can collect, reconstruct and present the heritage corridor itself and even the road environment and the landscape within the line of sight in a complete and full-fledged way, and save it as 'data' permanently. At the same time, the AI system can provide decision-making support for managers based on historical data and real-time conditions, such as emergency response strategies under extreme weather conditions, real-time broadcasting of the tour theme of the road section in front so as to make the heritage corridor culturally activated, on-site, and scenario, and thus promote the effective development of the construction of the 'all-time' tourist sites along the Duku Heritage Corridor.

The Duku Heritage Corridor is a 'full-time' tourist destination. With the development of modern science and technology, intelligent monitoring management system and computer network technology has been further optimised and improved. The construction of highways has also entered the era of intelligent transport, and intelligent service areas with higher service levels and more personalised functions have also emerged. Therefore, the digital intelligent management of heritage corridor is a systematic project covering many aspects, involving data collection, analysis and processing and application implementation. In concrete implementation, it is necessary to combine modern information technology, such as artificial intelligence, big data analysis, cloud computing and other technical means, to achieve effective protection and rational use of heritage corridors.

5.2 Systematic cognition of cultural landscape corridors of heritage world heritage sites

The core of the cultural landscape corridor as a world heritage site is to focus on the historical and human resources along the route, and the organisation of traditional festivals and events to bring economic benefits and brand economic benefits. With the development of artificial intelligence and machine learning technology, the accuracy of image recognition has increased dramatically, allowing for the automatic identification of past image data of the heritage corridor and its restoration. Using digital twin technology, panoramic 3D modelling and other technologies, the collected data can be transformed into virtual models, providing intuitive and accurate information support for management. Acquire high-precision images and 3D models of various types of natural-cultural heritage in the heritage corridor and accurately digitally record them, and provide support for the restoration of complex heritage corridor environments through the establishment of high-precision 3D models.To support this analysis, advanced methods such as digital footprint and user-generated content (UGC) from social media are utilized to capture and evaluate public interactions with the heritage corridor (Fig. 5).

The implementation of intelligent heritage and cultural corridor details and purposes can fully mobilise the enthusiasm of all stakeholders in the region along the route - including local government departments and other community groups of non-government organisations, increase the overall economic income of the region through the development of the regional economy of the road section, and enhance the attention and participation of all sectors of the community in the digital management of the heritage corridor. Enhance the community's interest and participation in the digital management of heritage corridors. Establish a digital archive of the heritage corridor for long-term preservation of heritage information to facilitate historical research and comparison of data for future restoration. Using the Internet platform, the results of the digital restoration will be shown to the public in the form of a virtual exhibition, so as to expand the dissemination of the culture of the Duku heritage corridor.(Fig. 6).

Fig. 5 The Duku heritage corridor is rich in multiculturalism

Fig. 6 The Cultural Inheritance Base of the Duku heritage corridor Area

5.3 Digital restoration of exemplary national parkways with Chinese characteristics

In addition to this, VR/AR technology is utilised to provide the public with an immersive experience of touring the heritage corridor, enhancing their knowledge and understanding of the cultural heritage. Introduce interactive technologies [12], such as intelligent guide systems and interactive exhibitions, to bring the stories of the exhibits to life and enhance the visitors' experience. Carry out monitoring and big data analysis of important historical and cultural heritage sites, nature reserves, special viewpoints, parking spots, etc. in the road area to monitor the status of the heritage in real time and carry out preventive protection of the heritage corridor. Comprehensively improve the supporting service facilities such as sightseeing stops, signage systems, service areas, parking areas and other facilities at suitable locations along the Duku; intelligent car park management system, road safety monitoring system, cable broadcasting management system, road traffic signal transmission and guidance system, WiFi network hotspot coverage management system, and high-definition bayonet anti-evasion management system. Developing intelligent systems for automated diagnosis, comprehensively applying modern information technology means, starting from data collection, management, display, dissemination, research, monitoring and other aspects, automatically identifying damages and diseases in the natural-cultural heritage, and improving the relevance and efficiency of regular segmented restoration work, as well as using robots to fine tune restoration operations in high-risk or manpower-intractable areas, such as high-altitude tunnels, traffic site areas. It is also necessary to consider factors such as regulatory and policy support, financial and human resources protection, etc., to comprehensively improve the systematic protection and digital intelligent management level of the Duku Heritage Corridor, gradually realise the digital transformation of the whole road section and the whole network of heritage sites, to form a provincial intelligent heritage corridor system, to promote the development of an intelligent restoration management system of the heritage sites, to let the public understand the importance of digital restoration, and to enhance the public's cognition of the multifaceted value of heritage protection and the national Parkway construction participation.

A Study on the Evolution Characteristics of the Spatial Layout of The Mountain Fortress System of Sichuan and Chongqing in China during the Song and Yuan Wars

Xiaohan Zhang; Yan Wang* , Wei Wu
Affiliation: Southeast University
Email: 220240264@seu.edu.cn

Abstract
The Song-Yuan Mountain Fortress System in the Sichuan-Chongqing region of China emerged from the 13th-century conflict between East Asian agrarian and nomadic civilizations. Preserving military engineering relics from both the Song and Yuan dynasties, it reflects the historical evolution of diverse civilizations in the region. This study employs GIS tools and knowledge graph technologies to analyse the mountain fortress system, identifying key value elements and their interconnections. By examining the socio-economic context of Sichuan, China, during the Song-Yuan wars, the research explores the factors and internal logic shaping spatial pattern evolution, aiming to support the comprehensive preservation of the system in the Sichuan-Chongqing region.

Keywords: Song-Mongol (Yuan) Wars; Mountain Fortress Defence System; Value Elements; Spatial Patterns; Holistic Conservation

1 Introduction

1.1 Background

Military cultural heritage is a product of history, with historical value reflecting its intrinsic nature. It encompasses the remains, artifacts, and the entire historical evolution formed by successive generations through military activities, as well as the comprehensive development process of these activities[1]. With the continuous advancement of international concepts for historical and cultural heritage conservation, holistic and integrated protection has gradually become the mainstream approach, and the types of heritage preservation have increasingly diversified. Against this backdrop, military heritage has emerged as a significant topic in the global field of heritage conservation, garnering growing attention from professionals in the discipline. Military heritage not only holds profound historical value but also plays an indispensable role in shaping national cultural identity and preserving historical memory.

The Southern Song Mountain Fortress Sites in Sichuan, China, or the "Sichuan-Chongqing Song-Yuan Mountain Fortress Sites," is the collective designation for the remnants of a system of mountain fortresses—combining newly planned administrative cities and military fortifications—entirely reconstructed in the Sichuan theater during the late Southern Song period amid the Song-Yuan wars[2]. These Sichuan-Chongqing Song-Yuan Mountain Fortresses represent the most intact ancient administrative urban system preserved in China, exemplify the historic use of mountainous and riverine landscapes to establish cities and regional defenses via land and water routes, and constitute the finest material evidence of the Song-Yuan conflicts in China's Sichuan-Chongqing region.

1.2 Overview of the Study Area

Geographically, "Chuan-Yu" denotes the broad region centered on China's Sichuan Basin, extending into southern Shaanxi, western Hunan and Hubei, northern Yunnan and Guizhou, and lying east of the Hengduan Mountains along the Jinsha River. This area corresponds to the territories administered by Ba, Shu, Hanzhong, and the various Nanzhong commanderies during the Qin and Han dynasties. Surrounded by mountain ranges—the Daba and Micang Mountains to the north, the Dalou Mountains to the south, the Hengduan Mountains to the west, and the Wuling Mountains to the east—the Sichuan Basin forms a relatively enclosed geographic unit[3]. Its periphery comprises the Three Gorges of the Yangtze River to the east, the Yunnan–Guizhou Plateau to the south, the Qinghai–Tibet Plateau to the west, and the Daba Mountains to the north, while its basin floor is divided into the eastern Sichuan parallel ridge-valley system, the central Sichuan hills, and the Chengdu Plain in western Sichuan (Figure 1).

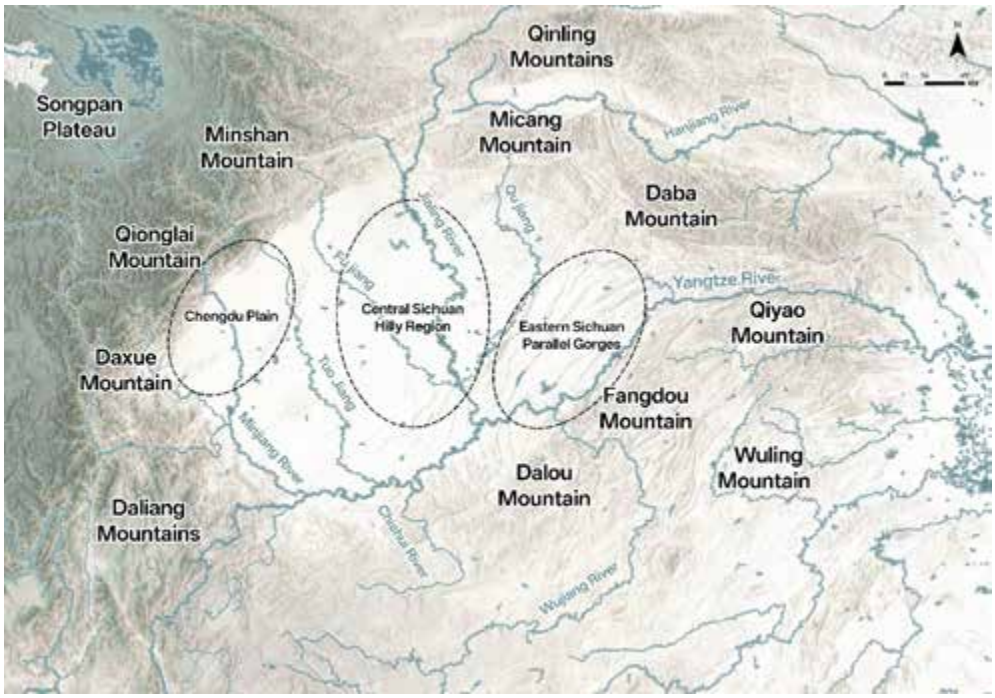

Figure 1 Geographical Division of China's Sichuan Basin (Source: the author)

In the fourth year of the Xianping era during the Northern Song Dynasty (1001 AD), the imperial court divided the former Ba-Shu region into four administrative circuits: Yizhou (present-day Chengdu, China), Zizhou (present-day Santai, China), Lizhou (present-day Guangyuan, China), and Kuizhou (present-day Fengjie, China). Collectively known as the "Four Lu (Circuit) of Chuanxia" or the "Sichuan Lu (Circuit)," these regions later gave rise to the abbreviated name "Sichuan." During this period, official positions such as the Sichuan Pacification Commissioner and Sichuan Military Commissioner were established. Historically, the water-rich Jianghuai region of China was easily defensible and difficult to attack. Northern campaigns to conquer the south, such as Emperor Wu of Jin's subjugation of Wu, Emperor Wen of Sui's destruction of Chen, and Emperor Taizu of Song's pacification of the Southern Tang—all involved first seizing Sichuan to control the Yangtze River, then advancing eastward along its flow. The strategists within the Mongol army likewise held this view[4].

1.3 Literature Review

Recent years have witnessed scholarly research on the Song-Yuan Mountain Fortress System in the Chuan-Yu region of China. For instance, Peng Feng's "Fortifying Cities to Hold Ground" and "Mutual Support between Jing and Shu": Adjustments in Late Southern Song Sichuan Defense Policies and Their Impact analyzes strategic shifts in the Southern Song's defensive policies before and after the Battle of Diaoyu Fortress, exploring their profound influence on the overall defensive framework of Chuan-Yu[5]. Wang Zhejun's Administrative and Economic Operations of the Mountain Fortress System in Sichuan During the Song-Mongol (Yuan) War investigates the economic and political characteristics of the region during the conflict[6]. Li Zhen's Characteristics of the Southern Song's Anti-Mongol Mountain Fortress Defense System in the Upper Yangtze from a Cultural Landscape Perspective examines the correlation between the fortress system layout and major transportation networks through spatial distribution and site selection[7]. Collectively, academic research has made progress in understanding the policies, economic conditions, defensive morphology, and spatial patterns of the Chuan-Yu region of China during the Song-Yuan wars. However, studies on defensive spaces largely remain confined to the "Eight Pillars of Sichuan" framework, lacking regional or holistic perspectives. Furthermore, research on the evolving spatial patterns and characteristics of fortresses across different phases remains inadequate.

Regarding GIS and knowledge graph technologies in heritage conservation, Hu Mingxing's Application of GIS Technology in Historical Neighborhood Conservation Planning establishes a GIS-based methodology for surveying, protecting, and planning historical districts[8]. Zhan Qingming's Suitability Analysis of Heritage Corridors Based on GIS and RS develops a landscape resistance evaluation system to assess corridor viability[9]. Xie Yongjian's

Knowledge Graph Construction for Shanghai's Outstanding Historical Buildings creates an associative network for 150 historic buildings, enabling single-attribute and cross-conditional searches while exploring shared traits and latent patterns[10]. Liu Yanchao's Digital Knowledge Graph for the Central Axis' Artistic Value Based on Neo4j proposes an AI-powered approach to excavate and interpret heritage values, using Beijing's Central Axis to reveal traditional Chinese philosophical essence across four dimensions[11]. Overall, domestic GIS applications in heritage conservation prioritize risk management and data mapping, with limited spatial feature analysis. Knowledge graph research in this field remains scarce, predominantly focusing on historic architecture or summarizing trends via CiteSpace, lacking urban/regional-scale studies and failing to reflect spatial distribution and evolution across historical periods.

Therefore, this study will apply emerging technological means to understand the spatial evolution characteristics of the Song and Yuan Mountain Fortress System in the Sichuan-Chongqing region of China. By using GIS tools, the coupling relationship between the mountain fortresses and ancient roads, water systems, and mountains in the Sichuan-Chongqing region during the Song and Yuan Dynasties will be explored. The distribution of mountain fortresses and the defense focus in different historical stages will be analyzed, and the spatial distribution characteristics of the mountain fortresses in the Sichuan-Chongqing region during the Song and Yuan Dynasties in each historical period will be summarized. Moreover, by combining knowledge graph technology, relevant historical materials and documents will be sorted and summarized, and the political and economic environment of the mountain fortresses in different stages in the Sichuan-Chongqing region during the Song and Yuan Dynasties, as well as the interrelationships among the mountain fortresses, will be revealed through visualized graphs.

2 Methodology

2.1 Research Objects

2.1.1 Sichuan-Chongqing Song-Yuan Mountain Fortress System

The Song-Yuan Mountain Fortress System in the Sichuan and Chongqing region of China is the most direct and intense product of the conflict between agricultural and nomadic civilizations in East Asia in the 13th century. It preserves the military engineering remains of both the Song and the Yuan (Mongol) sides, providing a complete witness to the conflict, exchange, and continuous integration between the two civilizations. The ideas of city defense system construction, military governance models, and engineering facilities reflected by it are the concentrated embodiment of outstanding military thoughts in ancient China in military engineering. At the same time, it also shows the confrontation and confrontation between the two sides of the war based on different military guiding thoughts in terms of offensive and defensive strategies, tactical methods, and engineering construction techniques. From the purity of the construction reasons, the particularity of the social environment at that time, the readability of the existing sites, as well as the war results and far-reaching influence, the Song-Yuan Mountain Fortress System in Sichuan and Chongqing is the most representative military heritage discovered so far, which can comprehensively reflect the historical evolution pattern of different civilizations in East Asia in the 13th century.

2.1.2 Sichuan-Chongqing Song-Yuan Mountain Fortresses

In the late Southern Song period, the Mongol army launched a massive invasion and occupied half of the territory, including Chengdu, the capital of Sichuan, China. The defensive system originally established by the Song dynasty along the mountainous edges of the Sichuan Basin collapsed. The Southern Song-controlled areas in Sichuan, China, found themselves in a situation devoid of natural defenses. To secure Sichuan as a strategic upper-reach shield of the dynasty's remaining territory, the Southern Song court intensified its defensive arrangements in the region. It began to construct fortifications by taking advantage of the natural barriers formed by mountains and rivers. Mountain fortresses and naval stockades were built at strategic points along the three major north-south rivers within Sichuan—namely, the Jialing River, the Tuo River, and the Min River—as well as along the east-west Yangtze River, which forms after the confluence of the three. Existing prefectural and county seats, which lacked sufficient natural defenses, were relocated to these mountain fortresses and water-based strongholds to counter the tactical superiority of Mongol cavalry. As a result, a defense system was formed that combined mountain and river fortifications as strategic nodes and used rivers as connecting lines, creating a coordinated network of mutual support between points and lines[12].

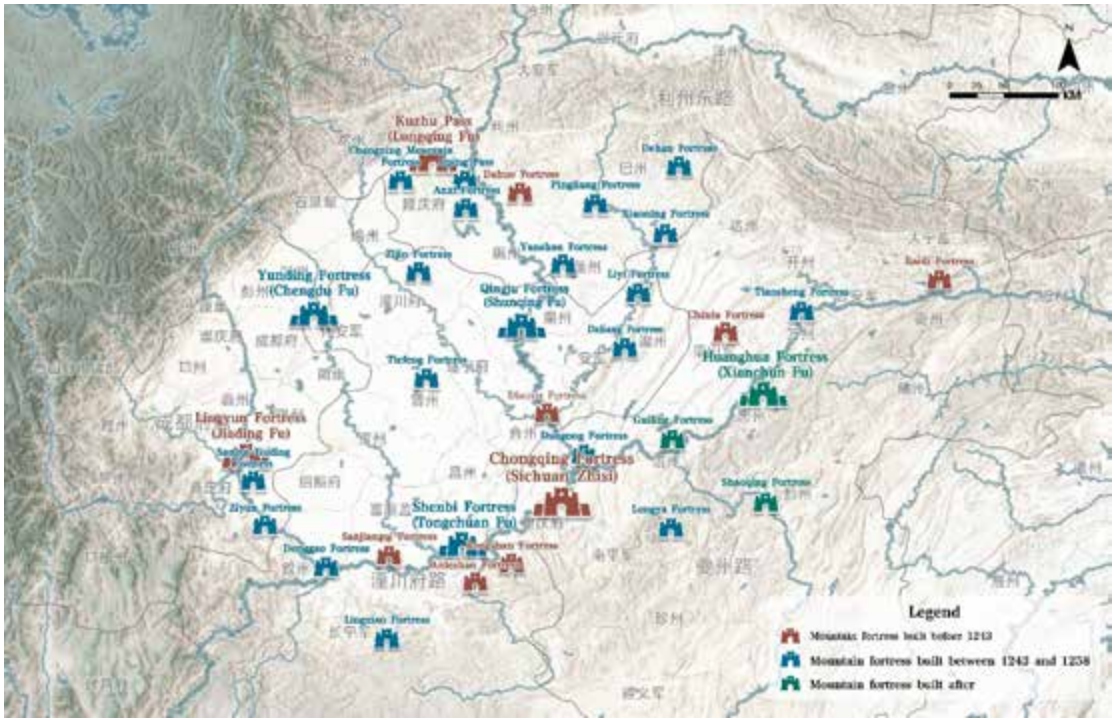

Figure 2 Distribution Map of Mountain Fortresses Built by the Song Military in Different Periods (Source: the author)

The Song Dynasty implemented a three-tier administrative system comprising Lu (Circuit), Fu/Zhou/Jun/Jian (Prefecture, Subprefecture, Military districts), and counties (Xian). Additionally, it also established overarching positions such as Xuanfushi (official positions in ancient China) or Anfu Zhizhishi (official positions in ancient China) to supervise multiple Lu. During the Southern Song period, the strategic demands of resisting northern invasions led to the progressive expansion of the Anfu Zhizhishi's authority in Sichuan, China. This elevated the role into a chief administrator overseeing military affairs, civil governance, and fiscal administration across all Lu. Consequently, Sichuan's mountain fortresses during the Song-Yuan War were organized into four administrative tiers aligned with this structure: Zhishi (overseeing the military affairs of a theater of war), Lu, Fu/Zhou/Jun/Jian, and county (Figure 3).

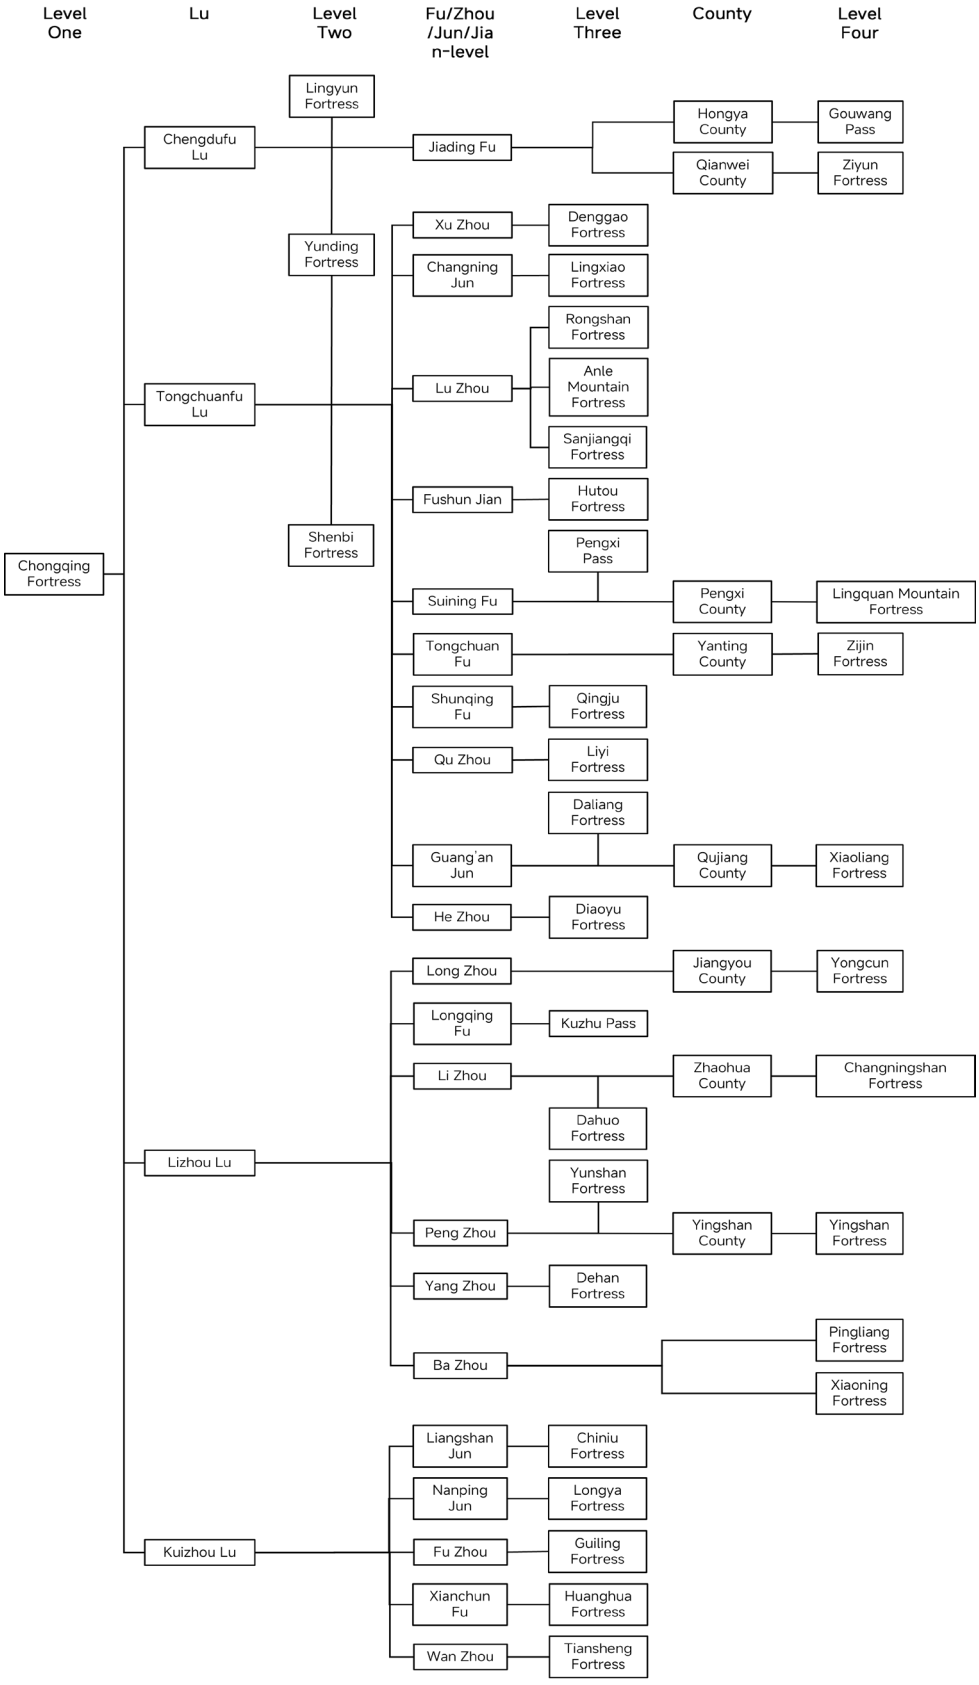

Figure 3 Administrative Hierarchy and Jurisdictions of Mountain Fortresses (Adapted from Zhou Siyan, 2017)

According to archaeological field investigations, no fewer than twenty identifiable Southern Song Mountain Fortress Sites remain within the Sichuan region of China[14]. Almost without exception, these mountain fortresses were constructed atop steep and rugged mountain peaks. After the conclusion of the Song-Yuan wars, administrative centers were relocated back to plains or gently sloping areas, resulting in minimal subsequent urban development that might have caused damage to these sites. As a result, the architectural structures of these mountain fortresses have been largely preserved, with many Song-era city walls still clearly visible today. Notably, nine city gates from the Song dynasty have survived, providing invaluable physical evidence for contemporary research into the history of the Song-Yuan wars, urban development, mountain fortress architecture, and the regional history of the areas where these fortresses are located[2].

2.2 Materials and Methods

2.2.1 Research Materials

This study draws upon archaeological literature, contemporary scholarship, and field investigations, utilizing materials including the History of Song, History of Yuan, and local gazetteers. Research materials were sourced through multiple channels such as library collections, CNKI (China National Knowledge Infrastructure), and Web of Science. An extensive review of domestic and international literature concerning military site research, the formation and development of the Song-Yuan Mountain Fortress System, and spatial morphology analyses of individual fortresses was conducted to comprehend current research trends and findings. Primary sources comprise the History of Song, History of Yuan, and Comprehensive Historical Events of Song, supplemented by local chronicles, publications on Chinese military history, and relevant academic papers. Through documentary analysis, the historical trajectory of the Song-Yuan conflicts in the Chuan-Yu region and the developmental stages of the Song Mountain Fortress System were systematically examined, laying the groundwork for subsequent GIS analysis and knowledge graph construction.

Figure 4 Related Reference Texts (Source: the author)

2.2.2 Geographic Information System

A Geographic Information System (GIS) represents an integrated information technology encompassing disciplines including geography, surveying, and computer science[15]. It constitutes a technical framework operating under computer hardware and software support for capturing, storing, managing, processing, analyzing, displaying, and describing geographically distributed data across the Earth's surface and near-surface atmosphere.

Within China's cultural heritage sector, GIS applications primarily focus on three domains: heritage conservation management platforms, visualization research for archaeological information, and disaster risk assessment of cultural assets[15]. Simultaneously, GIS facilitates spatial data management through capabilities for storing, editing, querying, and symbolizing historical heritage data, thereby providing geospatial support for knowledge graph construction. Leveraging GIS spatial analysis functions enables the identification of proximity and connectivity among geographical entities, revealing spatial distribution patterns of historical heritage.

2.2.3 Knowledge Graph

The concept of the knowledge graph was originally proposed by Google as a semantic network that describes relationships between entities. Knowledge graphs can be categorized into general knowledge graphs and domain-specific knowledge graphs based on their usage and scope. General knowledge graphs have broad coverage but limited depth of research. In contrast, domain-specific knowledge graphs focus on particular fields, requiring more rigorous data schemes and enabling deeper exploration. A domain-specific knowledge graph consists of a schema layer and a data layer and utilizes domain ontology technologies to transform unstructured data into structured data[16]. Within this framework, nodes are composed of entities, such as concepts, people, or objects, and form a network through interconnections defined by relationships and attributes.

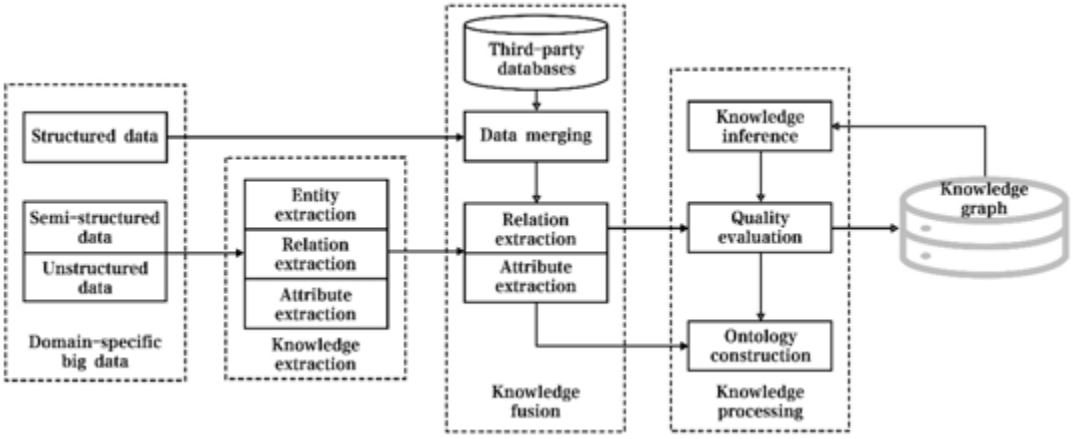

Figure 5 Architectural Framework of Domain-Specific Knowledge Graphs (Adapted from Liu, Y.C., 2020)

In a domain-specific knowledge graph, an ontology refers to a formalized framework that provides explicit definitions of entities and the relationships between them, serving as an abstract model for representing the objective world. The methods for constructing ontologies vary according to the needs of different domains and are mainly divided into bottom-up and top-down approaches. The bottom-up approach extracts entities, relationships, and attributes directly from underlying data before integrating them, and is more suitable for general knowledge graphs. The top-down approach involves constructing a domain ontology first, which then constrains and guides the structuring of data. Typically, domain-specific knowledge graphs adopt a combination of top-down and bottom-up approaches to meet the requirements for depth and accuracy within a specific field.

3 Spatial Evolution Characteristics Analysis of the Sichuan-Chongqing Song Army Mountain Fortress System Based on GIS

3.1 Kernel Density Analysis of Mountain Fortresses

The Kernel Density tool in ArcGIS calculates the density of point features around each output raster cell, aiming to identify areas of concentrated density and variations in distribution. In this study, 46 mountain fortresses with relatively well-defined geographic coordinates were selected based on historical documents and relevant local gazetteers. Combined with analytical results and the geographical division of the Sichuan Basin of China, it can be observed that Song Military Mountain Fortresses in the Sichuan-Chongqing region of China were primarily concentrated at the junction of the Jialing River and the Qinling-Daba Mountains, along the Jialing River, at the confluence of the Jialing River and the Yangtze River, along the Min River, and at the junction of the Yangtze River and the Wushan Mountains.

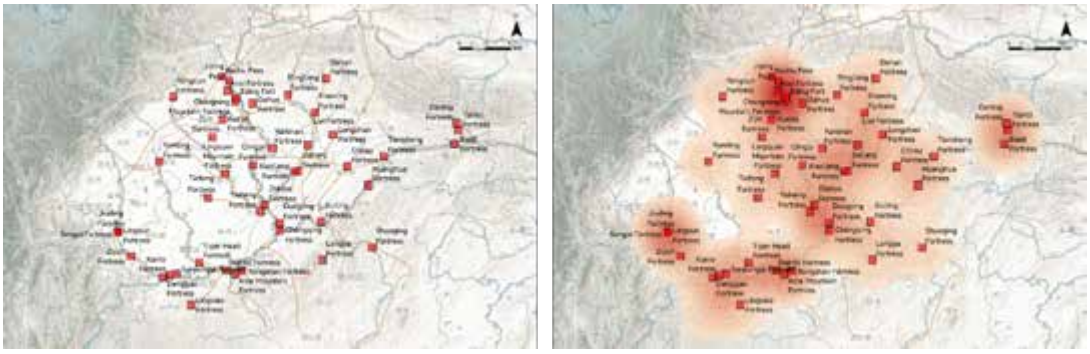

Figure 6 Kernel Density Analysis of the Song-Yuan Mountain Fortress System (Source: the author)

The ancient Qin-Sichuan route connected the Guanzhong Plain with the Sichuan Basin, organically linking most of the historical towns in the Shaanxi region of China. The distribution of historical and cultural relics along the Shu Roads, as well as the spatial patterns of historical towns, can be categorized into five major historical and cultural regions based on administrative divisions: the Guanzhong region, the Hanzhong region, the Guangyuan region, the Chengdu region, and the Chongqing region. As a historical cross-section, the system of Song-Yuan Mountain Fortress sites serves as a significant entry point for studying the military defense system along the ancient Shu Roads, the dynamic relationship between transportation and regional control, the integration of diverse cultures, and contemporary heritage conservation[17].

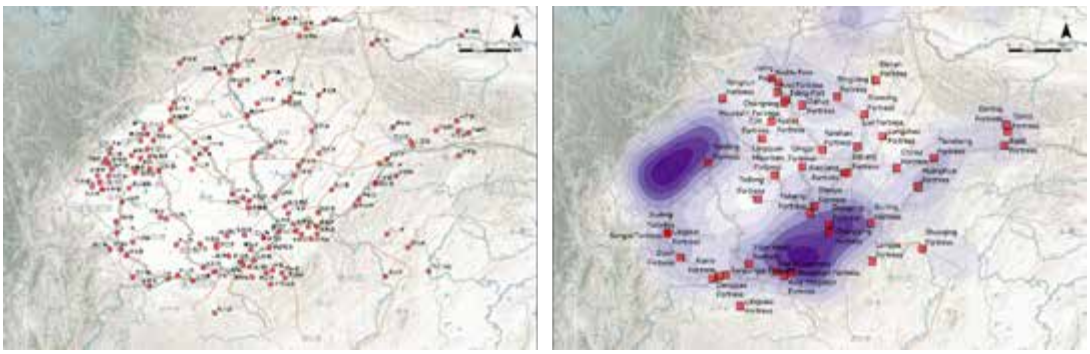

Figure 7 Kernel Density Analysis of Historical Settlements in the Sichuan-Chongqing Region of China (Source: the author)

By conducting a kernel density analysis of 155 historically significant settlements along the Qin-Sichuan route and overlaying it with the kernel density analysis map of the Song-Yuan Mountain Fortress system, it is evident that the overall distribution of mountain fortresses generally aligns with that of ancient settlements. The only notable exception is the Chengdu Plain of China, where numerous settlements are present, yet few mountain fortresses were constructed to guard Chengdu. This may be attributed, first, to the relatively flat terrain of the Chengdu Plain, which lacks natural defensive barriers, prompting the Song military to focus on controlling the upper reaches of the Jialing River to block the Mongol army's advance toward Chengdu, or to station troops in the Jiading area to slow the enemy's progress and provide timely reinforcement to Chengdu when necessary. Second, during the Song-Yuan wars, the Song military's deployment appeared more inclined toward the defense of the Chongqing region, resulting in a spatial distribution of mountain fortresses that was notably denser in the east than in the west, and more concentrated in the south than in the north.

Using the Sichuan Basin of China as the study area, five evaluation factors—elevation, slope, aspect, water availability, and soil texture—were selected for analysis. Single-factor evaluations were conducted using ArcGIS, and the weights of each factor were calculated using the Analytic Hierarchy Process (AHP)[18]. These single-factor evaluation maps were then subjected to spatial overlay analysis based on the evaluation model, resulting in a thematic map of arable land suitability levels and ultimately generating a spatial distribution map of arable land suitability across the Sichuan Basin.

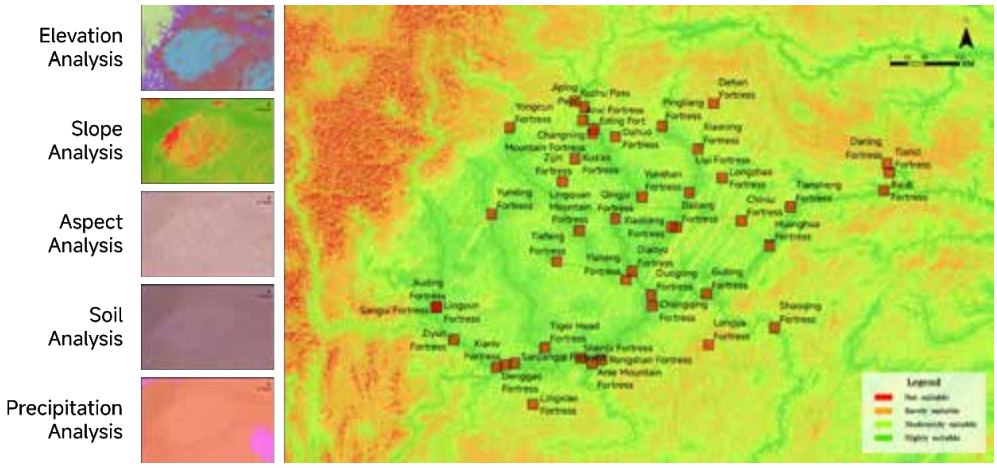

Figure 8 Map of Mountain Fortress Distribution and Agricultural Land Suitabil ity Assessment in the Sichuan Basin of China (Source: the author)

According to the results of the agricultural land suitability evaluation, the Sichuan Basin of China is generally highly suitable for cultivation, with the Chengdu Plain of China in particular standing out as an extensive area of high-quality arable land. By overlaying the distribution map of Song military mountain fortresses during the Song-Yuan wars, it can be observed that these fortresses were generally located in areas with fertile soil and adequate precipitation, which were highly suitable for farming. This pattern aligns with the overall operational model employed by the Song during the Mongol invasion, wherein local populations relocated a masse into mountain fortresses during periods of military threat and resumed agricultural activities in the surrounding areas once the Mongol forces had withdrawn. However, this also reveals that following the Mongol occupation of Chengdu, much of the high-quality farmland in the Sichuan Basin of China fell under threat from Mongol forces. Consequently, the continued functioning of the entire Sichuan-Chongqing Mountain Fortress system became heavily reliant on support from the Jinghu region.

3.2 Contour Analysis of Construction and Fall Times

The construction of the Song-Yuan Mountain Fortress System can be roughly divided into three phases, each corresponding to the growing military threat posed by the Mongol forces. Mountain fortresses built prior to 1243 mainly consisted of pre-existing fortresses as well as those constructed spontaneously by local military and civilian groups in the Sichuan-Chongqing region of China in response to evolving circumstances. Although limited in number, these fortresses occupied key transportation routes and played significant roles in subsequent military engagements. The mountain fortresses constructed between 1243 and 1259 were largely completed during the administration of Yu Jie. Following the large-scale invasion of the Sichuan-Chongqing region by Ögedei Khan, the Song military adopted the advice of strategic advisors and initiated the construction of a substantial number of mountain fortresses. This period witnessed the greatest number of fortress constructions, with a spatial distribution characterized by a higher concentration in the east than in the west. After 1259, the fierce offensives led by Möngke Khan resulted in the near-total collapse of the Song defensive system north of the Yangtze River within the Sichuan-Chongqing region. During this final phase, the number of newly constructed mountain fortresses was minimal, and their primary purpose was to reinforce the Yangtze River defense line and protect Chongqing.

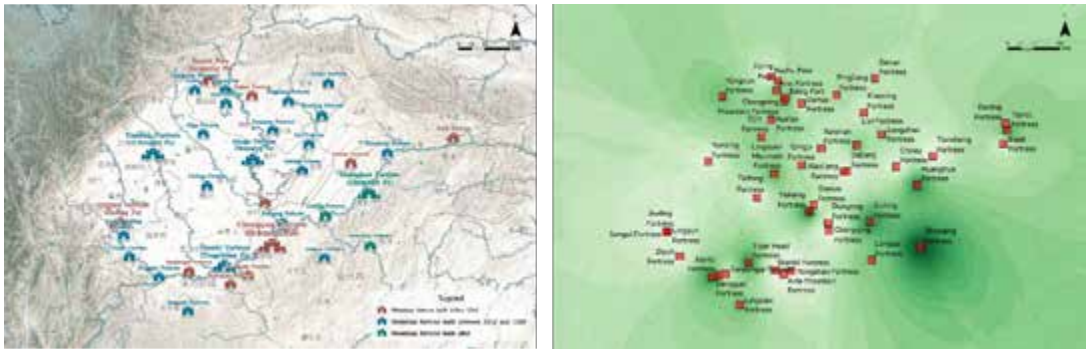

Figure 9 Analysis of Construction Timelines for Mountain Fortresses in the Song-Yuan Fortress System (Source: the author)

The Inverse Distance Weighted (IDW) interpolation method calculates weighted values based on the distance between interpolation points and sample points, considering only the distances between the interpolation point and its neighboring points during the interpolation process. It is commonly used in the construction of Digital Elevation Models (DEM)[19]. By applying the IDW method to analyze the construction dates of the Song-Yuan Mountain Fortresses (Figure 9), it is observed that the earliest-built mountain fortresses during the Song-Yuan wars were scattered throughout the Sichuan-Chongqing region of China. Subsequently, defensive efforts gradually intensified in three directions: northwest, southwest, and southeast. This pattern may be related to the late-stage Mongol occupation of Dali and the loss of Song fortresses in the upper reaches of the Jialing River, which forced the Song military to contract their defensive line to the Yangtze River area and strengthen defenses in the southwest.

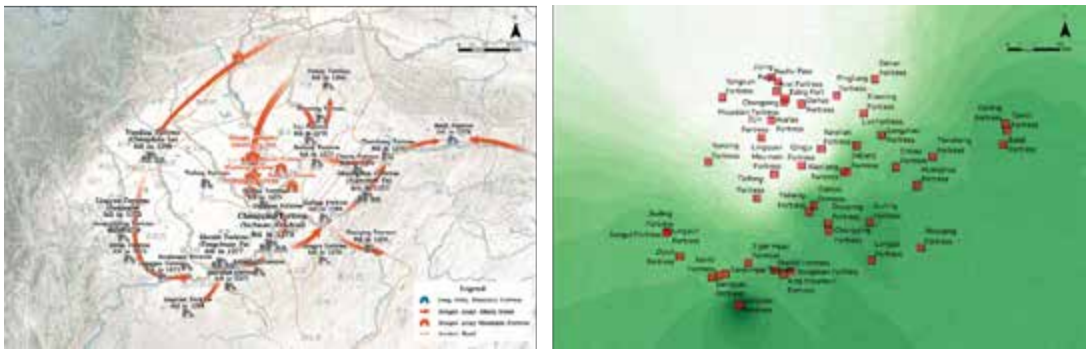

Figure 10 Analysis of Fall Timelines for Mountain Fortresses in the Song-Yuan Fortress System (Source: the author)

By analyzing the fall times of the Song-Yuan Mountain Fortresses using the Inverse Distance Weighted interpolation method (Figure 10), two distinct phases of fortress collapse become apparent. This pattern reflects the spatial contraction of the Song military defense in the Sichuan-Chongqing region of China from the upper reaches of the Jialing River to the main course of the Yangtze River. In 1258, the Mongol Great Khan Möngke personally led a three-pronged campaign against the Song, successfully breaking through the Song Mountain Fortresses around the Jialing and Min Rivers and advancing to the foot of Diaoyu Fortress. Although Möngke died at Diaoyu Fortress in 1259, during this period the Mongols also began constructing mountain fortresses themselves, utilizing the captured Qingju Fortress to establish several forward outposts north of Diaoyu Fortress. This development deprived the Song forces of any ability to reclaim lost territory and is likely the primary reason for the pronounced phased pattern in the fall times of the Song Mountain Fortresses.

3.3 Analysis of Mountain Fortress Defense Priorities Based on GIS

Since the Qin and Han dynasties, with the increasing strategic importance of Sichuan, China, the development during the Three Kingdoms, Wei-Jin, Southern and Northern Dynasties, and especially the Sui and Tang periods laid the foundation for the transportation routes in Sichuan during the Song dynasty[20]. The Shu Roads are divided into northern and southern sections, with the southern section comprising three main routes: Jinniu Road, Micang Road, and Litchi Road, among which the Litchi Road served as the key connection between the Sichuan Basin of

China and the Central Plains of China. Waterway transportation was the primary mode of travel in Sichuan at the time, with the Min River–Yangtze River system being an important channel for cargo and passenger traffic. The sites of the Song-Yuan Mountain Fortresses were all located near major water and land transportation routes in Sichuan. The mountain fortresses adjacent to land routes played a crucial supplementary role in resisting the Mongol invasion, jointly supporting the effectiveness of the anti-Mongol defense system.

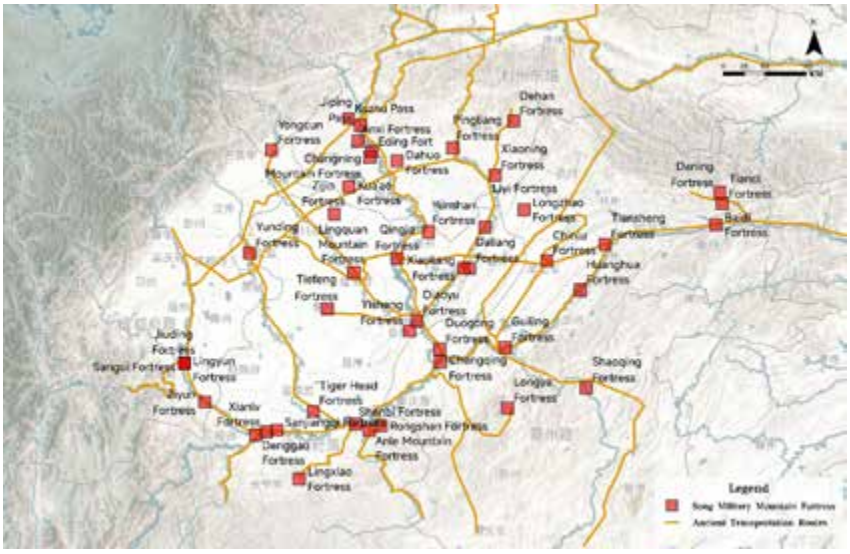

Figure 11 Map of Transportation Routes in the Sichuan-Chongqing Region during the Song-Yuan Wars (Source: the author)

Meanwhile, the defensive characteristics of the mountain fortress, formed jointly by fortification facilities and the terrain and landforms, together with the administrative functions transferred to the mountain fortress during wartime and its convenient access to both water and land transportation, collectively determined the regional defensive capability possessed by an individual mountain fortress within the entire Song-Yuan Mountain Fortress System.

The Analytic Hierarchy Process (AHP) is an objective analytical method that organizes and synthesizes subjective judgments. It is a systematic and hierarchical approach that effectively combines subjective and objective, qualitative and quantitative analyses[21]. Scores were assigned based on the mountain fortress's accessibility, defensive capability, administrative level, and terrain conditions, and AHP was employed to assess the relative importance of each evaluation factor. By comparing the significance of these factors, the weights (w) of the evaluation factors—accessibility (B1), defensive capability (B2), administrative level (B3), and terrain conditions (B4)—were determined, resulting in the construction of the evaluation matrix as shown in Table 1.

Table 1 Mountain Fortresses Defense Priority Judgment Matrix Table (Source: the author)

A	B1	B2	B3	B4	
B1	1	5	3	5	0.5579
B2	1/5	1	1/3	1	0.0963
B3	1/3	3	1	3	0.2495
B4	1/5	1	1/3	1	0.0963

To verify matrix consistency, the consistency index was calculated (n=4, CI=0.0145). Referencing Saaty's random consistency index (RI) table derived from 1,000 simulations, RI=0.90 for a 4th-order matrix yielded a consistency ratio , confirming matrix validity.

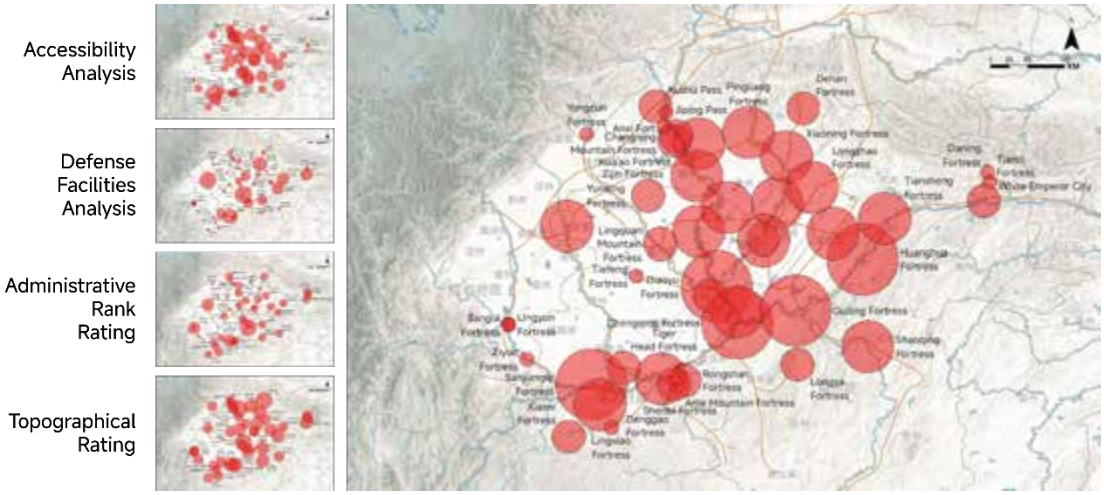

Figure 12 Evaluation of Regional Defense Levels for Song and Yuan Mountain Fortresses in the Sichuan-Chongqing Region of China (Source: the author)

Based on OD cost matrix analysis in GIS, the traffic accessibility of the mountain fortresses was evaluated using an ancient marching speed of 30 li (ancient Chinese unit of length equivalent to approximately 360 meters) per day as a reference, generating the accessibility analysis map shown above (Figure 12). Combining the evaluation results of the defensive capability, administrative level, and terrain conditions of the Song military mountain fortresses in the Sichuan-Chongqing region of China, and using the evaluation factor weights derived from the Analytic Hierarchy Process, a regional defense level evaluation map of the Song-Yuan mountain fortress system was produced. Among these, Chongqing Fortress, Diaoyu Fortress, Guiling Fortress, and Huanghua Fortress were classified as the first tier, possessing prominent regional defensive capabilities. While ensuring their own defensive strength, they were also able to effectively coordinate with surrounding mountain fortresses. Yunding Fortress, Qingju Fortress, Shenbi Fortress, and Yunshan Fortress were classified as the second tier, serving as important regional defensive strongholds capable of effectively resisting Mongol attacks. The third and fourth tiers of mountain fortresses generally functioned as supplementary defenses, reinforcing connections between mountain fortresses or filling gaps within the fortress system. Overall, a defense hierarchy was established with Chongqing City and its surrounding mountain fortresses as the first tier, mountain fortresses along the main road and waterway networks of the Sichuan-Chongqing region as the second tier, and third- tier and fourth-tier mountain fortresses providing supporting layers.

3.4 Summary of GIS Section

GIS-based spatial evolution analysis of the Southern Song Mountain Fortress System in the Chuan-Yu region reveals a high degree of coupling between its distribution patterns and geographical environments, military strategies, and transportation networks. The system exhibits an east-dense, west-sparse distribution pattern along strategic waterways, predominantly concentrated at tactical junctions including the Jialing River corridor, Yangtze mainstream-tributary confluences, with particular density clusters in the upper Jialing River defensive group and the Chongqing peripheral fortress complex. Kernel density analysis confirms spatial correlation between fortress locations and historical settlements, while the Chengdu Plain of China manifests a distinct "dense settlements but sparse fortresses" phenomenon—reflecting the Song military's strategic withdrawal from plains to mountainous terrain, prioritizing defense lines along the Jialing and Yangtze rivers.

Temporally, fortress construction demonstrates marked phasic characteristics. Early strongholds guarded the Shu Roads; mid-phase development under Yu Jie's governance established large-scale defensive networks; late-phase construction contracted to the Yangtze corridor. This spatiotemporal trajectory mirrors Mongol offensive pathways. Spatial differentiation in capture timelines reveals strategic shifts in defensive focus: after losing upper Jialing fortresses, the Song rebuilt defenses along the Yangtze anchored by core strongholds like Chongqing and Diaoyu Fortress. Analytic Hierarchy Process indicates hierarchical regional defense capabilities, with primary-tier fortresses (e.g., Chongqing Fortress, Diaoyu Fortress) forming command nuclei that integrated administrative control and military functions through multi-level, water-land coordinated networks.

Collectively, the fortress system established a tri-tiered defensive hierarchy (core-node-supplement) through its "mountaintop fortifications and waterside defenses" spatial configuration. This design leveraged synergistic terrain-fortification effects while maintaining strategic resilience through control of agricultural hinterlands and transportation arteries. Such a spatial defense paradigm represents both an evolution of traditional Shu Roads defensive frameworks and a concentrated manifestation of geo-military ingenuity under specific historical conditions, providing critical empirical insights into the spatial logic of ancient mountain warfare systems.

4 Spatial Evolution Characteristics Analysis of the Sichuan-Chongqing Song Army Mountain Fortress System Based on Knowledge Graph

4.1 Analysis of Defense Policy Association Graph Characteristics

The Southern Song Dynasty placed great emphasis on the defense and management of Sichuan and Chong regions of China. After Emperor Gaozong of Song fled south, pacified various bandits, and stabilized the regime, he devoted himself to constructing the defense system in Sichuan and Chongqing. Subsequent Southern Song monarchs also attached great importance to the defense of this region[5]. Overall, the defense policies of the Southern Song in the Sichuan-Chongqing area during the Song-Yuan wars can be roughly divided into three stages: the period of Mongke Khan Ögedei (1236–1243), the period of Yu Jie and Mongke Khan (1244–1259), and the period of Kublai Khan (1260–1288).

By extracting data from selected literature corpora, the obtained information units were categorized into periods, policies, key figures, mountain fortresses, and strategic positioning. The reclassified information was input into Gephi software to generate a knowledge graph, and modularity analysis was applied to produce the modular association diagram shown below (Figure 13). This association graph can be roughly divided into five categories: the collection of mountain fortresses initially constructed during Ögedei Khan's period, the collection of mountain fortresses forming the defensive system built during Yu Jie and Mongke Khan's period, the collection of mountain fortresses built during Yu Jie's offensive against Xingyuan Fu (Prefecture), the collection of mountain fortresses defending the southern border during Kublai Khan's period, and the collection of mountain fortresses maintaining the defensive system during the late stage of the Song-Yuan wars.

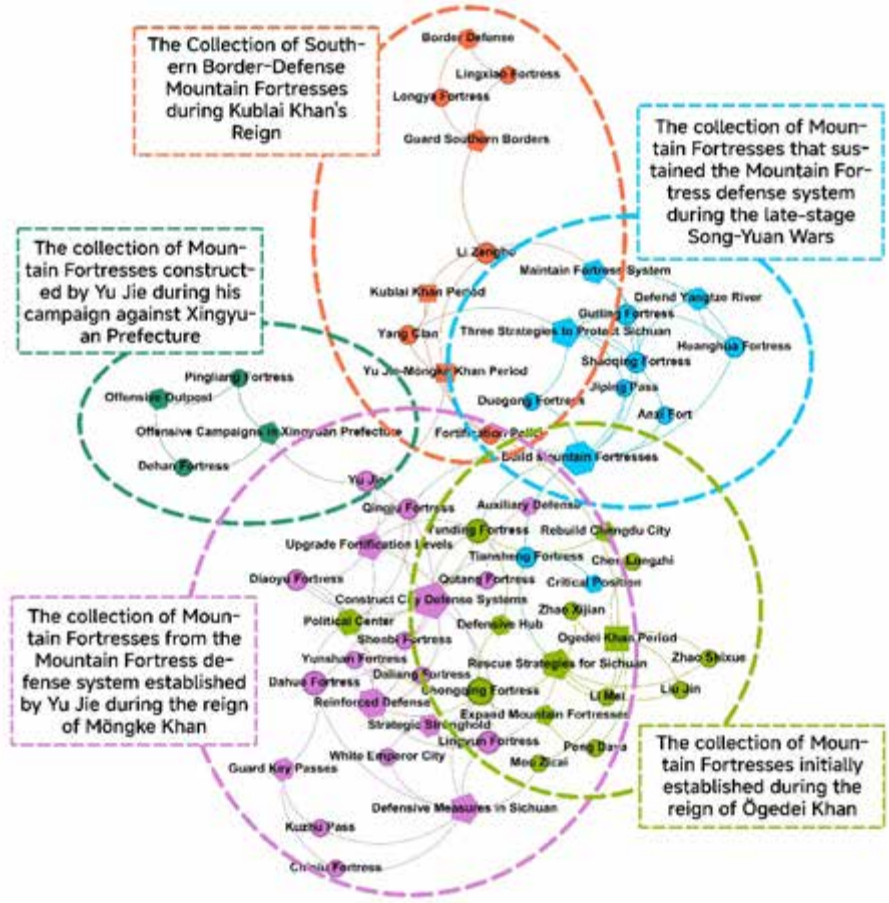

Figure 13 Modular Clustering Analysis of Policies and Mountain Fortress Construction in the Sichuan-Chongqing Region of China During the Song-Yuan Wars (Source: the author)

Based on the analysis of the modular knowledge graph, it can be observed that the construction policies of Song military mountain fortresses exhibited distinct characteristics during different historical periods. During the period of Ögedei Khan, the Song army built mountain fortresses primarily to support the court's strategy to rescue Shu, serving as emergency defensive measures following the Mongol army's first large-scale invasion in 1239. The majority of mountain fortresses were constructed during the period of Yu Jie and Mongke Khan, mainly to establish a defensive system of mountain fortresses for the Song army in the Sichuan-Chongqing region of China. It was also during this historical period that the Song forces still had the capacity to establish several forward offensive bases and launched large-scale attacks on Xingyuan Fu (Prefecture). During the Kublai Khan period, the Mongol forces expanded their territorial control to the southern borders of the Sichuan-Chongqing region of China, and the Song-Yuan Mountain Fortress System suffered severe damage following the battle with Mongke. Consequently, mountain fortress construction during this period was primarily aimed at maintaining the defensive system and guarding the border.

4.2 Analysis of Mountain Fortress Site Association Graph Characteristics

Analysis of existing archaeological evidence indicates that Southern Song Mountain Fortresses in the Chuan-Yu region during the Song-Yuan conflicts preserved not only military remnants but also numerous civilian and religious sites serving military and civilian populations. Through extraction and modular analysis of relevant documentary information, the modular association diagram presented below was constructed (Figure 14). Its nodes primarily form three clusters: living facilities sites, military facilities sites, cultural facilities sites and administrative facilities sites.

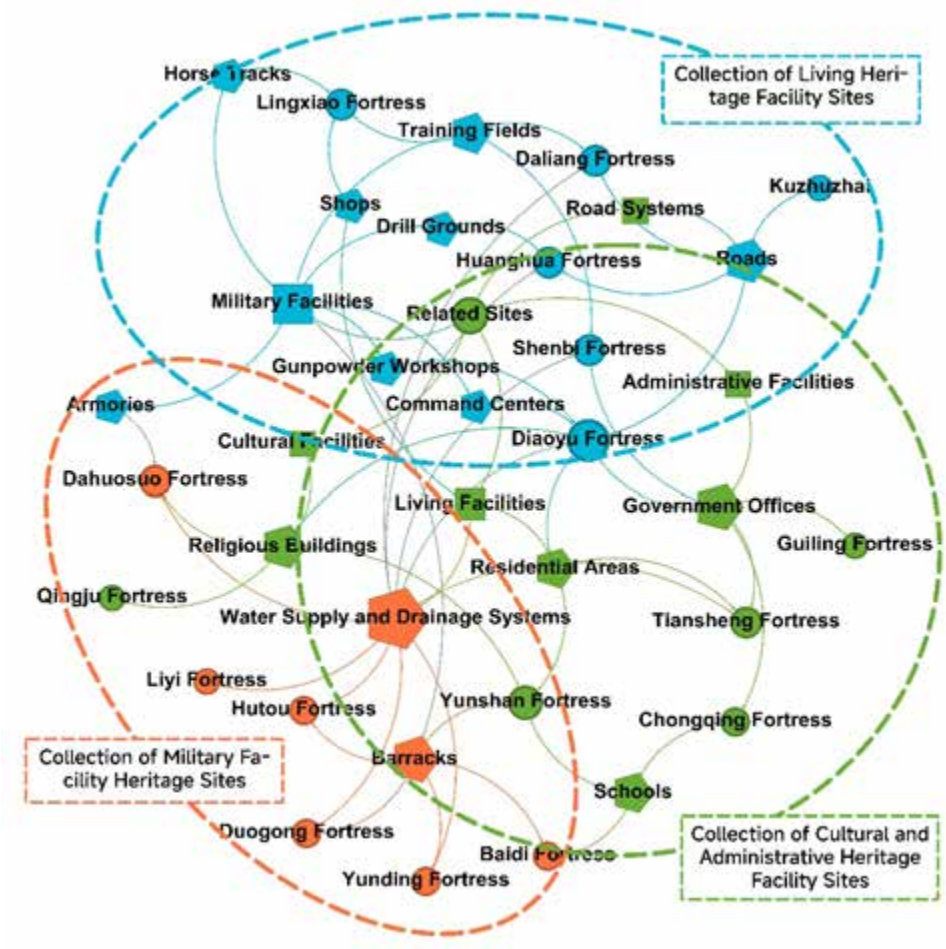

Figure 14 Modular Clustering Analysis of Mountain Fortress Archaeological Facility Sites in the Sichuan-Chongqing Region of China During the Song-Yuan Wars (Source: the author)

Based on the above modular analysis results, numerous sites related to military facilities, cultural facilities, living facilities, and administrative facilities of the Song army's mountain fortresses remain in the Sichuan-Chongqing region. This largely corresponds to the era's characteristic practice of relocating governing institutions and surrounding civilians into well-defended mountain fortresses. It also indirectly reflects that the daily life and agricultural activities of the Song military and civilians in the Sichuan-Chongqing region of China were severely hindered by the threat posed by the Mongol forces, restricting the entire region's productive and living spaces to the strategically prominent mountain fortresses.

4.3 Analysis of Historical Event Association Graph Characteristics

Recognizing repeated Mongol incursions into Sichuan, China, the Song court deemed the "upper Yangtze critically vulnerable," prioritizing Sichuan's defense as urgent since the river's strategic dominance relied entirely on Sichuan's security. Consequently, a strategic defense doctrine was established: securing the lower reaches required holding the upper reaches; defending the Yangtze necessitated controlling the Huai and Han River basins. Implementing this policy, the court empowered three theater commanders (Lianghuai, Jinghu, and Sichuan) with unified military authority over their jurisdictions. Repeated directives mandated fortifying strategic strongholds across theaters, while imperial decrees emphasized coordinated mutual support: "Sichuan's emergencies require Jinghu's aid; Hexian and Chaoxian's crises demand assistance from the Yangtze Command; Zhenjiang and Taizhou's perils necessitate relief from the Huaixi Command"[4].

Based on extant historical sources, events related to the Song-Yuan conflicts between 1223 and 1274 were systematically cataloged, with information specific to Chuan-Yu extracted to examine the region's economic, political, and military conditions during the reigns of Ögedei Khan, Yu Jie-Möngke Khan, and Kublai Khan. Modular analysis of this compiled data generated the knowledge graph presented below.

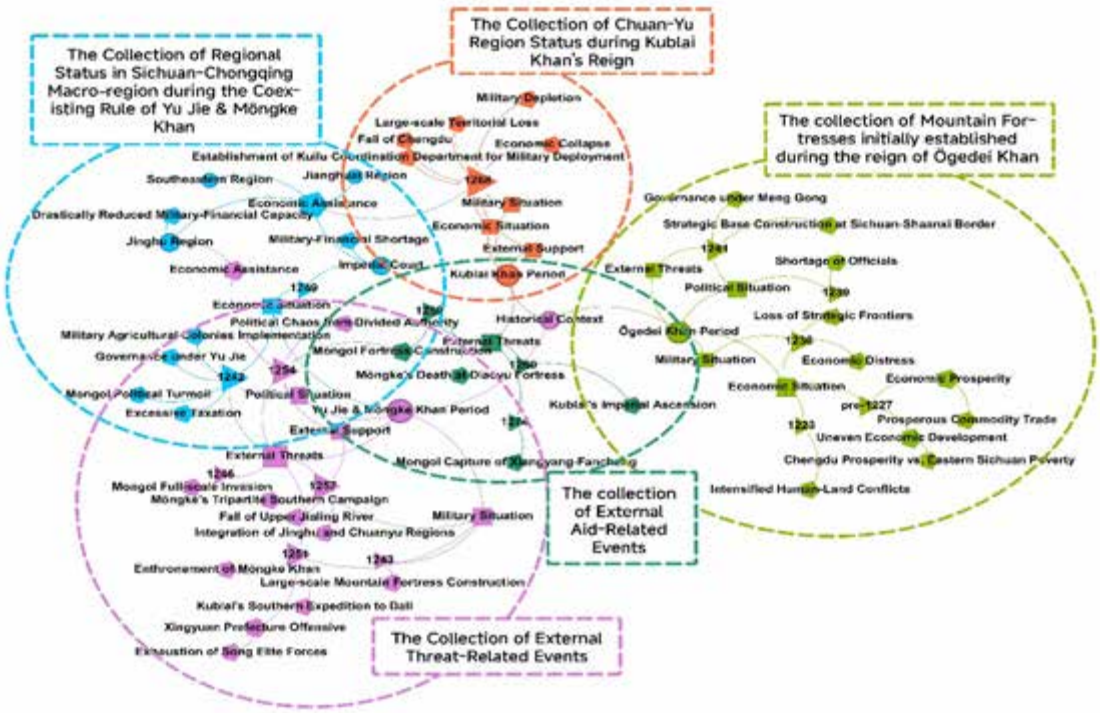

Figure 15 Modular Clustering Analysis of Historical Events in the Sichuan-Chongqing Region of China During the Song-Yuan Wars (Source: the author)

Based on the above modular analysis results, the historical event nodes related to the Song-Yuan war in the Sichuan-Chongqing region of China can be roughly divided into five sets: the status quo of the Sichuan-Chongqing region during the Kublai Khan period, the status quo during the Ögedei Khan period, the status quo during the Yu Jie–Möngke Khan period, events related to external assistance, and events related to external threats. Throughout the entire historical period of the Song-Yuan war, prior to the loss of Xingyuan Fu (Prefecture) by the Song army in 1227, the Sichuan-Chongqing region of China enjoyed relatively developed economic conditions, albeit exhibiting an unbalanced pattern characterized by the wealth of Chengdu and the poverty of the Qutang Gorge. The primary advanced economic system at the time was centered on commodity trade. As the Mongol forces gradually intensified their offensive against the Song army in Sichuan-Chongqing, the fertile Chengdu Plain became a focal point for Mongol plundering, and the region's commodity trade steadily declined amid prolonged warfare. Consequently, the economic situation in Sichuan-Chongqing deteriorated from prosperity to distress and even collapse. On the other hand, as the Sichuan-Chongqing economy became unable to sustain itself, it increasingly relied on the Jinghu region economically, and the Southern Song court made efforts to integrate Jinghu with Sichuan-Chongqing. However, continuous warfare severely depleted the military and financial resources of the Jinghu region of China, and the division of authority led to political chaos, laying hidden dangers for the later period in Jinghu.

4.4 Connections Between Mountain Fortresses

During the Song-Yuan conflicts in the 13th century, the Southern Song Mountain Fortresses in the Chuan-Yu region of China constituted an extensive and systematic "mountain fortress strategic defense system." These strongholds formed mutually responsive relationships through geographical positioning, military coordination, and resource complementarity. Leveraging the rugged terrain surrounding the Sichuan Basin, Song forces constructed fortresses on commanding heights along the Yangtze, Jialing, Tuo, Min, and Qu rivers, establishing a defense network that controlled strategic corridors through nodal points. Each mountain fortress provided

mutual support through waterways and land routes, forming a regionally interconnected network that functioned as complementary flanks, coordinating defenses and constructing a three-dimensional defensive system that operated with seamless precision.

This study selected representative Song fortresses with relatively precise geographical coordinates in the Chuan-Yu region to analyze their interrelationships in administrative division, collaborative defense, military assistance, and transit routes. Utilizing the Geo Layout plugin in Gephi software for geospatial positioning, modular clustering analysis of the constructed nodal network generated the knowledge graph association network illustrated (Figure 16). The resulting nodal network comprises four primary clusters: the Jialing-Qu River Defense Group, Eastern Sichuan Defense Group, Tongchuanfu Lu (Circuit) Defense Group, and Chengdufu Lu (Circuit) Defense Group.

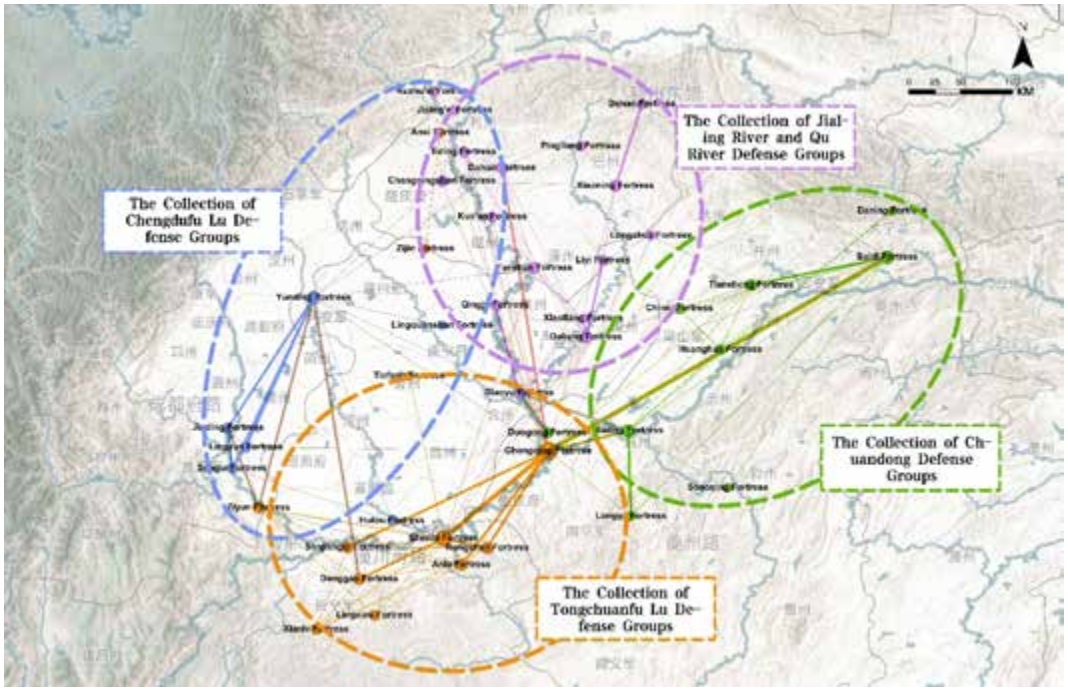

Figure 16 Modular Clustering Analysis of the Song Army's Mountain Fortresses in the Sichuan-Chongqing Region of China (Source: the author)

The size of each node in the relational network is determined by its eigenvector centrality. Eigenvector centrality is a metric used to measure the importance of nodes within a network. It considers not only the number of direct connections of a node (i.e., degree centrality) but also the importance of the nodes to which it is connected. Chongqing Fortress exhibits the highest centrality, reflecting its role as the strategic nexus of the system, functioning as both the military command hub and primary contested stronghold. Yunding, Shenbi, and Baidi fortresses demonstrate secondary centrality, serving as circuit-level administrative centers responsible for coordinating regional defenses. Fortresses such as Dahuo, Xiaoning, Yunshan, and Guiling represent the next tier, occupying critical tactical positions as pivotal nodes within the regional defense framework.

The clustering results derived from the modularized relational network reflect the regional defensive coordination among Song military mountain fortresses in the Sichuan-Chongqing region of China. According to the network analysis, during the Song-Yuan War, the Song mountain fortresses in this region can be categorized into four primary defensive clusters: one constructed around the Jialing and Qu rivers; one centered on the Chengdu Plain; another formed along the Tuo River and the upper reaches of the Yangtze River, known as the Tongchuanfu Lu (Circuit) cluster; and a final one established in eastern Sichuan, east of Chongqing. Within each cluster, the mountain fortresses maintained relatively complete systems of mutual support, collectively forming a coherent and interlocking defensive network that constituted the overall mountain fortress defense system of the Song military in the Sichuan-Chongqing region of China.

4.5 Summary of Knowledge Graph Analysis

Analysis of the knowledge graph association network reveals that the spatial evolution of the Southern Song's Mountain Fortress System in the Sichuan-Chongqing region of China during the Song-Yuan wars exhibited phased progression, hierarchical organization, and regional coordination. As Mongol offensives escalated, Southern Song defense policies transitioned through three distinct phases: emergency deployments under Ögedei Khan's incursions, systematic construction during Yu Jie's governance, and strategic contraction in the Kublai Khan era. Yu Jie's "mountain fortress defense system," centered on the "Eight Pillars of Sichuan," formed four defensive clusters along the Jialing and Yangtze waterways: the Jialing-Qu River cluster controlled eastern Sichuan's land-water junctions with Chongqing Fortress as the strategic nucleus; the Chengdufu Lu (Circuit) cluster maintained remnant plains defenses via strongholds like Yunding Fortress; the Tongchuanfu Lu (Circuit) cluster anchored by Shenbi Fortress dominated the upper Yangtze; and the Eastern Sichuan cluster shielded the Three Gorges gateway through Baidi Fortress. Within each cluster, fortresses established integrated "point-line-area" networks through waterway coordination and resource complementarity, while cross-regional command was facilitated by administrative hierarchies.

The spatial layout of this system was profoundly constrained by the wartime situation and economic changes. As the Mongol forces continued to devastate the prosperous areas, the defensive focus in the Sichuan-Chongqing region of China gradually shifted southward, ultimately forming a mountain fortress defense system centered on Chongqing and reliant on external support from the Jinghu region of China. The coexistence of military, residential, and cultural facilities found in archaeological sites confirms that the mountain fortress served both as a wartime stronghold and a place of survival. Although the coexistence of military and civilian populations enhanced the capacity for prolonged warfare, it also led to economic decline and social spatial tension within the region. Ultimately, the Mongol army compressed the living space of the Song forces by employing a strategy of "mountain fortress against mountain fortress." Coupled with the overall strategic retreat of the Southern Song, this defensive system—steadfast for nearly half a century—collapsed amid spatial fragmentation and resource depletion. Nevertheless, its regional defense concepts and mountain fortress defense system remain an important paradigm in ancient Chinese military engineering.

5 Conclusion and Outlook

5.1 Conclusion

This analysis, employing GIS and knowledge graph technologies, systematically reveals the spatial interconnections and structural features of the Song-Yuan Mountain Fortress System in China's Sichuan-Chongqing region. The fortress network exhibits a "dense in the east, sparse in the west, and strategic along the rivers" spatial pattern, relying on the Jialing and Yangtze River systems to form a three-tiered "core–pivot–supplement" defense framework. Core strongholds such as Chongqing City and Diaoyu Fortress coordinated via waterways and land routes to construct a multilevel, three-dimensional defense network, enabling regional cooperative operations. In both time and space, mountain fortress construction unfolded in three phases: an early stage of dispersed deployments along the ancient Shu Roads; a mid-stage of large-scale, systematic construction under Yu Jie's administration; and a late stage of contraction to the Yangtze corridor—reflecting the profound influence of wartime dynamics and economic transformations on the system's spatial layout. The Sichuan-Chongqing Song-Yuan Mountain Fortress System not onSly capitalized on the Sichuan Basin's interleaved mountains-and-rivers terrain but also reinforced strategic resilience by controlling key transport arteries and economic hinterlands, exemplifying the systematic and dynamic nature of ancient military geographic wisdom.

The collaborative analysis employing GIS and knowledge graph technologies provides a multidimensional theoretical foundation for the study of the distinctive values of Sichuan's Mountain Fortresses in China. Through kernel density analysis and the Analytic Hierarchy Process, GIS establishes a three-tiered "core–pivot–supplement" defensive framework, thereby quantifying the strategic significance of each mountain fortress. Meanwhile, knowledge graph technology captures the evolving wartime dynamics and economic transformations, illustrating the roles that individual mountain fortresses played within the Song military defense system amid the tides of history. These findings offer a scientific basis for uncovering the differentiated values of each mountain fortress and elucidating their historical significance and functions.

The integration of GIS and knowledge graph technologies can also provide critical support for the construction of heritage corridors for China's Sichuan-Chongqing Mountain Fortresses and their nomination for World Heritage status. By coupling kernel density maps with transportation network analysis, the structural framework of heritage corridors along the Jialing River and the main course of the Yangtze River has been precisely delineated, establishing protection priorities for core nodes such as Chongqing City and Diaoyu Fortress. The relational network derived from the knowledge graph further elucidates the systemic coherence of the mountain fortress network across administrative hierarchies, military coordination, and cultural transmission, thereby laying the foundation for the development of cross-regional collaborative preservation strategies.

5.2 Limitations and Prospects

This study acknowledges certain limitations. First, severe deterioration from age and natural erosion at some Song fortress sites in Chuan-Yu region of China, compounded by uncertain original locations, creates analytical gaps in reconstructing comprehensive defensive layouts. Second, interpretations of defensive patterns and structures at certain fortresses rely heavily on indirect archaeological inferences, where historical layering (e.g., later reconstructions or damages) may introduce biases in understanding Song-era military characteristics. Additionally, precise reconstruction of ancient Shu Road routes and historical waterways remains challenging due to geographical transformations.

Future research could advance in three directions: First, integrating Mongol offensive routes with Song-Yuan military technologies (e.g., siege engines, defensive structure iterations) to examine the system's adaptability to warfare modalities and reveal its strategic logic. Second, conducting granular studies of well-preserved exemplars like Diaoyu Fortress and Chongqing Fortress through archaeological excavations and 3D modeling technologies to validate defensive hierarchies and spatial configurations from military-geographical perspectives. Third, assessing natural disaster risks (e.g., landslides, floods) to develop GIS-based risk zoning and conservation strategies, thereby advancing preventive heritage protection. Furthermore, synthesizing multi-source historical materials with emerging technologies (e.g., remote sensing, artificial intelligence) to construct dynamic, high-precision historical-geographical databases holds potential for enhancing research rigor and optimizing heritage management efficacy.

Email: melisa.pesoa@upc.edu

Abstract
There are manifestations of graffiti in various places throughout the contemporary city. The drawings created by female graffiti artists can present different themes as a means of the consolidation of identities. However, does graffiti made by a woman symbolically influence public space? Focusing on the neighbourhoods of Santo Cristo in Rio de Janeiro and Poblenou with Provençals del Poblenou in Barcelona, this article proposes a methodological reflection on how to identify these actions and understand their cultural effects in a global phenomenon. In order to comprehend the impacts of these graphic expressions, a methodology based on a cartography was developed. Mapping graffiti created by women can be carried out in other cities and asserts the female presence as part of the occupation of public space.

Keywords: urban cultures, street art, cultural landscapes, critical cartography, right to the city

Introduction

The contemporary city presents layers of everyday graphic interventions carried out by different agents through multiple forms of expression. The urban landscape is in constant transformation, shaped by the creative and communicative capacities of citizens through their drawings and writings. In this context, urban public spaces are regarded as platforms for the expression of various groups, ranging from institutional organisations to popular forms such as graffiti. Graffiti raises questions about hegemonic power and brings artistic expression to the urban fabric; for this reason, it is relevant to the consolidation of identities and reinforces people's sense of belonging.

However, the artistic movement is predominantly male and female graffiti artists face difficulties in being accepted and have few records (Pabón-Colón, 2018), raising the question: why do female graffiti artists not receive the same visibility as their male counterparts? Authors such as Silvia Federici (2017) argue that realities like these reflect the social pressures of the patriarchal capitalist system[1]. According to Federici, the transition from the feudal system to capitalism caused a reconfiguration of power relations: to maintain power for men and in an attempt to compensate for the expropriated lands, women began to be treated as property under the imposition of social roles. Even so, this oppressive structure of objectification of women was not uncontested.

This history also includes women's struggles for the right to the city (Lefebvre, 2016). Some creative initiatives of place appropriation provide new perspectives on inhabiting cities based on women's own lived experiences. In this way, despite obstacles, they participate in urban development (Muxí, 2019) and in shaping the image of a place.

Given this context, it is necessary to identify where the interventions are located and what their messages are in order to understand the symbolic effects of graffiti on the landscape. Considering these issues, it is worth asking: can graffiti created by a woman transform the landscape of a city? To reflect on this question, this article focuses on analysing the impacts on public space caused by graffiti created by women.

The research employs critical cartography as a tool to understand the graphic-symbolic effects of graffiti as a global phenomenon with local specificities. Furthermore, it aims to develop a reproducible methodology for graffiti studies applicable in different cities to advance theoretical and methodological frameworks. Through an interdisciplinary approach combining Urban Planning, History of Art, Design and Geography, the study also seeks to reflect on the hypothesis that urban voids in a city are the spaces most sought after by female graffiti artists

1 Silvia Federici's (2017) study focuses on the period of the Middle Ages in Western Europe.

in pursuit of freedom of expression.
Focusing on urban voids, the research seeks to compare the Santo Cristo neighbourhood in Rio de Janeiro (Brazil) with Poblenou and Provençals del Poblenou[2] in Barcelona (Catalunya, Spain). These locations are recognised for their significance in graffiti history, offering an opportunity to build international networks. The neighbourhoods share similarities as they are currently experiencing predatory real estate development, resulting in fenced-off plots featuring interventions by female graffiti artists.

In order to analyse graffiti interventions made by women in these places in 2024, this article proposes a reflection on the methodology based on cartographic production. Cartography is a way to highlight artistic diversity in public space, showing how female graffiti artists form part of the cultural landscape and enabling the discovery of new graphic representations of the city.

Drawing as a Tool for Urban and Human Transformation
Historically, graffiti is considered a cultural movement in the United States and its purpose "is primarily an invitation to encounter and dialogue" (Gitahy, 2012, p. 16). The initiative originated from young black and Latino Americans living in the suburbs, who saw artistic expression as a way to denounce public authorities' neglect through codes and provocations in public spaces. The U.S. core of the artistic movement gained strength in the 1980s, consolidating its relationship with Hip Hop through initiatives in drawing, music and dance. In the same decade, the style spread internationally, sparked political clashes[3], was appropriated by art galleries[4] and challenged urban art (street art), which proposes focusing more on the end result on the street over the cultural process.

Although graffiti has gained acceptance among young people worldwide, Jessica Pabón-Colón (2018) points to the relative erasure of women in these narratives. The author states that female graffiti artists have existed from the beginning, with participants such as Eva62, Barbara62, Kivu 181, Lady Pink, and others, but records have predominantly focused on men. Challenging this situation, the increase in the number of women involved in graffiti was noted in the 1990s and expanded in the 2000s due to digital media. The female presence brought some changes to the style. They managed to form more collectives, introduce their perspectives in debates, magazines and studies to encourage other women in graffiti (Amorim, 2022).

Similarly, women's struggle for greater prominence is evident in other fields, as Urban Planning. Authors like Zaida Muxí (2019) share their professional experiences in municipal organisation to highlight the complexity of a woman's insertion into public administration, although they believe in the possibility of urban change through their participation. Supporting this view, Silvia Federici (2017) argues that the inclusion of women in power structures is part of the refusal of the 'disciplining of the body', as historically patriarchy controls cities, and women's involvement in urban life can be seen as a catalyst for creative initiatives questioning the hegemonic system.

Furthermore, artistic expressions also take place in public spaces, revealing that these urban fabrics are important "places of activism for most social and political movements of the past two centuries" (Kern, 2021, p. 160). The presence of women in these spaces is a way to strengthen social struggles through the dissemination of their debates and also symbolises resistance (Kern, 2021). While reality exposes accumulations of violence, women continue to resist through their artistic work and projects, such as female graffiti artists who use drawing as a tool for expression. Some artists prefer to remain anonymous for safety reasons, but their marks reaffirm the diversity of themes, techniques and styles.

Walking through the streets, it is possible to find graffiti on walls, construction fence, signs, and other surfaces. It becomes a challenge to understand the messages of these interventions within an environment with intense sensory stimuli. Thus, recognising whether a graffiti piece created by a woman is even more complex, because doesn't exist a pattern. According to Gilles Deleuze (1999), it may be possible to identify if the drawing was made

2 According to the Ajuntament de Barcelona (2024), Poblenou and Provençals del Poblenou are neighborhoods in the district of Sant Martí and are part of the 'traditional Poblenou'.
3 Debates about the legality of graffiti only intensified in the 2000s (Amorim, 2022).
4 Galleries primarily embraced the style through the works of Jean-Michel Basquiat and Keith Haring.

by an women artist through their style. For the author, personal style resides in the act of creation, in which the subject understands their experiences and produces a unique and non-transferable style. Therefore, each female graffiti artist has an identity and a style that provides a diversity of colours, themes and materials.

Thus, it can be said that there is no 'universal style of graffiti made by women' and creativity together with the act of drawing has added graphic layers to the landscape and transformed places. According to Henri Lefebvre (2016), inhabiting the city is a negotiation between powers. For this reason, citizens' creativity is a way of appropriating environments, a claim for the right to the city. Artistic action can subvert hegemonic control, especially as "art has resisted the meaning of the work; it offers multiple figures of times and spaces" (Lefebvre, 2016, p. 125). In other words, women can also act collectively in environments and their graffiti reinforces the power of drawing in the constitution of a drawn city.

A graffiti intervention can bring political debates, criticism, greater access to art, playful and popular representations, as well as codes of complex legibility into the public space. However, for the movement, beyond the result in the environment, the act of drawing itself is essential. The process incorporates shared experiences between artists, can create emotional bonds with places, enables communication with society and maintains the collective memory (Halbwachs, 2003) of an urban cultural tradition. These layers may be considered symbolic marks in the city, as even if they are not easily recognisable, they carry the weight of urban history and are part of the landscape.

With this context in mind, authors such as Denis Cosgrove (1989) argue that the construction of cultural and symbolic landscape takes into account the contribution of social groups that also create graphic markings on walls, revealing their varied understandings of urban life—just as happens with graffiti made by women. These artistic manifestations can heighten levels of communication. However, "to understand the expressions written by culture in the landscape we must know the 'language' used: the symbols and meanings alongside the culture" (Cosgrove, 1989, p. 125). Therefore, to deepen knowledge of the urban landscape, it is important to decode the drawings present and analyse the mutability of space.

Understanding the landscape as an envelope in constant formation through graphic elements is also central for Joy Till (2014), who states that "every city is, fundamentally, a human relational environment, a vast medium" (Till, 2014, p. 56). According to the author, the city gives rise to multiple forms of visual communication, enhancing a landscape built upon the layering of graphic productions. Thus, images created by citizens contribute to a graphic landscape and foster the individual's sense of belonging in place.

Considering that female graffiti is another graphic layer in shaping the contemporary city's landscape, one might ask: is it possible to locate graffiti created by women? To investigate this, mapping is used as a tool for research and representation of their presence, which may be expressed in different territories. Therefore, the cartographic methodology should be applied across various cities to reflect the diversity of urban interventions and demonstrate how the act of graffiti by women is a global phenomenon. With the intention of confirming these potentials, the territorial focus is on the neighbourhoods of Santo Cristo in Rio de Janeiro and Poblenou with Provençals del Poblenou in Barcelona.

Urban and Cultural Dialogues between Rio de Janeiro and Barcelona

To speak of the relationship between Rio de Janeiro and graffiti is to speak of the pioneering spirit of certain groups in the 1980s. The city played a significant role in the emergence of the first collectives, such as the FleshBeck Crew, who were influenced by the provocative phrases written by the figure known as Profeta Gentileza[5] in the port zone. In 2004, Latin America's first all-female graffiti group, TPM Crew, was also formed in Rio (Pabón-Colón, 2018). Since then, the number of female graffiti artists in the city has continued to grow. Their interventions can mainly be found in areas such as the city centre and the port area, particularly in the neighbourhood of Santo Cristo.

Santo Cristo, with approximately 9,936 residents[6], is one of the foundational areas of the city. It preserves its industrial past, shelters the favelas of Morro da Providência and Morro do Pinto, safeguards historic warehouses

5 José Datrino (1917–1996) became immortalised in the memory of Rio de Janeiro's residents through his panels bearing messages of love and peace.

6 Information obtained by IBGE (Instituto Brasileiro de Geografia e Estatística), 2022.

and sheds, and has become a highly sought location for many female graffiti artists. After years of urban transformation, the area is currently marked by urban voids[7]. Due to its strategic location near the sea and the administrative centre of the city, along with institutional political projects such as Porto Maravilha and Porto Maravalley, it has been significantly reshaped by the real estate market since 2024. Construction companies foresee major changes to the landscape, with the planned development of six new residential buildings and the arrival of an estimated 15,000 new residents[8].

The presence of graffiti in the area can be seen on walls, hoardings and within urban voids. It is believed that female graffiti artists choose these locations due to the relatively low level of policing, allowing them to appropriate the space for an indefinite period. However, as the neighbourhood undergoes transformation and its residents experience the effects, the presence of popular female graffiti in these areas takes on further symbolic layers: the resistance of presence and the preservation of graffiti's contestatory culture.

Like Rio, Barcelona is also a cosmopolitan city with a significant history tied to graffiti. Since the 1980s, symbolic graffiti murals have existed there[9], though the relationship with the municipal authorities has not always been harmonious. In the 1990s, graffiti was declared illegal. In the 2000s, however, artists' efforts to gain cultural recognition for the movement spurred initiatives to distance it from vandalism, instead valuing urban art more aligned with aesthetic expression than subversion. As a result, legalised spaces for graffiti were inaugurated, such as the park of Les Tres Xemeneies, and the city gained the title of capital of urban art (Bou, 2023).

Nevertheless, spontaneous graffiti continues to appear on ephemeral surfaces, especially in neighbourhoods like Poblenou and Provençals del Poblenou. Located in the district of Sant Martí, the have approximately 34,151 residents[10] and is historically significant for Catalunya's industrial heritage. It also features tourist, artistic and cultural landmarks[11] and has been similarly impacted by fast real estate development. Due to its proximity to the beach and the quality of local infrastructure, as well as institutional projects such as Plan 22@[12], the area has attracted property developers, leading to rising housing costs and an increase in urban voids destined for new construction.

Walking through its streets, one can observe a variety of landscapes within the same neighbourhood. There are areas marked by large warehouses, constructions that recall the industrial past, corporate skyscrapers, residential condominiums and ongoing building works. Even so, it is possible to find graffiti by women that asserts their presence and signals places where there is a relative sense of popular dissatisfaction regarding the state of local maintenance and the future of the neighbourhood. These interventions are most visible on the temporary hoardings surrounding vacant plots.

Considering the context of Santo Cristo in Rio de Janeiro and Poblenou with Provençals del Poblenou in Barcelona, it becomes clear that both are significant in the local and international history of graffiti. These areas were selected for the study precisely because they highlight urban voids as spaces desired by female graffiti artists. Despite undergoing radical urban transformations, these neighbourhoods have a vibrant urban life, which confirms the presence of women in the construction of the urban landscape.
In order to carry out the methodological exploration in these areas, a mapping-based methodology was applied. Cartography not only suggests a valorisation of the territory but also becomes a tool for visualising the networks among artists and documenting the process. Moreover, it is a practice that establishes spatial representations of the graphic marks and proposes another dimension of time and graphical depiction of the sites. It can be said

that mapping the landscape also constitutes a way of recording alternative modes of occupying and inhabiting the city from the perspective of female graffiti artists.

Methodological Paths: Studying Graffiti Space Between Walls and Maps

Mappings are laden with interpretations and bring to light realities that were previously invisible or unimaginable. Considering the technological advances in mapping, authors such as Gilles Deleuze and Félix Guattari (2021) regard cartography as a framework that assists in understanding the transformation of things in the world. For the authors, "the map does not reproduce an unconscious closed upon itself; it constructs it. It is part of the rhizome. The map is open and connectable in all of its dimensions" (Deleuze, G.; Guattari, F.; 2021, p. 30).

With this in mind, mapping is understood as an activity that may be guided by the method of becoming, in a non-linear process of learning-by-doing. The cartographic practice allows for the representation of layers of the contemporary city that are in constant transformation and, throughout its execution, new knowledge is produced. In this sense, this article proposes the creation of a map of graffiti made by women, based on the belief that cartography contributes to better visualisation of the public space where interventions are found and that it can be constantly updated — just as graffiti is created daily.

However, in order to assess whether the proposed methodology contributes to the study of the subject, this article is an exercise in methodological experimentation. With the aim of understanding the impacts of graffiti by women on the urban landscape in different cities, a comparative analysis is conducted between the neighbourhoods of Santo Cristo in Rio de Janeiro and Poblenou with Provençals del Poblenou in Barcelona. Among the procedures are mappings and the creation of a database, organised in five stages.

The initial step is to identify who the female graffiti artists active in these spaces are and to establish contact with them. These artists can often be found within artistic circuits and through their social media profiles, where it is possible to discover names and strengthen connections. The second stage involves visiting the sites of previously identified graffiti interventions. This phase is ideal for exploratory walks, which may begin at a starting point or specific piece of graffiti but are intentionally flexible. Here, the practice of drifting[13] through the city helps to uncover new places, artists, and works in unfamiliar urban settings, while also constructing a mental map of the territory. During fieldwork, each piece of graffiti should be documented through photographs and notes.

With some graffiti locations recorded, the third stage entails mapping these interventions by women. Regardless of the two territorial case studies, the process proceeds through digital mapping using Google My Maps, which enables swift registration of images and collected data. This platform can also serve as a basis for other visual representations, such as hand-drawn cartographies. Through intentional and critical drawing, it becomes possible to create a map that is not only objective and communicative but also aesthetically engaging — serving as both an analytical tool and a prompt for formulating new questions about public space.

The fourth stage runs parallel to the third and consists of processing the data gathered through mapping. Given the complexity of information associated with each graffiti work, it is essential to develop a database that organises specific details such as authorship, theme, style, date of execution, among others. This stage also offers the opportunity to experiment with visual formats such as diagrams and infographics, which can enhance the readability and accessibility of the data.

The final stage concerns how the research is shared. Most of the dissemination takes place online via social media, inviting diverse audiences to engage in conversations about how female graffiti shapes everyday landscapes. Creating an Instagram profile, for example, allows the project to connect the research, cities, artists and individuals across different locations. Furthermore, documenting interventions in digital format contributes to the preservation of their memory. Nevertheless, this space comes with its own challenges, such as shifting algorithms and uncertain longevity (Lanier, 2018). While acknowledging that such tools are not permanent, they are still employed due to their current relevance.

Given this methodology, the aim is to identify and document the presence of graffiti created by women in urban

13 The Situationist drift, grounded in psychogeography, is an exploratory form of walking that embraces the unexpected in urban contemplation.

public spaces. Applying this investigative framework across different cities may demonstrate its reproducibility and signal that the act of graffiti by women is part of an international phenomenon. One might say that mapping graffiti also offers an opportunity to spatialise the artworks and understand how certain women appropriate spaces through creative and artistic initiatives. Accordingly, this methodology was applied to the two case studies and produced significant results and analyses.

Results

Initially, the identification of female graffiti artists and their styles in the Santo Cristo neighbourhood was conducted through social contact with cultural centres, collectives and art schools. With this foundation, walking through the streets became a routine process of photographic documentation. Following these experiences, digital mapping was carried out, including metadata for each piece of graffiti and some charts were also created. The resulting map, photographs and specific details of the interventions facilitated contact with new artists and led to the discovery of additional graffiti works.

The mapping of Poblenou and Provençals del Poblenou began with a key challenge: how to apply this process in an unfamiliar territory? It was necessary to immerse oneself in and study the local culture, land use and other layers that informed attentive walks. Discovering art schools and cultural centres made it possible to connect with female graffiti artists and enabled the photographic documentation of some of them and their work. For the cartography, an independent file was created in Google My Maps. The process remained similar to that in Rio de Janeiro, but particular emphasis was placed on hand-drawn maps. Beyond offering alternative cartographic representations, these were essential for developing spatial familiarity and for valuing creative psychomotor work.

The execution of the procedures led to the identification of 23 graffiti pieces created by 12 female artists in the Santo Cristo neighbourhood of Rio de Janeiro, as illustrated in Figure 1. The number of women involved suggests a diversity of agents active in the streets. It can be said that the artists have appropriated underused spaces, construction hoardings and some of the main roads of the area, with one or more interventions each. According to the findings, the majority of the artworks bear signatures — making it easier to identify authorship — and are created on a human scale. Furthermore, in terms of visual content, the themes tend to revolve around playfulness, typography and critical commentary.

Figure 1: Map of graffiti made by women in the Santo Cristo neighbourhood (Rio de Janeiro), 2024. Source: Author's elaboration (2025).

In Poblenou and Provençals del Poblenou, seven graffiti works by seven different female artists were recorded, as

illustrated in the map in Figure 2. These pieces are strategically located in busy areas such as parks, technology and innovation hubs, art galleries, as well as in abandoned buildings or vacant lots. It was observed that the closer one gets to the residential zones, the fewer instances of female graffiti are found. Moreover, the artists — most of whom are Latin American or from other European countries — tend to create medium-scale pieces with themes related to typography, gender and playfulness.

Figure 2: Map of graffiti made by women in Poblenou and Provençals del Poblenou (Barcelona), 2024. Source: Author's elaboration (2025).

From the cartographic analysis of both locations, it was possible to identify some similarities and differences in how female graffiti artists operate. In terms of themes, artists in Santo Cristo tend to adopt a more activist stance, taking advantage of the visibility of certain areas — such as vacant lots earmarked for new developments — to assert their presence through character illustrations or typographic designs. In contrast, the work found in Poblenou and Provençals del Poblenou reveals a stronger concern with the aesthetic and technical aspects of graffiti, as illustrated in the mosaic in Figure 3. Furthermore, it can be argued that public space itself influences both the themes and styles of the graffiti. In both neighbourhoods, parks and artistic centres feature graffiti with symbols that reference the local context.

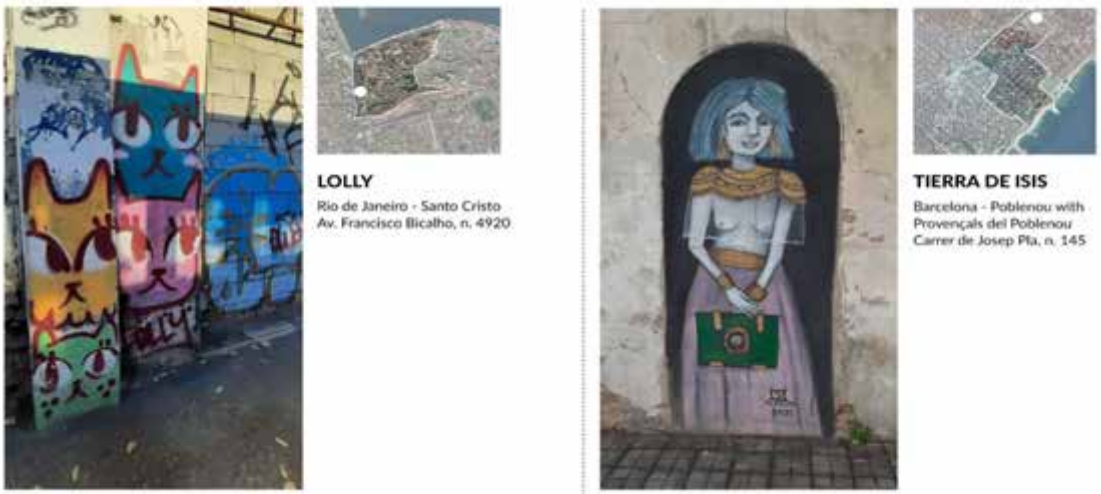

Figure 3: From left to right, graffiti by Lolly in Santo Cristo and work by Tierra de Isis in Poblenou with Provençals del Poblenou, with their locations. Source: Author (2025).

It is important to highlight that squares, playgrounds and skate parks not only convey cultural codes but also emphasise the significance of these spaces for urban life. These social spaces serve as invitations for gathering, contemplation and the creation of socio-spatial bonds. Because of this characteristic, it can be understood that some female graffiti artists feel encouraged to appropriate these environments. Another similarity between the cases is the type of surface on which the graffiti is found. The interventions are predominantly on large obsolete industrial facilities, underutilised and deteriorating buildings, and on metallic temporary fence around construction sites (see Figure 4), consolidating their ephemeral identities.

Figura 4: From left to right, graffiti by Las, Pam and Bia in Santo Cristo, and work by Mida in Poblenou with Provençals del Poblenou, with their locations. Source: Author (2025).

Similarly, it is interesting to point out the bond among the female graffiti artists, which strengthens friendships and fosters international exchange, as they leave their marks in other places with the help of colleagues. Looking at a mural with various graffiti, it is possible to distinguish that some were created at the same time (through use of the same paint or theme), but the artists are recognised by their individual styles. Thus, graffiti is not merely the final product, but rather the social relationships within the process. Observing the case studies, one can say that this global phenomenon is driven by women's search for belonging and their desire to be part of the

urban landscape. Consequently, public spaces with urban voids also become canvases for these interventions, influencing how the artists communicate with the contemporary city.

Conclusion

Bearing in mind the historic social oppressions faced by women, their participation in graffiti highlights struggles for the democratic right to inhabit the city. Since graffiti is based on experimentation and critique of hegemonic power, women have the opportunity to assert their existence in the world through their distinct codes and symbols. The trace left by a female graffiti artist on the street is also the construction of new graphic layers within public space. Thus, documenting the artists and their work contributes to the collective memory of urban culture — the graffiti movement — and to the cultural landscape.

From the methodological essay conducted in the Santo Cristo neighbourhood in Rio de Janeiro (Brazil) and Poblenou with Provençals del Poblenou in Barcelona (Catalunya, Spain), the rapid advance of the real estate sector in these territories was also evident. Both areas share a relatively deactivated industrial and port past, resulting in deteriorated buildings, urban voids and public spaces with poor maintenance by local authorities. With growing real estate market interest, new developments are underway, with noticeable impacts on rising living costs and landscape transformation. In this context, graffiti signals historically neglected spaces that might become the next real estate targets, becoming a popular code of dissatisfaction towards radical urban transformations.

Furthermore, it is clear that questioning whether graffiti made by women can symbolically transform the landscape is insufficient without considering the spatiality of these interventions. The methodology based on mapping proved helpful in this study. Fieldwork, graphic representations and direct contact with the artists demonstrated how lived experience and cartographic drawing walk hand in hand. It was confirmed that this methodology can be replicated in different cities.

Consequently, the comparative study allowed connections between the two cities and strengthened expressive drawing as a cartographic tool. It identified that urban voids are sought out by female graffiti artists due to low surveillance and the provision of ephemeral surfaces such as hoardings, which offer greater freedom of expression. The presence of similar themes across different contexts also reveals a global phenomenon where women resist and continue to engage in graffiti, connecting local identities through international dialogues. Therefore, graffiti interventions by women add symbolic meaning to public spaces and are part of the construction of the cultural landscape.

The Dilemma of Authenticity: The Conservation and Reconstruction of Traditional Residences in China —Taking Pingyao, Shanghai and Suzhou as Examples

Shuyin Li
School of Architecture and Urban Planning, Tongji University
Email: happylishuyin@163.com

Abstract
Thirty years after the release of the Nara Document on Authenticity, the concept of authenticity still faces many difficulties in its localization in China, which are manifested in three aspects: the contradiction between absolutization and relativization, materiality and spirituality, and authority and popularization. In China's historic cities, there are a large number of traditional residences, which constitute the background of the "authenticity" of urban heritage. However, due to the traditional wooden construction in China, these traditional residences have undergone nearly a century of historical changes and suffer from problems such as structural aging and long-term disrepair. Unlike the legally protected historical buildings in China, which are maintained by the state, most traditional residences are protected by individuals, and often encounter difficulties such as lack of funds and high maintenance costs during the conservation process. To a considerable extent, there are also calls for demolition and reconstruction among the public. How to maintain the authenticity of traditional residences? This paper takes three historic cities in China - Pingyao, Shanghai and Suzhou - as examples to explore three different conservation models caused by the different aspects such as construction history, construction scale, land values: comprehensive conservation, limited conservation, and "Three Original" conservation. It also discusses the similarities and differences in the attitudes of the government, experts and the public towards the protection of traditional residences, and how they maintain a delicate balance like walking on a tightrope to the greatest extent possible to preserve the authenticity of traditional residences.

Keywords: Authenticity; Dilemma; Traditional dwellings; Conservation; Reconstruction

After the release of the Nara Document in 1994, there was more attention and discussion on the adaptability of the concept of "authenticity" in the field of international heritage conservation to different civilizations around the world. The concept of "authenticity" originated from the cosmology and spatial-temporal view of Western civilization, and is significantly different from the concept of "authenticity" in ancient Chinese cosmology and spatial-temporal view. Firstly, analyze how to express "authenticity" in traditional Chinese construction culture, then discuss the challenges faced by the concept of "authenticity" in the contemporary Chinese context, and finally illustrate the way of "authenticity" in the field of Chinese heritage conservation through three cases of traditional residential protection in historic cities.

1. The concept of "authenticity" in traditional Chinese construction culture

In the traditional organic holistic cosmology and cyclic space-time view of China, humans and nature, matter and spirit, are a unified whole and are in eternal change, known as the "turning the tide and bringing prosperity" and "the movement of the opposite path". The construction of urban architecture should conform to the reflection of the " the Tao of Heaven " in the human world, that is, it should conform to the "ritual system" and "feng shui". Architecture is a dwelling place for "people "in the present world. Compared to the material existence of "eternity", the Confucian emphasis is more on the spiritual inheritance of "eternity ", which is known as the "Three Immortals " of "Set Moral Examples, Perform Great Deeds, and Spread Noble Ideas ". Architecture does not pursue eternity through "solidity ", but expresses the path of eternity through "replacement and reconstruction ".

1.1 Organic holistic cosmology

The ancient Chinese organic holistic cosmology believed that humans and nature form an inseparable whole, jointly adhering to the principles of heaven and ethics. Human beings are a part of nature, and architecture is also a part of nature. The highest level of architectural aesthetics is" although created by humans, like Heavenly". People or buildings dissolve into nature to achieve "eternity", rather than standing in nature and resisting nature to achieve "eternity".

1.2 cyclic space-time view

The concept of cyclic space-time in China originated from the Book of Changes, which established " No plain is not followed by a slope; no advance is not followed by return" as the fundamental law governing the operation of all things in the universe. The Yin Yang Eight Trigrams diagram in the Book of Changes originates from the

observation and setting of the 24 solar terms in nature by ancient people (Figure 1), emphasizing the cyclic and changing laws of yin and yang energies. Yuanjie Lin 2023) Buildings standing in the universe also follow this law without exception. The use of wood in ancient architecture, based on the characteristics of wood decay, can be consistent with the laws of the circulation of all things in the universe.

Fig 1. The 24 Solar Terms

The 24 solar terms are Start of Spring, Rain Water, Insects Awaken, Spring Equinox, Clear and Bright, Grain Rain, Start of Summer, Grain Buds, Grain in Ear, Summer Solstice, Minor Heat, Major Heat, Start of Autumn, The End of Heat, White Dew, Autumn Equinox, Cold Dew, Frost's Descent, Start of Winter, Minor Snow, Major Snow, Winter Solstice, Minor Cold, Major Cold.

1.3.Expressing the Way of Eternity through Maintenance and Reconstruction

The ancient Chinese imperial palace had a complete maintenance system. Taking the Forbidden City, which has been in existence for 600 years, as an example, it has a precise maintenance system of annual repair (regular maintenance), major repair (periodic reconstruction), and special repair (post disaster restoration). Establishing a royal timber factory to store the golden nanmu needed for the construction of the imperial palace, setting up a golden brick kiln in Suzhou to produce glazed golden bricks, and passing down the eight master craftsmen's systems of painting, tile making, and woodworking from generation to generation. The standard methods are fixed in the "Rules of Engineering Practice" to ensure the continuity of traditional construction techniques. Over the course of 600 years, the Hall of Supreme Harmony suffered from lightning strikes, wars, and burning, and underwent 4 reconstructions. (Figure 2-3) The maintenance system of folk architecture integrates patriarchal ethics and traditional craftsmanship, utilizing the winter agricultural off-season for maintenance and ensuring the reuse of old materials.

Fig 2. The Hall of Supreme Harmony

The Hall of Supreme Harmony in the Forbidden City is located in the Palace Museum in Beijing. It is the largest of the three outer halls of the Forbidden City and also the largest palace in the Forbidden City. Commonly known as the "Golden Luang Hall" among the people, it is located in a prominent position along the north-south axis of the Forbidden City. Built in the 18th year of the Yongle reign of the Ming Dynasty (1420).

Picture source: The official website of the Palace Museum https://www.dpm.org.cn/building/talk/224412.html

2.The dilemma faced by the concept of "authenticity" in the contemporary Chinese context

The concept of "authenticity" in the field of urban heritage conservation originated from Western civilization and has a strong Western cultural color. The concept of "authenticity" has had a significant impact on the field of heritage conservation in China since its introduction, but to this day, it still faces many contradictions in the process of "sinicisation".

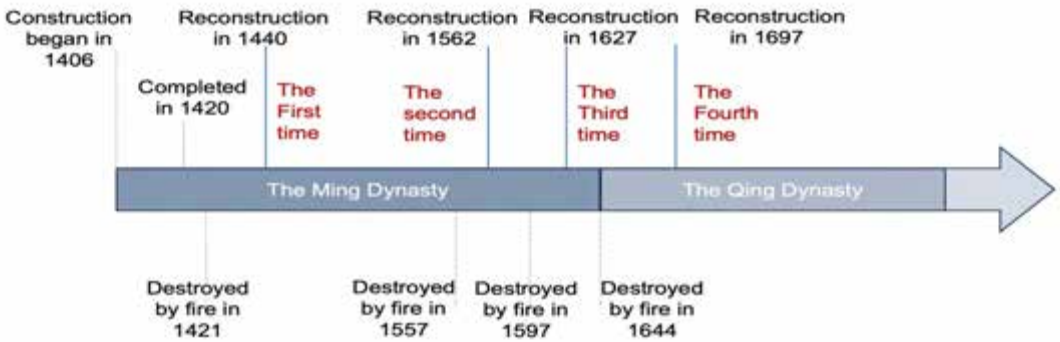

Fig 3. Over the course of more than 600 years, the Hall of Supreme Harmony has undergone four reconstructions
Diagram source: Drawn by the author of this article

2.1.The contradiction between absolutization and relativization
There are still a large number of traditional residential buildings in use in China, and these urban heritages are essentially dynamic, influenced by the passage of time and constantly changing cultural customs. However, the concept of authenticity in the field of international heritage protection often fails to adapt to changes and prioritizes preserving a fixed "absolutized" historic moment. In fact, authenticity should not be limited to a static "snapshot", but should reflect the cultural changes that are taking place, which give meaning to urban heritage.

2.2.The contradiction between materiality and spirituality
Chinese urban heritage is often full of profound spiritual significance, which cannot be expressed solely through material attributes. An important contribution of the Nara Authenticity Document is its recognition of the importance of intangible values. However, this intangible spiritual value challenges the traditional standards used to evaluate authenticity. The spiritual value in heritage is often marginalized, excluded, or misunderstood due to considerations of authenticity, even though it is crucial for the cultural identity of the heritage. Chritina Cameron 2024)

2.3.The contradiction between authoritarianism and popularization
The origin of the concept of "authenticity" in Western civilization is not a subjective evaluation, but comes from institutional authority, law, religion, or scientific rationality. Authenticity is often invoked as a method of social control or a mark of power relations: once something is defined as authentic, it is no longer questioned. (Jones, S. ,2010) The Nara Authenticity Document broadens the evaluation criteria for authenticity, emphasizes the importance of communities in interpreting and assessing authenticity, and recognizes them as the primary guardians of cultural heritage. However, the voices of local communities are still often marginalized, and experts and governments tend to prioritize material protection over community values and the views of local residents.

3.Cases of Traditional Residential Conservation in Three Historic Cities: Pingyao, Shanghai, and Suzhou
Pingyao, Shanghai, and Suzhou are three famous historic and cultural cities in China, which still retain a large number of traditional residential buildings that are still in use. These traditional dwellings, distributed in large patches, constitute the background of the authenticity of urban heritage. Traditional Chinese wooden architecture is a reflection of the traditional concept of cyclical time, emphasizing human habitation in the "present world" and reconstruction is a common occurrence. At present, most of these traditional dwellings suffer from problems such as structural aging and long-term disrepair. Unlike historical buildings in China that have legal protection status and are maintained by the state, most traditional dwellings are protected by individuals, often facing difficulties such as funding shortages and high maintenance costs during the protection process, and to a considerable extent, there are calls for reconstruction among residents. Experts have also raised questions that these wooden buildings, which have existed for a hundred years or even longer, have lost their maintenance. "What is the significance of completely preserving the dilapidated reality of these houses for the contemporary development of the city? Since conservation is for the inheritance and development of culture (Abdul Huq, S., Puthuvayi, B. 2024), will the purpose of contemporary historical and cultural protection be reversed by being limited to such static reality?" (Bing Zhang ,2011) How to better maintain the "authenticity" of traditional dwellings, while improving the quality of life of residents and raising their awareness of actively protecting traditional dwellings, is a problem that needs to be carefully considered. Pingyao, Shanghai, and Suzhou have provided different answers based on their own history and actual situations.

3.1.Government led + Resident autonomy - Pingyao
3.1.1.Strict and orderly courtyard model
Pingyao Ancient City has a history of 2700 years. The existing Pingyao Ancient City was formed in the 14th century and is an outstanding example of the Ming and Qing dynasties in China. It fully preserves the spatial sequence of traditional Chinese ritual architecture and was recognized as a World Cultural Heritage site by UNESCO in 1997. The entire ancient city covers an area of 2.25 square kilometers and has nearly 4,000 traditional residential courtyards, of which 90% are buildings from the Ming and Qing dynasties, and about 20,000 households live in them.

The traditional residential buildings in Pingyao Ancient City adopt the traditional Chinese solemn and orderly quadrangle courtyard model. There are clear axis lines, symmetrical left and right, and distinct primary and

secondary in the planar layout. Large courtyards are often composed of two or three courtyards, forming a "日" and "目" shape. (Figure 4)

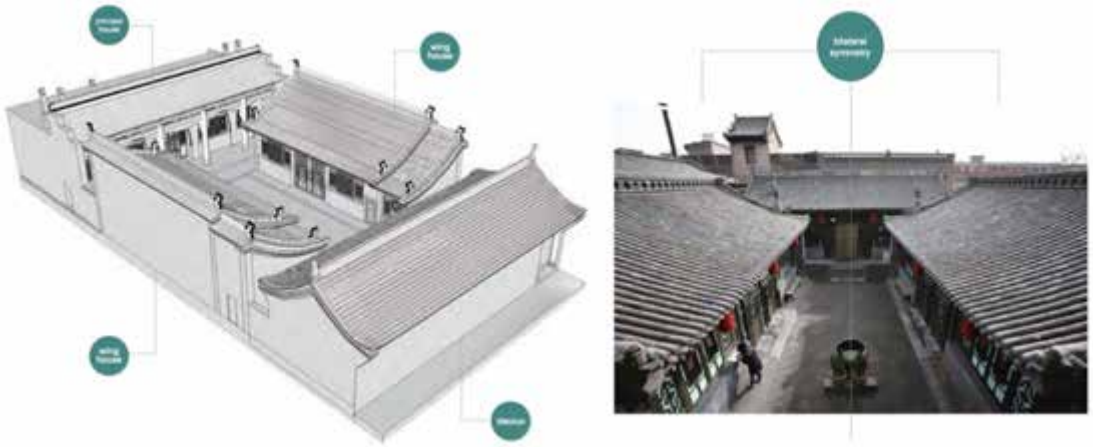

Fig 4. Typical Traditional Residential Courtyard in Pingyao Ancient City

There are various types of courtyard combinations in traditional residential buildings in Pingyao. The main courtyard is mostly a narrow quadrangle courtyard, while the auxiliary courtyards include chariot and horse yards or study courtyards.

Picture source: " Practical Conservation Guidelines for Traditional Courtyard Houses and Environment in the Ancient City of Pingyao "

During the Ming and Qing dynasties, a courtyard was the private property of a household. After two rounds of "private house socialist transformation" in 1958 and 1962, by 1966, more than 10,100 houses belonging to over 1,000 households in the ancient city had become "economic rental houses", and their property rights had changed from private property to public property. (Feng Tian, Wenzheng Shi, Junqing Wen, etc ,2016) Some courtyards have formed a mixed situation of public and private property, and residents have a low willingness to autonomous maintenance. Due to the low rent, the housing management office is unable to use the rent for house maintenance, resulting in widespread housing decay.

3.1.2.Comprehensive Conservation Policy

Since the 20th century, the tourism industry in Pingyao Ancient City has become increasingly developed, bringing about changes in courtyard functions and alienation of environmental landscapes. Traditional dwellings lack protection systems and financial support, and a large number of traditional dwellings have long lacked maintenance, resulting in poor living conditions. The traditional craftsmanship of restoration also needs to be adapted to modern protection concepts, lacking scientific and technical guidance. As early as 2010, the Global Heritage Fund (GHF) in the United States sponsored a pilot project for residential renovation in Pingyao. At that time, the concept of GHF was to use a courtyard as a model for renovation, providing reference standards and technical guidance for local residents.

The Pingyao County Government promulgated the "Implementation Measures for Financial Subsidies for the Conservation and Restoration of Traditional Residential Buildings in Pingyao Ancient City" in 2012, which was revised, improved, and implemented in 2013. The property owner shall submit an application to the county planning bureau and provide proof of property rights, original photos, restoration drawings, budget and other materials, which shall be reviewed and posted of the public notice by the government before being issued. Supervisors are composed of government deputies to the National People's Congress and members of the Chinese People's Political Consultative Conference, as well as experts, scholars, and social figures who love the protection of ancient cities. At the same time, the "Conservation Management Guidelines for Traditional Courtyard Houses and Environment in the Ancient City of Pingyao " and the " Practical Conservation Guidelines for Traditional Courtyard Houses and Environment in the Ancient City of Pingyao " were jointly initiated by UNESCO and the Pingyao County People's Government. The Shanxi Provincial Department of Housing and Urban Rural Development and Tongji

University jointly began to develop them, providing guidance for government management departments and residents' traditional residential building restoration and protection. (Figure 5) From the completed courtyards, government subsidies can basically account for one-third of the total project cost. On February 28, 2025, the Pingyao County Administrative Approval Service Management Bureau officially approved the "Pingyao Ancient City Historical and Cultural Block Renovation Project", planning to invest over 250 million yuan to inject new vitality into the protection and development of the ancient city. The funding source is 55.9471 million yuan from the county-level finance and 200 million yuan from the central finance application.

3.2.Government led + market participation - Shanghai
3.2.1.Joint layout of courtyard model
Traditional residential buildings in Shanghai, also known as Shikumen Lilong, are a combination of Chinese and Western architectural forms, built by foreign real estate developers or Chinese businessmen. Shikumen Lilong originated during the Shanghai Concession period in the 1870s and was built on a large scale in the 1910-1930s. The Shikumen architecture has the traditional form of a two-story courtyard or quadrangle courtyard in the regions south of the Yangtze River, with an overall layout following the Western style of row houses. (Figure 6-7)

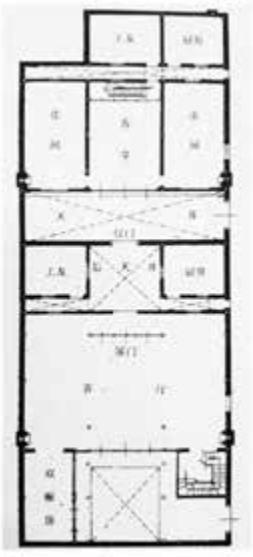

Fig 6. Shikumen Lilong Residences and the urban texture in old Shanghai.
Picture source: Collection of Shanghai History Museum (part of the original picture).

Fig 7. The plan of early Shikumen Hongdeli. Picture source: Qing Chang (2023)

Due to its construction during times of war, the land in the concessions was precious, and the opening and area of Shikumen buildings were greatly reduced compared to traditional residences. In 1949, 3 million people were squeezed into an 82.4km2 urban area. At that time, there were a total of 17.115 million square meters of new and old style lilong buildings in Shanghai, accounting for 72.5% of the total residential area. (Compiled by the Shanghai Residential Construction Chronicles Compilation Committee ,1998).

There are both a small number of high-end villas and mansions in Shikumen Lilong, as well as small courtyard houses in new-style lilong. Most of these high-quality lilong have protected identities and are maintained by the government or property owners. In addition, due to the real estate development method of renting land to build houses in Shanghai at the beginning of the 20th century, with a lease term of only 20-30 years, a large number of low-quality Shikumen residential buildings were also constructed. These residences, which experienced a wave of social movements from the 1950s to the 1970s, often had complex relationships between housing attributes and residency rights, crowded living conditions, inadequate living facilities, and safety hazards. They have long been referred to as "old-style lilong". Due to the lack of identity protection or the ambiguity of identity protection, the preservation of such old houses is often in a state of controversy. By the end of 2000, there were 14.1199 million square meters of old-style lilong in the central urban area of Shanghai center, which had been reduced to 8.13 million square meters in 2017, nearly half of which was secondary old-style lilong. By the end of 2018, there were still 2.38 million square meters of secondary old-style lilong in the central urban area of Shanghai center, with more than 100,000 residents.

3.2.2.Limited Conservation Policy

Faced with the protection and development of traditional residential buildings on such a large scale in Shanghai, as well as such complex historic relics, the principle of "authenticity" in the field of international heritage protection cannot be used for general comparison, because the scarcity of heritage is no longer comparable. (Qing Chang ,2023) Some experts believe that for the Shikumen architectural complex, active protection should be taken, but there is also a degree of protection. Not everything can be protected, and needs to be protected to its original state. When determining the scale, standards, structure, and degree of protection (architectural form, economic format, social ecology), except for cultural relics protection units, the principle of comprehensive authenticity may not necessarily be followed (protection units can only reflect the authenticity at the material level), and specific issues need to be analyzed case by case. (Yong Wan, Jianxiong Ge ,2011)

Since the 1990s, with the rapid development of Shanghai's economy and the soaring of land value and real estate prices, large-scale reconstruction of the old urban areas in the centre of Shanghai has been carried out. Shikumen Lilong is located in the central area of the city, facing the dual pressure of urban functional layout adjustment and land development intensity, which is intensifying. The government led mechanism for the renovation of old urban areas, with market access and "development plot ratio rewards" as its core features, quickly took over the dominant position, and the current social and material spaces began to be completely eliminated. Under the temptation of the real benefits brought by large-scale demolition, the government and market forces directly intervened in large-scale spatial reconstruction, thus forming an urban redevelopment model characterized by "large-scale demolition and construction, separation of people and land". (Gang Liu ,2016) (Figure 8-9)

Fig 8-9. "Xiesan Base" turned into Haihua Garden,1992-1994

On January 25, 1992, Shanghai signed a contract for the first phase of the "Xiesan Base" in Dapuqiao, the first old district renovation site to utilize foreign investment. Two years later, the site was built into a high-rise residential area called Haihua Garden. From then on, land leasing was fully implemented in various districts of Shanghai, marking the beginning of large-scale urban renewal in the city.

Picture source: [Memory of the city] "Xiesan Base"-a milestone in the history of Shanghai's old reform, News and Publicity Center of Shanghai Municipal Commission of Housing and Urban Rural Development

In recent years, the old district renovation model of "large-scale demolition and construction" has become unsustainable, and the concept of "urban renewal" based on stock development has gained more expectations. In 2017, the Shanghai Municipal Party Committee and Government proposed to adjust the renovation method of old districts from "demolition, renovation, and retention, with demolition as the main focus" to "retention, renovation, and demolition, with preservation and conservation as the main focus", and emphasized "allowing the city to retain memories and people to remember their homesickness". The renovation of old buildings in Shanghai has roughly gone through three stages, from "large-scale demolition and construction" to "demolition, renovation, and retention", and then to "retention, renovation, and demolition", with a greater emphasis on the conservation of historical features and urban texture. Due to the high investment and low return ratio of the renovation of old buildings, the government and state-owned enterprises have become the main sources of funding, and the participation of social capital in the renovation is relatively small. Since 2019, Shanghai has gradually explored the old and new system and operation mode of "urban cooperation and government enterprise cooperation", hoping to more effectively attract social capital participation. The new round of old area renovation projects will be implemented through the "housing expropriation" method, with monetary compensation as the main form of expropriation and physical resettlement as a supplement. For historic buildings that require conservation and preservation, renewal and functional reuse will be implemented after the completion of house expropriation, in order to achieve the goal of "people leaving the house and not demolishing it" for historic buildings. (Jingyun Xu, 2023) (Figure 10,11)

Fig 10-11. Zhangyuan before and after renovation,2018-2024

Zhangyuan is the largest and most well preserved representative of the Shikumen architectural complex in Shanghai. Before the protective expropriation of Zhangyuan, about 280 residents living here did not have independent bathrooms in their homes, and the internal space of the building was arbitrarily divided and overloaded. The aging, damage, and destruction of the building were serious, and the residents' desire to improve their living conditions became increasingly strong. In order to improve the quality of life of residents and continue the urban context, the Zhangyuan area will be renovated using the method of "expropriation without demolition", fully preserving the texture of the neighborhoods and alleys. After the expropriation is completed, the historic buildings will be protected, preserved, renovated, and reused according to the planning requirements.

3.3.Government led + Resident autonomy + Market participation - Suzhou

3.3.1.The courtyard model of living by the water

Suzhou has a 2500-years history of city construction, and most of the existing traditional dwellings were built during the late Ming, Qing, and Republic of China periods. The ancient city of Suzhou still maintains a dual chessboard pattern of rivers and streets, and traditional residential buildings mostly reflect the layout characteristics related to rivers. Suzhou residential buildings are often center-courtyard model, with "one-entrance gate courtyard" as the basic unit of residential buildings. Large residential buildings are composed of two to multiple entrance gate courtyards. (Figure 12,13)

In the 1950s, in order to solve the housing problem of residents, public-private partnerships were implemented, and traditional houses in the ancient city of Suzhou were rented out to residents in the form of contracts, with the whole old houses being separated and inhabited. In the 1990s, the permanent population of 142,000 square kilometers living in the ancient city of Suzhou was 342,000. Crowded living, lack of supporting facilities, complex property rights, aging building structures, and damaged building appearances are all challenges to the Conservation and renewal of traditional residential buildings in Suzhou.

Fig 12-13. Typical Traditional Residences in the Ancient City of Suzhou

Traditional Suzhou houses are arranged in groups horizontally or vertically, forming a continuous group of alleyway houses. The overall layout of residential buildings is closely related to the river channel. This high-density layout allows each household to occupy the smallest amount of riverbank and alley sections, compact the land area, and achieve convenient water and land transportation.

Picture source Ancient Charm of Jiangnan - Suzhou Residential Architecture Culture Ancient Architecture in China

At present, there are about 1.95 million square meters of traditional residential buildings in the ancient city of Suzhou, with 43,000 households living in them. In traditional residential buildings, there are approximately 840,000 square meters of private houses and 19,000 households, with an average area of approximately 44.21 square meters per household; Directly managed public housing covers an area of approximately 1.11 million square meters, with around 24,000 households and an average household area of approximately 46.25 square meters per household. Both public and private houses are unable to meet the basic living needs of 60 square meters per household, and many directly managed public houses face difficulties in being fully integrated.

3.3.2."Three Original" Conservation Policy

In the 1980s, Suzhou's economy began to develop rapidly, and urban expansion led to the demolition of traditional dwellings and the reconstruction of modern buildings in the ancient city, resulting in the destruction of the city's appearance. In 1982, Suzhou was listed as one of the first batch of Chinese historic and cultural cities, officially beginning the process of ancient city conservation. In order to maintain the integrity and authenticity of the layout and style of the ancient city, the 1995 Suzhou Urban Planning Regulations proposed that "the urban area of Suzhou should protect the style of the ancient city", explicitly stating that "within the protection scope of the

ancient city, it is not allowed to construct buildings (structures) that do not conform to the style and features of the ancient city". In 2003, the "Measures for the Conservation of Historical and Cultural Cities and Towns in Suzhou City" further refined the regulations, stating that "the form, volume, height, and color of buildings within the protection scope of the ancient city should maintain the inherent characteristics of moderate volume, light shape, elegant color, and especially the white walls and black tiles of Suzhou buildings, reflecting the traditional style of Suzhou ancient city." In 2011, the Suzhou Planning Bureau formulated and issued the "Regulations on the Planning and Management of Private Housing Construction for Residents in Suzhou City," which clarified that the renovation of "dilapidated houses" in traditional residential buildings in the ancient city should maintain the "original area, original height, and original style", abbreviated as the "three original" principle.

Before 1998, the number of approvals for the renovation of traditional residential buildings was about 100 per year. After the promulgation of the "Regulations on the Planning and Management of Private Housing Construction for Residents in Suzhou City", the planning and management of private housing construction for residents has been strengthened, and the number of approvals for traditional residential reconstruction has been reduced to 20-30 per year. After 2020, the number of approvals for traditional residential construction has increased to about 50 per year, and is showing a trend of increasing year by year. On September 1, 2022, Gusu District held a special conference on the participation of social capital in the revitalization and utilization of traditional residential buildings, exploring new paths for introducing social capital to participate in the collection and revitalization of traditional residential property rights, and providing greater strength for the protection and renewal of the ancient city. Whether it is residents' independent reconstruction or the activation and utilization of social capital, the "Three Original" principle is still a rigid principle that cannot be exceeded.

The "Three Original " principle embodies the concept of combining "protection priority" with "organic renewal", by limiting the area and height, thus controlling the development intensity and avoiding excessive high-rise and commercialization of the ancient city; By preserving the texture of streets, courtyards, and architectural styles, the ancient city style has been continued; Under the premise of protection, residents are allowed to carry out modernization of the interior, thereby improving the living environment and balancing the needs of people's livelihood. (Figure 14-15)

Fig 14-15. An example of the renovation of a traditional residential building located on Shantang Street in the ancient city of Suzhou 2024
Picture source: DEKONG STUDIO

This is an independent residential renovation project. The space of the original building has been re planned and the height of the floor slabs has been adjusted. By appropriately staggered levels (ensuring the height

of the main space and reducing the height of the auxiliary space), a new attic space has been obtained. Due to the partial decay of the original roof wooden structure, the entire roof was renovated by adding insulation and waterproof layers. In order to obtain a larger span, steel structures were locally added. The staircase was designed as a hollow staircase and skylights were added, making the staircase a lighting well and solving the problem of insufficient lighting in the original house.

4.Conclusion and Discussion: How to Understand Authenticity in the Chinese Context?

How to understand the "authenticity" of a large number of traditional residential buildings that are in disrepair and lack identity conservation in the contemporary context of China? How to renovate the buildings in traditional Chinese cities, mainly consisting of brick and wood structures, in order to maintain their "authenticity"? Maintaining the materiality and authenticity of traditional architecture is certainly important, but can the continuation of traditional urban functions and sense of place also be understood as maintaining the "authenticity" of historic sites? Looking back at the three historic cities of Pingyao, Shanghai, and Suzhou, Pingyao has adopted a comprehensive protection policy due to the small scale of traditional residential buildings and the relatively intact preservation of courtyards, which are funded and maintained by the government; Due to the large scale and varying quality of traditional Shikumen Lilong in Shanghai, a limited protection strategy has been chosen to preserve some of the Lilong; The scale of traditional residential buildings in Suzhou is in the middle, and the ancient city's water and land double chessboard pattern has been well preserved for thousands of years. Therefore, the "Three Original" principle of "small-scale gradual" preservation of urban texture and allowing residents who meet regulations to rebuild independently has been adopted. Table.1

Tab.1 Comparison of the Conservation of Traditional Residences in Pingyao, Shanghai, and Suzhou

	Traditional Residences in Pingyao	Traditional Residences in Shanghai	Traditional Residences in Suzhou
Construction History	During the Ming and Qing dynasties	From the late Qing Dynasty to the Republic of China period	From the late Ming Dynasty to the Republic of China period
Construction scale	The ancient city covers an area of 2.25 k and has nearly 4,000 traditional residential courtyards	In 1949, 3 million people were crowded within an 82.4k area of Shanghai's urban area, with a total of 17.115 million square meters of Shikumen Lilong and residential buildings. In 2017, the area decreased to approximately 8.13 million square meters	The ancient city of Suzhou covers an area of 14.2 k and has approximately 1.95 million square meters of traditional residential buildings, with 43,000 households living in it
Is it a World Heritage City	Listed in 1997	no	Suzhou Gardens as a World Cultural Heritage Site (1997, 2000)
Is it a historic and cultural city	Second batch (1986)	Second batch (1986)	First batch (1982)
Real estate prices	¥5,000-7,000 /square meter	About ¥120,000 /square meter in the central urban area	About ¥26,000 /square meter in Gusu District
Government conservation tendency	Comprehensive conservation policy	Limited conservation policy	"Three Original" conservation policy
Market participation situation	Less	More	Medium
Residents' willingness	Repair after applying for government subsidies	Looking forward to receiving the demolition compensation after the government's unified expropriation*	Prefer to rebuild or construct independently
Expert advice	Continue the "authenticity" of the World Cultural Heritage	Question the damage to "authenticity" caused by the early government's "large-scale demolition and construction" and the current "gentrification" process	Hoping that the government will introduce policies to encourage residents to carry out self-repair instead of reconstruction, so as to maintain the "authenticity" as much as possible.
Present situation	Keep almost completely	Collage-style retention	Continue the texture and style of the ancient city

Table source: Drawn by the author of this article

* If residents choose to stay, they can enjoy the potential appreciation of the house in the future after its restoration, but it also means they still have to live in the old house and continue to endure various inconveniences. However, by choosing to leave, residents can directly vacate their old houses. This not only enables them to get rid of the poor living conditions as quickly as possible, but also allows them to immediately obtain the benefits of expropriation and relocation, or by purchasing and exchanging for new houses, they can gain the potential appreciation of their properties in the future. Many people are not averse to lilong life, but under the influence of opportunity cost, they still choose to leave. (Jing Yu, 2024)

Regardless of the principle of protection, the attitude, function, and role of the government in preserving or rebuilding traditional dwellings are highly noteworthy. In addition to considering the continuation of traditional culture and the preservation of cultural memory, the government also needs to take into account economic benefits such as tourism consumption income, economic benefits from reconstruction, and the cost of demolition and resettlement for residents. The higher the land prices in historic urban areas, the more inclined the local government is to promote the reconstruction of traditional dwellings, and the more motivated market capital is to participate; For residents, this often means that they can receive a large amount of compensation for

demolition and substantial improvement in their living conditions (except for the unfavorable factor of needing to leave the city center); Heritage conservation experts are more inclined to restore and preserve traditional dwellings, opposing the "gentrification" process of historic urban areas and calling for the preservation of the material and spiritual "authenticity" of traditional dwellings. However, reality is often complex. As the number of traditional dwellings that can be preserved has greatly decreased, the overall trend in various historic cities is to prioritize protection over reconstruction (small-scale autonomous reconstruction, or government and market forces led demolition and reconstruction). After all, these cultural memories representing a nation should not be roughly erased.

Abstract
As spatial manifestations of human–environment relationships, traditional village landscapes are increasingly challenged by industrialization, urbanization, and globalization. This study focuses on the southern Taihang Mountains in China and applies a cultural ecology approach to construct a process-oriented model of settlement evolution. It systematically analyzes how agrarian culture shapes spatial forms across technological, institutional, cognitive, and practical dimensions, and reveals the transformation of settlements from ecological adaptation to spatial reconstruction under external disturbances. Integrating Holling's adaptive cycle theory, the research delineates four evolutionary stages of traditional settlements and employs network analysis to build a cultural ecosystem network, highlighting mechanisms of multi-scalar spatial restructuring. Based on this, a holistic protection strategy is proposed—from node activation and cluster coordination to regional network optimization. The study offers theoretical support for the dynamic reintegration and systemic revitalization of traditional settlements in the southern Taihang region, while providing a reference framework for adaptive protection of cultural landscapes globally.

Keywords Traditional Settlement Landscapes; Cultural Ecology; Evolutionary Mechanisms; Southern Taihang; China

Introduction

As a fundamental material basis of human civilisation, villages serve an irreplaceable function in preserving historical memory and transmitting cultural heritage-Barrientos et al.,2021-. Nevertheless, the rapid advancement of industrialisation and urbanisation, alongside profound socio-economic transformations, has posed significant challenges to rural settlements globally, manifesting in depopulation, functional decline, and even the complete disappearance of some villages-Mu and Aimar, 2022; Li, Westlund and Liu, 2019-. In the context of China's rural revitalisation strategy, traditional villages constitute a critical spatial unit. They not only facilitate the modernisation of rural areas and enhance the living standards of local populations but also play a pivotal role in sustaining regional cultural identity and ensuring social cohesion.Since the initiation of systematic protection efforts in 2012, China has implemented a six-phase listing programme (2012–2023), encompassing 8,155 traditional villages and thereby establishing the most comprehensive agricultural heritage conservation framework globally -Cheng et al., 2024-. Furthermore, starting in 2020, the Ministry of Finance and the Ministry of Housing and Urban-Rural Development have successively promulgated the Model Work Programme for the Intensive and Continuous Conservation and Utilisation of Traditional Villages. This initiative targets persistent issues such as spatial homogenisation and limited revitalisation pathways in traditional village development -Zhao et al., 2024-.Against this backdrop, an in-depth exploration of the spatial characteristics and generative mechanisms of regional traditional villages has become essential. Such inquiry is vital for addressing the fragmentation in current conservation practices, unlocking cultural and ecological potentials, and advancing both theoretical understanding and practical implementation of holistic settlement preservation and cultural system reconstruction.

Research on the spatial morphology of traditional settlements has undergone a progressive evolution of theoretical paradigms, gradually forming a composite explanatory system that integrates natural, social, and cultural dimensions. In its early stages, the dominant perspective was functionalism, which highlighted the interdependence between settlements and natural geographical conditions, yet largely overlooked cultural and institutional dynamics -Li and Zhang, 2012-. Later, central place theory introduced a hierarchical logic of settlement distribution and functions, advancing the modelling of spatial systems -Hill, 2003; Pacione, 1984-. Concurrently, cultural landscape theory underscored the notion that spatial forms are shaped by cultural choices, thereby integrating cultural behaviours into spatial analysis-Sauer, 2008-.Within the structuralist tradition, Rossi's theory of architectural typology interpreted settlements as material representations of collective social cognition -Rossi, 1984-, while Hillel's spatial syntax elucidated the organisational logic of space and human behaviour through topological structures-Yamu, Van Nes and Garau, 2021-. In recent years, interdisciplinary approaches have gained

prominence, fostering closer integration between theoretical inquiry and practical application. However, most existing studies still lack a systematic framework capable of explaining the dynamic generative mechanisms behind settlement morphology, particularly those shaped by long-term interactions among ecological, cultural, and institutional forces.To address these limitations, this paper introduces the theoretical perspective of the cultural ecosystem and proposes a four-dimensional analytical framework encompassing: technology–ecology, cognition–concept, organisation–institution, and practice–strategy. This approach aims to overcome the current fragmentation and unidirectional interpretations in traditional settlement research, offering a more holistic understanding of their spatial evolution.

As scholarly inquiry deepens, empirical research on the spatial morphology of traditional settlements has gradually matured across several dimensions, including research subjects, scale frameworks, analytical methods, and variable construction. A foundational analytical pathway has emerged, characterised by the sequence of "pattern identification – typological classification – factor analysis." Most existing studies concentrate on nationally recognised villages or prominent regional cases -Liu et al., 2022-, such as Guizhou Province -Yan et al., 2021- and ethnic minority areas-Chen, Xiao and Liu, 2024-. While such research has elucidated macro-level distribution patterns, it tends to overlook marginal regions and atypical cases, thereby constraining the generalisability and applicability of findings.In terms of scale, a widely adopted three-tier analytical framework—macro, meso, and micro—is typically employed, corresponding to spatial distribution evolution, typological differentiation, and intra-settlement structural analysis, respectively-Lin, Liang and Liu, 2024-. Common methods include kernel density estimation-Bi et al., 2024-, cluster analysis, and space syntax modelling-Qin et al., 2023-. With regard to variable construction, most indicators are derived from natural, social, cultural, and institutional dimensions. However, the analytical techniques employed are predominantly linear, such as regression analysis and structural equation modelling-Yuan et al., 2024-, which often fail to capture the complex nonlinear interactions and coupling mechanisms among variables.Despite notable progress, current research continues to exhibit limitations, including inadequate identification of spatial phenomena and insufficient integration of cultural-ecological dimensions. Moving forward, it is essential to optimise indicator systems and refine analytical approaches under robust theoretical guidance, in order to achieve a more systematic and comprehensive understanding of the evolutionary mechanisms underpinning the spatial morphology of traditional settlements.

Situated within the transitional geographic zone between the Central Plains and North China, the South Taihang region represents a typical mountainous and hilly terrain bridging the eastern edge of the Loess Plateau and the North China Plain. Characterised by its fragmented topography and ecological diversity, the region has nurtured a wide spectrum of traditional settlement forms. Embedded within this landscape is a convergence of diverse cultural lineages, including agrarian traditions, mountain-based defence systems, and nomadic frontier influences. These have collectively shaped distinctive village morphologies—such as fortress-type, trade route-based, and mountain-adapted settlements—rendering the region highly representative and of considerable academic interest.In recent years, however, the acceleration of urbanisation and the deepening reconstruction of rural spatial structures have triggered profound transformations in these traditional settlements. Their embedded cultural and ecological frameworks are experiencing significant disruption, thereby necessitating timely institutional responses to safeguard their evolutionary continuity and guide appropriate conservation strategies.

Accordingly, this study pursues two primary research objectives: (1) to elucidate the historical trajectories and spatial evolution patterns of traditional settlements in the South Taihang region; and (2) to develop a protection and reconstruction pathway grounded in the cultural ecosystem perspective. Through this, the study seeks to offer a theoretical foundation and strategic guidance for the systematic conservation of traditional settlements in complex mountainous landscapes.

Research Methods

Overview of the Study Area

The Taihang Mountains extend through central North China, with the South Taihang section located in Henan Province, spanning approximately 150 kilometres from north to south. This region is predominantly mountainous and hilly, and it hosts a rich array of traditional villages whose residential and architectural forms exhibit pronounced mountainous settlement characteristics-Duan et al., 2023-. However, the rapid pace of urbanisation and tourism development has resulted in the hollowing out and commodification of many villages. Concurrently,

land use transformations and ecological degradation have posed severe threats to their sustainable development. Existing conservation efforts tend to concentrate on individual villages, often overlooking broader regional dynamics, including inter-village interactions, resource flows, and spatial functions.To address this gap, the present study selects 43 representative traditional villages—each recognised at or above the provincial level—located in the South Taihang mountainous region as the research sample (Fig. 1). These villages are characterised by long-standing histories, relatively intact preservation, and high cultural landscape value.

Fig. 1 Map of the study area of South Taihang in northern Henan Province

Data Sources

The data utilised in this study were derived from multiple authoritative sources to ensure comprehensiveness and reliability. Geographic information, including 30×30 m resolution digital elevation model (DEM) data, was obtained from the China Geospatial Data Cloud Platform (http://www.gscloud.cn/). Administrative boundary data at the provincial, municipal, county, and village levels were sourced from the Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences (http://www.igsnrr.ac.cn/). Official lists of traditional villages were acquired from the Ministry of Housing and Urban-Rural Development of China and the Henan Provincial Department of Housing and Urban-Rural Development. GDP and population statistics were also retrieved from the Institute of Geographic Sciences and Natural Resources Research. Cultural heritage data were collected from the Ministry of Culture and Tourism of the People's Republic of China (https://www.mct.gov.cn/) and the Henan Provincial Cultural Relics Bureau (http://wwj.henan.gov.cn/). Additionally, Point of Interest (POI) data, along with information on the shortest travel time and distance between locations, were obtained from the Gaode Open Platform (https://lbs.amap.com/). To complement these secondary sources, field investigations were conducted to collect primary data on village profiles, infrastructure, architectural characteristics, as well as population and economic conditions.

Analysis Framework and Research Ideas

Evolutionary Mechanism Model of the Cultural Ecosystem in Traditional Villages

Traditional settlements are not merely historical accumulations of material space; they also represent the evolving outcomes of cultural ecosystems shaped by the dynamic interplay between natural, social, and cultural forces. Drawing on the principles of cultural ecology, human societies have developed a "culture-driven core" under resource constraints and institutional regulation, from which three major cultural dimensions—material, institutional, and spiritual—have emerged-Chen, Xie and Li, 2020; Shao, Cui and Zhang, 2024-(Fig. 2). These dimensions are systematically translated into spatial expressions through four structural levels: technology–ecology, organisation–institution, cognition–concept, and practice–strategy, forming the intrinsic mechanism underlying the spatial evolution of settlements.

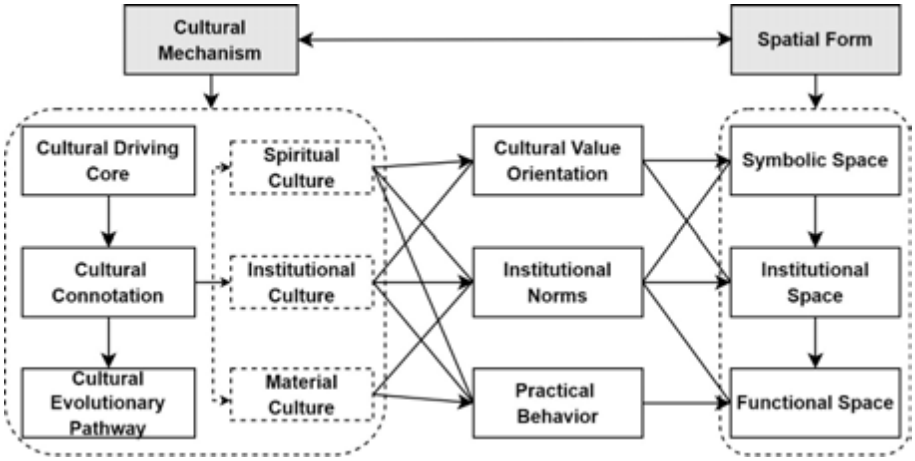

Fig. 2 Conceptual Framework of Cultural Mechanisms Driving the Formation of Spatial Forms in Traditional Settlements

To capture the temporal dynamics of this evolution, this study adopts Holling's adaptive cycle theory-Holling, 2001-, which conceptualises evolution in four phases: exploration, conservation, release, and reorganisation. This framework reveals how the culture-driven core undergoes phases of stabilisation, disintegration, and restructuring. Spatially, this process is embodied in a nested path of "culture-driven core—cultural connotation—spatial representation", leading to the construction of a three-tiered spatial network comprising nodes, clusters, and regions. This tripartite structure spans macro-regional scales, meso-level agglomerations, and micro-level settlement nodes. Overall, the proposed mechanism model demonstrates that cultural ecological spaces evolve through a dynamic process of variation–adaptation–integration, driven by self-organisation and network coupling under multiple external disturbances.

Construction of the Cultural Ecological Network of Traditional Villages

To uncover the patterns of cultural-spatial interaction among traditional villages in the South Tai hang region of northern Henan, this study constructs a cultural ecological network system. This system integrates cultural development indicators, applies the gravity model as its analytical logic, and employs social network analysis (SNA) as its methodological tool. First, a set of 16 specific indicators was developed across five criteria: historical and locational background, tangible and intangible cultural heritage, infrastructure, industrial activity, and economic status-Wang et al., 2023-, aiming to comprehensively assess the cultural development level of each village. These indicators were standardised using the extreme deviation method, and weighted through the entropy method-Chen, Zhong and Li, 2023-, yielding a composite cultural development score ranging from 0 to 1. This score serves as a proxy for the village's cultural attractiveness. Next, the traditional gravity model-Wang et al., 2025- was modified to incorporate both the composite cultural development scores and the shortest travel time between villages, thereby quantifying the intensity of cultural-spatial linkages. Based on this, a spatial cultural ecological network was established. Finally, SNA was employed to analyse the centrality of network nodes, the overall network topology, and to explore patterns of core–periphery differentiation, cohesive subgroups, and mechanisms of spatial interaction -Liu, Hao and Xia, 2024-.

Results

Stages in the Evolution of the Cultural Ecosystem of Traditional Villages

Agricultural Inception: The 'Livelihood–Adaptation' Phase of the Cultural Ecosystem

During the Ming and Qing Dynasties, traditional villages in northern Henan began to emerge and gradually coalesced into stable settlement systems. This period marked the initial formation of a cultural ecosystem grounded in agriculture as the primary mode of subsistence and ecological adaptation as the core dynamic. Although the spatial scale of these villages remained limited and their internal structures relatively loose, the foundational coupling of people–land–culture began to take shape. In response to challenges such as frequent Yellow River flooding, cold and arid climatic conditions, and scarcity of arable land, early settlers gradually constructed a preliminary yet stable cultural ecosystem. This was achieved through livelihood-based adaptation, conceptual reconstruction, organisational experimentation, and practical accumulation, laying a critical foundation for the

institutionalisation and networked evolution of traditional settlements.

Deconstructing the Intrinsic Mechanism: Origin and Adaptive Logic of the Cultural Ecosystem

In the formative stage of cultural ecosystem development, traditional agrarian settlements in northern Henan demonstrated a spatial logic rooted in livelihood adaptation.At the technology–ecology level, villages were typically situated along the seasonal water belts at the margins of the Yellow River alluvial fan. These locations enabled the construction of ridge-and-border farming systems well-suited to dryland agriculture. Productivity was enhanced through the use of agricultural tools such as waterwheels and ploughs, and small-scale settlements were spatially distributed according to topographic features.At the cognition–concept level, cultural consciousness was shaped by reverence for natural forces and adherence to agricultural seasonality. Symbolic spaces—such as land shrines and communal temples—emerged as centres of collective belief and practice, embodying the villagers' perceptual and spatial responses to ecological rhythms.

At the organisation–institution level, early village life was governed primarily by neighbourly cooperation and customary norms, with formal clan systems still in embryonic form. Nonetheless, the emergence of ancestral halls and sacrificial fields signalled the nascent development of institutional frameworks for communal organisation.At the practice–strategy level, villagers adopted a diversified risk-coping strategy involving small-scale mixed farming, crop rotation, and household-based handicrafts. They enhanced settlement resilience through cooperative practices such as ditch construction, flood control, and collective labour mobilisation. Simultaneously, early forms of interaction with local administrative structures were established, initiating the villages' gradual integration into broader regional governance networks.

Together, these four structural mechanisms—technological, cognitive, institutional, and strategic—constituted the spatial and functional basis of the early cultural ecosystem, establishing the point of departure for the sustained evolution of traditional settlements in northern Henan.

Spatial Representation: Prototypical Construction of Agricultural Settlements and Ecological Dependency Structures

In the early stages of development, agrarian settlements in northern Henan were predominantly situated along natural water systems—rivers, canals, shallow floodplains, and wells—forming a distinct ecological dependency structure that integrated agricultural production and daily living within a unified spatial context. These villages were generally small in scale, with vague or fluid boundaries, and the layout of dwellings reflected a terrain-responsive logic: houses were scattered based on topographical conditions, forming a proto-structural pattern centred around nuclear families, with miniature plots of farmland encircling the residential core.At this stage, internal functional zoning remained rudimentary, and the spatial structure was largely defined by a few critical nodes. Elements such as land shrines and wells served multifunctional roles, acting as centres for communal gathering, ritual worship, and local trade. The residential form was characterised by compact courtyard-style housing, where living and productive activities were highly integrated (Fig. 3), reflecting the underlying spatial principle of "life as livelihood."

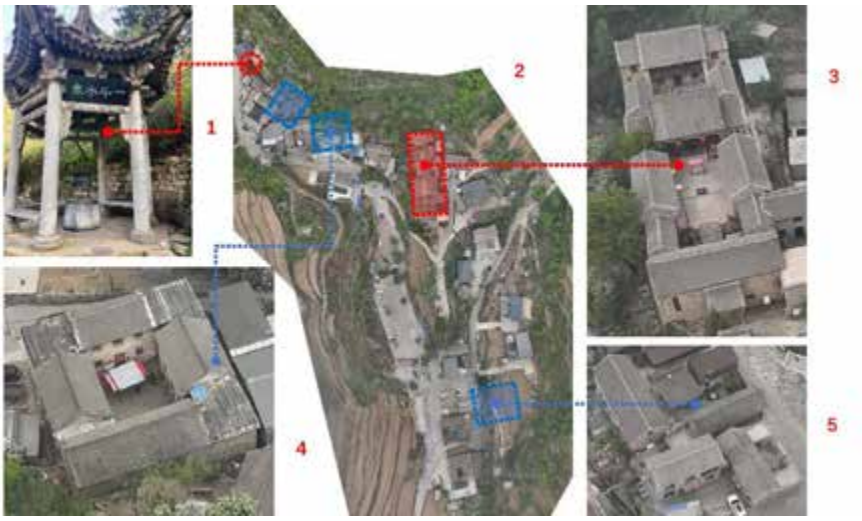

Fig. 3 Spatial features of Yidoushui Village in the 'Livelihood–Adaptation' phase of the cultural ecosystem: (1) the ancient spring well that served as the origin of settlement; (2) aerial view of the current village layout; (3) Guandi Temple, a spiritual and institutional cultural core; (4) courtyard dwellings providing commercial services during the early stage of development; (5) representative enclosed courtyards adapted for early trade and residence.

With the gradual stabilisation of agricultural cycles and the emergence of rudimentary institutional interventions, certain villages began to exhibit axial symmetry and defined residential base boundaries, marking a shift towards more organised spatial order. Simultaneously, the path system evolved into a functional network that linked residences, farmlands, and water sources—a configuration here referred to as the "house–field–water" network. This spatial transformation signified a critical transition from settlements based purely on ecological adaptation to those shaped by cultural organisation, thereby laying the structural groundwork for the subsequent institutionalisation and networked evolution of the traditional settlement system.

Agricultural Heyday: The 'Stabilisation–Adaptation' Phase of the Cultural Ecosystem

During the agricultural heyday, the advancement of agricultural technologies in northern Henan significantly enhanced human–land relations, ushering traditional villages into a phase of stabilisation-oriented evolution within the cultural ecosystem. In this stage, ecological constraints were no longer the primary limiting factors. Instead, cultural, institutional, and social dynamics emerged as the dominant shaping forces, steering the evolution of village spatial structures toward systematic organisation, functional differentiation, and networked synergy.

Deconstruction of Intrinsic Mechanism: Multi-Layered Homeostatic Synergy in Agrarian Cultural Ecosystems

At the technology–ecology level, northern Henan's geographic position—spanning both plains and hills—provided a favourable foundation for dry farming. From the Ming and Qing Dynasties onward, the widespread adoption of agricultural tools such as ploughs and waterwheels, coupled with improvements in water conservancy infrastructure, led to the development of an integrated "field–village–road" system. This structure linked irrigation networks with tributary channels, effectively boosting agricultural productivity and enhancing the external connectivity of settlements.At the cognition–concept level, ancestral halls and family temples became the spiritual and spatial axes of the village. The Confucian ideology of ritual-based governance) became deeply embedded in land allocation, residential spatial arrangements, and settlement planning. Ethical values centred on filial piety and ancestor reverence reinforced spatial hierarchies within the settlement and fostered the stable evolution of axial and enclosed spatial layouts.

At the organisation–institution level, village covenants, ancestral codes, and clan regulations—driven by lineage-based governance—effectively maintained collective order. Systems of centralised land management and collaborative farming strengthened the endogenous governance capacity of the village. Moreover, the nested interaction between formal administrative institutions (e.g., the bailiwick system) and informal clan

self-organisation provided a high degree of institutional resilience and governance flexibility.At the practice–strategy level, daily activities remained highly synchronised with agricultural seasonal cycles. Interactions across seasons, the establishment of market trading hubs, and the development of regional road networks promoted functional connectivity between villages. Additionally, Qing Dynasty rural policies—such as the establishment of marketplaces, patrolling mechanisms, and inspection systems—contributed to the institutionalisation of spatial nodes and facilitated the construction of inter-village cooperative networks.

Spatial Representation: Network Structure of Farming Villages under Institutional Embeddedness and Functional Synergy

The synergy of multi-level cultural ecosystem mechanisms during the agricultural heyday is spatially manifested in farming settlements characterised by systematic organisation, functional clarity, and enhanced network connectivity. Village layouts were typically centred around arable land and water resources, forming a spatially cohesive "cultivation–residence–ancestral shrine" structure. Within these settlements, the ancestral hall functioned as the spiritual and symbolic core, around which residential zones were organised—reflecting a spatial logic founded on the trinity of land, kinship, and faith (land–family–belief).Beyond the settlement core, roads, canals, and market access routes facilitated the construction of a rural spatial network linking adjacent villages. The implementation of market-day systems introduced a regular rhythm to local socio-economic life, transforming marketplaces into intermediary nodes for both economic exchange and cultural interaction. This system encouraged the evolution of villages from isolated spatial units into a networked and coordinated rural system, defined by multi-layered interactions and cooperative functions.

Overall, the spatial morphology of farming villages in this phase reflects the organic integration of natural, institutional, and cultural elements within a stabilisation-dominated cultural ecosystem. This period is marked by the typical features of institutional embeddedness, functional complementarity, and spatial hierarchy (Fig. 4). The resulting spatial network not only enhanced the resilience and adaptability of the settlement system but also laid a robust foundation for the future development of regional collaboration and cultural integration.

Fig. 4 Spatial Characteristics of Beizhu Village in the 'Stabilisation–Adaptation' Phase of the Cultural Ecosystem: (1) Village master plan with old village boundary (blue dashed line); (2) Bird's-eye view of fortress-like courtyard houses; (3) Clan ancestral hall as the core of spiritual and institutional culture; (4) Enclosed traditional courtyard with defensive spatial layout; (5) Main entrance and façade of a preserved residential courtyard.

Agricultural Decline: The 'Disturbance–Imbalance' Stage of the Cultural Ecosystem

Since the 20th century, driven by rapid industrialisation, urbanisation, and population mobility, the cultural ecosystem of traditional farming villages in northern Henan has entered a phase of "disturbance–imbalance". The core of cultural motivation has been severely disrupted, institutional mechanisms have disintegrated, spiritual order has collapsed, and the once-stable system has undergone fragmentation. This stage is marked by

structural dispersion and a marked weakening of spatial functionality.

Deconstruction of the Internal Mechanism: Systemic Imbalance in Traditional Cultural Ecosystems

At the technology–ecology level, the traditional agricultural system—once aligned with natural seasonal rhythms—has been supplanted by modern agricultural practices. While mechanisation and the use of chemical fertilisers and pesticides have increased productivity, they have also contributed to the degradation of soil and water resources, destabilising the ecological foundation. A significant portion of farmland has been abandoned, converted to non-agricultural uses, or left fallow, resulting in its redefinition as an inefficient and fragmented resource field.At the cognition–concept level, the societal shift toward urban employment has rendered the farming profession increasingly unattractive. Traditional cultural values such as "honour through cultivation and scholarship" and "ancestral reverence and filial piety" have weakened, leading to the erosion of cultural identity structures. The once-vibrant practices of faith-based rituals, seasonal festivals, and ancestral worship have faded, plunging village spiritual life into a state of low identification and low participation.

At the organisation–institution level, the introduction of the household contract responsibility system has restructured land-use relations, diminishing intra-village cooperation and weakening clan-based collaborative networks. Ancestral codes, clan regulations, and other traditional governance frameworks have largely become symbolic or obsolete. Grassroots village administration often persists in form but lacks substance, with governance systems existing without cultural legitimacy or communal recognition—a condition encapsulated in the notion of "the system is present, but the identity is absent."At the practice–strategy level, the collapse of seasonal agricultural rhythms and collective living practices has led to the decline of community rituals, such as temple fairs, neighbourly assistance, and village markets. The simultaneous outmigration of younger populations and aging-in-place of the elderly has critically undermined local organisational capacity. As a result, traditional settlements are increasingly reduced to spatial containers of low-frequency use, wherein everyday life becomes decoupled from spatial form, and the functional meaning of space deteriorates into obsolescence.

Spatial Characterisation: Decoupled Variation and Dysfunction of Settlement Structure

The collapse of cultural and ecological mechanisms is spatially reflected through significant distortions at three interrelated levels:First, the failure of ecological adaptation systems has led to the de-agriculturalisation of village peripheries. Farmland surrounding settlements has been increasingly abandoned, built upon, or repurposed for rental uses. These processes have disrupted the traditional "cultivation–residence–irrigation" spatial configuration, resulting in the blurring of settlement boundaries and fragmentation of functional zoning. Second, the degradation of symbolic cultural spaces has accelerated. Traditional spiritual landmarks—such as ancestral halls, temples, and sacrificial platforms—have lost their communal functions, becoming abandoned, repurposed, or neglected. These symbolic spatial nodes, once central to collective identity, have become cultural voids. Ancestral residences and study halls have been converted into storage sheds and barns, while public spaces have lost their ritualistic and integrative functions, transforming from centres of cultural life into static physical remnants.Third, the institutional spatial order has undergone disintegration. Unregulated housing expansion, ambiguous residential boundaries, and the juxtaposition of old and new structures have disrupted previously coherent axial or enclosed layouts. Former institutional nodes—such as council halls, well platforms, and clan assembly spaces—have lost their governance and symbolic roles. The result is a transformation from an orderly and synergistic spatial system to one marked by de-nucleation, decentralisation, and spatial disintegration.

Additionally, the collapse of communal living practices has further hollowed out the spatial vitality of traditional settlements. Streets and alleys lie deserted, public spaces remain unused, and the overall frequency of spatial engagement is extremely low. The proliferation of roadside construction, oriented with houses "facing away" from communal space, has produced a "back-to-the-road" layout, emblematic of spatial disengagement. Consequently, traditional settlements have fallen into functional silence, with a complete rupture in the cultural life network.In summary, the spatial pattern of settlements at this stage is characterised by structural fragmentation, functional dislocation, and cultural degradation (Fig. 5). These patterns reveal the disintegration logic of the cultural ecosystem in conditions of systemic imbalance, offering critical insights into the spatial evolution trajectory and mechanisms underlying rural decline.

Fig. 5 Spatial characteristics of traditional villages during the 'Disturbance–Imbalance' stage of the cultural ecosystem:(1) Overall spatial layout of Hankou Village: the core traditional settlement area (red dashed boundary) shows a dense and organically grown morphology with curved paths and compact buildings, contrasting sharply with the surrounding grid-like new development zones;(2) Aerial view of the core traditional zone in Hankou, showing decaying buildings and landscape disintegration;(3) Overall spatial pattern of Huanghou Village: buildings with dark roofs indicate preserved traditional houses, while blue roofs mark updated or reconstructed structures;(4) Aerial view of the inner central courtyard cluster in Huanghou, illustrating enclosed residential morphology;(5) Aerial view of edge-zone dwellings in Huanghou, representing transitional spaces undergoing functional and morphological fragmentation.

Eco-Capital Transformation: The 'Integration–Regeneration' Stage of Cultural Ecosystems

Following prolonged phases of institutional disintegration, population outflow, and functional decay, certain traditional villages in northern Henan have begun to explore new mechanisms for reconstructing their cultural ecosystems through the lens of eco-capital transformation. Distinct from earlier phases that relied primarily on endogenous resilience and passive recovery, this stage is driven by an integrated dynamic of ecological value recognition, institutional reshaping, cognitive renewal, and behavioural reactivation. Together, these four dimensions enable the simultaneous regeneration of both cultural systems and spatial structures.

Reconstruction of Intrinsic Mechanism: Pluralistic Activation of the Cultural System under the Logic of Ecological Capital

At the technology–ecology level, village ecological assets—including arable land, forests, mountains, water bodies, and courtyards—have been systematically evaluated and incorporated into a "resource–asset–capital–product" transformation chain. This is realised through digital mapping and suitability assessments, which facilitate the spatial integration of these assets into new development platforms such as "pastoral complex zones" and "eco-cultural tourism districts", enabling a shift from traditional agricultural spaces to composite ecological production landscapes.At the cognition–concept level, ecological resources have been reinterpreted as both "green wealth" and "cultural imagery." Through strategic mechanisms such as "nostalgia narratives" and "rural aesthetics", villages construct renewed cultural identities grounded in ecological memory and cultural symbolism. Spatially, this shift is embodied in the emergence of new cultural nodes, including agricultural heritage schools, festival plazas, and eco-exhibition halls, which enhance cultural attractiveness and reinforce a localized sense of place.

At the organisation–institution level, the implementation of land and resource rights confirmation reforms has clarified the ownership and usage boundaries of key ecological resources, such as mountains, forests, and waterways. This has laid the foundation for multi-party collaborative governance mechanisms, involving villages, communities, governmental entities, and private capital. Spatial governance has evolved from traditional self-organising models to platform-based, networked coordination, with newly delineated functional zones for culture, education, habitation, and ecological industry.At the practice–strategy level, villagers are no longer solely cultivators, but have transformed into "ecological stewards." Their daily practices now include eco-agriculture,

cultural tourism, community festivals, and participatory initiatives, forming an integrated "ecology + culture + participation" model of community life. In this transition, the village is redefined from a static residential unit into a dynamic cultural production and experiential space, simultaneously supporting ecological sustainability and cultural regeneration.

Reorganisation of Spatial Structure: A Mechanism for the Re-Scenarioisation of Settlements Driven by Ecological Value

Driven by the logic of ecological capital, the spatial structure of traditional villages has undergone a significant transformation, shifting from a single-function agricultural landscape to a multifunctional and synergistic spatial system. Former agricultural spaces have been reorganised into diversified zones, including ecological corridors, cultural districts, and shared public nodes, promoting the evolution of settlements towards forms characterised by block-based synergy and structural clarity. Cultural imagery and institutional networks are deeply embedded within these reorganised spaces, while everyday practices such as ecological farming, cultural tourism, and communal events revitalise spatial functions. This transformation generates a new spatial logic comprising three interrelated dimensions: platform-based governance operations, cultural expression as a symbolic axis, and scenario-based participation as a mechanism for community engagement. Overall, this phase reflects the trajectory of the cultural ecosystem through a process of system imbalance, structural reorganisation, and mechanism regeneration. It marks a critical shift from elemental dispersion to functional integration, achieving the dual transformation of spatial functionality and cultural revitalization (Fig. 6). By embedding ecological values into both material and symbolic space, this stage offers a practical paradigm for the holistic protection, adaptive reuse, and sustainable regeneration of traditional settlements.

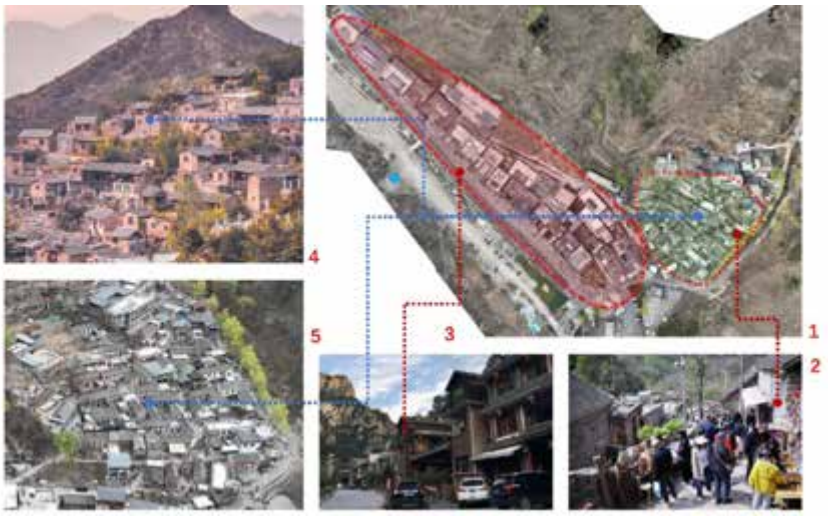

Fig. 6 Spatial reconstruction of Guoliang Village under the logic of cultural ecological capital activation: (1) current spatial layout, with the red strip representing newly developed areas and the green zone indicating the historical village core; (2) commercial landscape and streetscape in the traditional area; (3) newly constructed commercial street zone; (4) historical architectural form during the mature stage of village development; (5) current internal spatial transformation within the traditional village.

Characteristic analysis of traditional village cultural and ecological network structure

Characteristics of Network Individual Levels

Analysis of the cultural and ecological network structure of traditional villages reveals distinct patterns at the individual node level. Degree centrality results indicate that villages such as Xixiangping, Shijiagou, Wangjiatan, and Shuangmiao occupy central positions within the network (Fig. 7), with degree values significantly above the mean. These nodes demonstrate strong capacities for regional coordination and resource diffusion, functioning as key hubs. In contrast, villages such as Judeo and Lihe exhibit low degree centrality, signifying weak spatial connectivity and marginal positions within the network—factors that impede the overall network's cohesion and integrative potential.In terms of closeness centrality, villages like Xideng, Hankou, and Shijiagou possess high levels of accessibility, allowing them to quickly interact with other nodes. Their strategic spatial locations position

them as critical service hubs and network actors within the broader regional structure. Conversely, villages such as Xianmagou and Wenpo are characterised by low closeness centrality, reflecting their relative spatial isolation and reduced influence.

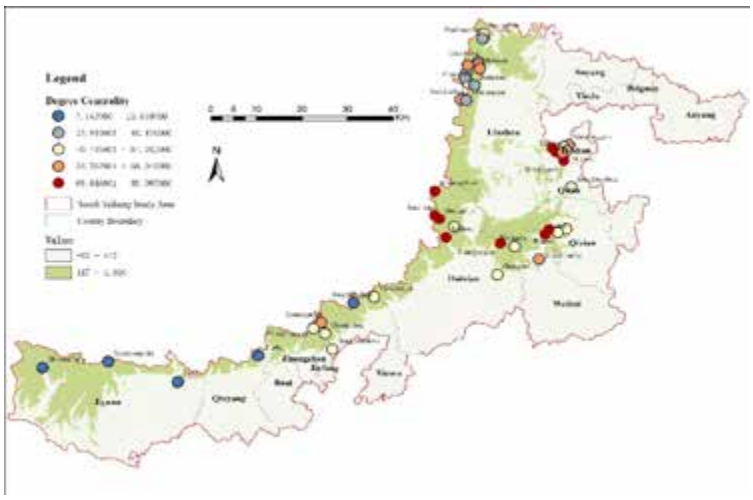

Fig. 7 Spatial Distribution of Degree Centrality of Traditional Villages in the Southern Taihang Region

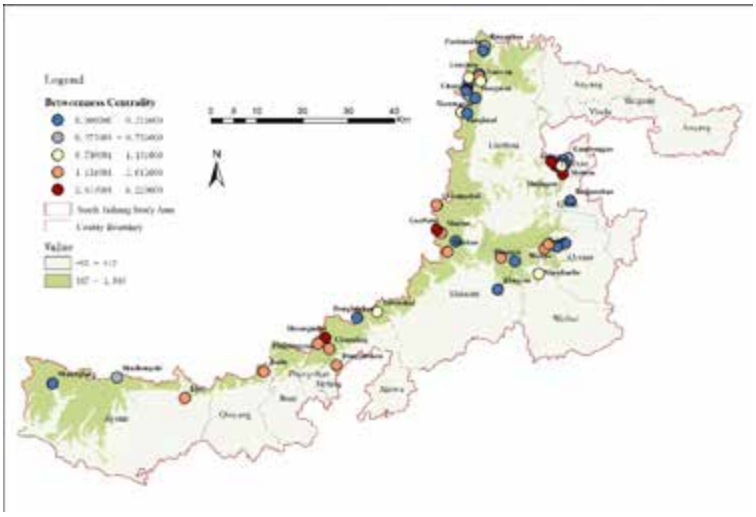

Fig. 8 Spatial Distribution of Betweenness Centrality of Traditional Villages in the Southern Taihang Region

Further, betweenness centrality analysis reveals that approximately 39.5% of villages function as bridges or intermediaries within the network, predominantly located in the central and southern subregions. These nodes exhibit strong capabilities in pathway control and resource intermediation, facilitating inter-cluster flow of information and functions. However, a subset of villages exhibits zero betweenness centrality, indicating a lack of transit or brokerage function, which restricts their role in fostering collaborative development and undermines network efficiency.Collectively, the traditional village network in the South Taihang region displays a multi-core spatial structure, characterised by core–periphery differentiation and centralised dominance. These structural features provide a critical foundation for subsequent network optimisation and the formulation of targeted conservation and revitalisation strategies.

Characteristics of Network Clusters

The spatial association network of traditional villages in the study area reveals distinct clustering patterns based on cohesive subgroup analysis, resulting in the identification of four primary network clusters. Subgroup I consists of eight villages, including Xiding and Wangjiatan, primarily concentrated in the northern area of Hebi City within the central part of the region. Subgroup II includes twelve villages, such as Xixiangping and Chefogou, encompassing all surveyed villages within Anyang City in the northernmost area. Subgroup III comprises thirteen villages, including Guoliang and Liyu, spanning ten villages in Xinxiang City and three in the southern part of Hebi City, thereby forming a central-southern transitional cluster. Subgroup IV includes ten villages, such as Donglinghou and Yidoushui, distributed across seven villages in Jiaozuo and three in Jiyuan, representing the southern part of the study area.

To further examine the relational dynamics among these subgroups, a network density matrix was constructed. Using the overall network density value of 0.531 as a threshold, intra- and inter-group densities above this value were assigned a value of 1 to represent strong linkages, while those below were assigned a value of 0, indicating weak or absent connections. This binarisation yielded a transmission relationship matrix that illustrates the potential paths of interaction and influence between clusters. The resulting structural pattern not only reflects the territorial proximity and administrative boundaries of the villages but also highlights the spatial logic of cultural exchange, ecological cooperation, and functional interdependence. These findings provide an empirical basis for promoting regionally adaptive conservation strategies and enhancing cross-cluster synergy in the holistic governance of traditional villages.

Discussion

Spatial Mechanisms Driven by the Evolution of Cultural Ecosystems

Current scholarly approaches to traditional settlement spatial studies generally follow two predominant theoretical trajectories. The first is the "taxonomy of cultural landscapes", which focuses on the classification and generalisation of settlement forms and cultural traits. While this path has yielded rich typological insights, it often remains confined to static descriptive analysis, lacking explanatory depth regarding the dynamic cultural mechanisms underlying spatial transformation-Duan et al., 2025-. The second trajectory draws on Lefebvre's theory of spatial production, which underscores the formative role of power relations and institutional structures in the production of space-Hu et al., 2019-. Although Lefebvre's "spatial triad" framework offers strong explanatory power in urban and abstract spatial contexts, its adaptability is limited when applied to ecologically, culturally, and historically intertwined traditional villages, where spatial form emerges from the long-term interplay of environment, culture, and collective practice.

To address these limitations, this study proposes an alternative analytical mechanism: the "culture-driven core – cultural connotation – spatial representation" chain-Qiao et al., 2022-. This framework integrates the logic of cultural and ecological evolution with the structural dimensions of spatial practice-Steward, 1972-, and further introduces a four-layer analytical model encompassing technology–ecology, cognition–concept, organisation–institution, and practice–strategy. This model not only clarifies the intrinsic logic of settlement spatial evolution, but also establishes a systematic framework amenable to quantitative methods such as geographic modelling and network analysis.The theoretical contributions of this study are threefold: first, it advances cultural landscape research by shifting from typological description to mechanistic interpretation; second, it offers a theoretically grounded and empirically operable paradigm for understanding the evolution of regional settlement systems, through the integration of cultural ecosystem theory and spatial network analysis; third, it promotes the deeper integration of cultural geography and rural spatial studies, enriching interdisciplinary dialogue and providing robust tools for analysing and guiding the sustainable transformation of traditional village landscapes.

Holistic Protection Path of the Regional Cultural Ecological Network

To achieve the holistic protection of traditional village cultural ecosystems, a hierarchical activation strategy should be established across the node–cluster–region scale. At the node level, functional typologies can be identified using network centrality indicators. Villages exhibiting high degree centrality (e.g., Xideng, Shijiagou) should be designated as cultural engines, serving as pilot areas for the integration of cultural heritage and tourism development. Villages with high closeness centrality may be developed as cultural dissemination hubs, facilitating regional cultural transmission. Those with high betweenness centrality can function as cultural corridors, enhancing inter-village connectivity and information flow. In contrast, peripheral nodes should focus

on revitalising endogenous cultural potential through resource re-evaluation and the reconstruction of local traditions and folklore practices.

At the cluster level, the cultural ecological network exhibits differentiated cohesion strengths among its four subgroups. Subgroups I to III, characterised by dense internal connections, should prioritise co-construction of shared resources, institutional collaboration, and the formation of integrated cultural ecological zones. In contrast, Subgroup IV, which demonstrates relatively weak connectivity, requires the cultivation of organisational systems and the construction of a "cultural bridge" to enhance its interaction with core clusters. The identity and linkage among subgroups can be further strengthened through initiatives such as "itinerant exhibitions of intangible cultural heritage", which foster inter-regional cultural recognition and cohesion.

At the regional level, a "core–linkage–periphery" spatial framework should be implemented to optimise the synergistic integration of cultural and ecological systems. This includes delineating a cultural protection red line in coordination with the existing landscape ecological patterns, thereby reinforcing the spatial co-evolution of culture, ecology, and landscape. Furthermore, the establishment of a multi-level co-governance mechanism—led by government coordination, supported by village self-governance, and enhanced through multi-stakeholder participation—can facilitate the transition of the cultural ecosystem from mechanism integration to systemic regeneration, ultimately contributing to the sustainable and dynamic revitalisation of traditional rural spaces.

Conclusion

This study focuses on the traditional villages in the South Taihang region of northern Henan Province, integrating cultural ecology theory with Holling's adaptive cycle model to construct a systematic analytical framework for understanding the evolutionary mechanisms of spatial morphology and the structure of the cultural ecological network in traditional settlements. The main conclusions are as follows:

(1) The spatial form of traditional villages represents the material expression of the long-term evolution of cultural ecosystems. Elements such as material culture, institutional arrangements, and spiritual beliefs, guided by the culture-driven core, are deeply embedded within settlement space, forming an interlinked chain of "culture–mechanism–space."

(2) Based on Holling's adaptive cycle theory, the evolution of settlement systems can be categorised into four stages: exploration, conservation, release, and reorganisation. Each stage reflects a shifting cultural core—ranging from agricultural subsistence to clan-based governance, defensive adaptation, and commercial transformation—alongside corresponding spatial characteristics that evolve from centralised to fragmented, and ultimately to composite and restructured forms. This progression reveals the non-linear, multi-causal interaction mechanisms that drive the spatial transformation of traditional villages.

(3) In terms of cultural network construction, the study introduces a multi-dimensional cultural development index system, and employs a modified gravity model combined with social network analysis (SNA) to uncover a "centre–periphery–bridge" network structure. This structure is anchored by villages of high cultural value, exhibiting spatial synergy and functional differentiation, and offering a new perspective for understanding rural cultural connectivity.

Theoretically, this study transcends the limitations of static typologies and isolated case analysis by proposing a "culture-driven → four-dimensional mechanism → evolutionary stage" model. By incorporating network analysis, the research achieves a paradigm shift from fragmented conservation to systematic spatial governance, thereby enriching the interdisciplinary dialogue between cultural geography, ecology, and human geography. Practically, the findings offer a solid basis for the classification, spatial optimisation, and policy-making of traditional villages. Stage-based typology enables the precise identification of settlement evolutionary phases, while network-based analysis facilitates the construction of cross-village collaborative mechanisms, supporting the transition from "point-based conservation" to "network-oriented governance" -Yuan et al., 2025-. Future research may extend this framework through cross-regional comparative studies and further develop dynamic modelling and mechanism validation for the evolution of cultural ecosystems.

Abstract
The marginality of inner peripheries – related to the chronic depopulation and abandonment - fosters the sense of subalternity of communities living in these areas. Nevertheless, inner peripheries' heritage still has an important transformative potential, acting both as a resource and as a catalyst for change and community empowerment. According to the Faro Convention, heritage goes beyond physical artefacts to encompass values, practices and meanings that define collective identities and can serve here as a powerful counter-narrative. This paper explores potential and limitations of community mapping in strengthening relations between heritage and community and discusses the first outcomes of a participatory process developed in a small town of the Tammaro-Titerno area (South Italy). The process highlights the deep historical stratification and the interplay between human practices and physical environment that contributed to shape the territorial heritage.

Introduction

Across Europe, inner peripheries (ESPON, 2017) are increasingly struggling with marginalization shaped by spatial, socio-economic, political, and symbolic dynamics (Schmidt, 1998; Kühn, 2015; Rodriguez-Pose, 2018). From a cultural perspective, marginalization manifests itself as geographical isolation, characterized by limited access to cultural centers and infrastructure, such as museums, theatres, and universities. This isolation reinforces perceptions of exclusion, while socio-economic trends, such as the emigration of young people, further deprive these areas of innovation and creativity. Moreover, the disconnection between local and global cultural networks, the limited influence on policy-making processes and persisting global urban-centered development models further exacerbate the sense of subalternity of communities living in inner peripheries. As a result, marginal territories are perceived as "places of elsewhere" (Membretti et al., 2022), distant from the values and dynamics of cultural production. This symbolic marginalization fosters a negative self-image within communities, reinforcing narratives of cultural subalternity and isolation. On the other hand, the main risk is that policies aimed at enhancing these territories are based on a romanticized imaginary of rural life in subordination to urban lifestyles, on the 'musealization' of historical centers and on the occasional leisure-time use (Coppola, 2023).

Despite these challenges, cultural heritage offers significant transformative potential for inner peripheries, acting both as a resource and as a catalyst for change and community empowerment (Duxbury, 2020).

According to the Faro Convention (CoE, 2005), heritage goes beyond physical artefacts to encompass values, practices and meanings that define collective identities, and it is intrinsically linked to community recognition. The latter is crucial for preserving and activating heritage as a resource.

This perspective is particularly relevant in inner peripheries, where cultural subalternity often arises from a lack of both internal and external recognition (Schmidt, 1998). Heritage can serve here as a powerful counter-narrative. Bottom-up approaches to the enhancement of cultural heritage can reverse the perceptions of marginality, fostering new visions and opportunities for local development.

Active relationships between a community and its environment are the basis for sustainable living (Magnaghi, 2010), envisioning trajectories of place-based enhancement (Barca et al., 2012). Many scholars (Wilson and Sanyal, 2013; Carrosio et al., 2018; Pappalardo and Sajia, 2020) recognize the active involvement of communities as an effective way for activating revitalization strategies to counterbalance the progressive abandonment of places

and their legacy. Reconnecting communities with their territories starts with awareness of local heritage. The Faro Convention (CoE, 2005) defines two fundamental concepts: cultural heritage and heritage community. Since the heritage community "consists of people who value specific aspects of cultural heritage which they wish [...] to sustain and transmit to future generations" (CoE, 2005, art.2 b), heritage goes beyond the institutional status attributed to the relevant places and extends to any place to which a community attributes a collective value. Cultural heritage is what people identify as "a reflection and expression of their constantly evolving values, beliefs, knowledge and traditions. It includes all aspects of the environment resulting from the interaction between people and places through time" (CoE, 2005, art.2 a).

In the context of inner peripheries, even more than in cities, both human–place relationships and the traces of the practices that have shaped them over time remain recognizable (Magnaghi, 2010; Ferraresi, 2012), (Magnaghi, 2010; Ferraresi, 2012), despite the risk of losing both heritage and its collective memory.

This contribution explores an ongoing process of community mapping a trigger for reviving the relationships between community and its local heritage and contributing to outline new trajectories for a place-based strategy beyond urban-centric models.

Losing the heritage of rural areas in Italy: the inner areas between abandonment and musealization
In Italy the term "Inner areas" was firstly introduced by the National Strategy for Inner Areas (Barca et al. 2014), and referred to the municipalities located significantly far from the supply centers of essential facilities (education, health, and mobility). According to the inner areas' classification updated in 2020[1], about half of the Italian municipalities can be classified as inner areas, hosting less than a quarter of the national population. These mostly hilly and mountainous villages face several interconnected problems resulting from long-term migration to cities: decreasing and aging of population, lack of accessibility, economic marginality, lack of job opportunities and higher education, physical abandonment of the architectural and infrastructural heritage, political and cultural marginality. Depopulation dynamics result in the loss of both tangible and intangible heritage. Indeed, heritage is what people identify as expression of their values, beliefs, knowledge and traditions. Therefore, such dynamics, altering or even breaking the relationships between people and places, often result into a loss of local culture, traditions, practices as well as changes in how inhabitants relate to the territory.

Moreover, inner and peripheral areas play a crucial role in ensuring the provision of ecosystem services at the territorial and regional scale (Borghi, 2017; Galderisi and Limongi, 2024). These territories own the major reserve of natural resources, biodiversity, and agricultural areas; hence, they play a role of paramount importance in regulating ecological balances and providing services for the entire population, including urban centers. However, the long-term provision of ecosystem services cannot be ensured by a relationship of mere and passive dependence for the multiple benefits they provide. An active and sustainable relationship between local communities and their territorial heritage entails shared responsibility and care. According to Magnaghi (2020), while ecosystem services are grounded in the objective value of nature for humans, eco-territorial services are grounded in the subjective and cultural value of territorial heritage. They depend on the mutual relationship between people and places and are essential for activating sustainable and place-based practices. Eco-territorial services go beyond the logic of extraction and foster a regenerative and place-based approach to territorial development. This applies for all the components of the territorial heritage (nature, architecture, culture, practices, etc.)

As a result, reversing the chronic processes of depopulation and abandonment requires reviving the relationships that have shaped territorial heritage over the years.
