Based on the results of emotional recognition: In the SY area, the smile rate among tourists peaked at 35% in the afternoon, while negative emotions accounted for approximately 40%(Figure 5). This suggests that tourists' perception of the SY street area is average. In the XC area, the proportion of smiles and happiness was highest in the morning, reaching approximately 80%, with negative emotions accounting for about 20%. This indicates that tourists' perception of the XC street area is very positive. In the KZ area, smiles and happiness were most prevalent in the morning, accounting for approximately 50%, with negative emotions at about 25%. This suggests that tourists' perception of the KZ street area is relatively positive. In the CT area, the highest proportion of smiles and happiness occurred in the morning, reaching about 40%, while negative emotions made up around 30%. This indicates that tourists' perception of the CT street area is average. In the SQ area, smiles and happiness were most prominent in the morning, accounting for about 35%, while negative emotions reached approximately 40%. This suggests that tourists' perception of the SQ street area is relatively poor. In summary, emotional recognition revealed that the XC street area had the highest positive emotional perception (happiness and smiles), while the SQ street area had the lowest. Additionally, this method not only provides insights into the emotional perception of entire streets but can also statistically analyze the emotional distribution of specific sections within a street.

3.3 Analysis of the Correlation Between Smile Rate and Street Space

This study built upon the research methodology of Xu, Fang[11], Liu Y., et al. Aesthetic evaluation of streets and analysis of influencing factors based on deep learning and multi-source data: A case study of Shanghai. Int. Urban Plan 2023, 38(06), 48–58.]], as well as Liu Y. et al., employing multiple linear regression analysis to explore the correlation between smile rate and street spatial elements. By utilizing the optimised YOLOv5 model, the study achieved a more precise and detailed quantification of tourists' emotional responses across various street spatial locations. Combined with (Equation 1), this methodology assigned quantitative values to distinct street spatial locations. Subsequently, the influence of street spatial indicators on the evaluation of spatial perception was analyzed using multiple linear regression through SPSS. The corresponding formula is as follows:

$$E=\beta 0+\beta 1*GKB+\beta 2*KD+\beta 3*ZSDM+....+\beta 13*FD+e \qquad (1)$$

The regression analysis included coefficients through, with representing the constant term and denoting the error term. Post-regression diagnostics indicated that the tolerance values, calculated as, were all greater than 0.1, confirming the absence of multicollinearity among the independent variables. The Durbin-Watson statistic for the model was 1.429 (Table 1), suggesting that the assumption of independence in the residuals was met; The coefficient of determination (F=5.031, P=0.000<0.05) indicated that the model possessed limited explanatory power (Table 2. While a statistically valid model was constructed, its interpretability was moderate.

In summary, the analysis of the smile rate and the spatial correlation of the street reveals the following:

(1) Various elements of the spatial environment influence tourists' emotions, although the extent of this impact is relatively limited. The constructed regression model exhibits an R^2 value of 0.198, indicating that the current spatial elements account for only a small proportion of tourists' emotional perception. To enhance the explanatory power of the model, incorporating additional street spatial elements could be considered to expand the range of influencing factors. Alternatively, future studies could explore other dimensions or variables that might have a stronger impact on tourists' emotions.

(2) Based on the Beta coefficients, KJFG emerges as the primary factor influencing tourists' emotional percep-

tions, followed by KD, which also has a significant impact (Table). This finding differs from previous research. A possible explanation is that tourists tend to experience heightened expectations and positive emotions when transitioning to the next street space, leading to generally higher recognition data during the analysis. The FD factor also exhibits a strong influence, suggesting that higher commercial density within the street can enhance tourists' positive emotions. However, the Beta coefficient for ZXJCDL is -0.227, indicating a negative impact on tourists' emotions. This may be attributed to the vertically intersecting streets, which fail to evoke favorable emotions. By contrast, winding streets appear to provide a more engaging and emotionally positive experience for tourists during their visits.

In conclusion, this study's findings are based on the existing data on tourists' emotions and the spatial organization, morphology, and interface elements associated with street spaces as discussed. The analysis identified five typical street spatial elements—F, FD, QZDCLM, KD, and KJFG—that have a positive impact on tourists. These elements could be prioritized in street space construction and planning to increase their proportion, enhance functional diversity, and improve the quality of transitional spaces between streets. Such measures would contribute to enriching the street space experience and promoting the sustainable development of tourism-oriented traditional villages.

4.Conclusions

In addition to being influenced by the spatial environment, tourists' emotional perceptions are affected by various other factors, such as their personal mood, conversations with companions, and weather conditions. This study proposes a novel method for identifying emotional states through image-based deep learning, enabling a detailed depiction of tourists' emotional feedback and changes during their visits. This approach offers a new tool for evaluating and providing feedback on spatial environments. By analyzing the distribution characteristics of tourists' emotional perceptions in the street spaces of tourism villages, this study explores the correlation mechanisms between 13 spatial elements—including spatial organization, morphology, and interfaces—and tourists' emotional types and intensity preferences. Through multiple regression analysis, it was found that the spatial segmentation factor of streets had a regression coefficient of 0.184, making it a key determinant of tourists' perceptions. Additionally, five typical street spatial elements were identified as having a positive influence on tourists. Based on these findings, this study proposes optimization strategies for enhancing tourists' emotional perceptions within street spaces. These recommendations aim to improve the street experience and support the sustainable development of traditional villages.

Abstract
Tourism development in traditional villages acts as a critical catalyst for local economic development, functions as an essential foundation for the conservation of historical and cultural heritage, and operates as a strategic mechanism for advancing rural revitalization. In recent years, alongside China's rapid economic growth and urbanization, traditional villages have confronted the dual pressures of modernization while simultaneously embracing unprecedented developmental opportunities. Tourism development in traditional villages plays a pivotal role in safeguarding cultural heritage. Leveraging tourists' experiential engagement in traditional villages to achieve the conservation and promotion of historical and cultural heritage under tourism-driven economic frameworks constitutes a critical strategy for the protection and sustainable development of tourism-oriented traditional villages. In the development of tourism-oriented traditional villages, distinct development models exert differential impacts on the functional integration of traditional cultural elements with modern tourism services in village streets and their corresponding spatial configurations, thereby shaping tourists' behavioral characteristics. Investigating this perspective constitutes a critical component in achieving the aforementioned objectives. Current research predominantly focuses on analyzing street space and tourist behavior under singular development models, yet it lacks a holistic exploration of how multiple development models organize the interplay between traditional cultural elements, modern tourism functions, and morphological configurations in tourism-oriented villages, as well as their collective impact on tourist behavior. This study addresses this gap by examining Yuanjia Village in Shaanxi Province, China, with a specific focus on street spaces under three development models: village collective-led development, developer-led development, and village-enterprise cooperative development. It investigates the correlation between the functional complexity and morphological diversity of street spaces and key tourist behavioral metrics—including walking speed, dwell time, and interaction patterns—across these development paradigms. In data collection, street space elements—comprising 13 objective indicators related to the integration of traditional cultural and modern tourism functions, as well as morphological diversity—were assessed through POI data crawling, field surveys, and scoring-based categorization, while behavioral metrics, including tourist walking speed, dwell duration, and interaction patterns, were captured via fixed-point video recordings to construct a composite subjective behavioral index. In data analysis, a multiple regression model was constructed to examine the relationships between tourist behavior and street space elements, enabling a quantitative assessment of the relative impacts of traditional cultural and modern tourism spatial elements on tourist behavior across distinct development models. Leveraging the empirical findings, this study further conducted a granular dissection of the causal mechanisms underlying the interplay between street space configurations and tourist behavior under the three development paradigms, thereby uncovering the nuanced interaction mechanisms inherent to these dynamics. This study applies a systematic analytical framework that integrates both subjective and objective elements, bridging the research void on the interplay between street space organization and tourist behavioral dynamics under multiple development models within an integrated tourism-oriented traditional village. It further delineates how the coordinated organization of multi-modal street spaces can harmonize tourism-driven growth with the safeguarding of cultural heritage. Methodologically, this study introduces a quantitative approach combining fixed-point video recording and POI data crawling, which enhances the comprehensiveness and precision of data acquisition. thereby providing a methodological framework for spatial-behavioral research in tourism-oriented traditional villages.

Keywords: Tourist Behavior; Street Space; Shareholding Cooperativ

1. Introduction

In recent years, the Chinese government has introduced pivotal policy documents such as the Guidelines for Promoting Sustainable Rural Tourism Development and the 14th Five-Year Plan for Tourism Development, outlining explicit directives for rural tourism and revitalization. These policies emphasize core principles including "inheriting and promoting outstanding rural culture," "highlighting the cultural distinctiveness of rural tourism," and "preserving rural characteristics." Driven by these initiatives, the rural tourism industry has experienced rapid growth, with substantial capital inflows significantly boosting local economies. However, this capital-driven development model has also generated pronounced negative externalities, notably homogenization issues such as over-commercialization, convergence of development approaches, and redundancy in tourism offerings, ultimately leading to monotonous visitor experiences and the erosion of rural identity. This phenomenon has gar-

nered significant scholarly attention. Early research predominantly focused on the positive economic impacts of tourism, but since the 1960s, scholars have increasingly examined its ecological consequences. The seminal work of Wall and Wright (1977) conceptualized the "tourism environment" as natural ecosystems and rigorously analyzed impact mechanisms, methodologies, and environmental carrying capacities[1]. Subsequent studies expanded these discussions, with recent scholarship prioritizing the balance between economic, environmental, and social outcomes in sustainable development[2]. Notably, research on tourism's socio-cultural impacts has gained momentum, emphasizing resident attitudes, community perceptions, and evolving tourist behaviors—reflecting heightened concerns for cultural heritage preservation and vernacular authenticity[3].

In recent years, China's rural tourism development has exhibited a marked shift toward sustainability and place-based differentiation[4]. Against this backdrop, traditional villages such as Xidi[5]and Hongcun[6] in Anhui Province have garnered significant attention for their unique spatial value and sustainable development models. Academic research has advanced multidimensionally: theoretically, scholars employ the "spatial genome[7]" framework to decode vernacular spatial characteristics; methodologically, studies tracking tourist behavior[8] and emotional perceptions[9] reveal interaction mechanisms between built environments and visitor experiences[10]; and design-wise, innovative concepts such as regional identity integration, scale moderation, and user-need alignment[11] have been proposed. Furthermore, an increasing number of studies are exploring spatial environment design methods from the perspective of tourist behaviour. These studies suggest that tourist behaviour is influenced by a combination of individual tourism purposes, the built environment[12], the social environment[2], social governance[13] and other factors. Scholars have approached this topic from dual perspectives: On one hand, studies analyzing tourists' spatial usage patterns and behavioral activities[14] have elucidated the interplay between built environments and visitor behaviors [15]. On the other hand, research examining behavioral metrics like dwell time, walking speed, and spatial vitality has informed evidence-based design principles for optimizing pedestrian-oriented environments. On the other hand, studies analyzing behavioral metrics such as dwell time, walking speed [16], and spatial vitality [17], alongside their interactions with the built environment, have proposed critical design principles for pedestrian-centric spaces. However, current research exhibits significant limitations: most studies focus on spatial analyses or behavioral observations under irregular development models, lacking systematic comparisons of functional hybridity and morphological diversity across development paradigms. Furthermore, they fail to thoroughly investigate the specific mechanisms through which these spatial characteristics influence tourist behavior. This research gap critically impedes a holistic understanding of the spatial-behavioral interaction mechanisms in tourism-oriented traditional villages.

Building on this foundation, this study selects Yuanjia Village in Shaanxi Province as a representative case. Through POI data crawling and field surveys, we quantified 13 functional and morphological indicators of street spaces under three development models: village collective-led development, developer-led development, and village-enterprise cooperative development. Concurrently, fixed-point video recording technology was employed to document tourist behavioral metrics, including walking speed, dwell duration, and interaction patterns. This integrated approach establishes a hybrid analytical framework that synthesizes subjective behavioral data with objective spatial parameters. This study utilises a multiple regression model to quantitatively analyse the intensity of the influence of street space elements on tourists' behaviours under different development modes and their intrinsic mechanisms. This analysis addresses a research gap concerning the interaction between street space and tourists' behaviours in traditional villages under the background of multi-modal development. The study provides a theoretical basis and a practical guide to the planning and management of tourist-type traditional villages. Methodologically, the integration of POI (Points of Interest) data with video analytics techniques enhances the comprehensiveness and precision of data acquisition, offering novel methodological frameworks for advancing research in this domain. The present study aims to reveal the influence of different development modes on the street space of traditional villages and tourists' behaviours. To this end, the functional organisation and morphological characteristics of the street space under the three development modes will be systematically examined, and their correlation with tourists' behaviours will be analysed. The study will provide a scientific basis for balancing the cultural protection and economic benefits in the development of tourism to promote the sustainable development of traditional villages.

2. Study area and target audience

Yuanjia Village, situated in Liquan County, Xianyang City, Shaanxi Province, constitutes the second group of traditional villages to be included in the Chinese traditional villages list. It is a natural village with a long history in Guanzhong, Shaanxi Province. Yuanjia Village has a significant number of tourists. As of 2023, Yuanjia Village has witnessed annual tourist visits exceeding 8 million, with its total annual tourism output value surpassing 1.2 billion Chinese yuan[18], establishing itself as one of the villages in Shaanxi Province with the most consistent visitor numbers throughout the year. The year-on-year growth in tourist visits and tourism revenue demonstrates that Yuanjia Village has emerged as a representative case of traditional villages achieving successful tourism-oriented transformation. The substantial visitor influx provides robust support for data collection on visitor behavior. Furthermore, the spatial configuration of Yuanjia Village's streets and alleys has evolved organically alongside the village's developmental trajectory. Notably, the tourism-oriented street spaces originated from early initiatives by the collective shareholding cooperative, particularly the Snack Street (XC) and Kangzhuang Street (KZ)The sustained year-on-year growth in tourist visits and tourism revenue positions Yuanjia Village as a paradigmatic case of traditional villages achieving successful tourism-oriented transformation. The substantial visitor base provides a robust empirical foundation for behavioral data collection, while the spatial evolution of its street network reflects adaptive development aligned with phased growth strategies. Specifically, the tourism-oriented street system originated from early-phase initiatives led by the collective shareholding cooperative, including the Snack Street (XC) and Kangzhuang Street (KZ). This developmental trajectory progressed to an intermediate phase characterized by land lease agreements to address financing constraints, enabling external developers to independently construct heritage-themed commercial spaces such as Sanqin Ancient Street (SQ); The later phase witnessed collaborative developments between the village collective and external developers, yielding culturally hybrid spaces such as the Academy Street (SY), Hui Muslim Cultural Street (HM), and Ancestral Hall Street (CT). The collective shareholding cooperative model, unique to rural tourism street development, exhibits distinctive spatial production characteristics and operational mechanisms that diverge fundamentally from urban development paradigms. In contrast, the developer-led model epitomizes conventional urban development approaches, often plagued by homogenization and unsustainable overexploitation of cultural resources. The joint venture development model embodies hybrid urbanization characteristics, reflecting a coordinated approach that integrates rural-urban spatial governance. Accordingly, this study conducts an empirical investigation across six street spaces representing Yuanjia Village's three development models (Figure 1). Tourists across these streets were selected as study subjects, with spatial metrics including architectural interfaces, pedestrian flows, and cultural signage systematically documented and statistically analyzed. This study focuses on examining street spaces under distinct development models in Yuanjia Village. Within its physical built environment, these three models are interwoven, with each manifesting unique spatial configurations, operational mechanisms, and visitor engagement patterns that collectively shape heterogeneous experiential landscapes. Analyzing variations in visitor experiences holds critical implications for evaluating and reflecting on existing built environments, offering empirical insights and transferable frameworks for implementing moderate tourism development strategies in traditional villages.

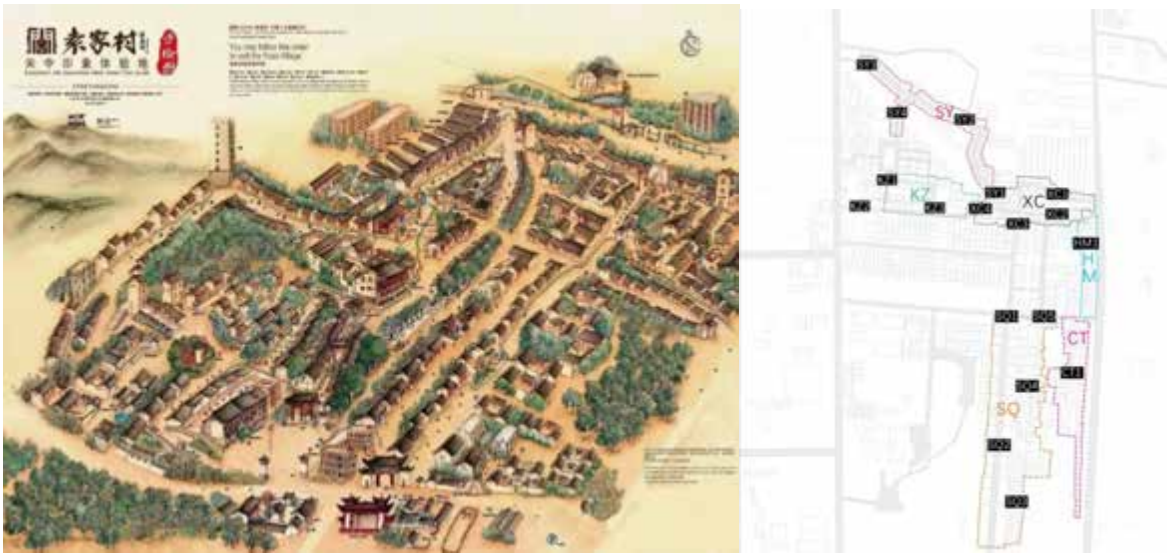

Figure 1 Yuanjia Village Illustrated Map (Left: Source: Yuanjia Village) and Key Street Plan(Right: Source: Author)

3. Research Methods

This study employs Yuanjia Village in Shaanxi Province as a case study, integrating fixed-position video recording with POI data analysis to systematically examine the dynamic interplay between street spatial configurations and visitor behavior patterns across three distinct development models: collective shareholding cooperative development, developer-led independent development, and joint venture collaborative development (as illustrated in Figure 2). The data collection protocol involved selecting representative streets under different development models within the core tourist area as observation sites. Between August and October 2024, video recording sessions were systematically conducted across weekdays and holidays using temporal segmentation (09:00-13:00; 13:00-17:00). Each observation site captured 5-10 minute behavioral episodes sampled hourly, ensuring temporal validity and comprehensive coverage of activity patterns. Video analytics were employed to extract behavioral metrics including pedestrian walking speed (calculated via fixed-distance traversal time), dwelling duration, and interactive acts such as consumption behaviors, photo documentation, and scenic observation. Concurrently, through the integration of POI data scraping and field investigations, thirteen quantitative indicators were systematically assessed to characterize the functional composition, environmental performance, and morphological patterns of street spaces. The analytical framework incorporates multiple regression modeling to quantify the influence of spatial metrics on behavioral characteristics, complemented by comparative analysis to unravel the mechanistic variations across distinct development paradigms. This research pioneers the integration of behavioral observation and spatial quantification methodologies, establishing an empirical foundation for spatial optimization in traditional village tourism development while also advancing a transferable methodological framework for related interdisciplinary studies.

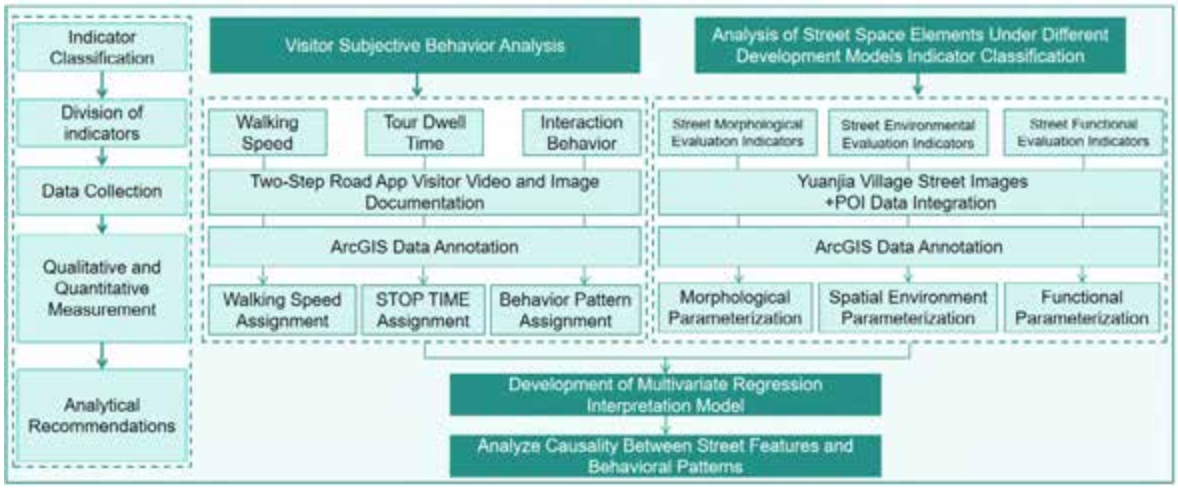

Figure 2 Methodological Framework

3.1 Construction of Perceptual Behavioral Metrics for Visitors

3.1.1 Assigning values to visitors' walking speed, length of stay and interaction pattern indicators

The post-processing of video recordings combined with crowd analytics yielded three principal behavioral metrics: walking speed (S), dwelling duration (D), and interaction patterns (J). Walking speed was categorized as slow pedestrian movement (<0.8 m/s), moderate pace (0.8–1.2 m/s), and accelerated transit (>1.2 m/s). Dwelling duration thresholds were defined as short-term stays (0–5 minutes), medium-term engagement (5–10 minutes), and prolonged occupation (10 minutes). Interaction patterns were quantified through proportional distributions of activity typologies across street segments, including commercial transactions, cultural engagements, and social congregation behaviors. The statistical outcomes of walking speed (S), dwelling duration (D), and interaction patterns (J) were systematically categorized and ranked using the Natural Breaks (Jenks) classification method. This analysis accounted for spatial heterogeneity across distinct street segments and temporal variations between morning and afternoon periods. A weighted ordinal scoring system (1, 3, 5, 7, 9) was applied to quantitatively characterize behavioral-spatial correlations, with values calibrated through iterative field validation cycles to reflect empirical observations of pedestrian-environment dynamics.

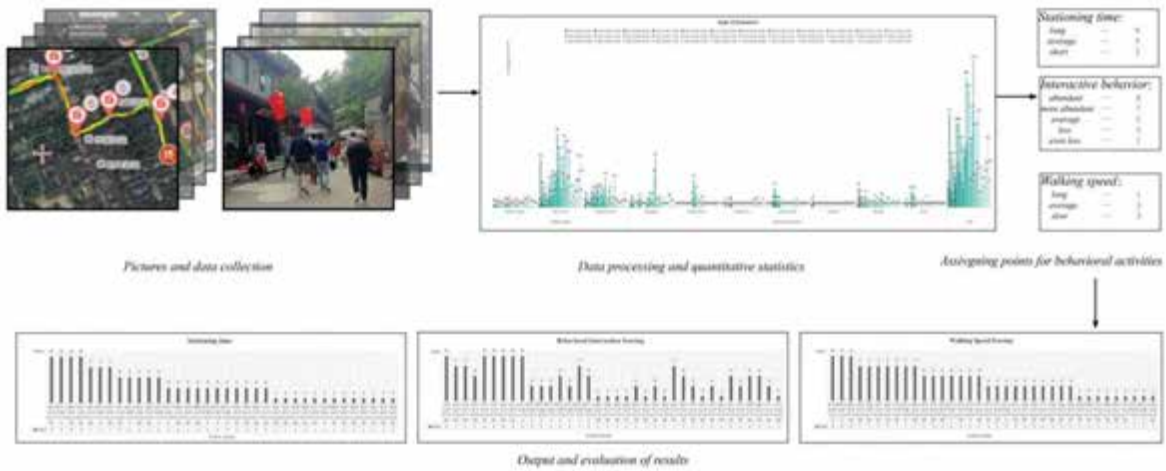

Figure 3 Behavioural and spatial data collection processes

3.1.2 Aggregate Subjective Behavioural Characteristics Index of Tourists

The composite subjective behavioural profile index (P) of tourists was influenced by walking speed (S), dwell time (D), and interaction mode (J). The amalgamation of the tourist interviews and the extraction of the subjective perception weights of these three factors (β1 = 0.18, β2 = 0.35, and β3 = 0.47) resulted in the formulation of a formula for calculating the subjective behavioural index (see Equation1). This subjective behavioural score was then used to correlate to the POI crawl points. It is evident that elevated scores on the Subjective Behavioural Characteristics Index (P) are indicative of enhanced behavioural dynamism, thereby signifying that visitors encounter a more positive experience in the village's street and shop environments.

"P=β1*S+β2 *D+β3*J" (1)

3.2 Indicators of spatial environment elements in streets

In this study, the work of Xu Leiqing [14], Zhang Zhang [8], Long Ying [20] and other experts in the field of street index measurement systems is referred to, in addition to the research group [9] in the Yuanjia Village street spatial elements of the system based on the proposed spatial elements of the index for the different development modes. In consideration of the aforementioned references and the premise of data availability, the indicators affecting the evaluation of street characteristics are classified into three major categories and 13 subcategories (see Figure 4). The first element to consider is the street spatial morphology, which includes the street width, street morphology, morphology scale, height-to-width ratio, and openness, amongst other factors. The second element is indicators of the street environment category, including street furniture and the green water system. The third element is indicators of the street functionality category, including the catering function, the entertainment function, leisure shopping function, attraction function, and accommodation function of the locality.

Category	Indicators	Label Name	Description	Scoring
Morphological Indicators	Overall Spatial Form (Length-Width Ratio)	CKB	Linear street form	1 (Linear Type)
			Enclosed street form (tending to cluster)	3 (Cluster-Leaning Linear)
			Independent clustered space	5 (Cluster Type)
	Single Store Scale	GM	Floor area ≤ 100㎡	1 (Small Floor Area)
			Floor area > 100㎡	3 (Large Floor Area)
	Distinctive Features	TSFM	Modern urban style, non-local materials	1 (Weak Distinctiveness)
			Guanzhong rural characteristics, locally sourced materials	3 (Strong Distinctiveness)
	Height-to-Width Ratio	GKB	Average building height / street width: ≥2	1 (Weak Enclosure)
			Average building height / street width: 1–2	3 (Medium Enclosure)
			Average building height / street width: 0–1	5 (Strong Enclosure)
	Interface Openness	OD	OD = Open length / Total interface length: 0–0.25	1 (Compact Interface)
			OD = Open length / Total interface length: 0.25–0.5	3 (Moderate Interface)
			OD = Open length / Total interface length: 0.5–0.75	5 (Open Interface)
Environmental Indicators	Modern Street Furniture	ZYBD	Street furniture (tables, chairs, sunshades, etc.)	1 (None)
				3 (Available)
	Local Characteristic Furniture	DYTSBS	Traditional items (millstone, roller, oil press, etc.)	1 (None)
				3 (Available)
	Landscape Environment	JGSX	Water features, greenery	1 (None)
				3 (Available)
Functional Indicators	Dining Function	CYGN	Diverse foreign cuisines (Korean, Western, desserts, etc.)	1 (None)
			Local specialty cuisines (noodles, spicy noodles, dumplings, etc.)	3 (Available)
	Entertainment (Gaming Experience)	YLGN	Foreign entertainment (haunted houses, amusement parks, live-action CS, etc.)	1 (None)
			Local experiential activities (tea drinking, opera, etc.)	3 (Available)
	Leisure & Shopping Function	XXGW	Foreign goods (accessories, toys, general merchandise, etc.)	1 (None)
			Local specialty goods (chili powder, yogurt, tofu, sesame twists, etc.)	3 (Available)
	Scenic Tourism Function	JDLY	Modern artificial attractions	1 (None)
			Historical-cultural attractions (Temple of Wealth, Guanyin Temple, Qin Qiong Tomb)	3 (Available)
	Accommodation Function	ZSGN	Foreign modern lodging (large hotels)	1 (None)
			Local characteristic lodging (Guanzhong-style hotels, designer B&Bs, rural homestays)	3 (Available)

Figure 4 Indicators of the spatial environment elements of streets and description of the assigned values

4. Result

4.1 The analysis of visitor behavioral characteristics derived from empirical data collection

This study employs temporal-spatial sampling analysis of visitor behavior video data from Yuanjia Village (10:00-13:00 and 13:00-17:00 daily, with hourly sampling of 5-10 minute segments), yielding 1,112 valid visitor trajectories through behavioral recognition algorithms and manual verification. The data reveals pronounced disparities in visitor distribution across streets with distinct development models: Collective Shareholding Cooperative-led Food Streets demonstrated the strongest visitor attraction, accounting for 47.3% of total footfall. Collaborative Development Streets (SY/CT/HM) collectively captured 27.4% of visitor flows. Developer-operated Heritage Commercial Street (SQ) showed the lowest engagement at 25.3%, indicative of potential cultural authenticity dilution in externally managed spaces. With regard to behavioural characteristics, the movement status data of 755 visits revealed the walking rate characteristics, while the stopping status data of 357 visits (see Figure 5) was used to analyse the length of stay and interactive behavioural patterns (see Figure 6). This data collection scheme lays a solid empirical foundation for subsequent in-depth analysis of tourist behavioural characteristics. Statistical analysis of visitor behavioral data in Yuanjia Village reveals distinctive patterns across three dimensions: walking speed, dwelling duration, and interactive behaviors. Regarding locomotion metrics, Snack Street (XC/KZ) exhibits the highest proportion of slow-paced pedestrians (≤0.8 m/s: 10.5%), significantly exceeding Sanqin Ancient Street (SQ: 5.1%) and collaboratively developed streets (SY/CT/HM: 5.4% combined). Notably, SQ demonstrates an exceptional prevalence of rapid pedestrian movement (>1.2 m/s: 8.9%), far surpassing the global average (1.7%), while collaborative development streets display polarized speed distribution (≤0.8 m/s: 23% vs. >1.2 m/s: 1.7%). In temporal engagement patterns, Snack Street achieves superior visitor retention (69.27% dwell ≥10 minutes),

contrasting sharply with SQ's transient visitation profile (≤5 minutes: 43.75%; ≥10 minutes: 8.33%). Regarding interaction patterns, the Snack Street (XC/KZ) with its diversified commercial ecology fostered multifaceted tourist engagements, whereas the monofunctional SQ Street exhibited pronounced behavioral homogenization in visitor activities. These findings provide empirical evidence for understanding behavioral divergences across development paradigms and offer critical insights for optimizing tourism spatial planning through context-sensitive design interventions.

4.2 Analysis of behavioural and spatial elements based on multiple linear regression

This study extends the methodological frameworks established by Xu [19] , Fang [20], and Liu et al. through a multiple linear regression analysis to investigate correlations between the Subjective Behavioral Vitality Index (P) and

streetscape elements under distinct development models. Field-derived spatial metrics were quantified using a weighted scoring system calibrated via the Natural Breaks (Jenks) classification method. Following Equation (2), statistical modeling was conducted in SPSS (v26.0) to assess the impact of street indicators on visitor behaviors:

$$E_n=\beta_0+\beta_1*CKB+\beta_2*GM+\beta_3*TSFM+....+\beta_{13}*ZSGN+e \quad (2)$$

Where, En is the relationship between the subjective behaviour index and the street index under the three development modes (E_1 represents the independent development mode of the developer; E_2 represents the cooperative development mode of the village collectives and the developer; E_3 represents the development mode of the village collective share cooperatives). β1-β13 are the regression coefficients Beta, β0 is the constant term, and e is the error term.

After establishing the multiple regression models for the three development models, the overall tolerance values were all greater than 0.1 , indicating that there was no covariance; the models D-W met the data independence requirements (Table 1); and the three models were statistically significant as detected by ANOVA analysis (Table 2).

Combined with Table 3 Behavioural and spatial data collection processes, this can be illustrated by the analysis of the spatial correlation between the composite behavioural index E and the three types of streets:

(1) The currently constructed indicators of spatial elements of streets have an impact on the subjective behaviour of tourists, but the degree of influence is not high enough. The regression model we constructed has a high R2 value and fair interpretability. It can be shown that the currently constructed spatial elements influencing tourists' subjective behaviours are more appropriate. Subsequently, more street spatial elements can be added to enrich the influence factors, and on the other hand, research can be carried out on other dimensions affecting tourists' behaviour.

(2) The spatial analysis of the developer-independent development model street shows that the JGSX element has the most significant impact on the perception of tourist behaviour (Beta=0.366), followed by the ZYBD element (Beta=0.096). This finding is at variance with established research, verified by field observation that the landscape water system area does effectively promote tourists to stay and rest, while the influence relationship of other morphological and functional elements is relatively ambiguous. It is worth noting that exotic goods shopping (XXGW) and attraction tourism functions (JDLY) also show high influence, and the research data show that such functions have special attraction to children groups (participation rate of 78%), while adult tourists mainly play the role of accompanying. Most alarmingly, the shop size element (GM) showed a significant negative effect (Beta = -0.763), indicating that too large a shop area would undermine tourists' perception of the appropriate scale of the countryside, a finding that is highly consistent with the results of the spatial experience assessment. In the street space of the cooperative development model between village collectives and developers, the recreational function element (YLGN) has the most prominent influence on tourist behaviour (Beta=0.719), followed by the ZSGN element (Beta=0.635). Meanwhile, the neighbourhood business (ZYBD) and attraction tourism function (JDLY) also showed moderate influence. However, the catering function element (CYGN) produced a negative effect (Beta=-0.294), and in-depth analyses revealed that the catering business operated by multiple small developers under this model lacked regional characteristics, resulting in lower satisfaction with the visitor experience. This phenomenon confirms the importance of localised operations in rural tourism development.

(3) In the street space of the village collective share cooperative development mode, the open space design element (OD) has the most significant influence (Beta=0.723), especially the open space in the east entrance area can effectively promote tourists to stay and take photos. The speciality food and beverage element (CYGN) also showed strong influence (Beta=0.527), contrasting with the other two development patterns. Further analysis reveals that the separate block space element (CKB) significantly lengthens visitors' dwell time) and increases the frequency of interactive behaviours through the creation of a meandering touring dynamic line in conjunction with the featured snacking function. The successful practice of this model fully demonstrates the value of

synergistic optimisation of spatial form and territorial function. (3) In the street space of the village collective share cooperative development model, the influence of the open space design element (OD) is the most significant (Beta=0.723), especially the open space in the east entrance area can effectively promote tourists to stay and take photos. The speciality food and beverage element (CYGN) also showed strong influence (Beta=0.527), contrasting with the other two development patterns. Further analysis reveals that the separate block space element (CKB) significantly lengthens visitors' dwell time) and increases the frequency of interactive behaviours through the creation of a meandering touring dynamic line in conjunction with the featured snacking function. The successful practice of this model fully demonstrates the value of synergistic optimisation of spatial form and territorial function.

(4) In summary, the index system of street spatial elements constructed in this study demonstrates good explanatory power, especially the successful identification of key influencing elements under different development modes. The research findings not only provide empirical evidence for rural tourism spatial planning, but also highlight the importance of synergy between the elements of regional characteristics and spatial form design. It is suggested that the follow-up study can be carried out in two aspects: firstly, to expand the indicators of spatial factors, especially to increase the influencing factors of socio-cultural dimensions; secondly, to carry out a longitudinal tracking study to examine the characteristics of the influence of the factors in the temporal order of change.

5. Discussion

5.1 Analysis of the environment and behaviour of the developer-independent development model

Launched around 2010, the developer's independently developed SQ Street adopts a typical urbanisation development pattern, presenting the following characteristics: in terms of the physical environment, the uniform building materials and construction pattern form a large-scale frame structure (building height of 12-15 metres), resulting in a serious homogenisation of the street space (similar shop sizes and repetitive functions); in terms of the spatial form, the 400-metre-long rectilinear layout In terms of spatial form, the 400-metre-long rectilinear layout, together with the street aspect ratio of 0.83-1.16 (the widest being 8.88 metres and the narrowest 4.7 metres), conforms to the theoretical comfort zone, but due to the lack of local characteristic elements and rest nodes (the interface spaciousness value is only 0.16), the actual experience is monotonous and tedious. Behavioural data show that this development mode has brought significant negative impacts: visitors' walking rate is significantly accelerated (>0.8m/s accounted for 24%, much higher than other types of streets), the type of interactive behaviour is the most homogeneous (reduced by 58% compared to the collective model of the village), and stopping to watch and experience activities have almost disappeared. The reason for this is that the developer is only responsible for the construction of the house without participating in the later operation and

management, leading to serious competition in homogenisation of the industry (72% duplication rate with the existing business in the village), which not only destroys the original vernacular landscape, but also fails to form an effective commercial synergy effect. This purely commercialised development model of 'build-and-sell' has ultimately created a 'dilemma' space that lacks both rural characteristics and urban commercial vitality, providing an important case for reflection on traditional village tourism development.

5.2 Behavioural analysis of the co-development model between village collectives and developers

Although HM, CT, and SY Streets were developed in partnership between the Village and the developer between 2012 and 2016, the spatial construction still has the developer's uniform housing pattern, which is constructed using homogeneous brick-variegated antique structures, and the functional division of the housing is homogeneous due to the constraints of the construction space. The functionality of the street is intermediate between the functions of the two development modes. The business types in this part of the street are a mix of snacks from Guanzhong and other parts of the country, but the participation of local villagers is low and mostly in the form of recruitment. The SY Street and CT Street (including shops of gold and silver jewellery, ceramic bottles and porcelain, milk tea and beverages, cultural and creative toys, etc.) It is an exhibition of all kinds of gourmet products and raw materials processed and sold in factories across the country, and the commodities and spaces are uniform, forming a single commercial function. Tourist behavioural interactions were not only homogeneous but also produced a low number of types. In particular, visitors to CT1 not only stayed for a short period of time but also had fewer interactive behaviours. Secondly, the overall spatial intensification and sense of place of HM, CT and SY Streets, which were developed by the village collectives in cooperation with the developers, did not result in a large number of interactive behaviours and stops by tourists as in the case of XC and KZ Streets.

5.3 Environmental and Behavioural Analysis in the Village Collective Share Cooperative Model

Yuanjia Village has successively set up eight workshop co-operatives since around 2012, including oil workshop, tofu workshop, yoghurt workshop, chili workshop, mash workshop, vermicelli workshop, vinegar workshop and flour workshop, and the operators of these co-operatives, all of whom are craftsmen imported from the neighbouring villages and towns, have been gradually integrated into the tourism development and social life of Yuanjia Village. The deep localisation of commercial functions has been realised, and this composite mode of development has enabled XC Street and KZ Street to display significant environmental advantages: in terms of spatial form, the curved and folded street layout of the 'zigzag shape' (different from linear streets such as SQ Street), together with the distinctive spatial organisation of the 'shop in front and factory at the back' not only optimise the visitors' gastronomical experience of the dynamic line, but also promote the natural slowing down of walking speed; in terms of interface design, the eastern entrance is green, and the eastern entrance is green, with a green area on the east side of the street, which is the most beautiful. In terms of interface design, high openness areas such as the green landscape at the east entrance (KZ3) and the open space for tea breaks (XC4) provide material carriers for visitors' gathering and interactive behaviours. Behavioural data show that the frequency of visitor interaction in the XC1 (13:00-17:00) and XC2 (10:00-13:00) areas is significantly higher than that in the other streets, with the highest proportion of behavioural types focusing on snack tasting and photo-taking. This organic spatial form formed by villagers' independent deliberation avoids the standardised drawbacks of the foreign development model, and ultimately presents a quality experience effect with the richest variety of interactive behaviours (32% more than the cooperative/independently developed streets), and the longest length of stay of the tourists (on average, 40% longer than that of the other streets), which confirms the unique value of the localised development model in preserving the characteristics of the villages and enhancing the quality of the tourists.

Yuanjia Village has successively set up eight workshop co-operatives since around 2012, including oil workshop, tofu workshop, yoghurt workshop, chili workshop, mash workshop, vermicelli workshop, vinegar workshop and flour workshop, and the operators of these co-operatives, all of whom are craftsmen imported from the neighbouring villages and towns, have been gradually integrated into the tourism development and social life of Yuanjia Village. The deep localisation of commercial functions has been realised, and this composite mode of development has enabled XC Street and KZ Street to demonstrate significant environmental advantages: in terms

of spatial form, the curved and zigzag street layout in the shape of a zigzag (as opposed to linear streets such as SQ Street), together with the characteristic spatial organisation of a 'shop in front and a factory at the back' not only optimise the dynamic line of the visitor's culinary experience, but also promote the natural slowing down of the walking speed; and in terms of interface design, highly open areas such as the green landscape at the eastern entrance (KZ3) and the open space for tea breaks (XC4) provide material carriers for visitor gathering and interactive behaviours. In terms of interface design, high openness areas such as the green landscape at the east entrance (KZ3) and the open space for tea breaks (XC4) provide material carriers for visitors to gather and interact with each other. Behavioural data show that the frequency of visitor interaction in the areas of XC1 (13:00-17:00) and XC2 (10:00-13:00) is significantly higher than that of the other streets, with the highest percentage of behavioural types dominated by snack tasting and photo taking. This organic spatial form formed by villagers' independent deliberation avoids the standardised drawbacks of the foreign development model, and ultimately presents a quality experience effect with the richest variety of interactive behaviours (32% more than the cooperative/independently developed streets), and the longest length of stay of the tourists (on average, 40% longer than that of the other streets), which confirms the unique value of the localised development model in preserving the characteristics of the villages and enhancing the quality of the tourists.

In summary, the empirical analysis of the three modes of tourism development in Yuanjia Village yielded the following important findings in terms of the two dimensions of spatial environment characteristics and tourists' behavioural responses (Figure 7). First, the development mode led by the village collective joint-stock cooperative shows significant advantages, as its characteristic functional configuration (eight local workshops), intensive spatial form (the 'back' layout), and rich rural environmental atmosphere together shape the spatial characteristics of the streets and lanes in a 'small but exquisite' way, which encourages tourists to form a slow tour, a long stay, and a rich and interactive behavioural pattern. Secondly, the developer-independent development mode shows the opposite characteristics, with standardised functional configuration, low intensive spatial form and a weakened sense of rural environment, forming a 'big and wide' spatial interface without special features, which leads to the behavioural characteristics of tourists' quick passage, short stay and limited interaction. It is worth noting that the model of cooperation between the village collective and the developer shows an intermediate state, although the functional configuration has certain characteristics (integration of Guanzhong and national snacks), but due to the lack of spatial form intensification (uniform antique structure) and insufficient environmental creation, the visitors' behaviours are characterized by the transition of medium-speed visits, short stays, and medium interactions. The comparative analysis of these three models clearly reveals the mechanism by which the choice of development model influences the quality of the spatial environment and then significantly regulates the characteristics of tourist behaviour, providing an important typological reference for rural tourism spatial planning.

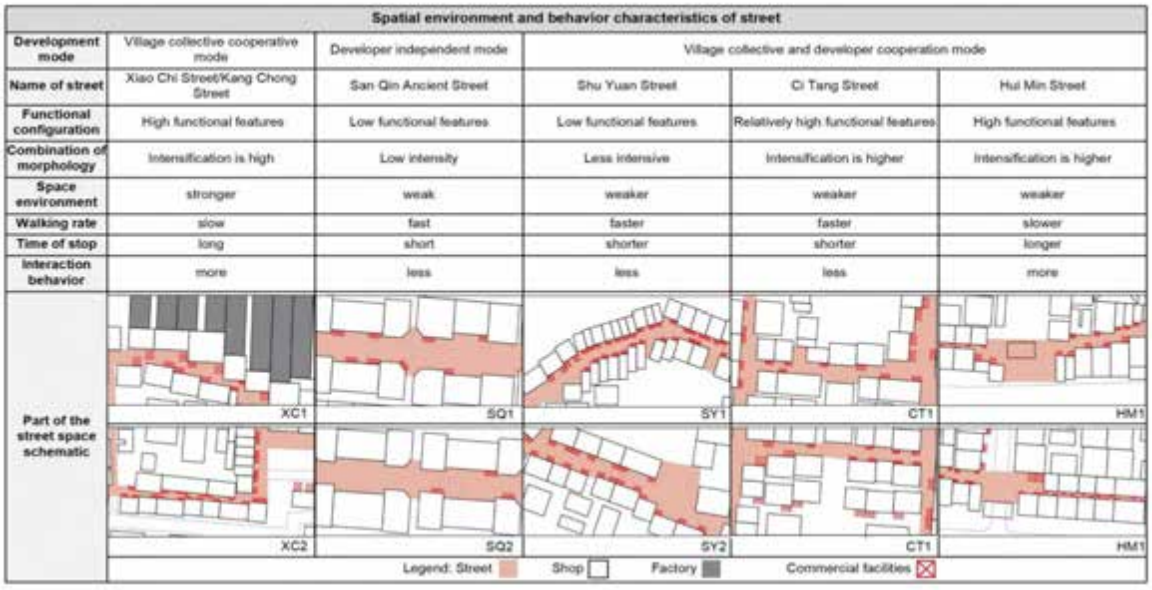

Figure 7 Spatial and Behavioural Characteristics of Streets under Different Development Patterns

5. Concluding remarks

China's rural tourism is in a stage of rapid development, but the destruction of rural landscape brought about by large-scale development and construction is often irreversible. Through a comparative analysis of the three development modes of Yuanjia Village, this study finds that the current mainstream blueprint planning (including the developer-led mode) is difficult to be effectively adjusted after completion due to the short construction period and large investment; while the villagers' self-organised incremental development mode demonstrates a significant dynamic adaptability advantage, which is able to continuously optimise the spatial layout and configuration of the industry according to the actual demand. It is worth noting that China has not yet established a perfect normative system for the construction of tourist-type villages, which directly leads to the lack of regional characteristics and spatial homogenisation (the duplication rate of SQ Street's businesses in this study is as high as 72%).

This study takes the built street space under different development modes in the countryside as the object, and constructs 13 objective element indicators in three aspects of street environment, function and form elements. Combined with the behavioural characteristics, we recorded the walking speed, length of stay and interaction mode of tourists through the video fixed-point filming, and constructed the comprehensive subjective behavioural characteristics indicators. The multiple regression model is used to analyse the influence between physical and spatial elements and behaviours under different development modes, and to analyse the reasons. The empirical evidence shows that intensive spatial patterns can increase tourists' interactive behaviours, regional characteristic functional layouts can enhance tourists' motivation, while excessive homogeneous spatial divisions can limit the diversity of tourists' behavioural activities. These findings provide important insights for rural tourism planning: firstly, a development model dominated by regional characteristics and moderately commercialised should be established; secondly, differentiated spatial modules should be designed for different types of tourists - for the gourmet tasting area, it is recommended to adopt a 'zig-zag' layout (with an openness of 0.4-0.6) and to install street furniture (spacing of 5-8m) to enhance the stay behaviour (Figure 8); for the recreation and leisure area, it is possible to arrange homogeneous spaces with a larger scale of division to facilitate the organisation of small open space functions; or multiple homogeneous group spaces can be combined into a larger space that can provide a variety of recreational possibilities. On the other hand, Yuanjia Village XC Street and KZ Street innovatively adopt the spatial organisation mode of 'shop in front and factory at the back' (Figure 9), which realises the industrial mode of 'integration of the three industries and local development' by integrating

the raw materials of agricultural products from the surrounding areas (from the neighbouring villages and Yixia Town, etc.), and then directly displaying them for sale after they are processed and produced in the village. This organic spatial combination of 'factory-shop-street' (represented by vinegar workshop, oil workshop, etc.) not only reconfigures the production and consumption space of traditional villages, but also significantly improves the enthusiasm and interactive experience of tourists. This study not only provides a quantitative basis for the spatial planning of rural tourism, but also points out the direction for the improvement of the construction evaluation and feedback mechanism, which is of great theoretical and practical value for the promotion of the sustainable development of rural tourism.

Research on the Construction of City Walk Tourism Routes from the Perspective of Cultural Heritage Conservation: A Case Study of Beiyuanmen Historic and Cultural District in Xi'an

Qinghang Cheng
Affiliation:Xi'an University of Architecture and Technology
Email:1992389230@qq.com

Abstract
The immersive tourism model represented by City Walk is reshaping the spatial narrative logic of historic districts. Additionally, the spatial organization of tourism routes faces multifaceted contradictions. Taking Beiyuanmen as a case study, this research employs space syntax analysis to deconstruct spatial morphological characteristics, constructs a supply-demand-balanced cultural heritage display route by integrating GIS-based spatial accessibility simulations with tourist behavior preference mining via social media semantic analysis. The research ultimately develops a heritage conservation-oriented route construction methodology, forming a new paradigm that harmonizes "heritage conservation, tourist behavior matching, and urban form adaptation." This framework aims to provide replicable strategies for revitalizing cultural heritage in historic districts, enhance tourists' recognition of heritage values, and promote sustainable cultural preservation.

Keywords: cultural heritage conservation; historic and cultural districts; City Walk; tourism route

1.Introduction

1.1 Research Background

Within the era of deep integration between culture and tourism and the vigorous development of the experience economy, immersive tourism models epitomised by "City Walk" are rapidly emerging. These models profoundly intervene in and reconstruct the spatial narrative logic of historic districts. This pedestrian practice, emphasising locality, a slow pace, and deep engagement, theoretically offers opportunities to revitalise cultural heritage and enhance public understanding of a place's historical stratification and cultural diversity. It achieves this by guiding tourists to intimately engage with the fabric of the streets and alleys through physical perception and interactive experience.However, in practice, the high-intensity influx of visitors and consumption-oriented focus spurred by the City Walk trend can readily, in the absence of effective guidance and regulation, catalyse the homogenisation and superficial expansion of commercial activities within historic districts. The rapid proliferation of numerous homogeneous trendy establishments and fast-food style cultural consumption spaces into the original urban fabric not only dilutes the district's unique historical ambiance and cultural authenticity but may also fragment or even distort its inherent historical and cultural context. This poses potential threats and challenges to the preservation environment of physical relics, the continuity space for intangible cultural traditions, and the living networks of local communities.Xi'an Beiyuanmen Historic and Cultural District, as the core area of the Huifang Quarter, bears profound historical sedimentation and distinctive ethnic cultural characteristics, serving as a vital living heritage landmark in the ancient capital of Xi'an. With City Walk increasingly becoming its dominant tourism experience, the pressing challenge is how to systematically design tourism routes that fulfil tourists' demands for deep engagement while effectively safeguarding the core value of the district's cultural heritage. This necessitates balancing commercial vitality with cultural authenticity for the sustainable preservation and development of the area.This research is grounded in this context, aiming to explore strategies for constructing City Walk tourism routes from the perspective of cultural heritage preservation.

1.2 Problem Statement

Three principal contradictions exist within the current City Walk routes of Beiyuanmen:The paradox between heritage display and preservation;The contestation for space between tourists and residents;The imbalance between route design and urban form.

1.2.1 The Paradox of Heritage Exhibition and Preservation

Current spatial organisation practices for tourism routes frequently encounter a profound "heritage paradox": to enhance visitor immersion and appeal, route design tends to concentrate and intensively showcase core cultural heritage nodes—such as historic buildings, distinctive sites, and traditional activity points—in high-density sequences. However, this intensive, high-frequency exhibition and utilisation of cultural heritage, when lacking refined regulation and carrying-capacity assessment, readily exceeds both the physical load-bearing thresholds and cultural resilience boundaries of the heritage assets themselves and their environments.This manifests in three primary ways:Material Degradation: Sustained dense footfall on fragile historic fabric—including ancient structures, pavements, and architectural components—accelerates their wear and even induces structural damage.Cultural Commodification: Traditional activities originally rooted in community daily life become simplified, staged, or even alienated into performative spectacles to cater to tourist experience and consumption demands, stripping them of their native cultural context and social function.Spatio-Temporal Disruption: Overemphasis on guiding visitors towards specific cultural symbols (e.g., mosques, traditional snack workshops) causes abnormal spatio-temporal clustering of crowds. This not only disrupts residents' daily routines and the solemn ambience of religious activities but may also displace authentic community functions.Consequently, resolving this paradox by exploring how to achieve synergy between "bearable display" and "dynamic preservation" at the spatial organisation level constitutes the core challenge and critical breakthrough point of this research.

1.2.2 The Spatial Contestation Between Tourists and Residents

The spatial organisation of City Walk routes also acutely instigates a more micro-level and intense spatial contestation within historic districts: an ongoing conflict and struggle between tourists' demands for immersive experiences and the spatial entitlements of local residents in their daily lives. This contestation extends far beyond mere physical crowding; fundamentally, it concerns the competitive usage and meaning-making over finite, highly valued spatial resources.On one hand, the narrow historic lanes and alleys that serve as the primary conduits for City Walks become inundated with visitors during peak periods. This directly encroaches upon the essential circulation and lingering spaces required for residents' daily activities—commuting, socialising, goods transportation, children's play—resulting in reduced mobility efficiency, diminished quality of life, and even safety hazards. Residents are thus compelled to either adjust their routines to avoid tourist surges or relinquish customary uses of public spaces, constituting an invisible erosion of their autonomy over daily life.On the other hand, the pursuit of "authentic" experiences inherent to City Walk often drives tourists to seek out spaces perceived as embodying "local life." Persistent gazing, photography, and even uninvited close observation not only intrude upon residents' sense of privacy and security but also risk creating cultural discomfort and imposing secularisation pressures on community sacred spaces. This occurs when tourist behaviour clashes with local cultural customs or religious sensibilities.Consequently, a core challenge in constructing City Walk routes lies in how spatial organisation and visitor flow management can effectively identify, respect, and safeguard residents' spatial rights. This necessitates seeking a dynamic equilibrium between tourists' experiential rights and residents' right to inhabit their living environment, thereby preventing the cultural heritage site from being transformed into a unidimensional tourist consumption space.

1.2.3 Imbalance Between Route Design and Urban Morphology

The prevailing City Walk route organisation model faces a fundamental structural misalignment: a profound disconnect exists between its premeditated, highly linearised touring logic and the intrinsic, organically complex "courtyard-alley-market" spatial morphology and functional organisation of the Beiyuanmen Historic and Cultural District. This imbalance not only diminishes visitors' perceptual depth but also risks distorting the district's spatial logic and exacerbating the aforementioned contradictions.Spatial Scale and Rhythm Conflict:Beiyuanmen's charm, honed over centuries of organic growth, lies in its multi-layered, networked, and densely collaged spatial fabric. This fabric emerges from the interplay of narrow winding alleys, inwardly focused courtyard units, and spontaneously evolved mixed-use market nodes. However, many City Walk routes—designed for efficiency and "check-in" coverage—over-simplify or artificially straighten this natural grain, imposing one or more clear, coherent, directionally explicit, and relatively broad touring arteries. This artificial linearisation:Concentrates pedestrian flows and commercial opportunities excessively along these primary routes,Marginalises second-

ary alleys and courtyard entrance spaces that harbour authentic living scenes and cultural nuances,Deprives visitors of serendipitous discovery through autonomous exploration and "getting lost,"Inhibits nuanced perception of micro-spatial layers and comprehension of the district's holistic organicity. Functional Disruption of the "Courtyard-Alley-Market" Organism:The district's "courtyard-alley-market" structure is inherently an organic entity where three functions—residential courtyards, social circulation alleys , and commercial market spaces—are spatially nested and dynamically balanced. Linear routes reduce this complex system to a "consumption conveyor belt," funnelling visitors rapidly from one commercial point to the next. This undermines the route's potential function as a framework for understanding the district's:Historical stratification,Social structure,Underlying spatial logic.Consequently, transcending simplistic linear sequencing to explore a route organisation model that:Is grounded in the "courtyard-alley-market" archetype,Respects the inherent networked spatial character,Encourages non-linear exploration and multi-layered perception,—is essential for constructing City Walk routes that genuinely align with cultural heritage preservation objectives and profoundly activate the district's distinctive appeal.

1.3 Research Aims

Building upon a critical analysis of Beiyuanmen Historic and Cultural District's core challenges under the City Walk phenomenon—namely the paradox of heritage exhibition versus preservation, the spatial contestation between tourists and residents, and the misalignment between route design and urban morphology—this research aims to transcend conventional tourism route planning paradigms. It seeks to move beyond singular efficiency-oriented approaches or static preservation mentalities by constructing a City Walk route system centred on the synergistic trinity of "Heritage Preservation – Tourism Experience – Community Coexistence".This system constitutes not merely a spatial superimposition of routes, but an adaptive framework integrating multidimensional elements, including:Spatial organisation,Activity programming,Interpretative information,Management and regulation.Its fundamental objective is to achieve, within the context of Beiyuanmen—a characteristic high-density, living, dynamic, multi-ethnic historic district—a dynamic equilibrium and long-term mutual reinforcement between:The sustainable safeguarding and transmission of cultural heritage, andThe high-quality development of tourism.

2.Literature Review

2.1 Cultural Heritage Preservation and Tourism Utilisation

The preservation and rescue of cultural heritage constitute a vital component of human civilisation and strategies for sustainable societal development, representing a collective societal obligation. Presently, China faces issues such as constructive damage and tourism-induced degradation in the balance between protecting cultural heritage and its exploitation for tourism purposes (ZHENG Xiaoxie). As historic districts, primarily valued for their historical and folk-cultural resources, become highly sought-after tourist destinations, scholars like YANG Guosheng caution against prioritising economic gains from tourism utilisation at the expense of damaging cultural heritage under the guise of economic development. Consequently, the regenerative utilisation of cultural heritage aims precisely to re-establish cognitive or emotional connections between the general public and heritage assets, enabling heritage to represent the identity of non-authoritative stakeholders, including residents and tourists; moreover, enhancing heritage tourism experiences can be regarded as a key metric for successful regenerative utilisation (ZHANG Jianwei). Building upon this, scholar ZOU Han proposes the concept of the "heritage trail," a regional linear cultural heritage conservation method applicable to smaller-scale historic areas. This involves planning and constructing tourist routes that link and integrate multiple cultural heritage resources, establishing visitor nodes and providing services. Similarly, "cultural routes" and "heritage corridors" emphasise the historical and cultural value of heritage while prioritising balance with economic benefits and socio-environmental value, though operating at larger scales. The former typically spans regions or nations, connected by cultural dissemination and dialogue, whereas the latter, operating at an intermediate scale, often integrates cultural resources to form linear landscapes connecting urban clusters or cities. This represents a lower-intensity tourism development approach, suitable for protection strategies involving "temporary retention, refurbishment and appropriate facility addition" within historic areas, exerting minimal impact on local livelihoods and lifestyles.

2.2 The Spatial Narrative Turn in City Walk

Spatial narrative, a method that combines a structural system of events arranged along the axis of time and causal logic with a spatial juxtaposition system characterized by coexistence and synchronicity, is described as a 'spatiotemporal complex.' (Xiao Jing) argues that current cultural heritage protection is increasingly showing a trend towards narrative and cognitive spatiotemporal positioning. The goal of protection is to restore abstract history and humanistic values to a complete spatiotemporal entity through the integration of spatial and landscape remains and their associated texts, allowing people to more intuitively, deeply, and systematically perceive, understand, and grasp the traces and interconnections left by human activities in both the spatiotemporal and conceptual worlds.Specific methods: On one hand, (Zhuang Xiaoping) developed a 'value cognition depth map' using 'historical richness' and 'time depth' as indicators to quantitatively assess the value of ancient city heritage. On the other hand, (Li Yuan) identified visual preference as the key factor influencing tourists 'decision-making and proposed a method for simulating pedestrian flow and optimizing tourist routes []. Thus, the spatial narrative shift initiated by City Walk is not merely an innovation in tourism products but a profound transformation in the perception and revitalization of historical districts. Using' walking 'as a medium and' narrative' as a link, it creatively integrates the spatial elements of cultural heritage with the needs of tourism development in a dynamic cultural experience space.

3.Methodology

3.1 Research Area

The Beiyuanmen Historical and Cultural Block, located in the northwest of Mingcheng District, Xi'an, is the area with the highest concentration of Muslim residents in Xi'an. Having experienced development from the Tang, Song, Yuan, Ming and Qing Dynasties to modern times, it preserves still the traditional 'seven temples and thirteen wards' layout of the Ming and Qing periods. The public spaces within the block, shaped by historical layers across different eras, have gradually formed the current appearance of the block. These public spaces are living elements that have continuously evolved in the daily lives and activities of Muslim residents. The existing types of public spaces mainly include public buildings (such as the Drum Tower, the City God Temple), mosques, and historical lanes.

3.2 Data Sources

Spatial data: CAD topographic maps, POI (Points of Interest) data.

Behavioural data: Over 200 travel notes from social media were selected by searching keywords like 'Beiyuanmen' and 'city walk' on Xiaohongshu. The places where visitors frequently appear in their daily routines are ranked as Shajin Bridge, Beiyuanmen, Guangji Street, North Guangji Street, Dapi Courtyard, Xuexi Alley, Muslim Street, Miao Hou Street, Gao Family Courtyard, Xi Yang Market, Huajue Alley, Xiaopi Courtyard, Great Mosque, Bell Tower, Xiaoxue Alley, Damai Market Street, Guangming Alley, Mai Xiang Street, Huajue Alley Mosque, Xuexi Alley Mosque, Bell and Drum Tower Square, Lianhu Park, and Hongbu Street. The main purposes for visitors to enter the block are to experience the food, history, Islamic culture and the local atmosphere.

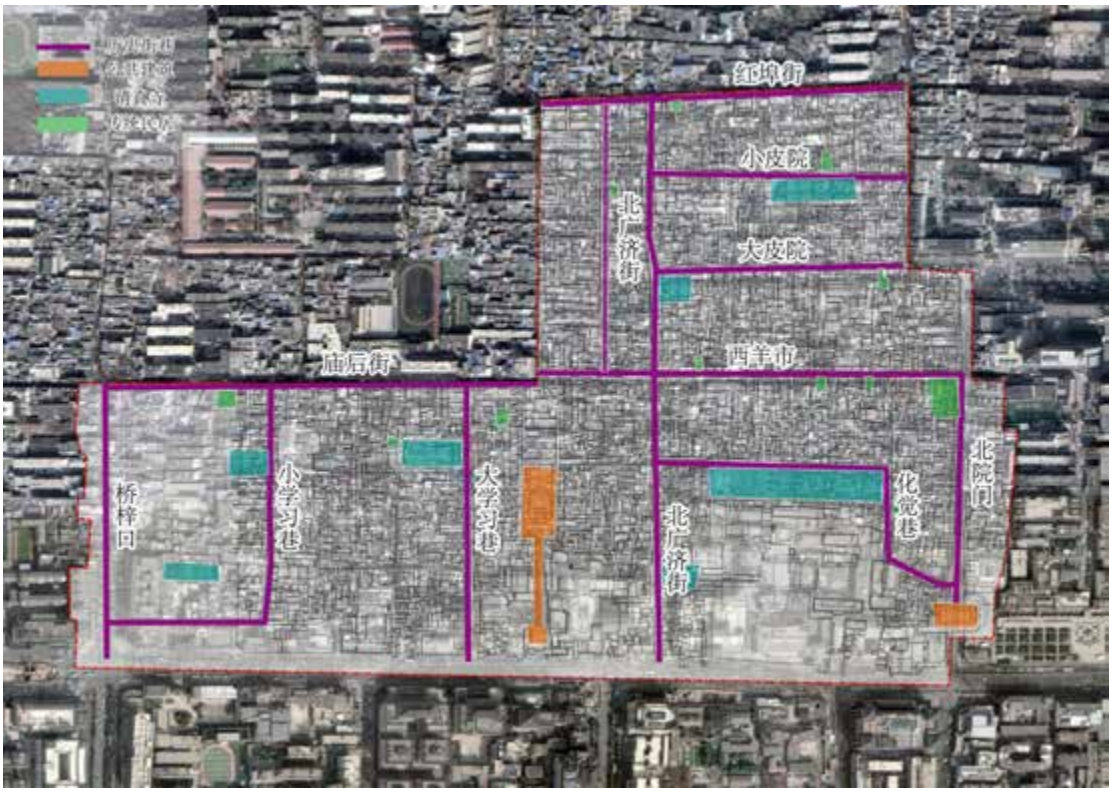

Figure 1 Research scope of Beiyuanmen Historical and Cultural Block

3.3 Technical Framework

This study applies a progressive technical route of spatial computation - behaviour sensing - semantic mining - intelligent optimisation. By integrating multi - source data and coordinating multiple models, it accurately analyses the spatial genes of the Beiyuanmen block, tourist behaviour patterns, and cultural cognition characteristics. Thus, it offers scientific evidence for creating a City Walk path system that integrates heritage conservation, tourist experiences, and community coexistence.Firstly, using the depthmapX platform to construct a block axis model and calculate key indicators to precisely identify the disharmonious areas between current paths and the block's natural texture.Secondly, in ArcGIS10.6 software, based on social media geographical tags and field observation points, applying kernel density estimation to generate tourist spatial aggregation heatmaps. Overlaying the distribution of heritage itself and local residents' living service facilities to visually present heritage display and commercial homogenisation expansion hotspots.Then, utilising travel notes published on social media to extract the main subjects tourists focus on, conducting visual - association to identify cultural cognition breakpoints and reveal tourists' perceptual blind spots of the block.Finally, performing multi - objective constraint optimisation of the historical and cultural block City Walk path.

4.Results

4.1 Spatial Form Characteristics

This study uses axial analysis and segment analysis. Axial analysis assesses the integration and connectivity of the Beiyuanmen Historical and Cultural Block, while segment analysis evaluates the selection of streets within the block. To begin, the research defines the spatial boundary. It extracts the street network of the block using CAD software based on the current situation, simplifies it to straight lines, exports it as a dxf - format file, and finally imports it into Depthmap software for spatial analysis of the block.

Integration, a key indicator of space syntax theory, reflects the accessibility of nodes in a spatial system and the closeness of their connections. It indicates the total steps needed to traverse all nodes from a starting point. A higher integration value signifies greater street accessibility. In the Beiyuanmen Historical and Cultural Block, Guangji Street has the highest integration, followed by Hongbu Street and Miao Hou Street. These streets are the most visited due to their excellent accessibility.Choice, the frequency a space appears on the shortest topological paths, is closely related to traffic potential. A higher choice value means more traffic and greater potential to attract people and vehicles. Some areas with high choice values but low integration are essential for local residents' daily activities, leading to their high traffic despite lower integration.Connectivity, the number of nodes connected to a specific node, indicates the spatial connections. Guangji Street has the highest connectivity in the block, followed by Xi Street, Hongbu Street, and Miao Hou Street. Other streets have lower connectivity due to numerous "T" intersections, causing traffic disruption and visual obstruction.

Figure 2-1 Integration

Figure 2-2 Choice

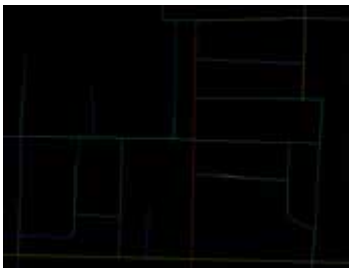

Figure 2-3 Connectivity

4.2 Heritage Perception Characteristics

The hotspots for heritage perception in the Beiyuanmen Historical and Cultural Block include historical and cultural heritages such as the Drum Tower and Guangji Street, as well as historical lanes with rich culinary culture like Xi Yang Market and Shajin Bridge. The City God Temple and Huajue Alley Great Mosque in the block attract a small number of tourists, while other cultural heritages are less known. Areas such as Qiaozikou, Damai Courtyard, Xiaopi Courtyard, and Hongbu Street, along with other mosques, are cold spots for heritage perception and are mostly visited by tourists seeking an in - depth experience of the local cultural atmosphere.

Firstly, this study conducted a Kernel Density Analysis of POIs in the Beiyuanmen Historical and Cultural Block, covering cultural heritage, public facilities, daily services, shopping, leisure, and dining services that cater to both residents and tourists. The results show that residents' daily and leisure services are mostly marginalised into non - core peripheral areas due to tourism - related space encroachment, with only a few shared public facilities evenly distributed. Tourists' activities mainly focus on historical lanes and cultural heritage sites, leading to a proliferation of shopping and dining services along these streets, which in turn crowds out residents' living spaces. Specifically, shopping services are concentrated in Beiyuanmen, Xi Yang Market, and North Guangji Street, near the Bell and Drum Towers, attracting tourists who mainly engage in superficial sightseeing. Dining services are mainly found in North Guangji Street, Shajin Bridge, Dapi Courtyard, and Miao Hou Street, which are more integrated into the local community and attract tourists seeking an in - depth experience.Secondly, through an analysis of travel notes posted on social media, including a word frequency analysis, it was found that the most frequently mentioned locations by tourists are "Shajin Bridge" and "Beiyuanmen", representing the block's culinary and cultural heritage highlights respectively. Other keywords often mentioned by tourists are related to various foods, reflecting the block's strong appeal to tourists through its ethnic culinary culture. Additionally, many historical lanes within the block are frequently mentioned, indicating that each lane has its own unique characteristics and points of interest, such as Guangji Street's culinary attractions and Beiyuanmen's shopping spots. Furthermore, an analysis of the correlations within social media travel notes reveals that tourists are particularly interested in experiencing the atmosphere of Xi'an's indigenous historical lanes. Several historical lanes and culinary elements are closely watched by tourists. Currently, the tour routes within the Beiyuanmen Historical and Cultural Block are closely related to historical and cultural heritage, historical lanes, and culinary culture.

4.3 Route Optimisation Plan

This paper proposes a "double loop" system for the City Walk tourist route in the Beiyuanmen Historical and Cultural Block. The main loop links core heritage sites, while the micro loop offers an in - depth experience within residential courtyards.The main loop, combining cultural heritage and halal food experiences, starts at the Drum Tower and follows a circular route. It links the "seven temples and thirteen wards" spatial pattern, enhancing the historical block's spatial experience. About 2.5 km long, it takes 2 - 3 hours and covers 90% of core resource spots.The main loop starts at the Drum Tower, goes through Huajue Alley, Xi Yang Market, Beiyuanmen, Gao Family Courtyard, Miao Hou Street, City God Temple, and back to the Drum Tower. Along the way, there are cultural spots like the Huajue Alley Mosque and Gao Family Courtyard. For food, places like Jia San Guan Tang Bao and Shaanxi Thirteen are included. Eco - friendly facilities like solar - powered charging seats are also available. Themed routes are offered at different times, integrating scattered historical fragments into a circular path for a hands - on experience of the block's cultural genes.There are two micro loops. One is the community culture experience route on the northeast side. It starts at Guangji Street, goes through Xiao Pi Courtyard, Mai Xiang Street, Beiyuanmen, and the Drum Tower, allowing participation in community activities and experiencing the halal community culture. The other is the halal food culture experience route on the west side. It starts at Guangji Street, goes through Miao Hou Street, Da Mai Market Street, and Shajin Bridge, where tourists can taste the food of century - old shops.

5.Discussion

5.1 Balancing Heritage Protection and Display Mechanisms

As a traditional settlement area in Xi'an Mingcheng District with distinctive local features, the Beiyuanmen Historical and Cultural Block preserves historical spatial texture since the Tang Dynasty and carries unique Hui Fang ethnic culture and market life traditions. The City Walk route aims to balance heritage protection and public display, and resolve the conflict between protection rigidity and utilisation flexibility.Core protection zones, covering sites like the Gao Family Courtyard and Huajue Alley Mosque, follow the minimal - intervention principle, focusing on static display and cultural interpretation.Style - coordination zones, including Ming and Qing streets like Xi Yang Market, allow moderate commerce but with strict business control, aiming for themed commercial experiences.Update - transition zones involve other general streets, which undergo minor changes to embed cultural spots.Also, to prevent tourist overcrowding on main streets, themed routes guide visitors to secondary streets. This spatial - temporal narrative reconstruction of cultural understanding eases core zone pressure and activates the block's heritage value.

5.2 Community Participation Implementation Path

The sustainability of heritage protection and display relies on community residents shifting from "managed objects" to "main participants". Beiyuanmen Block has designed multi - level and practical implementation paths for social participation to establish a real "bottom - up" co - governance mechanism. This ensures residents are not only cultural inheritance carriers but also decision - makers, interpreters, and beneficiaries of tourist routes. Firstly, local residents are recruited as City Walk guides to share their personal memories of the block's evolution, enhancing visitors' cultural experience.Secondly, intangible cultural heritage workshops are set up. With small scale, appointment - based, and in - depth interaction principles, these workshops avoid performance and commercialisation, aiming to restore historical scenes of value and offer deep cultural exchanges.Lastly, local shops are certified. Those using traditional crafts and highly rated by visitors and residents are added to the City Walk recommendation list. This safeguards the block's cultural authenticity against mass tourism and strengthens visitors' identity recognition during travel interactions.

6.Conclusion

Through integrated and innovative adaptive spatial strategies for high - density multi - ethnic blocks, this study builds an assessable, operable, and promotable City Walk route planning and management paradigm. First, it resolves the heritage protection - development paradox by suggesting a mechanism. Second, it reconciles tourist - resident spatial games to safeguard community spatial rights. Third, it bridges the route - spatial - form gap, creating an embedded network route. This paradigm serves Beiyuanmen Block's sustainable development and offers theory and practice references for similar global heritage sites, proving protection and development

can be dynamically balanced and mutually reinforcing through smart spatial interventions. However, given the unique spatial forms and routes of historical blocks with different cultural attributes, City Walk planning and management must be tailored to each block's specific characteristics.

Identification of Spatial Conflicts between Tourists and Local Residents: Based on "Nanjing Travel Pitfall Avoidance" Posts on Rednote

Yixuan Zhang, Shijie Sun
Southeast University
Email: zyx980720@163.com, sun_shijie@seu.edu.cn

Abstract
This study identifies spatial conflicts between tourists and local residents in Nanjing using Rednote "Nanjing Travel Pitfalls" posts, applying AI-based natural language processing and spatial analysis. Findings show: (1) Conflicts are "localised concentration and overall dispersion", with high-intensity zones in multifunctional areas like Laomendong and Xinjiekou; (2) Conflicts fall into three types: High-Intensity Clustered Type, Intersecting and Compressed Type, and Low-Frequency, High-Sensitivity Type; (3) Residents' perceptions focus on old town living spaces, tourists' are more dispersed, yet both align on key areas; (4) Social media amplifies conflicts via algorithmic recommendation and emotional contagion. The study suggests shifting from conflict control to spatial regeneration, promoting coexistence through time-sharing and community negotiation. It contributes theoretical and methodological insights to digital-era urban tourism governance.

Keywords: Spatial conflict; Social media; Urban tourism; Xiaohongshu; Nanjing

1 Introduction

With the ongoing popularisation, routinisation, and digitalisation of tourism activities, urban tourism spaces are undergoing unprecedented reconstruction. This transformation is evident not only in the shifting behavioural patterns of tourists but also in the blurring of traditional boundaries between tourism spaces and everyday living spaces. Through digital platforms such as Rednote, tourists now independently plan their itineraries, extending their activities beyond conventional scenic zones and increasingly embedding themselves into the daily spatial routines of local residents. While this spatial reconstruction enriches the diversity of tourism experiences, it simultaneously gives rise to new forms of spatial conflict. The recent surge of "Travel Pitfall Avoidance" posts on social media platforms like Rednote offers a vivid and direct reflection of these emerging conflicts. These user-generated contents not only document specific instances of spatial conflict, but also reveal deeper divergences in spatial use ideologies between tourists and residents. Systematic analysis of such content contributes to a more nuanced understanding of the challenges urban space governance faces in the digital age.

As an interdisciplinary research subject, the concept of spatial conflict has been continuously refined through academic inquiry. It has often been understood from a resource competition perspective, where incompatible demands for space among different groups generate conflict (Cocklin, 1988; Biagini, 1993). In the Chinese academic context, this concept has been further localised and expanded. One perspective emphasises the scarcity of spatial resources, portraying spatial conflict as a form of opposition during resource allocation (Zhou et al., 2012). Another interpretation draws attention to divergent development ideologies, which may lead to spatial imbalances and thus to conflict (Cheng, 2013). A more integrative approach sees spatial conflict as the result of intertwined processes, including resource redistribution, relational shifts, and value redefinitions (Chen et al., 2015). Overall, spatial conflict can be understood as a state of disharmony arising when multiple interest groups compete over established spatial resources and perceive their interests to be compromised. In this study, spatial conflict specifically refers to the tensions and oppositions between tourists and local residents that emerge within defined spatial and temporal contexts, due to discrepancies in resource usage, behavioural norms, and cultural understanding.

A review of existing literature reveals three prominent limitations in current research on tourism-related spatial conflict. First, in terms of research perspective, most studies have focused on specific types of tourism communities or rural destinations. A typical example is the analysis of multi-group conflict in Xijiang Qianhu

Miao Village, which sheds light on spatial dynamics within ethnic tourism settings (Liu and Zhao, 2021). However, comparative research in urban tourism contexts remains limited. Second, from a methodological standpoint, although some scholars have made progress in exploring spatial conflict mechanisms—particularly in tourism communities—the dominant reliance on qualitative analysis persists, with quantitative methods receiving less attention (Pan, 2021). Third, regarding data sources, most studies continue to depend on traditional methods such as surveys and in-depth interviews. While emerging research has begun incorporating data like GPS-tracked tourist mobility, concerns about data authenticity and representativeness remain(Li, Xie and Wang, 2018). Furthermore, social media data—rich in real-time, user-generated sentiment and spatial expression—has not been fully leveraged. These methodological limitations hinder a comprehensive understanding of the dynamic and evolving nature of spatial conflict in contemporary urban tourism spaces.

In response to these gaps, this study selects Nanjing as a representative case and uses the most viewed "Nanjing Tourism Pitfalls" posts on Rednote as its primary dataset. These posts offer unfiltered, real-time insights into tourists' and residents' emotional reactions and lived experiences of spatial conflict. By employing a mixed-methods approach that integrates qualitative content analysis and quantitative spatial analysis, the study systematically examines the characteristics of spatial conflict in the context of urban tourism. Specifically, it analyses these characteristics from three key dimensions: overall spatial distribution, dominant functional zones, and core subject object perspective. The study seeks to uncover the mechanisms driving the emergence of spatial conflict and to clarify the mediating role of social media—particularly through algorithmic recommendation systems and affective transmission—in amplifying these conflicts.

2 Methods

This study draws on data from the Chinese social media platform Rednote. Using Python-based web scraping techniques, we collected posts published before 5 April 2025 that contained keywords such as "Nanjing Travel Pitfall Avoidance", ranked by popularity. The initial dataset comprised 220 entries. Following manual screening to remove neutral or positive content, 181 negative posts were retained as valid samples for further analysis. To distinguish between different subject perspectives, user identities were classified as either tourists or local residents based on IP location metadata and profile information available on user homepages.

2.1 Spatial conflict point identification

The identification of spatial conflict points involved a hybrid method combining artificial intelligence (AI) technologies and manual verification. Natural Language Processing (NLP) techniques based on the DeepSeek model were employed to analyse post content, enabling the automated extraction of location-specific keywords that exhibit spatial characteristics—e.g., well-known tourist destinations such as "Fuzimiao" (Confucius Temple).

To ensure the precision of spatial identification, a three-stage manual verification process was subsequently implemented:

- Correction of non-standard toponyms – colloquial or abbreviated terms (e.g., "Nanbo") were matched with their full official names (e.g., "Nanjing Museum");
- Elimination of vague spatial references – imprecise descriptions such as "a mall in the city centre" were excluded;
- Removal of irrelevant or erroneous geographic information – spatial references lacking clear or accurate locational meaning were discarded.

2.2 Measurement of spatial conflict intensity

User interactions on the Rednote platform primarily include four forms: likes, favourites, comments, and shares. These metrics not only reflect the communicative popularity of a given post but also indirectly indicate the level of public attention and perceived impact associated with specific spatial conflicts. To quantify spatial conflict intensity, this study adopts a two-step approach: first, a weighted formula is developed to calculate the comprehensive heat value of individual posts based on the differential characteristics of each interaction type;

second, the total conflict intensity of each spatial conflict point is calculated by aggregating the heat values of all related posts.

(1) Calculation of post-level heat value

A weighted formula was established to determine the composite heat of each post:

$Post_Heat_i = 0.2 \times Likes_i + 0.1 \times Favorites_i + 0.4 \times Comments_i + 0.3 \times Shares_i$

where $Post_Heat_i$ denotes the heat of post i, and $Likes_i$, $Favourites_i$, $Comments_i$, and $Shares_i$ represent the corresponding interaction counts (Table 1).

Table 1 Weight design based on interaction behaviour characteristics

Interaction Type	Interaction Features	Weight
Likes	- Indicates user attention or recognition. - Often passive behaviour ("casual likes"). - May reflect content utility rather than stance on conflict. - Limited validity in capturing conflict intensity.	0.2
Favourites	- Represents archiving or bookmarking intent. - Primarily reflects the perceived usefulness of information. - Weak temporal association with conflict immediacy; exhibits a lag effect.	0.1
Comments	- Requires active engagement via text input. - Directly reveals depth and contentiousness of discourse. - Serves as the primary arena for local–tourist confrontation. - High indicator of conflict intensity due to two-way interaction.	0.4
Shares	- Captures the extent of information diffusion. - Greater share volume suggests broader public impact. - While motivations vary, sharing amplifies conflict exposure.	0.3

(2) Calculation of spatial conflict intensity

For a specific spatial location L, conflict intensity is computed by aggregating the comprehensive heat values of all posts associated with that location. This cumulative figure reflects the extent of public attention, emotional engagement, and discursive activity tied to the identified conflict site.

$$\text{Conflict_Intensity} = \sum_{i=1}^{n} (0.2 \cdot \text{Likes}_i + 0.1 \cdot \text{Favorites}_i + 0.4 \cdot \text{Comments}_i + 0.3 \cdot \text{Shares}_i)$$

(3) Classification of spatial conflict intensity levels

Based on the distribution of calculated values, spatial conflict intensity is categorised into five levels. The maximum observed intensity value is 42,406.6, and the minimum is 3.6. Classification criteria are presented in Table 2.

Table 2 Classification of spatial conflict intensity levels

Conflict Level	Value Range	Data Characteristics
Low	3.6 – 1,000	Scattered, low-engagement interactions; predominantly neutral content with minimal contentious expression.

Moderately Low	1,000.1 – 5,000	Occasional controversial topics; limited discussion scope; participants express fragmented, non-confrontational views.
Moderate	5,000.1 – 15,000	Emergence of polarised viewpoints; regionalised discussion patterns; significant increase in interaction frequency.
Moderately High	15,000.1 – 30,000	Sustained multi-group discussions; heightened emotional expressions; accelerated information diffusion.
High	30,000.1 – 42,406.6	Large-scale cross-community discourse; featured discussions on mainstream platforms; heightened need for content regulation.

2.3 Spatial analysis

This study employs ArcGIS 10.8 to conduct multi-level spatial analyses, including global spatial autocorrelation and kernel density estimation. These methods collectively uncover the spatial distribution patterns of tourism-related conflict.

Global spatial autocorrelation analysis utilises Moran's I index to evaluate whether conflict intensities exhibit clustering, dispersion, or randomness across space, thereby offering a macro-level perspective on the spatial configuration of tourism conflict in Nanjing.

Kernel density estimation visualises the spatial concentration of conflict points by calculating their frequency per unit area. This generates a continuous density surface, illustrating the spatial gradient of conflict intensity, identifying core conflict zones, and revealing potential diffusion pathways. This provides a valuable foundation for understanding the spatial propagation mechanisms of tourism-related conflict.

3 Research findings

3.1 Overall spatial distribution characteristics of conflict

(1) Spatial distribution patterns

The spatial distribution of conflict points between tourists and local residents in Nanjing exhibits a pattern of localised concentration and overall dispersion (Figure 1). Conflict hotspots are primarily clustered in two key areas: (1) the historic inner city, particularly around Xinjiekou and Laomendong; (2) the Zhongshan Scenic Area, located outside the old urban core. These zones serve as major tourist attractions while simultaneously functioning as vital public spaces for residents' daily activities.

In addition, sporadic conflict points are distributed throughout the central urban area beyond the old city, including locations such as Yuhuatai, Guochuangyuan, and Suojincun. Beyond the central districts, isolated instances of spatial conflict are also observed in the Niushou Mountain Scenic Area. This spatial pattern suggests that conflict emerges not only in core tourist zones but also in areas where daily residential life intersects with tourism activity, highlighting the complex socio-spatial entanglements within the urban tourism landscape.

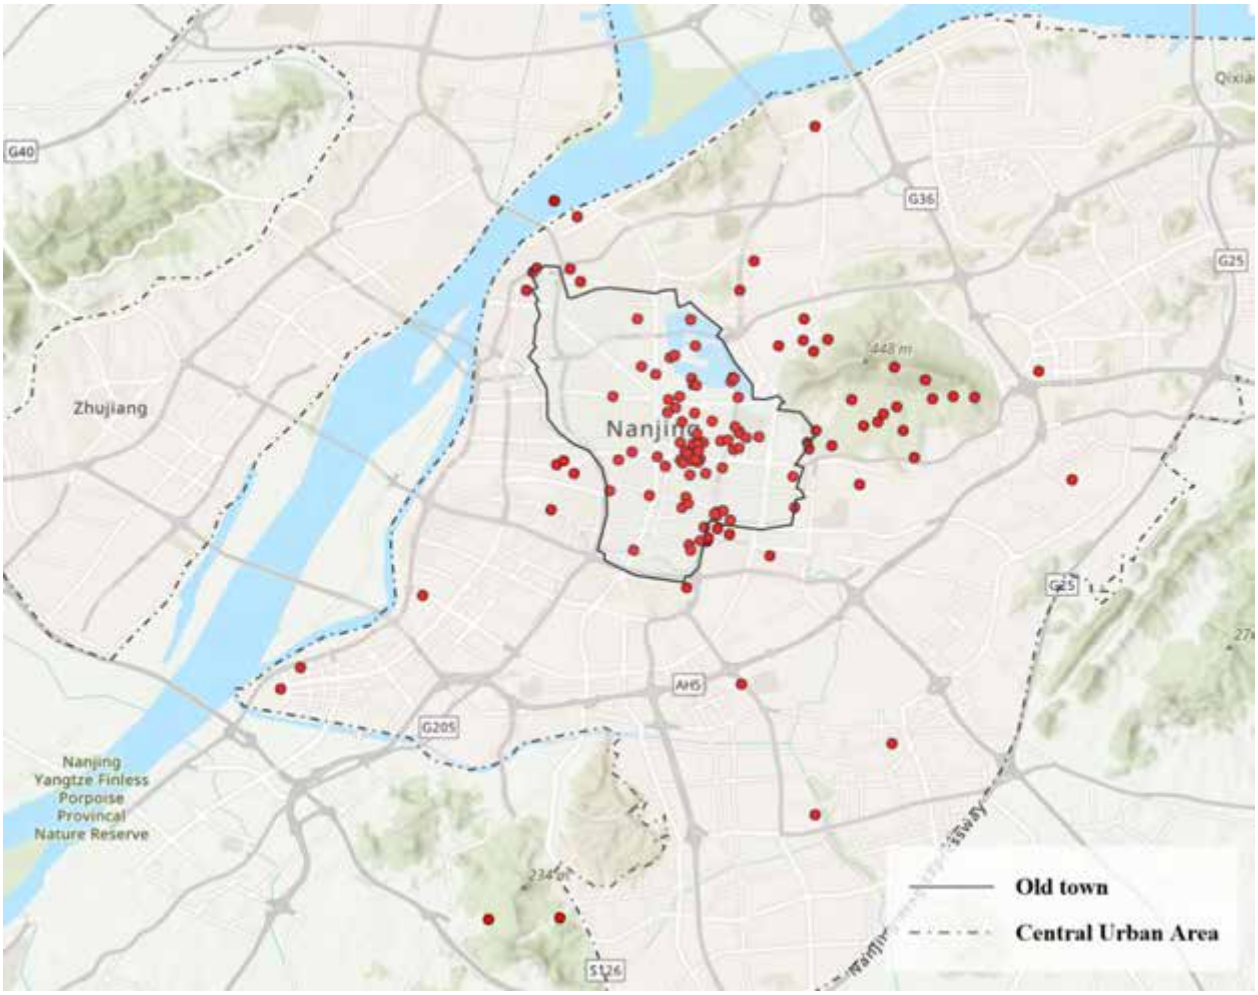

Figure 1 Spatial distribution of conflict points in Nanjing

Further analysis of spatial conflict intensity reveals that 38% of identified conflict points fall within the "moderate" to "high" intensity categories (Figure 2). These points are predominantly concentrated in Nanjing's old city centre and the Zhongshan Scenic Area. Specifically, seven locations—Laomendong, Xinjiekou, Jiming Temple, Nanjing Museum, Xuanwu Lake Park, the Memorial Hall of the Victims in Nanjing Massacre, and the Sun Yat-sen Mausoleum—are identified as sites of "high-intensity" spatial conflict. These areas are characterised by both high tourist footfall and the convergence of multiple urban functions, including culture, commerce and recreation.

Conflict points with "moderately low" intensity are mainly concentrated in Laomendong and Xinjiekou districts, reflecting periodic and localised tensions. In contrast, "low-intensity" conflict points are more diffusely distributed across the old city, indicating a spatial diffusion pattern from the core to the periphery. This outward dispersal trend corresponds with a gradual decline in both conflict frequency and intensity as distance from the city centre increases.

Figure 2 Spatial distribution of conflicts across intensity levels in Nanjing

(2) Spatial autocorrelation characteristics

The results of the global spatial autocorrelation analysis (Table 3) indicate that the overall distribution of tourism-related spatial conflict intensity in Nanjing exhibits a significantly dispersed pattern. Specifically, "high-intensity" and "low-intensity" conflict points tend to be spatially separated, rather than concentrated in particular areas.

Table 3 Results of global spatial autocorrelation analysis

Indicator	Value	Interpretation
Moran's I	-0.084664	Indicates a slight overall spatial dispersion (negative spatial correlation). High- and low-intensity conflict points are spatially distinct.
z-score	-2.024578	Deviates significantly from the mean of a normal distribution, confirming negative spatial correlation.
p-value	0.042911	Less than 0.05, indicating statistical significance.

3.2 Spatial conflicts under differentiated functional domains

(1) Typological classification and functional characteristics

Based on the dominant function of each spatial conflict location, a typological approach was adopted to classify conflict sites into eight categories (Table 4).

Table 4 Typology of spatial conflicts based on dominant functional attributes

Type Code	Type Description	Examples
T1	**Commemorative and Exhibitory Spaces**: Public spaces primarily focused on historical commemoration and cultural exhibition.	Nanjing Museum, Memorial Hall of the Victims in Nanjing Massacre
T2	**Tourist Attractions**: Nationally rated A-level scenic spots and other major tourism destinations.	Laomendong Historic District, Yihe Road Historic District, Sun Yat-sen Mausoleum
T3	**Commercial Consumption Areas**: Modern commercial complexes centred on shopping and consumer activities.	Golden Eagle International, The Mixc Mall, Greenland Zifeng Tower
T4	**Creative-Cultural Spaces**: Areas combining cultural industries with lifestyle experiences.	Librairie Avant-Garde, Guochuangyuan Innovation Park
T5	**Food and Leisure Spots**: Locations attracting visitors primarily for distinctive local cuisine and social consumption.	Hongfu Noodle Shop, Volcano Izakaya
T6	**Everyday Living Spaces**: Traditional residential communities and daily life areas.	Taogu New Village, Hongmiao Community, Kexiang Alley
T7	**Transport Nodes**: Key metro stations and major road intersections within the city.	Nanjing Yangtze River Bridge, Wutong Avenue, Beijing East Road

T8	**Scenic Parks**: Open green spaces focused on ecological leisure and recreation.	Hongshan Forest Zoo, Mochou Lake Park

(2) Spatial distribution characteristics

A systematic analysis of the 125 identified spatial conflict points (Figures 3 and 4) reveals significant variations in terms of quantity, conflict intensity, and spatial clustering across different dominant functional types.

In terms of quantity, spatial conflicts associated with Tourism Attractions (T2) far exceed those of other categories, totaling 35 cases, which accounts for 28% of the total sample. This suggests that although urban tourism space is becoming increasingly diversified, traditional tourist sites remain the primary arenas for spatial conflict. Food and Leisure Spots (T5) and Everyday Living Spaces (T6) registered 27 and 18 conflict points, respectively. This pattern indicates a growing tendency for contemporary tourism activities to penetrate the quotidian spaces of city life. By contrast, Creative Cultural Spaces (T4) exhibited the lowest number of conflict points (only 2), a phenomenon that may be attributed to their niche positioning and the relatively higher cultural literacy of their visitors.

In terms of conflict intensity, "high-intensity" conflicts are predominantly concentrated in Tourism Attractions (T2) and Commemorative and Exhibitory Spaces (T1). For instance, traditional sites such as Laomendong have experienced disruptions due to excessive tourist density, resulting in spatial disorder. Similarly, institutions like the Nanjing Museum and the Memorial Hall of the Victims in Nanjing Massacre manifest conflicts between visitor behavior and the solemn atmosphere required by such spaces. "Moderately high-intensity" conflicts, meanwhile, are more frequently observed in Transport Nodes (T7) and Food and Leisure Spots (T5). In the former case, conflict points such as Xinjiekou Station and Zhangfuyuan Station indicate that the urban commuting system has become a critical locus of tourism-induced spatial tension. In the latter case, disputes often arise from issues related to service quality, taste expectations, and pricing strategies.

In terms of spatial clustering, Tourism Attractions (T2) exhibit a dual-core agglomeration pattern, with concentrations in both the Zhongshan Scenic Area and the Laomendong Historic District. This indicates considerable spatial conflict pressure on traditional tourism zones. Commercial Consumption Spaces (T3) and Food and Leisure Spots (T5) together form a "composite conflict zone" around Xinjiekou, underscoring the spatial competition generated by multi-functional convergence in commercial centers. Everyday Living Spaces (T6) present a single-core clustering pattern centered in the Gulou District, where dense historic alleys and a rich local lifestyle atmosphere have recently attracted heightened attention from external tourists. This area's high concentration of long-term residents has further intensified the tensions between tourism practices and daily urban life.

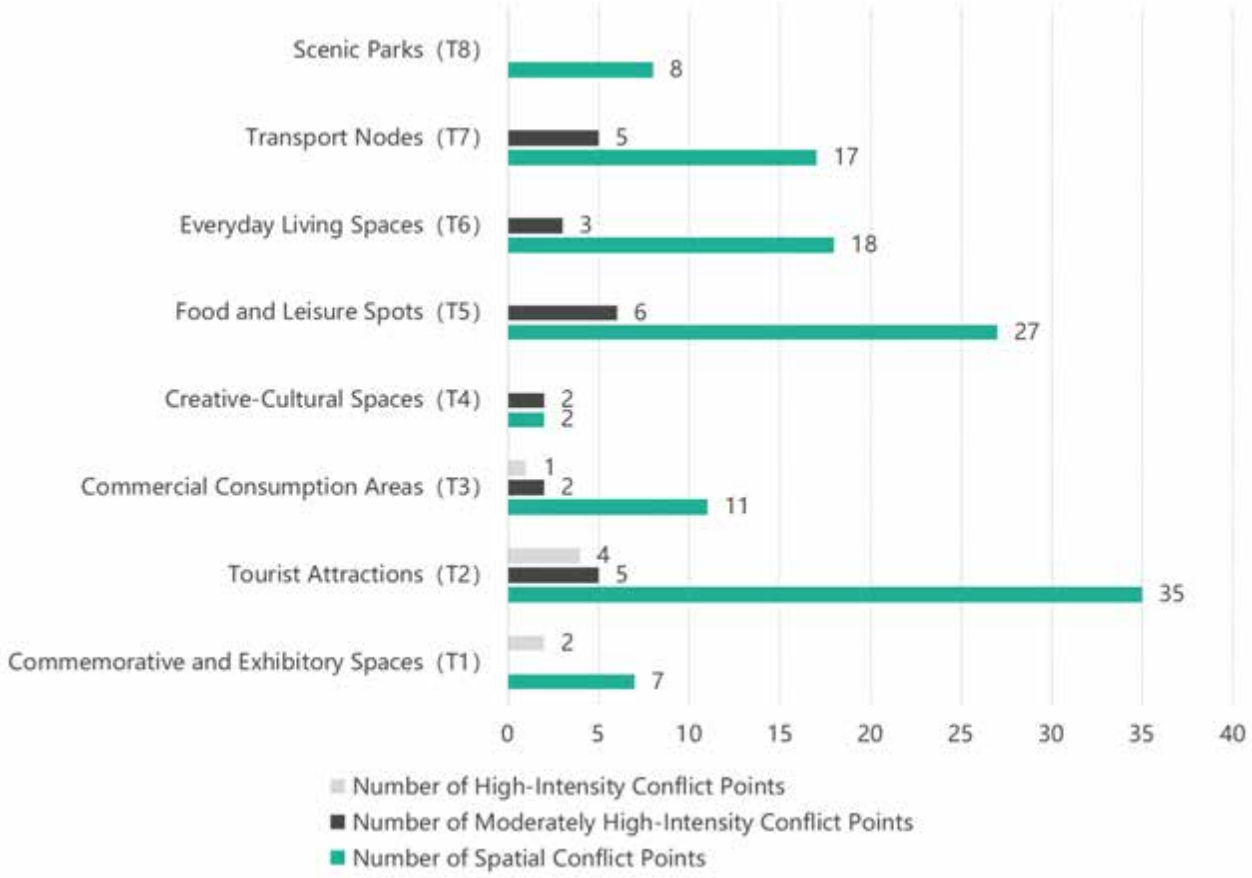

Figure 3 Statistical distribution of spatial conflict points

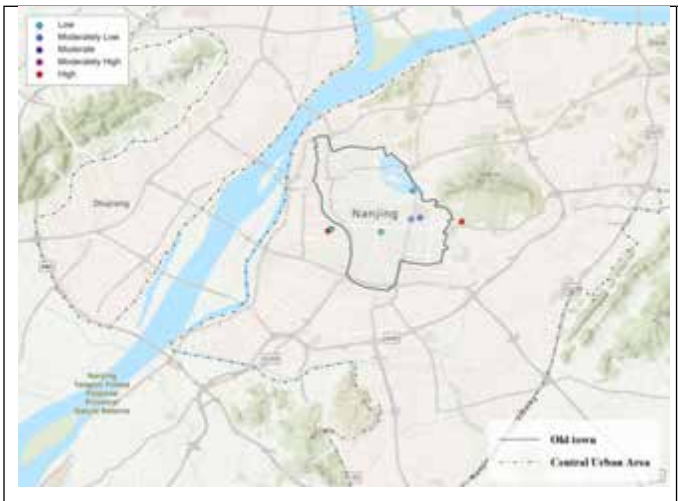
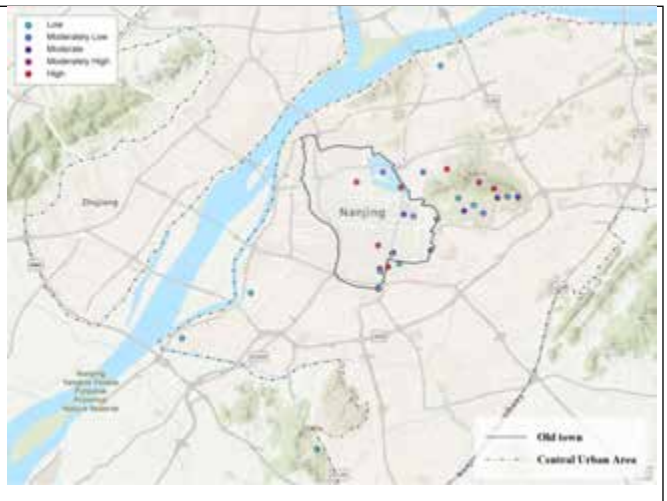


T1-Commemorative and Exhibitory Spaces



T2-Tourist Attractions

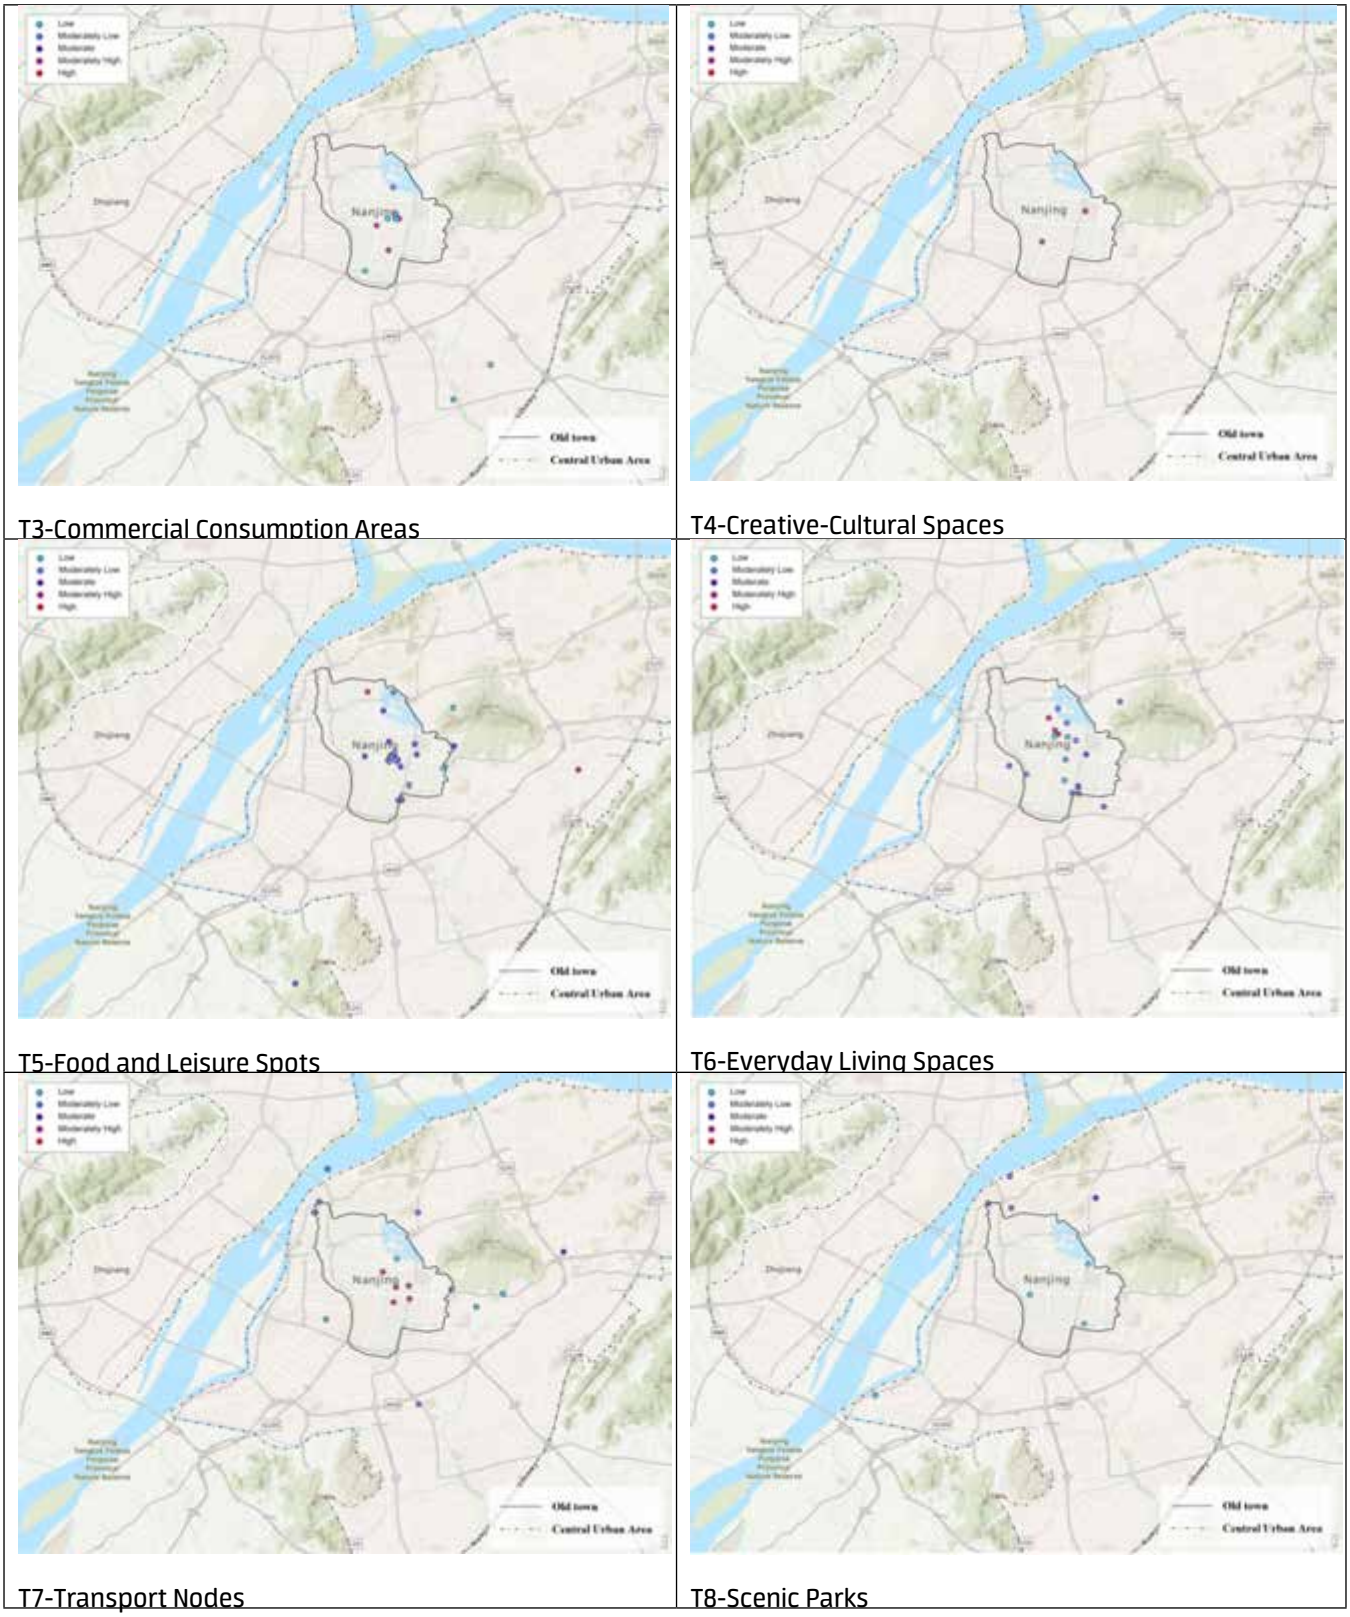


Figure 4 Spatial distribution of conflicts by dominant functional type

(3) Spatial conflicts and dominant functional types

Based on the typological classification and spatial distribution characteristics of conflict points, this study identifies three typical patterns that reflect the relationship between dominant functional types and the manifestation of spatial conflicts in urban tourism areas:

High-intensity clustered type: Tourist Attractions (T2), Food and Leisure Spots (T5)

This type of conflict pattern predominantly occurs in areas with the highest concentration of tourists and the most diverse range of tourism-related activities. These zones exhibit a high number and intensity of spatial conflict points, accompanied by a significant degree of spatial clustering. Representative cases include Laomendong, Sun Yat-sen Mausoleum, Xuanwu Lake, and the Xinjiekou commercial district. The conflicts in these areas are primarily driven by overcrowding, disruption of spatial order, and overloading of local resources, resulting in high-pressure scenarios. As such, these zones represent the primary risk areas in terms of urban tourism-related spatial tensions.

Intersecting and compressed type: Everyday Living Spaces (T6), Transport Nodes (T7)

This pattern mainly arises in urban spaces originally serving daily residential or transit functions. In recent years, such spaces have increasingly been integrated into the exploration-oriented tourist routes, such as "citywalk", due to tourists' growing interest in local lifestyles and authenticity. The overlap of spatial use between residents and visitors generates tensions rooted in mismatched temporal rhythms, spatial behaviors, and normative expectations. Typical examples include residential alleys in the Gulou District and metro station areas in the urban core. These spaces become points of friction as tourism penetrates into everyday life zones, challenging traditional patterns of use and social norms.

Low-frequency, High-sensitivity type: Commemorative and Exhibitory Spaces (T1), Creative-Cultural Spaces (T4)

Although conflicts in this category occur less frequently, the spaces involved carry strong symbolic and emotional significance, thus requiring a higher degree of behavioral regulation. When visitors' actions deviate from the cultural or normative expectations embedded in these spaces, even a limited number of conflict events can trigger strong emotional reactions and widespread public scrutiny. Notable examples include the Memorial Hall of the Victims in Nanjing Massacre and the Vanguard Bookstore. These spaces typically exhibit characteristics of "high sensitivity and low tolerance," where symbolic disruption outweighs quantitative frequency, and thus represent a unique and particularly delicate form of spatial conflict.

3.3 Spatial conflicts from the perspective of different actors

(1) Local residents

From the perspective of local residents, spatial conflicts are primarily concentrated in the eastern part of Nanjing's old city (Figure 5), generally forming a dual-core spatial distribution characterized by "one primary, one secondary" conflict center (Figure 6). The Xinjiekou area emerges as the most prominent conflict zone perceived by residents. As the commercial, transportation, and employment hub of Nanjing, Xinjiekou plays a crucial role in residents' daily commuting, consumption, and social interactions. However, the continuous influx of tourists has disrupted the balance of spatial usage, leading to intensified pedestrian congestion, overcrowding in public spaces, and frequent noise pollution. These disruptions have significantly lowered residents' tolerance for tourism-related activities in the area.

Laomendong constitutes the second core of perceived conflicts among residents. As a traditional neighborhood that retains both historical character and everyday life patterns, Laomendong has undergone a process of tourism-oriented transformation, which has attracted large volumes of visitors. Nevertheless, this has also triggered residents' discontent toward the "touristification of living spaces." The frequent overlap between visitor behavior and community life results in persistent intrusions on residents' privacy, tranquility, and daily routines, turning the area into a typical hotspot of "shared space conflict."

Notably, nearly all "moderate-to-high intensity" conflict points perceived by residents are concentrated within the old city boundaries. This highlights residents' heightened sensitivity and defensive responses to disruptions in their daily living environments.

In summary, residents' perception of spatial conflict primarily stems from the ongoing disturbance of established living patterns caused by tourism activities. The spatial distribution of these conflicts is concentrated in areas with dense residential functions and high tourist footfall, showing pronounced features of spatial centrality and conflict intensity.

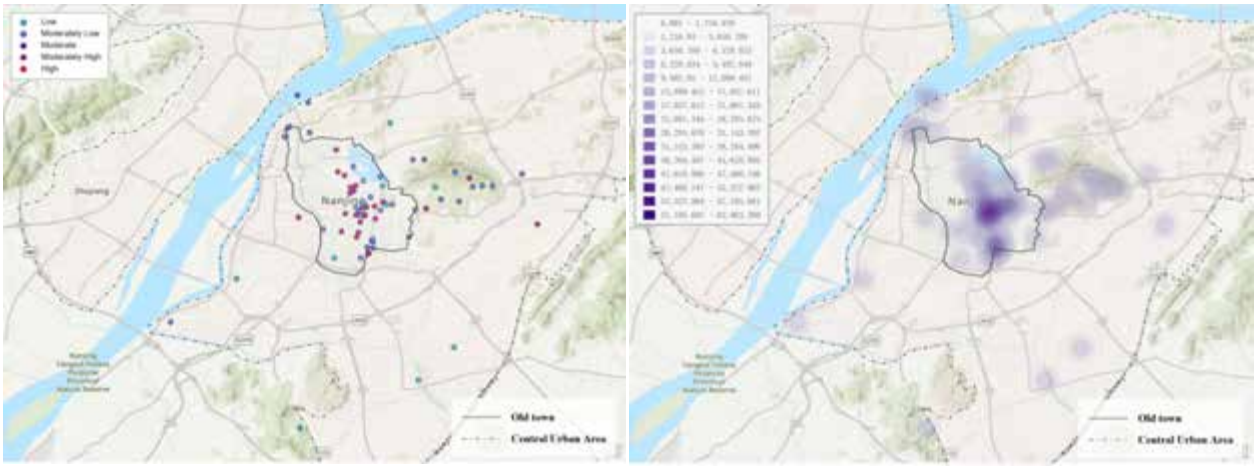

Figure 5 Spatial conflict distribution and intensity from the perspective of local residents

Figure 6 Kernel density analysis of spatial conflicts from the perspective of local residents

(2) Tourists

Unlike local residents, tourists exhibit a more dispersed perception of spatial conflicts (Figure 7), which overall presents a "one primary, three secondary" four-core distribution pattern (Figure 8). The Xinjiekou area remains the principal conflict perception zone for tourists, which aligns closely with the perspective of local residents. As a key node for shopping and transportation interchange—and often the first impression space encountered by tourists—this area bears significant functions related to public service provision and urban image. However, the coexistence of mixed spatial functions, unclear signage systems, insufficient service facilities, and aging infrastructure tends to generate a sense of disorientation during tourists' initial experience, thereby intensifying their perception of spatial conflict.

Similarly, the Laomendong area is another zone where tourist and resident conflict perceptions significantly overlap. As a historical district that attracts prolonged tourist visits, tourists often express concerns about the increasing commercialization, spatial homogenization, and excessive crowding. These issues, when intertwined with residents' resentment toward the "touristification" of their living space, highlight the area's typical "shared space conflict" characteristics.

The Presidential Palace–Kexiang neighborhood represents a boundary zone where tourism and everyday life are densely interwoven. Tourists frequently enter residential courtyards by mistake, generate noise, or loiter for extended periods during their visits, often resulting in friction with community life. On one hand, such behaviors may lead to discomfort or embarrassment for the tourists themselves; on the other, they further exacerbate residents' dissatisfaction with tourism-induced disruptions.

The Zhongshan Scenic Area, as a suburban-oriented core attraction with abundant natural and cultural resources, also emerges as a conflict zone during peak seasons. Despite its significance, the site suffers from inadequate navigation systems and severe congestion, which degrade the overall visitor experience and prompt short-term conflict perceptions.

In general, spatial conflict perceptions among tourists mainly stem from their immediate experiences with services, information, and spatial order in unfamiliar environments. These perceptions are spatially dispersed, with a clear multi-core structure, and the intensity of perceived conflict tends to be moderate and fragmented. This distribution stands in sharp contrast to the local residents' concentrated and high-intensity conflict patterns, revealing the differentiated mechanisms through which distinct user groups engage with urban space.

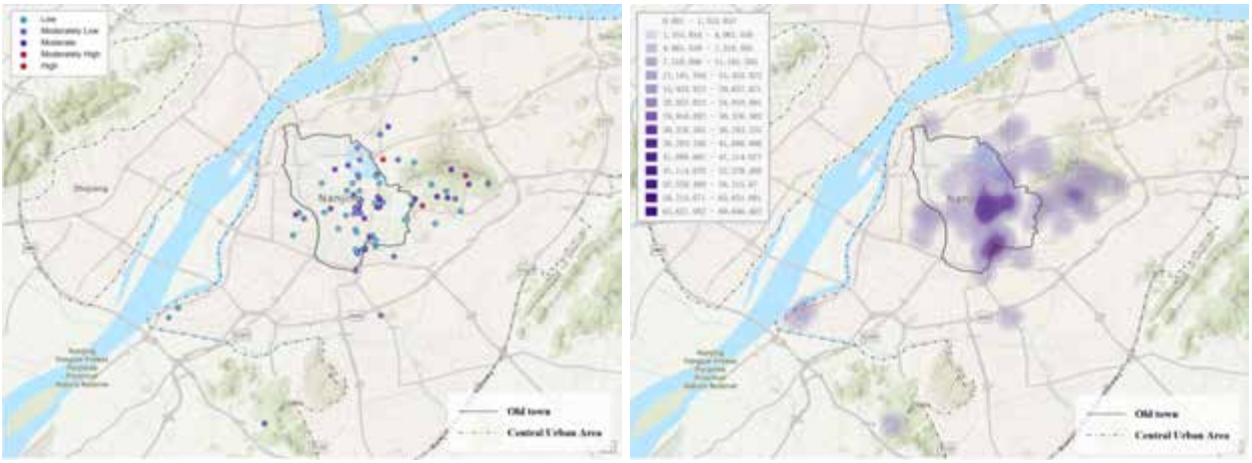

Figure 7 Spatial conflict distribution and intensity from the perspective of tourists
Figure 8 Kernel density analysis of spatial conflicts from the perspective of tourists

(3) Comparative differences

In terms of the number of spatial conflict points, tourists identified a total of 87 conflict locations, significantly more than the 73 points identified from the perspective of local residents. This discrepancy suggests that tourists, due to their broader activity trajectories in an unfamiliar city, are more prone to encounter experiential friction during movement, consumption, and interaction, thereby exhibiting a heightened sensitivity to spatial conflicts.

Regarding conflict intensity, local residents' perceptions are mainly concentrated within the old urban core, demonstrating a "high-intensity, high-density" clustering pattern. In contrast, the "high-intensity" conflict points perceived by tourists are more often located in peripheral scenic areas and key urban nodes, forming a distribution characterized by "high-value points, wide-area coverage." This reflects tourists' wider spatial scope and more scattered conflict experiences compared to the residents' localized concerns.

From the perspective of spatial structure, residents' perception of conflict presents a "concentrated" pattern, revealing their strong desire to protect the stability of specific everyday living spaces. Conversely, tourists' conflict perception shows a "dispersed" pattern, often emerging as incidental friction encountered during the tourism mobility process. The root of this divergence lies in differing urban space usage logics: residents emphasize the continuity and order of daily life, while tourists prioritize the completeness and comfort of short-term experiences.

Despite these differences, both groups show high levels of agreement in their conflict recognition within certain critical urban spaces (Figure 9). For example, Xinjiekou, as a multifunctional urban core where commercial,

transportation, and employment functions overlap, and Laomendong, a historic district where everyday life and tourism are tightly intertwined, are both frequently cited by residents and tourists alike. These areas jointly constitute the most prominent zones of spatial conflict in the city.

Overall, spatial conflict is not merely a manifestation of behavioral friction at the individual level. More profoundly, it reflects the tensions and coordination challenges among different social groups in the process of "sharing the city." Understanding these differentiated perceptions is crucial for formulating inclusive and responsive urban planning strategies.

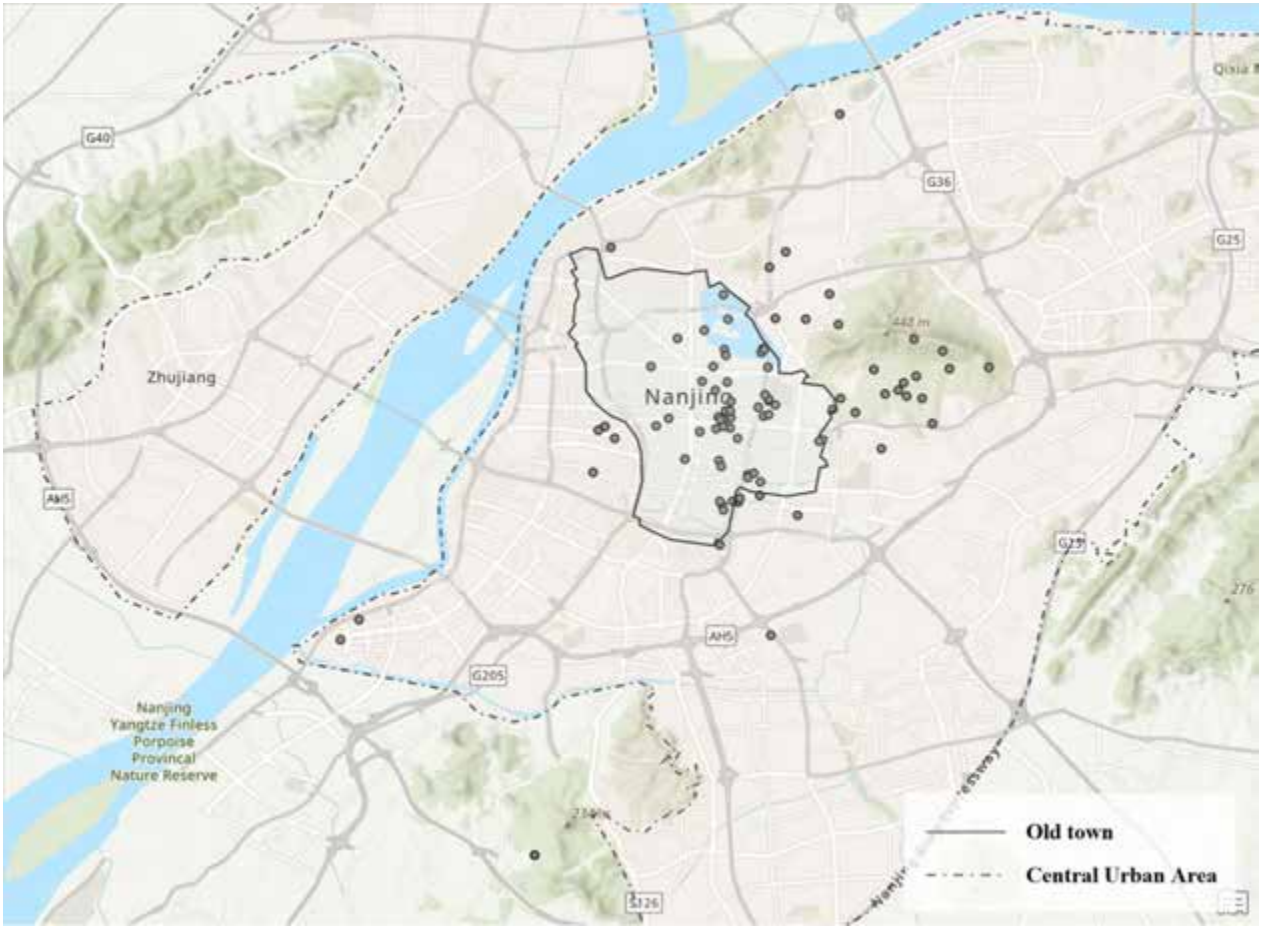

Figure 9 Shared conflict points from different actor perspectives

4 Discussion and Conclusion

4.1 The mechanism of spatial conflict generation: The interaction among structure, action, perception, and platform

Spatial conflicts in tourism are not merely the accumulation of isolated and accidental incidents; rather, they represent a systemic phenomenon embedded within the city's spatial structure, social behavior patterns, and digital platform mechanisms. To develop a more systematic understanding of the logic behind conflict generation, this study draws on Henri Lefebvre's theory of the "production of space" to construct a three-dimensional model encompassing the structural layer (representational space), the action layer (spatial practice), and the perceptual layer (representations of space).

At the structural level, urban planning regulations, tourism development policies, and the functional layout of

space provide the institutional and material foundations for spatial conflicts. In Nanjing—particularly within the old city—there exists a high degree of overlap between historical heritage and modern urban functions. Residential, transportation, commercial, and tourism activities coexist and often overlap, intensifying competition over space and increasing conflict intensity. Additionally, the lack of clear functional zoning, imbalances in infrastructure allocation, and uneven distribution of tourism resources all contribute to spatial tension and functional antagonism.

At the action level, spatial practices by diverse actors form the behavioral mechanisms through which conflicts emerge. Tourists, guided by social media platforms, tend to follow hotspot-driven routes of exploration, while local residents utilize the same spaces according to the rhythms of daily life. These two user groups differ significantly in their behavioral tempo, adherence to spatial norms, and expectations of space. Urban governance often lags behind these spatial dynamics; the boundaries of regulation remain ambiguous, and management mechanisms struggle to respond effectively. Meanwhile, the algorithmic recommendations, tagging systems, and hotspot aggregation functions of platforms further guide and reinforce individual spatial preferences, exacerbating tensions in space usage.

At the perceptual level, spatial conflicts are constantly generated and amplified through individual experiences, cognitive dissonances, and emotional expressions. Tourists who encounter negative experiences frequently share them on social media using warning-laden terms such as “red flags” or “traps,” turning their posts into user-generated content that enters the public opinion sphere. Local residents, feeling the encroachment of tourists, develop psychological defenses toward their living spaces, which often manifest as cognitive opposition to tourist activities. These emotional narratives and cognitive divergences overlap and reinforce one another within the digital environment, amplifying awareness and perception of conflict.

Social media platforms, as deeply embedded spatial agents, play a dual role in the conflict generation process. On one hand, they transform fragmented individual experiences into collective perceptions, enabling originally dispersed tensions to be “tagged” and “mapped,” thereby acquiring characteristics of public dissemination and cognitive stability. On the other hand, through mechanisms such as trending lists, check-in culture, and personalized recommendations, platforms reconstruct tourists’ spatial imaginaries and anticipated pathways, intensifying the spatial burden and disorder in hotspot areas and giving rise to new conflict nodes.

Therefore, the generation of spatial conflicts in tourism should not be oversimplified as a result of governance failure or individual misbehavior. Instead, it should be understood as a continuous negotiation among multiple actors within urban space over resource allocation, behavioral norms, and cognitive orders. Urban space is not a neutral physical container but a socially produced space constantly shaped through institutional structures, behavioral interactions, and emotional expressions. In this evolving spatial production, the mechanisms of digital platforms have emerged as indispensable participants in governance and influential forces in reshaping urban order.

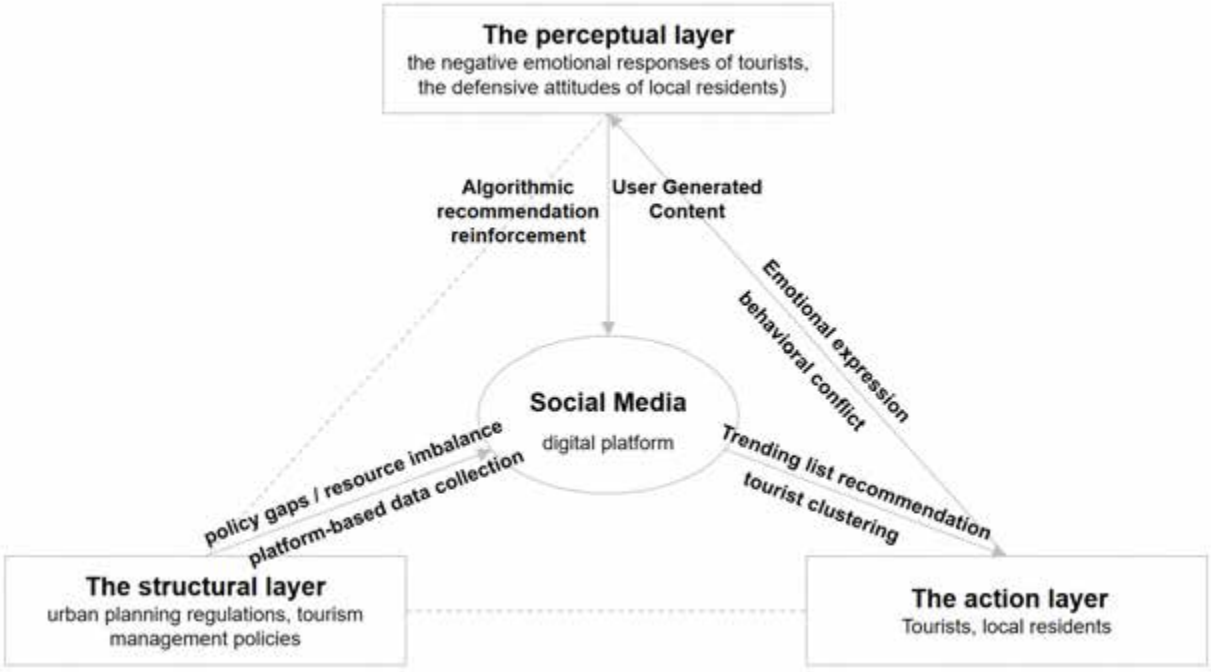

Figure 10 The mechanism of spatial conflict generation: the interaction among structure, action, perception, and platform

4.2 Governance shift of spatial conflicts: From passive management to spatial regeneration

In response to the growing prevalence of spatial conflicts in urban tourism areas, urban governance urgently needs to shift from a passive logic oriented toward emergency response and control to a proactive pathway of spatial (re)production centered on promoting coexistence. This transformation entails a systematic advancement in four key dimensions: enhancing spatial carrying capacity, optimizing behavioral guidance mechanisms, strengthening data feedback capabilities, and embedding adaptive renewal strategies—collectively shifting the governance paradigm from problem patching to spatial activation.

Enhancing the spatial carrying capacity and dynamic adaptability of high-intensity conflict zones. In high-conflict areas such as Xinjiekou and Laomendong, integrated strategies combining "micro-renewal" and "refined governance" can be employed to improve pedestrian accessibility, introduce temporary rest nodes, and incorporate flexible space-use mechanisms. These measures strengthen the area's resilience to high-density flows. During peak periods, time-sharing policies can be introduced to dynamically regulate tourist volume and mitigate disruptions to residents' everyday lives.

Recognizing and softly managing "gray conflict spaces." These spaces—typically found in residential alleys, transit hubs, or other non-typical tourist zones—often feature blurred functional boundaries and insufficient formal governance, making them potential blind spots for conflict generation. Soft spatial interfaces, participatory community co-management, and strengthened behavioral guidance can improve local self-regulation. For example, establishing "quiet hours," enhancing the readability of wayfinding systems, and creating communication platforms between residents and tourists can reduce friction.

Integrating social media feedback mechanisms into spatial governance frameworks. A dynamic feedback loop—consisting of conflict detection, consensus-building, and behavioral intervention—can be developed by incorporating platform-generated data. Real-time monitoring of spatial hotspots, semantic intensity, and actor

profiles enables early warning systems and cross-sectoral response, facilitating a shift from static regulation to adaptive coordination.

Embedding the governance of tourism-related spatial conflicts into broader urban renewal and regeneration strategies. Addressing spatial conflict can become a critical entry point for reactivating urban vitality and reconstructing publicness and collective identity. High-intensity conflict zones can serve as experimental fields for governance innovation, where cultural nodes, public art, and local life scenes are embedded to foster incremental, flexible renewal of old neighborhoods. This approach cultivates a public space culture grounded in humanistic care and shared values. The governance mindset thus transitions from "controlling space" to "empowering space," fostering a symbiotic relationship among tourism, everyday life, and urban development, and steering cities toward a more resilient and inclusive model of coexistence-oriented governance.

4.3 Reframing spatial conflict: From "Avoidance" to "Coexistence"

By analyzing the spatial semantics and typologies of UGC content categorized under "Nanjing Tourism Red Flags" on the Xiaohongshu platform, this study uncovers three emerging characteristics of urban tourism spatial conflicts under the influence of digital platforms:

Decentralized and fragmented conflict distribution. Spatial conflict is no longer concentrated in traditional tourist attractions but is widely dispersed across everyday alleys, transportation nodes, and consumption-oriented spaces. This fragmented pattern reflects both the increasing normalization of tourism within everyday urban life and the amplification effect of social media platforms that bring visibility to non-traditional tourist spaces.

Diversification and heterogeneity of conflict types. This study identifies three typical spatial conflict patterns: "High-intensity clustered type," "Intersecting and compressed type," and "Low-frequency, High-sensitivity type". These typologies reveal the complex interplay between tourist mobility patterns, residents' daily rhythms, and spatial governance logic. Each conflict type differs in its mechanism of emergence, spatial attributes, and emotional feedback, requiring tailored governance strategies rather than a one-size-fits-all approach.

Platform-mediated differentiation of perceptions and amplification of emotions. Social media platforms have transformed both the generation and dissemination of spatial conflict. Individual experiences are rapidly aggregated into collective perceptions, while behavioral frictions are compounded by perceptual divergences and emotional expressions, resulting in an emotionally charged digital public sphere. Differences in spatial expectations, cognitive tensions, and imagined orders between residents and tourists are continuously constructed and intensified through platform-based narratives.

Taken together, spatial conflicts in Nanjing's tourism context can no longer be treated as manageable "issues" within the purview of a single administrative department. Rather, they represent a complex phenomenon shaped by institutional logics, behavioral patterns, and media mechanisms. Social media platforms are no longer mere amplifiers of conflict—they have become deeply embedded actors in the (re)construction of spatial order.

Future urban spatial governance must move beyond traditional frameworks of physical space and administrative zoning, and instead, respond to the embedded mechanisms of platform-mediated spatial order. This study's empirical analysis of tourism-related spatial conflicts in Nanjing presents a multidimensional portrait of how urban conflict is produced in the platform era, offering both theoretical grounding and practical insight for constructing a "coexistence-oriented" governance system.

Further research could deepen this inquiry by integrating data across multiple platforms, tracing temporal evolution trajectories, and examining micro-scale individual behaviors, thereby enriching our understanding of how digital media intervenes in the production of urban space and the transformation of spatial conflict.

Assessment and Optimization of Sustainable Tourism Planning for Suburban Rural Areas of Metropolitan Fringe Areas Based on Ecological Landscape Unit Division: Evidence from Huanglongxian, Nanjing

Chao Zhang
Southeast University
Email:zhangchao973903078@163.com

Abstract
The rapid acceleration of urbanisation in China has led to the emergence of many big cities, which has greatly affected the development of tourism in the surrounding areas. As Metropolitan Fringe Areas increasingly serve as popular short-term travel destinations, the adjacent villages confront unprecedented developmental opportunities and challenges. This study examines the Paifang community in Jiangning District, Nanjing, China to investigate ecological landscape assessment and strategic tourism planning within the context of a sustainable tourism framework in Metropolitan Fringe Areas. First, this research delineates the landscape ecological units of the Paifang community and assesses ecological sensitivity. Through a combination of technical research, field surveys, and in-depth interviews, this study analyses the expectations of both residents and tourists, proposing targeted tourism planning strategies.

Keywords: Urban suburbs; Landscape ecological units; Sustainable rural tourism; Machine learning

1. Introduction

Urban areas worldwide have been steadily expanding, often at the expense of natural and semi-natural land (Martellozzo et al., 2018). The current "Rural Revitalization" strategy is continuously advancing across China, and a consensus has been reached: to rationally plan the spatial layout of urban and rural construction with holistic thinking and promote integrated urban-rural development. This implies that the models and experiences of urban construction cannot be directly applied to rural construction. As a special ecological-production-living space, rural areas need to build a harmonious relationship between humans and nature, organically integrating ecological and social systems (Central Committee of the Communist Party of China & State Council, 2018). However, as metropolitan fringe areas increasingly serve as popular short-term travel destinations, villages face unprecedented developmental opportunities and challenges. This involves the interaction and contrasting relationship between human activities and natural landscapes in rural areas. The penetration of tourism consumption culture has precipitated spatial alienation, manifesting through phenomena such as village relocations and population displacement (He et al., 2022). If the natural, historical, and cultural environment cannot be protected, there can be no expectations for sustainability in destination areas (Khizar et al., 2023). To mitigate both positive and negative impacts on residents' quality of life (QOL) arising from unsustainable over-tourism, it is essential to implement effective control measures (Mihalic et al., 2021). As a model for sustainable tourism development, alternative tourism emphasises the necessity of harmonious coexistence between tourism initiatives and rural communities based on ecological protection and cultural respect. Localised analysis of existing ecological and cultural resources is a prerequisite for the effective implementation of alternative tourism. The rural landscape is a spatial representation of the composite ecosystem comprising the social, humanistic, economic, and natural environments of the countryside, possessing dual characteristics of humanity and nature (Wang & Liu, 2003). On the one hand, the organisation and assessment of the current situation are crucial, and the scientific delineation of landscape ecological units is a fundamental prerequisite for regional research and environmental development. On the other hand, against the backdrop of accelerated urbanisation nationwide, how to maintain the diversity of regional characteristics in rural areas and carry out sustainable tourism development is a common issue faced by urban-rural planning and sociology(Zhang, 2021).

2. Development History and Current Situation of Huanglongxian

2.1 Overview of the Study Area

This study focuses on the Paifang Community, situated in the Jiangning District of Nanjing City, Jiangsu Province, China (Figure 1). The research aims to explore methodological approaches for delineating landscape ecological

units within rural environments, thereby contributing to strategies for sustainable rural development.

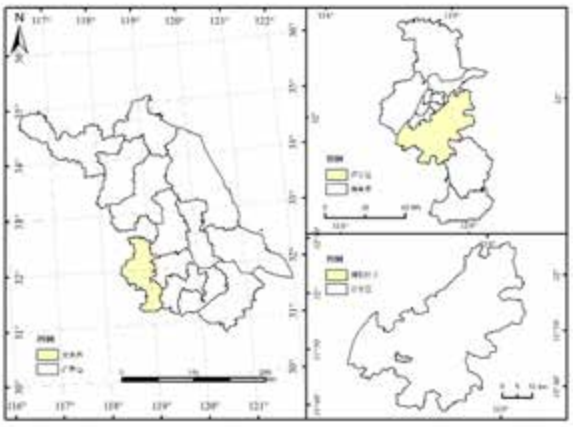

Figure 1. Location map of the study area.

Jiangning District of Nanjing belongs to subtropical monsoon climate, which is rich in plant resources and forms various types of landscape ecological environment. Paifang Community is located in the southeast of Jiangning Street, Jiangning District, Nanjing, with a total area of 8.2 square kilometers. It belongs to hilly and mountainous villages, and the western tourist corridor line passes through the territory. With beautiful scenery, beautiful environment and rich resources, the community is the location of beautiful countryside-Huanglongxian Tea Culture Eco-tourism Village. With the deepening of rural tourism development, the natural scenery and human activities in this area have more overlap, so it has high research value and reference significance.

2.2 Development History of Rural Tourism in Huanglongxian

The evolution of rural tourism in Huanglongxian can be divided into four distinct phases:

Initial Stage (Pre-2013): At this early juncture, Huanglongxian was a relatively impoverished mountainous village whose primary economic activity centred on tea cultivation. Its development was hindered by limited transportation infrastructure and weak public services.

Transformation and Enhancement Phase (2013–2016): Leveraging its unique landscape resources, the area underwent infrastructure and environmental improvements driven by coordinated efforts at district, street, and village levels. During this phase, the tea industry and tourism began to develop simultaneously, initiating what has been termed the "beauty economy."

Upgrading and Expansion Phase (2017–2020): This period was marked by efforts to deepen the integration of cultural elements. Key strategies included the construction of the "Rural +" industrial chain, the establishment of an ecological tea industry system, and the development of clustered guesthouses. Organised cultural events contributed to tourism brand-building and furthered the integration of various sectors.

Consolidation and Innovation Phase (2021–present): Since 2021, ongoing efforts have aimed to improve the ecological environment further. Initiatives such as the "toilet revolution" and "waste revolution" were implemented, alongside the development of sewage treatment infrastructure. Concurrently, traditional cultural practices, including tea culture, have been revitalised and incorporated into the tourism offering, enriching its cultural dimensions.

Community engagement has played a pivotal role in this development process. For instance, the spontaneous signing of the "Villagers' Environmental Protection Pact" has demonstrated enhanced local participation, contributing to co-creation and shared benefits. The historical trajectory of rural tourism in Huanglongxian highlights the critical importance of governmental guidance, ecological prioritisation, cultural revitalisation, industrial in-

tegration, and community participation. These elements collectively offer valuable insights for the sustainable development of rural tourism within the broader framework of China's rural revitalisation strategy.

3 Ecological Landscape Unit Delineation

3.1 Necessity of Delineating Rural Landscape Ecological Units

As previously mentioned, rural areas, as places with dual attributes of "space" and "resources," closely link human activities with the natural environment, while also possessing unique ecological conservation functions and potential for sustainable development. Consequently, there is a relatively rich variety of ecologically functional land use types within the rural landscape environment. However, changes in the land use structure of villages and towns have led to landscape fragmentation, resulting in a decline in the "sense of place" and "sense of belonging" in rural areas (Guo et al., 2013), loss of regional characteristics, and homogenisation of landscape features (Chen, 2012). The scientific protection and moderate development of rural landscapes are the developmental direction for rural construction. On the other hand, in rural areas, even the same type of land use can exhibit differences in ecological characteristics due to variations in area, hydrological climate, elevation, and vegetation cover. Therefore, to conduct a classified analysis of the landscape ecology of different regions within the study site, considering natural geographical conditions, climatic factors, locational environment, and the current vegetation conditions of different areas, the study area should be divided into different ecological units. This paper explores the integration of Python programming language with traditional landscape unit delineation techniques, aiming to obtain more objective results for landscape ecological unit delineation.

3.2 Existing Methods for Delineating Landscape Ecological Units

The concept of a "unit" originates from a fundamental concept in the modern scientific and technological system, representing a self-contained system with relative independence and function. It possesses basic characteristics such as systematism and self-containment, and when applied, the research object is considered as a whole or system (Wang et al., 2020). Ecological spatial units are landscape constituent units that must be recognised in the landscape design process and are also the most commonly used and studied scale types in landscape planning and design (Wang, 2018). Ecological unit mapping has become a fundamental method and tool for various planning and evaluation studies (Zhao, 2012). A landscape unit usually refers to the smallest unit expressed in landscape mapping, i.e., the spatial extent enclosed by baselines representing landscape characteristic types. In image maps, a landscape unit refers to the smallest homogeneous polygon that can be distinguished at a specific spatial resolution (Lou, 2016). A landscape ecological unit is a research unit generated by combining the resource base of geographical space with scale characteristics.

The application of research methods based on landscape ecological units is more common in urban landscapes and natural landscapes. With the vigorous progress of rural construction, landscape ecological units have emerged as a research perspective and entry point in rural landscape studies. Unlike landscape patches in purely natural environments, a village ecological unit is a composite ecosystem integrating natural, artificial, and social elements (Kang & Wang, 2019). Therefore, the method for delineating rural landscape ecological units lays the foundation for further research.

Currently, there are few existing methods for delineating landscape ecological units, and most focus on purely natural landscapes and urban landscapes. Research on rural landscapes is relatively preliminary. For instance, Gao Tian et al. (2010) summarised the history and methods of ecological unit mapping (Gao et al., 2010), including selective ecological unit mapping and comprehensive ecological unit mapping. Kang Yuan et al., in their study of Xiuri Village on the Qinghai-Tibet Plateau, mentioned the wisdom of constructing village ecological units, building the concept of village ecological units from an ecological perspective, and dividing them into residential landscapes, production landscapes, and cultural landscapes. They considered the village ecological unit as a multi-functional complex with humans as the main theme, with the research primarily focusing on local production and living areas with higher human congregation. Similarly, in the research on rural settlement ecological units by Wei Yanyan et al., while dividing them into geographical, landscape ecological, and human settlement units, they also combined macro-, meso-, and micro-perspectives (Wei et al., 2018). However, this approach faced

issues such as irregular boundaries when spatial lines overlapped and insufficient research precision. Another example is the Wusheng County unit delineation method conducted by Wang Zhifang et al. in 2020 (Wang et al., 2020), which utilised SPSS for data processing. However, due to limitations in computing power and data volume, it only studied three aspects: elevation, slope, and land use. The delineated grids were also relatively large, leading to problems such as irregular regional shapes, inconsistent areas, or unclear boundaries, which increased the workload for subsequent tasks.

3.3 Innovative Method for Delineating Landscape Ecological Units

The delineation of landscape ecological units requires the establishment of evaluation criteria. The same piece of land is often influenced by multiple factors; therefore, a single evaluation criterion is not suitable for delineating rural landscape ecological units. Referring to the characteristic evaluation factor system for rural landscape sensitivity assessment (Wang et al., 2021), standards for landscape unit delineation are established (Figure 2).

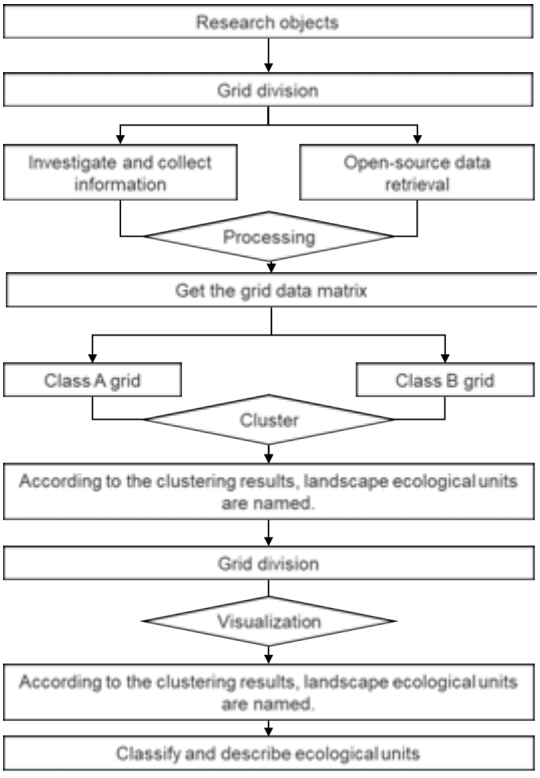

Figure 2. Technical route.

According to the definition and properties of landscape ecological units, the evaluation factors and data types generally considered for the study area include nine items: land use type, presence of surface runoff, flow rate, average temperature, annual precipitation, average elevation, slope, soil sensitivity, and vegetation cover. When there is no surface runoff or no significant surface runoff within the study area, the number of items actually considered for data clustering is six.

3.4 Grid Division and Data Linking

3.4.1 Fishnet Tool

For the study area of Paifang Community, based on the formulae: unit side length$x = \frac{L}{n}$, and total number of units $y = \frac{H}{x}$, it can be deduced that a 10m10m grid precision is suitable for this research object. According to the grid standard, the fishnet tool in ArcGIS was used to divide the bounding rectangle of Paifang Community into a grid (Yang et al., 2019), forming a total of 3530*5640 cells, establishing a system with individual cells of 10m*10m

(Figure 3). Fishnet labels corresponding to the geometric centre of each cell were created and designated as the sampling points for the cells. Finally, empty cells within the bounding rectangle were removed (Figure 4).

Figure 3. Matrix grid.

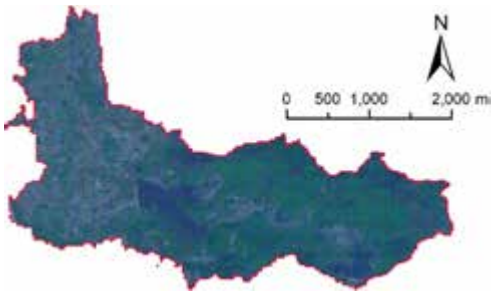

Figure 4. Study area grid.

3.4.2 Data Collection and Determining Factors

The data sources for this study include locally provided materials, field surveys, and satellite open-source data obtained from relevant public data websites. The finally collected effective geographical data include seven categories: elevation, slope, vegetation, temperature, precipitation, land use type, and soil sensitivity. Among these, the temperature data had poor precision and could not form regional differences, so it was excluded. Therefore, a total of six data items were studied.

Multi-band image maps of satellite remote sensing data were obtained from the Geospatial Data Cloud. The data were imported into ENVI. According to the formula in the research method of Li (Li et al., 2003):

$$\mathrm{NDVI} = \frac{\mathrm{float(b4)} - \mathrm{float(b3)}}{\mathrm{float(b4)} + \mathrm{float(b3)}}$$

data such as NDVI vegetation cover (FVC) were calculated. The obtained raster data were imported into ArcGIS and converted to vector data under the WGS_1984 coordinate system.

Where b1, b2, b3, and b4 represent four bands respectively (Figure 5):

Figure 5. Band Correspondence Table

Band	Colour	Wavelength (μm)	Application
Band-1	Blue	0.45-0.52	Water bodies, shallow water underwater features
Band-2	Green	0.52-0.60	Green reflectance of healthy vegetation, distinguishing vegetation types
Band-3	Red	0.63-0.69	Plant classification, distinguishing artificial land feature types
Band-4	Near IR	0.76-0.90	Distinguishing vegetation types, delineating water body boundaries

Taking Paifang Community as the research object, the main determining factors to be considered are six categories (Figure 6 -11): The terrain of Paifang Community is low in the west and high in the east, with the lowest elevation at 13.7m and the highest at 197m. The study area includes small reservoirs and mountainous landforms, with significant topographical variations. Therefore, elevation and slope are considered influencing factors. The

location experiences abundant rainfall and distinct seasons, with good soil conditions; thus, precipitation and vegetation cover are also influencing factors. Among the determining factors obtained from field surveys and literature review, the above four categories are continuous data, while land use type and soil sensitivity are discrete data. Clustering is based on continuous data. Therefore, discrete data need to be stratified and named 1, 2, 3... where the order does not represent priority but is only used for calculating Euclidean distances in the subsequent computational procedures. This method is flexible in determining factor weights, which are often determined based on the current situation and development needs of the study area. For simplicity, this paper sets all weights to $\varphi_i=1$.

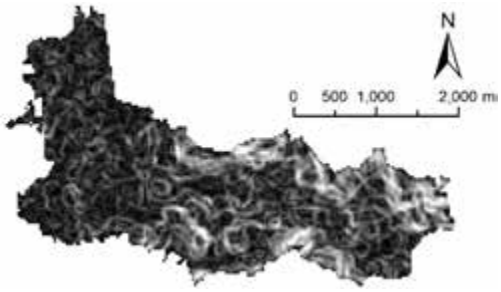

Figure 9. Slope.

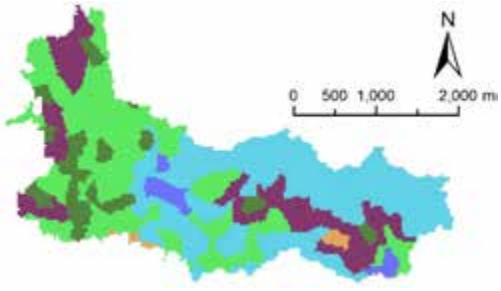

Figure 10. Land use.

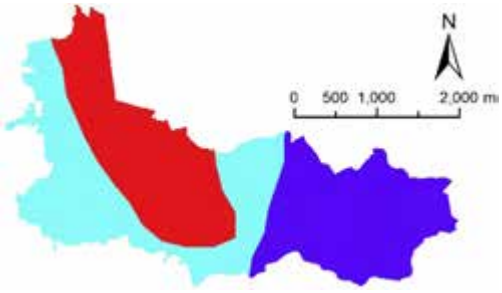

Figure 11. Soil sensitivity.

3.4.3 Grid Classification

As mentioned earlier, the size of the divided grid cells is 10m*10m. To make the delineation of ecological units more precise, this study primarily identifies and classifies two types of grid cells during the division phase: Type A grid cells, where the internal functions, composition, and morphology are relatively consistent; and Type B grid cells, where these aspects show significant differences. In this ecological unit delineation, the bound-

ary lines of different land uses were first identified to distinguish Type B grid cells. Since grid cells located on boundary lines contain two or more types of land use and exhibit high complexity, these cells were classified as Type B grid cells using GIS. The remaining grid cells within the area, containing only a single land use type, were classified as Type A grid cells.

3.4.4 Clustering Process

Taking the geometric centre of each 10m*10m grid cell as a sampling point, the spatial join tool in GIS was used to obtain various data for each sampling part. On the one hand, the data were standardised and outliers filtered to verify data integrity. On the other hand, discrete data were integrated, ultimately yielding the corresponding determining factor data for each grid cell.

In this process: first, randomly select an arbitrary number k (representing the final number of rural landscape unit types for the research object), and denote the k centres as μ_1 ,μ_2,..., Second, the mean of each cluster object is substituted into the group formula as

$$\mathrm{Dis}_j = \sqrt{\sum_{i=1}^{n} \varphi_i (x_i - \mu_j)^2} \quad ,$$

$$\mathrm{D}=\min \mathrm{Dis}j.$$

Calculate the Euclidean distance (Dis) of each object to these central objects, and reclassify the corresponding objects based on the minimum distance D. Then, calculate the cluster centre μ_k^m (the mean of all objects in that cluster) for each newly formed cluster. This process is repeated until the sum of squared errors (SSE) standard measure function begins to converge (Figure 12). The calculation formula is as follows:

$$\mathrm{E} = \sum_{i=1}^{k} \sum_{p=x_i} |p - \mu_i|^2$$

Where: E is the sum of squared errors for all objects in the database; p is a point in the space of the object; μ_i is the mean of cluster xi (both p and μ_i are multidimensional) (Chen et al., 2017).

Clustering was performed on the 6 types of data for Type A grid cells, and obtaining the results (Figure 13). After multi-point verification and troubleshooting, the clustering determining factors were improved. Finally, geographical information (longitude, latitude) was listed separately as a division factor to avoid a scattered distribution of results, thereby obtaining the final clustering result for Type A grid cells. On this basis, for the clustering of Type B grid cells, the item “included land use types” was added, resulting in a unit division result characterised by linear and point-like patterns. The clustering results for Type A and Type B were combined according to geographical information to obtain the final ecological unit delineation result (Figure 14). This includes 16 types of Type A landscape ecological units and 10 representative Type B ecological units.

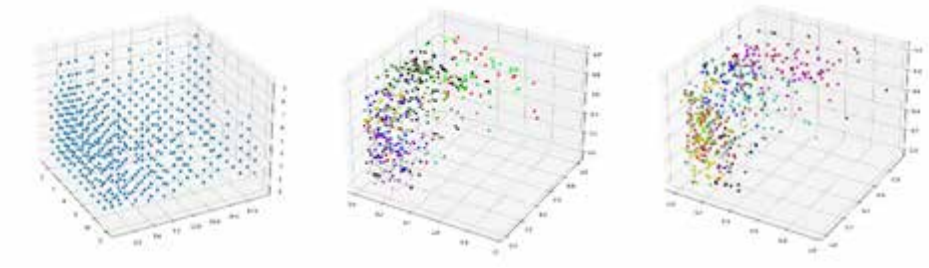

Figure 12. 3D model of the clustering process.

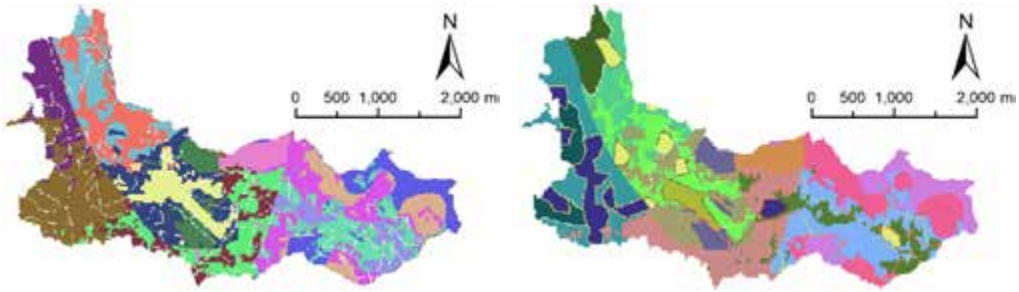

Figure 13. Type A clustering results without latitude and longitude.
Figure 14. Final clustering results incorporating latitude and longitude.

The division of ecological units in nature reserves can be classified according to the natural zoning method and the kilometre grid method (Zhou, 2006). Considering the complexity of rural areas, this paper, based on the kilometre grid, divides the rural research object into several unit grids, and then conducts ecological resource investigation, data registration, and comprehensive evaluation for each one.

During the process of equally dividing the study area, issues related to grid scale, number of grids, grid shape, and differentiated processing between grids are involved. For grid shape, considering the universality of the research object, the grid is defined as a regular quadrilateral. Simultaneously, the grid scale is defined as

$$x = \frac{L}{n}, \quad y = \frac{H}{x} \cdot n$$

Where x is the side length of a single grid, y is the total number of grids, L is the length of the long side of the bounding rectangle of the study area, H is the length of the short side of the study area, and n is the number of grids in the direction of the long side. In the division phase, two types of grids are identified: Type A grids, where the internal functions, composition, and morphology are relatively consistent, and Type B grids, where the internal functions, composition, and morphology show significant differences, thereby reflecting the differentiated processing between grids. Among these, Type B grid data, due to the complexity of the plots, include two or more types of land use and are all located on irregular boundaries. Therefore, data collection for Type B grids, in addition to the aforementioned conventional 9 data items, should also include the number of land use types

contained within a single grid range. For example, if a grid plot includes cultivated land, water bodies, and forest land (three types of land use), then the number of land use types is 3.

Finally, a matrix is initialised to store the data for each grid, including the grid's serial number and corresponding item data. According to the different types of items, the delineated landscape grids are divided into two parts for clustering.

4. Delineation and Evaluation of Ecological Units

4.1 Description of Ecological Unit Delineation Results

4.1.1 Naming and Description of Type A Landscape Ecological Units

The ecological unit delineation results are shown in Figure 16. Combining the type and position of the units, they are named sequentially from top to bottom, left to right as A1, A2, A3... As a relatively large-scale comprehensive evaluation result, the ability to accurately describe each ecological unit becomes an important criterion for judging the accuracy of the ecological unit delineation. After summarising the characteristic descriptions in the table (Figure 15), it can be found that various types of landscape ecological units have certain differences but often exhibit internal correlations, following the laws of land use type transformation and the spatial-temporal dynamic evolution mechanism of rural landscapes constituted by the functional transformation of "production-living-ecological spaces" (Fan et al., 2022). According to the complex intersecting conditions of different landscape ecological units, it reflects that natural conditions endow landscape ecological units with uniqueness and regionality, and also reflects the multi-functionality and inclusive uses of rural landscapes.

Figure 15. Description of Type A Units

Unit No.	Characteristics
A1	Paddy field with low elevation, gentle terrain, low soil sensitivity, and low precipitation.
A2	Villager residential area with low elevation, gentle terrain, low soil sensitivity, and low vegetation cover.
A3	Mixed area of dry land and residential land with low elevation, gentle terrain, high soil sensitivity, low precipitation, and low vegetation cover.
A4	Dry land area with low elevation, gentle terrain, low soil sensitivity, low precipitation, and high vegetation cover.
A5	Villager residential area with low elevation, gentle terrain, high soil sensitivity, low precipitation, and low vegetation cover.
A6	Mixed area of dry land and residential land with low elevation, gentle terrain, low soil sensitivity, low precipitation, and low vegetation cover.
A7	Dry land area with low elevation, distinct topographical undulation, low soil sensitivity, high precipitation, and high vegetation cover.
A8	Paddy field area with low elevation, gentle terrain, high soil sensitivity, low precipitation, and low vegetation cover.
A9	Forested land with high elevation, distinct topographical changes including slopes, high soil sensitivity, high precipitation, and high vegetation cover.
A10	Forested land with high elevation, distinct topographical changes including slopes, low soil sensitivity, high precipitation, and high vegetation cover.
A11	Forested land with high elevation, distinct topographical changes including slopes, medium soil sensitivity, high precipitation, and high vegetation cover.

A12	Paddy field with low elevation, gentle terrain, low soil sensitivity, and high precipitation.
A13	Paifang Reservoir, with strong topographical and landform characteristics.
A14	Area dominated by forested land with low elevation, gentle terrain, high soil sensitivity, and relatively high vegetation cover.
A15	Vegetation cover area with relatively high elevation, gentle terrain, medium-high soil sensitivity, and low precipitation.
A16	Forested land area with very high elevation, distinct topographical changes, medium soil sensitivity, abundant precipitation, and high vegetation cover.

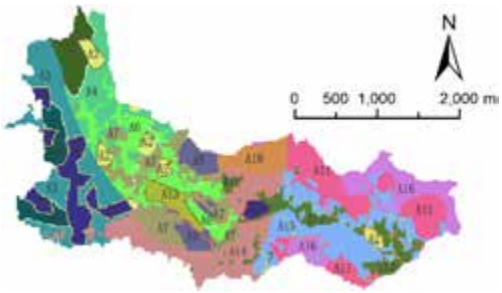

Figure 16. Type A unit numbering and selected points.

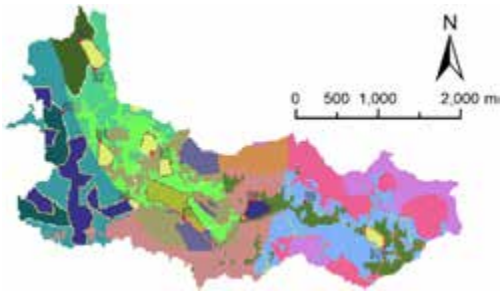

Figure 17. Type B unit numbering and selected points.

4.1.2 Naming and Description of Type B Landscape Ecological Units

The ecological unit delineation results are shown in Figure 17. Combining the features and position of the units, they are named sequentially from top to bottom, left to right as B1, B2, B3... Due to the generation method of Type B grids, these grids are small in area, elongated in shape, and diverse in type. In reality, various types of Type B ecological units share certain commonalities. They are classified and refined into ten representative units, and the table (Figure 18) below explains their characteristics and positional relationships. Type B units often exhibit characteristics of linear continuity and overall fragmented distribution. Typically, Type B landscape ecological units located at boundaries have greater landscape richness, biodiversity, and spatial diversity compared to Type A units. Their geographical location and environmental attributes often show strong similarity and dependence on adjacent Type A landscape ecological units. For example, Type B units adjacent to both villager residential areas and natural environments usually exhibit significant internal variation.

Figure 18. Description of Type B Units

Unit No.	**Figure**	Characteristics
B1		Interface between paddy fields and villager residential areas; low soil sensitivity, gentle terrain, low annual precipitation within the study area.
B2		Mixed land use of dry land and villager residential areas; at the boundary of high and low soil sensitivity, gentle terrain, distinct variation in vegetation cover within the unit, low annual precipitation.
B3		Interface between paddy fields and dry land; significant variation in soil sensitivity within the unit, but overall low sensitivity. Low vegetation cover, low annual precipitation.

B4		Mixed land use of dry land and residential areas; no significant changes in climatic and topographical conditions. Minimal variation in vegetation cover within the unit, low annual precipitation.
B5		Mixed land use of dry land and residential areas; low soil sensitivity, low elevation, distinct topographical undulation, distinct variation in vegetation cover within the unit, relatively drastic changes in precipitation.
B6		Mixed land use of dry land and residential areas; drastic changes in soil sensitivity, including high, medium, and low categories; no significant changes in climatic and topographical conditions.
B7		Interface between dry land and reservoir/ponds; strong landform characteristics, distinct topographical undulation, high vegetation cover, high annual precipitation.
B8		Boundary land use between residential areas and forested land; located in an area with high soil sensitivity, gentle terrain, distinct variation in vegetation cover within the unit, high annual precipitation, distinct landform changes.
B9		Boundary land use between paddy fields and forested land; high elevation, drastic changes in soil sensitivity, located in mountainous terrain, high vegetation cover, high annual precipitation.
B10		Interface land use among forested land, sparse woodland, and residential areas; distinct topographical changes, distinct variation in vegetation cover within the unit, diverse soil sensitivity, high annual precipitation.

4.2 Landscape Unit Evaluation

4.2.1 Ecological Gene Evaluation

This ecological unit delineation covers Type A and Type B landscape ecological units. Type A units are larger and relatively complete in form, with varying natural element characteristics such as elevation, terrain, soil sensitivity, precipitation, and vegetation cover. For example, A1 is a paddy field with low elevation, gentle terrain, low soil sensitivity, and low precipitation, reflecting the uniqueness and regionality of natural conditions, and follows the laws of land use type transformation and the spatio-temporal dynamic evolution mechanism of rural landscapes constituted by the functional transformation of "production-living-ecological spaces." Type B landscape ecological units are small, elongated, and fragmented in distribution. Typically, Type B units located at boundaries exhibit more complex landscape richness, biodiversity, and spatial diversity. Their geographical location and environmental attributes show strong similarity and dependence on adjacent Type A units. For instance, B1, at the interface of paddy fields and villager residential areas, has low soil sensitivity, gentle terrain, and low precipitation, demonstrating the multi-functionality and inclusive uses of rural landscapes. Overall, this reflects the complex intersecting conditions of the regional ecosystem.

4.2.2 Village Layout Gene Evaluation

The layout of Huanglongxian Village changes dynamically with the terrain, conforming to the traditional layout principle of "concealing wind and gathering qi" (Xiong et al., 2023). The village site selection exhibits a strong affinity for water, belonging to a dispersed layout, built along the foot of hillsides. The building layout is primarily guided by water systems and road orientations, generally presenting a strip-like pattern. The internal road network structure of the village is dendritic, with residences distributed along the main road. As the residential distribution changes, the main road further branches into many vine-like subsidiary roads, and residences in ad-

jacent areas are interconnected. Alleyways are often formed spontaneously by the passage between residences, without fixed planning traces. It is precisely because of this characteristic of alleyways that they embody ingenious spatial planning and human-oriented design concepts.

4.2.3 Architectural Gene Evaluation

Figure 19. Pedestrian Street.

Figure 20. Waterside residences.

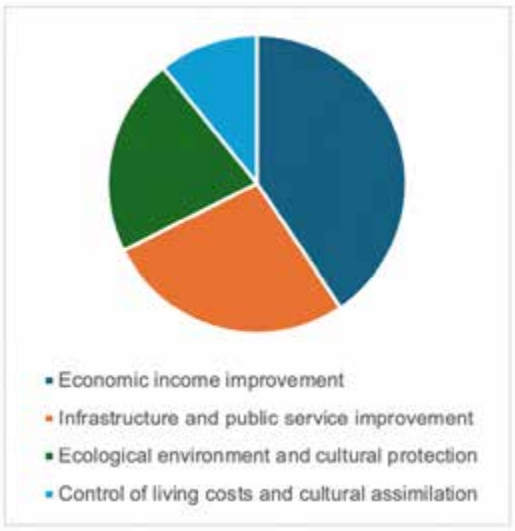
The residential architecture of Huanglongxian Village, influenced by traditional culture and hilly terrain (Figure 19), exhibits a style that is robust and simple, with a composed and introverted temperament. It possesses both the dignified grandeur of northern architecture and the delicate finesse of southern architecture. In terms of overall layout, the village's residential buildings demonstrate characteristics of adapting to the terrain and respecting nature (Figure 20). In terms of planar layout, they feature flexibility in scale and adaptation to local conditions. In terms of spatial structure, they highlight diverse forms and rigorous construction.

5. Sustainable Tourism Planning Strategies

Finally, based on the classification and evaluation of landscape ecological units, this study combines field surveys and in-depth interviews to thoroughly analyse the needs and expectations of residents and tourists in Huanglongxian Village. On this basis, the following targeted tourism planning strategies are proposed, aiming to construct a tourism model adapted to diverse tourist experiences while promoting local economic development, ecological protection, and cultural preservation.

5.1 Analysis of Resident and Tourist Needs

Through in-depth interviews and field surveys, pie charts illustrating the distribution of resident and tourist expectations were compiled (Figure 21-22).



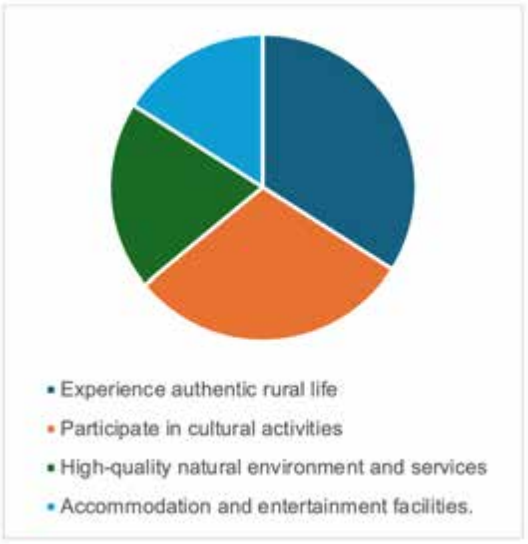


Figure 21. Distribution of resident expectations. **Figure** 22. Distribution of tourist expectations.

Residents of Huanglongxian Village generally expect tourism development to bring about an increase in economic income, while also hoping for improvements in infrastructure and public services, such as healthcare and education. Furthermore, residents show a strong sense of identification with protecting the local ecological environment and cultural traditions, but also express concerns that excessive tourism development may lead to rising living costs and cultural assimilation. On the tourist side, the main demands are concentrated on experiencing authentic rural life, participating in rich cultural activities, and enjoying a high-quality natural environment and tourism services. The needs of different types of tourists also vary; for example, leisure-oriented tourists pay more attention to the comfort of accommodation and entertainment facilities, while cultural experience-oriented tourists show strong interest in local historical buildings and tea culture.

5.2 Tourism Planning Strategies

From a sustainable development perspective, the linear and fragmented development of tourism spaces should be replaced by a cohesive strategy that integrates ecological protection and cultural revitalisation. In Huanglongxian, where rural tourism has developed for over five years, it is essential to re-examine the excavation of local culture and encourage greater public engagement. Based on this, five strategic directions are proposed: establishing ecological buffer zone standards, diversifying tourism products, enhancing community participation, developing a sustainable development assessment system, and strengthening brand identity.

It is essential to clearly define the ecological core zones of Huanglongxian according to the result of ecological units, such as the Paifang Reservoir and its surrounding forests, designating them as ecological protection areas. Designate these as ecological protection zones, restrict development and construction activities, and formulate strict environmental management measures to ensure the stability of the ecosystem and biodiversity. By setting up ecological trails, viewing platforms, etc., allow tourists to appreciate the natural beauty without disturbing the ecology, thereby enhancing ecological protection awareness. Simultaneously, conduct ecological education activities to popularise ecological protection knowledge among tourists and residents, promoting harmonious coexistence between humans and nature. Research has shown that the participatory management of eco-cultural trails enhances conservation outcomes while educating visitors (Lukoseviciute et al., 2024).

To maintain appeal and competitiveness, explore the connotations of Huanglongxian's tea culture and She eth-

nic culture to develop diversified tourism offerings. In addition to existing tea picking and processing experiences, in-depth tea culture-themed tour routes can be introduced, including visits to ancient tea gardens, learning about tea history, and studying tea art. Combined with the historical buildings and folk customs of the She ethnic village, create culturally distinctive experience projects, such as She ethnic song and dance performances and traditional handicraft making. Furthermore, develop rural leisure and holiday products, construct high-quality guesthouses and resorts, and provide services such as hot spring therapy and agricultural experiences to meet the needs of different tourist groups. Product diversification and culturally embedded experiences have proven effective in revitalising rural tourism destinations (Garau, 2015; Costantino et al., 2022).

Engaging local residents in tourism planning and operations enhances ownership and sustainability. Establishing a local tourism association, providing skills training, and implementing benefit-sharing mechanisms ensure fair economic returns and cultural continuity. Scholars argue that participatory frameworks are essential for the long-term management of cultural landscapes (Selman, 2004) and for achieving inclusive heritage tourism (Li and Hunter, 2015). At the same time, establish a reasonable benefit distribution mechanism to ensure that residents can obtain fair economic returns from tourism development, thereby enhancing their sense of belonging and satisfaction.

A sustainable tourism development assessment framework should evaluate environmental quality, economic benefits, social equity, and cultural preservation. The indicator system should include aspects such as tourism economic income, residents' quality of life, ecological environment quality, and cultural inheritance status. Based on the assessment results, timely adjust tourism planning and policy measures to ensure that tourism development is coordinated with ecological protection, cultural preservation, and social progress. Simultaneously, publicly disclose the assessment results to accept public supervision, improving the transparency and credibility of tourism development.

To establish a strong tourism identity, Huanglongxian should develop a distinct brand that integrates its tea heritage, She architecture, and local values. Branding elements such as logos, slogans, and cultural events reinforce recognition and pride. Sustainable tourism branding fosters long-term loyalty and encourages resident participation in cultural protection (Su et al., 2016; Landorf, 2009). When residents recognise the unique value of their local culture, they will more actively participate in cultural inheritance and protection, forming a virtuous cycle.

6. Conclusion

By employing a scientific ecological landscape unit division method combined with post - research surveys and interviews to comprehend diverse expectations, we aim for these strategies to enhance understanding of alternative tourism in rural development and boost Huanglongxian's sustainable tourism.

However, the research has limitations. The article's judgment factors, though broadly covering influential ones, lack detailed clarification due to data limits. The studied area's limited natural features result in an under - detailed determination factor system, like vegetation types and water conditions. Future regional analyses should adjust to local conditions, selecting suitable variable evaluation factors for more targeted outcomes. As China's rural construction evolves, there's a need for more theoretical reflection. Future large - scale machine learning could help create digital platforms for this research method.

In summary, these strategic tourism plans can help Huanglongxian Village achieve sustainable tourism development that meets residents' and tourists' needs, offering useful experience for metropolitan fringe area rural revitalisation.

Abstract
As an important supply strategic position during the Long March of the Chinese Workers' and Peasants' Red Army, Hadapu Town has obvious red cultural characteristics, and its red cultural tourism development has a certain source of customers. However, since the red cultural tourism in the town is still in its early stages, in view of a series of problems such as unreasonable industrial structure, lagging infrastructure, insufficient development funds, single homogeneous tourism products, and insufficient interaction between urban and rural areas, this paper selects the evaluation indicators of the spatial development performance of red cultural tourism in Hadapu Town based on national standards, relevant specifications and expert consultation, and constructs a relevant evaluation system on this basis. By introducing the AHP hierarchical analysis method, the criterion layer, indicator layer and factor layer of Hadapu Town are weighted and calculated to obtain indicators at all levels. At the same time, the fuzzy comprehensive evaluation method is introduced to construct a fuzzy evaluation set. On the basis of single-factor evaluation of secondary indicators, the fuzzy evaluation of the indicator factors at different levels of the development performance of Hadapu Town is carried out layer by layer, and the results of the assignment of indicators at four levels of the development performance of red cultural tourism in Hadapu Town are summarized in combination with the grade assignment. Through the comparative analysis of various indicators, the comprehensive level of the overall development performance of Hadapu Town is finally evaluated and obtained. It is hoped that it will point out the direction for further enhancement and improvement of the red cultural tourism space in Hadapu Town, and at the same time serve as a demonstration to drive the sustained, healthy development and vitality of other towns with red cultural tourism resources, provide more optimized strategies, and explore the establishment of a long-term mechanism for the protection and transformation of red cultural tourism towns.

Key Words: AHP; Fuzzy Comprehensive Evaluation Method; Hadapu Town; Red Cultural Tourism; Urban Development Performance

Introduction

The construction of characteristic small towns is an inevitable path for China's urbanization process. Its development is based on a comprehensive consideration of the social and economic level. It promotes characteristic development by tapping the value of urban resources, which conforms to the law of urbanization in the new era. In order to promote its standardized and healthy development, a number of policy documents have been issued at the national and provincial levels to improve the quality of development and make it an important carrier of regional economy. At present, many provinces have formulated construction standards, covering qualitative and quantitative indicators such as infrastructure, ecological protection, cultural excavation, industrial scale and social influence; the academic community is also conducting research on the evaluation system of characteristic small towns.

Hadapu Town is a small town located in the northwest of Dangchang , Gansu. It has been a key point of Gansu-Sichuan trade since ancient times. It was named after the post station established during the Ming and Qing Dynasties. It was once a medicinal material distribution center on the ancient Tea-Horse Road. As a " gas station " and an important decision-making turning point during the Long March of the Chinese Workers' and Peasants' Red Army, it carries the red gene of the great rejuvenation of the Chinese nation. In modern times, it has been recorded in history for its key role in the Long March: In September 1935, the Central Red Army broke through the natural barrier of Lazikou and entered Hadapu, where they rested, replenished supplies and obtained key intelligence. Mao Zedong convened a meeting of cadres above the regiment level at Guandi Temple and clearly put forward the strategic policy of " going to northern Shaanxi " for the first time , laying the foundation for the victory of the Long March. This historical moment not only reversed the revolutionary situation, but also made Hadapu one of the core symbols of the spirit of the Long March .

The core resource of Hadapu, Red Army Street (formerly known as " The First Street of the Long March of the Chinese Workers' and Peasants' Red Army "), is the most complete cluster of revolutionary sites in China: 382 original shops are distributed on the 1,200-meter street, including more than 10 national cultural relics such as Yihechang Pharmacy (Former Residence of Mao Zedong), Postal Agency (Site of Intelligence Discovery), Guandi Temple (Former Site of Decision-making Meeting). Its unique value lies in the protection of authenticity and dynamic inheritance: the street continues its commercial function to this day, integrating historical memory into contemporary life with innovative forms such as " Red Army Guokui " and " Red Army Liangfen " and the live-action drama "Red Star Shining over Hadapu".

In recent years, Hadapu has achieved revitalization by relying on the " red-green integration " model (red cultural tourism + Guan'egou ecological scenic spot). The opening of the Lanzhou-Yuxi Railway in 2017 broke the traffic bottleneck, the number of tourists surged, and the memorial hall received more than 3 million people in total; in 2021, it was selected as a key construction area of the " Long March National Cultural Park ", and Shangjie Village was rated as a pilot for red beautiful villages. Through cooperatives, it developed Red Army courtyards, homestays, and cultural and creative products to drive villagers' income. Its development results were listed as "National Red Tourism Typical Cases " . In 2020 , it became the only town selected in Shaanxi Province, confirming the feasible path of red resources empowering rural revitalization. However, the rapid urbanization development has also faced many challenges for Hadapu . For example, the lack of interaction between urban and rural areas and the regional linkage bottleneck: the " point linkage " with the Guan'egou scenic spot is significant, but the full-area integration mechanism is not yet mature ; Hadapu Town's infrastructure lags behind: it is manifested in insufficient carrying capacity, which restricts the upgrade of tourism experience ; insufficient development funds , imbalance between protection and development, and insufficient innovation momentum ; tourism products are single and homogeneous , the industrial chain is shallow, and competitiveness is declining . Under so many challenges , Hadapu Town urgently needs to guide construction with scientific planning concepts and optimize spatial layout by utilizing its own resource endowments. Based on the theory of new urbanization , this paper analyzes the current development characteristics of red cultural tourism in Hadapu Town , and based on practical problems, constructs a red cultural tourism development performance evaluation index system and evaluation model in Hadapu Town from a multi-dimensional level . After conducting empirical research, it proposes a suitable development model and corresponding planning improvement strategy for the red cultural tourism space in Hadapu Town . It aims to provide reference and practical basis for the further improvement of the red cultural tourism space in Hadapu Town (Rogersons. 2019) .

1. New Urbanization Theory and Red Culture Tourism Planning

1.1 New urbanization theory

Urbanization is a development process involving multi-dimensional transformation of social structure, system, culture, etc (Mandelbaum, 1996). After the reform and opening up, extensive urbanization has intensified the contradiction between urban and rural areas, giving rise to economic and ecological problems, prompting the country to propose a new urbanization strategy with people as the core. This strategy regards characteristic small towns as urban-rural connection hubs and regional transformation platforms, and promotes coordinated urban and rural development and factor agglomeration through differentiated industry cultivation (avoiding experience copying) and resource integration to build a characteristic system, ultimately achieving the goal of livable, green and sustainable urbanization (Mc Gehee & Andereck. 2004).

1.2 Coupling of new urbanization and red cultural tourism planning

The new urbanization strategy and the national red cultural tourism planning are coupled through the "space-industry-governance" triple achieve coordinated development . In terms of spatial coupling , red resources are mostly distributed in small towns in old revolutionary areas (such as the Dabie Mountain area). New urbanization uses characteristic towns as nodes, integrates scattered sites to form regional cultural and tourism belts (such as the Huanggang-Xinyang-Lu'an red tourism circle), and simultaneously improves urban functions. For industrial coupling , the focus is on breaking through the traditional ticket economy, extending the red industry chain (cultural and creative, homestay, digital experience), driving agricultural product sales and employment (such as

Hong'an County's " red IP + specialty " model), and promoting urban industrial upgrading. In terms of governance coupling , through cross-departmental coordination (such as the provincial red tourism special team) and revenue sharing (community dividends) and other mechanisms, the problem of resource division is solved to achieve a win-win situation for cultural inheritance and improvement of people's livelihood. The essence of the two is to use culture and tourism as a link to transform the soft power of red culture into hard support for urban development, and promote the revitalization of old areas and urban-rural integration.

2. Current status of red cultural tourism development in Hadapu Town

2.1 Insufficient interaction between urban and rural areas, and the overall integration mechanism is not yet mature

Green Ecological Scenic Area in Hadapu Town has formed a preliminary linkage with the Hadapu Red Cultural Town. Tourists often visit the Hadapu Memorial Hall after visiting Guanegou, but the reverse diversion effect is weak. For example, Hadapu receives nearly 3 million tourists per year, but most tourists only stay for a short time and fail to effectively attract consumption links such as accommodation and catering in Guanegou.

The industry collaboration is shallow and the value chain integration has not been formed. The specific manifestation is that the two places only stay at the route recommendation level in the combination of "red and green resources" and have not built an industrial complementary chain. For example, the traditional Chinese medicine industry in Hadapu (such as the Qikun Logistics Base) focuses on planting and warehousing, and has not been deeply integrated with the health tourism in Guanegou; the local specialties sold in Guanegou homestays are mostly from other places, and local agricultural products (such as Hadapu traditional Chinese medicine) have not been included in the tourism commodity system.

Deep-seated institutional and planning obstacles, brand marketing is done independently. Guan'egou focuses on "health and wellness secrets", Hadapu emphasizes "red gas station", but no unified IP has been established in the county. Take the "May Day" event in 2025 as an example: Guan'egou launched cable car discounts and traditional Chinese medicine therapy; Hadapu held a food festival alone. The two themes are unrelated and failed to form a "red and green integration" package product.

2.2 Lagging infrastructure and insufficient carrying capacity restrict the upgrade of tourism experience

Weak transportation connection . Although the opening of Lanzhou-Chongqing Railway in 2017 significantly improved external accessibility, the internal transportation system of the scenic area is still imperfect . For example, the railway station to the core scenic area (Red Army Street, Memorial Hall) relies on sightseeing trains for transportation, with limited trains and tight capacity during peak seasons, and tourists are often stranded; the internal pedestrian path of Red Army Street is narrow (5-6 meters wide) , and the flow of people is congested during peak hours, affecting evacuation efficiency and tour comfort.

Accommodation and service facilities are in short supply . During the peak tourist season, the hotel occupancy rate exceeds 100%, but the town has less than 2,000 standardized accommodation beds, forcing tourists to travel back and forth on the same day or to go to the county seat, weakening their consumption potential; the coverage rate of public toilets, rest areas, and barrier-free facilities along Hongjun Street is low, limiting the reception capacity for elderly tourists and groups.

Smart construction lags behind . There is a lack of real-time passenger flow monitoring and online reservation and tour guide systems around the scenic area, and management relies on manual scheduling, resulting in chaos on peak days such as July 1st when more than 3,000 individual tourists pour in every day.

2.3 Insufficient development funds , imbalance between protection and development, and insufficient innovation momentum

First, there is a gap in the funds for the protection of revolutionary resources . For example, although the renovation of the appearance of 443 households on Hongjun Street has been completed, some shops in the

late Qing Dynasty have structural problems due to disrepair. Special repair funds rely on allocations from higher authorities, and local supporting capacity is weak; the digital protection of revolutionary cultural relics (such as the original copy of the Ta Kung Pao and Red Army equipment) is slow, and the coverage rate of constant temperature and humidity equipment is less than 30%.

Secondly, the industry investment channels are single . For example, cultural tourism projects mainly rely on government subsidies (for example, the start-up capital of the village-run cooperative is only 830,000 yuan), and the participation of social capital is low, resulting in the long-term shelving of planned projects such as the Red Theater and the Long March Theme Hotel; specialty stores (Red Army Shoe Factory, Liangfen Shop) are small in scale and lack brand incubation funds. Gao Yueju Cloth Shoe Factory produces 20,000 pairs of shoes a year but is unable to expand its production line, which restricts the employment-driven effect.

In addition, investment in innovation and research and development is insufficient . Live-action dramas such as "Red Star Shining over Hadapu" rely on villagers' amateur rehearsals, and professional upgrades such as editing, directing, lighting, and special effects are difficult to advance due to lack of funds, weakening cultural expression.

2.4 Tourism products are homogeneous , the industrial chain is shallow, and competitiveness is declining

The sightseeing-oriented products are similar . For example, the core experience is still limited to site visits (Yihechang Medicine Store, Guandi Temple) and static exhibitions, which are highly similar to the red scenic spots in the surrounding areas, and tourists stay for only 2-3 hours; the live performances are concentrated on historical scenes such as "Go to Northern Shaanxi" and "Welcome Relatives in Hada Puli", lacking technological empowerment (such as AR battlefield restoration and immersive narrative), making it difficult to attract young customers.

Product development is rudimentary . Specialties are mainly snacks such as " Red Army Liangfen " and " Guokui " and handmade cloth shoes. The design lacks in-depth IP exploration and is highly homogenized. Cultural and creative products are limited to low value-added categories such as badges and manuals, and the " Hadapu " brand system has not been formed.

The industry linkage is superficial . For example, the " red + green " model only stays in the promotion of Guanegou joint tickets, and no cross-scenic area theme routes (such as " Long March Trail + Ecological Hiking ") are designed, and the tourist conversion rate is less than 20%; the integration of agriculture and tourism is weak, and local medicinal materials such as angelica and astragalus have not been transformed into special health products, missing the opportunity to experience " red study + traditional Chinese medicine culture " .

3. Measurement and evaluation of the development performance of the red cultural tourism space in Hadapu Town based on AHP and fuzzy comprehensive evaluation method

In view of the problems existing in the planning of the red cultural tourism space in Hadapu Town , this paper attempts to quantitatively examine the problems by constructing an evaluation system for the red cultural tourism space in Hadapu Town, so as to comprehensively evaluate its development quality level, clarify the specific reasons that affect the development results, and provide direction for the future tourism development strategy of the town. Specifically, a development performance evaluation index system for the red cultural tourism space in Hadapu is constructed from the aspects of town construction, tourism development, human settlement environment and policy environment, in order to systematically analyze its development deficiencies.

3.1 Selection of evaluation system indicators

3.1.1 Basis for indicator selection

(1) National, provincial and municipal standards and assessment criteria

In 2016, the State issued the document "Guiding Opinions on Accelerating the Construction of Beautiful Characteristic Towns (Cities)", which mentioned that the development and reform departments at all levels should learn from the experience of Zhejiang Province's characteristic towns and strive to create a number of

beautiful characteristic towns (cities) with emerging industry clusters, traditional industry upgrades, flexible systems and mechanisms, strong cultural atmosphere, and beautiful ecological environment. The "National Tourism Standardization Development Plan (2016-2020)" deepened and standardized the standards for tourism development from the national, local, and industry levels. Subsequently, various provinces and cities successively issued plans and standards for the evaluation of characteristic towns. The Zhejiang Provincial Quality Supervision Bureau issued the "Characteristic Town Evaluation Standards" and took the lead in issuing local standards for the evaluation of characteristic towns. It clearly stipulates the development, creation and naming standards of characteristic towns, and proposes a characteristic town evaluation index system including common indicators and characteristic indicators. Starting from the four dimensions of industry, function, form and system of characteristic towns, three-level indicators for the evaluation of characteristic towns are set for different industrial types of tourism towns, and the assessment content and standards of indicators at all levels are clarified. Chongqing has proposed the "3+3" construction and development goals in the construction of characteristic towns. The "3 characteristics" refer to the characteristics of industry, style and function, plus the "3 clusters" refer to the clustering of space, industry and population. Sichuan Province has issued detailed standards for evaluating the development quality of cultural tourism towns. The scoring criteria involve resources, industry, planning, management, and the construction and comprehensive benefits of the town's tourism image, which can conduct a more comprehensive and systematic quality assessment of tourism towns. In terms of tourism evaluation, according to the normative information mastered by this study, it also includes the classification and evaluation standards of the quality level of tourist attractions and the construction and service level of smart tourism, which also provide a standard basis for the selection of performance evaluation indicators for the development of Hadapu Red Cultural Tourism Town.

(2) Research on the evaluation system of tourist towns

At present, some scholars have conducted research on the evaluation index system of characteristic small towns, including research on ecological construction evaluation , maturity evaluation , core competitiveness , and sustainable evaluation of characteristic small towns. The research on relevant rating index systems will provide a theoretical basis for the construction of this study on the performance evaluation system for the development of tourist small towns (Han, 2023).

3.1.2 Indicator selection

Tourism towns are a comprehensive development system, involving many and complex factors affecting urban development. The purpose of constructing the index system in this study is to evaluate the development performance level of tourism towns. The characteristics and laws of urban development should be followed in the construction of the evaluation system for the current status of urban construction, and the selection of indicators should be able to reflect the personality and characteristics of tourism towns. Therefore, based on the understanding of the development characteristics of tourism towns through questionnaire surveys and data collection and reading, this study mainly takes the evaluation rules of cultural tourism towns in Sichuan Province as the main basis, combines the existing national and local relevant standards and the theoretical achievements of the academic community on the evaluation system of tourism towns, and proposes a preliminary Hadapu tourism town development performance evaluation index system. After consulting the expert questionnaire, the original evaluation system content is adjusted to finally determine the overall framework of the Hadapu tourism town development performance evaluation system. The overall framework consists of four layers. The first layer is the target layer, namely the performance evaluation of the development of the red cultural tourism space in Hadapu Town ; the second layer is the criterion layer, which is divided into four dimensions: resource value , tourism development level , economic and social benefits, management and sustainability ; the third layer is the indicator layer, which is mainly a further refinement of the criterion layer, including 10 indicator layers: tourism resources, cultural protection, infrastructure, transportation facilities, tourism supporting functions, human living environment, industrial development, social impact, government support and planning management; the fourth layer is the element layer, which is composed of specific element contents.

Table 1 Judgement System of of Hadapu Red Culture Tourism

Target layer	Criteria Level A	Indicator layer B	Feature layer C
Performance evaluation of red cultural tourism space development in Hadapu Town	A1 Resource Value	B1 Tourism Resources	C1 The richness of red culture themed tourism activities
			C2 Variety and richness of red cultural tourism products
			C3 Construction of Hadapu Red Town and Guanegou Special Scenic Spot
		B2 Cultural Protection	C4 Protection level of tangible cultural heritage
			C5 Inheritance level of intangible cultural heritage
			C6 Continuity and integrity of cultural space
	A2 Tourism Development Level	B3 Surrounding Infrastructure	C7 Number of red cultural facilities
			C8 Number of red cultural tourism service facilities
			C9 red culture theme guide system settings
		B4 Surrounding transportation facilities	C10 Traffic accessibility
			C11 Parking convenience
			Construction status of C12 scenic sightseeing road, etc.
		B5 Tourism Support Function	C13 B&B/Hotel Service Level
			C14's professionalism and service level
			C15 Construction level of smart scenic spots
		B6 Living Environment	C16 Landscape greening coverage of built-up areas in towns
			C17 Waste transfer and treatment rate
			C18 Rainwater and sewage treatment rate
	A3 Economic and social benefits	B7 Industrial Development	C19 Number of people employed in the tourism industry
			C20 Annual income from tourism
			C21 Average length of stay of tourists
		B8 Social Impact	C22 Popularity of tourist attractions
			C23 Community participation in tourism projects
			C24 Tourist growth rate after the opening of Lanzhou-Chongqing Railway
	A4 Management and Sustainability	B9 Policy Support	C25 Special Fund Investment
			C26 Completeness of planning documents
		B10 Planning and Management	C27 Balance between development intensity and ecological carrying capacity
			C28 Planning Innovation

3.2 Evaluation technology path

3.2.1Model building

Regarding the development performance evaluation of the red cultural tourism space in Hadapu Town, since the evaluation index system involves multiple indicators, most of the indicators tend to be qualitative and the factor information is fuzzy, that is, the indicators are easily affected by the subjective cognitive level of the respondents. Therefore, in order to improve the scientificity and objectivity of the evaluation process , this study uses the fuzzy comprehensive evaluation method to obtain the fuzzy membership of each factor indicator through the hierarchical analysis method, and then conducts a comprehensive evaluation of the index system based on this result, which can more scientifically and reasonably determine the development of the red cultural tourism in Hadapu Town .

3.2.2 Determination of index weights based on analytic hierarchy process

The analytic hierarchy process (AHP) is a multi-objective decision-making method proposed by TLSaaty in the 1970s and is suitable for complex system evaluation. Its core is to decompose the decision system into a multi-level structure, compare factors pairwise by constructing a judgment matrix, calculate the weights of factors at each level and test the consistency, and finally obtain the comprehensive weight ranking of each factor. The main steps include: establishing a hierarchical model, constructing a judgment matrix, single-level ranking and

consistency test, and combining weight calculation and ranking.

The main steps of the hierarchical analysis method are: (1) Establish a hierarchical structure of goals ; (2) Construct a judgment matrix: Use the 1-9 scaling method to compare the indicators at the same level in pairs to form a judgment matrix that reflects the relative importance; (3) Calculate the weight coefficient: Calculate the eigenvector of the judgment matrix and normalize it to obtain the weight of each indicator; (4) Single-level sorting and consistency test: Calculate the maximum eigenvalue, consistency index CI and consistency ratio CR (CR=CI/RI, RI is obtained by looking up the table). When CR≤0.1, the judgment logic is considered reasonable (consistency is acceptable), otherwise the matrix needs to be adjusted; (5) Overall hierarchical sorting and consistency test**: Calculate the composite weight of each level of indicators to the overall goal, and perform a similar consistency test.

3.2.3 Comprehensive evaluation of tourist towns based on fuzzy comprehensive evaluation method

The fuzzy comprehensive evaluation method is based on the membership theory of fuzzy mathematics and is applicable to problems where the evaluation factors are fuzzy and difficult to quantify. Its core steps are: ① Determine the factor set U: including all evaluation indicators (multiple levels can be set).

② Determine the comment set V: define the evaluation level and its score (usually 3-5 levels). ③ Determine the weight vector W: obtain the weight of each factor by methods such as hierarchical analysis. ④ Construct the membership matrix R: element rij represents the degree of membership of factor ui to level vj (0-1). ⑤ Perform fuzzy synthesis: calculate the comprehensive evaluation vector C = W · R. ⑥ Calculate the evaluation results: the weighted average method is often used to calculate the final score P.

3.3 Comprehensive evaluation of overall development performance

3.3.1 Calculation of indicator weights

According to the idea of analytic hierarchy process, a hierarchical model of the evaluation object is constructed. The Delphi method is used to obtain the importance of the indicator elements of the evaluation hierarchy. The Delphi method is an expert scoring method. It divides the relative importance of the indicator elements based on the scaling method, designs an expert scoring consultation questionnaire, and sends questionnaires to experts and scholars in the research topic field. The questionnaires are divided into two channels: online and offline. According to the distribution and collection of questionnaires, a total of 18 valid questionnaires were obtained. Because the invited scoring experts have studied and published relevant research results in the fields involved in the research topic of this study, the questionnaire data obtained has a certain authority and can support the empirical research of this study on the research object. Using the analytic hierarchy process auxiliary tool, the recovered questionnaire data on the indicator element scoring questionnaire are statistically classified, and the data are sorted and consistency tested to obtain the indicator weight coefficients corresponding to the indicators at each level.

1. Criteria layer weight calculation

At the criterion level, through the auxiliary calculation of the hierarchical analysis method software tool, the weight coefficients of the judgment matrix of the four levels of indicators, namely resource development, urban construction, comprehensive benefits and institutional management, in the performance evaluation index system of Hadapu tourism small town development are calculated, and a consistency test is carried out.

Table 2 Judgment matrix and weight values of criterion level indicators

index	Resource Value	Tourism development level	Economic and social benefits	Management and Sustainability	Weight
Resource Value	1	3	3	4	0.5082
Tourism development level	1/3	1	3	1	0.2121
Economic and social benefits	1/3	1/3	1	1/2	0.1061
Management and Sustainability	1/4	1	2	1	0.1735
When the maximum eigenvalue λmax=4.1550 and n=4, CR=0.0580 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.					

2. Indicator layer weight calculation

Through the auxiliary calculation of the hierarchical analysis method software tool, the weight coefficients of the judgment matrix of the two indicators of tourism construction and cultural protection in the resource development level are calculated, and the consistency test is carried out.

Table 3. Indicator layer (resource value) judgment matrix and weight value

Resource value (A1)	**Tourism resources**	**Cultural Protection**	**Weight**
Tourism resources	1	2/3	0.4
Cultural Protection	3/2	1	0.6
When the maximum eigenvalue λmax=2 and n=2, CR=0.0000 < 0.1, the consistency test of the judgment matrix passes, and the obtained weight is valid.			

Table 4. Judgment matrix and weight values of indicator layer (urban construction)

Tourism development level A2)	**Surrounding infrastructure**	**Surrounding transportation facilities**	**Tourism supporting functions**	**Living Environment**	**Weight**
Surrounding infrastructure	1	3	3	1/2	0.3092
Surrounding transportation facilities	1/3	1	2	1/3	0.1501
Tourism supporting functions	1/3	1/2	1	1/3	0.1056
Living Environment	2	3	3	1	0.4351
When the maximum eigenvalue λmax=4.1222 and n=4, CR=0.0458 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.					

Table 5. Judgment matrix and weight values of indicator layer (economic and social benefits)

Economic and social benefits (A3)	**Industry Development**	**Social Impact**	**Weight**
Industry Development	1	3	0.75
Social Impact	1/3	1	0.25
When the maximum eigenvalue λmax=2.0000 and n=2, CR=0.0000 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.			

Table 6. Judgment matrix and weight values of indicator layer (management and sustainability)

Economic and social benefits (A4)	Policy support	Planning Management	Weight
Policy support	1	2	0.6666
Planning Management	1/2	1	0.3334
When the maximum eigenvalue λmax=2.0000 and n=2, CR=0.0000 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.			

Through the auxiliary calculation of the hierarchical analysis method software tool, the weight coefficients of the judgment matrix of 28 element indicators in the four levels of resource value, tourism development level, economic and social benefits, management and sustainability were calculated, and the consistency test was carried out.

Table 7. Indicator layer (resource value) judgment matrix and weight value

Tourism resources (B1)	The richness of red culture themed tourism activities	The variety and richness of red cultural tourism products	Construction status of Hadapu Red Town and Guanegou characteristic scenic spot	Weight
The richness of red culture themed tourism activities	1	7	5	0.7235
The variety and richness of red cultural tourism products	1/7	1	1/3	0.0833
Construction status of Hadapu Red Town and Guanegou characteristic scenic spot	1/5	3	1	0.1932
When the maximum eigenvalue λmax=3.0658 and n=3, CR=0.0633 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 8. Judgment matrix and weight values of indicator layer (cultural protection)

Cultural Protection (B2)	Protection level of tangible cultural heritage	Inheritance level of intangible cultural heritage	Continuity and integrity of cultural space	Weight
Protection level of tangible cultural heritage	1	5	4	0.685
Inheritance level of intangible cultural heritage	1/5	1	3/2	0.1729
Continuity and integrity of cultural space	1/4	2/3	1	0.1424
When the maximum eigenvalue λmax=3.0444 and n=3, CR=0.0427 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 9 refers to the judgment matrix and weight values of the element layer (surrounding infrastructure)

Surrounding infrastructure (B3)	Number of red cultural facilities	Number of red cultural tourism service facilities	Guide system settings under the red culture theme	Weight
Number of red cultural facilities	1	3	2	0.5131
Number of red cultural tourism service facilities	1/3	1	1	0.2381
Guide system settings under the red culture theme	1/2	1	1	0.2488
When the maximum eigenvalue λmax=4.0341 and n=3, CR=0.0128 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 10 refers to the judgment matrix and weight value of the element layer (surrounding transportation facilities)

Surrounding transportation facilities (B4)	Transportation accessibility	Parking convenience	Construction status of scenic sightseeing trails, etc.	Weight
Transportation accessibility	1	3	5	0.6333
Parking convenience	1/3	1	3	0.2650
Construction status of scenic sightseeing trails, etc.	1/5	1/3	1	0.1062
When the maximum eigenvalue λmax=3.0387 and n=3, CR=0.0656 < 0.10, the consistency test passes, and the obtained weight is valid.				

Table 11 Judgment matrix and weight values of the index element layer (tourism supporting functions)

Surrounding transportation facilities (B5)	B&B/hotel service level	Professionalism and service level of interpretation	The level of smart scenic spot construction	Weight
B&B/hotel service level	1	2	1/3	0.2461
Professionalism and service level of interpretation	1/2	1	1/4	0.1975
The level of smart scenic spot construction	3	4	1	0.5564
When the maximum eigenvalue λmax=4.0818 and n=3, CR=0.0360 < 0.10, the consistency test passes, and the obtained weight is valid.				

Table 12 refers to the judgment matrix and weight value of the element layer (human living environment)

Surrounding transportation facilities (B6)	**Landscape greening coverage degree of town built-up area**	**Waste transfer and treatment rate**	**Rainwater and sewage treatment rate**	**Weight**
Landscape greening coverage degree of town built-up area	1	3	3	0.5961
Waste transfer and treatment rate	1/3	1	2/3	0.229
Rainwater and sewage treatment rate	1/3	2/3	1	0.1749
When the maximum eigenvalue λmax=3.0183 and n=3, CR=0.0176 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 13 refers to the judgment matrix and weight values of the factor layer (industrial development)

Surrounding transportation facilities (B7)	**Number of people employed in the tourism industry**	**Annual income from tourism**	**Average length of stay of tourists**	**Weight**
Number of people employed in the tourism industry	1	1/6	1/3	0.096
Annual income from tourism	6	1	3	0.653
Average length of stay of tourists	3	1/3	1	0.251
When the maximum eigenvalue λmax=3.0183 and n=3, CR=0.0176 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 14 refers to the judgment matrix and weight values of the factor layer (social impact)

Social Impact **(B8)**	Popularity of tourist attractions	Community participation in tourism projects	Tourist growth rate after the opening of Lanzhou-Chongqing Railway	**Weight**
Popularity of tourist attractions	3/2	1	1/2	0.2854
Community participation in tourism projects	1	2/3	1/2	0.218
Tourist growth rate after the opening of Lanzhou-Chongqing Railway	2	2	1	0.4966
When the maximum eigenvalue λmax=3.0183 and n=3, CR=0.0176 < 0.10, the consistency test passes and the obtained weight is valid.				

Table 15 refers to the judgment matrix and weight values of the factor layer (policy support)

Economic and social benefits (B9)	Special fund investment	Completeness of planning documents	**Weight**
Special fund investment	1	2	0.6666
Completeness of planning documents	1/2	1	0.3334
When the maximum eigenvalue λmax=2.0000 and n=2, CR=0.0000 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.			

Table 16 refers to the judgment matrix and weight values of the element layer (planning management)

Economic and social benefits (B10)	Balance between development intensity and ecological carrying capacity	Planning innovation	**Weight**
Balance between development intensity and ecological carrying capacity	1	2	0.6666
Planning innovation	1/2	1	0.3334
When the maximum eigenvalue λmax=2.0000 and n=2, CR=0.0000 < 0.10, the consistency test of the judgment matrix passes, and the obtained weight is valid.			

According to the above method, the indicators at each level in the performance evaluation index system of tourism small towns development are analyzed.

The weight coefficients are calculated, w1 represents the weight coefficient of the criterion layer, w2 represents the weight coefficient of the indicator layer, and w3 represents the weight coefficient of the factor layer. The actual weight calculation formula of each indicator element in the performance evaluation index system for the development of tourist towns is: $wj = w1 * w2 * w3$ The final weight table of indicators at all levels in the performance evaluation index system for the development of tourist towns is obtained.

Table 17

Target layer	Criteria Layer	Indicator layer	Feature layer	Weight

			Planning innovation	0.0143

Judging from the weight of the evaluation system, the core of the development of tourist towns is resource development (with the highest proportion), which is the foundation of tourism development. The key lies in exploring resource value and cultural connotation. The second is the level of tourism development, whose material space level directly affects the tourist experience and environmental quality. The third is management and sustainability. As an operational guarantee, efficient macro-management can improve service quality and tourism image. Finally, economic and social benefits reflect the fundamental purpose of developing tourism - improving economic benefits, industrial vitality and social influence. Overall, the weight and importance of resource development and town construction are significantly higher than institutional management and comprehensive benefits.

3.3.2 Fuzzy comprehensive evaluation

In order to ensure the data accuracy of the fuzzy evaluation matrix of the development performance of Hadapu Red Cultural Tourism Space, this study selected four types of evaluation subjects: master and doctoral students in related fields, local government staff, business operators and tourists, and balanced subjective bias through multi-perspective combination. The fuzzy comprehensive evaluation method was used to first conduct a single factor evaluation on the secondary indicators, and then synthesize them step by step, and finally obtain the comprehensive level of overall development performance.

(1) Determine the review set V

In order to make the research evaluation results more intuitive, this study defines the evaluation set of tourism town development performance as

U = {very good, good, average, poor, bad}, that is, the evaluation results are divided into five levels according to the development status of the town in each indicator factor:

Table18: Fuzzy evaluation comments

Rating	Level connotation description
very good	Meeting development requirements
better	Basically meet the development requirements
generally	Partially meet development requirements
Poor	Many parts have not yet met the development requirements
Difference	Development requirements not met

(2) Single factor fuzzy relationship evaluation

Through online and offline questionnaires and interviews with experts, business operators, tourists and some government staff, the data results were sorted and classified, and the initial quantitative values of various indicators of urban tourism development performance were obtained. A total of 142 questionnaires (or interviews) were issued, and 120 valid content was collected. The following is a summary of the corresponding content and the final data normalization.

Table19:

Indicator layer	Feature layer	very good	better	generally	Poor	Difference
B1 Tourism Resources	C1 The richness of red culture themed tourism activities	0.2	0.4	0.6	0	0
	C2 Variety and richness of red cultural tourism products	0	0.2	0.5	0.3	0

According to the fuzzy relationship matrix of indicator factors, the single factor evaluation matrix of each secondary indicator in the development performance evaluation system of Hadapu tourism town can be calculated in turn. Combined with the weight coefficients of each level in the evaluation indicator system calculated in the previous article, a fuzzy comprehensive evaluation of the development performance of tourism towns is carried out. First, a fuzzy comprehensive evaluation is carried out based on the fuzzy matrix of the factor level indicator factors. Taking the single factor fuzzy relationship of the B1 indicator tourism construction as an example, the numerical matrix is arranged and calculated. According to the previous pages of the article, the weight coefficients of indicators at all levels are obtained by using the hierarchical analysis method to determine the weight coefficient of tourism construction factors : W 1 = [0.7235, 0.0833, 0.1932] . Then the fuzzy evaluation value of tourism construction (B1) index factor is C 1 = [0.1990, 0.5802, 0.1930, 0.0278, 0.0000] , according to the maximum membership principle , the membership of the evaluation result belonging to " good " is the largest, and the development of Hadapu's red cultural tourism construction is judged to be good. By analogy , several other values are obtained and their memberships are judged in turn. Finally, the red tourism cultural space development performance value S of Hadapu Town is S=C*V T, and its final value is 2.1667. According to the overall development performance evaluation table of tourist towns, the comprehensive level of the development performance of the red tourism cultural space in Hadapu Town can be divided into intervals. The final evaluation results show that the red tourism development performance evaluation of Hadapu is 2.1667 points.

Table 21

Comprehensive evaluation valueS	**(4,5]**	**(3,4]**	**(2,3]**	**(1,2]**	**(0,1]**
Level	Very good performance	Better performance	Average performance	Poor performance	Poor performance

4. Facilitation and discussion

The comprehensive rating of tourism development in Hadapu Town is "average", indicating that the regional competitiveness is weak and the driving force for sustainable development is insufficient, and it is urgent to make up for the shortcomings. Analysis at the criterion level: Resource development scored the highest, showing that it relies on resource advantages to drive the economy; comprehensive benefits and institutional management are second, reflecting the effectiveness of policy guidance and industrial integration; urban construction scored the lowest, reflecting that service facilities and levels need to be improved. Analysis at the indicator level: Cultural protection, community functions and planning management scored high (>2.5 points), highlighting

cultural heritage and residents' benefits; human settlement environment performance is low, the main reason weight is small and urban and rural development is uneven. This analysis clarifies the direction for subsequent improvements. The strategies are as follows:

The following is a detailed supplement to the optimization strategy for the red cultural tourism space in Hadapu Town, Gansu Province. Combined with the actual development needs and successful experiences of the local area, a specific implementation plan is proposed:

① Space optimization: expand the Red Army Street Cultural and Creative Zone and add immersive experience projects

Implementation path:

Site protection and scene restoration - Based on the renovation of the existing Red Army Street (443 households and 46,600 square meters have been renovated), the "Red Army Life Experience Area" will be expanded to restore the post office, pharmacy, cooperative and other scenes from the Long March period, and use AR technology to display historical events (such as the Red Army's rest and recuperation, the expansion of the Red Army and the establishment of the government) to enhance tourists' sense of involvement.

Immersive performance upgrade - relying on the successful experience of the existing live-action drama "Red Star Over Hadapu", a night light and shadow theater will be added, using 3D projection technology to present dynamic historical stories on the walls of the revolutionary ruins; a "role-playing" project will be developed, where tourists can change their clothes and participate in interactive tasks such as "raising food to support the front" and "military-civilian carnival" to deepen their experience.

Expansion of cultural and creative consumption space - setting up a "Red Cultural and Creative Workshop" to centrally display and sell special products such as Hadapu medicinal incense and Red Army snacks, and opening a DIY experience area (such as printing Red Army slogan cloth bags and making Chinese herbal medicine sachets) to extend tourists' stay.

Expected effect: Enhance the depth of tourists' immersive experience and drive secondary consumption; the average length of stay per visitor is expected to be extended by 1.5 hours, and the proportion of cultural and creative income will increase to 30% of total revenue.

② Industrial linkage: Deepen the "red + green" model (the joint ticket system bundles the Guanegou Scenic Area)

Implementation path:

Route design and joint ticket mechanism - launch the "red and green dual-core" joint ticket (Hadapu Memorial Hall + Guanegou Scenic Area), integrate the transportation connection services within 36 kilometers, and design a one-day tour route of "red education in the morning and ecological sightseeing in the afternoon". Cooperating travel agencies launch packages including transportation, explanations, and meals, with a 20%-30% discount.

Resource complementarity and brand linkage - add a Hadapu Red Culture Exhibition Corner in the Guanegou Scenic Area, and simultaneously broadcast a promotional video of the natural scenery of Guanegou on the Red Army Street; jointly organize theme activities (such as the "Retracing the Long March and Exploring Guanegou" hiking race) to share customer traffic.

Data sharing and precision marketing - establish a scenic spot passenger flow data intercommunication platform, analyze tourists' preferences and push customized itineraries (such as recommending the "Red Script Killing + Forest Study" combination to the study team).

Expected results:

The tourist mutual guidance rate will be increased by 40%, and the joint ticket coverage rate will exceed 60%; in 2023, the tourism revenue of Guanegou will reach 3.9 billion yuan, and after the linkage, the number of tourists in

Hadapu is expected to increase by 25% annually.

③ Community empowerment: Promote the "cooperative + farmer" model (refer to the operation experience of the live-action drama in Shangjie Village)
Implementation path:
Professional operation of cooperatives - copy the model of Shangjie Village Tourism Cooperative (which has attracted more than 50 villagers to participate in performances and increased annual income by 20,000 yuan per person), establish a town-level tourism cooperative alliance, and unify the management of the three major sectors of performances, homestays, and agricultural specialties. Set up a "Red Skills Training Fund" to regularly carry out tour guide, handicraft, and performance training.

Diversified business model shareholding and dividends - Encourage farmers to invest in cooperatives with idle houses and land:

The performing arts group recruits villagers to participate in live-action performances (e.g. the newly added "mass actor" position in "Go to Northern Shaanxi") and distributes dividends according to the number of performances; For the homestay group, the cooperative uniformly renovated the residential houses on Hongjun Street and created the "Hongjun Inn" brand (currently there are more than 60 rooms). Farmers can get 60% of the profits by investing in the houses they own.

In the production and marketing group, the cooperative centrally purchases local specialties (Red Army jelly, Chinese medicinal materials), packages them into "Long March Grain Packages" gift boxes, and sells them online through live broadcasts (referring to Gaolan County's "agricultural network terminal + e-commerce" model).
Governance coordination mechanism - promote the "Longnan Civil Direct Talk 1234 Working Method", and the party branch of the cooperative will regularly hold villagers' meetings to coordinate issues such as income distribution and service quality to ensure farmers' voice.

Expected results:
It has mobilized more than 200 farmers to participate, with an average annual increase of 30,000 yuan per household; the village's collective economic income has increased by 50%, forming a closed loop of the "performing arts - homestay - specialties" industrial chain.

Through the linkage of three major strategies, Hadapu can build a development model of "deepening of red scenes - integration of red and green resources - long-term community benefits", promote the transformation and upgrading of red culture from "sightseeing and checking in" to "experience and get rich", and provide a paradigm for the revitalization of the old revolutionary areas in Northwest China.

Planetary Gentrification of Rural China: the case of *yangjiale*

Yifan Song[1], Paulina Maria Neisch[2]
1 Architecture and Civil Engineering at the City University of Hong Kong, yifansong4-c@my.cityu.edu.hk;
2 Department of Architecture and Civil Engineering, City University of Hong Kong, pmneisch@cityu.edu.hk;

Abstract
Yangjiale is a form of homestay in Mount Mogan Village, Zhejiang Province, China. Newcomers from surrounding metropolises rented abandoned village houses in the local area, turning them into BnB, thus initiating a form of rural tourism called *Yangjiale*. Later, Indigenous Mount Mogan people, who lived in the surrounding cities, returned to their places of origin to exploit the new opportunities given by *yangjiale*. After a fast period of initial growth, such a new form of rural tourism began to cool down, possibly due to the progressive loss of the quality experience made available in the early years of *yangjiale*. This paper offers an overview of the phenomenon since its inception, focusing on the land use change associated with it associated. First historical data about the location of y*angjiale* homestays was retrieved from local administrations and verified by fieldwork conducted in 2024. The complied dataset allowed for longitudinanl understand of the locational patterns in the evolution of *yangjiale* services from 1934 to 2022 second the land-use change analysis with a focus on Mout Mogan Town administrative area was made possible via secondary data provided by the local administration, rendering the territorial transformation occurring from 2006 to 2020. Further investigation considered the planning scheme, released in 2021 with 2035 horizon. The findings reveals a progressive shrinkage and fragmentation of agricultural land. In contrast, the areas designated for orchards, tea plantations, and gardens have shown a notable increase. Rural residential areas have continued to expand, indicating a growing trend in continue expansion. The emergence and development of y*angjiale* can be explained in light of a global gentrification process, which shows the urban entrepreneurial consciousness generated by the combination of international market forces and the new possibilities given by digital platforms. Thus, the process of touristification in rural China can be discussed as a form of counter-urbanization driven by the platform economy.

Keywords: *Yangjiale*, touristification, counter-urbanization, urban entrepreneurialism, planetary gentrification, consumerism, platform economy

1.Background

Rural areas have become an important part of China's economic revitalization. In order to improve the infrastructure of these areas and stimulate economic activities, China has introduced various policies, including the Ten Million Project and Beautiful Countryside initiatives. Inspired by China's ongoing rural revitalization policy, the picturesque rural homestays at the foot of Mogan Mountain in Zhejiang Province, near Shanghai, have brought significant changes to the entire Chinese homestay industry.

In the 18th century, especially between 1891 and 1894, American missionaries promoted the beauty of Mogan Mountain to the West through newspapers (Liu, 2025). This publicity attracted many Western dignitaries who built summer villas here, including representatives from the United States, Britain, Germany, Russia and other countries. In addition, due to Mount Mogan's proximity to Shanghai and its beautiful scenery, many Chinese celebrities during the Republic of China period also came here. Those who built villas here included Huang Li, the then mayor of Shanghai, as well as various politicians, intellectuals, financiers and missionaries. Notably, Chiang Kai-shek, the top leader of the Republic of China, and his wife Soong Mei-ling also built villas and lived here. Today, 250 modern villa buildings are preserved in Mount Mogan (Liu, 2025). After the peak of villa construction during the Republic of China, the hotel industry in Mount Mogan ushered in a recovery in 2007. At that time, a young South African working in Shanghai discovered the area and opened the naked castle homestay. This homestay brought considerable income to the homestay industry and attracted other non-Chinese people to open their own homestays in Moganshan. For example, a Frenchman named Stuart built a successful mountain homestay in the area (Liu, 2025). Many non-Chinese people began to rent abandoned farmhouses from local farmers and renovate them into homestays. This led to the birth of the homestay brand *yangjiale*, which represents the

understanding of the homestay model by non-Chinese people. This model is in sharp contrast to the previous concept of *nongjiale*, *nongjiale* refers to the simpler homestay services provided by Chinese farmers, who mainly decorate houses and provide farmhouse dishes (Zhang et al., 2019). The creation of the *yangjiale* homestay brand marks the first stage of its development, namely the *yangjiale* stage. The term *yangjialelization* summarizes the phenomenon of *yangjiale* BnBs and the various impacts it has produced (Song & Neisch, 2025). The second stage of *yangjiale* and *yangjialelization* originated from the success of the first batch of non-Chinese BnB founders. This attracted designers and senior professionals from major cities around Moganshan, such as Shanghai, Hangzhou, and Nanjing. Many of them have deep roots in Mount Mogan and gradually moved to big cities for development as they grew up. This group of country gentry from surrounding cities has become the second generation of the *yangjiale* market. They usually rent abandoned village houses from local farmers, or use their own houses in their hometowns, and transform them into new BnB projects after careful decoration and design. To a certain extent, they continue the management and design concepts of the first generation of non-Chinese BnB founders. Their efforts to transform and integrate into the market are not only popular, but also have far-reaching impacts. Among them, Da Le Zhi Ye co-founded by Ji Xiaoxiang and Yang Mohan is one of them. Ji Xiaoxiang and Yang Mohan were both born in Mount Mogan and graduated from the Department of Architecture and Planning of Tongji University in Shanghai. This homestay has become a model project for the development of the second generation of Chinese country gentry in the *yangjiale* market (Song & Neisch, 2025). The third generation of *yangjiale* homestays is mainly composed of local farmers from the Mount Mogan area and residents of Moganshan County. Inspired by the success of the first and second generation founders of *yangjiale*, many local farmers with innovative thinking and ability learned from the management experience of early homestay operators and began to renovate their own houses and independently operate homestays. Typical cases in this stage include Xipo founded by Qian Jiliang, a native of Moganshan County, and Mount Mogan Mansion founded by local villager Zhu Jindong. The first generation of *yangjiale* homestays flourished from 2007 to 2012, the second generation emerged from 2013 to 2015, and the third generation emerged from 2016 to 2017 (Song & Neisch, 2025). In the third stage, the two-wheeled homestay industry gradually emerged.

2. Literature Review

Planetary gentrification is a new concept that represents the latest global theoretical development since Ruth Glass proposed the concept of gentrification in 1964 (Glass, 1964). Glass's critique has evolved into a global postcolonial challenge to the cognitive violence of Western imperialism, a neoliberal theory of human competition rooted in 19th-century social Darwinism and eugenics. In the article "Resisting Global Gentrification: The Value of Survival in the Struggle to Defend Homeland", the concept of plantetary gentrification is explored, pointing out that the international community's resistance to gentrification is intensifying. This resistance is considered a key struggle for social justice in global cities. The author examines global resistance to gentrification by re-examining the value of survival and advocates learning from different contexts in the ongoing challenges brought about by global gentrification (Loretta Liss, Sandra Annuziata, Clara Rivas-Alonso, 2017). Patrick Rérat interprets the literature on gentrification with spatial capital as the center and expands this concept to a global scale (Patrick Rérat, 2018). Elvin Wyly argues that the global communication technology revolution, known as "cognitive capitalism" and "borderlessness", is enabling a multicultural interweaving. This phenomenon clearly reflects the changing class dynamics of urban space, which adapt to multiple factors such as urban history, sociocultural differences, state power, and local resistance (Wyly, 2015). Cross-border gentrification is a contemporary form of urbanization that narrows the rental gap by attracting high-income immigrants from Nordic and North American countries (Matthew Hayes & Hila Zaban, 2020). There are many cases of gentrification and regional upgrading in both urban and rural areas of China. However, there are few studies on global gentrification in rural China. This study will focus on the cases of global gentrification in rural areas of developed China, as this represents a clear research gap.

Exploring neoliberalism in the Chinese context, especially in the rural context, is a growing trend in domestic research. Anita Koo (2021) explores the neoliberal experiences of rural migrants in her book Individualized Negotiations in Neoliberal China: Youth Transformation in a New Generation of Rural Migrants. Lu Xinyu (2024) further explores the relationship between collectivism and neoliberalism in rural China in his study Neoliberalism or New

Collectivism in Rural China. He argues that Chinese neoliberalism functions as a form of collective capitalism and emphasizes that China faces the challenge of balancing liberal and social democratic demands while ensuring a common minimum standard of living. Yang Zhan and Xiaoxi Tong (2018) also focus on the manifestation of market neoliberalism among rural migrant populations. In addition, some scholars have explored the connection between the rise of rural areas as centers of post-carbon transformation and neoliberalism (Marsden, 2016). However, there is little research analyzing the neoliberal characteristics of rural commercial activities in China.

Many Chinese studies on transnationalism have explored the identities of Chinese and foreign Chinese during the Huaqiao Festival (Louie, 2008), the identities and transnational experiences of students participating in transnational education (Jiang, 2021), and the identity issues faced by transnational migrants who obtain flexible citizenship through education (Yang & He, 2024). However, few studies have explored the issues of transnationalism that emerge in rural China, such as how villagers view foreign entrepreneurs and how their self-identity evolves in this process. In addition, many studies have explored whether traveling to Africa and accepting infrastructure assistance from other countries represent neocolonial behavior. In contrast, there is a lack of literature on the potential neocolonial impact of Western entrepreneurial immigrants bringing lifestyle changes to rural eastern China.

This paper aims to fill the gap in the study of the planetary gentrification theory in rural China. This paper explores the application of neoliberal theory to rural commercial activities and homestay tourism in China. In addition, this paper examines the concepts of neocolonialism and transnationalism in the context of Moganshan, a rural area in eastern China.

3. Research Objectives

Taking Mogan *yangjiale* as an example, this paper explores the perspective of understanding the phenomenon of Mogan *yangjiale* and its rural global gentrification process.

The phenomenon of Mogan *yangjialelization* refers to the influx of a large amount of non-Chinese capital into the Chinese market, which has caused a strong response and has become a benchmark for Chinese homestays, while also promoting changes in the national homestay industry. As a unique phenomenon, *yangjiale* deserves attention and scholars who study the development trend of Chinese rural areas. In addition, *yangjiale* is also a case of global capital entering developing countries and promoting comprehensive regional upgrading. Examining the phenomenon of *yangjiale* from an international perspective helps us understand how Chinese rural areas continue to develop and evolve under the influence of global gentrification.

Understanding the dynamics and interactions between different stakeholders in the *yangjiale* ecology.
By studying the interactive ecology between various stakeholders in *yangjiale* and its *yangjialelization* process, we can gain a deeper understanding of how these stakeholders interact and influence each other. Their interactions constitute the overall ecological framework of *yangjiale*, allowing us to understand how different stakeholders are interconnected in the *yangjiale* interest ecological network. By exploring the mutual influence and relationship between *yangjiale* stakeholders, we can gain a clearer understanding of the Mogan *yangjiale* phenomenon. This understanding can serve as a new economic case to examine the development of rural tourism in China, while also providing insights into the current status of rural spatial development in China and serving as an example of how global gentrification is eroding rural areas in the Global South and Southern China. Ultimately, this study deepens our understanding of how global gentrification theory manifests itself in the real world.

Investigate the spatial influence of various stakeholders on the development of Mount Mogan *yangjiale* in the process of rural planetary gentrification.

Based on the background of urban planning, we investigated the mechanism of mutual influence between the stakeholders of Mount Mogan *yangjiale*. This analysis helps us understand how different stakeholders affect

the changes in local space during the development of *yangjiale* Homestay and its transformation into *yangjiale* Homestay, and gain insight into the role of various stakeholders in the transformation of rural space in the process of planetary gentrification.

4. Research hypothesis and arguments

4.1 Hypothesis

Yangjiale, Moganshan, is experiencing a process of rural global gentrification.

This paper hypothesizes whether *yangjiale* has triggered some form of global gentrification in the region and plans to verify this hypothesis through interviews and research on land use changes.

4.2 Arguments

Mount Mogan *yangjiale* is a political arena where stakeholders such as indigenous people, tenants, government and electronic platforms are interdependent, reflecting the influence of neoliberalism, neocolonialism, transnationalism and government in the context of eastern China.

The rise of Mount Mogan *yangjiale* is influenced by multiple factors. As one of China's most economically developed urban agglomerations, the Yangtze River Delta Economic Development Zone demonstrates how rural development fits in with national development goals. The development of Mount Mogan *yangjiale* also reflects the broader direction of rural development in China. Given China's important position in East Asia and the Global South, this case study highlights rural development models and trends that may be applicable to moderately developed developing countries in East Asia and the Global South, including China. The case study of Mount Mogan *yangjiale* is highly representative. It successfully established its own brand through non-local investment and operation, attracting capital and experienced professionals from the Yangtze River Delta region. This strategy enabled the brand to develop, ultimately leading to the booming homestay industry in the Mount Mogan area and profoundly influencing and changing the landscape of homestays in China. Mount Mogan *yangjiale* represents the intersection of various rights and stakeholders. Ideologically, it is a testing ground for neoliberalism, neocolonialism, transnationalism, and government practices in East Asia and rural China. In addition, it serves as a platform for the expression of multiple rights discourses.

The following diagram (Figure 1) shows the relationship between the various stakeholders involved in the construction of Mount Mogan *yangjiale*. As the manager of local development, the government plays a vital role in nurturing various innovative business enterprises, including the design and operation of local farmhouses that originally inspired the mountain homestay model. This also covers the various forms of rural entrepreneurship that emerged during the mountain homestay process, including the digital nomad self-media entrepreneurship that later emerged among migrant workers in nearby large cities. In addition, the government has set standards for the height and number of rooms in homestays, aiming to protect the environment and help the many farmers who opened homestays inspired by early homestays. The government has developed a set of guidelines to standardize and unify the exterior design of homestays, aiming to create a more cohesive and aesthetic collective homestay environment. The government has also cooperated with several domestic travel websites (such as Booking.com, Qunar, and Fliggy) to hold a series of lectures and small workshops. These activities invite villagers and homestay operators to participate and help them learn how to create attractive slogans and videos for online travel platforms. Participants will also learn the skills of organizing events and live broadcasts to attract a larger online consumer group. The situation of local farmers is a process of constantly adapting to changes and coexisting with outsiders who bring capital and knowledge. Starting with the *yangjiale* initiated by outsiders who arrived in Mount Mogan, local villagers gradually accepted and began to learn from them. They accepted new lifestyles, such as drinking coffee, and began to cooperate with outsiders, renting out their dilapidated village houses at low prices for long-term use, allowing them to operate and design homestays. As the *yangjiale* model was promoted nationwide and achieved market success, local villagers began to participate more fully in it and learn from this model. As *yangjiale* became an important local industry, many young and middle-aged people who left Mount Mogan to work returned to the countryside. They began to get involved in the homestay industry or related fields, becoming housekeepers, managers, etc. of homestays. The development of *yangjiale* also led

to the growth of local villagers' income. Farmers' awareness of investment and entrepreneurship gradually increased, and many houses were rented to homestay operators, realizing the value of the houses. In the popular Yu Village, villagers also began to use the land to earn lucrative parking fees. Over time, the villagers learned to live in harmony with young people who returned from large IT companies in surrounding cities such as Hangzhou and Shanghai. Many entrepreneurs in industries such as self-media have begun to choose picturesque villages as mobile office locations. As the *yangjiale* model gradually heats up and the market gradually cools down, the hospitality of the villagers is particularly important, and they create a warm environment for newcomers. The founders of local homestays have experienced three generations of inheritance and development. Many homestay entrepreneurs cooperate with local small businesses, such as jointly promoting the use of local agricultural and sideline products. In addition, a large number of homestays use online platforms to promote their brands and attract a large number of customers. The rural homestay industry is also undergoing a platform transformation. While these local homestays are booming, the government has also vigorously supported the rise of large-scale hotel industries. These international hotels provide standardized services, causing many homestay operators to feel that their business has been impacted. Therefore, large-scale hotel development projects vigorously promoted by the government have formed competition with the local homestay industry. At the same time, with the success of homestay brands such as Naked Castle and Da Le Zhi Ye incubated by *yangjiale*, many homestays have begun to establish chain operation models in scenic spots in other regions and develop homestays similar to *yangjiale*. In addition, some local governments, such as the Ningxia Xiwei region in central and western China, are working hard to create homestay clusters to attract customers and stimulate the local economy. To this end, they actively introduced the chain homestay brand incubated by *yangjiale* and operated it at a significantly reduced cost. Platformization, that is, the rise of Internet platforms, has had a significant impact on the local government of Mount Mogan area. This cooperation includes promoting unique local homestays in Mount Mogan.

From an ideological perspective, Mount Mogan is an active arena for the intersection and expression of various rights and ideologies, showing the interaction and status of multiple rights discourses in rural areas in the Yangtze River Delta region of eastern China. First, the influx of migrants into the rural market and the establishment of new homestay models mark an important step in neoliberalism's attempt to penetrate China's marginal rural areas, especially in typical Chinese neoliberal cities such as Shanghai. As a form of neocolonialism, tourism is largely dominated by ideologies rooted in the perspectives of the West and the world's North. The process of villagers accepting and absorbing foreign ideas and lifestyles has both neocolonial and postcolonial characteristics. For example, local farmers simply copy or imitate the business models and management practices introduced by migrants, which can be seen as a form of modern neocolonialism and postcolonialism. However, neocolonialism has undoubtedly provided opportunities for cities and regions in the global South, such as the Moganshan region, to develop a vibrant homestay industry cluster using local resources. It is worth noting that after the epidemic, many of the original non-local entrepreneurs left, leading them to re-acquire the homestay brands they originally founded. This suggests that the profit maximization stage of foreign homestays may have ended, highlighting the original non-local people's perception of neocolonialism. Their actions can be interpreted as a kind of speculation in the global South in the context of global gentrification. In addition, the rise of foreign homestays is also deeply influenced by globalization and transnationalism. However, the local government has cleverly seized this global opportunity and turned it into a competitive advantage. Initially, abandoned houses in prime locations were rented out at very low prices to the first non-locals eager to set up homestays, a strategy that continues to attract more innovators of the foreign homestay model. The local government actively cooperated with these initial creators and took various measures to enhance the local visibility and influence. These measures, including leveraging the personal connections of non-local homestay creators and obtaining recognition from prestigious publications such as The New York Times, have greatly contributed to their achievements.

Yangjiale embodies the characteristics of neo-colonialism and rural green gentrification, while creating profits for local villagers and promoting rural green gentrification.

The emergence of the *yangjiale* homestay model has completely changed the traditional farmhouse model. By integrating high-end design, personalized operations, and the beautiful local natural scenery, the *yangjiale*

model provides a rural experience that is in stark contrast to the earlier simple farmhouse model. This business model was developed by a group of people from large Chinese cities such as Shanghai who were eager to experience the natural scenery around Moganshan. They have lived in metropolises such as Shanghai for a long time and realized that Moganshan not only has a convenient geographical location but also has amazing natural scenery. They used their own resources and knowledge to create the *yangjiale* model and successfully attracted the attention of the market. Initially, when these outsiders chose the site, they were warmly welcomed by the local government, allowing them to rent village houses in prime locations at very low prices. The *yangjiale* model embodies how the global elite from the Global North can invest in the Global South region to appreciate, a process often associated with planetary gentrification. After establishing the *yangjiale* model, these people not only introduced a new business model, but also brought the Global Northern lifestyle and philosophy to rural communities in China's Yangtze River Delta. Local farmers readily accepted these changes, and their enthusiasm for learning skills such as coffee making and English grew. This interaction between Chinese resources and foreign capital can be seen as a strong neo-colonial color; however, the villagers did benefit from it. Abandoned village houses that were once considered worthless began to generate long-term rental income. In addition, the popularity of the *yangjiale* model has also created a large number of jobs, including positions as homestay cleaners. Many villagers have also borrowed from the *yangjiale* model to improve their homestays, and residents in popular areas have begun to charge high parking fees due to the increase in tourists.

By comparing the land use change map of Yangjiale in the past 15 years (Moganshan County Government, 2006; Moganshan County Government, 2021), it can be seen that the Ten Million Project launched by the government in 2003 laid the necessary foundation for the development of *yangjiale*. In addition, the booming *yangjiale* industry has also significantly affected the lives and vitality of local farmers. The development of tourism has also quietly changed the overall lifestyle in rural areas (Figure 1).

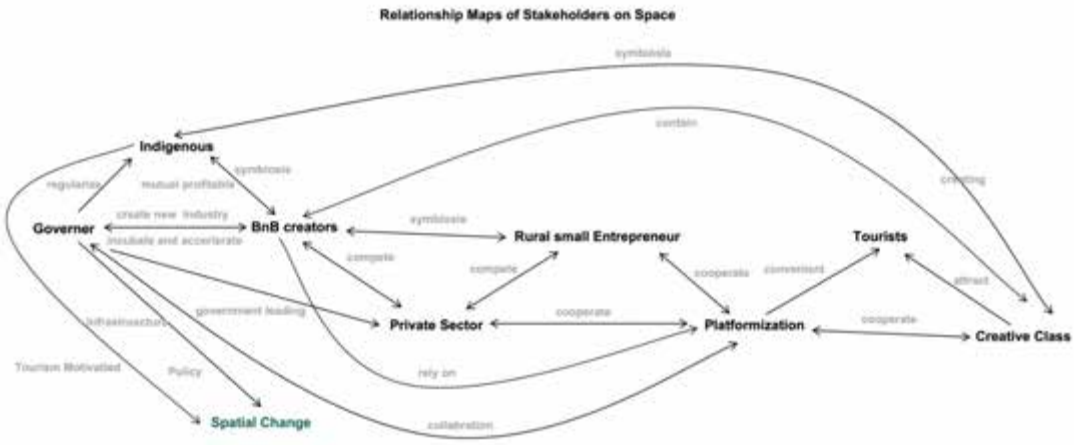

Figure 1. Relationship Map of stakeholders in Mount Mogan Yangjiale on space

Government-led tourism projects and products launched by large private enterprises are undermining the profitability and development of the localized, grassroots *yangjiale* homestay model. This situation is closely related to the broader regional upgrading and rural gentrification process.

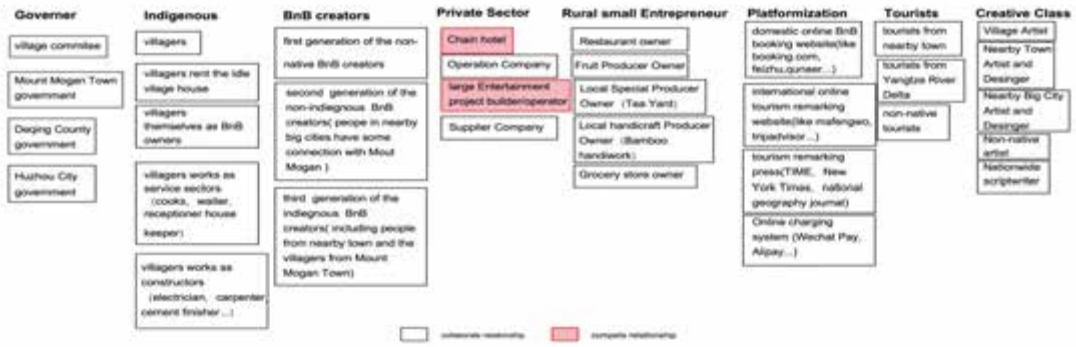

Figure 2. Relationship Map of stakeholders in Mount Mogan yangjiale

During the development of *yangjiale*, especially in the years after the epidemic, the local government leadership changed and introduced various international hotel brands in order to highlight its political achievements. However, these top-down international hotels compete with *yangjiale's* unique local hotel model (Figure 2). Many consumers believe that international hotels of the same price offer more complete and standardized services. As a result, these international hotels have attracted a large number of old customers of *yangjiale*, causing dissatisfaction among local homestay operators. They believe that the government's introduction of international hotel brands has disrupted the grassroots homestay ecosystem of *yangjiale*. In addition, the entry of international hotels has also triggered the phenomenon of tourism gentrification in the area. These hotels are often isolated from the surrounding rural environment, exacerbating the local gentrification phenomenon and separating new developments from existing communities.

4.3 Research Questions
What is the global gentrification process in *yangjiale* Village?
By examining the gentrification process in *yangjiale*, this paper provides a deeper understanding of the region itself and the wider global gentrification phenomenon. This will provide a relevant empirical case for the study of global gentrification in the Global South and help to analyze the levels and dynamics of this process in East Asia in more depth.

In the process of rural planetary gentrification, how do different stakeholders interact to shape the social ecology of *yangjiale*?

By examining the interactive ecological network of *yangjiale* stakeholders, this paper has a deeper understanding of the formation background, formation process and development context of *yangjiale*. This will help to more clearly understand the mechanism behind *yangjialelization* and deepen the comprehensive grasp of this phenomenon.

What are the spatial impacts of these interactions and dynamics in the process of gentrification of rural *yangjiale*?
By examining the interactions and participation of stakeholders in the process of *yangjiale* occurrence and *yangjialelization*, the focus of the study is shifted to the disciplinary context of urban studies.

5.Methodology
Interview
This study included two semi-structured interviews. The first interview was conducted in the summer of 2023 with 61 participants (N=61), including 19 tourists, 11 villagers, 8 village-level organization staff, 11 BnB owners, 8 small and micro business owners (such as coffee shops and agricultural product owners), 2 Moganshan County Government staff, and 2 operating company employees. The second interview was conducted in the summer of 2024 (N=4) and focused on four BnB owners and managers.

Spatial analysis

This study examines the changes in land use during the 15-year development of *yangjiale* BnB in Mount Mogan area. The study was conducted by communicating with local government departments and collecting online information. Through communication with government departments, we obtained the Moganshan County Master Plan 2021-2035 and the Moganshan County Text Atlas 2006-2020. The analysis focused on comparing the changes in land use planning maps to evaluate the changes in industrial land spatial use in Mount Mogan area during the 15-year development of *yangjiale* BnB.

Field investigation

This study conducted two field surveys in the summer of 2023 and the summer of 2024 to gain an in-depth understanding of the current status of the local homestay industry, understand the attitudes of local residents and government officials toward the *yangjiale* homestay industry, and understand the actual situation and business model of local homestays through personal experience.

6.Analysis and findings

In order to more effectively describe the *yangjiale* phenomenon and the characteristics of its various stages, this paper adopts the SCEEP model (Figure 3). This model mainly draws on the STEEP model, which outlines the sustainability of enterprises. The STEEP model contains five quadrants: social quadrant, technological quadrant, economic quadrant, environmental quadrant and political quadrant. The SCEEP model replaces the technical quadrant with the cultural quadrant.

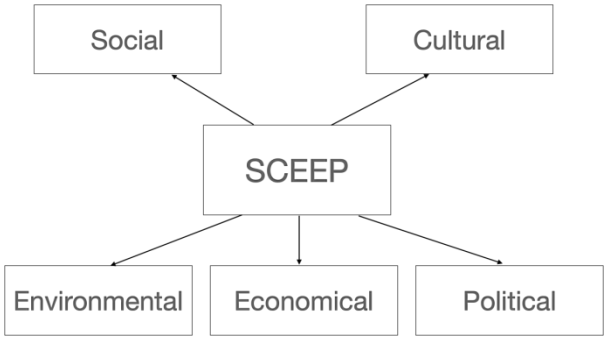

Figure 3. SCEEP model

The five quadrants of SCEEP represent the following areas: S stands for society, including demographic influences, income distribution, education, population development and security, covering social aspects such as family, friends, colleagues, neighbors and the media. C stands for culture, covering factors such as language, religion, customs, traditions and values, as well as gender, attitudes, lifestyles and consumption trends. The first E stands for economy, involving factors such as economic growth, inflation, interest rates, exchange rates, taxes, unemployment, income levels, business cycles, world trade and resource availability. The second E stands for environmental factors, including materials and resources, waste disposal, emission regulations, energy, transportation routes, life cycle, and the impact of issues such as ozone layer depletion and global warming. Finally, P stands for politics, covering policy frameworks, labor market policies, government regulations, competition supervision, legislation, political stability, tax policies, trade barriers, safety requirements and subsidies. Each quadrant plays a vital role in our understanding of the various influences and interactions in *yangjiale* society.

	Definition
Social	demographic influences, income distribution, education, population development, security. Aspects within society such as family, friends, colleagues, neighbors and the media.
Cultural	language, religion, customs, traditions, and values, sex and gender, attitudes, lifestyles, consumer trends.
Political	policy frameworks, labor market policies, government policies, competition oversight, legislation, political stability, tax policies, trade barriers, security requirements and subsidies.
Economical	economic growth, inflation, interest rates, exchange rates, taxation, unemployment, income, business cycles, world trade and resource availability.
Environmenatl	material, resources, disposal, emission regulations, energy, transport routes, life cycles, effects of the ozone hole and global warming.

Figure 4. Definition of SCEEP model

Through the SCEEP model, we can fully understand the characteristics of the development of Yangjiale, the phase characteristics and the relationship between the stages (Figure 5). Using the SCEEP model to describe the characteristics of *yangjiale* in different stages, we can find several aspects. In the first stage, before 2007, *yangjiale* was in its embryonic stage. From a social perspective, the rise of *yangjiale* was influenced by the influx of the middle class in neighboring metropolises and a lifestyle trend known as neo-colonialism. This trend, influenced by Western culture, triggered a wave of lifestyle entrepreneurship in China. This period can be seen as a manifestation of the global gentrification process in rural eastern China. From a cultural perspective, the Western middle class began to reshape the pastoral utopia in the farmhouses in the east, integrating local customs and combining local and Western utopian ideals. Initially, the exploration of *yangjiale* attracted only a few non-locals who were eager to experience the wildness. Unlike large standardized international hotels, *yangjiale* BnBs focus on anti-standardization, private customization and a sense of community, *yangjiale* cleverly combines globalization and localization, embodying the concept of glocalization. There are also historical precedents. Many non-Chinese people were attracted by reports about Mount Mogan and went to Mount Mogan to build villas, which reflects the tradition of historicism in the process of globalization. From a political perspective, the Ten Million Project launched in 2003 laid the foundation for infrastructure construction in rural areas, providing the necessary transportation networks, roads and transportation facilities to support the growth of tourism. From an economic perspective, the early success of *yangjiale* BnB benefited from the gathering of high-spending people in the surrounding urban agglomerations. *Yangjiale* is located in the mountainous area closest to Shanghai and is surrounded by one of the most affluent consumer groups in mainland China, the Yangtze River Delta urban agglomeration, which benefits from its inherent source of customers. In addition, the low long-term rent of village houses also made the founders of the first batch of *yangjiale* lucrative. The consumer groups in Jiangsu, Zhejiang and Shanghai are deeply influenced by consumerism and show a tendency to high-priced, experiential and conspicuous consumption. From an environmental perspective, the successful establishment of *yangjiale* BnB in the early stage had a positive impact on the surrounding environment and laid the foundation for future development.

From 2007 to 2015, it was the second stage of the *yangjialelizatin* phenomenon, when a large amount of Chinese mobile capital poured into the market. From a social perspective, the foreign homestay areas began to show agglomeration effects, and the platform model gradually emerged. During this period, *yangjiale* also developed their own local homestay brands and opened chain homestays in various places to achieve expansion.

From a cultural perspective, during this period, a large amount of Chinese capital poured into the homestay industry, and the participation of gentry in surrounding large cities also accelerated the localization process of homestays. In addition, many creative classes moved from urban centers to rural areas to participate in rural development, demonstrating their entrepreneurial spirit. At the policy level, underdeveloped areas continued to send representatives to Mount Mogan to learn from experience and invite local homestay brands to take root in their rural tourism areas at the lowest cost to attract consumers. Rural governments in central and western regions also actively developed local homestay groups through various forms of cooperation. At the economic level, *yangjiale* attracted a large amount of domestic capital during this period. With the rise of the Mount Mogan homestay industry, the cooperation between the government and homestay brands has also increased, which has promoted young people who have gone out to work to return to their hometowns to start businesses. The cooperation between the Internet economy, homestay brands and local governments is also gradually emerging, such as web page recommendations, online publicity training camps, etc. On the environmental level, the second phase of *yangjiale's* development has entered a climax, and the establishment of many homestays has effectively promoted regional upgrades and improvements in the rural environment.

After 2015, *yangjialelization* entered the third stage, and a large number of local farmers began to participate in the *yangjiale* market, and many copycat homestays also appeared. From a social perspective, the problems of homogeneity and market saturation were more obvious at this stage. From a cultural perspective, the entrepreneurial spirit of the villagers was highlighted at this stage. In response to the homogeneity problem, the government proposed a themed operation model, encouraging each homestay to create a unique theme to attract specific consumer groups. In addition, the government has established cooperative relationships with many IoT tourism platforms. From an economic perspective, the *yangjiale* reached the stage of commercialization at this stage. In order to pursue consistency in economic interests, the characteristics and products of Mount Mogan were commercialized and lost their authenticity. From an environmental perspective, tourisitification was particularly prominent at this stage, and the entire area experienced an upgrade due to tourism development. However, with the development of *yangjiale*, the natural landscape that was originally free to enjoy became exclusive to homestays, and the cost of getting close to nature also increased.

	Social	Cultural	Political	Economical	Environmental
First Phase (Before 2007)	Mobility of jacent metropolitan world middle bourgeoisies Lifestyle New-colonialim Planetary gentrification	Combination of Native and Western Utopianism Anti-standardization and private customization and clubbing Glocalization Historicism of Globalization Disneyfication	Government infrastructure development	Natural High Consumer Group Global Regional Rent Gap Consumerism of natural environment	Infrastructure improvements
Second Phase (2007-2015)	Agglomeration Effect platformization Local brand breeding B&B chains	Lobalization Urban Entrepreneurship of the Local Creative Capitalist Class	Governments of underdeveloped regions cooperate to join B&B brands Central and western Chinese government to develop tourism B&B clusttering	Attracting domestic capital Government and B&B Brands Collaboration Return of local labor Internet platform economy	Regional renewal and upgrading of the countryside
Third Phase (After 2015)	homogenization oversaturation	Urban Entrepreneurship of Local Villagers	thematic promotion of Government Cooperation between Governments and the Internet platform economy	commodification	Touristification

Figure 5. SCEEP of different stages of yangjiale

The study shows that the various characteristics and phenomena in different stages are interrelated (see Figure 6). In the first stage of *yangjialelization*, the global mobility of middle-class elites created opportunities for neo-colonialism and spread Western lifestyles at the social level. In this stage, foreign homestays may be experiencing the so-called planetary gentrification, which is attributed to their unique economic location and natural scenery. The Ten Million Project launched by the government in 2003 supported the improvement of regional infrastructure, enabling foreign homestays to drive regional development in the subsequent stage. From an economic perspective, the consumer groups in the Yangtze River Delta region have formed a desire for natural experience-based conspicuous consumption. As *yangjialelization* entered the second stage, the rise of industrial clusters laid the foundation for the rise of the platform model. The initial stage of *yangjialelization* attracted capital and nurtured the potential for further localization. The homestay brands that landed in the Mount Mogan area were successful in the market and began to expand in the form of chain homestays. This success has stimulated the interest of central and western regions to cooperate with the government and local homestay brands (such as the Chinese version of *yangjiale* homestay brand Da Le Zhi Ye. In the third stage of *yangjiale*, platformization brought challenges such as homogeneity and market oversaturation. In the second stage, the influx of returning youth stimulated the entrepreneurial spirit of farmers and laid the foundation for growth in the third stage. The initial disneyfication trend of *yangjiale* influenced the government's subsequent development plans. The cooperation between the government and the Internet platform reflects the evolution

of the Internet economy, transforming regional development into rural transformation and ultimately achieving tourism development in the third stage..

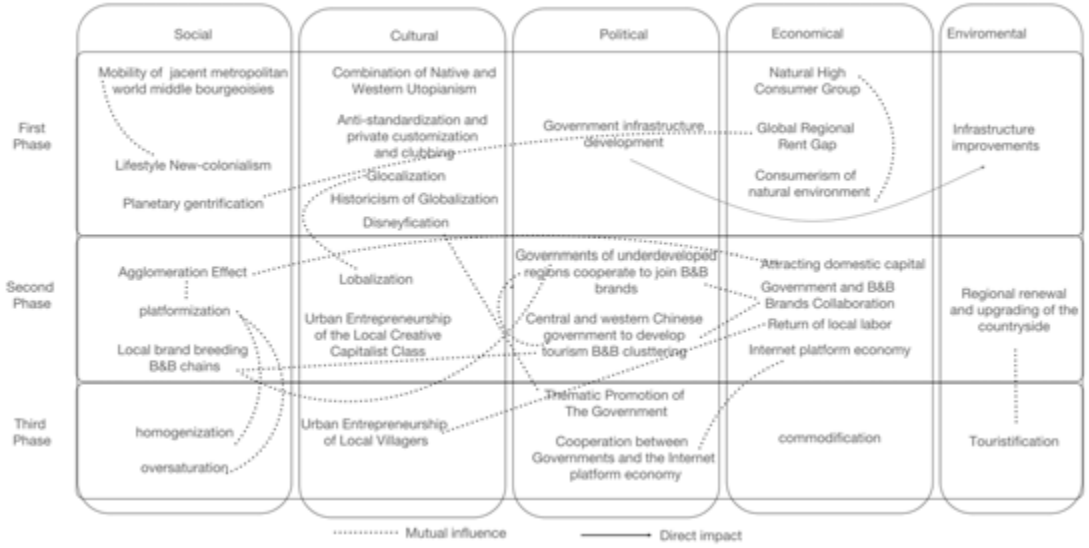

Figure 6. relationships of different stages of yangjiale

Comparing the changes in *yangjiale's* land use planning over the past 15 years, especially the land use planning of Moganshan County from 2006 to 2020 and from 2021 to 2035 (see Figures 7 and 8), the cultivated land area is decreasing and becoming increasingly fragmented.

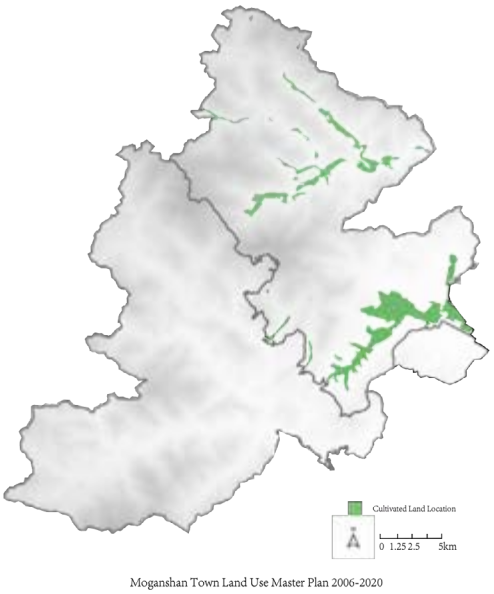

Figure 7. Moganshan Town Land Use Master Plan 2006-2020

Moganshan Town Master Plan 2021-2035

Figure 8. Moganshan Town Land Use Master Plan 2006-2020

Analyzing the relationship between stakeholders and land use change in *yangjiale*, it can be found that villagers' participation in homestay tourism has reduced the importance of cultivated land, leading to the separation of cultivated land and homestay development areas. The emergence of platform-based homestay clusters has further accelerated this development. In addition, the clustering of homestays has enriched the lives of villagers and expanded their living areas to more scenic places. At the same time, under the promotion of the government, the original central area of Moganshan County was designated as the Moganshan Scenic Area, and the size of the town has been reduced (see Figure 9).

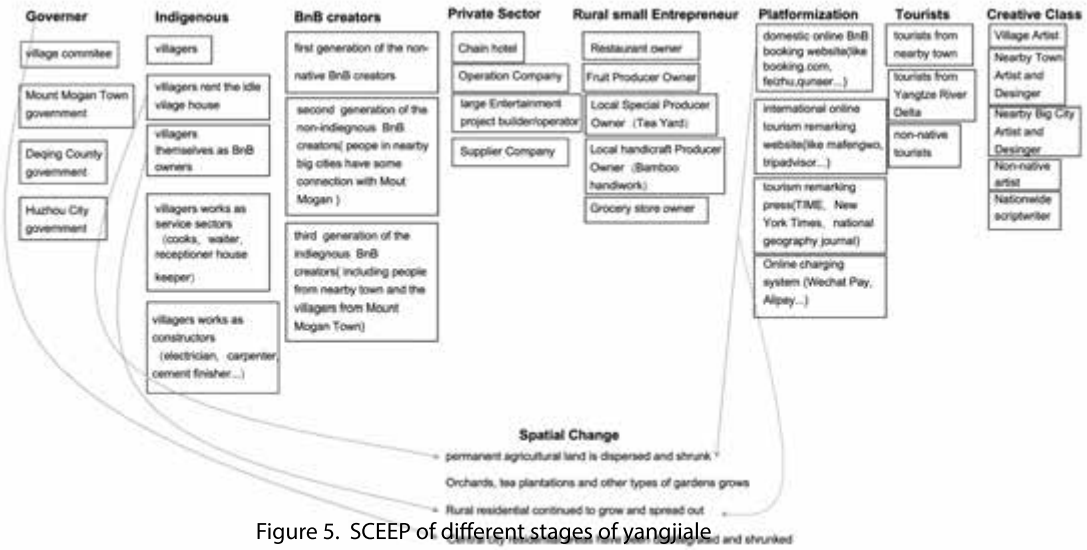

Figure 5. SCEEP of different stages of yangjiale

Figure 9. Stakeholders' impact on Yangjiale in space

In summary, *yangjiale* has gone through three different stages of change, with stakeholders both supporting and competing with each other, forming a unique business model and ecosystem. The SCEEP model can succinctly describe the characteristics of these three stages and highlight the causal relationship between them. Government planning documents reflect the changes in local land use in *yangjiale* over the past 15 years. Combining this information and combining it with the stakeholder relationship map, we can further analyze how different stakeholders in *yangjiale* affect the land use pattern in Mount Mogan.

7.Impact, signifiance and future directions

Understanding and studying the Mogan *yangjiale* BnB industry will help us better understand the implementation of policies such as China's beautiful countryside construction.

By studying the development history of the *yangjiale* BnB industry, we can have a deeper understanding of the direction and model of China's rural economic development, especially in the Yangtze River Delta region. This study will also help understand China's agricultural policies such as the Beautiful Countryside and the Ten Million Project aimed at promoting rural development and reform.

Given that the development of *yangjiale* has benefited from foreign investment, studying this region helps us understand the dynamics of village development and gentrification in the Global South.
The background and development of *yangjiale* show how global capital and talent invest and start businesses in developing countries in East Asia. Mogan *yangjiale* is an excellent case study to examine the global gentrification process in East Asian villages. By observing and studying Mogan *yangjiale*, we can gain a deeper understanding of the impact of global gentrification on rural China in the broader context of East Asia.

Yangjiale's case study can provide a reference for rural development in other underdeveloped regions of China and in the global South.

Yangjiale's successful experience can provide valuable reference for other regions, including Africa, Southeast Asia, and any country that hopes to promote rural economic development through homestay tourism. By sharing *yangjiale*'s story through academic research, we can help other rural areas develop local economies and improve the livelihoods of local farmers in a similar way.

Future research directions include exploring the rural economic development model in Zhejiang Province, examining the identity formation process of the Mount Mogan *yangjiale*, predicting the overall development trend of the Mount Mogan *yangjiale* studying the counter-urbanization and rural digital nomadism phenomena in the Mount Mogan *yangjiale* industry, and examining how Mount Mogan *yangjiale* can serve as rural spaces to ease the tension between elitism and populism in today's world.

The key directions of future continuous research are as follows: As the leader of China's rural economy, how can Zhejiang build a sustainable rural economic model and effectively narrow the urban-rural gap? The rural economic development model of Zhejiang is the focus of future research. As mountain tourism destinations that have not yet established a dominant position in the surrounding economic circle, Moganshan and *yangjiale* have become models of Chinese tourist homestays. This study will explore in depth how they successfully cultivate local identity. The inspiration of this study on shaping local identity will provide reference for other regions to shape their own identity and regional brand and establish the cognition of landmark buildings in the minds of consumers. The development of *yangjiale* has attracted a large number of young and middle-aged people from rural areas to urban employment, resulting in the phenomenon of counter-urbanization in some rural areas. Research on this counter-urbanization trend is another important research direction in the future. In the post-epidemic era, the development of *yangjiale* has declined; however, more and more residents of Mount Mogan and *yangjiale* are integrating into the local community. A new type of maker group has emerged among the residents of Mogan Village, known as digital nomads. They live in surrounding metropolises, but choose to move to the countryside to work in mobile offices or start their own media businesses. The rise of this group, as well as

the future of rural development and innovative human settlements, represents an important research direction. *Yangjiale* is a model of cooperation and symbiosis between foreign elites and local grassroots farmers, which has promoted the success of the homestay industry and comprehensive industry reform. Given the ongoing debate and tension between elitism and populism, case studies from villages and foreign homestays provide an opportunity to bridge these differences and promote mutual learning and cooperation and symbiosis between the two groups.

Acknowledge
This article thanks the Moganshan Homestay Association for its generous support and all the Moganshan County residents who participated in the interviews and surveys. We also thank the village staff and homestay owners who contributed to this survey. Finally, I would like to thank my doctoral supervisor Prof. TALAMINI Gianni for his important guidance on this research and his suggestions on the content of the article, which were of great help in the implementation of this research.

The messy interplay between forces of resistance and forces for change in territorial transitions: A case study of an Alpine ski resort

Aida Arik[1]*, Emmanuelle George[1]
[1]Univ. Grenoble Alpes, INRAE, LESSEM, Grenoble, France
*aida.arik@inrae.fr

Abstract
Winter tourism and its associated development has reshaped mountain communities of France and established itself as a major economic engine at a micro and macro scale. However, ski resorts built around this economic model are facing an increasingly uncertain snow future, especially at mid-mountain altitudes. In this paper, we examine the case of a mid-mountain community in the Alps that initiated a collaborative planning effort to decide the fate of their loss-generating ski lift equipment. This case illustrates that climate change adaptation is not a mere question of pecuniary or normative decisions. Rather, to better understand the forces at play, we take a territorial transitions approach to examine the multi-scalar inertial forces in the material, institutional, and ideal dimensions of this community.

Keywords: winter tourism, climate change, territorial transitions, French Alps, mid-mountain ski resort

1. Introduction

Fluid mechanics provides an apt analogy for what many territories are facing in terms of direct and indirect impacts of anthropogenic global warming—it defines three flow phases: laminar, turbulent, and transitional. Laminar flow mirrors harmonious territorial operations, turbulent flow represents chaotic and unpredictable disruptions of territorial systems, and transitional flow reflects territorial systems between the former two regimes, oscillating between stability and instability. In this paper, we focus on the French Alps, which exemplify a transitional "flow" (territorial) phase. In France—a country facing average temperatures increases greater than Europe and the world, on average (FAO, 2023)—areas at greater altitude are facing even faster warming than those at lower altitudes (Adler et al., 2023). Thus, the mountains of France are seeing decreasing snowpacks, especially at mid-altitudes, and increasing uncertain snow regimes (Dayon et al., 2018; Gerbaux et al., 2020). This poses an existential problem in many communities whose economies were built around ski resort tourism (Spandre et al., 2019; Steiger et al., 2019; François et al., 2023; Berard-Chenu, Métral and Cognard, 2024; Bonanomi et al., 2024).

For better or for worse, these mountain communities offer an opportunity to gain important lessons for areas around the world that are facing economic transitions as a direct or indirect impact of climate change. In an essay about declining tourism prospects due to increasingly uncertain snowpack of mountain territories built around ski resort tourism, Bourdeau (2009) describes the French Alps as a "laboratory of post-tourism experimentation." The author hypothesises that with climate change, mountains could return to a pre-ski development model of the mountain is the summer vacation destination of the coming decades, supporting this hypothesis through evidence of growing residential transition of mountain tourist areas, lifestyles that support more place-based activities, and a declining interest in long-distance travel (Bourdeau, 2012). Whereas this represents a rather radical interpretation of the tourism and population signals in mountain territories, it does however represent one bookend scenario of possible futures for individual ski resort villages among a plethora of possible trajectories based on climate, economic, and cultural forces. For the ski resort villages most impacted by these exogenous forces, there is a clear role for planning in directing these territories through their transitional phase towards stability (laminar) and away from instability (turbulent).

Post-modern planning has produced a fractalized landscape of many normative (post-positivist) theories (Allmendinger, 2002). In its essence, normativity in planning is driven by what we should do because it's the right thing to do for the future (Healey, 2003), although there are many arguments to be made around the meanings hidden behind each loaded word. In contemporary times, we have an unequivocal global consensus based on

decades of research that indicates that we should adapt to climate change impacts because it is the right thing to do for the future (IPCC, 2023). Yet, we also have ample evidence that, on a global scale, governments are not meeting the pace and scale of adaptation needs (Berrang-Ford et al., 2021). Zooming into the local-level, there may be a plethora of valid reasons (Rittel and Webber, 1973) why climate adaptation measures are difficult to implement, inadequate, or ineffective (including important cultural, psychological, and political reasons). Nonetheless, it raises the question of whether our current planning paradigms are equipped to address contemporary challenges effectively, both in terms of scale and pace, to find stability with future climate regimes. Indeed, Pavoni et al. (2024, p. 1) pose a critically relevant question to planners: "What if the problem with planning was its very relation with normativity and future?" Indeed, planning is challenged by the very nature of adaptation, which cannot be confined to frameworks and requires a constant process of learning and adjustment.

While there are many strands of post-positivist planning theories, collaborative planning remains a dominant theory in post-modern planning (Tewdwr-Jones and Allmendinger, 2002). In this paper, we aim to take a closer look at the collaborative planning processes relation with normativity and the future to understand some of the tangible and less tangible elements that constrain outcomes (i.e., non-transformative planning efforts that do not seem to meet climate adaptation needs). Pavoni et al. (2024) interrogate these notions of normativity and the future, suggesting planning "not as a strategy to act in the present in order to build a different future, but rather as a strategy to release in the present those futurial presences...that are already there." Our goal of this paper is to examine how collaborative planning can be used to help release a territory from its inertial forces that transcend our abstractions of the future, and at the same time manage transitions without necessarily transforming all outputs.

In this paper, we consider a collaborative planning process taking place in the Chartreuse Mountains of the French Alps. La Montagne Autrement 2030, is a local effort focused on the ski resort village of Saint-Pierre-de-Chartreuse (SPC) concentrating on an imminent and divisive decision facing the community on what to do with their ski lift equipment. We aim to take a closer look at the tangible and less tangible elements that can constrain territorial transitions and the role of the collaborative planning effort.

2. Background

2.1. Setting the scene: the rise of winter tourism in France

It is no coincidence that the growth of winter sports tourism corresponds to the mechanisation and motorising of snow removal equipment in the wake of the world wars, but the idea and allure of ski sports was slowly being developed and implanted into the imaginaries well before. In France, we can trace some of the major factors that contributed to the rise of ski tourism and the eventual widespread establishment of ski resorts across high altitude spaces (Figure 1). With the establishment of the first ski clubs at the end of the 19th century and beginning of the 20th century, the Alps played a major role in the rise of ski in France and the eventual establishment of the first generation of ski resorts. During WWII under the Vichy Regime, mountains were used as a 'tool' for the masculinisation of young boys under an educational philosophy emphasising physical fitness and outdoor training, again with a focus on the Alps. Following the war, populations movements towards economic opportunity led to a trend of rural flight and decline in agriculture that impacted mountain territories.

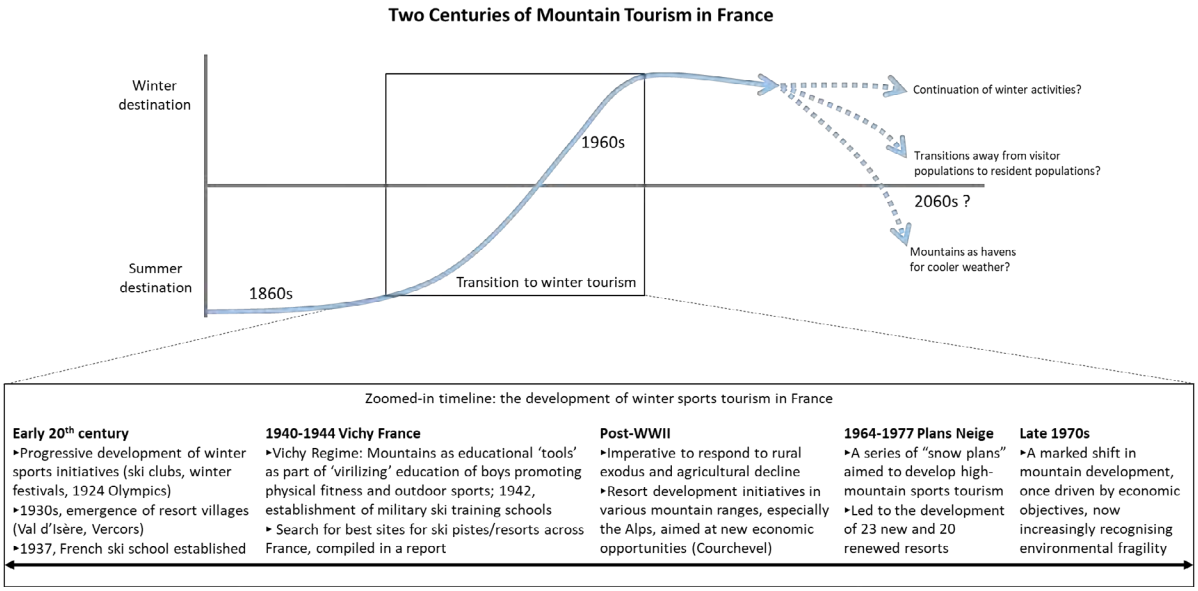

Figure 1. The shift of mountains in France from summer destinations to winter destinations was driven by the alignment of many events over the course of nearly a century. Ski and winter tourism remains important to the economy and culture in France. However, despite the strong heritage of ski resort development, the future of winter tourism is becoming increasingly uncertain with climate change. The future of individual ski resorts is contextual, with some ski resorts continuing investments in ski tourism with success, while others are phasing out ski.

In recognising the potential of winter tourism as a means to boost the economy in these mountain territories, the French government began identifying locations favourable to skiing and investing in infrastructure, leading to the so-called second generation of ski resorts similar to Courchevel (Cumin, 1974). The continuing rise in the popularity of skiing, its marketing, continued technological improvements of ski infrastructure and the profitability of the ski resorts eventually set the stage for the emergence of the Plans Neige by the French government and the emergence of a third generation of ski resorts. These were a series of "Snow Plans" starting in 1964 that outlined widescale development of purpose-built ski resorts, called integrated resorts often built ex-nihilo with the developer playing a major role (Perret, 1992). Between 1964 and 1977, the Plans Neige led to the wide-scale development of many new ski resorts and the renewal existing resorts. By the late 1970s, the development frenzy driven by the Plans Neige was waning, as the initial motives—curbing rural exodus and boosting mountain economies—were challenged by new concerns. Ski resort expansion faced growing criticism, not only for its environmental impacts from unbridled urban planning and enormous accommodation capacities but also from external actors who promoted efforts to restore local control and create more balanced development. Land was increasingly designated for protection through National Parks, in attempting to counterpoise tourism-driven economic growth with environmental safeguards. Nevertheless, ski resort development continued into the end of the 20th century even if at a slower clip.

2.2. The writing "in the snow"

The imprint of ski and winter mountain tourism since its accession in the mid-20th century remains strong. However, across France, as well as Europe and in many places around the world, ski resorts with winter sports-based economies are facing existential questions about their future with an increasingly uncertain snowpack (Steiger et al., 2019; François et al., 2023; Dumont et al., 2025). While many ski resorts use snowmaking and snow grooming to ensure continuous operations in spite of decreasing snow conditions (Damm, Köberl and Prettenthaler, 2014; Schlegel and Schuck, 2024), there are many questions about its continued function as climate change impacts continue to amplify (Spandre et al., 2019; Berard-Chenu et al., 2021; Morin et al., 2023; Scott, Knowles and Steiger,

2024). Indeed, without snowmaking, François et al. (2023) estimate that with 4°C warming, 98% of ski resorts across 28 European countries are at a very high risk for snow supply. Whereas, the number drops to 71% with snowmaking, but raises very serious questions about the its contribution to the vicious cycle of electricity and water demand, carbon footprint, and further contributions to local impacts and global warming, by becoming maladaptive strategies.

With the recognition that the French ski business model is becoming increasingly financially and environmentally unsustainable for many ski resorts (Cour de comptes, 2024), questions emerge about the future of these mountain spaces. Diversification has long been and continues to be a strategy for shifting away from a dependence on winter sports tourism, especially for mid-mountain ski resorts that are on the frontlines of global warming impacts (Achin, 2015; Rouch, George and Rieutort, 2022; Steiger et al., 2024). However, in the process of moving away from a solely ski-based economy, it is important in the planning of such transitions to consider the wider territory and not just the ski resort concerned (Achin and George-Marcelpoil, 2013), as well as other socio-cultural forces beyond tourism that play a role in reshaping these territories in transition (Bourdeau, 2012, 2021).

3. Methodological Notes

3.1. Defining territorial transitions

Taking a broad historical view of a territory allows us to trace major transitions and the forces that shaped them, as seen in the rise of winter tourism in France. However, when it comes to adapting to climate change, the past not only sets constraints on future possibilities but also interacts with dynamic factors that shape the range of viable solutions (Haasnoot et al., 2020). This is referred to as "path-dependency," which helps understand the possible range of strategies for addressing climate change for a given context. Within path dependency, there may be instances of adaptation inaction or maladaptation that create "lock-in." Lock-in describes how rules, land-use patterns, and infrastructure can lock a system into a trajectory that is costly to change (Abel et al., 2011). When certain actions are implemented on top of existing structures or an adaptation opportunity is missed, it is not only potentially locked in for its lifecycle, but the surrounding values, knowledge, and institutions tend to continue to uphold and reproduce that trajectory (Meynard et al., 2018). In a similar vein to collaborative planning, Garrelts and Lange (2011) propose that process-oriented bottom-up approaches can help tackle the spatial and temporal complexities among diverse actors posed by path dependency.

However, climate change adaptation is in many ways fundamentally different from adapting to climate impacts on winter sports tourism, where the existential threat from climate impacts is imposed on an economy from which a space is built rather than the space on which the economy depends, for the former. Thus, in planning for futures of ski-reliant communities, we are particularly concerned with creating pathways for social and economic sustainability (Gill and Williams, 2018). To clarify the meaning behind the word 'territory,' we adopt the approach as defined by Pachoud, Koop and George (2022). The authors explain the concept of the territoire rooted in French geography (Lajarge and Sadoux, 2023) as an interaction between its material, institutional, and ideal dimensions, which serves as a framework for understanding how human activities shape and are shaped by multi-scalar contexts. The authors argue that although geography scholars tend to use the concept to understand dynamics of a territory over short time spans, the concept can also be used to understand potential pathways toward sustainability. The three dimensions can thus help us understand the dynamic nature of the territory: the material, which includes all physical human and non-human elements like resources, infrastructure, and land use; the institutional dimension, which encompasses the formal and informal structures of governance whose role is to organise and manage space while balancing social interests; and the ideal dimension that reflects the cultural, emotional, and social values ascribed to a space by its inhabitants (ibid).

In this paper, we explore the question of inertial forces in the territory that act to either resist or direct change. Mahoney (2000) describes social inertia as processes that are set into motion towards a particular outcome that stay in motion and continue to track that outcome. Some explain the persistence of social structures in terms of reproduction, in that institutions reproduce themselves over time for social stability, causing self-reinforcement that resists directional changes, even if the status quo is unsuitable for the present or future (Barnett et

al., 2015; Brulle and Norgaard, 2019). There are a number of case studies in the literature that name inertia as an impediment to adaptation action, especially related to the persistence of modernist engineering approaches in institutional cultures and development regimes of territories (Harries and Penning-Rowsell, 2011; Taylor, 2016; Meng et al., 2022; Robert, Quercy and Schleyer-Lindenmann, 2023). For this paper, we are particularly interested in the framework laid out by Munck af Rosenschöld, Rozema and Frye-Levine (2014) that connects the concept of inertia to new intuitionalist literature, which we will describe further in Section 3.3.

3.2. Where does "economics" fit in?

Hagimont (2020) describes the case of the development of tourism in the French Pyrénées with the onset of ski tourism to illustrate, on the one hand, the commodification of the human-nature relationship, and on the other hand, the disconnection of all that is less desirable in such a relationship (as rural life in the mountains at the turn of the 20th century was a hard living). The early successes of ski tourism set the stage for viewing mountain territories as areas that could be planned, controlled, and commodified, and no doubt contributed to solidifying the imaginaries supportive of the planification of mountain territories for ski tourism in the mid-20th century via the Plans Neige. Indeed, with the building of transport infrastructure and mechanised snow management equipment, the very relationship with snow for mountain residents radically transformed for many mountain residents from an encumbrance to a potential source of revenue. The heritage of the Plans Neige has ensured France as a major international ski destination (2nd to the United States) with mountain tourism accounting for more than 20% of the overnights stays even as visitor numbers have been in the decline for the past decade (Cour de comptes, 2024).

In contrast, Vindevoghel (2024) describes a 21st century view of rural mountain areas of France providing a key opportunity for reconnecting the human-nature relationship towards sustainable transitions in order to move past the legacy created by the Plans Neige. However, the commodification of snow for now is still a major economic mechanism for many mountain communities. Complicating matters further, France has a specific system of ski area governance. Unlike many countries, which have fully or mostly privately operated and managed ski resorts, France considers ski lifts a form of public service. As a result, local authorities with ski areas choose to either manage their own ski area or delegate management to a private entity via a process known as a public service delegation (Cour de comptes, 2024). Therefore, local authorities may be eligible for subsidies under public policy schemes regardless of their size or financial viability. Public funding for tourist activities shifts costs from users to taxpayers, raising legal concerns about financing public industrial services, financial risks for authorities if businesses fail, and questions about the appropriateness of public spending (ibid).

France's model of treating ski lift equipment as public service infrastructure, necessitates decision-making across the material, institutional, and ideal dimensions. For example, a private owner and operator of ski lift equipment might prioritize operational decisions based primarily on demand and return on investment—keeping decision-making largely within the material dimension—as is the case in the North American ski resorts (Knowles, 2019). Ski lift equipment as public infrastructure introduces additional institutional and societal considerations that shape governance beyond pure market forces. Where market forces play a downsized role, institutional and ideal dimensions can play a large role in driving decisions about the future of ski lift equipment. Thus, planning for the future of French ski resort towns better fits under the framework of new institutional economics and understanding the associated transaction costs of planning (Shahab, 2022). As Alexander (1992) explains, economic and political markets they represent an aggregate of self-interested decisions; however, interorganisational systems need planning because transaction costs are inherently high.

3.3. Evaluating territorial inertia

Since market decisions are not the key decision-making mechanism for French ski resorts, understanding inertial forces can a useful guide to planning, especially where there is not concrete objective. Munck af Rosenschöld, Rozema and Frye-Levine (2014) offer a framework pulling from new institutional literature to understand institutional inertia and climate change policy implications. The authors define five mechanisms producing institutional inertia: costs, uncertainty, path dependence, power, and legitimacy. In this paper, we examine how inertia

presents itself in the case of a ski resort village. We first make the case that the decision for the future of the ski lift equipment is not solely a cost-benefit ratio decision. We describe a collaborative planning process underway that enables collective decision-making over the future of the ski lift equipment and, beyond that, how the community wishes to define the future habitability of their village. We use the framework outlined in Table 1 to evaluate inertia, with collaborative planning as a strategy to mitigate inertial forces.

Table 1. Five mechanisms of institutional inertia and collaborative as a potential strategy to address them. Adapted from Munck af Rosenschöld, Rozema and Frye-Levine (2014).

Inertia generating mechanism	Collaborative planning strategy
Costs - coordination expenses and other transaction costs that can be less visible but discourage action	Although coordination expenses may increase in the short-term, shared resources can reduce overall transaction costs and coordinated efforts can reduce long-term monetary costs.
Uncertainty - incomplete information that rationalises postponement of action	Bringing diverse stakeholders together allows for a broader exchange of knowledge, making risks clearer and alleviating hesitation to action.
Path dependence - self-reinforcing mechanisms that lock institutions into past decisions, technological systems, practices, and discursive frameworks, making change difficult despite evolving challenges	Collaborative planning enables institutions to assess and challenge entrenched practices, opening pathways for innovation and reducing reliance on outdated systems or practices.
Power - embedded in social structures, relationships, and discursive frameworks that reinforce institutional arrangements, making resistance to change a result of entrenched interests rather than rational calculations	As multi-stakeholder processes, collaborative planning can challenge dominant interests that resist change and create momentum for more equitable strategies.
Legitimacy - institutional norms and power structures determine which climate policies are accepted or resisted, often reinforcing existing economic and political interests instead of driving meaningful change	Consensus-driven approaches build trust and reinforce the legitimacy of climate policies, ensuring they are widely accepted and implemented rather than dismissed or blocked by political or economic interests.

These mechanisms of territorial inertia either reinforce resistance to change, favouring the status quo, or can diminish in favour of transitioning to a changed state. This dynamic can be expressed as:

$$I_{\text{status quo}} > I_{\text{change}}$$

Where represents the sum of inertial forces. For a territorial transition to occur, inertial forces must reach a critical mass[1], leading to a directional inversion toward change:

$$I_{\text{status quo}} < I_{\text{change}}$$

At this threshold, transition becomes the favoured course of action, where there is no longer enough resistance to maintain the territorial status quo. However, as long as the path dependency, power, and legitimacy are each greater in the status quo than that of the potential changed state, and conversely, if the costs and uncertainty in the status quo are each less than that of a changed state, the status quo is favoured. The inertial forces within the same territorial state can accordingly be represented as the sum of costs (C), uncertainty (U), path dependency (D), power (P), and legitimacy (L):

1 Territorial changes may unfold over years or decades. For example, in the case of the transition of mountain areas in France transitioning from summer to winter destination (Figure 1), there was an amalgamation of many events that led to this overall transition.

$$I = D + P + L - C - U$$

Applying this framework can help identify forces that may be contributing to the territorial resistance to change, even where transition would otherwise, from an outsider's perspective, be the logical course of action.

4. Case Study

4.1. Research context: Saint-Pierre-de-Chartreuse/Le Planolet

Located in the Alps of Southeastern France, Saint-Pierre-de-Chartreuse-Le Planolet (SPC) is a mid-mountain ski resort community with a population of less than 1000 residents (INSEE, 2023). SPC is located in the Chartreuse Mountains about 25 km north of the City of Grenoble and about 35 km south of Chambéry. As with many ski communities in France, SPC started to develop in the early 20th century and became a ski resort village in the 1950s, with major re-investments in the 1980s and 90s. The area features 26 trails covering 35 km, served by 14 ski lifts and three access points, with altitudes ranging from 900m to 1789m at the Scia summit. As a mid-sized resort with a capacity of nearly 3,000 persons per kilometre per hour, it caters to both families and seasoned skiers.

However, several metrics indicate a delicate financial situation. Over the past 15 years (2015-2023), the ski resort attained an average annual revenue of €1.4 million, with a peak of €2 million during the particularly snowy winter of 2008-09. Between 2015 and 2020, it recorded an average of 130,000 skier-days per season, while the domain was operational for an average of 73 days per year. Despite these figures, the resort faces a negative operating leger, burdened by €2 million in loan repayments, worsened by an aging lift system with high maintenance costs and an oversized fleet compared to similar resorts (Chambre régionale des comptes, 2023).

Furthermore, regional plans create a contradictory structure for economic diversification in the face of climate change. SPC is located within the Auvergne-Rhône-Alpes administrative region (AURA), which provides oversight and planning for the broader regional area in coordination with local entities. Climate change adaptation efforts in the AURA region overwhelmingly prioritise snow security and winter activity safety, with nearly three-quarters of its funding commitments directed toward maintaining ski resort viability rather than diversifying tourism options. For instance, the Region's Mountain Plan (2016-2021) allocates €49.8 million for snow security and €4.5 million for tourism diversification. Similarly, while the Tourism Plan emphasises diversification, its focus on valley areas where there is one or more resorts means that a majority of its budget goes towards ski resorts. Given the high costs of ski infrastructure maintenance, it is reasonable that a significant portion of the budget is allocated to its upkeep; however, this continued investment reinforces a persistent focus on traditional winter tourism (i.e., reinforces path dependency) rather than broader adaptation strategies (Chambre régionale des comptes, 2024).

The SPC ski resort has long struggled to establish stability, with some investments proving unsuitable for the station's scale and capabilities. The municipality of SPC is one of 17 that make up the Communauté de communes Cœur de Chartreuse (CCCC), an intercommunal federation of municipalities. Over the past 20 years, the ski area's management has shifted between local authorities, joint public operations, and private operators, testing various governance models before returning to control under the CCCC in 2023. In fact, the Regional Chamber of Accounts for AURA conducted an audit of the management of the Saint-Pierre de Chartreuse-Planolet ski area syndicate for the period 2009 to 2014 (before the CCCC took oversight) (Chambre régionale des comptes, 2016). According to the report, the financial situation of the SPC ski area syndicate at the time was already exceedingly precarious, with debt levels exceeding 18 years of gross self-financing capacity and making it nearly impossible to secure loans for necessary future upgrades and maintenance of its outdated infrastructure. These financial difficulties had already emerged during the previous syndicate's management of the ski area, ultimately leading to its dissolution and the transfer of authority to the CCCC.

Although five ski lifts are currently not in service, they still impose financial obligations due to ongoing loan and insurance costs. However, restoring them to operational status and ensuring compliance with regulations comes

with a hefty price tag (Table 2). While management by the CCCC enables a broader territorial view[2], they lack the financial resources to support the ski lift deficits of SPC and has yet to devise a clear plan for either adapting or ending operations. Today, the local community has embraced a collective planning effort to confront their climate realities and economic pressures linked to the uncertainty of ski operations. This case highlights the co-existence—and at times, strong opposition—between forces of resistance to change and transformation, while demonstrating the importance of collective planning in reshaping actors' imaginaries about transitions before implementing conflict-minimizing adaptive actions.

Table 2. Out-of-commission ski lifts in the SPC ski area and their associated situations (figures presented at a public meeting in Saint-Pierre-de-Chartreuse, 6 December 2024).

Ski lift	Current situation	Re-commissioning costs and procedures
Scia chairlift	• **Not in use since March 2020** • Suspension of operation • Safety order, March 2026	Estimated re-commissioning costs at **€350,000**
Essarts gondola lift	• **Not in use since March 2020** • Suspension of operation • Safety order, March 2025	Estimated re-commissioning costs at **€820,000** (without an update of equipment)
Fraisses chairlift	• **Not in use since March 2020**	At least the major inspections order of 2022 and 2023 need to be implemented
Combe de l'Ours chairlift	• **Not in use since February 2023** • Major inspections order over 3 years: phase 1 completed in 2022, phases 2 and 3 incomplete	For a return to service: completion of inspections order, compliance audit, and tower diagnostics. Remaining cost of order and re-commissioning estimated at over **€400,000**

4.2. A collaborative planning effort (La Montagne Autrement 2030)

The Montagne Autrement 2030 initiative, spearheaded by local authorities including the CCCC and the municipalities of SPC and Saint-Pierre-d'Entremont (SPE), has provided a platform for reflecting on the future of the ski domain amid the challenging context outlined in section 4.1. This collaborative initiative stands out as a distinctive and exemplary approach to territorial transitioning, conceived in response to the financial difficulties of the SPC ski domain and the declining snowfall at mid-altitude. A bottom-up effort in 2020 debuted this effort, which has brought together various stakeholders—including local public actors, residents, business owners, and economic actors—to discuss not only the future of the ski area but also the broader evolution of the local tourism offering. Through sustained dialogue, this diverse coalition of participants has explored ways to shape a tourism model that aligns with emerging challenges and opportunities (Figure 2). As part of this effort, the EU-funded Interreg TranStat project (Transitions to Sustainable Ski Tourism in the Alps of Tomorrow)[3] designated SPC as a 'Living Lab,' actively exploring innovative strategies in climate adaptation and sustainable tourism, where the project seeks to promote new models of Alpine development and transition in the face of changing climate. The TranStat project aims to helping provide the collaborative effort with information about economic realities, environmental concerns, and evolving visitor expectations.

2 In the CCCC territory, there are a range of Alpine and Nordic resorts, several of which are managed by associations through delegated management or private operators (e.g., Le Granier, Les Egaux).

3 https://www.alpine-space.eu/project/transtat/

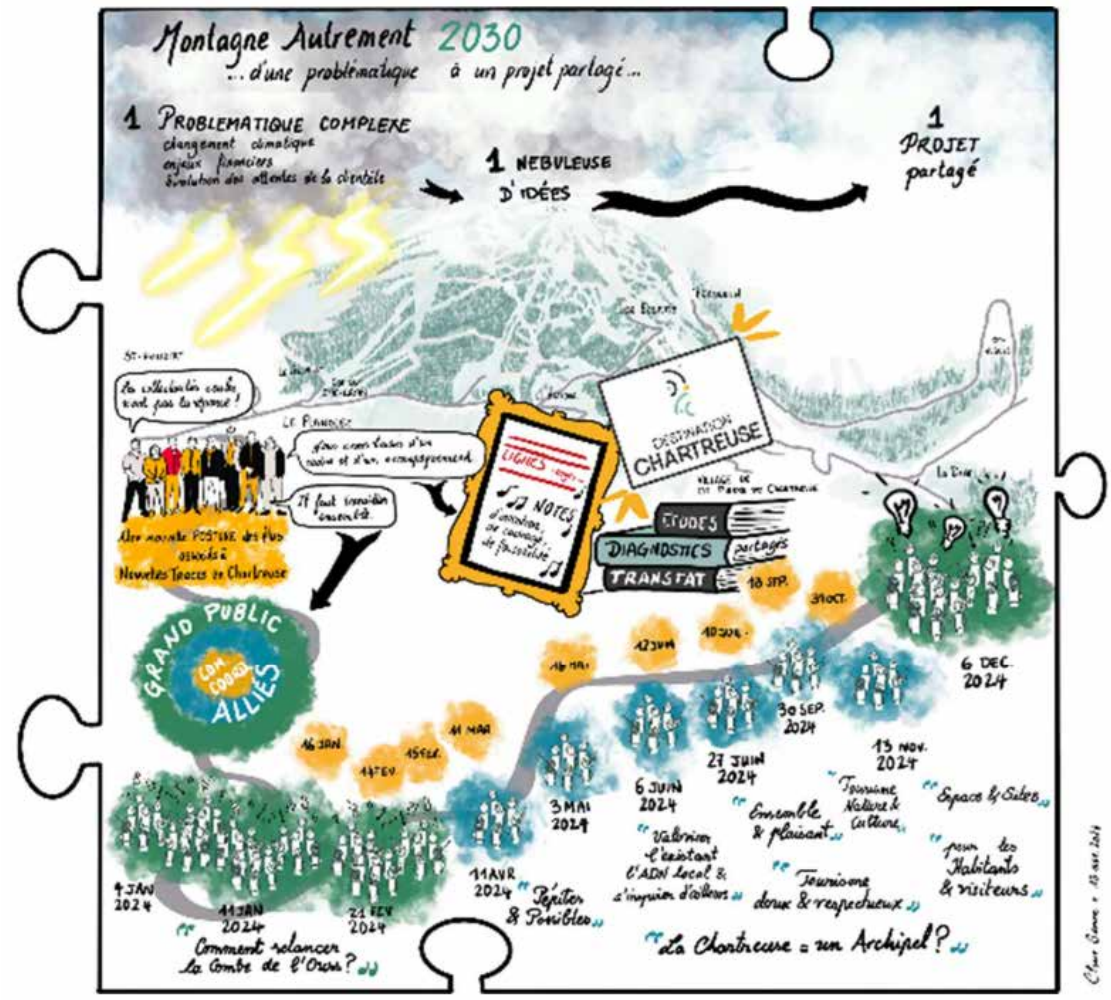

Figure 2. A facilitator-artist's rendering of the collaborative planning process, La Montagne Autrement 2030. Illustration by Claire Simon.

This collaborative process ultimately led to a scaled-down ski domain, now managed by two separate entities under public service delegations, marking a pivotal shift in the governance model. The association Nouvelles Traces en Chartreuse has taken charge of five ski lifts in Le Planolet sector, while the private operator Stass' manages five lifts in the Essarts sector, both under five-year agreements. The decision not to reopen the chairlifts and cable car was driven by financial constraints, as the costs of inspections and refurbishment far exceeded available funding. However, the CCCC has now commissioned a feasibility study to explore the sale and dismantling of these lifts, aiming to ease financial strain and ensure long-term economic viability. This transition reflects a broader shift toward a four-season tourism model, prioritising sustainability, cost reduction, and adaptability. The ongoing debate among stakeholders—between those who view the closures as an opportunity to innovate and those who struggle to let go of the past—illustrates the deep emotional attachment to traditional ski operations, requiring a transformation of imaginaries to embrace new possibilities.

Beyond infrastructure adjustments, the Chartreuse region has embarked on a broader ecological transition, seeking to redefine its tourism identity amid climate uncertainty. This vision-building effort is exemplified by the Chartreuse à +4°C initiative, launched building on the work of the TranStat project and La Montagne Autrement 2030, which brings together scientists, policymakers, and local residents to collectively reimagine life in the mountain territory under a +4°C scenario. A participatory event held in 2025, fostered discussions on

adaptation strategies, exploring alternative economic models, environmental conservation efforts, and the future of mountain landscapes through design fiction workshops. These efforts reflect an intentional shift toward integrating local knowledge, science, and community engagement, ensuring that transitions are inclusive and forward-thinking rather than reactive. The transformation of actors' imaginaries—encouraging stakeholders to visualise new futures beyond the reality of today—is crucial to building a resilient, adaptive Chartreuse, where tourism can flourish year-round while preserving both economic stability and ecological integrity.

4.3. Beyond the numbers: the 'invisible' costs of adaptation

Taking a simplified view of the situation in Saint-Pierre-de-Chartreuse (SPC), focusing primarily on financial considerations. The real monetary costs of maintaining the status quo—keeping the ski lift equipment non-operational—are significantly higher than dismantling and selling the infrastructure. Likewise, recommissioning the lifts would not provide a long-term return on investment, yet some stakeholders still advocate for reopening them. If we consider only financial aspects, the logical course of action would be dismantling and selling the ski equipment, as such:

$$C_{\text{recommission}} \gg C_{\text{status quo}} \gg C_{\text{decommision}}$$

However, since this decision has not yet been made, other inertial forces—beyond costs—are clearly influencing the continuation of the status quo. In terms of status quo (SQ) versus change (Ch), this suggests (building on section 3.3):

$$I_{SQ} + C_{SQ} > I_{Ch} + C_{SQ}$$

Or:

$$(D_{SQ} + P_{SQ} + L_{SQ} - U_{SQ}) > (D_{Ch} + P_{Ch} + L_{Ch} - U_{Ch}) \underbrace{-(C_{Ch} - C_{SQ})}_{\text{net positive}}$$

Since C_{SQ}-C_{Ch} is net positive, given that dismantling and selling the ski lifts is the least cost-depleting option, financial logic alone would dictate their removal. However, the decision remains unresolved, suggesting that other forces in the status quo (left-hand side) have a greater overall value. It should be recognised that the costs associated with the ski equipment represent the most significant tangible financial burden compared to other expenses borne by various local actors. However, additional costs also play a role, such as the time and resources invested in the collaborative planning efforts, which require coordination across multiple stakeholders. Furthermore, decisions about the ski lifts have a cascading effect, influencing economic structures that still rely on these assets in various ways. While these inertial forces related to institutional and individual actors could be examined as well, the focus here remains on how broader financial and socio-economic dynamics shape decision-making within the territory.

Beyond financial constraints, uncertainty is a key factor, closely tied to the future climate and socio-economic scenarios. The TranStat project seeks to reduce these uncertainties, offering knowledge on climate impacts and socio-economic implications of different pathways. Similarly, publicly provided cost data helps mitigate financial uncertainties, offering stakeholders greater clarity. Legitimacy, in turn, is tied to uncertainty—the status quo is familiar, making it inherently legitimate. The collaborative planning effort and the transparent dissemination of information serve to enhance legitimacy, a crucial factor in securing socio-institutional support for transition. In SPC, this process has been bottom-up, placing the decision of legitimacy in the hands of the public, rather than solely policymakers. This also connects to power dynamics. By fostering a bottom-up decision-making model, local leadership acknowledges the role of legitimacy in community-led planning while also distributing power among local actors. In contrast, other ski resorts may experience heavy lobbying pressures, which do not seem prevalent in SPC. Historically, initiatives like the *Plans Neige* followed a top-down model, where State power was used to push through ski resort development. Finally, path dependency plays a significant role in shaping this process. The legacy of the ski domain—its historical role, socio-economic ties, and ingrained expectations—con-

tinues to exert influence, reinforcing resistance to change even when economic logic suggests otherwise. Even still, the Chartreuse à +4° demonstrated that ski does not have a strong presence, if any, in the residents' long-term vision of the habitability of their community.

5. Concluding Remarks: Inertial Forces as an Impediment to Transitions

The evolution of mountain territories has long been shaped by the collective imaginary built around ski resorts and their associated economies, a legacy reinforced by decades of investment and infrastructure planning. However, as financial difficulties, shifting environmental conditions, and uncertain transition models challenge the future viability of these ski domains, the question of territorial inertia becomes central to understanding the pace and feasibility of change. Factors such as economic debt, social ties, and environmental impact contribute to this inertia, making transitions complex and slow-moving. The key to facilitating successful planning efforts lies in identifying critical moments along the trajectory of these stations—moments where intervention could have the greatest impact in overcoming inertia and steering toward a more sustainable model. Without this strategic foresight, planning efforts risk being reactive rather than proactive, limiting their chances of meaningful success.

The interplay between transaction costs and local imaginaries further illustrates why change remains contested. In Saint-Pierre-de-Chartreuse, for instance, the financial burden of maintaining non-operational ski lifts outweighs the cost of dismantling them, yet this purely economic reasoning does not dictate outcomes. Instead, the cultural and emotional significance of the ski infrastructure continues to carry as much weight as structured planning efforts, leading some to describe this phase as a grieving period rather than a transition. While perceived transaction costs often constrain change, cases like Chartreuse à +4°C reveal that when residents are freed from immediate financial concerns and encouraged to imagine the future without real-world limitations, they engage with transition more fluidly. These two collaborative efforts highlight a broader truth: successful adaptation requires both pragmatic planning and a transformation of collective imaginaries embedded in territorial transitions. Moving beyond incremental shifts, communities must consider what timescales allow transitions to occur without being stalled by inertia yet remain tangible enough to be actionable within present-day realities.

Abstract
The concept of "overtourism," introduced by Claudio Milano in 2017, refers to the unsustainable growth of mass tourism and its negative impacts on local communities. These include overcrowding, traffic congestion, seasonal economic dependency, housing pressure, environmental degradation, and reduced contributions to the local economy. Such pressures often lead to social discomfort, loss of belonging, and displacement. Since the 2000s, studies have increasingly focused on how residents perceive these impacts. This study aims to measure the level of overtourism in Bodrum, a key tourist destination in the Mediterranean, by adapting international overtourism indicators. Using surveys and statistical data, it identifies the physical, economic, social, and environmental pressures experienced by locals. The findings contribute to developing strategic planning approaches for more sustainable tourism governance in overburdened coastal settlements.

Keywords: overtourism; tourism capacity; tourism impact studies; local community perception; sustainable tourism

Introduction

Although the concept of overtourism is relatively recent, the impacts of tourism on settlements have been studied since the 1960s, initially with an economic focus, later expanding to environmental concerns. The social dimension, particularly local perceptions, gained attention in the 2000s, culminating in the emergence of overtourism as a distinct concept in 2017.

Dodds and Butler (2019) argue that the rise of overtourism stems from the public's growing opposition to tourism and the widespread transformation of once-untouched areas into tourist destinations. Milano, Cheer, and Novelli (2018) emphasize the importance of local perspectives, identifying key indicators such as overcrowding, housing pressure, environmental degradation, and economic leakage.

Koens et al. (2018) note that these impacts are no longer confined to Europe, increasingly affecting vulnerable coastal and heritage destinations globally. As a response, various international organizations now promote locally tailored indicators and management strategies aimed at balancing visitor experience with resident well-being. The first step in addressing overtourism, however, is to define and measure its presence. This study aims to fulfill that step for Bodrum. (Kuduban, Yerliyurt, 2023)

The Concept of Overtourism

In the literature concerning the impact of tourism on settlements, tourism was historically an activity exclusive to noble families between the 14th and 17th centuries. After World War II, during the period from the 1960s to the 1980s, tourism emerged as a tool for economic development. Consequently, early tourism research predominantly stemmed from economic sciences, focusing on tourism's positive effects as a means to justify steps toward economic growth By the 1980s and 1990s, the rise of mass tourism movements driven by globalization and neoliberal policies transformed tourism into an industry, resulting in significant changes in its impacts. Consequently, literature during this period began to critique the environmental issues associated with the large-scale movements generated by mass tourism. (Postma, Schmuecker, 2017).

Since the early 2000s, the growing emphasis on sustainability and the widespread adoption of strategic planning approaches have led to a more comprehensive examination of tourism's effects. Research during this period expanded to include not only economic impacts but also physical and social dimensions. Nevertheless, environmental impacts continued to be a dominant topic in the literature.

Post-2010, influenced by postmodern movements, approaches emphasizing the social presence of a place rather than viewing it solely as a destination for consumption gained prominence. This period saw an increased focus on the social impacts of tourism, particularly from the perspective of local communities. These discussions, often highlighting negative aspects, coincided with the emergence of the concept of overtourism.

In 2018, the UNWTO defined overtourism as "the impact of tourism on a destination or its parts that excessively influences residents' perceived quality of life and/or visitors' experiences" (UNWTO, 2018). Consequently, overtourism has become a significant focus in contemporary tourism literature. While settlements are expected to have some degree of flexibility in accommodating varying and diverse populations, the tourism sector, once seen as a relatively sustainable development model and an economic driver following the 2008 financial crisis, has undergone substantial changes with the integration of mass tourism into modern conditions. (Postma, 2013)

One of the most distinctive and visible elements of overtourism is the significant shift in local residents' perceptions of tourism. Gürsoy and Rutherford argue that successful tourism development largely depends on local community support (Gürsoy & Rutherford, 2004). Similarly, Ap emphasizes that local communities play a crucial role in determining the success or failure of the tourism industry (Ap, 1992). Thus, local residents may either shape, facilitate, or oppose tourism. They may support tourism if they perceive it as contributing to their well-being or develop negative attitudes toward tourists. The concept of overtourism first emerged in Barcelona, a prominent tourism destination. Claudio Milano of the University of Barcelona was the first to define the term in 2017. Milano noted that by the 2010s, many destinations had reached capacity saturation. The term was initially used by Spanish citizens and later by residents of Venice and other major destinations to express dissatisfaction with tourism's impacts. Milano described overtourism as the negative perception created by unsustainable tourism activities on local communities (Milano, 2017). Since 2018, local residents, civil society organizations, academics, and urban activists have expressed their reactions in various ways. For example, key tourist destinations such as Barcelona, Ibiza, Palma de Mallorca, Malta, Florence, and Venice published a manifesto outlining their concerns and demands. From a social and perceptual perspective, the continuous sharing of urban space between locals and tourists in daily life has increasingly caused discomfort among residents

In pioneering research, Jordan, Pastras, and Psarros emphasized that overtourism fundamentally results from mass tourism. They argued that the presence of large groups of tourists in settlements for certain periods creates density-related issues, particularly seasonal imbalances. They identified insufficient infrastructure and services to meet seasonal demand, alongside the uncontrolled consumption of available services, as both a cause and a consequence of overtourism (Jordan, Pastras, & Psarros, 2018).

Many measurable different indicators are used in researchs. An important outcome of any evaluation of overtourism is the lack of a universally accepted set of indicators. This prevents effective evaluation of destinations that are either at risk of overtourism or have already entered into overtourism. In this context, indicators should be specialized according to the characteristics of the settlement (Peeters et al., 2018; Milano et al, 2018; Kim et al, 2020). Alongside these statistics, which are key components of overtourism, it should not be overlooked that the local population's perspective on this situation is also one of the most important indicators. For this reason, surveys and in-depth interview studies are increasing. After the investigations, the goal is to identify the level of overtourism and problematic areas, and to generate input for strategies.

As a result, the necessity of a management strategy to ensure the sustainability of tourism has been emphasized in the literature since the early stages. This strategy primarily involves the identification of area-specific indicators and the development of strategies based on the analysis of these indicators. In this regard, the strategy

sets of organizations such as UNWTO, TRAN, Responsible Tourism Partnership, ENAT, and IUCN and many more are very important; (Goodwin, 2017; Koens, 2018; Postma, Papp, 2018; Koens, Papp, Postma, 2018; Peeters et al, 2018)

Case Study

a) Destination Selection

The top three tourism destinations of national and international significance in Turkey are Istanbul, Antalya, and Muğla (Çakir Zeytinoğlu and Sadiç, 2013). This can be examined through various data such as the number of accommodation facilities, bed capacity, and statistics from the Ministry of Culture and Tourism. These three coastal provinces, being areas with various disaster risks, rich cultural heritage, and ecological diversity, appear to be worth testing in terms of the perception of the local population, which is a key indicator of overtourism. While Antalya and Muğla stand out with sea, sun, and sand tourism, Istanbul is known for cultural tourism. In this context, it can be said that Antalya and Muğla exhibit the indicator of excessive dependency on a single season, which is an important indicator of overtourism, while Istanbul has a tourism dynamic spread across all four seasons.

The primary reason for choosing Muğla over Antalya between the two provinces is that the bed capacity per capita criterion in Muğla indicates that locals and tourists encounter each other more frequently in the urban space. Selected critera are shown in the following table. [Table 1 near here]

Table 1. City selection index

City	The Number of Accommodation Facilities Per Resident Population	The Number Of Beds Per Resident Population	Coastline Length (km)
Antalya	4,166,471,961	4.16	630
İstanbul	5,935,467,777	59	614
Muğla	4,436,673,377	4.43	1479

Formula Used: Value: x; Normalized value: y; Smallest value of the data series: minimum; Largest value of the data series: maximum: y= (x-minimum)/(maximum-minimum)

Muğla, with a coastline of 1.114 km, has a population of 1,066,736 (TURKSTAT, 2023). Located in the NUTS 1 level classification of Turkey, Muğla lies between the coordinates 36° 17' and 37° 33' North latitude and 27° 13' and 29° 46' East longitude. Situated at the southern tip of Western Anatolia, Muğla covers an area of 13,338 km². As mentioned earlier, tourism in Muğla is concentrated in coastal settlements, and therefore, the issue of over-tourism primarily affects these areas. Bodrum, Marmaris, and Fethiye are significant tourism destinations both for Turkey and Muğla. For the fieldwork, the selected district was determined through an evaluation of Muğla's coastal districts. The main reason for evaluating the coastal districts is that Muğla has a tourism structure dominated by sea-sun-sand tourism, while rural characteristics are observed as one moves inland from the coast. District selection criterias are;

- Resident Population Size (TUIK)
- Presence of Cultural and Natural Heritage Areas (Protected areas, conservation areas, national parks, museums, archaeological sites, etc.)
- Tourism Bed Capacity
- Number of Accommodation Facilities (Operating Certificate + Investment Certificate)
- Second Home Population Projection for 2025 (Territorial Plan, 2016)

Results are shown in the following table and map. [Table 2 and Figure 1 near here]

Table 2. District selection index

Districts	Arithmetic Mean
Bodrum	**91,963**
Fethiye	64,045
Marmaris	40,974

In the next step, to measure the perception of the local community, a sample representing the entire settlement was determined, and an evaluation was conducted at the scale of coastal neighborhoods in Bodrum. To determine the sample area for the field study, five statistically accessible criteria were identified for the Bodrum district, and an expert opinion analysis was conducted using the "Online Delphi Technique" with experts from academia, the sector, and institutions. The research questions of the project were given to the experts, and the question, "How important do you think these parameters are in answering the research question?" was asked. Based on the selected parameters and results, a new index study was conducted in 28 coastal neighborhoods out of 56 neighborhoods in Bodrum. The results are shown in the table [Table 3 near here] According to these criteria and the multipliers determined by the experts, the top three neighborhoods with the highest over-tourism pressure were selected as the areas for the survey studies and in-depth interviews.

Table 3. Neighborhood selection index

Project Area Neighborhood Selection Criteria	Importance Coefficient According to Expert Opinions
Population Density	1
Average Population Growth Rate (2018-2022)	0,6
Change in the Number of Accommodation Facilities (2019-2022)	0,4
Coastal Length	0,1
Tourism Facility Bed Capacity	0,3

Formulas Used a) Value of the Observation: x, Mean of the Data Series: μ, Standard Deviation: σ Z = (x - μ) / σ b) Value: x, Normalized value: y Minimum value of the data series: min Maximum value of the data series: max y= (x-min)/(max-min)

The neighborhoods identified as the highest in over-tourism pressure were "Çarşı (0.24 points), Tepecik (0.21 points), and Gümbet (0.16 points)" neighborhoods, which are considered the center of Bodrum. [Table 4 near here] The field study was conducted in these neighborhoods.

Table 4. Overtourism levels of neighborhoods

Bodrum Coastal Neighborhoods	Overtourism Level Score
Çarşı	**0,24**
Tepecik	**0,21**
Gümbet	**0,16**

b) Bodrum, Turkey

Bodrum is one of the most tourism-intensive settlements in Turkey and the Mediterranean region, primarily known for sea-sun-sand and yacht tourism. With a history dating back 5,000 years, formerly known as Halicar-

nassus, it is both a significant cultural heritage site and a fragile ecological zone.
The town gained prominence in the 1980s with growing tourism investments, which led to rapid spatial expansion. This growth has significantly exceeded the area's carrying capacity, triggering substantial changes in land use, water resources, and ecological integrity. Between 1990 and 2018, urban land expanded by over 1,000 hectares, with a 330% increase in spaces dedicated to tourism and second homes (Arslan & Örücü, 2019). Bodrum's official population in 2023 was 198,335, but this number swells to approximately 500,000 during the summer months (TURKSTAT, 2023). The rise in tourism and seasonal migration has led to issues such as water scarcity, traffic congestion, infrastructure strain, and loss of biodiversity due to construction in conservation areas. The neighborhoods of Çarşı, Tepecik, and Gümbet stand out as the most over-touristed zones. Çarşı and Tepecik form the historic and cultural core of the city, located within a 3rd-degree archaeological site, while Gümbet, a natural bay, lies within a designated natural conservation zone. These sub-regions reflect global tourism hotspots characterized by high environmental sensitivity and historical value, now facing challenges of unplanned growth and unsustainable tourism development.

c) Survey

To reveal the local perceptual response to unsustainable tourism activities, over-tourism indicator sets were analyzed and adapted according to the specific dynamics of the study area. The diagram shown in Table 5 illustrates the relationship between the survey questions and indicator categories. In addition to these questions, the survey included questions to better understand the profile of the respondents. A filter was applied to ensure that the respondent resided in Bodrum. Along with questions about the respondent's profession and educational background, the question "Does anyone in your family work in the tourism sector? How many people?" was also asked. The main purpose of this question was to determine whether the involvement of the respondent or their family members in the tourism sector influences their perspective on the questions related to the impacts of tourism on the settlement. The core sample group of the research was selected to represent all segments of the local population in Bodrum to analyze the local perception of tourism. The survey sample consisted of 50% women and 50% men. When looking at the age distribution of the group, 26% of the respondents were in the 18-29 age range, 27% were in the 30-39 range, 22% were in the 40-49 range, 17% were in the 50-60 range, and 8% were in the 60-70 range. This distribution provided an opportunity to evaluate the impact of tourism on different age groups more comprehensively.

Table 5. Survey Questions Categories

Indicator Category	Focus of Survey Questions
Social Structure Perception	Safety, sense of belonging, local-tourist interaction, cultural impacts, desire to relocate
Economic Structure Perception	Job opportunities, seasonal instability, rising housing costs, cost of living, local benefit
Physical Structure Perception	Overcrowding, adequacy of public spaces, traffic, transportation, infrastructure strain
Environmental Structure Perception	Urbanization of natural areas, pollution levels, aesthetic change, impact on olive groves

Survey Findings

The findings indicate that excessive tourism in Bodrum exerts significant pressure on the physical, environmental, economic, and social structures of the city. Statistically significant results from factor analysis, regression, and ANOVA tests, along with qualitative insights from in-depth interviews, reveal how local perceptions vary based on education and length of residence.

1. Physically, Bodrum's infrastructure struggles to cope with seasonal population surges. Key issues include overcrowding in public spaces, traffic congestion, water shortages, and restricted access to the coastline. In-

terviewees highlighted infrastructure deficits and unregulated growth, while long-term residents were more sensitive to service inadequacies.

2. Environmentally, overtourism contributes to pollution, ecological degradation, and increased disaster vulnerability. Rapid urbanization, construction in fragile areas, and unplanned coastal development have altered local microclimates and increased water scarcity. Local perceptions show that urbanization and environmental pressures are felt more acutely by long-term residents.

3. Economically, although tourism creates jobs and stimulates local markets, it simultaneously raises the cost of living and fosters inequality. Real estate prices and basic goods costs have increased, especially during the tourism season. Residents reliant on tourism income expressed dissatisfaction, noting that perceived economic gains do not translate into better quality of life. Seasonal dependency and the "all-inclusive" model have also weakened local businesses.

4. Socially, overtourism leads to a weakened sense of belonging, identity loss, and discomfort toward tourists. Statements like "I feel like a foreigner in my own town" had high factor loadings. Issues such as rising crime, exclusion from tourism planning, and loss of cultural values exacerbate this. Educated and long-term residents report lower trust in governance and higher discomfort. Local movements like the "Free Beaches Movement" reflect emerging resistance to overtourism's social impacts.

Overall, the findings suggest that excessive tourism in Bodrum deteriorates local life quality across multiple dimensions. Sustainable, inclusive tourism strategies are urgently needed to safeguard the city's identity, environment, and long-term livability.

Conclusion

Overtourism, driven by seasonal overcrowding and unbalanced economic dependence, has increasingly transformed tourism-dependent settlements, particularly coastal areas like Bodrum. Once shaped by small-scale, interactive tourism, Bodrum has evolved into a destination marked by infrastructure strain, seasonal unemployment, environmental degradation, and social tensions.

This study confirms that Bodrum has reached its carrying capacity. Local residents report serious challenges, including:

- Seasonal overuse of infrastructure (water, waste, transport),
- Displacement of public spaces by private tourism enterprises,
- Rising living costs,
- Environmental degradation,
- Lack of effective governance tools such as a tourism master plan or accurate statistical monitoring.

Current indicators are insufficient due to gaps in data on second-home ownership and informal employment. This undermines efforts to monitor or manage overtourism effectively. A national level, flexible but binding tourism strategy is urgently needed. Local planning tools such as Integrated Coastal Area Management Plans and Transportation Master Plans should include mandatory environmental and social impact assessments. Additionally, alternative tourism models and strict visitor caps should be considered in saturated areas. Policies must also protect local businesses and housing markets from displacement pressures, particularly in zones affected by platforms like Airbnb. Ultimately, planning must prioritize local communities as core stakeholders. Sustainable tourism requires participatory governance, fair distribution of benefits, and protection of local residents' quality of life. The findings of this study offer a roadmap for designing context-specific strategies in Bodrum and other regions vulnerable to overtourism.

Abstract
In recent years, celebrity-related travel across cities in China has increased markedly, reflecting emerging trends where consumption converges with production, and emotional attachment intersects with community participation. This article proposes the concept of fandom tourism to address the limitations in existing popular culture and media tourism literature, particularly in accounting for fans' active cultural and spatial practices. Based on exploratory interviews with Chinese fan travellers, the study identifies key patterns of fandom tourism, examines the affective and community-driven decision-making processes underlying travel behaviour, and explores how such practices contribute to the re-inscription and symbolic revalorisation of urban space. The fandom tourism framework offers a critical conceptual lens for understanding the affective economies and participatory dynamics that shape contemporary popular culture-induced mobility.

Keywords: fandom tourism; cultural consumption; urban regeneration; tourism behaviour; China

"Travelling for concerts" has become a popular tourism pattern in China (He and Fu, 2024). Besides attending performances, travellers would often explore the host city and enjoy local cuisine. A growing number of people—especially celebrity fans—are now willing to travel to another city for a single event. According to the China Association of Performing Arts, the total box office revenue of offline performances in 2024 reached nearly 580 billion Chinese Yuan (approx. 81 billion USD) (Zheng, 2025). Over 60% of attendees at large-scale events such as concerts were from outside the host city (Zheng, 2025), indicating that more than half of the audience consisted of non-local tourists. This influx of visitors has brought significant economic benefits to host destinations, with total audience-related spending exceeding 2000 billion Chinese Yuan (approx. 280 billion USD) (Zheng, 2025). This emerging consumer trend, which integrates cultural consumption and tourism activities, has drawn increasing attention from municipal cultural and tourism departments across China. In collaboration with the local service industry, tourism sector, and performance organisers, these departments are upgrading urban hospitality services and infrastructure to attract more audiences, fans, and visitors (Zhou and Zhou, 2024)

This form of tourism driven by cultural, or media consumption is not a new phenomenon. As early as the 1980s, researchers observed that television and drama series could motivate audiences to visit filming locations and influence their travel decisions (Nakayama, 2021). This type of travel behaviour was conceptualised as film (induced) tourism and has since attracted sustained attention within tourism studies. Later, the impacts of novels (Reijnders, 2011; Belarmino, 2023), anime (Jang, 2020), sports competitions (McManus, 2020), and music festivals (Kinnunen & Honkanen, 2021) on tourism experiences was also acknowledged. Popular culture and media products could act as key drivers of tourism. In response to this widespread phenomenon, several interdisciplinary frameworks have been developed, such as content tourism and event tourism. The former emphasises the cross-media experiences offered to tourists through the integration of various media forms—such as films, television series, manga, anime, novels, and video games—with real-world destinations (Graburn and Yamamura, 2020). The latter focuses on planned events that are strategically developed and marketed in an integrated manner, including commercial, sporting, and festival activities (Getz, 2008).

These concepts and frameworks are typically defined around specific media products or events, as these serve as the core motivational forces behind such forms of tourism. The impetus usually stems from audiences' or fans' desire to establish a physical connection with beloved celebrities or media personas. For example, American fans of Japanese anime may travel to Japan to visit locations featured in the animations (Clyde, 2020), while

Chinese fans of Korean idols often take photos outside their favourite idols' entertainment agencies in Seoul (Li et al., 2025). These meaningful sites are perceived as unique attractions—or even secular "sacred places." For fans, travel becomes a form of pilgrimage, a notion widely discussed in tourism studies (Reijnders, 2010; Goh, 2014; Clyde, 2020; Waysdorf, 2021; Li et al., 2024). However, existing research has primarily examined fan tourism through a consumerist lens, overlooking fans' active role as producers within these practices.

More specifically, fans would not merely visit sacred sites—they actively participate in creating them (Jang, 2020). For instance, fans may collaborate with cafés near concert venues to stage themed exhibitions, temporarily transforming these otherwise ordinary spaces into fan-relevant "attractions." For those seeking a deeper connection with their favourite celebrities and fellow fans, such temporary sites often hold greater appeal than official tourist attractions—even when they have no actual interest in the café itself. Fans who visit these spaces typically take photos, socialise, and share content on social media, collectively imbuing the site with symbolic meaning. Through these shared cultural practices, fans could construct new sacred spaces out of otherwise unrelated urban settings.

This highlights how fans' active involvement could blur the boundaries between tourists, media content, and destinations—posing a challenge to existing theories that primarily focus on media-induced tourism. Furthermore, while current frameworks emphasise the emotional bond between individuals and media personas/products, they may fail to account for the significance of fan-to-fan relationships and fan community dynamics in shaping travel motivations and practices. Therefore, it is necessary to develop a new framework centred on fandom to better account for these complex tourism behaviours and experiences.

Fandom functions as an affective community, offering both emotional and practical spaces for fans to engage in production and consumption. It operates not only as a site of collective meaning-making, but also as a network of intimate relations (among celebrities, fans and communities) (Jenkins, 1992; Hills, 2002). In China, the fan economy is rapidly expanding, with fan-organised activities becoming increasingly diverse and visible. Fans actively appropriate urban spaces and transform otherwise ordinary places into new fandom attractions through their practices. As both consumers and producers, fans engage with the cultural functions of the city while simultaneously contributing to its spatial and symbolic renewal. These dynamics cannot be adequately explained by existing frameworks such as content tourism or event tourism.

To address the gaps in existing research, this study proposes a theoretical framework of fandom tourism, offering an exploratory overview of this emerging phenomenon. First, the study identifies three primary types of fandom tourism activities, outlines their key characteristics, and provides a foundation for understanding the structure of fandom tourism. Second, it examines the mechanisms behind fandom-related travel decisions, particularly those shaped by affective consumption and community-based interaction. Third, the study highlights how fans engage with and reconfigure urban infrastructure and physical space, offering new perspectives for understanding destination image formation.

Importantly, this research situates the entire fan travel experience within an integrated framework, rather than focusing solely on aspects directly linked to media texts or products.

Literature Review

Fan and Fandom

What is a fan? The term fan is derived from the abbreviation of fanatic, which in turn comes from the Latin word fanaticus, carrying connotations of religious devotion, fervour, or even madness (Jenkins, 1992). While this etymology implies a somewhat negative and pathologising view, such stereotypes have been increasingly challenged and corrected by the rapid development of fan studies. Scholars in media and audience studies have emphasised the distinctions between fans and general audiences or consumers. Fans are often seen as loyal audiences (Kozinets, 2001), or in some cases, excessive consumers (Fiske,1992)—individuals who are intensely devoted to, or enthusiastic about, specific figures such as celebrities, actors, films, or more broadly, media content

and public figures, and who engage with these objects of affection in active and participatory ways (Kozinets, 2001; Yan and Yang, 2021).

This distinction has been attributed by media psychology researchers to various emotional mechanisms, including empathy (Taylor, 2015), worship (Chen et al., 2022), a sense of belonging (Fong, 2020), identification (Kim and Manoli, 2022), attachment (Stever, 2011), involvement (Bee and Havitz, 2010), and loyalty (Stevens and Rosenberger, 2012). In other words, emotional connection lies at the heart of what defines a fan. Motivated by such affective bonds, fans often develop intense feelings of intimacy and commitment towards celebrities or media characters—despite not having any real-life interaction with them—and are willing to offer various forms of support (Tukachinsky, 2010). Scholars have conceptualised this as an emotional connection that resembles real-world social relationships, with one crucial difference: it is non-reciprocal. Information, emotion, and resources typically flow in one direction—from the fan to the media persona. As such, these intimate yet one-sided relationships are referred to as parasocial relationships (Horton and Whol,1956).

This perspective helps explain why fans often engage in what might be termed "excessive consumption"—because such acts are understood not merely as purchasing behaviour, but as meaningful expressions of support. For example, repeat purchasing is a common practice among fans of East Asian idol groups, where individuals may buy dozens of copies of the same album to help their idols climb sales charts (Bai, 2021). Within parasocial relationships, fans are emotionally invested in the success and well-being of their favourite media figures (Tukachinsky, 2010), and this affective bond becomes a key driver of their consumption patterns and decision-making. Another way to understand excessive consumption is through the fan's desire to interact with and deepen their relationship with the media persona (Rubin and McHugh, 1987; Tukachinsky, 2010). However, given the non-reciprocal nature of parasocial ties, such desires cannot be fulfilled through direct exchange. Instead, fans repeatedly engage with media products—re-watching, re-purchasing, and re-circulating content—to sustain and simulate connection.

However, the media industry can only provide a limited range of content for specific fan groups, which often fails to satisfy the full spectrum of desires embedded in parasocial relationships. As these relationships are constructed within the fan's imagination, some fans attempt to bring their imagined connections into the physical world. For instance, they may visit celebrities' former workplaces, favourite restaurants, or hometowns (Yan et al., 2024; Li et al., 2025). Such practices help bridge the gap between fantasy and reality by providing tangible experiences that anchor intangible emotions, thereby creating a sense of closeness. Fans often describe these journeys as acts of pilgrimage, and particular sites become sacred because they hold deep symbolic meaning (Jang, 2020; Li et al., 2024). The notion of "pilgrimage" is widely recognised across global fan cultures (Jang, 2020).

Consumption is not the only way fans seek connection with media figures—they also engage in creative production. Fans often appropriate original media texts to produce new content, such as writing sequels to a TV series after its conclusion. Jenkins (1992) describes such activities as part of participatory culture, in which fans actively participate in textual construction and content creation. Fans are thus both consumers and producers. This creative practice also extends to place-making: fans may designate previously unrelated locations as sacred sites through ritualised visits and symbolic validation via social media (Li et al., 2024).

The creation of such "sacred spaces" is rarely an individual act; rather, it is often a collective endeavour within the fandom community. Through negotiation, sharing, and imitation, ordinary locations are imbued with meaning, sanctified, and granted a sustained cultural presence. The fandom community not only operates as a site of symbolic production (Jenkins, 1992), but also as a network of intimate relations, since fans form parasocial relationships not only with media figures but also with each other (Elfving-Hwang, 2018). Hills (2002) conceptualises fandom as an affective community, one that provides both emotional and practical space for fan-based production and consumption. Sacred sites, for example, are collectively recognised, sustained, and re-signified through repeated visits and ongoing acts of communal interpretation.

In sum, fan practices are rooted in emotional attachment and forms of intimacy—both between fans and media figures, and among fans themselves. These cultural practices blend consumption and production, driven by a fundamental desire to translate imagined meanings into real-world experiences.

Media and Tourism

In media studies, visiting sites associated with beloved celebrities or media content is commonly regarded as a form of fan practice. In tourism studies, however, such activities are conceptualised as a specialised form of tourism. One of the earliest frameworks to enter the field was film (induced) tourism (Lexhagen, Ziakas and Lundberg, 2023), defined as "visitation to sites where movies and TV programmes have been filmed, as well as to tours to production studios, including film-related theme parks... (any) tourist activity associated with the film industry, be it on-site in the field, or at (or near) the production studio" (Beeton, p. 11). This concept sparked widespread scholarly interest, especially in relation to its economic impact—such as the role of film in shaping destination image and marketing (Vagionis and Loumioti, 2011; Busby & Haines, 2013; Camprubi, 2020) —as well as its influence on tourists' decision-making processes (Frost and Laing, 2015; Waysdorf and Reijnders, 2019; Zhou et al., 2023).

Subsequent studies have shown that the intersection between media content and tourism extends well beyond film, encompassing sports (McManus, 2020), music (Roberts, 2014), literature (Belarmino, 2023), video games (Thompson, Taheri and Scheuring, 2022), and manga/anime (Clyde, 2020). Audiences and fans of these different media forms often travel to relevant destinations in pursuit of experiences associated with particular content, subcultures, or celebrities (Lee, Bai and Busser, 2019). Accordingly, the field has seen the emergence of new subcategories such as sports tourism, literary tourism, video game-induced tourism, and animation tourism.

These forms of tourism are generally defined by their specific motivating media content. Some involve visiting fixed, long-term, and relatively static attractions—such as film locations—while others are driven by short-term, temporary, or cyclical events, such as the Olympics or music festivals. In response, some scholars have proposed the concept of event tourism to describe travel motivated by planned and strategically marketed events, including festivals and celebrations, entertainment, and leisure events, political or state occasions, scientific and artistic gatherings, commercial and corporate events (e.g. conferences, conventions, expos, and exhibitions), as well as personal milestones such as weddings or fan-based social activities (Getz, 2008). In short, event tourism focuses on the planned and integrative development and promotion of events (Getz, 2008).

Some scholars have argued for a more integrated approach that brings together different types of popular cultural content under a unified analytical lens. One prominent interdisciplinary framework is contents tourism, originally introduced by the Japanese government as a strategy to stimulate regional tourism. It refers to tourism that is wholly or partially motivated by narratives, characters, locations, and other creative elements found in various forms of popular media—including films, television dramas, manga, anime, novels, and video games (Graburn and Yamamura, 2020).Contents tourism emphasises the multi-platform use of the same content across different media formats (Lexhagen, Ziakas and Lundberg, 2023), and treats the site itself as a form of media, highlighting the importance of transmedia experiences for tourists (Graburn and Yamamura, 2020). For example, a novel, its manga and anime adaptations, and the real-world locations depicted across these formats can all be understood as part of the same content universe. In addition, some scholars have proposed the broader concept of popular culture tourism in an effort to encompass the wide-ranging intersections between popular media and the tourism industry (Lexhagen, Ziakas and Lundberg, 2023).

Fandom and tourism behaviours

Although these different types of tourism are defined in various ways, one prominent research focus across the literature is their economic impact. It is widely acknowledged that such niche or media-induced forms of tourism tend to generate positive economic outcomes, partly because associations with popular culture can enhance a destination's perceived distinctiveness (Lexhagen, Ziakas and Lundberg, 2023). This perceived uniqueness can directly or indirectly influence both travel intentions and decision-making. For instance, Lee, Scott and Kim (2008) found that celebrity attachment positively affects fans' familiarity with and intention to visit destinations

linked to those celebrities—such as their hometowns or filming locations—which in turn influences their travel decisions. In addition to directly motivating travel, media content may also indirectly shape tourism intentions through its influence on destination image and place attachment (Yen and Croy, 2016; Wong, Song, and Zhang, 2021; Lexhagen, Ziakas and Lundberg, 2023; Zhou et al., 2023).

However, not all studies report positive correlations. Rajaguru (2014) for example, found that although respondents reported emotional connections with Korean actors in media content, this did not significantly influence their intention to travel to South Korea. Similar findings have been echoed elsewhere: while film can play a significant role in shaping the travel decisions and experiences of certain tourists, for many others, film remains a minor or negligible factor in travel decision-making (Busby & Klug, 2001; Croy & Heitmann, 2011; Heitmann, 2010; Lee, Bai and Busser, 2019)—even when it positively affects destination image (Croy 2007).

One possible explanation for these discrepancies is that different samples may yield different measurements of media content's influence on tourism decisions (Yen and Croy, 2016). Lee and Yoo (2015) argue that fans with higher fandom levels tend to show greater loyalty toward both the destination and celebrity-related activities. This suggests that it is insufficient to treat tourists, fans, and general audiences as a homogenous group when analysing media-related travel behaviour. Even among travellers emotionally connected to specific cultural content, the degree of fandom matters. For instance, highly devoted fans may revisit the same destination repeatedly, viewing the experience as a form of homecoming (Waysdorf and Reijnders, 2019)—a behaviour rarely observed among casual viewers or less engaged fans.

Importantly, the "black box" in existing research is not limited to treating fans and general audiences as undifferentiated. Waysdorf (2021) raises a crucial question about how tourists interpret the tension between media representation and reality. While travel offers fans an opportunity to connect the sacred spaces of media texts with real-world environments (Reijnders, 2011; Waysdorf, 2021), a gap always remains. Waysdorf (2021) highlights the role of individualised imagined experiences, whereas Belarmino (2023) focuses on shared experiences constructed within fan communities. These findings underscore the fact that fans, as tourists, are not merely consumers—they are also producers. They may even create new destinations, such as turning subway advertisement boards featuring beloved characters into newly recognised sacred sites through collective ritual and social media recognition (Jang, 2020). Moreover, Belarmino (2023) notes that more creatively engaged fans behave differently during travel compared to casual fans or general audiences.

In discussing the limitations of contents tourism, Graburn and Yamamura (2020) point out that fans' active forms of production blur the boundaries between tourism producers and consumers, destabilising the clear-cut roles of tourist, content, and destination. This makes it difficult to explain such phenomena solely through the lens of contents tourism. Nor do other existing frameworks sufficiently address this gap. These observations reinforce the need to construct a new framework centred on fandom. Current research has yet to fully explore how fan emotions shape travel decision-making. The dual role of fans as both consumers and producers during travel also warrants greater scholarly attention. Furthermore, fans often travel not as isolated individuals, but as members of a fandom community, sharing affect, coordinating actions, and co-creating experience. Such communal travel practices differ significantly from those of conventional tourists. Existing theoretical models remain limited in their ability to account for these affective, collective, and participatory travel experiences rooted in fandom communities.

Methods

Building on the identified gaps in the existing literature, this study explores travel experiences driven by fandom as a core motivational force. It focuses on three key aspects: (1) the individual and collective experiences that fans undergo during travel; (2) the role of multiple forms of intimacy—including but not limited to relationships between fans and celebrities, between fans themselves, and between fans and their wider communities—in shaping travel decisions; and (3) how fans engage with and utilise urban space in the course of their travels.
The research concentrates on tourism activities within the context of Chinese fandom culture. Accordingly, the

sample consists primarily of celebrity fans based in China. Participants were recruited through open calls on social media platforms and snowball sampling. The selection criteria were: (1) participants must be long-term fans of a specific celebrity; and (2) they must have undertaken at least one instance of cross-city travel primarily motivated by participation in celebrity-related activities. Given the exploratory nature of the study, in-depth interviews—an approach well-suited for understanding how phenomena operate and how different factors are interrelated—were employed for data collection (Denscombe, 2021).

The research draws on semi-structured interviews with 16 participants, focusing on their most memorable travel experiences. Topics discussed included their fandom histories, the celebrities they support, the activities that motivated their travel, their interactions with other fans, the overall travel experience, their decision-making processes, and their emotional responses. Interviews continued until no new insights or information were emerging. Interview durations ranged from 45 to 90 minutes, totalling 973 minutes of recorded data. The participants were fans of a range of public figures, including idols, actors, singers, musical theatre performers, and athletes. The collected data were coded and analysed using thematic analysis. This process led to the identification of three main types of fandom tourism activities, as well as the mechanisms that underpin how these activities structure the fan travel experience.

Findings

Three types of activities in fandom tourism

Based on the level of direct association with celebrities, this study identifies three typical types of activities within fan tourism: core activities, related activities, and other activities, ranked from highest to lowest in terms of their proximity to the celebrity figure. This categorisation forms the foundation for understanding the structure and behavioural logic of fan tourism.

1. Core Activities

Core activities are the primary motivators of fan travel. They are directly related to the celebrity and typically form the most fixed and non-negotiable part of the travel itinerary, regardless of a fan's level of enthusiasm. Examples include concerts, sports events, fan meetings, and other occasions involving direct physical presence or interaction with the celebrity. These events are usually organised by official entities or authorised representatives and take place in formal, large-scale venues such as cultural and sports complexes. As such, they place specific demands on a city's infrastructure and event-hosting capacity.

2. Related Activities

Related activities revolve around the core event but are indirectly linked to the celebrity and more directly associated with the fandom community. One common example is the creation of new sacred sites, such as temporary exhibitions about the celebrity held in cafés near concert venues. These sites typically feature fan-generated content, serve as spaces for social interaction, and are actively shared through social media. Such activities are often the result of collective fan production and are accompanied by rituals and group dynamics rooted in the fandom community. They fulfil a strong social function and generate demand for communal spaces. Emotional interaction is central to these activities, and their occurrence is closely linked to the fan's level of engagement and the accessibility of the venue. These activities are typically organised either by fans or by event organisers and often take place in public urban spaces near the core event, such as commercial districts, parks, or open plazas.

Related activities reflect more complex forms of community participation and meaning-making. Fans creatively reinterpret urban spaces, turning them into new "attractions" or sacred sites that become significant within the shared narratives of the celebrity, the fans, and the fandom community.

3. Other Activities

Other activities refer to elements of the fan travel experience that are not directly connected to either the celebrity or the fandom community. These typically include visiting local attractions, shopping, or engaging in social

interactions with non-fans. These parts of the itinerary tend to be more flexible and are entirely controlled by the individual fan. Interestingly, even during these more conventional tourist activities, fans may incorporate elements of fandom—such as carrying printed images of their favourite celebrity and taking photos with them at landmarks. In such cases, urban spaces are used for their original functions, but may still acquire secondary symbolic meanings.

Although these activities resemble conventional forms of tourism, many fans report experiencing higher levels of enjoyment and relaxation during them. The blend of everyday tourism practices with subtle fandom expressions adds an extra emotional layer to the travel experience, making even ordinary moments feel more meaningful.

The structuring mechanisms of fandom tourism

1. Community interaction and emotional reward models in fandom tourism

This study finds that an individual's fandom level is a decisive factor in shaping their fandom tourism itinerary, as it is closely tied to what can be described as a community interaction–emotional reward model. Three typical fan types were identified:

1.1 Active content producers

These fans take on organising and content-creating roles within fandom communities and are often perceived as opinion leaders. They tend to gain attention by providing scarce resources—such as exclusive celebrity updates, high-quality images, or video content—or by coordinating community efforts. Their decisions around travel are often influenced by how they use and maintain cultural capital within the fan community. Beyond interactions with the celebrity, the emotional reward for this group is derived from building and sustaining influence within the fandom.

1.2 Highly engaged social participants

This group forms the core of the active fan base. They engage in practices such as creating fan support materials, participating intensively in fan-related social interactions, and exchanging gifts. Their emotional rewards are largely drawn from a sense of identity, belonging, and active participation within the fan community, in addition to their admiration for the celebrity.

1.3 Experience-oriented individual fans

These fans are more passive in community engagement and primarily act as consumers. While they may not actively contribute to or maintain a position in the fan community, they are by no means rare. Their emotional reward is primarily derived from the celebrity and from their own travel experiences, rather than from social interaction within the fandom.

2. Influencing mechanisms behind the distribution of activities in fandom tourism

The way in which the three types of fandom tourism activities are distributed within an itinerary is influenced by three major factors: individual fan attributes, travel duration, and destination characteristics.

2.1 The influence of fandom level on activity distribution

Fandom level influences identity formation and determines a fan's emotional needs, shaping their preferences for community interaction and emotional reward. These factors, in turn, influence how much time and energy is invested in different types of activities:

- Fans who engage in content production tend to focus intensely on core activities, closely following the celebrity's schedule. Their itineraries are usually fixed and streamlined.
- Fans who are socially motivated invest more time in related activities, such as community rituals and social events, in addition to attending core events.
- Experience-oriented fans, while still attending core activities, tend to allocate more time and energy to other activities like sightseeing and shopping. Their decision-making more closely resembles that of general tourists—though interestingly, they report greater enjoyment and relaxation during fandom tourism compared to

conventional travel.

2.2 Travel duration
The amount of time available for travel directly affects the arrangement of activities. While core activities are fixed and form the primary motivation for travel, the time available beyond these events varies among fans and enables different levels of participation in related and other activities. Although energy levels and personal stamina also play a role, in general, longer trips allow for greater flexibility and a wider variety of engagements.

Most core activities (e.g. concerts, fan meetings) are scheduled on weekends to maximise attendance. As a result, many fans opt for short trips lasting one to two days. However, trips lasting three days or more allow fans to engage in more diverse, loosely structured activities, resulting in richer travel experiences.

2.3 Destination characteristics
The type of city influences the physical and cultural infrastructure available to support different types of activities. Urban environments with a well-developed commercial landscape, strong tourist appeal, and convenient services offer more opportunities for related and other activities. Moreover, fans' perceptions of the destination—shaped by its reputation, accessibility, and consumption options—also affect how they plan and anticipate their trip.

3. Spatial distribution mechanisms of activities in fandom tourism
The spatial distribution of activities in fandom tourism is shaped by both the location of core event venues and their relationship to urban public and commercial spaces. These factors determine the range and positioning of fan activities. In addition, fandom level, travel duration, and the quality of urban infrastructure jointly influence the degree of spatial dispersion and the number of activity cores. Overall, the findings suggest that the spatial layout of fandom tourism activities emerges from situated behavioural choices and path constructions under specific event-driven, social, and geographical contexts.

At the foundational level, the location of core activity venues—and their proximity to public and commercial spaces—forms the primary structure of spatial distribution. Large-scale cultural facilities such as concert arenas, stadiums, exhibition centres, or sites directly associated with celebrity appearances (e.g. filming studios, commercial events, broadcasting stations) serve not only as geographical anchors but also as emotional centres for fandom communities. These venues, when coupled with adjacent public spaces (e.g. plazas, metro stations, green spaces) and commercial establishments (e.g. shopping malls, cafés, restaurant clusters), shape patterns of fan aggregation and dispersion. On this structural base, a fan's level of enthusiasm influences the overall extent of spatial activity.

Furthermore, fandom level, travel duration, and urban infrastructure collectively determine the extensibility and structure of spatial activity. Fans with more time and higher mobility—particularly in geographically larger cities—are more likely to move across multiple areas and change accommodations, thereby forming secondary activity clusters and additional cores. The quality of urban infrastructure significantly affects the feasibility and efficiency of such inter-district mobility.

More specifically, in cities with well-developed infrastructure and abundant tourism resources, fans are more likely to distribute their activities across different areas. This results in a shift from a single-core spatial model to a multi-core networked pattern. In contrast, in smaller or resource-constrained cities, fan activity tends to remain highly concentrated around a single core location.

The impact of fandom tourism on urban space and the construction of city image
Fandom tourism affects urban space on multiple levels. These impacts range from the utilisation and reconfiguration of urban infrastructure and physical space to fans' subjective impressions and emotional attachment to the city. The study finds that the spatial distribution and experiential depth of the three main types of fandom

tourism activities directly shape how fans move through, perceive, and relate to the urban environment. Specifically, core activities establish the baseline expectations for the city, related activities drive micro-renewals of urban space, and other activities influence the upper limits of city image construction and play a key role in inspiring intentions to revisit.

Core activities place concrete demands on a city's infrastructure and governance capacity. On the one hand, large-scale events such as concerts and fan meetings are typically held in major cultural complexes—stadiums, arenas, and performance halls—which require advanced logistical support, including crowd management, security, and technical facilities. These events also test the city's ability to deliver effective transport, service provision, and public order. On the other hand, even smaller-scale events such as programme recordings or commercial appearances still rely on basic infrastructure and urban governance. The fan experience at core activities establishes their baseline evaluation of the destination. In other words, if significant negative experiences occur during these events, they can strongly diminish both overall satisfaction and emotional assessment of the city.

Related activities are often held in commercial and public spaces surrounding core venues and involve creative repurposing of urban infrastructure. These include spontaneous fan gatherings, merchandise exchanges, and social rituals such as group check-ins. Usually organised informally by fandom communities, these activities are temporary and highly interactive. They not only generate short-term increases in foot traffic in commercial and public areas, but also hold potential to stimulate micro-scale urban renewal. In post-industrial cities, such activities may provide new models for space activation beyond top-down planning. Some Chinese cities have already seen such practices emerge: in certain commercial centres, management collaborates with fan groups by providing venues for fan events and organising themed campaigns—such as playing celebrity-related songs and videos on birthdays or offering fan merchandise in exchange for in-store purchases. These models demonstrate alternative pathways for urban revitalisation and spatial reproduction through fan-driven participation.

Other activities play a particularly distinctive role by contributing to fans' emotional experience and shaping their impression of the city. Unlike traditional tourism, where sightseeing is often the main purpose, fans treat core activities as emotional anchors, which lowers expectations and removes pressure from the rest of the itinerary. As a result, fans are able to explore the city more casually, without the rigid time management and checklist mentality typical of conventional tourism. Even highly structured travellers report this sense of unplanned enjoyment. This freedom leads to moments of serendipity and unexpected joy, significantly enhancing fans' overall impression of the city. In this sense, other activities provide emotional surplus value, allowing fans to form unique affective connections and place-based attachments through spontaneous discovery.This mechanism suggests that the quality of urban services, atmosphere of local neighbourhoods, and lived texture of everyday life become key elements in shaping the city's image and encouraging return visits in the eyes of fandom tourists.

Conclusion

Similar to existing tourism frameworks, fandom tourism is also goal-oriented, with core activities remaining the primary motivation for travel. These core activities are centred around specific times, locations, and organisers, and are characterised by temporality, spatial concentration, and site-specific presence. Like other forms of event-driven tourism, they are influenced by uniqueness and non-repeatability. However, in fandom tourism, the emphasis is not on conventional events or media content per se, but rather on their close association with the celebrity figure and their perceived authority.

At the same time, as with contents tourism, many activities in fandom tourism are not strictly dependent on scheduled events. Instead, they are often driven by affective identification with the celebrity, symbolic meaning, and shared recognition within the fandom community. In addition, fandom tourism also generates economic and social impacts on destination cities. On the one hand, it brings short-term economic stimulation with potential for long-term conversion, demanding both consumption and experiential engagement. On the other hand, it contributes to the accumulation of emotional and brand memory within the destination.

In the context of post-urbanisation, many cities face challenges of transformation and spatial reorganisation. As a driving force for urban optimisation, cultural consumption has become a core element of the "beyond-growth" framework. This study develops an analytical model to better understand fandom tourism and its impact on urban space. Fandom tourism offers potential pathways to improve public services, revitalise underused urban spaces, and support the integration of cultural and tourism industries, while also advancing knowledge of contemporary travel behaviour and sustainable development.

From the perspective of urban development, fandom tourism provides an alternative lens through which to understand contemporary mechanisms of urban cultural production. In the post-urbanisation context, traditional capital-driven models of urban growth are increasingly revealing structural limitations, while lifestyle-oriented development logics centred on cultural consumption are gaining traction. Such logics suggest that urban regeneration need not rely solely on top-down planning. This study fills a gap in empirical research on fandom tourism in China and contributes theoretically by distinguishing fandom tourism from contents tourism and event tourism. It highlights three key features: emotional motivation, spatial creativity, and intensive community interaction. This framework offers a useful analytical tool for examining how different types of cultural consumers shape urban space, contributing to future research in urban cultural studies and tourism behaviour.

From a practical standpoint, this research provides policy insights for cultural tourism and urban regeneration in large Chinese cities during the post-urbanisation stage. Urban managers and tourism stakeholders should recognise and leverage fandom activity as a new tourism resource. By providing appropriate public spaces, infrastructural support, and policy guidance, cities can unlock the economic potential of fandom-based tourism. This not only enriches the city's cultural functionality but also offers new strategies for reactivating urban space and advancing sustainable development under the beyond-growth paradigm.

That said, the study has certain limitations. First, the number of semi-structured interview participants is relatively limited, which may introduce sampling bias. Second, the current analysis does not fully account for the differentiated manifestations of fandom tourism across city types or its long-term impacts. Future research could expand the sample size and apply this theoretical framework to larger-scale behavioural studies. In addition, adopting a longitudinal perspective and conducting comparative analyses across different cities or regions would offer a more comprehensive understanding of the spatial and social implications of fandom tourism.

Email: angelica.devito@santannainstitute.com

Abstract
The interplay between universities and their diverse urban environments presents both unique opportunities and challenges. This case study explores how university-led participatory strategies address the tourism–liveability nexus in the small city of Sorrento, facing increasing pressure from overtourism, rising housing costs, and resident displacement. Through a Human Rights Practicum students engaged residents, municipal authorities, and businesses in co-designing place-based solutions. Using surveys, interviews, and workshops, the initiative identified key challenges—including housing affordability, infrastructure strain, and lack of community voice—and proposed actionable responses grounded in human rights principles. The project demonstrates the power of integrating academic instruction with participatory practice to foster engagement, policy innovation, and resilience. It offers a scalable model for aligning tourism development with community well-being in small cities worldwide.

Keywords: Sustainable Tourism, Human Rights, Urban Regeneration, Small Cities, Participatory Practice

Introduction

The intricate relationship between universities and their host urban environments necessitates a balanced approach that leverages the opportunities presented by these institutions while mitigating potential challenges, particularly in tourism-dependent locales (Silvestrelli, 2012). This study delves into the application of participatory practice methodologies within a university classroom setting to address pressing issues in Sorrento, a city grappling with the dual pressures of a burgeoning tourism sector and the imperative to maintain a high quality of life for its residents (Zarb & Jones, 2017). It examines how best to mitigate challenges while building on opportunities using participatory practice approaches in the university classroom (Larty, 2021).

In Sorrento – a coastal city on Italy's Bay of Naples – tourist arrivals have surged significantly over the past decade. In 2016, Sorrento welcomed approximately 640,000 tourists; by 2018, nearly 9.9 million travellers passed through Naples Capodichino Airport reflecting the region's growing appeal (ISTAT, 2023). This "overtourism" trend raises urgent questions about liveability and human rights in the city. Long-time residents voice concerns that allude to crowded public spaces, rising prices, and loss of cultural identity. While national officials have sometimes downplayed overtourism –claiming "too much tourism" (Positanonews, 2025) is not a real problem – local experiences strongly contradict this statement. Sorrento faces challenges that mirror those of larger metropolitan destinations (Aragú et al., 2021). These are tied to rising housing costs, exacerbated by the growth of short-term rentals and growing pressures of tourists on city infrastructure. These dynamics have strained local residents, many of whom struggle to remain in their communities due to financial pressures and limited housing availability (Kennedy, 2020).

The pedagogical strategy employed in this study integrates theoretical instruction with hands-on participatory activities, fostering collaborative relationships between the university community and various local stakeholders, with the aim of developing viable solutions to identified issues (Consilvio, 2024). Sorrento's unique position as a small destination city renowned for its rich cultural heritage and a dynamic tourism industry makes it an ideal case study for exploring the complexities of balancing economic development with the well-being of local communities (Lalicic, 2019).

Through Leveraging participatory approaches, the study highlights the integration of university populations, residents, municipal authorities, and other relevant stakeholders to co-create solutions that balance the needs of locals with the demands of tourism (Innella et al., 2024). Key findings from surveys and interviews reveal that residents feel underrepresented in decision-making, with many voicing concerns about the prioritization of tourism over local needs. By promoting open dialogue, fostering community engagement the research identified and presented possible solutions, such as improving regulations on short-term rentals, implementing rent controls, enhancing public transportation, and developing a place-based, interactive responsible tourism campaign as a catalyst for education, awareness, and larger human-centred urban regeneration projects (Innella et al., 2024).

Moreover, the study underscores the importance of embedding human rights principles—such as the right to housing and cultural participation—into policy frameworks to ensure equitable outcomes (Greene, 2011). Through student coursework using in-depth exploration of human rights law, participatory practice, and sustainable development principles, students utilized their curriculum in theory and practice to engage directly with the Sorrento community in their university neighbourhood. The Service-Learning (Saija & Pappalardo, 2024) course design and place-based engagement serve as a conduit to foster strong bonds within the community through research, data collection, group discussion, and surveys.

Co-design and co-creation are powerful tools that require collective brainstorming, cooperation, and collaboration. These types of exercises use real-world examples and case studies to build a sense of problem ownership (Cruz et al., 2022) and motivation, shaping the students as part owners of the Peninsula's problems, but also key players in the solution for its resilience. This case study demonstrates that participatory practice is an effective and necessary tool for creating sustainable and inclusive urban environments, especially in small cities, offering a model for other destinations grappling with similar challenges (Arellano et al., 2016). Through collaboration and innovation, Sorrento has the potential to reconcile the needs of its residents and its role as a global tourist destination through a participatory system approach that fosters long-term bonds with tourists, residents, higher education institutions (Barnet et al., 2021), and their students.

This paper illustrates the beginning two semesters of the action-research project engaging the international student population, local residents, and Sorrento's municipal authorities. In Fall 2024, the Human Rights Practicum course focused on diagnosing Sorrento's tourism impacts through a human rights lens (Lucia et al., 2021). While in Spring 2025, building off those findings, students co-designed Sorrento Saggia – Be Sorrento Smart, a responsible tourism campaign aimed at building local partnerships, improving awareness, and fostering coexistence between visitors and locals. The title "Sorrento Saggia" (Italian for "wise Sorrento") captures the campaign's ethos of being "smart" tourists who respect the host community. This unique approach leverages participatory methods to bridge theoretical insights and practical solutions.

The significance of this case study is twofold. First, it applies a human rights-based approach to urban tourism, aligning local challenges with fundamental rights such as housing, culture, and participation. Sorrento's situation exemplifies how unchecked tourism can infringe on residents' rights – from the right to adequate housing and standard of living to the right to partake in cultural life (Milano et al., 2019). Second, it situates these local efforts within the broader discourse of sustainable urban planning. International agendas like the UN Sustainable Development Goals (e.g., SDG 11 on sustainable cities) emphasize inclusive, participatory planning and the balance between economic development and quality of life (Trane et al., 2023).

This paper reviews the methodology of the participatory activities conducted. It then synthesizes key findings from the Fall 2024 research on Sorrento's tourism challenges, grouped into four themes: affordable housing, community engagement, mobility & infrastructure, and cultural sustainability (Innella et al., 2024). Subsequently, it describes the Spring 2025 work undertaken to create a 'Vision Brief' for the Sorrento Saggia campaign through PAR, co-design and co-creation processes, including the resulting "10 Easy Ways to be Sorrento Smart" guidelines for visitors. A discussion section connects these results to human rights principles and sustainable plan-

ning practices – critically examining successes, limitations, and the path forward for Sorrento. These methods not only provide valuable insights into the concerns and priorities of local residents but also serve as platforms for education and capacity building, empowering community members to actively participate in shaping the direction of tourism development (Ginanjar, 2023).

Methodology

Community involvement in tourism planning is essential for fostering sustainable benefits and ensuring the industry's long-term viability, yet it faces challenges in developing countries due to operational, structural, and cultural obstacles (Reindrawati, 2023). Effective community participation requires empowering residents in tourism development, although achieving genuine participation can be difficult without such empowerment. Successful community involvement can be achieved through social empowerment, which enhances residents' self-esteem and enables them to support tourism development (Rachmawati et al., 2022).

This study employed a Placed-based System approach employing Participatory Action Research (PAR) with co-design and co-creation frameworks in which students, residents, and officials collaboratively investigated problems and devised solutions. Rather than a traditional top-down research project, the process was iterative and co-creative (Ward et al., 2024), blending qualitative and quantitative methods over two academic semesters.

Fall 2024 – Human Rights Practicum:

In the first phase, a class of international students at Sant'Anna Institute in Sorrento undertook a practicum course with the goal to "learn where we live" by examining how human rights concepts manifest in the local context of Sorrento's tourism economy (Bianchi et al., 2024). Students first familiarized themselves with international human rights law and frameworks (e.g., the Universal Declaration of Human Rights and relevant covenants) and studied global cases of tourism-related rights challenges. With this foundation, they turned to Sorrento, conducting surveys and interviews with local residents to gather first-hand perspectives.

Approximately 50 residents from Sorrento and nearby towns in the Sorrentine Peninsula participated, providing insights into tourism's impacts on their daily lives. The survey instrument included both closed (Figure 1) and open-ended questions designed to elicit opinions on tourism's impacts on housing, infrastructure, culture, and quality of life (Wang & Wang, 2018). In addition, semi-structured interviews were carried out with a subset of stakeholders, ranging from young professionals and small business owners to long-time residents.

The data collected were then analysed through the dual lenses of human rights and urban liveability. Students coded interview transcripts to identify recurring themes and specific human rights articles implicated. For instance, a comment about unaffordable rent was linked to UDHR Article 25 - right to an adequate standard of living, while remarks about exclusion from decision-making evoked UDHR Article 21 - right to participate in government (United Nations, 1948). This grounded approach ensured that local voices drove the problem identification. Finally, students conducted a brief literature and precedent review to see how other tourist cities have tackled similar issues (e.g., Amsterdam's regulations on short-term rentals). The Fall phase culminated in a presentation of findings and preliminary solution ideas to local government officials, including the Deputy Mayor and community representatives.

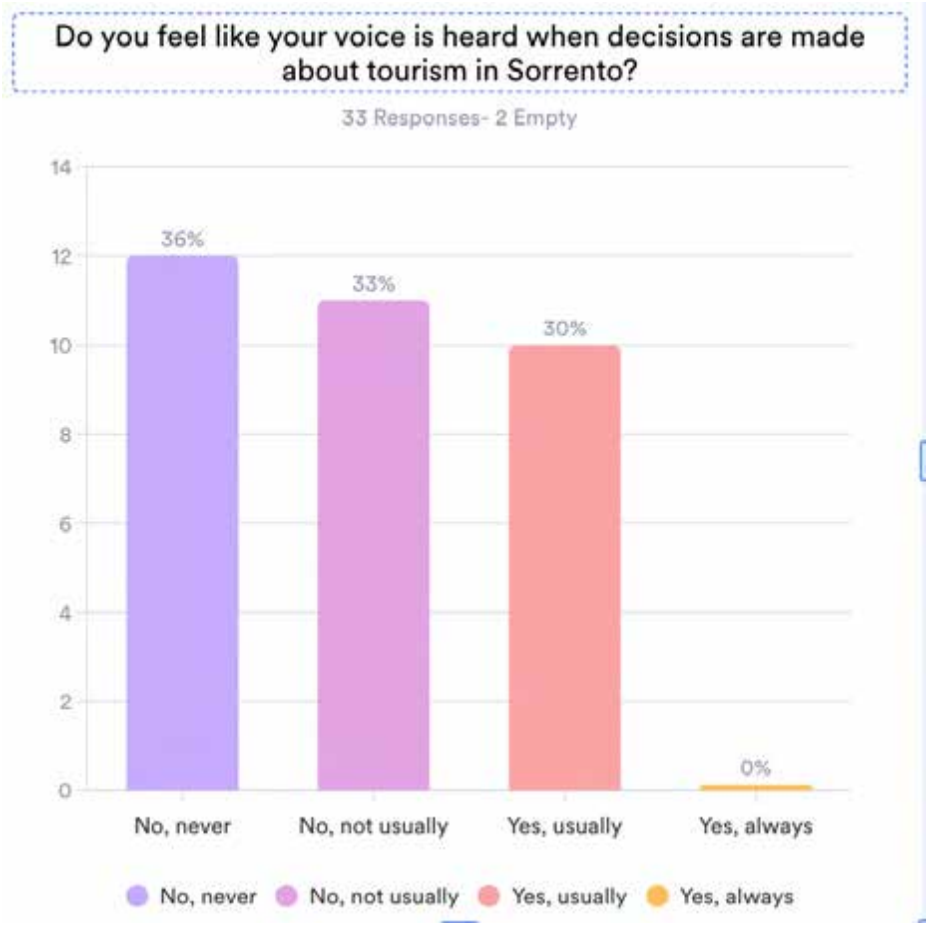

Figure 1. Fall HR Practicum Survey (generated with Jotform)

Spring 2025 – Sorrento Saggia Campaign Design:
The second phase shifted from analysis to solution-building. A new group of students, with continuity from the fall, engaged in a project-based course to create an actionable responsible tourism campaign proposed as "Sorrento Saggia – Be Sorrento Smart" with the focus on place-based cultural-driven storytelling. The pedagogical approach this semester was explicitly co-creative and multi-method. It included:

• **Participatory Co-Design Workshops:** Students and instructors facilitated brainstorming sessions to develop the campaign concept. Techniques like Business Model Canvas (Echavarria et al., 2022) exercises were used to map out the value proposition, target audiences, key partners, and resources for the campaign. This helped ensure the proposed solution was grounded in local reality and feasible (Figure 2).

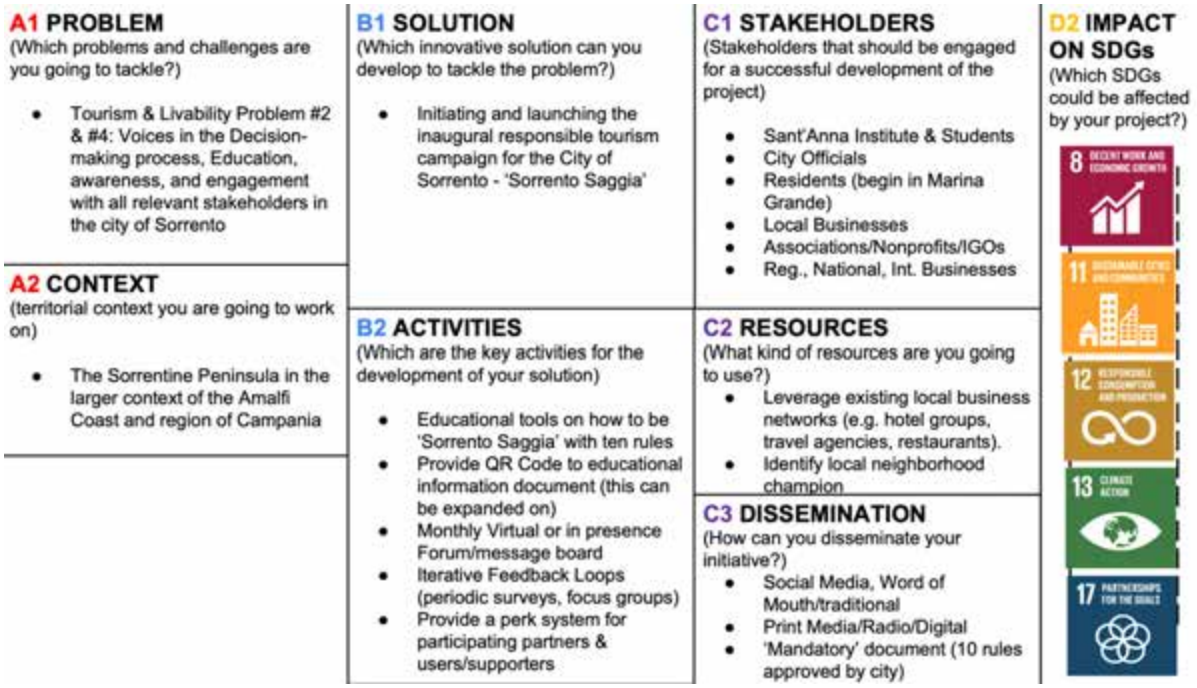

Figure 2. Sorrento Saggia Adapted Business Model Canvas from "Decision-making" for Sustainable Development Goals Course – Politecnico di Torino.

• **Stakeholder Analysis & Power Mapping:** Building on political science frameworks (e.g., Dente's (2014) model of actor resources (Konstantinidis et al., 2021)), the class identified key stakeholder groups and analysed their levels of interest and power regarding tourism management. Stakeholders ranged from political actors to special interest groups (local business owners, tourism operators), general interests (the resident community at large), and experts (NGOs, academic institutions). By categorizing stakeholders and the resources they control (political, economic, legal, cognitive), students gained insight into potential allies and barriers for the campaign. A classic power-interest matrix (Cottafava & Corazza, 2020) was constructed to visualize where to focus engagement: for example, local residents and business owners have high interest in liveability issues, but varying degrees of power to influence policy; the municipality has high power but needed to be convinced to prioritize human-centred tourism (Figure 3).

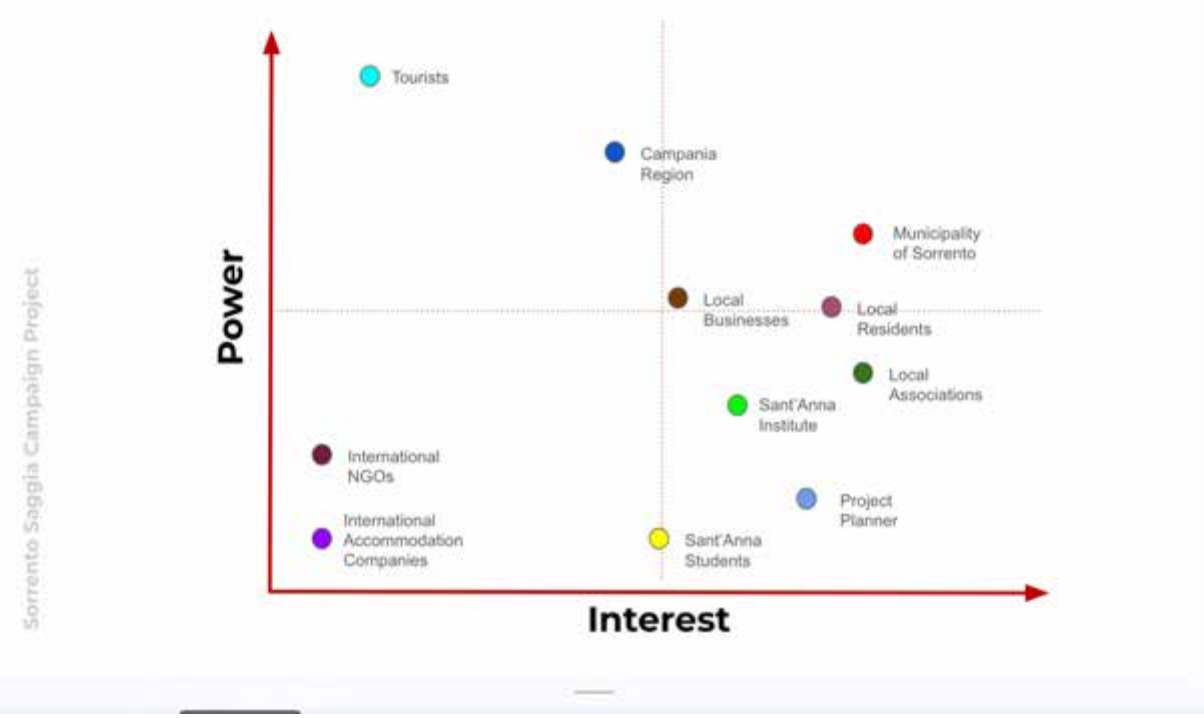

Figure 3. Stakeholder Power-Interest Matrix

• **Follow-up Interviews and Surveys:** To design effective campaign messages, the students conducted additional interviews with stakeholders, particularly those in the tourism sector, to gather feedback on proposed ideas. In total, 8 in-depth interviews were carried out in Spring 2025 with individuals representing different roles – such as a hotel employee, a travel agency owner, a vacation rental manager, a student program coordinator, and local business owners. These interviews were less about diagnosing problems (as that had been done in fall) and more about co-envisioning solutions and gauging stakeholders' willingness to collaborate. For instance, interviewees were asked how tourists could be educated to respect local norms, or what incentives might encourage businesses to support the campaign.

• **Place-Based Systems Approach:** Throughout, the project was guided by a place-based perspective – meaning it sought solutions tailored to Sorrento's specific cultural and geographic context, rather than one-size-fits-all fixes. This involved site visits to areas like Marina Grande (a traditional fishing village in Sorrento) where the university is located, as well as the residence of many of the students. This localized the initiative as deeply as possibly for students to observe tourist-local interactions in their own neighbourhood, and mapping of "hotspots" where conflicts or overcrowding were most pronounced.

Using these methods, the Spring team developed the content and implementation plan for Sorrento Saggia. The campaign was envisioned as a partnership between the city government, local businesses, community organizations, and tourists themselves. The mixed-methods approach – combining community-based research in fall with co-design and stakeholder engagement in spring – exemplifies how universities can serve as facilitators in complex urban issues. It allowed for continuous feedback loops: preliminary solutions were adjusted based on stakeholder input, increasing local buy-in. The methodology's participatory nature is itself a finding – it modelled the inclusive decision-making that residents had illustrated a greater need for in their community.

Findings: Tourism Impacts and Liveability Challenges in Sorrento
The Fall 2024 research revealed a nuanced picture of how tourism growth has affected Sorrento's liveability. Four interrelated challenge areas were identified, each linked to residents' enjoyment of their rights and quality of life. These are:

(1) Affordable Housing
In response to the housing crisis, the Fall 2024 practicum explored various **policy options and best practices**. Students presented a menu of regulatory ideas gleaned from other cities: for example, short-term rental caps as implemented in Amsterdam, (Tedds et al., 2021), stricter licensing and primary residence requirements for rental hosts, zoning restrictions to protect residential zones, and even community-driven solutions like Community Land Trusts (Phang, 2018; Williams, 2018) to secure affordable units. They also discussed how cities like Vienna invest in government-subsidized housing to keep prices stable. While local Sorrento officials have been limited by current national and regional regulations these examples provide a roadmap. Any durable solution will likely require applying a bidirectional action of top-down policy (e.g., regional law to limit short-term rentals) and bottom-up action (e.g., locals forming cooperatives to buy and rent homes at affordable rates). The immediacy of the issue is, however, very clear. Without intervention, Sorrento risks losing its local community, thereby also losing the authentic character that draws visitors to the peninsula initially.

(2) Voices in the Decision-making Process
The second major theme was a feeling among residents of being excluded from decision-making about Sorrento's future. Over two-thirds of surveyed citizens reported (Figure 1) that they do not feel heard by local government on tourism and liveability issues. Many believed that tourists' needs may often be put before their own in municipal priorities (Aragú et al., 2021). Notably, some respondents observed that during local elections and political discourse, the problems of overtourism or housing seldom receive serious attention – politicians rarely mention these issues, focusing instead on the benefits of tourism. This has fostered a sense of disconnect and disempowerment among the public.

During stakeholder interviews in Spring 2025, this theme of voice re-emerged. For instance, the CEO of Fondazione Sorrento (a local cultural foundation) stressed the importance of Sorrentini youth having an active role in changing the public perception of their city. He introduced the idea of "turismo versus turismi" – suggesting that there isn't a single monolithic tourism, but multiple ways tourism can manifest, and that locals and tourists must collaborate to shape a diversity of experiences. Implicit in his view is that local voices (especially young people's voices) should help redefine Sorrento not just as a mass-tourism hotspot but as a living city with artistic, cultural, and educational dimensions. This perspective bolsters the argument that participatory approaches are not just feel-good extras, but central to rebalancing tourism on more equitable terms.

In summary, the research highlighted a democratic deficit in Sorrento's tourism governance. Addressing it will require effort both from the government to actively solicit and listen to citizen input (Innella et al., 2024) and from residents to organize and articulate their demands. The Sorrento Saggia campaign itself was partly an answer to this: a citizen-aware initiative that could amplify local perspectives. By involving residents in the creation of the campaign (PONTIKAKIS et al., 2024), the project attempts to embed local engagement as a cornerstone of the solution.

(3) Strains on Mobility and Infrastructure
Addressing mobility issues requires both supply-side improvements that call for better transport services, infrastructure upgrades and demand management through controlling the flow of vehicles and people (Ebbesson, 2022). Sorrento's relatively small geographic footprint means creative solutions. Some are already in use in limited ways, such as electric minibuses or timed entry to certain areas (ZTL zones). However, it is still not enough supply to support the demand of the transportation infrastructure (PONTIKAKIS et al., 2024), especially during high tourist traffic months. Involving residents in designing these solutions – for instance, consulting them on which streets could be pedestrianized without hurting local access – will be crucial, in creating buy-in and ownership

for any future proposed solutions. The measures must aim to benefit locals as well as enhance the tourist experience by alleviating the frustrations of congestion (Coni et al., 2020).

(4) Cultural and Environmental Impacts.
The fourth challenge area revolves around the **preservation of Sorrento's cultural heritage and environment** in the face of mass tourism. Sorrento is steeped in intangible cultural heritage – from the evening passeggiata (leisurely stroll) tradition to its culinary and artisanal practices. Residents are proud of these traditions, yet many fear that excessive tourism is diluting its authenticity (Wang et al., 2022) and putting natural sites at risk. The Sorrentine Peninsula's unique ecosystem (cliffs, marine areas, lemon groves) is under pressure. Issues raised included litter and waste management challenges (Saija & Pappalardo, 2024), strain on water resources in high season, and damage to trails or beaches from overuse.

While most locals acknowledge tourism's importance to Sorrento's economy, many fear that without intervention the city may lose the character and culture (Kennedy, 2020) that makes it so unique and attractive to visitors. The challenge is how to channel tourism in a way that enhances rather than erodes local culture and environment. In Fall 2024, students highlighted that Sorrento needs to find a balance where tourism and local quality of life "thrive in unison." This aligns with the concept of human-centred tourism, which was notably being discussed in the region under the banner "Umanesimo nel Turismo" (Humanism in Tourism). In fact, in April 2025 a summit of Amalfi Coast mayors resulted in the "Carta di Amalfi," (Positanonews, 2025) a charter pledging a new humanistic approach to tourism focusing on people and cultural respect. Such high-level commitments show the growing recognition that tourism must be reoriented to value community and culture alongside profit.

The project's findings contributed to this dialogue by identifying specific local cultural values to safeguard. For example, the tradition of the evening passeggiata was repeatedly mentioned as something tourists should respect and even participate in, rather than disrupt. Likewise, cultural sites like Marina Grande's fishing village or historic monasteries should not be treated as mere backdrops for Instagram, but as living communities (Acampa et al., 2020).

To address these issues, the proposed solutions centred on education and mutual respect – essentially, fostering a two-way awareness: educating tourists about local norms and encouraging locals to engage with visitors in sharing their culture (Panneels, 2023). This leads directly into the Sorrento Saggia campaign, which was the actionable outcome focusing largely on this domain of awareness (Thojampa et al., 2023) drafted an initial "10 Rules" list for responsible tourist behaviour based on survey feedback. These rules (elaborated in the next section) include cultural etiquette like respecting local customs, being mindful of noise, learning a few Italian phrases, and so forth. The underlying principle is that if tourists adjust their behaviour — even just a little — negative impacts can be mitigated, the visitor experience can be enriched, and bridges can be built on which locals feel less estranged in their own community.

It is worth noting as well that the cultural sustainability is also tied to housing and community: if local families and youth are forced out by costs, who will carry on traditions? The economy relies heavily on tourism, but the community also will not survive without conscious efforts to maintain local life. The mutual dependency (Kennedy, 2020) of locals and tourism means solutions must be holistic, inclusive, and innovative.

The Sorrento Saggia campaign attempts to operationalize many of the insights gathered by the Fall 2024 and Spring 2025 student cohorts, particularly by focusing on awareness, education, and stakeholder partnership (Andreoni et al., 2024) to make tourism more responsible and human centred. Drawing on the challenges identified in the Fall 2024 practicum, the Spring 2025 team further developed the initial **"Sorrento Saggia – Be Sorrento Smart,"** (Figure 4) idea into a pilot campaign aimed at promoting responsible tourism and improving coexistence between tourists and locals in Sorrento. The campaign's name uses the Italian word saggia (wise) to encapsulate the idea of a "smart" tourist – one who is mindful of their impact and engages positively with the community. The campaign's content and strategy were co-created with local input and seeks to initially address the issues

of housing, voice, mobility, and culture through the lens of awareness and behaviour change.

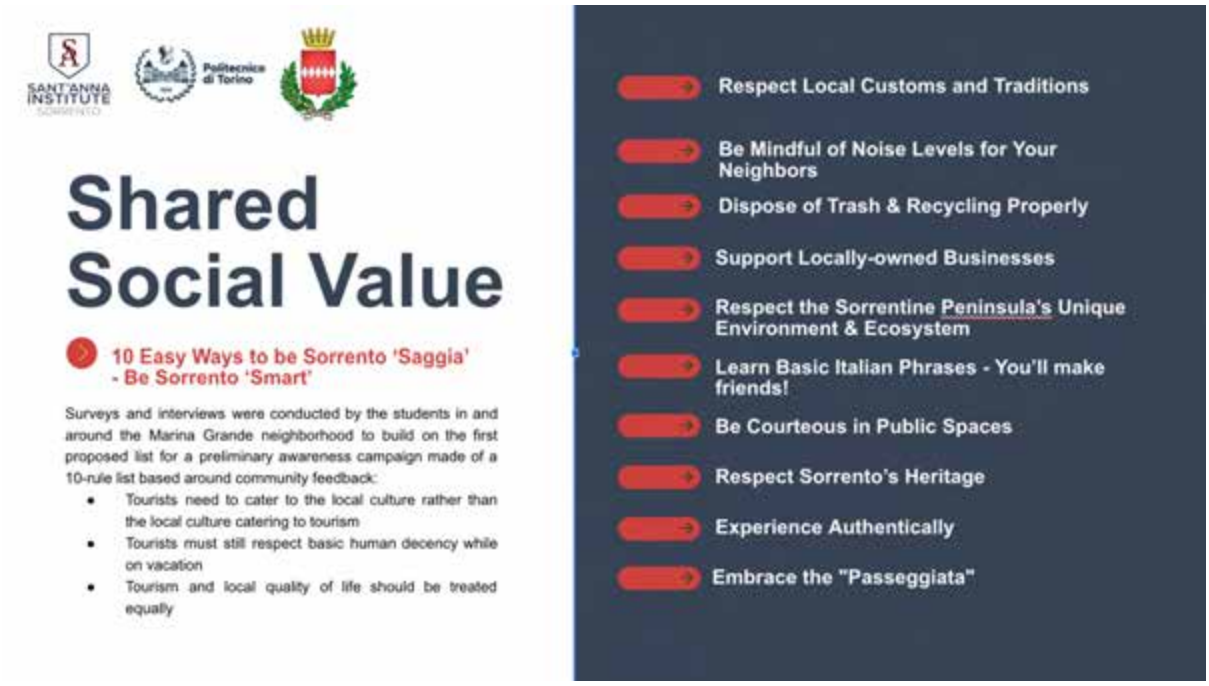

Figure 4. Current draft of '10 Easy Ways to be Sorrento Saggia – Be Sorrento Smart!"

This decalogue of good tourist behaviour is meant to be simple, positive, and empowering rather than scolding (Pisters et al., 2019). The tone is "Be Sorrento Smart," implying that smart travellers get a better experience by following these tips, and locals benefit too. Notably, many of the rules echo the issues discussed earlier: for instance, supporting local businesses can mitigate the dominance of outside investors (connecting to housing economics), proper trash disposal helps environmental sustainability, and courtesy/noise awareness addresses social frictions (Panneels, 2023). The rules also implicitly promote human rights values: e.g., respecting heritage ties into the right to culture, supporting local economy touches on the right to work and decent livelihood for locals, etc (Sarid & Goldman, 2021).

Stakeholder Partnerships and Participatory Implementation

Beyond messaging, Sorrento Saggia was conceived as a partnership-based **initiative**. Recognizing that no single entity can solve overtourism, the campaign proposed a network of collaborators (Cruz et al., 2022):

• **Municipal Government:** The City of Sorrento's buy-in is crucial for legitimacy and resources. The campaign was to be presented to the mayor and council (indeed, the project's final deliverable was a Vision Brief for the municipality). The hope is that the city would formally endorse Sorrento Saggia, perhaps integrating it with the official tourism promotion strategy. Support could include modest funding for materials, placement permission for posters, and encouragement of participation (e.g., Mayor publicly urging businesses to join).

• **Local Businesses:** Hotels, restaurants, shops, and tour operators are on the frontlines of tourist interactions. The campaign sought to create a **coalition of businesses** that commit to promoting responsible tourism – for instance, by displaying the Sorrento Saggia logo and rules, offering information to customers, or even providing small incentives (Innella et al., 2024). One idea raised was a "Sorrento Saggia Card" or stamp program. Tourists who follow certain good practices (like using recycling bins or visiting a local cultural event) could get stamps or points redeemable for discounts at participating businesses. An Airbnb manager liked the idea of a benefits card, noting it would drive conscious tourists to those businesses and reward good behaviour. While a full-fledged rewards system might be complex to implement initially, even symbolic gestures (a free limoncello after a tourist

fills a recycling bag, for example) can gamify (Kavouras et al., 2023) responsible behaviour.

• **Educational Institutions:** Sant'Anna Institute and possibly local schools can sustain the campaign's momentum. Students can continue as volunteers or interns to run social media, conduct surveys with tourists about their awareness, and update campaign content, supporting iterative feedback loops (Larty, 2021) for initiative evolution and long-term resilience. The involvement of youth not only provides manpower but also keeps the initiative innovative. The Fondazione Sorrento CEO explicitly noted the importance of youth engagement for shifting perceptions, and indeed younger locals can be great ambassadors if empowered.

• **Community and Associations:** Local civic groups (environmental clubs, cultural associations, neighbourhood committees) were identified as key partners. For example, a local fishermen's association in Marina Grande could co-host an event where tourists are invited to a morning of fishing and beach cleaning – exemplifying rules from the list like respect the environment, and experience authentically. These types of grassroots events provide concrete action under the campaign umbrella (Arellano et al., 2016).

• **Tourists themselves:** Uniquely, Sorrento Saggia considers visitors not just as targets to educate, but as potential allies. The campaign encourages a view of tourists as temporary citizens who can contribute positively (Corte et al., 2018). Mechanisms for feedback were suggested, such as a QR code on the poster linking to a short survey or pledge: "Sign the Sorrento Smart Traveller Pledge". Tourists who take the pledge to follow the rules might get a digital certificate or be featured (with permission) as example travellers on social media. The point is to create a sense of community among responsible tourists, turning it into a type of movement that transcends the borders of the Sorrentine peninsula even after they have returned home (Pasquinelli et al., 2021). In an era when travellers increasingly seek meaningful, sustainable experiences, this could tap into an existing segment of conscientious tourists.

The implementation plans emphasized starting with a pilot in one neighbourhood — Marina Grande was chosen due to the University's 'home' location, its historical significance, and resident-tourist character. There, the campaign could be rolled out in a contained setting, refined, and then scaled up across Sorrento and potentially to nearby towns in the peninsula and Amalfi Coast. The place-based strategy (Grieco et al., 2024) aims to utilize informed tailored messaging for the community, leveraging feedback from the residents as campaign components are rolled out.

Human Rights and Urban Sustainability Framing

What distinguishes Sorrento Saggia from a generic "respect the city" campaign is its explicit rooting in human rights and sustainability principles. The educational materials don't overtly lecture about UN articles to tourists but kept the principles as a guiding framework (United Nations, 1948):

• By promoting respect for local culture, the campaign helps uphold the right of locals to enjoy their culture (UDHR 27) and combats the alienation overtourism can cause.

• Emphasizing support for local businesses touches on the right to work and favourable conditions (UDHR 23) for Sorrentini – the campaign indirectly advocates livelihoods by steering tourism revenue to those who live and work here.

• The focus on mutual respect and dialogue echoes the right to freedom of expression and information (UDHR 19) – encouraging open cultural exchange between locals and visitors. It's about sharing the "story" of Sorrento in an inclusive way.

• Environmentally, respecting the ecosystem aligns with the right to health (clean environment as part of well-being) and with SDG 11's sustainability targets.

The campaign also unites with the emerging regional policy context. The "Carta di Amalfi" signed in April 2025 signalled a commitment from local leaders to human-centric tourism (Positanonews, 2025). Sorrento Saggia could be seen as a ground-level implementation of those positive ideals – turning words into action in the city of Sorrento. If successful, the Sorrento Saggia campaign could serve as a model for other Amalfi Coast towns (Positano, Amalfi, etc.) which share similar issues. A bottom-up approach from a small city (Pignatelli et al., 2023) like Sorrento can be an example for larger destinations – a living laboratory for managing overtourism in a way that major cities might learn from (Barnet et al., 2021).

The Municipality of Sorrento is expected to continue its active role in the initiative, including assistance with local promotion, identifying key performance indicators, and maintaining long-term collaboration on sustainable tourism programs.

Potential Impact and Sustainability of the Campaign
While Sorrento Saggia was in a proposal/pilot stage by Spring 2025, its anticipated impact can be considered. The campaign set a goal of achieving visible changes within 1–2 years, such as improved tourist behaviour, stronger local-business-tourist networks, and enhanced community pride. Even partial uptake and adoption of the campaign could yield benefits:

- If even 30% of tourists read and heed the 10 rules, that might significantly reduce complaints about noise or litter.
- If a dozen key businesses actively promote the campaign, others may follow, creating a tipping point where responsible tourism becomes part of Sorrento's brand – its story and identity.
- By establishing an iterative management and feedback loop, the campaign can adapt and possibly expand into broader initiatives – for instance, feeding into discussions of establishing "tourist carrying capacity" limits or new city ordinances (with public backing).

A critical factor is measurement (Jurado et al., 2012). The plan includes tracking certain indicators: number of businesses participating, number of tourists signing the pledge or engaging online, changes in resident satisfaction (perhaps through follow-up surveys). Over time, more concrete metrics like reduction in waste or noise complaints could be examined. Though these are challenging to attribute directly to a campaign, they help in evaluating overall progress.

Sorrento Saggia is not a cure-all for larger planning issues like housing affordability – those require policy innovation and adaptive governance. However, it addresses the softer side of the problem: culture, awareness, and the social contract between hosts and guests. By improving the daily micro-interactions between tourists and locals, the campaign can alleviate tension and build goodwill that makes bigger changes possible (Consilvio, 2024). For instance, a community that sees tourists willing to adapt might be more unified in pushing for housing regulations, knowing the goal is not to stop tourism but to ensure its respectful and balanced.

In summary, the Sorrento Saggia campaign represents a practical output of the participatory process (Cruz et al., 2022). It translates abstract human rights and liveability concerns into tangible actions for everyday life in a tourist city. Its collaborative formation is as important as the content – the process empowered stakeholders, creating a sense of shared ownership of Sorrento's future (Barnet et al., 2021).

Human Rights as a Framework for Urban Tourism:
One of the project's key contributions is framing tourism impacts in terms of human rights. This lens proved effective in Sorrento by re-centring the conversation on people rather than just economics (Pasquinelli & Trunfio, 2020). Often, tourism development debates get reduced to metrics like visitor numbers, revenue, or GDP contribution.

By contrast, a rights-based approach asks: How are residents' rights and needs being affected? In Sorrento, this

meant recognizing housing as a right, elevating the importance of cultural life for community identity, and asserting that locals should have a say in policies (Brewer & Kliewer, 2023).

Participatory Planning and Co-Creation: The process used in Sorrento underscores the value of participatory planning in tackling complex urban issues. The active engagement of students, who acted as neutral facilitators and researchers, helped bring out community voices that might otherwise be ignored (Collins et al., 2022).

Balance of Power – Challenges in Implementation: Despite the positive aspects, one must critically acknowledge the **power dynamics** and potential challenges. While students and community members can propose and pilot solutions, lasting change in Sorrento will depend on those in power – local government, regional authorities, tourism businesses – taking up and institutionalizing measures (Greenway, n.d.). Housing affordability, for example, ultimately requires policy changes (like those mentioned: caps or incentives for long-term rentals) that only officials can enact.

Scalability and Sustainability: Another point of discussion is how scalable and sustainable these participatory efforts are. The Human Rights Practicum and subsequent project were academic exercises with limited duration (Flanagan et al., 2019). For the impact to last, local institutions need to absorb and continue the work. Encouragingly, the involvement of entities like Fondazione Sorrento and interest from the mayor's office (who received the final presentations) suggest potential for institutionalization (Ivona et al., 2019).

One possibility could be establishing a permanent working group or forum on Sustainable Tourism in Sorrento, possibly chaired by the municipality but with citizen and business representatives, and perhaps advised by academics and/or technical experts. This group could continue monitoring issues and implementing initiatives like Sorrento Saggia.

In terms of geographic scalability, Sorrento Saggia could be adapted by other towns along the Amalfi Coast, which would benefit from a regional coherence (especially since tourists often visit multiple towns along the Amalfi Coast). The DMO (Destination Management Organization) being created for the Sorrentine Peninsula is a key opportunity (Positanonews, 2024). While DMOs traditionally focus on marketing, modern ones also manage sustainability. Feeding the lessons of this project into the DMO's strategy (e.g., making responsible tourism a core pillar) could amplify its reach.

Theoretical Implications for Sustainable Urban Planning: The challenges Sorrento faces are a microcosm of urban tourism in historic cities worldwide – from Venice and Barcelona to Bali and beyond. The interplay between tourism and housing gentrification, infrastructure stress, and cultural change is widely recognized in literature on "touristification" and "overtourism." Giovanna Russo Krauss's study (2019) of Capri highlights how excessive luxury tourism altered the island's cultural landscape over time.

Sorrento adds to discourse by providing a case where stakeholders are actively responding with a rights-based narrative. It supports the argument that sustainable urban tourism requires integrating planning disciplines with community development (Esposito, 2023). Urban planners often deal with land use, transportation, etc., while tourism management deals with marketing and service. The transdisciplinary approach in Sorrento blends these by treating tourism as an integral part of city planning (Rogerson, 2019) that must include residents' voices. The project can thus be seen as a practical application of the theory of collaborative planning (Healey, 1997) in a tourism context – where diverse actors negotiate and co-create urban policy.

Community Empowerment and Social Cohesion: A positive, if intangible, outcome of the participatory process is increased community empowerment and potentially social cohesion (Anderson & Jung, 2023). Knowing that their concerns were studied and presented to city officials may give residents a sense that change is possible. Also, the narrative shift from "tourists vs locals" to "tourists and locals vs the problem", while subtle can shift perspective and inspiration when it comes to problem ownership. By casting irresponsible tourism behaviours and lack

of planning as the problem – not tourism or tourists inherently – the campaign frames it as a solvable issue with everyone's cooperation (Bianchi et al., 2024).

Monitoring Human Rights Fulfilment: By explicitly referencing human rights (like housing, culture, work) in local discussions, Sorrento sets a precedent for possibly monitoring tourism impacts against rights indicators (Cole & Eriksson, 2010). For instance, the city could track whether the percentage of resident population is stabilizing (or still declining) as one measure of the right to housing/local residency or survey their satisfaction with access to public spaces (right to leisure and culture). These could become indicators in the city's urban plan or the DMO's performance metrics, ensuring that tourism is always evaluated in terms of community well-being, not just economic output.

Conclusion & Limitations

Sorrento's journey through the Fall 2024 Human Rights Practicum and Spring 2025 Sorrento Saggia campaign demonstrates a promising pathway for tourist cities seeking liveability (Bizzarri & Micera, 2021). By diagnosing tourism's impacts through a human rights lens and actively involving the community in crafting solutions, Sorrento has begun to reclaim the narrative of its future – striving to ensure it remains both a welcoming destination and a fulfilling home.

The project balanced theory and practice (Ranieri et al., 2023): principles like the right to housing and cultural life were translated into concrete actions like rule lists, forums, and partnerships. This showed that human rights need not remain abstract in local governance; it can directly inform city policies and visitor conduct (Arnstein, 1969). Meanwhile, students and residents working side by side exemplified how universities can serve their host communities, acting as catalysts and mediators in complex urban issues.

Limitations: It's important to candidly acknowledge some limitations of this study and project. The sample size of surveys and interviews was relatively small and may not capture all perspectives (e.g., perhaps not many voices of hotel developers or big tour operators, who have a stake too). As a student-led project, it may have gaps in expertise – professional urban planners or economists might refine some proposals. The campaign's efficacy is unproven as of this writing; it is based on theories of behaviour change and anecdotal support, but whether it truly changes tourist behaviour remains to be seen. There's also the issue of language and cultural barriers – many international tourists may not speak English or Italian well enough to engage deeply with the campaign content. Thus, materials need to be multilingual and culturally sensitive (something the team considered by planning translations).

Critical Next Steps: For Sorrento, a key next step is to integrate these efforts with formal policy. One suggestion is for the city to declare an objective like "Make Sorrento a model of responsible tourism by 2030" and outline actions in its strategic plan (Piano Urbanistico Comunale). This could secure funding and continuity. Additionally, pushing for the region (Campania) to pilot tourist zoning or rental limits in Sorrento could complement grassroots actions on housing. The synergy of top-down and bottom-up is needed: neither community campaigns nor regulations alone will suffice. As an analogy, public health issues are tackled with education campaigns and laws; similarly, overtourism may require soft measures like Sorrento Saggia and hard measures like limits on cruise passengers or Airbnb permits.

Abstract
This study examines the intersection of gastronomy tourism, gentrification, and reverse migration in Urla, a peri-urban area in İzmir. It introduces "gastro-driven gentrification" to explain how culinary tourism reshapes space, fuels property speculation, and displaces long-term residents. While promoting economic growth and global visibility, these changes intensify socio-spatial inequalities and cultural commodification. Reverse migration accelerates transformation by bringing affluent newcomers focused on lifestyle over local identity. The study highlights tensions between development, justice, and sustainability, situating Urla's case within broader tourism and environmental crises. By situating Urla's transformation within the broader context of planetary crises and unsustainable tourism trends, it calls for sustainable planning that balances growth with cultural authenticity, ecological resilience, and spatial equity.

Keywords: Gastronomy Tourism, Gastro-Driven Gentrification, Reverse Migration, Peri-Urban Transformation, Urla Izmir

1. Introduction

Gastronomy tourism has emerged as a significant global trend, intertwining culinary experiences with cultural exploration in both urban and rural contexts. Over recent decades, this relationship between tourism and gastronomy has undergone remarkable transformations, driven by globalization, technological advancements, and a growing demand for authentic and localized experiences, making gastronomy play a crucial role in tourism planning and destination branding, making it an essential focus for understanding socio-spatial and economic dynamics (Pérez et al., 2024). Food, as a universal cultural and social phenomenon, continues to influence urban life profoundly. According to Sasaki Report (2014), which tried to answer, "What makes a city great?", 82% of urban residents value their city's culinary offerings, while 41% highlight food and restaurants as essential aspects of their consumer activities and 46% go out of their neighborhood to try a new restaurant, demonstrating food's role as a major driver of social and economic interactions.

This article focuses on the relationship between gastronomy tourism, gentrification, and reverse migration in peri-urban geographies. The dual connection between tourism and gentrification offers a compelling framework for analysis. Gravari-Barbas and Guinand (2017) suggest that tourism both results from and facilitates gentrification, a dual process, evolving through different phases as neighborhoods transform. Early stages of gentrification often stimulate tourism, while more advanced phases may resist further tourism-driven developments. Within this context, Clark's (2005) definition of gentrification becomes particularly relevant. It emphasizes two key dimensions: demographic shifts in land-users, closely tied to migration, and physical transformations of the built environment, reflecting changes in urban geography. These processes take on unique forms in peri-urban areas, as Lees (2011) points out, where "different forms of gentrification emerge in different places at different and indeed the same times," underscoring the spatial complexity of gentrification in these intermediate spaces between urban and rural settings.

Despite extensive research on tourism's role in urban gentrification and economic development in urban (Gravari-Barbas & Guinand, 2017; Cocola-Gant, 2018) and rural (Xu, Wang, & Zhang, 2022; Ma & Su, 2023) context, significant gaps remain in the literature. Peri-urban geographies, which are the regions that blend rural and urban characteristics, have been relatively overlooked, even though they are uniquely positioned to exhibit mixed land

uses, dynamic demographics (Rajendran et al., 2024), and the overlapping influences of urban and rural transformations. Furthermore, while tourism-driven gentrification has been well-documented in urban centers (Bourlessas et al., 2021; Lütke & Jager, 2021), and relatively less-documented in rural (Nemes & Tomay, 2022), limited attention has been given to how gastronomy tourism, particularly through high-end establishments like Michelin-starred restaurants, drives gentrification and socio-spatial inequalities in peri-urban areas.

This study aims to address these research gaps by analyzing the dynamic interplay between gastronomy tourism, gentrification, and reverse migration in the peri-urban context of Urla, Türkiye. Through a critical examination of how Michelin-starred restaurants act as catalysts for spatial and socio-economic transformation, the research contributes to a deeper understanding of the socio-spatial impacts of gastronomy tourism. It also evaluates the implications of these transformations for urban justice, particularly in terms of inclusion, displacement, and accessibility.

The research is guided by three primary objectives: (1) to explore the relationship between gastronomy tourism, gentrification, and reverse migration; (2) to analyze how these processes transform peri-urban geographies; and (3) to evaluate the socio-spatial impacts of gastronomy tourism. Central to this exploration is the fundamental research questions: How are the co-constitutive relationships between gastronomy tourism, reverse migration and gentrification processes have been established? and how does this relationships transform peri-urban geography in the case of Urla, İzmir?

By addressing these objectives and questions, the study not only contributes to the theoretical discussions on tourism and gentrification; but also provides practical insights as well into the socio-economic and spatial dynamics of peri-urban areas. This research is particularly relevant in understanding how gastronomy tourism reshapes local geographies and offers a framework for ensuring more equitable and sustainable development in rapidly transforming regions like Urla.

2. Theoretical Framework

Tourism has long been a driver of socioeconomic and spatial transformations, but its impact on gentrification is increasingly nuanced and multifaceted. Tourism gentrification, as defined by Cocola-Gant (2018), is a process where the influx of visitors disrupts the existing population's right to remain in place. In advanced economies, this phenomenon is often framed through a cultural economy lens, emphasizing the consumption patterns of tourists and gentrifiers who share similar tastes and spaces. In contrast, in peripheral economies, tourism gentrification is heavily influenced by state and private capital initiatives aimed at creating destinations as a means of economic development. Across these contexts, tourism reshapes urban and rural spaces, often leading to residential, commercial, and place-based displacement. Residential displacement occurs as housing is increasingly converted into tourist accommodations, while rising land values accelerate commercial displacement by replacing local stores with visitor-oriented amenities. These processes are accompanied by place-based displacement, where local residents experience tensions as their neighborhoods are transformed into spaces primarily designed for tourism consumption (Cocola-Gant, 2018). Collectively, these changes drive socio-economic inequalities, such as reduced housing accessibility and economic restructuring, while altering spatial landscapes, including the transformation of agricultural and commercial spaces.

Tourism itself is evolving in response to changing consumer demands, technological advancements, and the proliferation of low-cost airlines. Traditional forms of tourism, which prioritized visual observation, have given way to a growing desire for immersive, multi-sensory experiences that foster deeper connections with destinations (Gálvez et al., 2017). This evolution has significant implications for gastronomy tourism and its role in gentrification. High-end dining establishments, such as Michelin-starred restaurants, and viticulture activities have played a critical role in the typology of gastronomy-driven gentrification, raising important questions about how these spaces contribute to displacement and broader socio-spatial transformations.

The role of restaurants on gentrification has been evaluated with different accounts. Restaurants play a significant role in shaping gentrification processes through their cultural, social, and economic impacts on neighborhoods. For example, Hyde's (2014) research from the Downtown Eastside of Vancouver highlights how restaurants frame notions of "authenticity" and "ethical entrepreneurialism" in ways that attract affluent newcomers while reshaping the symbolic value of low-income areas. These establishments, often praised for their eclectic and casual gourmet offerings, reflect broader shifts in high-status consumption from exclusivity to populism. They also underscore tensions between achieving cultural distinction and addressing structural inequalities in gentrifying neighborhoods. Similarly, according to Zukin et al., (2015), online restaurant reviews, such as those on Yelp, contribute to gentrification by constructing positive or negative perceptions of neighborhoods, thus influencing economic investment. Reviews often valorize "authentic" cuisines and locales in ways that favor affluent.

Food, as Lütke and Jager (2021) suggest, transcends its physical purpose, serving as a cultural and spatial force that can create displacement atmospheres. Within these atmospheres, food culture becomes a form of symbolic capital, enabling privileged consumers to assert social distinction and facilitating broader urban development projects (Bourlessas et al., 2020; Kinkaid and Platts, 2024). The quest for authenticity, often tied to food culture, is a powerful driver of urban economic growth and socio-spatial differentiation (Zukin, 2010; Rossi, 2017/2022). Gastronomy tourism, by responding to this demand for authenticity, not only transforms culinary landscapes but also catalyzes gentrification processes.

The dynamics of authenticity and food consumption further illuminate the complexity of urban culinary geographies. Ritzer's (1993) concept of "McDonaldization" captures the standardization and predictability of fast-food culture, appealing to the Fordist "McBody" consumer (O'Neill, 1999, as cited in Bell, 2002). In contrast, the post-Fordist "la petite bourgeoisie nouvelle" (Bourdieu, 1979, as cited in Stock and Schmiz, 2019) consumer seeks authenticity, scarcity, and distinction through high-end, artisanal food experiences. These twin modalities—McDonaldization and authenticity—are interdependent, defining each other through their oppositional characteristics while shaping the socio-spatial dynamics of urban foodscapes (Bell, 2002).

Several key concepts help elucidate the relationship between gastronomy tourism and gentrification. The concept of "foodification," introduced by Bourlessas et al. (2021), critiques the growing emphasis on food culture in urban environments and its gentrifying consequences. Their study on Turin's Porta Palazzo highlights how high-end food spaces create a "displacement atmosphere" through three interrelated elements: discourse, materialities, and practices.

Discourses of food quality and urban regeneration stigmatize traditional markets as outdated, while the aesthetic and material transformation of food venues appeals to affluent consumers seeking distinction. These shifts are accompanied by changes in consumption patterns, favoring knowledge-based, sedentary experiences in new eateries and bars, ultimately contributing to broader urban gentrification and the exclusion of marginalized communities. Complementing this, Lütke and Jager (2021) propose the concept of "gastrofication," emphasizing how the proliferation of gastronomic venues reshapes neighborhoods by catering to elite tastes. While they argue that gastrofication alone does not trigger gentrification, it functions as a key component within broader structural and commercial redevelopment. In a rural context, Nemes and Tomay (2022) analyze the transformation of Hungarian villages into "gastro villages," showing that while gastro-tourism brings economic benefits—such as rising visitor numbers, real estate values, and business activity—it also produces challenges like population displacement, socio-economic inequality, and "split realities" between tourism and local life. The authors stress the need for neo-endogenous development strategies that integrate tourism with local sustainability, cautioning that without such measures, gastro-tourism risks eroding the very cultural and social foundations that make rural destinations attractive in the first place.

When we approach the issue in peri-urban contexts, the initial movement of population in gentrification process takes on a different form as reverse migration. As many study indicate a defining characteristic of gentrification is the migration of middle-class individuals into economically disadvantaged neighborhoods (Lütke and Jager,

2021). Nemes and Tomay (2022) also identify the first stage of gastronomy-driven gentrification as initial attraction due to the unique gastronomic offerings. For a peri-urban or rural context, this movement takes place from metropolitan or urban to peri-urban or rural, which means "reverse migration". As another form of migration, amenity migration which is described as "the movement of largely affluent urban or suburban populations to rural areas for specific lifestyle amenities" (Abrams et al., 2012) gives insight for understanding this type of population movement as well. According to Takahashi et al. (2021), food is an important common value of this type of migration. Nemes and Tomay (2021), similarly, highlights the role of food and gastronomy in creating a romanticized rural idyll, which appeals to urban tourists seeking slower, more authentic experiences.

A cultural political economy perspective provides a valuable framework for analyzing these dynamics, particularly in peripheral regions such as the Mediterranean. As Cocola-Gant (2018) notes, tourism gentrification in these regions has been underexplored compared to studies of advanced capitalist cities in the global North. By examining gastronomy-driven gentrification in the peri-urban context of Urla, Türkiye, this study highlights how cultural and economic processes converge to reshape local geographies.

Within this context, the key indicators of gastro-driven gentrification include the presence of gastronomy-related planning actions, the rise of Michelin-starred restaurants, the increased tourism revenues, the commercialization of local culinary heritage, and the proliferation of gastronomy-related events such as food festivals. These processes are accompanied by economic transformations, including rising property values and shifts in business types, as well as social impacts, such as demographic changes and socio-economic inequalities. Physical transformations, such as land-use changes and urban planning interventions, further illustrate the profound effects of gastronomy tourism on peri-urban geographies. Together, these interconnected processes provide a comprehensive framework for understanding the socio-spatial dynamics of gastronomy-driven gentrification.

3. The Case Study: Urla, İzmir

Urla in the city of İzmir, with its population of 77.599 (TURKSTAT, 2023), a district in western Türkiye, is located within the Aegean Region. Situated approximately 35 kilometers from İzmir's city center, Urla occupies a strategic position along the southern coast of the İzmir Peninsula, extending from coastal regions to inland areas (Fig. 1). Known historically for its olive groves, viticulture, vineyards, and maritime activities, Urla's significance as a center of commerce and agriculture dates back to ancient times (Urla Şarapçılık, n.d.). Today, Urla exhibits a distinct peri-urban character, blending rural and urban features, making it an ideal site for analyzing the socio-spatial dynamics of peri-urban transformations. Its recent evolution into a hub for gastronomy tourism and reverse migration has accelerated significant changes in its socioeconomic and spatial structures, offering valuable insights into the complex interplay of tourism, urbanization, and gentrification.

The genesis of Urla's gastronomic transformation is deeply rooted in planning initiatives and infrastructural developments spanning decades. Planning decisions from the 1950s onward illustrate Urla's shifting identity. During this period, the district's agricultural character began to integrate with a second-home-focused structure, driven by İzmir's coastal development strategies. The 1955 İzmir Master Plan further reinforced Urla's connectivity to İzmir along the Çeşme-Pınarbaşı axis (Güner, 2006), while the 1973 İzmir Master Plan designated the district and its surroundings as key areas for tourism (Arkon & Gülerman, 1995) and second-home production, solidifying its identity as a summer resort destination.

The 1980s marked a turning point with the planning of the İzmir-Çeşme Highway. With the opening of the Çeşme Highway in 1994, this infrastructure development significantly enhanced Urla's accessibility, catalyzing an influx of second-home developments along its coastline (Güner, 2006). The leading factor in the district behind the second-home dominated development, especially from the mid-1990s and rapidly increasing from the 2000s to the present, is the İzmir-Çeşme Highway passing through the district of Urla (Can et al., 2018). Although its center is approximately 40 km far from the city center of İzmir, Urla has become an accessible site of living, thanks to the construction of the highway in the mid-1990s.

Figure 1. The Location of Urla

Zoning laws enacted during the same period accelerated speculative real estate activities, transforming the district's spatial dynamics and by the late 1990s, Urla's rural identity began to erode, with luxury housing projects and gated communities driving rural transformation and early stages of gentrification (Avar et. Al, 2024). The establishment of the İzmir Institute of Technology (İZTECH) in 1992, further contributed to these shifts, increasing the young population and employment opportunities, while fostering socioeconomic changes (Can et al., 2018).

In the 2000s, Urla began to attract high-income groups as a desirable living space. Efforts to revive traditional agricultural activities, particularly viticulture and olive groves, were initiated under sustainable development strategies led by the İzmir Development Agency (İZKA) and İzmir Metropolitan Municipality (Avar et. Al, 2024). These strategies emphasized Urla's gastronomic potential and introduced projects promoting sustainable tourism and agrotourism, leading to the rise of high-end wineries, luxury restaurants, and countryside hotels, which have become defining features of Urla's transformation as well as seasonal festivals promoting local products, such as the Artichoke Festival and Herb Festival (Avar et. Al, 2024). These developments reinforced Urla's reputation as a center for gastronomy and tourism.

By 2013, the establishment of the Urla Vineyard Road marked a significant milestone, attracting luxury wine producers and high-end gastronomic establishments. Events organized to promote local culinary heritage, including thematic festivals, contributed to the region's identity as a gastronomic destination. "The Peninsula Sustainable Development Strategy" (IZKA, 2014) further positioned Urla vision as "an alternative living city with its natural texture intact, cultural richness preserved, planned, contemporary culture and art city, world-renowned for its olive oil and wines, prominent for agrotourism and gastronomy tourism, developed sea tourism, productive and participatory."

In Izmir Regional Plan (IZKA, 2015), Urla was identified within regional settlement belt together with Torbalı, Kemal-

paşa, and Aliağa. Together with these districts, Urla was planned as a regional growth focus which are districts that are the gateway to the region, where certain service functions are concentrated and developed to serve their surroundings and where innovative sectoral formations with high added value are supported.

The COVID-19 pandemic in 2020 accelerated reverse migration trends (the highest annual growth rate in last 15 years in 2021 with 4,58% (TURKSTAT, 2023)), with many individuals relocating from urban centers like İzmir to Urla in search of lifestyle changes. This shift coincided with the district's emergence as a global gastronomy tourism destination, marked by the opening of Michelin-starred restaurants and the growing popularity of local vineyard houses, wine production facilities, and farm-to-table restaurants. These developments have solidified Urla's position within the international gastronomy tourism market, aligning with sustainable gastronomy principles that prioritize the use of local products and traditions.

In 2023, when the Michelin guide included İzmir and Bodrum in its selection for the first time outside of Istanbul in Türkiye, Urla achieved significant success by receiving 6 Michelin stars alone. This accomplishment is particularly noteworthy when compared to Athens, a city with a population of 5.5 million, which received five Michelin stars in 2019. This distinction underscores Urla's emergence as a significant gastronomic destination, highlighting the region's dedication to culinary excellence and its potential to rival established European culinary hubs (Özkök, 2023a). At this point, Urla has 10 Michelin-starred restaurants.

In current conditions of urban development, Urla serves as a microcosm for understanding the impacts of gastronomy tourism on peri-urban geographies. Its evolution reflects the complex interplay between infrastructure development, planning decisions, reverse migration, and the commodification of local culture. The district's rise as a gastronomy hub, particularly through the influence of Michelin-starred restaurants, exemplifies how tourism can drive significant socioeconomic and spatial transformations in peri-urban contexts. As such, Urla offers a valuable case study for exploring the intersections of tourism, gentrification, and urban justice in rapidly transforming regions.

4. Methodology

This study employs a qualitative case study methodology to explore the interrelated dynamics of gastronomy tourism, gentrification, and reverse migration in the peri-urban context of Urla, Türkiye. The case study approach is particularly suited to uncovering the complex, place-based interactions between socio-economic processes and spatial transformation.

Data were gathered through a combination of secondary sources, including planning documents, regional development reports, academic literature, and statistical data from institutions such as TURKSTAT, the Ministry of Culture and Tourism, and the İzmir Metropolitan Municipality. These sources of data provided insights into demographic shifts, economic indicators, and tourism development patterns.

To analyze spatial change, land cover data from ESRI for the years 2017 and 2023 were used. GIS-based visual analysis was conducted to identify changes in built-up areas, cropland, rangeland, and tree-covered zones. This spatial data supported the assessment of land use transformations linked to tourism and urban expansion.

By triangulating spatial, statistical, and conceptual data, the methodology aims to reveal the socio-spatial consequences of tourism-driven transformation in peri-urban areas, with Urla serving as a representative and timely case.

5. The Transformation of Urla Within the Broader Contexts of Gastronomy and Gentrification

5.1. Socioeconomic Indicators

Urla has undergone significant demographic, socioeconomic, and spatial transformations in recent decades, driven by an influx of upper-middle-class counter-urbanizers (Avar et al., 2024) and a burgeoning gastronomy tourism sector. These changes have redefined the district's identity and dynamics, positioning it as a prominent

peri-urban destination. The demographic growth in Urla has been remarkable. Its population increased from 26,066 in 1980 to 77,600 in 2023, reflecting a steady rise over the decades (TURKSTAT, 2023).

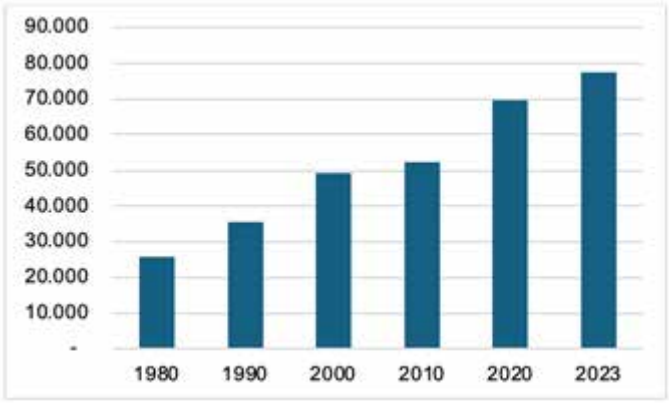

Figure 2. Urla Population Change Between 1980 - 2023

This growth accelerated particularly after the COVID-19 pandemic in 2021, outpacing comparable peri-urban districts such as Çeşme. The influx of counter-urbanizers, predominantly white-collar professionals commuting from İzmir, has been a key driver of this population increase (Avar et al., 2024). These newcomers have brought with them higher education levels and a relatively affluent socioeconomic profile, contributing to Urla's distinction as more developed in terms of education and socio-economic status compared to Türkiye's and İzmir's averages. In terms of the rate of university and postgraduate students, Urla ranked 6th with 30.6% in 2020, the year the pandemic began, as of 2023 Urla ranks 4th with 34,5%, among the districts of İzmir, after the central districts of Güzelbahçe, Karşıyaka and Narlıdere (İzmir Büyükşehir Belediyesi, 2023). However, while Urla surpasses Çeşme in education levels, it lags behind in overall socio-economic status as measured by wealth indicators (Endeksa, n.d.).

Socio-economic data further illustrate Urla's evolving profile. According to the Socio-economic Development Index (SEGE), Urla ranked 32nd among 858 districts in 1996, 43rd in 872 districts in 2004 (T. C. Devlet Planlama Teşkilatı, 1996 / 2004), dropped to 93rd in 2017, and climbed back to 59th in 2022 (T. C. Sanayi ve Teknoloji Bakanlığı, 2017 / 2022). These fluctuations reflect both the challenges and opportunities associated with its rapid transformation.

The district's fertile lands, close proximity to İzmir, and the migration of middle and upper-income groups have fostered rural entrepreneurship, altering livelihoods in the countryside and driving economic diversification (Güçü, 2022). The rise of gastronomy tourism has also contributed significantly to Urla's development. The number of facilities with operation and investment certificates grew from just two facilities with 154 beds in 2012 to 21 facilities with 514 beds in 2023, illustrating the rapid expansion of tourism infrastructure (T.C. Kültür ve Turizm Bakanlığı, 2023). This development has been accompanied by the establishment of high-end wineries, restaurants, and farm-based businesses, further solidifying Urla's status as a gastronomic hub. However, this growth has also driven significant changes in the real estate market. Between 2018 and 2024, the square meter prices of houses for sale in Urla increased by 1,432%, nearly double the rate observed in Çeşme (Endeksa, n.d.), highlighting the intense speculative pressures on Urla's land market (Uştuk, 2024).

These economic and demographic shifts have not been without consequences for native residents. The influx of affluent settlers, particularly from İstanbul, has created an expensive standard of living that many long-term residents find difficult to sustain. Rising land and rental prices have contributed to the displacement of native inhabitants, driven in part by what Uştuk (2024) describes as an "exile strategy" employed by new elite settlers to fulfill their gentrification demands. This gentrification process, coupled with the increasing commodification of local culture and heritage, has reshaped Urla's socio-spatial fabric.

In sum, Urla's transformation over the past decades illustrates the multifaceted impacts of counter-urbanization, rural entrepreneurship, and gastronomy tourism. While these developments have brought economic growth and enhanced its cultural appeal, they have also exacerbated socio-spatial inequalities and raised critical questions about sustainability and inclusivity. As the district continues to evolve, the tension between preserving local identity and accommodating the demands of its affluent newcomers will remain a key challenge.

5.2. Spatial Indicators

The spatial transformation of Urla, influenced by gastronomy tourism and related development, reveals significant changes in land use, particularly in agricultural and rangeland areas. While agricultural production continues on some lands, rural livelihoods are increasingly diversified with new functions such as consumption and experience, which are associated with the growing gastronomic sector (Güçü, 2022). However, these shifts in land use reflect a broader trend of changing priorities in rural areas, where production is supplemented by tourism and leisure activities.

Between 2012 and 2021, Urla's total agricultural land decreased significantly, shrinking from 9,421 hectares to 6,869 hectares, marking a substantial reduction in the district's agricultural footprint (Urla Belediyesi, 2015; T.C. Tarım ve Orman Bakanlığı İzmir İl Müdürlüğü, 2023). This trend highlights the increasing pressure on agricultural land as it is repurposed for urban development and tourism-related activities.

In order to understand the effects of these changes on the peri-urban geography of Urla, land cover change was analyzed using land cover data for the years 2017 and 2023 obtained from ESRI. When examining land use changes across the entire district between 2017 and 2024, built areas increased by 18%, reflecting the district's rapid urbanization. Concurrently, cropland decreased by 27%, while rangeland saw an 8% decline, and tree-covered areas increased slightly by 5% (Table 1). These changes underscore the competing demands on land as urban development and tourism infrastructure expand at the expense of agricultural and grazing areas.

Table 1. Urla District Land Cover Change (2017-2023)

	Built Area	Crops	Rangeland	Trees
2017	7.629	3.332	26.830	35.063
2024	9.041	2.426	24.675	36.954
Percentage Change	18%	-27%	-8%	5%

The land cover maps of 2017 and 2023 visually reinforce these trends. The expansion of built-up areas, particularly around Urla's urban core and coastal zones, is clearly observable, signaling intensified urbanization. Simultaneously, there is a noticeable reduction in cropland and rangeland, especially in peripheral and formerly agricultural zones, indicating the displacement of productive land uses. While there is a slight increase in tree-covered areas, the overall trend reflects a shift away from traditional agricultural and pastoral land uses toward residential, touristic, and leisure-oriented development. This spatial reconfiguration highlights the competing pressures on land and the transformation of Urla's peri-urban geography under the influence of gastronomic and lifestyle-oriented change.

6. Discussion and Conclusion

Urla's transformation illustrates how gastronomy tourism, when combined with reverse migration and planning strategies, can rapidly reshape peri-urban geographies. The concept of gastro-driven gentrification captures the dynamics at play—where high-end restaurants and lifestyle-driven newcomers contribute to rising land values, changing land use patterns, and the displacement of long-term residents.

While these developments have boosted Urla's global visibility and economic appeal, they have also intensified

socio-spatial inequalities and placed pressure on agricultural landscapes. Land cover analysis confirms a shift from productive uses to consumption-oriented spaces, reflecting broader tensions between development and sustainability.

Ultimately, Urla's case underscores the need for planning approaches that prioritize spatial justice, ecological preservation, and community inclusion. Without such efforts, gastronomy-led growth may deepen inequalities and erode the very cultural and environmental assets it seeks to celebrate.

Cultural route perspective: heritage tourism value evaluation and route optimization of the Silk Road (Shaanxi section)

Wei-ning Shi*, Zuo-bin Wu, Chao Ma
School of Architecture, Xi'an University of Architecture and Technology, Xi'an 710048, People's Republic of China
Email:1591842513@qq.com

Abstract
Spanning millennia, the Silk Road connected Eastern and Western civilizations. Xi'an served as its eastern terminus, while the Shaanxi province segment stands as the core protection zone for the route. Existing research often focuses on isolated heritage sites, neglecting their historical links to the route and undermining its cultural integrity.From the perspective of cultural routes, the study identifies 82 potential heritage sites and establishes a three-tier evaluation system. The tourism value of each heritage resource is quantified through an analytical model incorporating historical significance, route connectivity, and visitor experience metrics. Through quantitative analysis, we assess their tourism value and optimize routes to enhance visitor experiences, strengthen cultural coherence, and offer a model for global cultural route tourism planning.

Keywords: cultural routes, silk road, tourism value evaluation

1. Introduction

The Silk Road emerged during the reign of Emperor Wu of the Western Han Dynasty (141–87 BC), with its eastern terminus at Han Chang'an City (present-day Weiyang District, Xi'an) [1]. As the historical starting point and core economic zone of the Silk Road, Shaanxi Province hosts an extensive network of routes and abundant cultural heritage along its course, bearing witness to the thoroughfare's origins, growth, and prosperity [2,3]. In recent years, the rapid expansion of cultural heritage tourism has seen a proliferation of Silk Road-themed cultural tourism projects. However, existing tourism activities remain predominantly concentrated at iconic heritage sites such as the Big Wild Goose Pagoda and Little Wild Goose Pagoda, resulting in tourists' limited ability to grasp the overall historical context and cultural connotations of the Silk Road systemically.

As a key catalyst for socioeconomic development, tourism activities undertake a dual mandate: cultural heritage dissemination and heritage conservation. While existing research on Silk Road heritage tourism has focused primarily on heritage value, tourism development, and tourist experience, comprehensive investigations into the intrinsic value of heritage tourism remain limited [4]. Conducting systematic evaluations of heritage tourism value not only clarifies development potentials but also identifies challenges in historical and cultural heritage management, enabling the formulation of targeted activation strategies.

As a distinct category of cultural heritage, cultural routes embody the exchange of cultures, ideas, knowledge, and values arising from human cross-regional interactions, forming dynamic systems intertwined with their historical contexts and cultural legacies. The Silk Road, as a paradigmatic cultural route heritage, not only exhibits the characteristics of conventional cultural heritage but also demonstrates distinct integrity and systemicity owing to its linear spatial configuration.

Current academic research on the tourism value of the Silk Road primarily relies on theoretical frameworks for evaluating traditional cultural heritage. However, it fails to fully address the unique attributes of linear cultural heritage, which differ from dotted and planar heritage forms, and lacks a holistic perspective in the value assessment process [5,6]. Consequently, developing a tourism value evaluation model aligned with the characteristics of cultural route heritage represents a critical theoretical priority in contemporary heritage tourism research.

This study focuses on the Shaanxi segment of the Silk Road, constructing a three-tier evaluation system—comprising target layer, criterion layer, and index layer—tailored to the tourism value assessment of cultural route heritage. By integrating the analytic hierarchy process (AHP) and geographic information system (GIS) technology, we conduct systematic value assessments for 82 heritage sites in Shaanxi. On this basis, we optimize tourism

route planning through spatial visualization tools, aiming to expand heritage experience options for tourists and enhance their holistic understanding of the Silk Road's historical connotations. The research results provide theoretical support and practical guidance for the sustainable development of heritage tourism in the Shaanxi segment of the Silk Road.

2. Research methods and data sources

2.1 Evaluation method of heritage tourism value

This study employs a mixed-methods approach, integrating qualitative and quantitative research, to systematically develop an evaluation system for the heritage tourism value of the Silk Road (Shaanxi segment). In the qualitative research stage, a systematic literature review is conducted to synthesize international cultural heritage protection frameworks and relevant domestic and foreign research, from which initial evaluation indicators are extracted. Building on the typical characteristics of cultural routes, such as historical continuity and spatial connectivity, characteristic indicators are systematically refined and expanded through thematic analysis. The process concludes with multiple rounds of expert consultation using the Delphi method, ultimately leading to the establishment of an evaluation system comprising 4 criterion layers and 12 index layers. During the quantitative research phase, the Analytic Hierarchy Process (AHP) is employed to assign weights to evaluation indices, while kernel density estimation and weighted overlay analysis using the ArcGIS platform are utilized to visually represent the assessment results. The study culminates in the optimization of cultural tourism routes based on the evaluation outcomes.

2.2 Evaluation index data sources

The research data is sourced from multiple verified channels, including (1) topographic maps obtained from the Standard Map Service System of the National Administration of Surveying, Mapping and Geoinformation; (2) road network data provided by the Resource and Environmental Science Data Center of the Chinese Academy of Sciences; (3) heritage site lists and attribute information derived from the Shaanxi Provincial Cultural Relics Bureau's cultural relics census; (4) POI data for public service facilities such as dining, hotels, and parking lots collected via the Baidu Maps platform; (5) historical records including Hanshu and Tangshu retrieved from the Chinese Basic Ancient Books Library; (6) and results from structured questionnaires administered to experts and tourists.

3. Construction of tourism value evaluation system

3.1 Selection of evaluation indicators

In constructing the evaluation index system, this study adheres to the principles of hierarchy, guidance, and simplicity, adopting a three-tiered structure consisting of a target layer, criterion layer, and index layer. This framework ensures both systematic evaluation and precise measurement across hierarchical levels. The target layer focuses on assessing the heritage tourism value of the Silk Road (Shaanxi segment) through a cultural route lens. The criterion layer delineates key evaluation dimensions, while the index layer operationalizes these dimensions into quantifiable metrics. The final index system was finalized via the Delphi method, involving multiple rounds of expert consultation for indicator screening and categorization. The evaluation index system is presented in Fig. 1.

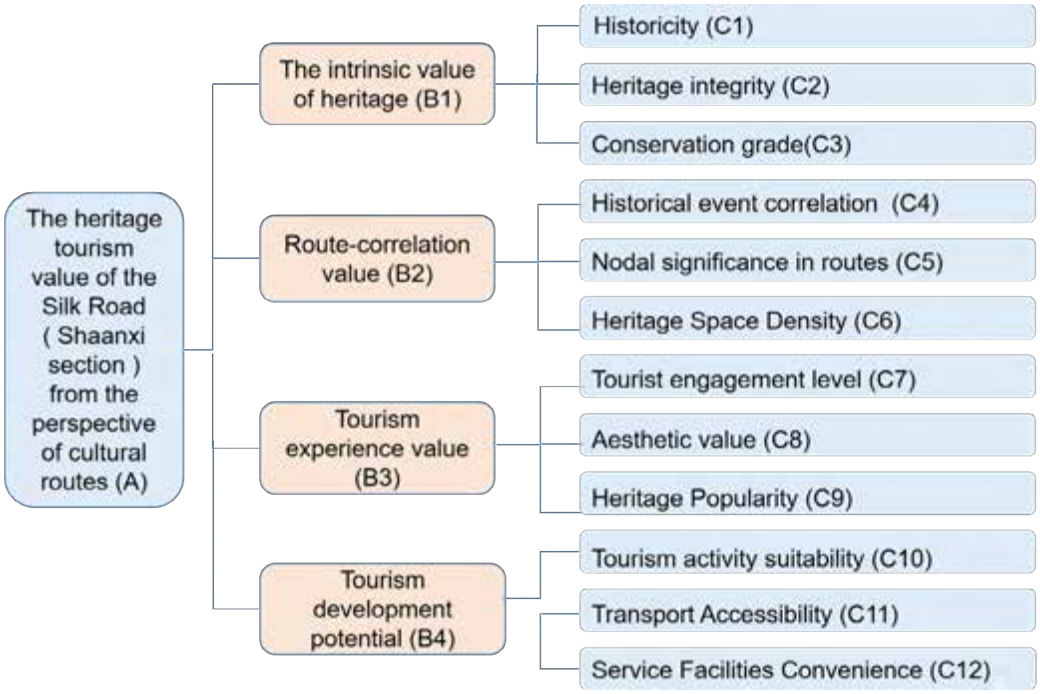

Figure.1 Evaluation System for the Tourism Value of the Silk Road Heritage in Shaanxi from the Perspective of Cultural Routes

The intrinsic value of heritage (B1) manifests its irreplaceable and essential worth as a self-contained entity. Drawing on the cultural significance framework outlined in ICOMOS' Barra Charter (2013) [7], the criterion layer identifies indicators across three dimensions: Historic Evidence, Material Fabric, and Social Connections. The Historicity of heritage carry the Silk Road's diachronic value, while its Heritage integrity dictates the preservation state of these value-laden material carriers. conservation grade reflects societal institutional recognition of heritage value, serving as an important marker of the social consensus surrounding its cultural significance.

Route-correlation value (B2) constitutes the core dimension of heritage evaluation from the cultural route perspective. Its indicators encompass Historical event correlation, Nodal significance in routes,and Heritage Space Density. The historical event correlation index measures the extent to which a heritage site is connected to major historical processes. Drawing on Norbert Schulz's Place Theory [8], historical events infuse spaces with spiritual connotations, as the occurrence of significant historical milestones often endows specific locations with cultural significance transcending their material form. The nodal significance in routes assesses the functional role of heritage sites within the network, evaluating their position and influence in facilitating historical interactions and exchanges along the route. Building upon the central place theory in transportation geography [9], key nodes along cultural routes often exhibit higher accessibility and functional complexity, serving as critical markers of the routes' historical development and evolution. The heritage Space Density enables the quantification of spatial continuity along the route [10]. The spatial density index of heritage sites is derived using kernel density analysis in ArcGIS, calculating the number of heritage sites per square kilometer and their nearest neighbor index to determine the final evaluation score.

Tourism experience value (B3) evaluates heritage tourism products from the tourists' perspective, encompassing three indicators: Tourist engagement level, Aesthetic value, Heritage Popularity. Drawing on the World Tourism Organization's (UNWTO, 2018) research on tourist behavior, which indicates that 73% of travelers prefer culturally iconic destinations [11], popularity serves as a measure of public awareness of heritage and directly influences tourists' decision-making [12]. Engagement reflects the depth of tourists' participation and is a key metric for assessing the effectiveness of heritage tourism development [13]. Building on Berlyne's Aesthetic Response The-

ory (1971), visual stimuli directly impact tourists' emotional arousal and willingness to stay [14]. Heritage sites with stronger aesthetic appeal evoke tourists' aesthetic pleasure through visual salience, thereby enhancing the overall experience quality [15].

Tourism development potential (B4) are evaluated through three key dimensions: Tourism activity suitability, Transport accessibility, and Service facility convenience. Tourism activity suitability systematically assesses the environmental carrying capacity of the heritage site's surrounding area, reflecting the feasibility of developing heritage tourism under the premise of ecological sustainability and serving as a foundational indicator for tourism construction planning. Transport accessibility is measured by using ArcGIS to calculate the proximity of heritage sites to various road networks (expressways, national highways, provincial roads), thereby evaluating the ease with which tourists can reach their destinations. Service facility convenience, positively correlated with tourism experience quality, is determined through Kernel Density Estimation to analyze the agglomeration patterns of catering, accommodation, medical, and other supporting facilities, providing a quantitative measure of regional service accessibility [16].

3.2 Determination of index weight

In evaluation systems, index weights are quantitative values assigned to reflect the relative importance of each indicator, representing their contributions to the overall assessment [17]. Each weight is normalized such that the sum of all weights equals 1 (or 100%). Here, we employ the analytic hierarchy process (AHP) to determine index weights. First, a judgment matrix was constructed using the 1–9 scale method, and questionnaires were distributed to 24 experts specializing in tourism planning, heritage protection, and related disciplines. Twenty valid responses were received, yielding an 83.3% response rate. Consistency of the judgment matrices was verified using Yaahp software, confirming that all matrices satisfied the consistency ratio criterion [18]. Arithmetic means of the valid weighted judgments were calculated to derive the final weights for each index element, presented in Table 1.

Table 1. Weighting of Heritage Tourism Value Indicators

Criterion layer	Indicator layer	Weight	Scoring standard				
			20	40	60	80	100
Heritage ontology value (B1) (0.21)	Historicity (C1)	0.06	Ming-Qing dynasty	Song-Yuan dynasty	Sui-Tang dynasty	Wei jin southern and northern dynasties	Han Dynasty and before
	Heritage integrity (C2)	0.07	Only the remains of the site	Local retention	Subject retention	Relatively complete	Complete
	Conservation grade (C3)	0.08	Unrated	Municipal	Provincial	National	World-class
Line correlation value (B2) (0.31)	Historical event correlation (C4)	0.12	Very poor	Poor	General	Important	Very important
	Nodal significance in routes(C5)	0.11	Very poor	Poor	General	Important	Very important
	Heritage Space Density (C6)	0.08	The nearest neighbor index (NNI) of cultural heritage points was calculated using kernel density analysis and normalized.				
Tour experience value (B3) (0.22)	Tourist engagement level (C7)	0.09	Very poor	Poor	General	Important	Very important
	Aesthetic value (C8)	0.07	Very poor	Poor	General	Important	Very important
	Heritage Popularity (C9)	0.06	Unknown	Regional famous	Province famous	Country famous	Word famous
Tourism exploitation condition (B4) (0.26)	Tourism activity suitability (C10)	0.10	Very poor	Poor	General	Suitable	Very suitable
	Transport Accessibility (C11)	0.10	Very poor	Poor	General	Suitable	Very important
	Service Facilities Convenience (C12)	0.06	Very poor	Poor	General	Convenient	Very convenient

The results show that the connectivity of routes has the highest weight, which validates the core perspective of the cultural routes theory. The value of heritage is not only reflected in individual characteristics but more importantly in its interconnections within the route system. Meanwhile, the relatively high weight of tourism development conditions also indicates that, on the premise of prioritizing protection, rational tourism utilization is an important means of realizing the inheritance of heritage value.

4. Heritage identification and tourism value evaluation

4.1 Potential Heritage Identification

This study systematically compiles official datasets, including the Shaanxi Province Unmovable Cultural Relics List (2020 Edition), to conduct a comprehensive inventory of cultural heritage resources in Shaanxi Province. Multi-source data cross-validation ensures that each potential heritage site satisfies the following criteria: (1)

possesses physical remains confirmed by field surveys; (2) has complete cultural relics archive records; and (3) its historical context is traceable to periods relevant to the Silk Road. Extending spatial analysis across the entire province of Shaanxi to account for historical variations in the Silk Road's cultural influence, we identify heritage elements significantly associated with the route. A total of 82 core heritage sites are selected, including seven inscribed in the Silk Road: The Road Network of the Chang'an-Tianshan Corridor World Cultural Heritage list.

Table 2. Statistics of Potential Heritage Sites

Serial number	Heritage name	Dynasty	Seat	Type
1	Dayan Pagoda	Tang	Xi'an city	Ancient architecture
2	Small Wild Goose Pagoda	Tang	Xi'an city	Ancient architecture
3	Han Chang'an City Site	Western Han	Xi'an city	historic urban archaeological sites
4	Xingjiao Temple Pagoda	Tang	Xi'an city	Ancient architecture
5	Tomb of Zhang Qian	Han	Hanzhong city	Ancient burials
6	Maoling Mausoleum	Western Han	Xianyang city	Ancient burials
7	kumarajiva dagoba	Tang	Xi'an city	Ancient architecture

4.2 Evaluation of heritage tourism values

Using the evaluation framework for the heritage tourism value of the Silk Road (Shaanxi segment) established above, assessments are categorized as quantitative or qualitative based on data type. Quantitative indicators encompass C1 (Historicity), C3 (Conservation grade), C6 (Heritage Space Density), C11 (Transport Accessibility), and C12 (Service Facilities Convenience). For C1 and C3, data derived from the authors' field surveys and literature reviews were processed in SPSS for sorting, calculation, and dimensionless normalization [19]. Spatial analyses for C6, C11, and C12 were performed using ArcGIS 10.8. Specifically, C6 employs kernel density estimation to quantify heritage clustering (Fig. 2(a)), while C11 utilizes multi-ring buffer analysis (3,000m/5,000m/10,000m/20,000m) to calculate road network coverage (Fig. 2(b)) [20]. C12 integrates POI kernel density and entropy weight methods to assess service facility distribution intensity (Fig. 2(c)) [21].

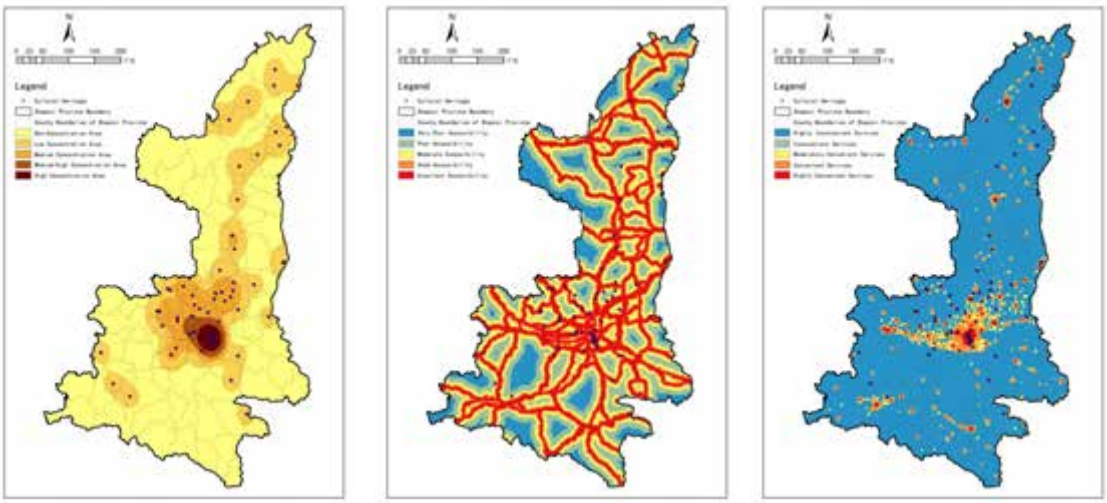

Figure 2. (a) Spatial Density Evaluation of Heritage Sites (b) Road Network Accessibility (c) Service

Facility Convenience Assessment

Qualitative indicators encompass C2 (Heritage integrity), C4 (Historical event correlation), C5 (Nodal significance in routes), C7 (Tourist engagement level), C8 (Aesthetic value), C9 (Heritage Popularity), and C10 (Tourism activity suitability). C2, C4, and C5 were determined via the Delphi method, involving three rounds of Likert 5-scale scoring by six experts with expertise in Silk Road heritage. For C7–C9, data were collected through online surveys, yielding 36 valid responses. C10 was assessed using the Limits of Acceptable Change (LAC) framework, where three ecological experts integrated remote sensing imagery, field monitoring data, and construction carrying capacity analyses to evaluate biological sensitivity [22].

4.3 Analysis of value evaluation results

Using the developed comprehensive evaluation framework, this study systematically assesses the tourism value of 82 heritage sites in the Shaanxi segment of the Silk Road, classifying them into three categories based on weighted scores (Fig. 3).

Figure 3. Statistical Results of Heritage Evaluation

Class I Heritage (≥80 points) includes 9 sites, comprising 11.0% of the total. These are core heritage sites with outstanding historical value and tourism development potential, such as the Han Chang'an City Ruins (92.6 points) and the Giant Wild Goose Pagoda (92.4 points). These sites hold an irreplaceable important position in the development of Silk Road tourism. Class II Heritage (70-80 points) includes 30 sites, accounting for 36.6%. These sites have medium tourism value and can serve as important supplements to the Silk Road tourism routes, such as Zhang Qian's Tomb (79.2 points) and the Daxingshan Temple (79.2 points). Class III Heritage (≤70 points) includes 43 sites, accounting for 52.4%. These sites have relatively limited tourism development value and can be considered as optional visiting points.

Spatially,Class I Heritages exhibit pronounced clustering, predominantly concentrated in the core region of Xi'an (Fig. 4). Class II Heritages are primarily distributed in peripheral regions of Xi'an and Xianyang cities, while Class III Heritages are scattered along historical ancient roads. This distribution pattern strongly aligns with the historical commercial routes and regional development priorities of the Silk Road, reflecting the intrinsic link between heritage value and historical context.

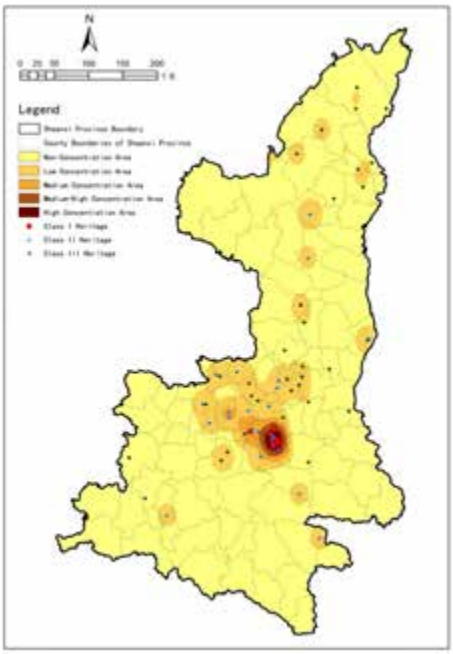

Figure 4. Comprehensive Heritage Evaluation Results

5. Optimization of tourist route

Leveraging systematic evaluations of 82 heritage sites, this study uses ArcGIS network analysis tools to incorporate national and provincial transport network data (expressways, national highways, provincial roads) to optimize Silk Road tourism routes. By designating Class I Heritage sites as mandatory nodes and Class II and Class III Heritage sites as optional nodes, and optimizing for the shortest path while integrating constraints such as road classification and traffic capacity, we employ ArcGIS network analysis to model route configurations. Following iterative model runs and manual refinement, a complete cultural tourism route for the Silk Road (Shaanxi segment) is finalized (Fig. 5). The route efficiently connects 9 core heritages, 12 secondary heritages, and 8 tertiary heritages, enabling systematic exploration of diverse heritage resources and immersive engagement with the historical and cultural continuum of the ancient Silk Road.

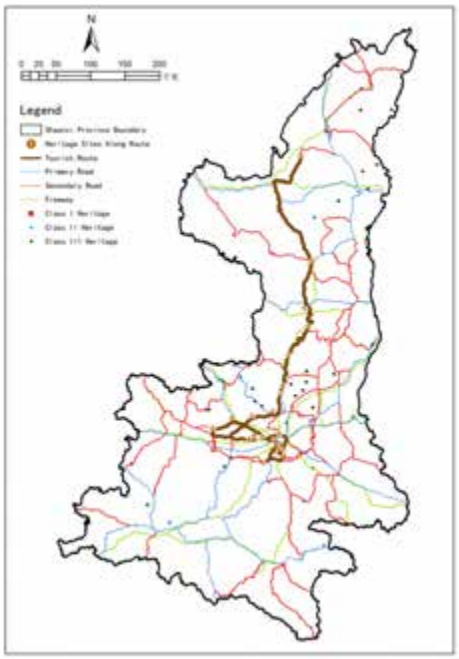

Figure 5. Cultural Tourism Route of the Silk Road (Shaanxi Section)

6. Conclusion

This study introduces an innovative framework for evaluating heritage tourism value, systematically constructing a multidimensional assessment system. Compared with conventional approaches, it features three distinct advances: (1) Emphasizing the overall value of cultural routes, it quantifies the historical connections between heritage sites and routes, fully presenting the characteristic of cultural routes that "the whole is greater than the sum of its parts." (2) It establishes a multidisciplinary evaluation dimension, comprehensively considering factors such as nodal significance in routes, tourism development, and visitor experience need. (3) By utilizing the ArcGIS platform for geospatial quantitative analysis, it significantly enhances the scientific rigor of evaluations.

This study still has limitations, including insufficient objectivity in the evaluation process and limited representativeness of evaluation subjects. Future research should focus on improving quantitative methods for indicators, establishing a multi-stakeholder participation mechanism, and expanding the scope of case applications. These improvements will enhance the scientific rigor and generalizability of the evaluation system, thereby providing more robust theoretical support and practical guidance for the sustainable development of cultural route heritage tourism.

Energy Justice in Underprivileged Neighbourhoods: Reimagining Energy Transitions Through Community Storytelling

Lena Verlooy

Email: lena.verlooy@ugent.be

Abstract
Achieving just energy transitions in underprivileged neighbourhoods is essential for sustainable urban renewal yet remains difficult. Residents often face energy injustices due to unaffordable and inaccessible renewables. Structural inequalities further limit collective action and community cooperation, depriving inhabitants of the resources and opportunities needed to develop their capabilities. While energy justice literature addresses distributional, recognitional, and procedural inequalities, it often overlooks deeper constraints on people's agency. In response, this paper proposes storytelling as a creative and participatory method to strengthen agency in underprivileged neighbourhoods. Storytelling enables residents to imagine alternative futures, build shared narratives, and engage with energy transitions on their own terms. This conference paper offers an initial exploration of how this approach can inform future research in the Watersportbaan neighbourhood.

1. Introduction

Achieving fair and inclusive urban energy transitions is a pressing societal challenge, particularly in inner-city underprivileged neighbourhoods. While the energy justice literature addresses distributional, recognitional, and procedural inequalities, it often overlooks deeper constraints on people's agency. We argue that agency represents a critical "missing foundation" in the energy justice framework. It falls short in addressing structural barriers that constrain residents' capacity to act. In underprivileged neighbourhoods, where residents struggle with immediate survival needs, deteriorating housing conditions, social stigmatization, and uncertain futures, the ability to envision and participate in long-term energy transitions is severely limited.

Drawing on feminist ethics of care, we explore storytelling as both a methodological tool and a means to strengthen agency among marginalised communities. Storytelling can make energy systems more visible and relatable, democratise energy conversations by lowering barriers to participation, and help communities envision alternative futures beyond current constraints.

The empirical research is situated in the Watersportbaan neighbourhood in Ghent, Belgium, characterised by high-rise social housing, deteriorating living conditions, and planned large-scale redevelopment. Through exploratory fieldwork, we identify key narratives that reveal the complex socio-spatial dynamics shaping residents' relationship with energy systems and their capacity for engagement.

The scope of this paper encompasses two interconnected objectives: first, to establish the theoretical foundation for why storytelling represents a transformative tool that can address the agency deficit in current energy justice frameworks; and second, this paper aims to present our initial findings through a collection of key narratives that illustrate the complex socio-spatial dynamics limiting residents' energy agency, and demonstrate how storytelling can engage with and potentially transform these constraints. Rather than presenting definitive conclusions, this paper establishes the groundwork for future co-creation activities where these exploratory narratives will be developed into community storylines to eventually be meaningfully implemented into the neighbourhood energy transition plan, ultimately contributing to more just energy futures.

2. Energy justice

Energy justice is defined as "a global energy system that fairly distributes both the benefits and burdens of energy services, and one that contributes to more representative and inclusive energy decision making" (Sovacool et al., 2017, p. 677)2017. The concept is rooted in environmental justice literature, which was initially used by researchers and activists to uncover the uneven distribution of environmental risks from hazardous facilities, disproportionately burdening people with lower incomes or people of colour (Carley and Konisky, 2020; Iwińska, Lis and Mączka, 2021). Energy justice is gaining popularity in academic literature (Jenkins et al., 2021). The concept has been widely used for energy scholarship in humanities and social sciences, as energy justice is a helpful concept for dissecting the different justice dimensions of various energy-related issues (Iwińska, Lis and Mączka, 2021).

Typically, energy justice literature deals with three tenets of justice. Distributional energy justice refers to the equal distribution of risks and benefits, procedural justice to open-decision making processes, and recognitional justice to the recognition of underprivileged groups (Walker and Day, 2012). These tenets are deeply tied to another, as an inequitable distribution, a lack of recognition and limited participation can influence another, further (re)producing (energy) injustices (Schlosberg, 2004).

Higher risks of energy injustices are reported in relation to the energy transition. The transition may, at least on the short term, lead to higher costs, due to new investments in infrastructure or technology, causing distributional energy injustices. Higher costs may impact low income households more, who often already pay a larger share of their income on the energy bill (Walker and Day, 2012; Carley and Konisky, 2020). This may be compounded even more, as low income households are likely to live in lower efficiency housing, with outdated energy consuming technologies or heating (Walker and Day, 2012). Additionally, distributional injustice has been discussed in the context of employment losses in declining carbon-intensive industries, such as the coal mining industry (Carley and Konisky, 2020). Although clean energy industries are expected to create more job opportunities, those that currently hold jobs in carbon-intensive industries will still be deeply affected (Carley and Konisky, 2020).

Recognitional injustices are a consequence of social groups being overlooked and stigmatised. As Fraser (1995, p. 69) argues, a lack of recognition is foundational to distributional inequalities. Concerning energy transitions, processes or disrespect, stigmatisation and othering (Jenkins, Sovacool and McCauley, 2018) in policies, laws or professional practices cause vulnerabilities to stay invisible. This leads to the reproduction of marginalisation instead of the targeting of needs (Willand, Torabi and Horne, 2023)this study explores the role of trusted in termediaries in recognising and identifying hidden energy vulnerability. Hidden energy vulnerability is the propensity of households to experience harm from energy deprivation because their situation is not captured by common indicators of energy poverty or because they do not request help. Previous research has focused on datadriven, systematic strategies to identify households in hidden energy vulnerability, however, there is little un derstanding of the opportunistic ways that affected households may be identified through intermediary social networks.","-container-title":"Energy Research & Social Science","DOI":"10.1016/j.erss.2023.103013","ISSN":"22146296","journalAbbreviation":"Energy Research & Social Science","language":"en","page":"103013","source":"DOI.org (Crossref. Epistemic injustice is a particular form of recognition-based injustice. It is the consequence of unfairly dismissed credibility due to prejudice, or of people lacking tools or concepts to understand or express their experiences. This results in specific forms and outputs of knowledge that often outweigh other valuable forms of knowledge, such as local or experiential knowledge (Gürtler, 2023).

Procedural justice refers to fair and equitable institutional processes, including access to information, access to (meaningful) participation in decision-making and access to legal processes (Walker and Day, 2012). Policies regarding the energy transition often remain untransparent, with little inclusion and participation in decision-making of various stakeholders, especially low income households (Stojilovska, 2023).

Energy justice offers a multifaceted framework to analyse and shape both the justice aspects of the current energy system and the transition to sustainable energy. While this framework has gained significant traction,

critics have pointed to several limitations of the framework as well, which are discussed below.

2.1 Limitations in the current application of energy justice & gaps in addressing structural inequalities
Several scholars have discussed the entailing limitations of the energy justice literature. Sovacool et al. (2017) criticise the field's western theoretical orientation and the too narrow focus on anthropocentric relations. Damgaard, McCauley and Reid (2022) argue that while energy justice is useful for analysing institutions and policy decisions, its focus on individual rights overlooks relationality and interdependence as core aspects of existence. It moreover lacks a strong theorization of responsibility (Damgaard, McCauley and Reid, 2022), an important gap as energy initiatives increasingly aim for more active energy citizenship (Beauchampet and Walsh, 2021; Biresselioglu et al., 2024). Bouzarovski and Simcock (2017) note the absence of spatial dimensions, proposing an explicit spatial focus through the concept of spatial justice.

Healy and Barry (2017, p. 452) point to a critical gap in the energy justice concept in addressing power relations: "While a number of scholars assert that politics is a critical component in the transitions approach, it is largely missing from much of existing analysis of socio-technical energy transitions and the energy justice literature". Haldar, Grillitsch and Bazaz (2024) critique the energy justice framework for neglecting human agency in sociotechnical transitions, highlighting insufficient engagement with political economy paradigms that reproduce injustices.

Lee and Byrne (2019, p. 2) argue that the three-tenet approach fails to address the "political and economic forces that routinely produce energy injustice". By prioritizing "tailpipe problems" like accessibility and affordability, it neglects deeper structural and ideological factors, such as the bias toward large-scale technical solutions, distanced decision-making from local communities, technocratic interpretations of sustainability, and path dependencies, that perpetuate inequality. Similarly, Elmallah, Reames and Spurlock (2022) emphasise that current energy justice literature inadequately connects to policy and systemic change. They argue that energy inequities are caused by underlying structures and institutions, and that the energy justice framework falls short to challenge the capitalist roots of energy and climate injustice.

These critiques reveal that the current energy justice literature, while valuable, fails to adequately address structural power relations, spatial inequalities, and the role of agency in enabling or constraining participation in energy transitions. This is particularly true in underprivileged urban areas, where marginalisation is spatially and socially embedded (Verlooy et al., 2024). In the next section, we argue that agency is a missing yet essential foundation for a more just energy transition.

3. Agency, the "missing foundation" problem in underprivileged neighbourhoods
In this article we focus on complex inner-city neighbourhoods that have been characterised as underprivileged, due to a lack of access to resources and opportunities and compounding processes of marginalisation (Counted and Newheiser, 2023). We emphasise how structural barriers in underprivileged neighbourhoods affect people's capacity to act. The literature elucidates that structural injustices can lead to a lack of a sense of agency, resulting in a sense of powerlessness (Gaupp, Constantino and Pereira, 2023). We argue that agency represents a crucial "missing foundation" in energy justice discourse, particularly in underprivileged contexts.

This absence of agency is embedded in geographically differentiated so-called "opportunity structures" (Roberts, 2009; Bouzarovski and Simcock, 2017), that constrain residents' capacity to envision and participate in neighbourhood energy transitions, ultimately leading to energy injustices. In underprivileged neighbourhoods, socio-material inequalities manifest in several ways: low-income inhabitants more often occupy poor quality, low energy efficiency housing, in need of retrofitting and equipped with outdated heating systems (Bouzarovski and Simcock, 2017). Without the financial means to improve energy performance, residents are effectively locked into energy-poor conditions.

Beyond material deprivation, socio-spatial factors further restrict agency. Dense urban morphologies, resulting

in a limited availability of public space and private space, and a high proportion of renters, can collectivity restrict the opportunities for integrating renewables (Middlemiss and Gillard, 2015; Knox, 2019; Derkenbaeva et al., 2022; Verlooy et al., 2024). In addition to these constraints, the literature highlights how misrecognition and the stigmatisation of disadvantaged areas contributes to their neglect in policy and planning processes (Hastings, 2009; Walker, 2009). These neighbourhoods are often associated with negative, stigmatised identities, which not only affect how they are served, but also how residents perceive themselves and their communities. The internalization of stigma can lead to community disengagement, reducing levels of civic participation and weakening connections both within the community and with outsiders (McNamara, Stevenson and Muldoon, 2013). The socio-spatial contexts in underprivileged neighbourhoods are not just backdrops but active components shaping what people perceive as possible. Marginalisation in these contexts may lead to a diminished sense of agency, but it can also constrain the imagination of the underprivileged, making it more difficult to envision alternative future trajectories. Poverty impacts people to focus on short-term goals to secure 'basic' necessities to survive (Counted and Newheiser, 2023). This results in lower expectations for the future, which may be particularly problematic in the context of energy transitions, projects that inherently rely on long-term visions. Moreover, residents are frequently left out of energy-related initiatives due to limited access to relevant information or decision-making processes, which are typically dominated by institutional actors. This disconnect reinforces the exclusion of those already disadvantaged and limits their ability to shape or benefit from local transitions (Walker, 2009).

Finally, these issues are often compounded by risks of displacement. Urban regeneration and energy transition initiatives, when not carefully designed, can fuel gentrification pressures and lead to the exclusion of long-term residents (Golubchikov and O'Sullivan, 2020). In this context, energy transitions risk reproducing spatial and social injustices, rather than resolving them.

To conclude, in underprivileged neighbourhoods, agency – the capacity to make purposeful choices and shape outcomes (Gaupp, Constantino and Pereira, 2023) – is absent and undermined. However, agency is crucial in transformation processes (Westley et al., 2013). At the individual level, agency is shaped by self-awareness and self-knowledge (Novalia et al., 2020). Agency becomes most powerful when it transcends the personal and becomes collective. When individuals pool their knowledge, skills, and resources to actively shape their shared future they can form "transformative agency", which can trigger large societal change (Gaupp, Constantino and Pereira, 2023).

Despite this, current energy initiatives have largely overlooked the role of agency, limiting just transitions. While initiatives such as Renewable Energy Communities (RECs) and Positive Energy Districts (PEDs) claim to enhance participation and tackle energy poverty, their capacity to do so in marginalised contexts remains limited. Although these models promote prosumership and community involvement (Hanke and Lowitzsch, 2020), their implementation often fails to reach those most affected by energy injustice (Hanke, Guyet and Feenstra, 2021). Hanke, Guyet and Feenstra (2021) refer to the "romanticised narrative" of energy communities, while they overlook structural challenges underprivileged communities may face for benefiting from these initiatives. They report that general outreach activities, as well as engagement with underprivileged groups fall short, due to a discrepancy between the recognition of these groups' specific needs and the actual implementation of tailored communication and engagement strategies. Goedkoop and Devine-Wright (2016) emphasise that a crucial step is frequently overlooked: the need to build mutual trust. On the one hand, there is often a lack of confidence in the capacities and agency of residents; on the other, insufficient support from developers or governmental actors can further erode cooperation.

We conclude, based on the research by Hanke et al. (2021), that while energy justice frameworks have thoroughly explored issues of distributional, recognitional, and procedural inequities, they have paid too little attention to the deeper constraints on people's capacity to act, particularly in underprivileged neighbourhoods, where limited agency fundamentally hinders participation in energy transitions. This argument is supported by Damgaard, McCauley and Reid (2022) who argue that for the concept of energy justice to apply, it should emphasise the nec-

essary interconnection of rights, responsibility and agency. This integration is particularly relevant for addressing energy vulnerability, as it acknowledges that enhancing agency requires not just recognizing rights but also enabling responsibilities and capacities for action. Just energy transitions require a focus on people's agencies and relations (Sol Cueva, 2025).

4. Researching with care: a narrative approach

Just energy transitions require a fundamental shift in thinking and practice, driven by collaborative and proactive decision-making processes (Williams and Doyon, 2019). Advancing energy justice requires centring historically excluded voices and prioritising bottom-up perspectives (Elmallah, Reames and Spurlock, 2022). This entails restructuring institutional systems, including how research funding is distributed, how scholarly work is published, and the methodologies employed in energy research, in order to support inclusive and equitable transitions. It requires transformative and emancipatory approaches (Elmallah, Reames and Spurlock, 2022).

We advocate for inclusive, creative, and participatory approaches to energy futures, engaging more directly with everyday lived experiences. Strengthening transformative capacity requires participatory co-creation that recognises individuals as agents of change (Ziervogel, Cowen and Ziniades, 2016). Co-producing knowledge helps overcome stigma by sharing local experiences and leveraging individual actions (DellaValle and Sareen, 2020). True participation treats stakeholders as knowledge holders and experts, valuing diverse wisdom beyond tokenistic involvement (Turhan, Şorman and Larsen, 2018). This may slow development but offers a more equitable pathway to energy justice.

This connects to researching with care, a feminist approach to knowledge production that foregrounds responsibility, relationality, and attentiveness to those being researched (Brannelly, Barnes and Tronto, 2022). This is vital in marginalised contexts, where information is often extracted from communities without return. Residents in marginalised neighbourhoods frequently experience epistemic injustice (Fricker, 2007), where their knowledge and experiences remain invisible due to a lack of interpretive frameworks. Researching with care aims to turn these injustices. It centres on marginalised voices, with experiential and local knowledge at the core of research. By placing lived experiences of oppression, marginalization, and resistance at the centre of knowledge production. Furthermore, it emphasises the need of the researchers recognizing conducting research is itself entails responsibilities, that it should strive towards social change. This requires participatory research methodologies that aim to include the voices of people who have been silenced, muted or devalued (Brannelly, Barnes and Tronto, 2022).

4.1 storytelling for underprivileged neighbourhoods

Against this backdrop, we turn to storytelling as a method that, unlike more traditional single disciplinary interpretative lenses, can reintroduce the messiness of thought, belief, action, emotion and value in living together in the technological world. Storytelling starts from the narratives people craft about their lives, embraces complexity and foregrounds the interconnections between people, places, and experiences. It offers a pathway towards epistemic justice (Brannelly, Barnes and Tronto, 2022).

Storytelling holds methodological and transformative value. It can serve as a tool to stimulate agency among residents (Jørgensen, 2022; Ortiz, 2022) because it enables communities to challenge stigmatised identities and to envision alternative futures (Goldstein et al., 2013; Ortiz, 2022). As energy concepts increasingly emphasise decentralised systems and active citizenship, storytelling helps transform community members from passive consumers to active agents. As Sol Cueva (2025) research with market vendors demonstrated, participants in the storytelling game portrayed themselves as active agents, involved in designing and troubleshooting energy systems, reflecting a shift toward more empowered roles in energy transitions. At the same time, storytelling is a powerful methodological tool for researcher as it can mobilise for social change. In this way, storytelling serves a dual purpose: it contributes to strengthen agency at the community level while also providing a participatory, relational method of research, that aligns with the ethics of care (Brannelly, Barnes and Tronto, 2022).

Storytelling emphasises the act of crafting, of the performance, how a story evolves, based on audience, purpose, and context, and how that can be told in different ways, depending on the context (Sol Cueva, 2025). There are several reasons why storytelling can be an interesting method for just energy futures. Stories are more fixed data points, they help to communicate, influence or engage with different audiences (Moezzi, Janda and Rotmann, 2017).

First, storytelling can emphasise the relational nature of energy and highlight the social dimension of too one-sidedly approached technical systems. Current visions of energy futures often rely on computational models and expert-driven, technocratic methods centred on economic trends and infrastructure. These narrow approaches can exclude diverse voices and result in incomplete, homogenised visions. In response to growing dissatisfaction with these dominant representations, storytelling signals a broader epistemological shift, away from abstract experimentation, expert-driven narratives and a focus on technological innovations. Instead, storytelling can be a tool than can capture the complexities of energy systems and transitions and its interconnection with everyday life (Sol Cueva, 2025). Stories can connect energy with the lived experiences, emotions, aspirations, and struggles of underprivileged communities, enabling a deeper understanding of how infrastructures, fuels and technologies are (and will be) produced, provided, used, and perceived within a given society (Sol Cueva, 2025). This helps to understand that energy use is socially and culturally situated, and that people use energy in different ways depending on their lives, habits, and needs. Yet many policies and technologies treat everyone the same, as if one solution fits all. Interventions respond to a particular way of “the problem” with energy use, instead of looking at how systems could better support daily life. Stories challenge this, understanding energy use in different contexts, and supporting better design interventions (Lockton, Renström and Bowden, 2014).

A second advantage of storytelling is its ability to make energy more visible. Since energy is often perceived as hard to grasp, stories can help to ground it in tangible experiences, helping people to "see energy” (Miller et al., 2015) and bringing policies closer to the public. Moreover, stories offer what Miller et al. (2015, p. 67) call "linguistic currency", to discuss technical issues in more accessible ways. This creates lower-threshold platforms for participation, engaging underprivileged communities in “speaking energy” (Miller et al., 2015, p. 67). Energy literacy significantly impacts public acceptance and participation in transition initiatives (Awolesi, Salter and Reams, 2024).

Third, storytelling has the power to bring people together by creating space for a multiplicity of voices and perspectives, challenging current “mess first, fix later” approach often seen in energy policymaking (Turhan, Şorman and Larsen, 2018). It helps to focus on the neglected things, and to include marginalised perspectives to share counter-narratives (Sol Cueva, 2025). Miller et al. (2015) emphasise that stories can open the conversation to participation by people who may not otherwise feel competent, which can help bring together a wide range of knowledge, insights and perspectives. This helps to democratise the conversation on energy transitions (Sol Cueva, 2025). Furthermore, storytelling holds interdisciplinary and transdisciplinary value. It can engage diverse people with different kinds of knowledge from various fields and with different roles, such as policymakers, industry representatives, and community members (Winskel, 2018; Sol Cueva, 2025). In doing so, storytelling blurs the boundary between lived experiences and expert data (Ottinger, 2017). Storytelling can moreover be a valuable method for bringing communities closer together and building a shared identity. Different stories can contribute to build a collective narrative, that provides insights into the beliefs, values and lived experiences of a community (Miller and Bridger, 2019; Sol Cueva, 2025). In that sense, storytelling can facilitate collaboration. When communities engage in storytelling, they also engage in mutual learning, about their community, technologies and energy practices (Sol Cueva, 2025). This process can support community building (Smith et al., 2017), fostering a sense of collective ownership.

Fourth, storytelling highlights the significance of local contexts in shaping energy systems (Sol Cueva, 2025), which is gaining more and more attention in current policy frameworks, such as Positive Energy Districts (Derkenbaeva et al., 2022), that however have difficulty being implemented in more underprivileged areas (Hearn et al., 2022; Verlooy et al., 2024) due to systemic socio-economic inequalities and socio-spatial complexities. In that light, storytelling can be a tool that helps to anchor energy transitions in local realities (Devos, De Blust and

Desmet, 2018), making it a valuable approach for addressing the implementation gap in marginalised areas. As Devos, De Blust and Desmet (2018, p. 7) argue, "narratives can be a powerful tool to bridge the gap between social and spatial research and local knowledge".

Fifth, storytelling can support imagination, helping underprivileged communities to envision alternative future trajectories (Sol Cueva, 2025). By adopting more fluid and non-linear conceptions of time, storytelling may enable communities to transcend their current constraints or circumstances. It enables them to envision new possibilities, reconnect with past aspirations, and envision radically different futures (Moezzi, Janda and Rotmann, 2017; Sol Cueva, 2025). This ability is particularly valuable in energy futures research, where the aim is often to envision transformative changes (Sol Cueva, 2025).

5. Case Study Watersportbaan

Dedicated to performing doing care-full research, we distance ourselves from social sciences that decontexDedicated to performing doing care-full research, we distance ourselves from social sciences that decontextualise research. Knowledge is inherently situated, rooted in the relational and material conditions that make it possible (Puig de la Bellacasa, 2017). As such, our research does not begin from pre-defined "gaps" in the academic literature. Instead, we align with the view that meaningful research questions often arise from "the real life of affected people", (Brannelly, Barnes and Tronto, 2022). From 2024 till 2025 we have indulged in our case study Watersportbaan, in Ghent, Belgium, having conversations with inhabitants, social welfare workers, energy experts and government officials.

Watersportbaan houses social tenants in high-rise modernist apartment blocks constructed in the 1960s. Residents face ongoing marginalisation and stigmatisation, compounded by deteriorating living conditions. Many of the apartments are in urgent need of renovation, with upcoming redevelopment plans likely to result in large-scale displacement and uncertain housing situations. Additionally, the area is marked by significant challenges related to liveability. Increasing reports of garbage accumulation, crime, feelings of insecurity, noise pollution, squatting, substance abuse, mental health issues, and homelessness reflect a growing sense of social and infrastructural neglect. Furthermore, people working and living in the neighbourhood have highlighted a sense of isolation, partly attributed to the design of the high-rise housing blocks, which limit opportunities for interaction between neighbours. This is further exacerbated by the deteriorating state of public spaces, which lack accessible, welcoming communal or meeting areas. Consequently, the area is characterised by low levels of social capital, foundational for collective action (Ziervogel, Cowen and Ziniades, 2016).

Transformative changes are planned in Watersportbaan, including the construction of a fossil-free heat grid and renovation and demolition of the social housing blocks, leading to large scale relocations of current inhabitants. A visioning plan for the area has described several ambitions that may contribute to transform the neighbourhood to a fossil free environment (Vervloesem et al., 2024). One of the ambitions is to further research and set up a collective heating network on residual heat. Currently this plan, despite still being in an early phase, is initiated by large scale institutions in the neighbourhood, such as the hospital, university campus and the social housing association. In addition to this, the plan envisions the sharing of locally produced renewable energy across the neighbourhood, potentially through the creation of an energy community that enables more equitable distribution. Moreover, the energy transition is seen not merely as a technical or environmental shift, but also as a social lever: a means to empower residents and encourage energy-conscious behaviour. Despite these promising ambitions, such as creating an energy community (Vervloesem et al., 2024), interviews lay bare that there are multiple challenges that may come across in the energy transition of the area.

In Watersportbaan, the energy transition is currently run by large institutional stakeholders that are residing in the area, planning a heating network. However, this risks occurring "over the heads" of residents, with little genuine involvement from those most affected. The social complexities surrounding energy transition and energy poverty remain largely invisible to the institutional frontrunners currently leading renewable energy initiatives in the area. These organizations demonstrate limited insight into residents' actual needs, wishes, or capacities,

often underestimating the potential contributions residents could make if meaningfully engaged. Simultaneously, social welfare workers emphasise that for many residents, the energy transition feels like a distant concern, far removed from their immediate challenges and daily realities. The persistent stigmatization of the neighbourhood and its residents further complicates engagement efforts. As we have discussed above, this can lead to community disengagement and undermine solidarity (McNamara, Stevenson and Muldoon, 2013).

5.1 Situating the research in Watersportbaan

Watersportbaan's current energy future is mainly determined by institutional stakeholders, with residents having little say in their neighbourhood's energy transition, leading to institutional stakeholders overlooking their social realities and impact of the transition on daily life. A storytelling approach emerged as a fitting and necessary method to make visible the complex, situated experiences of underrepresented communities and to democratise energy transition discourses.

To set up storytelling as the research methodology, we follow a similar approach as Devos, De Blust and Desmet (2018) that is based on three iterative phases: 1) identifying narratives, 2) co-constructing storylines and 3) strategic implementations. For the scope of this conference paper, we will focus on the first step, identifying narratives.

As Devos, De Blust and Desmet (2018) describe, entering a neighbourhood requires exploratory research to "get a grip" on its conditions. This was done as part of the CO2PED research project, by conducting interviews, workshops, and organising neighbourhood walks (2024-2025). Based on this, we identified community narratives (phase 1) in relation to energy transitions. These narratives are constructed on 'meta' themes that consistently emerged during the various conversations we had in and about the neighbourhood. They provide a lead for further research and dialogue in the next stages of the CO2PED research project in co-constructing storylines and strategically implementing storylines (phase 2 and 3). In the next section, we deconstruct five narratives from Watersportbaan, connecting them to energy injustices. Drawing on our theoretical framework, we argue that storytelling holds significant potential in addressing the injustices that these narratives lay bare, by enhancing community agency.

5.1.1 Identifying narratives in Watersportbaan

5.1.1.1. narrative 1 – lacking neighbourhood services and meeting spaces

One of the dominant narratives emerging from the exploratory fieldwork in Watersportbaan revolves around the lack of neighbourhood services and meeting spaces. Residents and social welfare workers repeatedly mentioned the absence of places where people can informally gather, share experiences, or simply spend time together. This lack of shared space not only limits opportunities for building social cohesion but also contributes to a broader sense of fragmentation and isolation in the neighbourhood.

Interestingly, the presence of a collective laundromat, one of the few (semi)public spaces in the area, is a narrative that can spark conversations. This symbolises a dependency on shared facilities, reflecting the broader housing model idea in the neighbourhood that is built around collectivity and sharing. However, more and more, this collectivity is disappearing. The laundromat also highlights the everyday use of energy, embedded in routines, which opens up avenues for discussing energy as part of daily life. The laundromat furthermore offers a space for casual encounters and conversations in a rather isolating neighbourhood. However, criminal activity is increasing around the laundromat, moreover, washing here is quite expensive. Therefore, the space is losing its popularity. These seemingly mundane moments reveal deeper socio-spatial dynamics: the limits of public infrastructure, the social consequences of housing precarity, and the reliance on collective systems in a context where collectivity is not meaningfully supported.

Storytelling can make visible the relational and situated nature of energy, revealing the complex interconnection of energy with everyday life. Current energy transition models tend to rely on abstract simulations and expert-led forecasting tools, which overlook the complexity of people's everyday realities (Sol Cueva, 2025). In contrast, storytelling allows us to explore how people in Watersportbaan use, experience, and interpret energy

differently, shaped by their specific housing conditions, cultures, socio-economic situations and socio-spatial situations. Furthermore, researching with care aims to make visible what is often made invisible and devaluated, such as washing as housework.

5.1.1.2. narrative 2 – deburdening social renters

Another dominant narrative used by policymakers, the housing corporation or energy experts is the need of deburdening the inhabitants, by reducing the responsibilities, pressures, or expectations placed on them. The planned implementation of a heating network, while intended to contribute to more sustainable energy provision, is mostly discussed in highly technical terms, dominated by expert-led discourse and engineering logic. Residents so far have not been involved in this process. They argue that social renters must be completely deburdened, however, this has contributed to the idea that that energy systems are "not for them to understand or question", and that "experts know best".

This approach can be seen as patronizing. It risks underestimating the knowledge and capacity based on lived expertise of local inhabitants. This technocratic approach ignores the socio-cultural dimensions of energy use, reducing residents to passive recipients of infrastructure rather than active participants in shaping their energy futures. As a result, engagement can be discouraged, with eroding agency as a consequence.
Storytelling can help to reframe the technical conversation, to make energy more visible and relatable, not as an abstract system, but as part of everyday life. In a neighbourhood where many feel excluded from formal planning processes, this is particularly important. Stories about comfort, cold, control, costs or worries can help residents to articulate their needs, experiences, and priorities. These stories surface understandings of energy systems that are often dismissed as anecdotal and irrelevant, yet they are important for designing just interventions. Moreover, storytelling resists the potential patronising logic of deburdening through valuing input based on local experiences.

5.1.1.3. narrative 3 – lacking sense of collectivity

There is a narrative in Watersportbaan of lacking collectivity, which limits the neighbourhood's ability to engage in community-driven energy transitions. As we discussed earlier, Watersportbaan is marked by limited meeting spaces and a lack of infrastructure that boosts social interaction. Residents and social workers repeatedly spoke of a widespread sense of disconnection, not only from one another, but also from the future of the neighbourhood. This is closely tied to the morphological layout of the area: high-rise social housing blocks with vertically compartmentalised corridors limit interaction between neighbours. The declining public space contributes to feelings of isolation and disconnection. Both inhabitants and other stakeholders involved in Watersportbaan feel that this neighbourhood is isolating, which, as a result, undermines social cohesion, vital for collective agency.

At the same time, Watersportbaan has evolved into what might be described as a marginalised tenant enclave. Residents live in deteriorating apartments, with outdated energy infrastructures. They face social stigma attached to poverty and public housing. Coupled with the looming uncertainty of future renovations and possible relocation, this erodes place-based attachment. With little sense of belonging and minimal incentive to engage in collective projects, it becomes increasingly difficult to imagine a shared energy future.

In this fragmented social context, storytelling holds transformative potential. It can create inclusive spaces for dialogue where a multiplicity of voices and perspectives are not only welcomed but actively shape the conversation. Stories open up energy conversations to those who may not feel competent to participate, thus lowering the barrier to engagement and democratising the discourse. Storytelling enables residents to build a collective narrative that reflects shared concerns, values, and hopes. In doing so, storytelling can function as a community-building practice in Watersportbaan, capable of strengthening collective identity and agency.

5.1.1.4. narrative 4 – "no man's land"

The area in Watersportbaan has been narrated as being a "no man's land" (Vervloesem et al., 2024). The neighbourhood's isolating feel, as described above, due to lacking services, high rise fragmentation, and neglected

public space in between the high-rise towers. However, due to its morphology, multiple opportunities arise for sustainable energy infrastructures.

Beyond the physical landscape, this “no man’s land” narrative also reflects deeper mismatches. There is a disconnect between local needs and the objectives of supra-local actors involved in neighbourhood transformation. Large stakeholders, including housing providers and policy institutions, often pursue energy transition goals, such as the implementation of heating networks or district-wide retrofits, without grounding them in the realities of local life. As a result, energy-related decisions are driven by abstract targets or financial incentives, while local knowledge and everyday energy needs remain undervalued or ignored. Social welfare organisations, which could potentially play a key bridging role, face limitations: energy transitions are treated as technical domains outside their expertise, and they lack the resources, time, and mandate to engage meaningfully.

In this context, storytelling can be a method that can re-anchor energy transitions in local realities, showing that neighbourhoods are not “blank slates”. Storytelling helps to bridge the gap between expert-led visions and local, experimental knowledge, creating space for residents, social workers, and overlooked voices to express their energy needs and aspirations in accessible ways. Storytelling supports the significance of place in shaping energy systems, enabling to approach energy transition in a context-sensitive way. Moreover, by allowing for diverse perspectives and counter-narratives to be shared, storytelling challenges power asymmetries. It can help build mutual understanding among residents, social actors, and institutional stakeholders, creating a common ground where collaboration becomes possible.

5.1.1.5. narrative 5 – living in limbo

Another dominant narrative that emerged during our fieldwork in Watersportbaan relates to the difficulty of involving residents in shaping the energy future of their neighbourhood. As the literature suggested, poverty tends to orient people's attention toward short-term survival, making it harder to invest in or even imagine long-term goals. This disengagement is further deepened by the uncertainty surrounding large-scale renovation and relocation plans in the neighbourhood. The apartments in Watersportbaan are in urgent need of renovation. Many residents of social housing live with the expectation that they may soon have to move, as their homes are scheduled for demolition or upgrading. This "living in limbo" creates a fragile connection to place and very little incentive to participate in decisions that shape the future of the area.

In this context of uncertainty and the resulting disengagement, storytelling can offer more than just a method for collecting data, it can be a tool for reclaiming imagination and reconnecting people to future possibilities. Storytelling can allow communities to envision alternative trajectories beyond their current constraints. Especially when people are “living in limbo,” storytelling provides a way to move beyond linear conceptions of time, empowering residents to hold on to past aspirations, interpret the present differently, and creatively imagine new futures.

Storytelling can help to break through deterministic narratives of decline. It can revisit hope, shifting the focus from imposed futures toward those imagined by the community itself. Whether grounded in actual life experiences or speculative scenarios, stories can inspire agency and support a sense of ownership over the future, even in a context marked by displacement and instability.

5. Conclusion & planned research

This paper examined energy justice limitations in addressing structural barriers faced in underprivileged neighbourhoods during energy transitions. While the three-tenet approach offers a valuable framework, it often overlooks the foundational issue of limited agency in marginalised communities. In these neighbourhoods, residents face compounding processes that restrict their capacity to envision and participate in energy transitions: socio-material inequalities manifest in poor housing conditions, dense urban morphologies limit renewable integration opportunities, stigmatization leads to community disengagement, and institutional stakeholders often

implement initiatives with limited understanding of residents' needs.

Guided by feminist care ethics, our research in Watersportbaan (Ghent, Belgium) reveals a significant disconnect between institutional energy transition ambitions and local realities. We propose storytelling as a transformative methodology that can strengthen collective agency by emphasizing energy's relational nature; making energy more visible and accessible; creating platforms for multiple voices; highlighting local contexts; and supporting the imagination of alternative futures. Storytelling positions community members as active participants rather than passive consumers, bridging the gap between transition plans and local knowledge.

This paper only describes the first stage of a research trajectory that will unfold in future research in Watersportbaan. We identified five key narratives in this neighbourhood—lacking neighbourhood services, disempowering deburdening approaches, eroding collectivity, a "no man's land", and uncertain living conditions—that erode community agency. We highlighted how storytelling may counter these dominant narratives. In the second phase of our research, we plan to use these narratives as conversation starters, co-constructing storylines with inhabitants, aiming to eventually strategically implement them into the neighbourhood transition plan. Based on the personal stories and experiences of residents we have collected by initiating low-tech actions, we aim to break stereotypes and narrow the gap between the policy makers, social housing associations and energy experts initiating the energy transition of Watersportbaan.

A Community Out of the Box: Understanding Flexibility and Justice through Self-organised Housing in the Netherlands

Renzo Sgolacchia
Amsterdam Academy of Architecture
Email: renzosgolacchia@hotmail.com

Abstract
The article examines the Roma community at De Witte Plas, Netherlands, as a case study of informal, self-organised housing practices that resist dominant corporate systems. Through a combination of fieldwork, design-driven research, and collaborative workshops, the study explores how community members creatively reconfigure containerised housing using recycled materials and digital platforms. Framed through the dual meaning of flexibility, the article argues for informality as a strategic, emancipatory paradigm. It proposes a reconceptualisation of migrant workers' housing that highlights user autonomy, adaptability, and social embeddedness, challenging the limitations of institutionally regulated models like flexwoningen.

Keywords: flexibility, self-design, workers' housing

Introduction

In their book *Informal City: Caracas Case*, Brillembourg and Klumpner investigate the informal processes supporting spontaneous urbanisation, seeking to identify the implicit logics and structures that organise what might initially seem as disorder (Brillembourg, Klumpner, 2005, pp. 16-23). Crucial to their analysis is the concept of flexibility, framed as a model of self-organised development that challenges conventional planning approaches and is manifested in the adaptive construction practices characteristic of informal settlements (Brillembourg, Klumpner, 2005, pp. 248-259).

In recent times, however, the concept of flexibility has shifted to a more restrictive meaning, primarily addressing housing emergencies. Temporary, mobile, modular, containerised, and prefab became synonyms of flexible. In the Netherlands, *flexwoningen* (flexible housing) are designed to accommodate migrant workers and defined by containerised and temporary nature. These units can be "moved, stacked, connected, or split," provided that at least "one of the following aspects is temporary: the house itself, the occupation through temporary lease, or the location" (Housing Expert Team, 2021). This narrow definition, focused on mobility and temporariness, implicitly excludes user adaptation and self-design.

The efficiency criteria of *flexwoningen* and the design of dormitories as simulacra of vacation accommodations enable employment agencies to consolidate their pervasive presence and maintain constant surveillance. By reducing inhabitants to a condition of "bare life" (Agamben, 1998, pp. 21, 169-170), workers' housing seems instrumental in developing a disciplinary code to educate the workforce. Agencies control workers' lives through inspections, warnings, and organising shifts and transport via algorithms. These coercive practices reveal the oppressive and panoptical nature of workers' housing, where hyper-rationalised layouts amplify workers' stress (Sgolacchia, 2023). A relevant example is the orthogonal grid layout of mobile home parks, which enables a complete view (fig. 01). Security officers and agencies' personnel can monitor the entire outdoor area simply by walking along the site's perimeter, while the layout offers no blind spots in the field of view of surveillance camera. This spatial arrangement transforms the campsite into a fully observable environment, revealing the disciplinary logic embedded in its design.

Stichting Normering Flexwonen (SNF) regulates the architectural standards of migrant workers' housing, defining the "minimum requirements for liveability," such as square meters per person, cupboard volume, and bed dimensions (SNF, 2022, pp. 5-8). A prefabricated mobile home, which workers usually call a "bungalow" or "chalet," typically includes three bedrooms, a bathroom, and a living room with an open kitchen, housing three to four people. In this type, the SNF estimates the minimum space for a single room at 3.5 m^2, specifying that such fig-

ures are largely based on guesswork and intuition.[1] This approach reveals SNF's insensibility to the lived realities and needs of inhabitants, regulating only the minimum thresholds for liveability.

By contrast, the Roma community at De Witte Plas, a campsite in North Brabant, close to the Belgian border, represents an emblematic case of informal spatial reconfiguration and self-designed housing, subverting dominant corporate architectures in the Netherlands. Mario and Lavi, two Roma individuals from Bistrita-Năsăud county in Romania, arrived in the Netherlands in 2020.[2] After initial work experiences under the control of recruitment agencies, they emancipated themselves finding alternative accommodation outside the agencies' system and living with their children, who are excluded from workers' dormitories and often left in the country of origin. Having reached an agreement with De Witte Plas campsite owner, they settled there with their families and invited relatives and fellow villagers from across Europe. Currently, the Romani community comprises almost three hundred residents at the campsite of which nearly a hundred primarily work as pickers at Bol.com, a major Dutch webshop, in its distribution centre in Waalwijk. Functioning as a de facto trade union, the community collectively negotiates directly with factory management on specific requests and employment conditions.[3] The community's informal approach is exemplified by their resistance to the dormitory labour regime and their self-construction of homes, adapting and extending standard containerised units to house newcomers (fig. 02).

Objectives

The article explores the Roma community's practices within broader theoretical debates on flexibility and informal architecture, emphasising their relevance in reimagining contemporary urban forms. These practices, including self-planning, recycling and sourcing building materials, and the negotiations of labour conditions, challenge the rigid models of workers' housing conceived and imposed by agencies and regulated by SNF.

By actively subverting the formal systems that govern their lives, the Roma community embodies Adrian Forty's concept of "flexibility as a political strategy" (Forty, 2000, p. 147). According to him, this notion of flexibility emerged as a countermeasure to the capitalist control of space, which limits individual freedom by compartmentalising domestic life, leisure, and work into distinct functional zones, transforming them into commodified spaces with exchange value (Ibidem). Forty analyses the Situationist International's "appropriation of existing buildings with predetermined uses" in the late 1950s and Henri Lefebvre's "resistance to dominated space" theorised in his 1974 book, The Production of Space (Ibidem). These examples demonstrate a collective pursuit of "freedom of use," promoting the reinterpretation of buildings and cities beyond their prescribed functions (Ibidem). In this sense, flexibility is not merely an architectural feature of buildings, but a political act to adapt spaces for diverse everyday uses.

The main hypothesis of the article is that, by rejecting the compartmentalisation of life into rigid functions, typical of *flexwoningen* designed to optimise profit and control labour, the community's informal strategies demonstrates how workers' housing can be reconfigured into adaptable, circular, and participatory frameworks that better respond to the inhabitants' needs. In other words, how containerised housing types can be repurposed into truly flexible dwellings.

The community's approach emphasises the appropriation and transformation of existing buildings and resources by users, who apply flexibility and multifunctionality as tools of collective care and resistance. The article seeks to position these self-organised practices as an emancipatory response to the pervasive systems of control embedded in the Dutch corporate housing regime, while also integrating the community's practical, tacit knowledge into architectural research.

1 Interview with Jolet Woorders, the secretary of SNF, 8 December 2022.
2 Interview with Mario, 2 July 2022.
3 Ibidem.

Furthermore, the article argues for a reconceptualisation of the boundary between formal and informal architecture, proposing a hybrid paradigm in which user autonomy, adaptability, and social embeddedness are central to the design of inclusive environments.

Methods

The adopted method combines field study and design-driven research. Data were collected through spatial analysis and fieldwork conducted in the spring of 2024, including a series of qualitative interviews at De Witte Plas campsite with the inhabitants. In addition, a 12-minute documentary filmed on site offers a visual impression of community life.

Engaging in a research-by-design process involves using design not just as a problem-solving activity or a means of architectural production, but as a method for inquiry and exploration.[4] Collaboration with the Romani community took the form of workshops focused on their spatial practices, emphasising the role of negotiations and the potential of their architectural tacit knowledge. As part of this process, I briefly reconstructed the community's informal approach, particularly their strategy for extending containerised units and optimising resource flows. Drawing, as a visually-oriented experience, served as a medium for mutual learning and knowledge exchange during these workshops.

To develop the design-driven investigation, I selected a specific case study: the home of Mario's family, which exemplify a typical construction process initiated by Roma people at the campsite. Mario methodically organised the project into five phases: purchasing a mobile home on the site, storing building materials, preparing the extension, constructing internal partitions, and installing a roof. This progression illustrates the transformation of a rigid, containerised unit into a self-designed, adaptable dwelling, highlighting the community's capacity to manage complex logistical operations and produce sustainable, inhabitable space (fig. 03).

A defining feature of the Roma community's informal approach is their strategic activation of existing logistical functions embedded within digital platforms. As Clare Lyster argues, apps that mediate between users and urban systems offer an interesting model for sharing infrastructure and goods (Lyster, 2016). The community's use of classified advertising platforms such as Marktplaats and Facebook Marketplace, augments access to recycled building materials and second-hand furniture. They benefit from these platforms to employ the material surplus of other users, selecting listings within a 50 to 100 kilometre radius of De Witte Plas, and linking otherwise disconnected basements, storages, and depots into a distributed supply network. The community subverts the platforms' profit-driven models, which rely on listing fees, advertising, and subscriptions, by sourcing materials free of charge, typically from private homeowners, and bypassing paid services entirely.

The construction of Mario's home exemplifies the community's resourcefulness and its strong collective commitment. The project involves eight months of planning, namely researching, negotiating, purchasing, transporting, and storing materials, followed by one-month of on-site construction. Mario, his son Edy, and other community members rolled up their sleeves to participate, transforming the project into a shared endeavour and a powerful symbol of self-sufficiency.

Discussion

This building process illustrates two key outcomes. First, it disrupts the agency-imposed logic of containerised housing by demonstrating how rigid, prefab units can be reconfigured into adaptable dwellings. Second, it emphasises the broader social cohesion that emerges from these construction efforts. The focus extends beyond individual homes to include forms of social aggregation and collective infrastructure within the campsite. At De Witte Plas, the Roma community has established mutual aid systems, collective bargaining practices, and knowledge-sharing networks, functioning as a civic organisation. These mechanisms challenge the isolation typical of migrant workers' housing and their impact contribute to include forms of social aggregation and the creation of

4 The research-by-design method is extensively investigated by the CA2RE+ seminars. See for instance one of the publications: *CA2RE+ Delft Recommendation, Book of Proceedings*, (TU Delft: Open Publishing, 2023).

shared facilities within the campsite. Considering the lack of formal public spaces, shared outdoor areas of the campsite have been informally repurposed for rituals, celebrations, religious ceremonies, and communal childcare, creating vital nodes of everyday life and cultural expressions.

To better understand this self-organised process, the notion of the architect as a bricoleur, as developed by Irénée Scalbert, provides a clear analogy for understanding the Roma community's informal. Scalbert describes the bricoleur as "at once designer, builder, and user," characterised by "improvisation, resourcefulness, and adaptability," someone who creates something new using whatever materials or tools are at hand, often operating outside formal, conventional practices (Scalbert, 2011). He introduces this figure from Claude Lévi-Strauss's distinction between the bricoleur and the engineer, developed in his 1962 book La Pensée Sauvage (The Savage Mind): while the engineer subordinates materials to a predefined project, imposing a conceptual framework on reality, the bricoleur, by contrast, adapts their design to a specific and limited inventory and recycles the remains of older projects in response to present needs (Ibidem).

Like Scalbert's *bricoleur*, the Roma community operates in an environment of constraint, where access to conventional building materials and institutional support is limited. They creatively respond to these limitations reconfiguring available resources through online platforms and adapting second-hand materials and tools to fit their immediate needs. This process mirrors the bricoleur's method of assembling disparate elements into a coherent whole, constructing meaningful spaces from what others might consider unusable or insignificant. This ability to work fluidly with what is at hand demonstrates a deep flexibility, a peculiar quality of Scalbert's *bricoleur*.

De Witte Plas emerges as a key site of alternative and informal architecture, shaped by what Edwin Buitelaar calls the "spontaneous order" of a "free society." This concept stands in contrast to a "designed order," which typically involves nationally-operating developers, active land-use policies, and formal zoning regulations (Buitelaar, 2020, pp. 38-39). Spontaneous order, by contrast, relies on minimal and generic building regulations (Ibid.). In such contexts, social and spatial order emerges organically, without a central organising authority, and inhabitants establish rules to prevent unjust actions between individuals (Ibid.). At De Witte Plas, familial and neighbourly connections among residents help regulate relations and prevent injustices, reinforcing the principles of spontaneous order and showing its practical implications in creating a just and supportive community.

Scholars argue that institutional frameworks must meet certain justice requirements, such as establishing fundamental freedoms and equal rights (Buitelaar, 2020; Moroni, 2019). In this particular conceptualisation of the just city, the Roma community achieved a significant progress when they successfully registered their residency with the municipality of Schijf in 2020.[5] This registration marked a key moment, as the spontaneous order at De Witte Plas emerged primarily from the community's own initiative rather than from institutional planning. Nevertheless, the municipality played a crucial role by formally recognising and certifying the community's desire to reside at the campsite, thereby guaranteeing their freedom of choice.

Conclusions

The findings reveal the Roma community's capacity to negotiate autonomy within the constraints of global logistics and labour systems. Their housing practices, rooted in circular economy principles and participatory design, demonstrate how informal architecture can create adaptive, fair, and resilient environments. This case study contributes to understanding informality as a strategic paradigm, offering insights into the transformative potential of grassroots action. It suggests urban planning frameworks that foster community agency, flexibility, and sustainability, redefining justice and equity in spatial arrangements.

Water justice, scarcity and environmental flows. The case of Marseille

Nicola Russolo
Affiliation: PhD-SDC, Università Iuav di Venezia & IUSS Pavia[1]
Email: nrussolo@iuav.it

Abstract
In the context of the present global ecological crisis, water emerges as one key element to take care of for avoiding a planetary ecocide. The link between water scarcity, justice and environmental flows is explored, opening to a more-than-human perspective and recognising the connection between water biopolitics and urban design. The Mediterranean context is identified as a hotspot for investigating these intertwined themes, with the city of Marseille as a relevant case study. The territorial scale water system is described in relation to water justice, present conflicts and future perspectives. Finally, the features of the urban area are presented in relation to issues and opportunities linked to possible transformations towards a more circular and just water metabolism for the city and the surrounding territory.

Keywords: urban political ecology; water biopolitics; ecological commoning

Introduction

An unprecedented anthropogenic water crisis is hitting the planet, with a responsibility for spatial design disciplines that is strongly related to distribution and justice, and that requires re-thinking some of our perspectives on water management. After exploring the global context and the Mediterranean region, the city of Marseille is investigated for its paradigmatic water system and challenges driven by growing scarcity. The choice of a city as study case is related to the fact that urban areas – albeit in connection with their 'planetary hinterland' (Brenner & Katsikis 2020) – are more than ever the hotspot of energy consumption and global warming generation, so that for imagining a more sustainable future we need to investigate urban environments and metabolism. More-than-human justice perspective is introduced starting from the concept of 'environmental flows', not only for taking 'water's side', but also because in urbanism this perspective is emerging as a key "to avoid a planetary ecocide" (Fieuw et al., 2022). For a comprehensive understanding of the city's ecologies and flows it is then fundamental to enlarge the scope of urban ecology studies to the territorial context (Grulois et al., 2018). For this reason, examining water justice issues with a spatial lens requires to embrace a wide enough area – in relation to water catchments – rather than concentrating on a 'city proper' close-up. At the same time, the shapes, the devices, the surfaces and the materiality of the city – and of landscapes and infrastructural systems – define the environment and the possible flows of water, other matters, and lives. For these reasons it is interesting to look at multiple scales, considering certain city spaces, the urban metropolitan area, and the wider territorial context.

Water scarcity in the global and Mediterranean context

In the context of the present ecological crisis and worsening global warming, addressing the issue of water justice, access and distribution is most compelling. Freshwater is a biologically necessary and irreplaceable substance for all terrestrial life, so that its access is universally considered a basic need and a fundamental human right. The attention towards this theme is underlined by its prominent involvement in international programmes and policies. Indeed, one of the Sustainable Development Goals (SDGs) agreed by the United Nations in 2015 is specifically dedicated to freshwater access ('Goal 6: Ensure availability and sustainable management of water and sanitation for all') and water availability is closely connected to most other SDGs' themes[2], which

1 This paper and related research have been conducted during the Italian inter-university PhD course in sustainable development and climate change (link: www.phd-sdc.it)

2 Survival of life on Earth is undeniably linked to water, therefore any quest for sustainability needs to take its availability and quality into account. In particular, it can be argued that at least 14 out of 17 SDGs have strong connections with water distribu-

are dealing with food, health and equality, energy and goods production, ecosystems, sustainability and climate (UN, 2024a). Furthermore, one of the nine 'Planetary Boundaries' set for monitoring the anthropogenic pressure on the so-called Earth system is 'Global freshwater use' (Rockström et al., 2009), more recently reframed as 'Freshwater change' in order to "comprehensively reflect anthropogenic modifications of Earth system functions of freshwater changes[3]" (Richardson et al., 2023). Also in this case many of the other 8 indicators have a strong connection with water depletion or with its renewal cycle, as on top of being related to the availability of freshwater for human consumption, they also affect climate regulation and ecosystems[4].

Given this framework, when tracking the overall progress of the SDGs and the anthropogenic pressure on the Earth system it seems clear that present policies and actions are ineffective: the latest SDGs progress report states that "the world is severely off-track to achieve the 2030 Agenda" (UN, 2024b), and 6 out of 9 Planetary Boundaries were transgressed as of 2023, delineating a worsening trend compared to previous updates and reflecting "unprecedented human disruption of Earth system" (Richardson et al., 2023). If we look at the Freshwater change indicator, globally "Transgressions of both the blue and green water boundaries occurred a century ago", however according to this world-scale quantitative approach the control values haven't reached the 'High risk zone' yet (ibid.); moreover, looking at a more comprehensive perspective on water and sanitation actions' progress, the latest SDGs report by the UN (2024b) states that "None of the SDG 6 targets are on track to be met", with some of them improving too slowly and others stagnating or even regressing, including exposure to water stress. In the end, despite the recognition conceded by official international organisations and the academic world, "The world is facing an unprecedented water crisis. [...] one-quarter of the world's population [is] currently exposed to extremely high water stress annually" (Kuzma et al., 2023).

In the referenced documents the concept of 'water stress' refers to a condition in which water availability (also in terms of quality and ecological flows) cannot cover the "human and ecological demand" in a given moment; 'water scarcity' is instead the mid-term occurrence of a stress condition, a "consequence of anthropogenic impacts on the availability of water resources" happening when human exploitation of water exceeds the sustainable supply in a context (EEA 2021). Water scarcity is therefore directly linked to anthropic processes and their environmental pressures. For this reason, while drought events (essentially linked to precipitation deficit) can exacerbate water shortages, the concept of water scarcity is the preferred lens for investigating the territorial dynamics of dryness as linked to spatial transformations. It follows that understanding the relationship between water distribution, its depletion, and the climate-related dynamics that undermine its availability is of foremost importance – and it is fundamentally a matter of justice: "the scarcity at the heart of the global water crisis is rooted in power, poverty and inequality, not in physical availability" (UNDP, 2006, p.2).

The Mediterranean region is a particularly relevant study area for the relationship between global warming related

tion and ecosystems, including: 1. No Poverty, 2. Zero hunger, 3. Good Health and Well-being, 5. Gender Equality, 6. Clean Water and Sanitation, 7. Affordable and Clean Energy, 8. Decent Work and Economic Growth, 9. Industry, Innovation and Infrastructure, 10. Reduced Inequalities, 11. Sustainable Cities and Communities, 12. Responsible Consumption and Production, 13. Climate Action, 14. Life Below Water, 15. Life on Land. On top of this, also Education and Peace (Goals 5 and 16) are cited as key elements in the UN 'World Water Development Report 2024: Water for Prosperity and Peace' (UN, 2024a)

3 "streamflow [is used] as a proxy to represent blue water (surface and groundwater) and root-zone soil moisture to represent green water (plant-available water). […] The new green water component directly accounts for hydrological regulation of terrestrial ecosystems, climate, and biogeochemical processes, whereas the blue water component accounts for river regulation and aquatic ecosystem integrity" (Richardson et al., 2023)

4 "Global manipulations of the freshwater cycle affect biodiversity, food, and health security and ecological functioning […]. Threats to human livelihoods due to deterioration of global water resources are threefold: (i) the loss of soil moisture resources (green water) due to land degradation and deforestation, threatening terrestrial biomass production and sequestration of carbon, (ii) use and shifts in runoff (blue water) volumes and patterns threatening human water supply and aquatic water needs, and (iii) impacts on climate regulation due to decline in moisture feedback of vapor flows (green water flows) affecting local and regional precipitation patterns." (Rockström et al., 2009). Freshwater use/change is therefore linked to: Climate change, Biogeochemical flows (and previously chemical pollution), Biosphere integrity (previously biodiversity loss), Land system change.

climate change, water scarcity and water justice. According to the 6th IPCC report (2023, p. 2253) "climate models consistently project regional warming at rates about 20% above global means and reduced rainfall (-12% for global warming of 3°C)", so that the area can be considered a 'climate change hotspot', also "due to the high exposure and vulnerability of human societies and ecosystems to these changes"; the report particularly underlines the resulting water-related issues, for "rising temperatures trigger extensive [...] evaporation [which] leads to shrinking water resources on land, direr soils, reduced river flow, and significantly longer and more intensive drought spells". Associated risks include "important and increasing water shortages, already experienced by 180 million people" and "growing demand for water by agriculture" (IPCC, 2023, p. 2254), on top of the reduction of all wet surfaces and related ecosystems. The projections draw the worrying picture of a region severely affected by water scarcity, with higher demand also due to an increasing population and mainly located in coastal areas, where sea level rise will entail additional scarcity dynamics linked to aquifers and soils salinisation and loss of terrestrial ecosystems (MedECC, 2020). The MedECC report (ibid., p 206) also notes that "future increase in human activities [...] may have more impact on water demand than climatic changes", underlying the anthropic source of water scarcity, where (anthropogenic still) global warming is only a worsening factor.

Water (in)justice and biopolitics, a spatial perspective

In the Mediterranean, as elsewhere and globally, water availability is unequal at the regional scale – with around 73% of renewable freshwater resources held by northern countries (MedECC, 2020) – as well as within societies and territorial ecologies. Indeed, the IPCC (2023) observes how water and food scarcity affects disproportionately women and children in urban areas, and especially disadvantaged social groups. This inequality is worsened by 'climate injustice' (Otto, 2025), which links the impact of global warming and social injustice from the global to the local scale, as for example vulnerable communities can often afford to inhabit only the highest risk (and cheapest) areas: there is therefore a strong link between these dynamics and spatial justice issues (Soja, 2010). The unequal water distribution and quality that are provided (for example to low-income areas and informal settlements) are a form of social and spatial injustice, so that in the context of global warming and increasing scarcity, water justice (Boelens et al., 2018) becomes a central issue to climate, social and spatial (in)justice: water is so vital that "hydraulic infrastructures can shape social relations and mediate power" (Mukerji, 2022). Forms of social and spatial injustice are complex and rooted in the present socioeconomic and ecologic system of power – defined by Moore (2017) as Capitalocene – and its pervasive planetary production dynamics, linked to the exploitation of 'nature' (i.e. land, materials, flows) and lives (Brenner & Katsikis, 2020; Patel & Moore, 2020). These processes have consequences on spaces at different scales, bringing forward the political nature of spatial transformation. As Soja (2010) points out we are 'spatial beings', as we exist in space, shape and are shaped by space, therefore spatial transformations are inherently political, and they influence (in)justice relations. Territorial transformations linked to water become a crucial lens for investigating spatial justice, as much as the spatial perspective is fundamental for describing and tackling the theme of water justice.

While water control has always been a key concern for societies, growing scarcity dynamics are triggering novel social and geopolitical conflicts worldwide – and at the same time water deprivation is being used as a weapon (Secchi, 2010; UN, 2024a), as in this moment in the Mediterranean, within a long tradition of colonial territorial processes. It is important to notice that the use of water as a population control tool (hence biopolitical, in the Foucault's sense) isn't an incidental event, and it can be linked to the development of territorial rationales instead – which in certain contexts are constructed for and by colonial exploitation practices (Bandieramonte, 2013). Indeed water systems, in terms of infrastructures and governance, need to be "critically scrutinized in terms of their attempts at governing life and the distinctions they make between different forms of lives", as water and its allocation is "inherently political and, more specifically, biopolitical" (Hellberg, 2018, p.1). Spatial design disciplines – and European urbanism in particular – take part in this biopolitical action, planning such infrastructures on top of defining populations' spatial distribution and land use (Secchi, [2014] 2015), therefore 'making space' for humans and non-human lives and matters alike.

Water justice and environmental flows

The study of the relationship between water scarcity and spatial justice should not actually be restricted to the

human society, as freshwater is essential to all terrestrial life forms, and their survival (human species included) depends on the biosphere as a whole. From this point of view, it can be noticed that actions and projects related to water biopolitics often represent an example of multispecies injustice, as 'water justice' (and water distribution) are mostly linked to human needs and consumption. This is part of the same anthropocentric perspective entailed in the concepts of 'resources' and 'scarcity': these cannot be applied to the territory unless a human relationality is put in place (Dematteis, 2014). The two concepts are therefore relational – a 'resource' exists when it is functional to a demand, and it is 'scarce' only when there is not enough for satisfying a certain demand – and exist because of the dualistic society/nature 'metabolic rift' at the base of capitalist exploitation (Moore 2014). Forms of water (in)justice that go beyond human consumption can be searched in the concept of 'environmental flow', which since the 1980s has emerged to determine the 'minimum' river flows for maintaining the riverine ecosystem; the concept has since then evolved, and while initially it was limited to defining the minimum water stream necessary for the survival of a particular species, it came to encompass multiple aspects of a river's 'health', including indicators such as the interaction with the surrounding terrestrial environment, water quality, sediment presence, temperature and human pressures (Morrison & Bray, 2019). The point of view (which is the same of the mentioned notion of 'water stress' that also includes "ecological demand" – EEA 2021) expressed in the 'environmental flow' related literature is anyway anthropocentric and deterministic. In this literature, the river's 'health' is important because it is related to its 'direct and indirect' benefits for humans, which comprehend the 'Ecosystem Services' (ES) provided to human society (Gebreegziabher et al., 2023); the determination of what is the minimum flow for a river to be 'in good health' infers that the river should be measured and that a certain amount of water in it can be 'enough' or not for a function defined by humans.

It has been argued that a change in perspective by embracing multispecies justice is key to achieve also a fair society (Chao, 2022), therefore we need to enlarge the scope of spatial and water justice for a truly and comprehensively sustainable future. The yet more inclusive and open concept of more-than-human justice can enlarge justice's subjects from the biosphere to also include water itself. More specifically, a 'political ecology of things' perspective can foster an ethical behaviour towards the world as a whole, because harming one part of the interconnected 'web' means harming oneself; widening and changing the notion of self-interest may be a positive way to change our way to inhabit the planet, opposite to the "image of dead and thoroughly instrumentalized matter", i.e. resource to be exploited and consumed (Bennett, 2010, p. X). In this perspective, water and its agency should be regarded as a 'vibrant' matter with a value in itself that transcends the functions linked to anthropic processes: rather than calculating a minimum 'environmental flow' that is strictly functional to human processes, we may have to reflect on how to limit ourselves to a 'minimal extraction flow' while aiming at a 'non extractive metabolism' altogether as a form of care towards the water systems and related ecologies. Indeed human action can also be positive with regards to water ecologies, with actions that reinforce and extend the interaction between soil and water instead of letting it run off quickly; these practices (for example traditions linked to water retention and oases formation in dry climates) have aspects of circular metabolism, as sustainable use of freshwater allows for its renewal while keeping an ecological balance (Watson, 2019) in antithesis with linear extraction and depletion metabolic processes of modern western urban areas.

In recent decades, juridical systems around the globe have increasingly recognised water bodies' rights with the intent of protecting their ecosystems, as part of a wider trend that is granting legal rights to the environment. For example, New Zealand, India and Colombia have recognised a number of rivers as 'legal persons' – with a common feature, the existence of 'environmental water managers', human groups that advocates for the non-human subject's interests and rights (O'Donnell, 2018). In modern legal systems, water bodies can paradoxically weaken their stand by achieving such rights, for example with a "shift in language used to describe the aquatic environment, from a legitimate need for water to 'just another user' of water" (ibid.), therefore it's complicated to grant more-than-human water justice even when water bodies enter the society's juridical system of rights. Environmental water managers are part of broader and complex governance systems, often working within frameworks such as multi-actor river contracts, in which water use conflicts arise and are settled by stakeholders – with legal regulations often lacking some aspects of protection, for example in relation to groundwater pollution or the comprehensive dynamics of catchment areas. A universal perspective on water justice that would include

this matter in all its states and gradients as present in the 'critical zone' (Latour, 2014) may help protecting water more than the recognition of 'personal' legal rights of one single water body. Once water's necessity to all organisms is recognised and its existence is considered as a common good, a 'recommoning' (Geagea et al, 2024) approach in which water in all its forms is managed and taken care of collectively may be more effective than the single 'juridical' approach. A novel perspective, strongly connected to spatial justice (Soja, 2010; Swyngedouw, 2004), could include democratizing the water (eco)systems management, with city residents (of all kinds) take part with their own agency in relation to water – which can be linked to water retention, depuration, infiltration, and not only social governance and distribution – and stop being considered as mere 'consumers'.

Water scarcity or abundance? The case of Marseille

The worrying climate projections for the Mediterranean expect "future annual and summer warming rates are projected to be 20% and 50% larger than the global annual average, respectively" (IPCC, 2023, p 2237) which come together with lower freshwater availability. And although drier climates (and many worrying scarcity dynamics) are located on the south side of the sea, "summer warming is projected to be particularly strong in the north" side (ibid.), where societies and territories are built on the basis of water abundance coming from the Alps, now endangered. As glaciers are quickly disappearing, it becomes interesting to study the dynamics of water scarcity, extraction and injustice in a context on the north side of the Mediterranean, which will have to evolve and adapt its water uses and water-related spaces. The MedECC report (2020, p. 200) states that "for the Durance River in southern France, regulated by large reservoirs, decrease of mean annual renewable water resources has been demonstrated, with a decrease in summer low flows, associated with a greater pressure on water demand". The Durance, main tributary to the Rhone, is the river that provides freshwater to the whole arid Provençal coastal region where Marseille, the second city of France and main centre of the area, is located. This region is characterised by the lack of major surface water bodies and limited groundwater reservoirs, but paradoxically Marseille seems not to be affected by water scarcity even during the worst drought periods (Jean, 2011), thanks to the water infrastructure system constructed since the XIX century (Figure 1).

The city benefits from an abundant freshwater supply of the best quality (often proudly defined 'the best of France'), mainly coming through the Canal del Marseille, which since 1849 brings water from the Durance River to the city. The tradition of modern water infrastructures in this region, started with the Craponne Canal (1554-1559), built in order to introduce irrigation to the dry Crau plain. The 80km long Canal de Marseille was constructed after a centuries-long history of studies and proposals by many technicians, who tried to defy the complex region's orography for reaching Marseille and putting an end to its thirst (Jean, 2011). After a few projects that were trying to build a unique canal for both Aix and Marseille, finally the city took a historic decision in 1834, the titanic infrastructure had to be built 'at any cost'. The canal would indeed mark the city's history, landscape, architecture, and identity (ibid.), while also transforming the land uses of the surrounding territory with the introduction of widespread irrigation (Vidal-Naquet, 1993). The Canal de Marseille has undergone multiple modifications and technical improvements, but its substance hasn't changed to this day. The territorial water system instead has greatly evolved, especially in the second half of the XX century, with the construction of the Canal EDF (Electricité de France), the Canal de Provence, and several storage basins (constructed and managed by EDF) on the Durance and the Verdon, its main tributary (Jean, 2011). These infrastructures, which came after the 1955 law for the hydroelectric management of the rivers' system, on top of energy production and water distribution have the goal of regulating floods and drought effects by storing considerable amounts of alpine freshwater that can then be used during dry spells. At the same time, they have heavy consequences on the rivers' ecosystems, so that most of the water of the catchment area is now diverted from the riverbeds.

The EDF Canal's main function is hydroelectricity production, although it is also used as the main derivation from which other canals draw their water. The Canal de Provence is mainly distributing water to the coastal area urban centres, and to agricultural and industrial users as well, via a network that is mostly pressurised, making it extremely 'efficient' by minimizing leaks (ibid.). This system creates a total disconnection between the catchment areas and the territory: the Durance-Verdon system has most of its water subtracted, and the infrastructural system bypasses the surrounding landscapes for the benefit of anthropic consumption especially in urban areas,

while for example the smaller rivers of the Marseille area do not supply water to the city since the beginning of the XX century. This dynamic rises questions about water justice at the territorial scale, where the metropolitan area of Marseille is the main user of water and energy in the region: a concentrated abundance that creates injustice and scarcity dynamics for a wider territory.

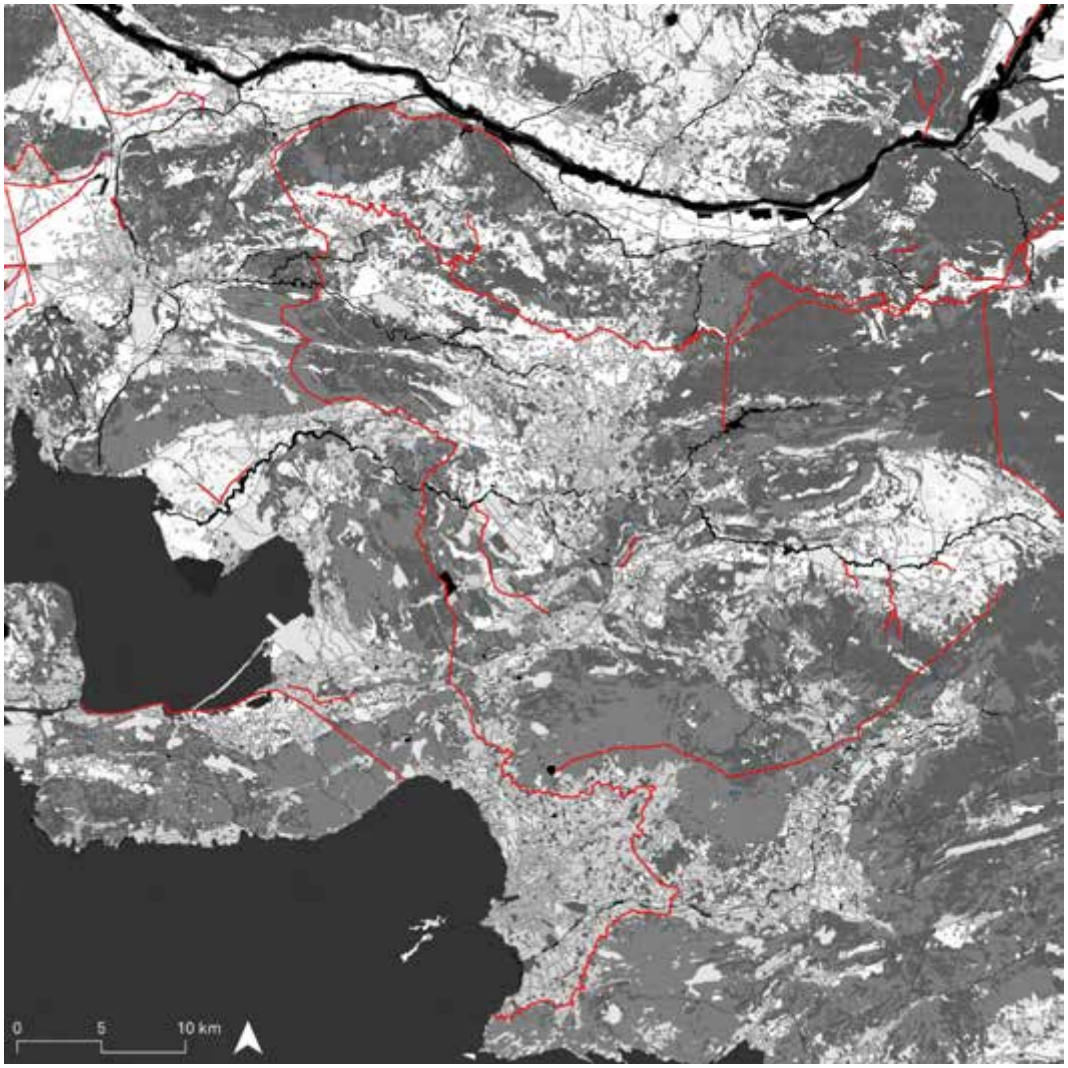

Figure 1. Systems of water in the territorial context of Marseille. Legend: urban areas, light grey; main water canals, red (EDF canal excluded, black); freshwater to sea water, from black to dark grey; forests to grasslands, from dense to light hatching. N. Russolo

Conflicts at the territorial scale

Already at the end of the XIX century, before the most substantial post-1955 works, the water abstraction imbalance gave rise to increasing conflicts, especially linked to the agricultural production. The irrigation issues during dry spells became very divisive, so that in 1907 a law established the 'Commission Exécutive de la Durance' (CED), with the goal of defining and regulating every (anthropic) water needs and rights along the river's course (Dumoullin et al., 2022). Thanks to the evolving negotiated distribution principles and to the large alpine reservoirs, human consumers' conflicts are basically not an issue anymore – although more than 70% of the irrigate surfaces are outside of the river basin. The Durance River instead, doesn't have a legal personality, lacking full representation for its environmental flows needs, which are regulated and protected by a complex governance system that since 2008 includes a river contract. The SMAVD (Syndicat Mixte d'Aménagement de la Vallée de la Durance) is the multi-actor institution responsible for the river contract and for the basin's monitoring and planning, comprehending

a vast array of stakeholders; the institution monitors and rules the allocation of water (SMAVD, 2020). While the SMAVD is working towards a better management of the Durance and its environmental needs[5], the priorities of the river basin system are hydroelectric production – the EDF infrastructure produces here 35% of the region's energy, with 15 power plants between the highest Serre-Ponçon reservoir and the Étang de Berre, and 8 more in the basin (Dumoullin et al., 2022) – and human consumption, to the point that the infrastructures extract by far most of the Durance's water flow. This unbalance causes a heavy alteration of the river's hydromorphology, with a worrying biodiversity and ecological continuity loss, as 68 barriers are present along its course (Étang Nouveau 2013). The environmental flow of the Durance is connected to many ecosystems in a vast territory, starting from the large and complex riverbed and its alluvial plain and aquifer. As most of the water extracted from the river is discharged into the brackish Étang de Berre wetland via the EDF Canal, the environmental seawater/freshwater balance of the étang is heavily disrupted. The smaller inflow from the Durance to the Rhone is also substantially changing the main river's environmental flow in its last section, on which the Camargue delta system depends.

A few years before the establishment of the Durance river contract, a conflict that entangles human use, wetland advocacy and ecological survival questioned the artificial canals' system flows. The 'Syndicat professionnel coordination des pecheurs de l'étang de Berre et de la région' (Coordination of the professional fishermen's union of the Étang de Berre and of the region) brought EDF to the European Court in 2003 because of the disturbance of the brackish environment of the Étang de Berre water body, winning a historic stance for the protection of the étang's ecosystem balance[6]. After the ruling, in 2006 EDF has modified the last part of the infrastructure so that one part of the freshwater goes back to the low Durance course in Mallemort (Figure 2); this was coupled with a better control of industrial and urban wastewater discharge, and has seen an improvement in flora and fauna in the étang (Étang Nouveau 2013).

The effects and perspectives of global warming are worsening existing conflicts and issues related to water scarcity and justice. In particular, with a temperature increase of 1 to 3°C, around year 2050 the Durance system (and therefore the whole PACA Region) is going to dispose of circa 30% less freshwater compared to 1980-2009 levels (Sauquet et al., 2015). At the same time water demand is supposed to increase consistently in the area because of a combination of rising evaporation and anthropic consumption (ibid.). One example of crisis moment, that is projected to become much more frequent in the next years, is represented by the 2022 drought, during which around 1200 water courses in France went dry, resulting in potentially irreversible habitat loss, on top of substantial damages to agricultural and hydroelectric production. (Bertrand et al., 2023). In the Durance river basin, an exceptionally dry period started in January of that year and transformed into a harsh drought coupled with heatwaves from April and throughout the end of the summer; in that period, the river lost around half of its water flow (SMAVD, 2023). In the aftermath of this dry spell the region's farmers denounced the fact that most of the system's water is still invariably discharged into the Étang de Berre: a foolish waste from their perspective, linked to the unequal territory's energy demand.

5 www.smavd.org – Among the objectives of the river contract, there are also "finding a new morphological balance for the riverbed" and "managing the alluvial plain by conciliating uses and resource's preservation" (SMAVD, 2020, author's translation)

6 The ruling of case C-213/03, Judgment of the court 15 July 2004 requires "prohibiting […] the discharge into a saltwater marsh communicating with the Mediterranean Sea of substances which, although not toxic, have an adverse effect on the oxygen content of the marine environment." Documentation available at: https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=celex:62003CJ0213

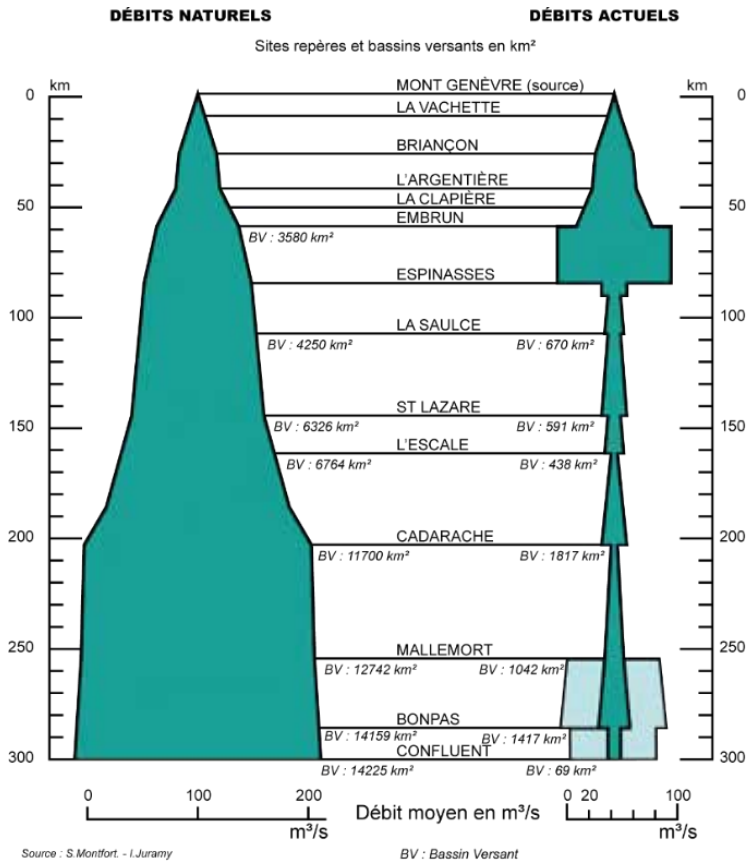

Figure 2. The flow diagrams show how more than 90% of the 'natural' average flow of the Durance has been diverted from its riverbed with the post-1955 EDF works (solid colour, original diagram from Juramy & Montfort, 1987). The lighter part of the right side diagram represents the 2400 million of m^3/ year flow returned to the Durance in Mallemort since 2006 (Étang Nouveau, 2013)

The extremely heavy withdrawals create imbalances that aren't limited to the distribution of freshwater. The weakened Durance stream struggles to transport sediments along its complex riverbed, so that water ecologies along its course are being additionally interrupted, and the lack of sediments' discharge into the Camargue delta through the Rhone is contributing to the coastal retreat of the low-lying brackish wetland; furthermore, silt discharge into the Étang de Berre is additionally unbalancing its environment (Balland et al., 2002). Another important aspect is linked to alluvial aquifers, which would normally be recharged by the river and give water back in its lower flow moments with a balancing effect on the ecosystem (Morizot & Husky, 2024); the Durance's alluvial aquifers – once a substantial freshwater reservoir – are suffering from depletion and from a rising pollutants' concentration, both due to the severely drained river (Étang Nouveau 2013).

Because of the heavy infrastructures and alterations, the Durance is classified as a 'Masse d'Eau Fortement Modifiée' (MEFM), and therefore according to the EU Water Framework Directive[7] it must be restored to a 'good ecological potential' within 2027. This necessity raises questions about the priorities of the territorial water system, where the granted 'environmental flow' isn't enough for the river ecosystem: can the system move towards the perspective of a 'minimal extraction flow'? The issue of a different distribution in water uses for a more sustainable territorial footprint is very complex. To give one example, hydroelectric power is the 1st 'renewable' energy production in France and worldwide, and once the (environmentally costly and disruptive) infrastructure is built its footprint is very low. On top of that, hydropower doesn't suffer from the constant availability fluctuations

7 2000/60/EC of the European Parliament. Available at: https://eur-lex.europa.eu/legal-content/EN/ALL/?uri=celex-:32000L0060

of wind and solar energy – until a prolonged drought, or structural water cycle modifications such as glaciers disappearance, arrive. In the perspective of a drier future for the region, a sustainable territorial metabolism project and river future requires re-thinking water and energy use, and therefore a negotiation of 'new social alliances' extended to matter (Secchi, 2011; Bennett, 2010) which should take into account degrowth propositions (Koller, 2020). The extractive paradigm of the Capitalocene for the Marseille urban/territorial water system is based on the existence of 'cheap nature' (Patel & Moore, 2020) at the regional scale, that involves artificial basins in the alps, impressive infrastructures, and heavily anthropized urban grounds that don't take good care of the water of the urban area.

Urban water, spaces and ecologies

The relationship of Marseille with water has completely changed since the Canal de Marseille was completed, with a celebration that included the construction of the magnificent Palais Longchamp, and the abandonment of the city's rivers for relying only on the territorial extractive infrastructure. With the alarming perspective of diminishing regional freshwater resources due to global warming (and the shrinking Alps' glaciers) while scarcity dynamics driven by water consumption are being accentuated – for example due to a growing number of data centres in the city – the imperative is finding strategies towards a more sustainable urban ecology and water footprint. This means a change in the territorial water metabolism, abandoning the current linear/extractivist practices and looking for opportunities of circular dynamics (Grulois et al., 2018).

The main element of the Marseille local water system is the Huveaune river, often mistaken for a stream or a canal, or even unknown by the some of the city's population. Its presence is linked to the only substantial valley which breaks the hills' crown that surround the city. This morphological feature, together with the presence of other towns along the river, made it the preferential axis for mobility infrastructure and industrial development. The presence of water is of course a fundamental asset for manufactures, taking advantage of the river's freshwater by consuming it, withdrawing it for plants' cooling, and discharging waste. Indeed for many years, the urban water courses were used as untreated industrial wastewater collectors, with serious pollution consequences. In 1972, because of the high levels of pollution, the Huveaune was diverted towards Cortiou in the Calanques National Park, with a moveable dam stopping its course and a doubling of the underground canal that was already discharging urban wastewater in Cortiou; this presents multiple problems, especially in terms of ecological continuity (EPAGE HuCA, 2015), thus creating an even more radical disconnection between the city and its waters. On top of this, with an apparent paradox for a city deprived of water, Marseille often experiences flooding events in case of substantial rainfall, because of the highly sealed soils: only 12% of the ground in the metropolitan area's urban spaces isn't sealed and can support vegetation or water infiltration (agaM, 2020). As the precipitations quickly saturate the drainage network, the polluted water coming from rain and runoff is directly discharged into the sea together with the Huveaune, which re-gains its original riverbed as soon as it reaches a flow of 30 m^3/s (EPAGE HuCA, 2015).

The presence of water courses within the urban area could be an occasion for rethinking the city-water relationship – in a different urban ecological perspective (Orff, 2016) that includes more-than-human water and spatial justice, where urban soils can be transformed to support life and interact with water. Once the pollution dynamics are halted, the urban rivers and their surrounding alluvial plains have the biggest potential for welcoming and expanding ecologies: giving more space to water and connected ecosystems could become part of a larger phytoremediation process for Marseille, where polluted urban surfaces now intoxicate water runoffs. The freshwater inflow from the Huveaune and the other minor rivers could be used for non-drinking urban water needs, starting to move away from the solely linear territorial scale metabolism that is now present. Revealing superficial water flows in connection to situated depaving of the urban ground may help managing rainwater (avoiding its total inclusion in the sewage system) and foster urban ecologies, also helping the creation of a better urban environment in response to a hotter climate[8]. At the same time, a new awareness of urban water, at present completely hidden from sight and discourse (Kaika, 2005) may help recognise the global

8 A number of EU-funded projects are experimenting on the relationship between water, urban comfort and the environment, for example Cool Noons https://coolnoons.interreg-euro-med.eu/

necessity of a new ecological balance with the larger territory related to flows – with possible connections to social movements interested in environmental justice that are already active in the city. In an urban area where spatial justice is a complex theme (ETH, 2020), citizen groups are advocating for river ecosystems to be preserved and restored, as with the Ruisseau des Aygalades, which crosses some of the most deprived neighbourhood in the north of Marseille. The project for a new park along the water course[9] is going to positively transform the urban landscape, with the risk of a gentrification processes that must be controlled for avoiding the worsening of spatial injustice. Also the Huveaune River is interested by a project, this time at the metropolitan scale and essentially linked to active mobility, which also includes some river 'renaturation' sites, called Voie Verte de l'Huveaune (Huveaune greenway)[10]. The potential linked to wider action on water ecosystems suggests that the river spaces could undergo a more substantial transformation, linked to slowing down and reinforcing its flow and ecologies (Morizot & Husky, 2024). As for centuries Marseille has only counted on its groundwater reservoirs for its urban freshwater (Vidal-Naquet, 1993), by taking good care of water from the territorial and metropolitan scale to the materiality and pollution of urban surfaces the city aquifers may also come back as a tool helping the local water needs, in connection with the renewed city's rivers. A systemic change with the introduction of local water sources may configure a hybrid collaboration between centralised large-scale infrastructure and decentralised water systems (Wong et al., 2020), that can be an important occasion for designing a better urban environment while 'making space' for ecosystems.

An open ending

In the territorial context of Marseille, the main urban area is the biggest water consumer, therefore domestic and urban water-efficient measures including diffused building-scale reservoirs and recycling devices (Correljé & UNEP, 2008) could be an important contribution towards a more sustainable water footprint. These practices should be coupled with the described wider urban and territorial transformations that can take advantage of the local water presence in a regenerative way, in a new environmental and spatial justice perspective. The associations and citizen groups already present in the city, who are working on the themes of water and the environment, represent a great potential of social interaction and ownership in the perspective of a water recommoning process (Geagea et al, 2024), that may become a first step towards of a wider ecological commoning future for urban ecologies.

A re-design for better and comprehensive water justice will have to take into account the ground's materiality and relationship with the rivers, their alluvial aquifers and groundwater systems. On top of the spatial modifications, a successful strategy for a more sustainable urban water footprint will have to include the social and more-than-human justice aspects within a renewed governance. In this perspective, the city-centred water withdrawal from the Alps may find a new balance between urban water use and the territorial needs, starting to reconcile local ecologies with their water systems.

While water is a fundamental resource for a sustainable future, the current trend is of accelerating its consumption and depletion. We must be aware that the present global water crisis can't be solved by a small amount of water reuse, as it necessitates a radical change in the way 'resources' are extracted and consumed especially since the exponential increase of energy and goods production that happened during the XX century. Water is now widely extracted and consumed like many other externalities, but being a vital necessity, it should be managed like a universal 'commons' (Harvey, 2011). This perspective must enter the urban design discourse, as its availability is strongly connected with spatial justice for the society and beyond. In the Marseille area, water is locally present but for the last century it has not been part of the city's metabolism. There are possibilities for the metropolitan area to take advantage of local freshwater reservoirs for a new urban ecology, and these should be investigated in order to mitigate the water scarcity and injustice dynamics that affect the wider territory.

Abstract
The transition to a clean energy economy requires securing critical minerals—such as nickel, copper, and cobalt—vital for low-carbon technologies. The EU Critical Raw Materials Act (2023) promotes domestic sourcing to reduce reliance on external suppliers. Our investigation explores the environmental and socio-economic impacts of renewed extraction in Europe, focusing on Italy, which holds 16 of the 34 listed materials but has seen no active metal mining since the 1970s. Using Punta Corna, a former cobalt mine in the Alps, as a case study, we analyze tensions between extractivist strategies and local economies based on tourism. Through cartographic analysis, we contrast industrial development with protective territorial approaches, raising questions on sustainability, peripheralization, and governance. The findings illuminate broader trade-offs in implementing green transitions within contested Alpine landscapes.

Keywords: re-mining, alpine region, territorial patrimonialisation, extractivism, depopulation

Introduction

The transition to a clean energy economy requires secure access to critical minerals—such as nickel, copper, and cobalt—which are indispensable to advanced technologies and low-carbon infrastructures. The European Critical Raw Materials Act (2023) addresses this imperative by promoting the domestic extraction, processing, and recycling of such materials, with the aim of strengthening the EU's strategic autonomy[1] while reducing its dependence on external suppliers. This paper explores the environmental and socio-economic implications of renewed extractive activities in Europe, focusing in particular on Alpine landscapes. Among European countries, Italy presents a particularly relevant case: despite possessing 16 of the 34 critical raw materials listed in the CRMA, the country has not hosted active metal mining operations since the 1970s.

Our investigation centres on the Italian government's current strategy, which aligns with European directives and proposes the reopening of former mines and the exploration of new sites, especially in the Alpine regions. This strategy is paralleled by the necessity of substantial investments to recover industrial and technological capacities eroded over decades. A particularly emblematic case is that of Punta Corna, once the largest cobalt mine in Europe, which today represents a critical site for interrogating the tensions between extractivist development and alternative local economies grounded in tourism, environmental valorisation, and territorial patrimonialisation.

Through cartographic and discursive analysis, we examine the conflicting narratives surrounding these mining

1 Strategic autonomy refers to the European Union's capacity to act independently in key policy areas—such as defence, energy, technology, and industrial supply chains—without excessive reliance on external powers. Originally developed in the context of security and defence, the concept has expanded in recent years to include economic and technological dimensions, particularly in response to geopolitical instability, global supply chain disruptions, and the growing rivalry with China and Russia. Within the framework of the Green and Digital Transitions, strategic autonomy has become central to EU policy discourse, justifying initiatives like the Critical Raw Materials Act as means to reduce vulnerability and strengthen Europe's resilience in a rapidly changing global landscape.

initiatives. On one side stands a re-emergent extractivist paradigm; on the other, what Boltanski and Esquerre (2019) term the "enrichment economy", oriented around ultra-protective territorial strategies and the valorisation of heritage, landscape, and place-specific assets. These competing visions raise fundamental questions concerning the sustainability of new extractive projects and their alignment with the values and aspirations of local communities, often situated on the margins and affected by processes of depopulation and infrastructural retreat.

By framing Punta Corna as a case study, we argue that it serves as a privileged lens through which to understand the socio-political and territorial impacts of the Critical Raw Materials Act. The site functions as an experimental laboratory where local fears and hopes surrounding extractive futures materialise, offering broader insights into the contradictions embedded in Europe's green transition and the contested geographies of sustainable resource governance.

In this context, the reactivation of mining frontiers in the Alps occurs not in a vacuum, but amid rapidly accelerating climatic and ecological changes. As one of the fastest-warming regions in Europe, the Alpine space is experiencing the retreat of glaciers, permafrost thaw, and hydrological shifts that threaten both ecosystems and livelihoods. These transformations form the critical backdrop against which new extractive activities must be assessed.

The paper is structured in four main parts. Part 1 introduces the European Critical Raw Materials Act (CRMA) within the broader framework of the green transition, outlining its objectives, regulatory mechanisms, and geopolitical implications. Part 2 turns to the Italian context, describing national strategies for the reactivation of mining activities and the tensions these raise with existing territorial models centred on heritage, tourism, and environmental valorisation. Part 3 shifts the focus to the Alpine region, analysing how renewed extractive pressures intersect with accelerated climate change and historically stratified landscapes. Part 4 presents the case study of Punta Corna, examining local conflicts, governance asymmetries, and the competing visions for development in marginal mountain areas. The conclusion reflects on the broader stakes of extractive reterritorialisation in Europe, advocating for more situated, democratic, and ecologically attuned approaches to resource governance.

1. The Critical Raw Materials Act and the Return of Mining in Europe

In her State of the Union address of September 2022, President von der Leyen, while addressing Europe's dependence on Russian gas, also drew attention to the risk of overreliance on third countries for the supply of rare earths. On that occasion, she announced the forthcoming European legislation on strategic raw materials: the so-called Critical Raw Materials Act (CRMA). This strategy aims to reinforce the European supply chain through a combination of trade agreements with countries such as Canada, Japan, and Vietnam; the promotion of material recycling; and—most controversially—the development of new mines within EU borders and the reopening of old mining sites ("re-mining") using advanced technologies.

In March 2023, the European Commission outlined the contents of the CRMA, whose main goal is to guarantee a "secure, diversified and sustainable" supply of critical raw materials—resources deemed essential for both the green and digital transitions. One of the key aims of the CRMA is to reduce Europe's excessive dependence on a single supplier country, in line with the broader objective of strengthening the EU's strategic autonomy in an increasingly unstable geopolitical landscape. At present, the EU's dependence on imports is both acute and highly concentrated: 98% of its heavy rare earths and 99% of light rare earths, along with 93% of magnesium, come from China; 68% of cobalt is imported from the Democratic Republic of Congo; 78% of lithium from Chile; 71% of phosphorus from Kazakhstan; 64% of bauxite from Guinea; and 62% of antimony from Turkey (Il Sole 24 Ore 2023a) (as shown in Fig.1). This reliance on non-European suppliers raises not only questions of strategic vulnerability but also significant ethical and environmental concerns. For example, cobalt extraction in the DRC has repeatedly been linked—by Amnesty International and other organisations—to child labour, human rights violations, and severe environmental degradation (Martin Sanchez, Gori Nocentini 2025).[2]

2 Almost three quarters of the world's cobalt production takes place in the Democratic Republic of Congo. Most mining

Fig. 1. Main suppliers of critical raw materials to the European Union. Source: European Council.

The European response is twofold: to increase extraction and processing capacity within its own borders, and to diversify its international supply base. The EU's approach to critical raw materials also includes a stated commitment to minimising environmental externalities and promoting circularity across the value chain. The CRMA sets out three primary targets for 2030: at least 10% of the critical raw materials consumed within the EU should be extracted domestically (up from the current 3%) (Bourgery-Gonse 2023); 40% should be processed within Europe; and 15% should be sourced from recycling activities (Circular Economy Network 2023). The regulation also stipulates that no more than 65% of the EU's annual consumption of any given strategic raw material should be supplied by a single third country—an objective that, as previously noted, remains far from being achieved.[3] The Act also updates the list of critical raw materials, identifying 34 substances, 16 of which are classified as "strategic"—including copper, cobalt, lithium, natural graphite, nickel, and rare earths.[4].

operations are controlled by large multinationals, mainly Chinese, but at least 20% of the exported material comes from 'artisanal' mines that use child labour and do not respect elementary labour and human rights conditions.

3 Other measures envisaged in the framework of the Critical Raw Materials Act are: the simplification and acceleration of regulations for extraction projects: a maximum of 24 months for extraction permits and 12 months for processing and recycling permits; simplified procedures supported by easier access to funding lines; greater coordination between Member States in order to have an accurate picture of national reserves; investment in research and training with the creation of a Raw Materials Academy to develop the new skills needed by workers engaged in this sector. In addition, measures are planned to increase recycling rates and the use of secondary raw materials.

4 In the European Commission's draft regulation, there are 34 'critical raw materials': antimony, arsenic, bauxite, baryllium, bismuth, boron, cobalt, coking coals, copper, feldspar, fluorspar, gallium, germanium, hafnium, helium, heavy rare earth elements, light rare earth elements, lithium, magnesium, manganese, natural graphite, nickel - battery grade, niobium, phosphorite, phosphorus, platinum group metals, scandium, silicon metal, strontium, tantalum, titanium metal, tungsten, vanadium. Of these 'critical'

In its communication A Secure and Sustainable Supply of Critical Raw Materials in Support of the Twin Transition (European Commission 2023a), the EU provides projections that illustrate the dramatic rise in demand for these materials: demand for rare earths is expected to increase 4.5 times by 2030 and 5.5 times by 2050, while lithium demand—primarily driven by the growth of electric vehicle batteries—is forecast to rise elevenfold by 2030 and seventeen fold by 2050. As with other domains of the green transition, the implementation of this new EU framework for critical raw materials reveals that the transition—often portrayed as clean, sustainable, and immaterial—is, in practice, underpinned by extractive logics that produce tangible and far-reaching effects on European territories, economies, and ways of life (Martin Sanchez, Gori Nocentini 2025).

2. Re-mining Italy: National Strategies and Territorial Contradictions

Despite the near-total dismantling of its mining sector over the past five decades, Italy remains geologically endowed with a wide array of minerals now considered strategic under the European Critical Raw Materials Act (CRMA).[5] According to official data from the Ministry of Enterprises and Made in Italy, the country holds confirmed or potential availability of 16 out of the 34 critical raw materials listed in the regulation. However, the extractive industry—particularly in the field of metal mining—underwent a gradual and definitive decline during the 1970s, due to a combination of increasing labour costs, growing technical and financial challenges linked to deep extraction, and the broader economic crisis triggered by the oil shocks (Madeddu 2020). Since then, metal extraction has effectively ceased, and Italy has become fully reliant on imports to meet its industrial and technological demands.

In this context, the CRMA has provided renewed impetus to national discussions on resource sovereignty and strategic autonomy. The Italian government, through the Ministry of Enterprises and Made in Italy and the Ministry of the Environment, has outlined a strategy aimed at mapping disused or dormant extraction sites, with the goal of reopening or activating new ones in response to the anticipated surge in demand for strategic materials. This mapping process—entrusted to ISPRA within the framework of the PNRR-funded GeoSciencesIR programme—has resulted in the development of the GeMMA database, a national inventory of geological, mining and environmental data presented in early 2024 (ISPRA 2024).

According to this updated national dataset (refer to Fig.2), Italy hosts around 900 sites historically associated with metal extraction, none of which are currently active. At present, only feldspar and fluorite—non-metallic but CRMA-listed materials—are being commercially extracted. These minerals are essential for the ceramic, glass, and electronics industries. In particular, the fluorite mine of Genna Tres Montis in southern Sardinia—currently undergoing restructuring—is expected to become one of Europe's most significant sites (Ispra, 2024). Other formerly productive fluorite mines, especially in Lombardy, Trentino, Lazio, and Sardinia, are being reassessed, as the market price of fluorite has quadrupled since the 1990s (Il Sole 24 Ore 2023a)).

raw materials, 16 are considered 'strategic': bismuth, boron-metallurgical grade, cobalt, copper, gallium, germanium, lithium-battery grade, magnesium metal, manganese-battery grade, natural graphite-battery grade, nickel-battery grade, platinum group metals, rare earth elements for magnets (Nd, Pr, Tb, Dy, Gd, Sm, and Ce), silicon metal, titanium metal, tungsten.

5 With a law of 1982, the Italian state attempted – unsuccessfully – a revival of the sector by deploying substantial public resources to support activities from mining research to production (Madeddu, 2020).

Fig. 2 Cartographic representation of identified critical raw material reserves across the Italian territory. Source: ISPRA, 2024. TO BE UPDATED

While active extraction of metallic critical raw materials is currently absent, ISPRA's data confirm the presence of numerous promising deposits. Copper, for instance—crucial to both energy systems and digital infrastructures—is documented in the Colline Metallifere, the Ligurian-Emilian Apennines, the western Alps, Trentino, Carnia, and Sardinia. Manganese was historically extracted in Liguria and Tuscany. Tungsten, often found alongside lead and zinc, is present in Calabria, Sardinia, and the central-eastern Alps. Cobalt is found in Sardinia and Piedmont, where the deposit at Punta Corna has been explicitly identified as a site of strategic relevance at the European scale (ISPRA 2024). Other resources include magnesite in Tuscany, magnesium salts in the Venetian Prealps, and bauxite in Apulia and northwestern Sardinia, particularly at the Olmedo site, the last operational metal mine in the country before its closure.

The Alpine arc, in particular, re-emerges as a key spatial node in this renewed extractive geography. From Friuli-Venezia Giulia to Piedmont, passing through Trentino-Alto Adige, Veneto, Lombardy, and Liguria, northern Italy hosts a significant share of the country's identified strategic resources. In Liguria, the well-known titanium deposit located within the Beigua Regional Natural Park—a UNESCO Geopark—is currently excluded from development due to environmental concerns. In the Veneto region, deposits of blende, pyrite and mixed sulphides, magnesium salts, clay, cement marl, baryte mines, and deposits of betontite, bleaching earth, refractory earth and kaolin are currently explored for a reopening. Abandoned in the 1950s they are located in areas of high landscape, naturalistic and tourist interest (Corriere del Veneto 2023, 2024). In parallel, new extraction frontiers are emerging in geothermal contexts: recent studies have confirmed the presence of lithium in geothermal fluids across Tuscany, Lazio, and Campania, with multiple research permits issued in 2023, especially in the Lazio region (Il Sole 24 Ore 2023b).

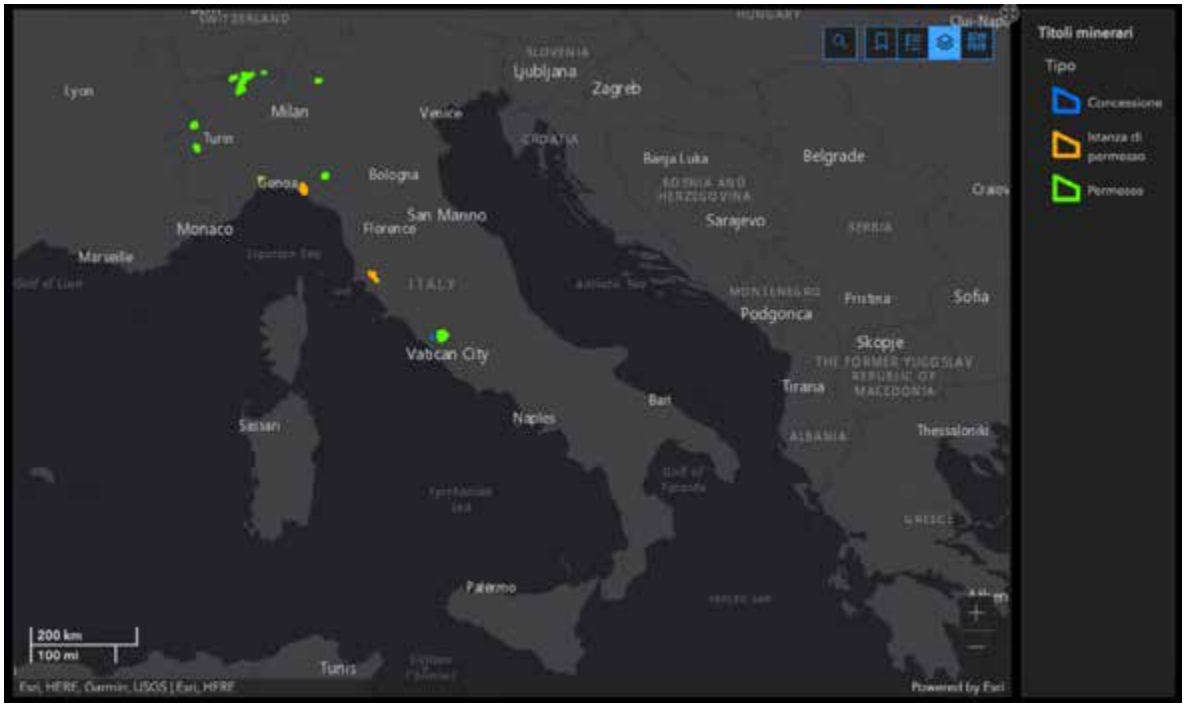

Fig. 3. Mining titles: concessions, permit applications, and permits. Source: ISPRA, 2024. TO BE UPDATED

These developments are now feeding into the elaboration of Italy's forthcoming National Mining Strategy, mandated by EU Regulation 1252/2024 and assigned to ISPRA through Decree Law 84/2024. This strategy is expected to define a comprehensive framework for the evaluation, prioritisation, and potential reactivation of mining operations, marking a shift from decades of abandonment to a new phase of institutional and economic attention to subsoil resources.

However, the reopening of mining sites in Italy after decades of inactivity raises a number of issues regarding the long-term sustainability of such projects and their compatibility with the development trajectories and imaginaries of local communities. For instance, mining appears in clear tension with the broader economic repositioning that Italy has undergone in recent decades—a shift that Boltanski and Esquerre (2019) define as the transition toward an economy of enrichment. This model marks a rupture with the Fordist paradigm of mass production that characterised the post-war period, and instead centres on niche markets and high-end goods, whose value is tied less to functional utility than to uniqueness, authenticity, and territorial specificity (Martin Sanchez, Gori Nocentini 2025).

In this context, patrimonialisation has increasingly become a strategic tool for territorial development. It seeks to identify and mobilise undervalued or overlooked resources—be they historical, cultural, or environmental—and turn them into economic assets. Often, this results in the transformation of dormant heritage into active heritage, enabling actors to appropriate and even reconfigure history in order to increase the perceived value of goods and services. As Boltanski and Esquerre (2019) note, this process tends to strip concepts such as heritage, identity, tradition, and memory of their inherent ambiguity and complexity, recasting them instead as instruments of market differentiation (Ibid.).

Against this backdrop, the return of extractive activities not only disrupts the symbolic coherence of such strategies, but poses deeper contradictions regarding the role and meaning of territory in contemporary Italy. As Pank (2022) reminds us, the production of operational landscapes for mining requires profound transformations in material arrangements, value systems, and property regimes. These are not merely technical operations, but political reconfigurations—often at odds with the logics of territorial enhancement and with the forms of economic life currently dominant in many of the areas targeted by the CRMA.Yet, the reactivation of mining frontiers in the

Alps does not occur in isolation. These developments unfold within a context marked by increasing ecological vulnerability and climatic instability (Longhin, 2025), which profoundly shape the implications of extractive activities in these territories.

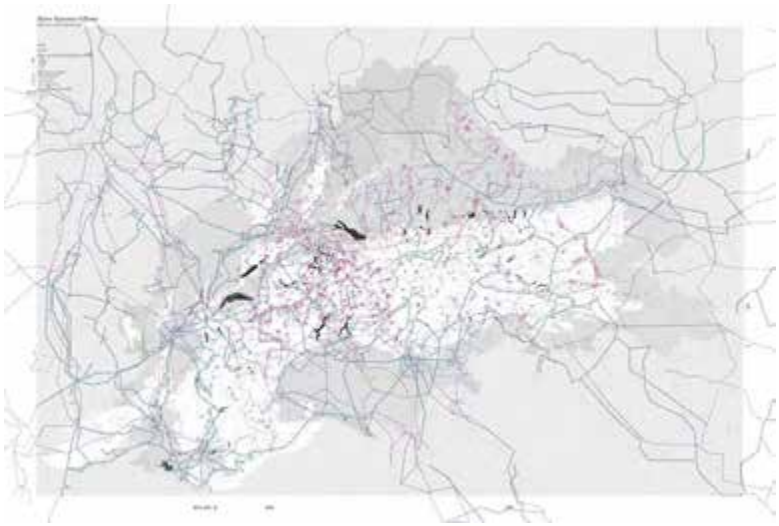

Figure. Cartography of the Alpine Operationalising Landscape. Author's elaboration, 2025. TO BE UPDATED

3. The Alpine Landscape at the Crossroads: Extractivism and Climate Dynamics

Over the past decades, the Alps have become a paradigmatic site for observing the entangled effects of climate change and extractive development. In this mountainous region—characterized by steep topography, fragile ecosystems, and historically layered forms of human appropriation—the accelerating retreat of glaciers, permafrost degradation, biodiversity loss, and the intensification of extreme weather events are reshaping both ecological processes and the viability of long-standing economic activities (Cherisch et al., 2015, Longhin, 2025). Climate change here is proceeding at more than twice the global average, with temperatures in the Alps rising by nearly two degrees over the past 150 years (Permanent Secretariat of the Alpine Convention, 2019a; 2022). These environmental shifts converge with deeper structural transformations in land use and territorial economies, placing new pressure on already fragile alpine regions (Longhin, 2025).

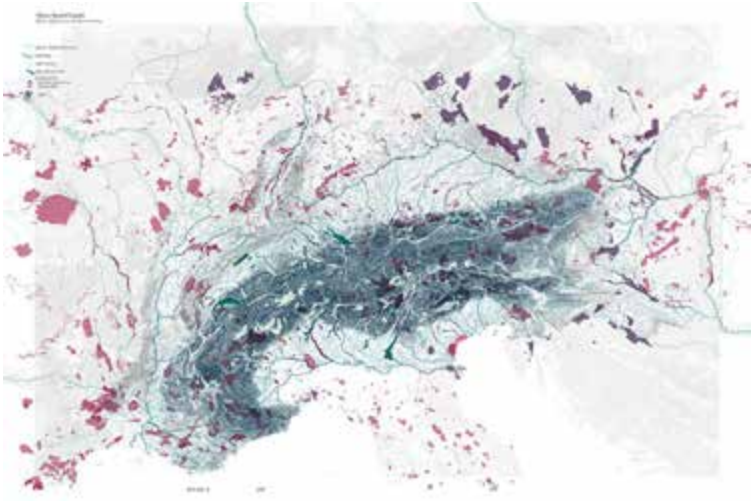

Figure. Cartography of the Alpine Spatial Capital. Author's elaboration, 2025. TO BE UPDATED

Among the most emblematic of these pressures is the resurgence of mining, which is increasingly promoted as a strategic response to Europe's demand for critical raw materials (CRMs). In recent years, extractive activities have re-emerged not only as an economic opportunity but as a geopolitical imperative, reframing peripheral mountain territories as potential resource frontiers in the green transition. Yet these dynamics are not new. Across the Alps, extractive infrastructures—ranging from mineral quarries to hydropower networks—have long left material and symbolic imprints, inscribing the landscape with layers of industrial heritage and unresolved socio-environmental tensions. The historical development of alpine regions is inextricably linked to extractive logics: mining, forestry, water appropriation, and later, tourism and industrialization, have all contributed to the transformation of the alpine space into a complex operational landscape (Modica, 2022, Longhin, 2025).

This landscape, far from being a neutral container for development, reflects the cumulative impacts of extraction and the often-conflicting interests inscribed within it. Alpine valleys, in particular, bear the marks of infrastructural and territorial regimes that have alternated between periods of exploitation, abandonment, and selective reinvestment. Brownfield sites, depopulated mining villages, and residual industrial infrastructures stand as material evidence of cycles of accumulation and neglect, often concentrated in areas with limited political voice. Today, the push toward a new mining economy risks reproducing these asymmetries under the banner of sustainability and energy transition. In this sense, the Alps can be read not only as a hotspot of climate vulnerability, but also as a testing ground for the contradictions of contemporary extractivism: where green imperatives collide with local ecologies, contested legacies, and demands for environmental justice (Longhin, 2025 forthcoming).

Understanding the transformations underway in the Alps thus requires a multi-scalar reading—one that situates renewed extractive pressures within broader climatic, economic, and political shifts. It also demands critical engagement with the histories sedimented in alpine landscapes, which continue to shape the possibilities and limits of territorial futures. The mining resurgence is not happening in a vacuum: it is embedded in long-standing territorial imaginaries, institutional fragilities, and the socio-material residues of previous extractive cycles. As such, it calls for planning and design approaches that are not only technically adaptive, but historically and ecologically situated.

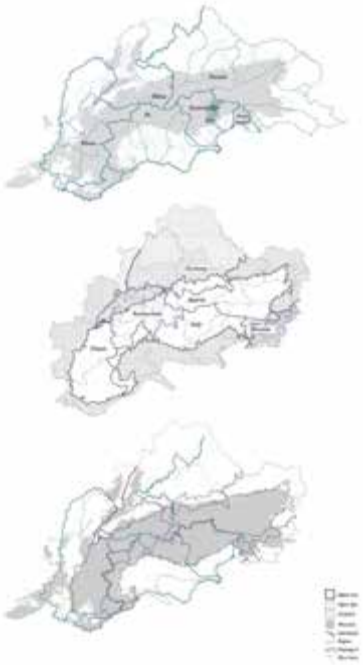

Figure. The legislative subdivisions of the Alpine Space. E. Longhin's elaboration, 2021. From: The Machine in the Mountain, PhD IMAGE TO BE UPDATED

4. Punta Corna: Between Neo-Extractivism, Depopulation, and Territorial Valorisation

Punta Corna, a peak in the Piedmontese Graian Alps rising to 2960 metres, offers a paradigmatic example of the dynamics shaping many Italian mountain regions. Situated in the Lanzo Valleys, between the Viù and Ala valleys, this territory has followed a markedly different trajectory from neighbouring areas such as the Susa Valley, where the Agnelli family initiated mass winter tourism in the 1930s through the development of the winter resort town of Sestriere. In contrast, the Lanzo valleys have seen limited touristic infrastructure and investment. Their economy remains fragile, supported in part by slow and nature-based tourism, as well as a high incidence of second homes. Traditional practices such as sheep farming and the seasonal use of malghe—high-altitude pastures used for summer grazing and artisanal cheese production—continue to play a central role in local livelihoods (Figure to be integrated here).

Within this seemingly pastoral context, the Piedmont Region granted in 2019 an exploration licence for cobalt, nickel, copper, silver, and associated minerals at Punta Corna to the Australian company Altamin. Altamin is a so-called junior miner, focused on a limited number of targeted projects involving exploration and prospecting activities. In Italy, the company operates through two subsidiaries—Strategic Minerals srl and Energia Minerals srl—and is involved in four active projects. Its most advanced initiative, concerning zinc extraction in Gorno (Bergamo province), was rejected in June 2022 by the Ministry for Ecological Transition (Pons 2022). At Punta Corna, however, the exploration licence was renewed in December 2022.

Contrary to appearances, mining is not a recent phenomenon in this area. Between 1753 and the 1930s, Punta Corna hosted what was, at the time, Europe's largest cobalt mine. Many of the settlements in the area originated from this mining economy (Forti 2023). Initially used as a pigment, cobalt lost economic relevance with the introduction of synthetic dyes in the early twentieth century, leading to the mine's decommissioning. However, cobalt has since become central to a wide array of industrial applications, owing to its distinctive chemical and physical properties. Today, it is employed in the production of superalloys for jet engines and gas turbines, in high-performance permanent magnets, in high-strength cutting tools, as well as in chemical processes such as the synthesis of adipic acid for nylon production. Cobalt's strategic value has increased significantly in recent decades due to its role in lithium-ion batteries for portable electronics, electric vehicles, and other clean energy technologies. With the EU's planned phase-out of petrol and diesel vehicles by 2035,[6] cobalt demand is expected to rise sharply. It is therefore not surprising that, as early as 2020, the European Union classified cobalt as a strategic raw material—alongside lithium, coltan, and rare earth elements—in support of both the green and digital transitions.

The Punta Corna deposit lies between two municipalities in the Lanzo Valleys: Usseglio and Balme. These local governments have expressed diverging positions regarding the potential extractive redevelopment of the site. Their respective stances are emblematic of the broader debate over development strategies in contemporary mountain areas: on one side, a model rooted in extraction and energy production—a legacy of modern industrialisation; on the other, a model aligned with Boltanski and Esquerre's (2019) economy of enrichment, centred on niche markets, tourism, and territorial patrimonialisation.

In the municipality of Usseglio, the legacy of modernity is embodied by the large dam built in the 1930s for hydroelectric production, which gave rise to the artificial Lake Malciaussia and submerged the original village bearing the same name. The construction, emblematic of early twentieth-century modernisation, brought roads, a railway, and new employment opportunities to the Lanzo valleys.[7] Today, the Usseglio administration views the prospective reopening of the cobalt mine as a potential catalyst for revitalising a region suffering from

6 The European Parliament on 14 February 2023 gave final approval to the measure banning the sale of vehicles with combustion engines from 2035. The measure is part of the 'Fit for 55' package to halve pollutant emissions in the EU by 2030 and sets a target of zero emissions from new cars and vans for sale in the EU from 2035.

7 Cf. A. De Rossi. The construction of the Alps. The twentieth century and Alpine modernism (1917-2017).

infrastructure deficiencies—particularly digital connectivity[8]—and long-term depopulation (Forti 2023).[9] Mining, from this perspective, is seen as complementary rather than antagonistic to existing economic activities such as tourism. However, significant frictions emerge between mining ambitions and the region's orientation towards tourism, environmental conservation and heritage-based development. The environmental and spatial impacts of mining—long the subject of extensive critical scholarship[10]—are difficult to reconcile with the experiential and ecological qualities that sustain mountain tourism (Martin Sanchez, Gori Nocentini 2025).

In stark contrast, the municipality of Balme, located on the Val d'Ala side of Punta Corna, passed a resolution in June 2020 opposing Altamin's exploration activities (Pons 2022). Balme's local economy revolves around nature-based tourism and environmental valorisation. One of its areas, Pian della Mussa, has been part of the European Natura 2000 Network since 2016. Yet Balme is not devoid of extractive activity: the Pian della Mussa Srl company bottles spring water in the area. However, this activity is framed as compatible with the landscape and falls within the logic of the economy of enrichment—relying on the symbolic and ecological value of place, and oriented towards niche, high-quality production. From this perspective, mining represents a radical disruption to the narratives and uses of territory that have underpinned Balme's development strategy.

Still, processes of territorial patrimonialisation are not without their contradictions. Designating a landscape as a heritage asset necessitates its valorisation (Lazzarotti 2003), which can lead to the commodification of territorial identity and the marginalisation of other narratives and uses. While official recognition—such as inclusion in the Natura 2000 Network—may support local development, it can also result in what D'Eramo (2017) calls iconic reduction: a flattening of territorial complexity into standardised images tailored to tourism. Moreover, the protocols for environmental protection may exclude local actors from participatory forms of territorial transformation, as Vassallo and Martin Sanchez (2022) have argued.

Balme thus stands as the site of a profound and unresolved tension between two contrasting territorial visions. The mountain, once conceived as a productive landscape, is now framed primarily as a space to be preserved—even if this means restricting opportunities for change. In such a scenario, combating depopulation appears contingent on strengthening infrastructures that could attract new residents and support the tourism sector.

What this case study illustrates is the absence of a shared vision for Punta Corna's future. In Usseglio, the mining project is seen as compatible with existing economic practices and potentially able to attract investment and development. In Balme, by contrast, the mine is viewed as fundamentally incompatible with the territorial model based on conservation, tourism, and symbolic valorisation. Yet both municipalities share a concern with reversing demographic decline and revitalising local economies and welfare—whether through new industrial activities or enhanced touristic appeal (Martin Sanchez, Gori Nocentini 2025).

Finally, the divergent local perspectives on Punta Corna's future—brought to the fore by the mining project—currently lack a meaningful space for deliberation. The project itself exemplifies a top-down policy dynamic: rooted in a European regulatory framework (the CRMA), implemented by two national ministries, and executed by a private actor operating under a regional licence. Local governments, by contrast, are relegated to a consultative role and hold no real decision-making power (Forti 2023). This asymmetry raises pressing questions not only about governance and legitimacy, but about the actual capacity to imagine and construct plural, situated futures

for marginalised territories (Ibid.).

Conclusion

This article has examined the socio-environmental and territorial implications of renewed extractive strategies in Europe through the lens of the Critical Raw Materials Act and its potential implementation in the Italian Alpine context. By focusing on the case of Punta Corna—a former cobalt mine now identified as a site of strategic interest—the analysis has traced how European green transition agendas become materially and spatially articulated in marginalised mountain regions. These agendas are not merely technical responses to supply chain vulnerabilities but are embedded in specific territorial configurations, historical trajectories, and socio-political tensions.

The Alpine arc—already under significant pressure from accelerated climate change, infrastructural obsolescence, and demographic decline—emerges as a critical arena for interrogating the contradictions of contemporary extractivism. In this context, the promise of re-industrialisation and strategic autonomy coexists uneasily with alternative territorial economies rooted in tourism, ecological valorisation, and patrimonialisation. As demonstrated, the logics of extraction and enrichment not only diverge but also expose deep-seated asymmetries in governance, wherein supranational imperatives and corporate actors hold disproportionate influence over processes of territorial transformation.

The Punta Corna case foregrounds the limitations of existing policy frameworks in addressing the multiplicity of values, claims, and temporalities that characterise alpine landscapes. It highlights the absence of meaningful deliberative mechanisms for local actors, who are often confined to consultative roles within broader top-down governance structures. In this sense, the reactivation of mining frontiers raises not only environmental and economic questions but also those of democratic legitimacy, distributive justice, and spatial equity.

Rather than treating mining as an inevitable corollary of the green transition, this analysis calls for more situated, historically informed, and democratically grounded approaches to resource governance. This entails recognising the Alps not simply as repositories of strategic materials, but as complex and contested territories shaped by layered histories of appropriation, resistance, and reconfiguration. In this light, the future of sites such as Punta Corna will depend less on their geological potential than on the capacity of planning, design, and policy to engage with the plural vulnerabilities, identities, and aspirations of the regions they seek to reshape.

Abstract
Across Europe, interrelated crises – economic, environmental, social, and demographic – are increasingly undermining quality of life in urban contexts, with direct implications for the affordability of everyday living, and the resilience of the public welfare system. This paper investigates the evolving dynamics of multifactorial poverty, vulnerability and fragility within cities. Urban space is conceptualised as a 'capacitating' infrastructure – one that enables individuals, regardless of their socio-economic condition, to pursue flourishing lives. From this standpoint, urban design must transcend the conventional binary of domestic versus public space and instead embrace a networked approach that integrates housing, welfare services, and collective spaces into more accessible, personalised, and innovative support systems. These theoretical reflections are applied to an 'inner periphery' of Trieste – a medium-sized Italian city facing population ageing and decline, economic hardship, gentrification, and increasing strain on welfare provision. The research focuses on the urban district named Barriera Vecchia and its transformation into a *supportive and de-fragilising* neighbourhood. The methodology employed comprises: (i) stakeholder engagement through the organisation of discussion events and participatory placemaking initiatives; (ii) data analysis on housing conditions and the socio-demographic profiles of residents; (iii) spatial mapping of resources and criticalities – including the distribution of facilities and open spaces, and their inclusiveness and usability in relation to mobility, accessibility, and environmental quality; and (iv) the development of a local masterplan aimed at strengthening the connections between collective assets and service networks for vulnerable populations.

Keywords: Housing affordability; Fragility; Trieste.

1. Introduction

Today, in Europe, multiple ongoing crises – economic, environmental, social, and demographic – are significantly impacting the quality of life in urban areas. These crises have direct consequences on both *life affordability* – understood as the cost not only of housing but of living conditions as a whole – and the resilience of welfare systems, which are expected to support individuals in achieving and sustaining adequate living standards. In fact, the goals of sustainability, inclusivity, and accessibility 'for all' have become key themes in many urban regeneration projects and urban design guidelines (among the others: Gehl, 2010; UN-Habitat, 2018; Sim, 2019), with the aim of fostering human-scale environments that are responsive to the needs of persons of all ages and diverse social, economic, gender, and cultural backgrounds. However, the translation of these goals into concrete local actions often suffers from vagueness and generality, or, in the worst cases, from a lack of careful selection of the specific places and processes on which to intervene. In the absence of spatially guided and well-inte-

grated management of the various urban policies that these actions – often designed according to a top-down approach – are expected to coordinate and synthesise, there is a recurring risk of generating depoliticised decision-making processes and producing *negative externalities*. Chief among these is the displacement of residents in favor of real estate-led valorisation processes (Swyngedouw, 2007; Checker, 2011; Bunce, 2017; Anguelovski et al., 2018). These considerations highlight the urgent need for a project-based reflection on the spatial conditions of well-being and well-living, their multiple dimensions, and the policies, actions, and actors involved in ensuring their just implementation 'in place'.

This paper stems from the activities developed within the project *iNEST – Interconnected Nord-Est Innovation Ecosystem* – Spoke 4 (2022–2025), co-financed by Italy's EU-funded National Recovery and Resilience Plan (PNRR). The Research Topic, coordinated by the University of Trieste and entitled *Solutions to Improve the Well-being and Quality of Life of Fragile Groups*, focuses on the multifactorial distress affecting urban populations in many European cities, including small and medium-sized ones. The occasion for a deeper and place-based reflection is provided by 'research by urban design', conducted with the students of the fourth year of the full cycle degree in Architecture of the University of Trieste (academic year 2024-25) in an 'inner periphery' of Trieste, a medium-sized city in the Northern part of Italy. Specifically, the second paragraph of the paper critically examines the different terms – poverty, vulnerability, and fragility – that are commonly used today to describe the conditions affecting large parts of urban populations. Their meanings, along with their theoretical and operational implications, are considered from the perspective of urban regeneration, with particular attention to the relationship between individual living spaces and collective spaces at the neighborhood scale. The underlying hypothesis is that the *city can act as a capacitating and de-fragilising spatial and social infrastructure*. The third paragraph describes a number of quantitative and qualitative surveys, data and indicators helping investigate the various spatial conditions of fragility and de-fragilisation, including housing and living affordability, access to school facilities and food, climate and environmental comfort, and inclusive accessibility and usability of spaces and services. These tools are described through practical examples of their application in mapping, policy design, and urban regeneration processes. The fourth paragraph examines the design work conducted in Trieste's Barriera Vecchia neighbourhood. It discusses the involvement of local stakeholders and the use of spatialised data and information to identify and represent various forms of fragility, along with the ways they manifest in specific locations within the urban context. The paragraph also outlines the steps taken towards the development of a masterplan aimed at transforming Barriera Vecchia into a *supportive and de-fragilising* neighbourhood. This is conceived as a design exploration and strategic framework intended to revitalise public spaces, collective facilities, and services, with particular attention to the needs of vulnerable populations. Finally, the conclusions outline key theoretical and practical insights for a de-fragilising approach to urban design and policy-making.

2. Poverty, Vulnerability, and Fragility in Urban Contexts

What follows is a brief exploration of the concepts of poverty, vulnerability, and fragility, with a focus on how their meanings have evolved toward the recognition of complex and stronger synergies between the conditions of individuals and households and their living environments. While these terms and their related analyses still primarily belong to the socio-economic fields of research and practice, the aim here is to emphasise, on the one hand, their connection with the *physical organisation of urban contexts*, and on the other, their *multifactoriality*, that is the interplay of factors impacting on individuals' everyday lives. This perspective helps highlight the multiple – social, economic, and spatial – dimensions of urban distress, as well as the need for inclusive and resilient planning beyond mere physical renewal and valorisation of specific urban areas.

2.1 Terms in Evolution: from Measurement to Meaning

Poverty is generally understood as a *condition of deprivation* – specifically, the lack of material resources necessary to meet basic needs. This condition undermines the ability and opportunities of individuals and households to build and sustain their quality of life and well-being over time. From an economic perspective, three notions of poverty are widely recognised in institutional statistics and data sources: 'absolute poverty', 'relative poverty',

and 'subjective poverty' (ISTAT, 2024; Saraceno, 2023, 2025; EUROSTAT, 2025a)[1]. While the first two imply statistical measurement and appraisal, the third involves a strong personal component, as the identification of a minimum threshold required for a decent life is obtained through interviews and questionnaires addressed to target groups. However, defining poverty solely in economic terms is reductive (Sen, 1976; Bourguignon and Chakravarty, 2003; Aaberge and Brandolini, 2015). Poverty has long been recognised as a multifaceted phenomenon, typically rooted in multiple causes and affecting not only an individual's economic condition but also various interrelated *dimensions of quality of life* – including immaterial, relational, and contextual assets. As a result, its social outcomes may vary significantly depending on the specific location and spatial context (Desmond, 2023; Gallo and Bonacini, 2023; Caritas Italiana, 2024).

From this perspective, a number of agencies and research institutions have challenged the conventional concept of poverty by incorporating dimensions related to various aspects of everyday quality of life. For example, the *Global Multidimensional Poverty Index (MPI)*, developed by the Oxford Poverty & Human Development Initiative (OPHI), is a widely used measurement of acute multidimensional poverty. Its datasets – spanning from 2011 to 2023 – cover more than 100 countries worldwide, allowing for comparisons over time. The MPI combines traditional poverty metrics with indicators of deprivation organised into three dimensions: i) Health (nutrition, child mortality); ii) Education (years of schooling, school attendance); iii) Living Standards (cooking fuel, sanitation, drinking water, electricity, housing, and assets such as a car, bicycle, phone, television, or computer) (UNDP and OPHI, 2024; Lemmi, 2025). All these elements are, to varying degrees, directly linked to spatial planning and welfare policies. Closely related and complementary to this tool is the *Human Development Index* (HDI), developed by the United Nations since 1990 to evaluate key parameters that contribute to human well-being. The focus shifts from a 'lack-based' lens to the analysis of the assets and opportunities that enhance material well-being. Like the MPI, the HDI also incorporates three main dimensions: i) A Long and Healthy Life (measured by life expectancy); ii) Knowledge (measured by years of schooling); iii) A Decent Standard of Living (measured with reference to inequalities in income distribution) (Fig. 1). HDI indicators not only reflect the availability, quality, and accessibility of the physical components of collective facilities, but also emphasise that people and their capabilities – not economic growth alone – should be the ultimate criteria for assessing a country's development (UNDP, 2025).

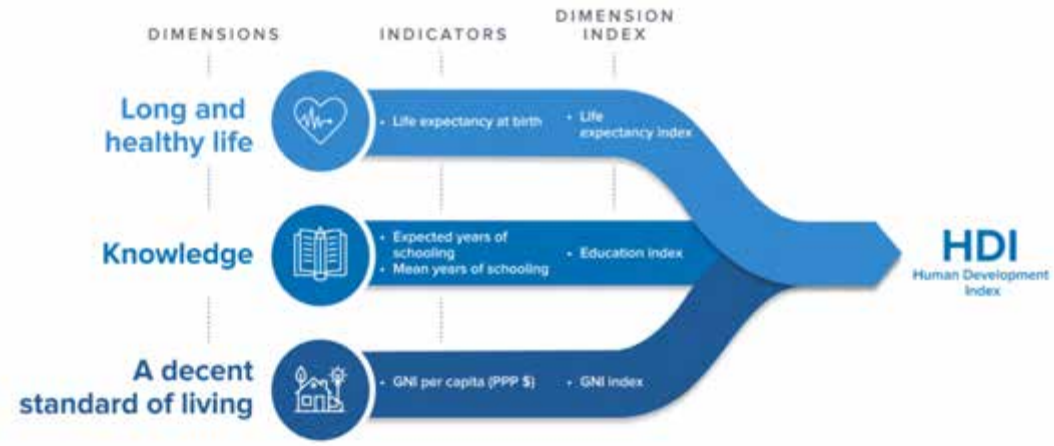

Fig. 1. Human Development Index dimensions and indicators (Source: UNDP, 2025).

1 'Absolute poverty' is defined as the inability to meet one or more basic needs for a period sufficiently long to threaten or seriously compromise survival. It is measured with reference to the economic capacity to cover the cost of a standard basket of essential goods and services (such as housing, food, healthcare, clothing, etc.). A person or household is conventionally considered 'relatively poor' if their available income (or consumption) falls below half – or, in some cases, 60 percent – of these average (or median) per capita values in a given reference area. Finally, the starting point of the assessment of 'subjective poverty' is individuals' perception – what circumstances they consider indicative of a state of poverty, whether related to income levels, lack of certain goods or opportunities, both material and relational.

HDI is largely based on the widely debated *Human Development Approach* (HDA) (Nussbaum, 2011), first conceptualised in economics by Nobel laureate Amartya Sen, and later applied across diverse research fields. According to HDA, also known as the *Capability Approach*, "well-being" is framed in terms of "functionings" (Sen, 1985) – that is, whether a person is able to 'be' (e.g., well-nourished, sheltered, healthy) and 'do' desirable things (e.g., work, receive an education, participate in community life). An individual's "quality of life" is thus defined through their freedom of choice and personal responsibility (Nussbaum and Sen, 1993). In this sense, "capability" refers to the real opportunities that individuals have to accomplish what they value; it denotes the various combinations of functionings (beings and doings) that a person can achieve, reflecting their freedom to lead one type of life or another (Sen, 1989; 1992). Conversely, "poverty" is understood as a deprivation of capabilities – "the failure of the ability to achieve precisely those things that are ultimately important" (Drèze and Sen, 1989, p. 45) – often resulting in social discrimination and marginalisation. A meaningful response to poverty and its multiple dimensions therefore involves expanding the *choices and capabilities* that individuals can access and put into practice to lead lives they have reason to value. Within this perspective, the economic component is only one dimension of a broader equation balancing failures and opportunities where spatial conditions that can enable or hinder individuals' capabilities should be evaluated, particularly in relation to access to housing, education, social and healthcare services.

The term *vulnerability* also refers to a person-centred approach – the condition of 'being vulnerable' – emphasising the *exposure* of individuals or communities to risks such as displacement, environmental hazards, or socio-economic shocks, combined with a limited capacity to cope with or recover from them often due to pre-existing personal conditions such as gender, age, health status, or disabilities (Martinuzzi and Lahoud, 2020). The underlying assumption is that managing vulnerability-related risks is a critical concern for urban governance and a range of public policies and interventions, including spatial planning and design. Over time, this concept has been applied to various fields – from socio-economic studies to political science (e.g., 'social' and 'institutional' vulnerability) – but has more recently been used to highlight the impacts on populations and their overall living conditions of natural disasters, public health crises, and climate change (Biswas and Nautiyal, 2023). Today, vulnerability is increasingly recognised as a *constitutive concept of contemporary societies and cities* (Beck, 1992; Jabareen, 2015), fostering a deeper understanding of risk itself, its spatial and multidimensional implications and consequences, its potential to exacerbate existing inequalities in specific places, and the ways in which urban contexts and their inhabitants can adapt to uncertainty and threat. If vulnerability is defined as a reduced capacity of a person or group to anticipate, withstand, and recover from the impacts of natural or human-made hazards, then this capacity is also closely linked to the availability and accessibility of urban infrastructures and services. As a consequence, and from a spatial perspective, vulnerability can also be framed as a matter of location and disadvantaging configuration of an urban context – such as limited disposal of housing, facilities, and services; poor environmental comfort; gender segregation; or barriers to an inclusive use of urban resources. This conceptualisation is directly linked to the notion of spatial inequality and, by contrast, to the development of more just cities and planning strategies (Fainstein, 2010).

Finally, *fragility refers to a precarious and uncertain condition* – whether affecting individuals and households, communities, physical spaces, or institutional systems – that is *susceptible to breaking under external pressures*. Such susceptibility derives from the intersection of intrinsic characteristics with social, demographic, economic, political, and policy-related factors (EURISPES, 2018). It can ultimately manifest in, for example: loneliness and unstable family conditions; ageing and health problems; insecure and low-paid employment; unaffordable housing and living costs; as well as ineffective sectoral organisation of public institutions also linked to shortages of funding and personnel. Reaching a peak during and immediately after the Covid-19 pandemic, the use of the term fragility has increased in the academic discourse, including spatial planning and urban design. In this context, it specifically refers to the condition of an entity (e.g., a territory, a city, a society, a person or a group, a set of public and private institutions and actors) that may collapse even under minimal stress or retreat in the face of ordinary and minor challenges, due to the rigidity and inflexibility of its conditions, the lack of external support, as well as insufficient infrastructures and networks that might otherwise help develop new capacities, equilibrium, and resilience (Blečić and Cecchin, 2016; Sendra and Sennet, 2020; Pasqui and Curci, 2021; Curci and

Chiffi, 2024). "Interestingly enough, something fragile is not necessarily vulnerable if it is protected from certain external events or agents able to potentially trigger or accelerate its breaking process" (Chiffi and Curci, 2019, p. 56). Here again, space plays a dual role: both as a driver of fragility and as a device that can help mitigate it. From this duality stems the concept of "antifragility" and its use to highlight the possibility of gaining positive outcomes after a shock in an uncertain situation (Taleb, 2012; Aven, 2015). Since not all uncertainties can be prevented, the idea behind antifragility is not just to survive trauma, or simply improve the performance of a given system in response to a shock, but to reinvent and evolve the system as a whole.

2.2. Space as a Capacitating and De-Fragilising Infrastructure

When defining "a new urban question" at the beginning of the 2010s, Bernardo Secchi identified three fundamental aspects of the issue: mobility as the right to accessibility, the consequences of climate change, and social inequalities and exclusion (Secchi, 2010). In line with the theoretical framework of the "right to the city" – from Lefebvre (1968) to Castells (1972) and Harvey (2013) – the city is portrayed as a space where people come together, but also one where they are divided and marginalised due to disparities in work opportunities, access to goods and services, cultural and religious backgrounds, and conflicts among diverse social groups. Even when considering only the modern history of city-making and urban governance, spatial and planning tools have had direct and often disastrous consequences on mechanisms of confinement and segregation between "rich" and "poor" populations, typically favouring the former and displacing the latter. Again, the term "poor" refers not only to those with limited financial means, but also to individuals who cannot enjoy essential facilities (such as healthcare and education) due to locational barriers or uneven service distribution; who face limited access to social support; and who are stigmatised because of the bad living conditions or negative reputation of their residential areas. Therefore, spatial policies bear significant responsibility in addressing inequality and rebalancing urban territories from both social and economic perspectives (Secchi, 2013).

Starting from these considerations, the hypothesis here is that spatialising poverty and vulnerability in the urban context can enable a reinterpretation of the relationship between fragility and space – one in which urban environments are conceived as *capacitating infrastructures*, where all individuals, regardless of their material, social, or physical conditions, can live a good life and achieve personal fulfilment. Accordingly, urban design is called to move beyond the dichotomy between 'individual space' (within the home) and 'collective or common space' (understood as the sum of open areas and public facilities), toward a *networked and integrated conception of indoor and outdoor living environments*. In this conception, the arrangement and design of urban spaces are oriented towards enhancing the effectiveness and personalisation of a plurality of welfare provisions – ranging from housing and traditionally defined collective facilities, to other types of equipment and services, such as those dedicated to food production and distribution, or to the creation of climate-resilient environments. This also includes their interrelationships and conditions of both physical and organisational accessibility. Furthermore, this perspective – drawing on the Capability Approach – invites rethinking urban space and welfare by recognising *individuals as active agents* of change, rather than passive recipients of predefined benefits (Sen, 1999). This implies building a collaborative framework in which institutional, social, and personal capitals are jointly mobilised. Accordingly, public welfare is called to expand and integrate its spheres of action, joining forces with other stakeholders and the inhabitants, and transforming facilities from isolated delivery points of standardised services into proactive devices. These spaces should interact with a diverse range of other collective places, enabling healthy and care-full practices to be tailored to individuals' needs, bodies, and lifestyles, also through social interaction, mutual support, and the shared performance of outdoor activities (Marchigiani, 2022a).

In essence, rather than conceptualising antifragility as a form of preparedness to confront unexpected crises and potentially benefit from them, the focus is here on the de-*fragilisation of individuals' and households' conditions of vulnerability*. These conditions often stem from various forms of deprivation and are closely intertwined with the spatial settings of living environments. The process of de-fragilisation is pursued by intervening in space from a *person-centered perspective*, through the development of new social and spatial infrastructures. The underlying assumption is that an integrated organisation and configuration of urban space and essential services can help prevent fragility from becoming a manifest, disruptive, and persistent condition. This design operation

should begin with the collection and critical interpretation of both quantitative and qualitative information about the population living in a specific urban context, gathered through indirect and direct observation, listening, and participatory processes. The aim is to identify the "dispositions" (or predispositions) individuals possess to either cope with or succumb to the emergence of critical conditions (Choi, 2008). However, this commitment is far from straightforward. While it promotes the recognition and enablement of individual capabilities, social activation, and collaboration between institutions and residents, it also requires careful attention to avoid the pitfalls of a *new humanistic functionalism* (Bianchetti, 2016). Indeed, when based on a superficial collection of data and indicators, there is a risk of inadvertently reinforcing forms of spatial or social determinism. This, in turn, may lead to the reimposition of rigid standards and urban design metrics, reducing people – and their everyday, embodied experience of living spaces – to mere statistical and functional units (Bianchetti, 2023).

3. Mapping Plural Fragilities as a Tool to Address Urban Policy Design

Within the framework of the iNEST research, mapping is a key tool. Its role is complex and multifaceted: i) to spatialise the overlap between quantitative data and experiential knowledge; ii) to investigate the relationships between places and people, identifying the concrete spatial dimensions of various forms of poverty, vulnerability, and fragility; and iii) to select locations where different types of fragility converge, which therefore require special attention to improve living conditions in specific urban areas.

Spatial analysis and visualisation of multiple deprivations are receiving increasing attention worldwide. This growing interest reflects the need to better understand and make unequal living conditions visible, as well as the processes that produce them. Such analyses can support public institutions in resource allocation, land management, and policy design (Martínez et al., 2016). In Italy, two particularly noteworthy examples are the *Mapping Inequality* research platform (Vinci et al., 2025) and *MappaRoma* (Lelo et al., 2019, 2021; MapparomaLab, 2025). The former offers a georeferenced "Atlas of Urban Inequalities", exploring this issue in several large Southern European cities – specifically Palermo and Naples – using small-scale indicators from various domains, including income distribution, housing conditions, access to fundamental services and facilities, and exposure to environmental risks. The latter is an in-depth analytical project focused on the Rome metropolitan area. Drawing on datasets at both municipal and sub-municipal levels, *MappaRoma* brings together a wide range of data to highlight the spatial distribution of social, demographic, economic, planning, and political differences. Both initiatives are of considerable interest for their capacity to construct a spatialised knowledge base that underpins innovative methods and tools aimed at mitigating the spatial inequalities produced by urban policies and at informing future urban transformations. This holistic approach proves particularly effective at the scale of the entire city or metropolitan area, as it facilitates the comparison and superimposition of multiple layers of information, enabling a deeper understanding of the diverse, and at times contradictory, forms that urban inequalities assume across time and space.

The following paragraphs explore in greater depth how various concepts and dimensions related to poverty, vulnerability, and fragility can be interpreted in spatial terms, and in relation to more specific spatial features. The focus is primarily on a selection of European and Italian experiences, ranging from observatories and atlases to analytical and interpretative efforts aimed at supporting urban policies and regeneration projects. Their relevance to iNEST research lies in the attempt to spatialise and interrelate different types of data and information, with a view to their potential application at the scale of *urban sectors and neighbourhoods.*

3.1. Housing Location Affordability

In contexts marked by multiple crises and overlapping factors that undermine the quality of life in urban areas, the fulfilment of the right to adequate housing (Kenna, 2012; The Shift, 2025) should be regarded as a cornerstone of welfare policies, future EU priorities, and planned investments (Vlad, 2024). Across Europe, *housing poverty* manifests itself in a wide spectrum of situations, ranging from extreme forms of exclusion and deprivation to more widespread conditions of housing insecurity. These are often driven by an insufficient supply of public rental housing – both social and 'very social' – as well as by rising rents in the private market (Tosi, 2017; Bricocoli

et al., 2021; Fondation Abbé Pierre and FEANTSA, 2024; Marchigiani and Novak, 2024). Moreover, *affordable housing* is not only a fundamental welfare provision that helps prevent the risk of homelessness, but also, as described by Habitat for Humanity, "a ladder out of poverty for families" (2021, p. 5). Ensuring stable residency is, in fact, a basic prerequisite for the enjoyment of a broader range of civil rights, public services, and social support – including political representation, employment, healthcare, and education.

However, the very concept of *housing affordability* is increasingly being called into question, as its definition is recognised as multifaceted and not easily measurable through simple parameters (Peverini, 2023). The traditional threshold – set at 30% of the ratio between housing costs (whether rent or mortgage) and total household income – rises to 40% when all housing-related expenses are taken into account. To more thoroughly investigate households' ability to access adequate housing in suitable locations and at acceptable costs, a variety of measurements and indicators have been developed, as evidenced by international statistical platforms and observatories (EUROSTAT, 2025b; OECD, 2025). These tools help construct a picture of the varying degrees of *housing poverty and vulnerability*, though some limitations persist in terms of data collection and interpretation (OECD, 2021). Considering the general conditions of both the supply and demand sides, quantitative methods for measuring housing affordability rely primarily on indicators related to real-estate values, rental costs, housing maintenance expenses, and households' disposable income. Other indicators – such as the overcrowding rate, measures of housing quality, and subjective perceptions of affordability – can offer a more nuanced picture of housing's impact on residents and their increasing *social fragilities*, including the negative effects of limited space and overcrowding on health and well-being. However, such indicators rely on data that are more complex to collect, often requiring qualitative methods like interviews and questionnaires (Heylen, 2023). In fact, the quality and adequacy of housing in relation to the needs and resources of households vary significantly according to cultural differences, age, and family composition (which are becoming increasingly unstable due to demographic shifts and rising divorce rates), job and income security (highlighted by the growing number of 'working poor'), and the burden of inflation reducing the purchasing power of households' wages (Marchigiani and Novak, 2024). Moreover, when housing affordability is understood as a component of the overall cost of living within a given urban context, it encompasses not only rent or property prices but also broader living expenses. To effectively inform supportive housing policies, affordability must therefore be assessed in relation to the availability, accessibility, and public character of a wider range of services. This highlights its strongly *site-specific nature* and the need for a closer, more integrated investigation of local spatial, social, and economic conditions.

From this perspective, recent experiences highlight innovative approaches focused on *location affordability*, understood as encompassing the spatial dimensions and conditions of affordability, and highlighting a strong link between housing, urban planning, and urban welfare policies – for example, those related to transport planning, land use, and the broader supply of affordable rental housing. However, the call for a more comprehensive analysis – as evidenced by theoretical models and frameworks developed globally – has so far resulted in only a limited number of practical initiatives (Mullinere and Maliene, 2012; Peverini, 2023; HUD, 2025). Among them there is OCA – *Osservatorio Casa Abbordabile* (Observatory for Affordable Housing), an initiative jointly promoted in Milan by the Politecnico di Milano and third-sector organisations. OCA draws attention to housing affordability as the relationship among individual or household income, the cost of accessing housing (whether for rent or purchase), and a wider set of conditions related to spatial location. The mapping and analysis of various public datasets (ISTAT, MEF, and OMI)[2] highlight how inequalities in access to different types of housing supply (including social and regulated rental housing, tourist accommodation, and short-term rentals) by a growing variety of social demand (from long-term residents to students and workers) are closely connected to commuting patterns and costs, measured in terms of both transport expenses and travel time. These investigations are carried out not

2 ISTAT is the Italian National Institute of Statistics; it collects and analyses data on various topics, including the socio-economic conditions of the population and the housing stock (https://www.istat.it). MEF is the Italian Ministry of Economy and Finance, which provides data on the incomes declared by individuals (https://www.mef.gov.it). Finally, OMI, the Italian Real Estate Market Observatory, collects and disseminates real estate quotations for defined homogeneous territorial areas within each municipality, indicating a minimum/maximum range of market and rental values per square metre, based on property type and condition (https://www.agenziaentrate.gov.it/portale/schede/fabbricatiterreni/omi).

only within the administrative boundary of the municipality of Milan but also in its wider regional context, where housing values have skyrocketed and people with average or low incomes can no longer access the inner-city housing market, while the supply of council housing remains stagnant (DAStU et al., 2025; Bricocoli et al. 2025). Given that housing policy is currently limited to the municipal scale, this insight is crucial for reorienting interventions at a broader territorial level, thus opening up new perspectives for future decision-making.

What can be learned from ongoing reflections and experiences is that a more complex and integrated framework of housing affordability indicators and indexes – along with related data sources and operational procedures for analysing, cross-referencing, and interpreting them – are necessary to support the implementation of multilevel urban policies and spatial regeneration strategies at the regional, urban and local scales. The pandemic and, more recently, the decline in living standards and broader processes of social fragilisation, have shown that the private space of the home (when available!) is not, in itself, sufficient to ensure a decent life. In fact, housing vulnerability goes beyond the mere availability of affordable housing. It requires a closer examination of living patterns and household compositions, which are becoming increasingly less standardised, as well as of individuals' levels of autonomy, including considerations related to social, health, and age conditions. These factors demand careful assessment of the spatial qualities of housing with respect to the size and configuration of households, as research activities within the *UAH! Unconventional and Affordable Housing project* (2023–25) are attempting to demonstrate (Aa.Vv., 2025)[3]. UAH! operates at the intersection of urban and architectural design of individual and shared spaces within the home, collective spaces and equipment at the neighborhood scale, public housing policies, and informal practices carried out by residents in collaboration with a variety of institutional, community and third-sector actors.

3.2. Schools and Urban Learning Contexts

Within the framework of essential services aimed at reducing vulnerability and fragility through the creation of spatial and social infrastructures complementing the home environment, access to schools and education represents a fundamental condition for enhancing individual capabilities and acquiring the knowledge and skills necessary for autonomous living. In contrast, *educational poverty* refers to the lack of opportunities for children and adolescents to learn, grow, face life's challenges, and develop their talents and aspirations (Save the Children, 2014). Driven not only by insufficient provision (in terms of quantity and distribution) of facilities, educational poverty is also linked to cultural disparities among household groups, the duration and quality of education, and spatial accessibility to schools. In this regard – in Italy as well as all over Europe – early school leaving and competence levels measured by standardised tests serve as key indicators (European Commission, 2024). From this perspective, educational poverty is also recognised as a root cause of unemployment and social exclusion (European Commission, 2015).

In relation to these issues, in 2014 Save the Children Italia developed an *Index of Educational Poverty* (IPE). In 2019, the IPE was applied to monitor the Italian context, highlighting relationship with social inequalities and their spatial distribution across the country. The indicators used refer not only to the availability of educational spaces in a given area, but also to directly associated facilities (e.g., school canteens, libraries, gyms, courtyards) and the frequency with which they are used by children (Save the Children, 2014; Openpolis and Con i Bambini Impresa Sociale, 2019). In addition, the IPE considers the range of activities children engage in outside of school, either during or after school hours – such as visiting museums and exhibitions, going to the cinema, to sports facilities and libraries. This assessment not only examines the availability of basic school services – highlighting which areas within a city or region lack adequate provision – but *also establishes a strong connection between the school system and other urban facilities*, evaluating their attractiveness and suitability for children and young people. From this perspective, what matters is how schools are used and how they support access to other urban services, as well as how they serve the community and how open they are to different user groups at various times of the day, week, and year (Gammino, 2024). Here, again, spatial organisation and setting of these facilities at territorial,

3 UAH! is co-financed by Italy's EU-funded National Plan for Recovery and Resilience (PNRR). The partners are DAStU of the Politecnico di Milano (leader partner, coord. Gennaro Postiglione), Università di Trieste (coord. Elena Marchigiani), and Università e Politecnico di Bari (coord. Daniele Petrosino).

urban and local scales constitute pivotal issues.

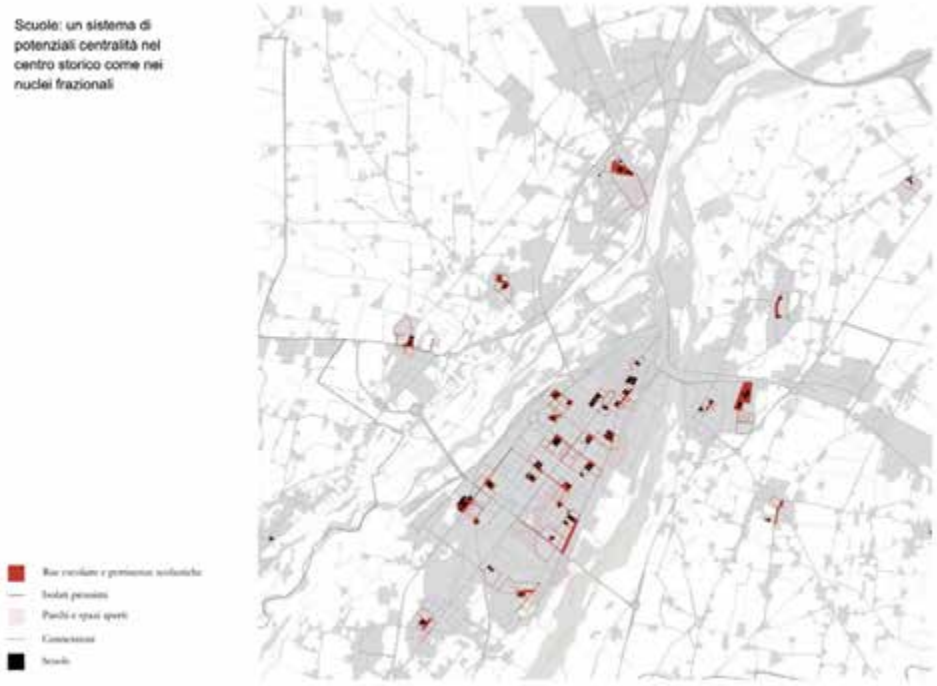

Fig. 2. Schools: a system of potential hubs in the historical centre and in the external neighbourhoods. Urban and territorial strategic regeneration strategy for Sustainable Cuneo city (Source: Renzoni and Vassallo, 2021b).

The importance of planning and design of educational spaces in reducing urban and social fragilities is not a new concept. In Western contexts, schools have long been recognised as focal points within neighbourhoods or urban areas, and as tools for equitably equipping different parts of the city while fostering cohesive local communities. More recently, their relevance has been revitalised worldwide within the '15-minute City and Neighbourhoods' concept (Moreno, 2024). In parallel, school facilities have been examined from a spatial perspective as catalytic elements within the network of urban welfare spaces. In a growing number of European experiences, the role of *learning contexts* is not limited to school buildings alone, but extends as well to streets and public spaces understood as part of a collective educational infrastructure fostering independence (among the others: Ward, 1973; Ceppi and Zini, 1998; Kyttä, 2004; Munarin et al., 2011; Marchigiani, 2022b; Renzoni and Savoldi, 2022).

From this perspective, among the most advanced experiences aimed at supporting urban policies and design strategies, there are those recently developed by research groups at the Politecnico di Milano and Politecnico di Torino. These studies focus on various Italian metropolitan and medium-sized cities in the Lombardia and Piemonte regions, investigating the connections between educational facilities, urban accessibility systems, and other urban services (Renzoni et al., 2021a; Pileri et al., 2022; Renzoni and Savoldi, 2023; Savoldi and Baldissera, 2025). Specifically, within the studies for the strategic plan of Cuneo, four guiding principles are recognised. They focus on: open and public spaces; cultural heritage; social and healthcare services (crucial in the context of an increasingly ageing population); and school facilities, in relation to their surrounding spaces. As part of the masterplan for the regeneration of the urban fabric, the school hubs connect their associated facilities and courtyards to streets and spaces nearby, structuring a potential network of 'school roads' that is porous, liveable, and safe for people of all ages (Renzoni et al., 2021b) (Fig. 2).

3.3. Food Atlases

Another domain of welfare aimed at supporting socio-economically fragile individuals is access to healthy, affordable food, as well as the infrastructures related to its production and distribution. The lack of such conditions is referred to as *food poverty* – a complex phenomenon that has been exacerbated and diversified by recent crises, even in advanced capitalist countries. In contexts such as Italy, the problem lies less in the availability of food than in the access to a healthy and adequate diet. This reflects the paradox of *scarcity in abundance*, defined as "the impossibility for parts of the population to access adequate nutritive resources despite their (over)abundance in the context where they live" (Maino et al., 2016, p. 26; translated by the authors). Food poverty is also defined as "one of the most severe and comprehensive forms of material deprivation, leading to the inability to obtain or consume food of adequate quality or quantity in socially acceptable ways" (Toldo et al., 2023, p. 141). These definitions capture the phenomenon's multidimensional nature: material deprivation, social exclusion from food-related practices, and psycho-emotional effects such as stigma and shame from relying on public aid.

However, the difficulty of situating food poverty within a unified critical framework makes it equally challenging to measure and assess its multidimensional nature. Available data are often fragmented and focus almost exclusively on economic dimensions, failing to fully capture the phenomenon – particularly from a spatial perspective. This gap has contributed to framing food poverty merely as a condition of need, thereby obscuring the issue of access to food as a fundamental right. In Italy, a significant attempt to address these limitations has been undertaken by ActionAid. In its most recent report, three tools are used to investigate food poverty: the Material and/or Social Food Deprivation Index (DAMS); the risk of food poverty; and relative food poverty (Ciancimino and Sensi, 2024). The report highlights how food poverty is shaped by multiple factors – including education, housing conditions, and access to the labour market – as well as by demographic characteristics, and the resources available in local contexts. It also raises critical questions about the adequacy of a response system based solely on material aid, particularly in cases not linked to extreme deprivation. Finally, the report underscores the urgency of developing local monitoring systems that consider not only food affordability, but also diet quality, food literacy and well-being, and the role of social participation in food practices.

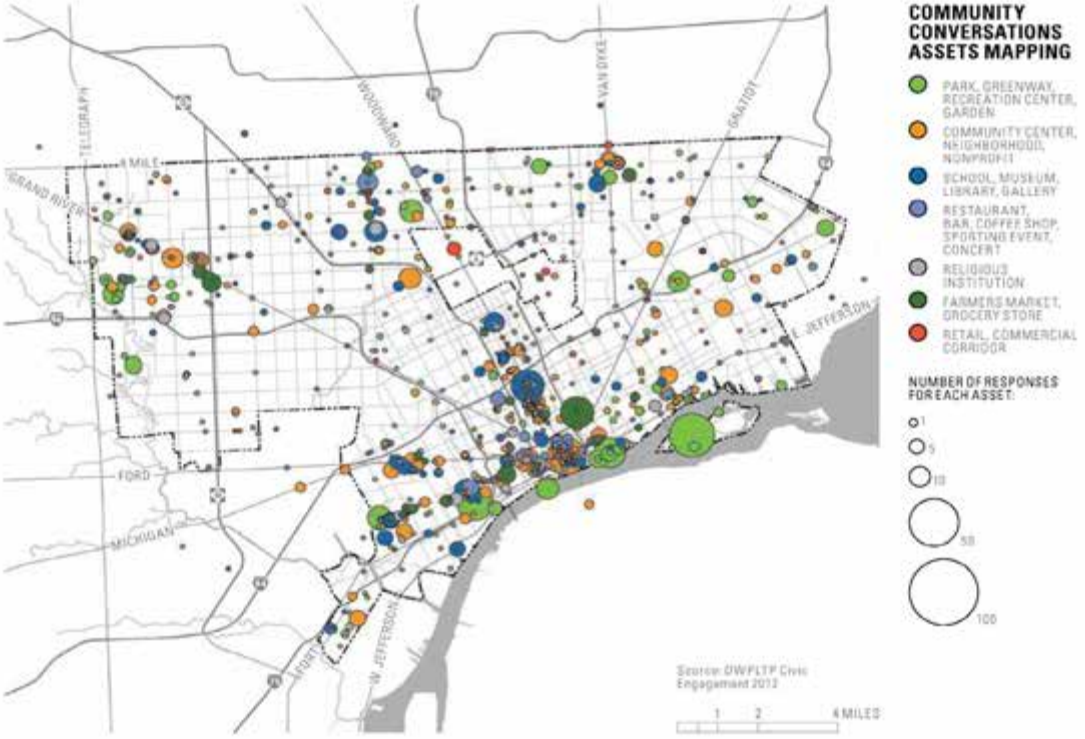

Fig 3. Food and social facilities: supports for transforming neighbourhoods (Source: Detroit Future City, 2012).

In this framework, the concepts of *food empowerment and food environment* play a major role. The latter – understood as the set of conditions that enable or constrain food choices – specifically highlights the importance of urban space. This approach was already evident in the Strategic Framework Plan for Detroit, developed to address urban shrinkage and severe social and economic crises (Detroit Future City, 2012). Within this plan, urban agriculture and the reclamation of vacant lots are recognised as key interventions; furthermore, this tool envisions a multi-scalar network of food-related spaces and landscapes – from home gardens to farms linked to employment districts and food processing industries – as a cornerstone of a more resilient and equitable urban structure (Fig. 3). In fact, mapping food retail and distribution alone is insufficient to fully define a local food environment. A comprehensive understanding also requires the integration of spatial accessibility (e.g., the territorial distribution of food-related services – from supermarkets to open-air markets) with indicators such as food affordability, local food production, and the presence of solidarity networks. Within the *Atlante del cibo* (Food Atlas) of Rome metropolitan territory (Marino et al., 2022), this spatial approach makes it possible to identify 'food blackout areas', characterised by a systemic disruption in food access. In these areas, the intersection of multiple forms of fragility – economic, productive, spatial, and social – leads to a complete breakdown of local food systems, leaving communities without adequate support (Bernaschi et al., 2023).

3.4. Climate-proof cities and neighbourhoods

Especially in densely built urban contexts, *climate vulnerability and fragility* are today key issues that must be urgently addressed. This is particularly relevant for urban planning and design interventions in consolidated and highly 'mineral' urban districts, where natural elements are scarce. Southern Europe is mostly affected by three climate-related phenomena: heatwaves, or prolonged periods of above-average temperatures; heavy rainfall leading to flash flooding; and droughts, which contribute to wildfires and put pressure on water supplies (European Environment Agency, 2024). The effects of heatwaves and heavy precipitation are amplified where soil sealing is widespread and there is a lack of natural elements and vegetation. These hazards have a significant impact on the *comfort and health of urban dwellers*. In particular, prolonged heat stress, associated with rising temperatures and exacerbated by the urban heat island effect, can severely affect individuals already suffering from health problems, older adults, and children. Furthermore, these risks are heightened in situations of housing overcrowding and poor-quality dwellings. It is therefore not surprising that, within the broader context of the ecological and climate crises, the interrelation between environmental well-being and individual health is increasingly recognised as a matter of spatial justice and welfare. This recognition calls for an integrated policy framework situated at the intersection of spatial and environmental planning and social welfare – commonly referred to as 'ecosocial policies' (Carrosio and De Vidovich, 2023).

From a spatial planning and design perspective, enhancing green provision – encompassing tree cover and permeable green surfaces – emerges as a strategic intervention. In this regard, the implementation of Nature-Based Solutions (NBS) provides a practical and integrative approach to improving the functionality of green and open space networks, as well as mobility infrastructures within urban neighbourhoods, thereby linking urban regeneration with climate adaptation goals (Farlè, 2020). However, precisely because such interventions can significantly enhance quality of life in urban areas, 'urban greening' initiatives may also contribute to rising property values, reduced affordability of housing and public services, and the onset of gentrification processes that disproportionately affect socioeconomically vulnerable populations (Checker, 2011; Anguelovski et al., 2018). As such, these initiatives must be critically and contextually assessed to mitigate potential adverse social impacts.

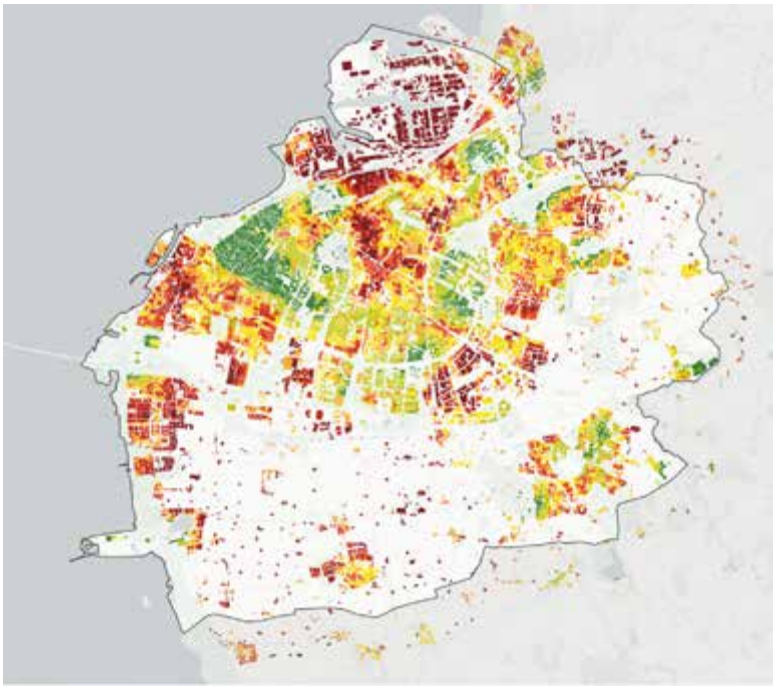

Fig. 4. 3+30+300 rule scores for buildings in Malmö, Sweden. Green and yellow indicate buildings and areas that meet or exceed the criteria, while orange and red highlight those with insufficient scores (Source: Konijnendijk et al., 2025).

Among NBS, depaving and the 3-30-300 rule have recently gained prominence in academic debate and design practice. While the former is a method aimed at improving soil permeability, the latter functions both as an index for assessing the quality of green spaces and as a strategic framework for territorial and urban planning (UN-ECE, 2021). Introduced in 2021, the 3-30-300 rule promotes healthier urban environments through a principle of redistribution: "ensuring that every resident can see at least three mature trees from their home, lives in a neighbourhood with 30% tree canopy cover, and has access to green space within 300 metres" (Konijnendijk, 2021). The Yggdrasil project, developed as part of the Nordic Council of Ministers' Vision 2030 initiative, represents one of the first attempts to extend the 3-30-300 concept at an interregional level across the Nordic countries (Denmark, Norway, Sweden, Finland, and Iceland). This experience demonstrates how data from various international databases can be harmonised – for example, using the World Cover map by the European Space Agency to analyse tree canopy cover, and OpenStreetMap to assess mobility and accessibility in relation to the availability of green infrastructure in urban contexts (Konijnendijk et al., 2025) (Fig. 4). Notably, the study also highlights access to green spaces and trees in connection with dimensions of socioeconomic vulnerability, visualising potential disparities between areas with differing income levels, employment rates, and proportions of migrant populations.

At a neighbourhood scale, the City of Paris has implemented various NBS strategies within the framework of the *OASIS Schoolyard Programme*. In response to increasingly severe heatwaves in the urban environment, the project transforms schoolyards within disadvantaged neighbourhoods from hard-surfaced, enclosed spaces into green, open areas. Funded by the EU Urban Innovative Actions (UIA) programme, this pilot initiative involving a number of schools was carried out as part of the *Paris Resilience Strategy* addressing climate adaptation at multiple levels across the metropolitan area (Sitzoglou, 2020; Resilient Cities Network, 2025). A key concept behind this project is that green schoolyards are designed not only as a response to escalating climate threats, but also as a tool to foster inclusivity within local communities. The schoolyards remain open after school hours, serving as neighbourhood pocket parks for the most vulnerable residents.

3.5. Inclusive Spatial Accessibility

Spatial accessibility is here understood as the set of spatial conditions that enhance individuals' ability to move independently on a daily basis from their homes to workplaces, public spaces, and essential facilities. This fundamental quality of urban environments enables people – regardless of their age, gender, health, income, or social status – to lead autonomous and healthy lives, actively participate in society, and shape their own conditions of well-being and social interaction. However, the physical layout of cities often hinders access to essential services (such as education and healthcare), due to their dispersed location, the absence of pedestrian infrastructure or public transport links, and the presence of architectural and urban barriers (Marchigiani, 2023). Moreover, conditions of so-called accessibility poverty exacerbate social and economic inequalities, resulting in territorial segregation and the marginalisation of both people and places. In this regard, spatial accessibility – being a "capital" that can help or prevent a full performance of a person's capabilities (physical and social, economic and cultural) (Kaufmann, 2011; Marchigiani, 2022a) – becomes a matter of urban justice and a key component of urban equity and inclusiveness.

Addressing these challenges requires a shift in perspective beyond the spatial distribution of services and facilities. Accessibility encompasses not only the availability and geographical placement of these assets, but also their functional quality, user-friendliness, and systemic connectivity. Additionally, the health implications of active mobility should not be overlooked, as they play a pivotal role in individual and public health outcomes. Environmental sustainability is likewise a key consideration, since the implementation of integrated and low-impact mobility systems contributes significantly to reducing the environmental footprint associated with conventional, car-dependent transport modes. From this perspective, services and facilities must not only be accessible, but also reachable and effectively interconnected via safe, comfortable, and adequate routes. The concept of *proximity* thus assumes a central role (Gall, 2024), yet it needs a robust design framework capable of guiding interventions within a comprehensive vision for urban planning and regeneration (Marchigiani and Bonfantini, 2022). Beyond physical distance, several additional factors must be considered, including average travel time (whether on foot, by bicycle, or via public transport), the availability and quality of transit options, the presence of physical and perceptual obstacles, safety conditions, and the degree of alignment with users' needs. Specifically, the provision of barrier-free, walkable environments is highly important for individuals with different types of fragility. In fact, understanding the impacts of accessibility poverty requires particular attention to the groups most affected. Vulnerable populations – such as children and, more notably, persons with motor, sensory, or cognitive disabilities, whether permanent or temporary – are disproportionately impacted (World Health Organization, 2001). For these individuals, accessibility is a determining factor for social participation itself. Moreover, the likelihood of experiencing disability increases with age, making this a critical consideration in the light of current demographic trends within Europe (Eurostat, 2024).

Therefore, by adopting a Universal Design (UD) approach (Müller, 2023), urban space should be organised and reconfigured through the lens of bodily diversity and inclusivity (Bianchetti, 2020). Furthermore, limitations in accessibility should be regarded as design opportunities to reconsider the relationships between mobility, local economies, social practices, and the spatial distribution of essential services. Enhanced access to key facilities supports the development of *person-centred and place-based welfare systems*; thus, inclusive accessibility emerges as a strategic instrument for addressing complex territorial and social vulnerabilities. Orienting urban planning and regeneration around accessibility entails the involvement of multiple stakeholders and requires strong public leadership and coordination, whereas spatial connections between public facilities should serve as the *backbone of an urban infrastructure* capable of generating positive impacts across multiple scales and fields of action (Marchigiani and Basso, 2021). The liveability of streets – aimed at promoting safe and slow mobility – is a central concern. This calls for the implementation of a range of interventions, including pedestrian zones, 30 km/h speed limits, and the redesign of pavements and crossings, to help reduce conflicts between travel modes and improve accessibility for individuals with mobility impairments.

Several recent initiatives embody these principles. Notably, FVG *Accessibile* – a project developed by the Italian Friuli Venezia Giulia region in collaboration with the Universities of Trieste and Udine, and the Regional Informa-

tion Centre on Architectural Barriers and Accessibility – has established an ICT-based mapping system focused on the spatial and functional components of the urban environment, with accessibility assessed through Universal Design (UD) lens (Regione Autonoma Friuli Venezia Giulia, 2025). This initiative aims to integrate representations of facilities and public buildings, streets and connecting spaces, alongside the identification of various types of indoor and outdoor obstacles and barriers, in order to detect critical issues and support integrated planning processes. In this context, accessibility emerges as a cross-cutting concept that links spatial comfort, social welfare, and the effective usability of urban spaces and services (Marchigiani et al., 2022). Among the various approaches used to assess accessibility to essential facilities through active mobility, the *Inclusive Accessibility by Proximity Index* (IAPI) emerges as another valuable and context-sensitive tool for informing urban planning strategies aimed at promoting more inclusive and sustainable urban environments. This was demonstrated through its application at the neighbourhood scale in the city of Bologna. The IAPI is based on a comprehensive set of data sources and indicators relating to: the technical performance of pathways; traffic safety and road impacts; the safety and social appeal of public spaces; the design and diversity of public spaces and the built environment; and the accessibility of public and collective services, assessed using isochrone-based methods. The result is a synthetic representation of accessibility levels to essential services at the local scale, enabling the identification of potential issues related to both service provision gaps and the perceived quality of cycling and pedestrian routes, open and built spaces (Lanza et al., 2023).

The relevance of this integrated approach is clearly demonstrated in the Site-Specific Assessment *Guidelines* (UN-Habitat, 2020), where "suitability maps" are employed to visualise urban accessibility and usability within a neighbourhood, in order to support the development of inclusive and sustainable mobility 'for all' (Fig. 5).

Fig. 5. The network of services and facilities at the neighbourhood scale (Source: UN-Habitat, 2020).

4. Design Explorations in Trieste: Toward a Supportive and De-Fragilising Neighbourhood

The opportunity to test the concepts and methodologies outlined thus far was provided by *research by urban design* conducted in the district of Trieste called Barriera Vecchia, within the activities of an Urban Planning Atelier at the University of Trieste. Owing to time constraints and the design-oriented nature of this experience, the development of complex indicators was not entirely feasible. The investigation therefore focused on the material quality of urban spaces. This shift, however, enabled emphasis on a layer of analysis that is often still superficially addressed in the aforementioned studies.

Specifically, the work pursued two main objectives. The first was to experiment with approaches for analysing

the quality of everyday life in an urban district that is characterised by the coexistence of multiple forms of fragility. This was achieved by systematising methods and tools that are rarely integrated into mainstream urban design practices. The second objective was to develop a design masterplan to transform this urban sector of Trieste into a *supportive and de-fragilising neighbourhood*. The aim was to enhance existing spatial and social assets, amenities and resources – improving the environmental performance of collective spaces, and proposing the implementation of new services to support overall upgrading of living quality and affordability. This was addressed through listening to and collaboration with public authorities, and third-sector organisations. The work employed both qualitative and quantitative data and information, with the purpose of rethinking the forms and methods of spatial regeneration. Overall, the intention was to foster social and institutional innovation capable of preventing and mitigating the emergence and escalation of conditions of vulnerability.

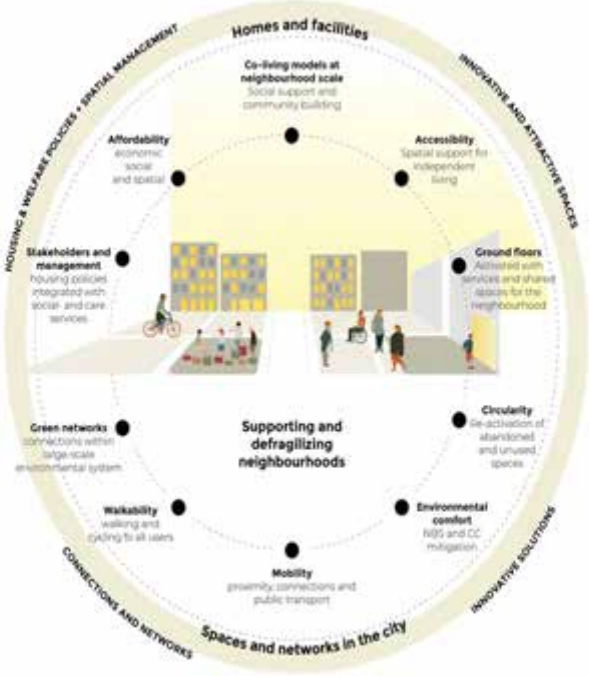

Fig. 6. Supporting and de-fragilising neighbourhoods: domains and actions (Author: Teresa Frausin).

More broadly, by integrating multiple domains of quality assessment – including uses and users, amenities, comfort and safety, the green environment, and accessibility – the organisation of the city into supportive and de-fragilising neighbourhoods provides a spatial framework for the integration of housing and facilities (Fig. 6). This approach focuses on lived spaces beyond individual dwellings, specifically on public and collective spaces conceived as enabling infrastructures capable of hosting collaborative practices and supporting place- and people-sensitive spatial and policy design. However, before outlining the overall process, it is necessary to clarify its context and the rationale underpinning its design outcomes.

4.1. Working in the Inner Periphery of a Medium-sized city

Trieste is located on Italy's north-eastern border and currently has a population of approximately 200,000 inhabitants. It is a *medium-sized city*, occupying a spatial and functional position distinct from both large metropolitan areas and suburban, inner, or marginalised territories. These characteristics, along with their specific contextual conditions, have made medium-sized cities – and the so-called *intermediate urban areas* – a focus of recent Italian research, as well as of experimentation with more context-sensitive planning and design approaches and tools (see, among others, Lanzani and Curci, 2018; Gabellini et al., 2023; Renzoni et al., 2023; Caramaschi et al., 2024; Lanzani, 2024a).

While Trieste shares with other medium-sized cities across the country population stagnation/decrease and demographic change, some of these trends are particularly pronounced here, making the capital of the Friuli Venezia Giulia region stand out in the national context. Notably, acute patterns of population ageing combine with a significant presence of migrants and individuals with a migration background. These dynamics contribute to a growing segment of the population experiencing social and economic hardship, placing considerable strain on local welfare services. At the same time, the effects of 'touristification' – including rising real estate values – are undermining housing affordability. This is further exacerbated by strong housing demand from temporary populations, particularly a large number of university students and researchers (Marchigiani, Novak, 2024).

Fig. 7. The neighbourhood of Barriera Vecchia within the city of Trieste (Source: Google Earth, edited by the authors).

Within the city, the research focused on a semi-central area (Barriera Vecchia), extending east of the historic centre and constituting its contiguous expansion dating from the late 19th and early 20th centuries (Fig. 7). Data collected by the municipal administration as part of the newly established RUPA – *Osservatorio Rigenerazione Urbana e Politiche Abitative* (Observatory for Urban Regeneration and Housing Policies) (Comune di Trieste, 2025) indicate that this area is characterised by a very high concentration of foreign residents, a significant presence of working-age individuals comparable to that of elderly persons, and a predominance of single-person households. The area's attractiveness is strong among young persons, who frequently choose this neighbourhood as their place of residence. This preference is linked to the fact that, despite its close proximity to the city centre, property values in Barriera Vecchia remain moderate to below average in terms of residential sale and rental prices, and are lower than those recorded in adjacent districts. However, this occurs within a broader context of significantly low household incomes compared to other parts of the city.

Owing to these dynamics, Barriera Vecchia can be defined as a specific articulation of the concept of *inner periphery*. While this concept is predominantly applied to suburban and rural contexts within the scope of European territorial cohesion policies (Ietri and Pagetti, 2019; Oppido et al., 2023; Galderisi and Limongi, 2024), it nevertheless provides a valuable interpretative framework for understanding disparities that also emerge in the most densely urbanised areas. The marginality of Barriera Vecchia does not stem from a condition of remoteness from more central and economically dynamic districts, to which it is in fact close and well connected by local public transport, nor – as will be shown in the following paragraphs – from a lack of facilities and services, which it actually has in abundance. What contributes to defining its marginality are: a high use value connected to a significant presence of individuals and groups in vulnerable or fragile conditions – related to age, health, social isolation, the burden of caregiving responsibilities, and low income; the lack and poor maintenance of pedestrian

areas, which compromises the creation of social spaces and inclusive accessibility; and widespread conditions of physical decay or underuse of individual residential buildings, often linked to poor energy performance and a spatial layout of housing units that does not reflect the actual composition and size of households.

4.2. Masterplanning as a Framework for Multiple Fields of Public Action

Over time, public intervention in Barriera Vecchia has consisted of a few fragmented initiatives focused on the refurbishment of individual spaces, while the low market value of private properties has made substantial renovation efforts economically unfeasible. Today, designing and managing renewal and retrofitting processes in urban areas where precarious conditions and multiple forms of fragility – affecting both the spatial environment and its inhabitants – are concentrated, demands more careful consideration of the appropriate scales, locations, and approaches to regeneration.

From this perspective, a preliminary and significant issue addressed by the research concerned the development of an approach for constructing a tool capable of 'translating' a regenerative design vision. This refers not merely to a device aimed at defining the location and spatial extent of individual interventions, the types of assets specifically involved, or their predominant uses. Rather, the work carried out with students was directed towards the definition of a *comprehensive masterplan*, complemented by design explorations focused on strategic themes and spatial systems of sites. This approach reflects a practice now adopted not only in academic settings but also within more institutional domains of urban and spatial planning. An example is the concept of "local strategies" included in the Town Plan approved in Bologna in 2021. These are described as "figurative guidelines for steering actions in the territory that aim to connect, relate, and create synergies between parts of the city, places of public life, and sites of memory and sedimented identity. [...] They indicate requirements and performances to be ensured in the transformation of urban spaces, without prefiguring their final form" (Comune di Bologna, 2021; translated by the authors).

A deeper reflection is nevertheless required on the meaning ascribed here to the term 'masterplan'. Specifically, it is understood as a tool for defining and guiding regeneration processes that are sensitive to both place and people, particularly within already-inhabited urban contexts equipped with infrastructure but marked by severe and interrelated forms of precarity. The aim of such processes should be not only to counteract fragility, but also to empower individuals and strengthen their relational and spatial capabilities. A central element in the development of the masterplan is the existing infrastructure of public spaces – that is, the set of social, health, and educational facilities; places dedicated to the distribution and shared consumption of healthy food; existing open and green spaces, their connections and conditions of environmental and climatic comfort. An equally strategic move consists in uncovering and integrating other 'opportunity spaces', actions, and actors, in response to social needs that have not yet been adequately addressed by public policies.

Moreover, in developing the masterplan, the approach should not be confined to data collection and 'external' analyses, nor to the identification of a few prominent sites for selective action. Likewise, processes of listening, collaboration, and participation should not be relegated to a merely instrumental role aimed at mitigating conflicts arising from top-down strategies. Rather, the masterplan is conceived here as a process of immersion in place, involving interaction with local stakeholders and residents, and aimed at identifying the multiple domains of integrated public action – also extending beyond the scope of urban planning and design – upon which future spatial transformations and welfare policies may be grounded.

4.3. The Tale of a Process Toward a Place- and People-Sensitive Regeneration

The masterplanning process comprised several key steps, which are briefly outlined in the following paragraphs, with a focus on their principal findings and conceptual frames. The initial stage involved engaging with and listening to local stakeholders; it provided valuable insights and concrete indications. Building on this, both quantitative analyses and qualitative investigations were carried out, drawing on the systematisation and interpretation of available data, site surveys, and technical readings of spaces and their uses. This process led, on the one hand, to the development of an information base essential for the spatial representation of various dimensions

of fragility – referring to social and education facilities, as well as to food provision, climate and environmental comfort, mobility, and accessibility – and, on the other, to the identification of critical issues and opportunities that informed the masterplan's strategic orientation.

4.3.1. Listening: In-depth Engagement with Place and Stakeholders

The listening phase involved a diverse range of stakeholders operating at both urban and neighbourhood scales. These included public institutions – such as the Agency for Public Housing (ATER), the Public Health Authority, and the Social and Urban Planning Departments of the Municipality of Trieste – with a central role played by the Public Company for Personal Services (ITIS), a social and healthcare hub deeply embedded in the local care infrastructure. Third-sector organisations were also engaged, particularly those specialised in support policies for individuals facing multiple vulnerabilities (e.g., Caritas Trieste, Lybra social cooperative, and San Martino al Campo). Additional participants included bank and social foundations, trade associations, labour unions, students, and local residents.

Specifically, at the urban scale, the process was carried out by the University research group through the organisation of two round tables on housing conditions in Trieste, direct dialogue with key actors, and in-depth interviews with various subjects. These activities addressed key challenges, in particular the role of public residential assets as catalysts for urban regeneration, the provision of adequate affordable rental housing, and the development of integrated service systems. In parallel, at the neighbourhood scale, a more in-depth listening process and a placemaking event involving residents – conducted in collaboration with other ongoing projects related to the healthcare system – enabled the identification and *mapping of local needs and challenges*.

Within these activities, particular attention was paid to factors influencing well-being, such as healthy lifestyles, economic security to meet basic needs, and the ability to move freely in order to access public spaces and amenities. Additionally, a strong desire emerged for a sense of identity and belonging, intergenerational social interaction, and access to education that promotes autonomy. Several critical issues were also identified, including spatial barriers to mobility, poor safety conditions in open spaces, and social isolation. Finally, this collaborative process facilitated the shared mapping of collective neighbourhood spaces with high potential for community use, alongside existing cultural, sports, healthcare, and community facilities that can be networked, reactivated, or – when privately owned – opened up to the neighbourhood through shared use. Overall, this phase laid the foundation for the development of genuinely place-based urban analyses and design approaches, aimed at more accurately responding to the actual needs of the community.

4.3.2. Data Analysis: Housing Spaces and Dwellers

As part of the masterplanning process, a further step involved a more precise delimitation of the field of technical analysis and intervention, based on the spatial configuration of the Barriera Vecchia neighbourhood and its actual patterns of use. This stage revealed a mismatch between, on the one hand, the boundaries of administrative and statistical areas – used to collect data on housing characteristics, sociodemographic profiles, household income, and property values – and, on the other, the complex topography of Trieste, where steep gradients often make places that are close in planimetric terms effectively distant and inaccessible (Fig. 8). This process underscored the inherent difficulty of translating city-level statistical data into more accurate, localised applications.

Fig. 8. Barriera Vecchia neighbourhood (in red). On the left, the city topography; on the right, the boundaries of administrative districts
(Source: Urban Planning Atelier, the University of Trieste, 2024-25).

Specifically, the processing of municipal registry data (Anagrafe comunale), based on administrative divisions, proved insufficient to capture socioeconomic phenomena at the neighbourhood scale (Comune di Trieste, 2025). Similarly, data on property values (from the Real Estate Market Observatory – OMI 2024) and income levels (Personal Income Tax, IRPEF – MEF 2023, based on areas defined by postal codes) remain tied to relatively large zones, which do not correspond to the spatial articulation of the territory. As such, they can be used to indicate median values and general trends, but not for detailed spatial analyses. It was therefore decided to rely on the spatialisation of data provided by ISTAT (Italian National Institute of Statistics), as their level of detail – structured at the scale of census tracts – allows for closer observation of local dynamics. Due to the high settlement density in the central area of the Municipality of Trieste – and Barriera Vecchia in particular – census tracts often correspond to individual urban blocks[4]. ISTAT data enable a specific focus on the age structure of the population, household composition, presence of foreign residents, as well as the distribution of dwellings and number of rooms per unit. Overall, despite numerous limitations, their GIS-based mapping and comparison – when possible – with other available datasets prove highly effective in visualising key issues and facilitating cross-analysis between different topics.

The analyses conducted in this way show that the Barriera Vecchia accounts for 11.2% of the Municipality of Trieste's population (22,192 residents) compressed in just over 1% of the city's total surface area, with a residential density amounting to 214.7 inhabitants per hectare – approximately ten times higher than the municipal figure. The average age of the population is 46 years, compared to 49.5 at the city scale, and the 25-64 age group accounts for 65.7% of the area's residents, as opposed to 52.6% in the wider municipality. However, this should not overshadow the significant presence of older residents: more than a quarter of the population is over 65 years old. This pattern is consistent with the demographic structure of Trieste, where over-65s represent 28% of the total population. The analysis of household composition shows that Barriera Vecchia is predominantly characterised by single-person households or those with two members, accounting respectively for 55.0% and 23.4% of the total. There is also a significantly higher proportion of foreign residents (21.5%) than in the rest of the city

4 In fact, ISTAT data are not without their challenges. On the one hand, reconstructing time series – for example, between the last two available censuses (2011 and 2021) – is difficult due to changes in boundary definitions. On the other hand, working with spatial units that do not correspond to sub-municipal administrative boundaries requires substantial data processing efforts.

(11.2%), with a major concentration in the 30–54 age group (10.0%).

Taken together, the analyses developed from ISTAT and MEF data outline a territorial context characterised by a generally younger population and smaller household units than in nearby districts and the city, set within a high-density urban environment marked by conditions of social and economic fragility. Building on the spatial representation of this quantitative information, a map was produced to highlight the tension between the characteristics of the 'containers' (the dwellings and their dimensional configurations) and the 'contents' (namely the people who inhabit them). This map illustrates the subdivision of the Barriera Vecchia neighbourhood into distinct 'Areas' (Fig. 9). The northernmost part of the district (Areas 1, 2) is mainly characterised by the presence of single-person households and large-sized dwellings, which are, however, mostly vacant or occupied by non-residents. This suggests a prevalence of short-term rental arrangements, likely for students or tourist accommodation. The central portion of the neighbourhood (Areas 3, 4, and 5) presents a significant concentration of foreign residents, working-age individuals (25-64 years), elderly people, and relatively large families living in dwellings of varying sizes, though predominantly small. Lastly, in the southern portion (Areas 6, 7), larger households generally prevail, with a significant proportion of foreign residents and co-residents living in small dwellings.

The marked internal differentiation of Barriera Vecchia offers valuable insights for identifying design issues and potential sites of intervention – ranging from domestic environments to public spaces and support services for the most vulnerable groups. For instance, the presence of very large families living in small apartments, or multiple single-person households aged 20-35 sharing the same dwelling, underscores the importance of relational spaces outside the home and the need to strengthen links with socio and educational facilities. Similarly, the concentration of elderly residents living in large dwellings shows a potential for new living arrangements – such as intergenerational co-housing – and for home-based support models that extend beyond the dwelling to encompass a broader network of external services.

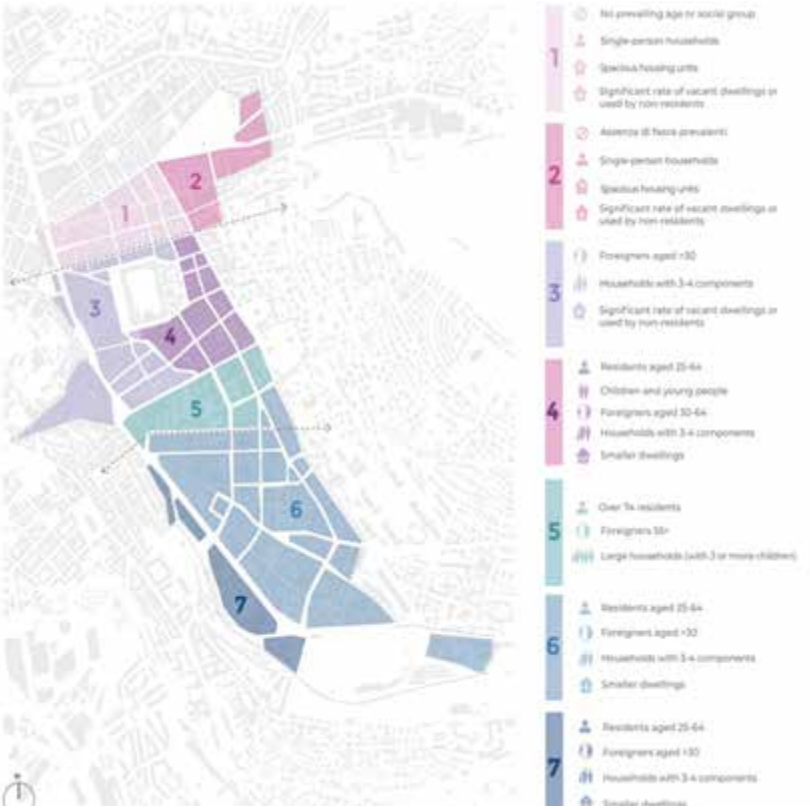

Fig. 9. Containers and contents. Map of the sociodemographic and housing conditions analysis (Source: Urban Planning Atelier, the University of Trieste, 2024-25).

4.3.3. Fieldwork and Site Analysis: Supportive Spaces

In parallel with desk-based work, on-site observations and surveys were conducted. The focus was on the distribution and physical setting of amenities, different forms of mobility – particularly pedestrian – public open spaces, green areas, council housing estates, and buildings providing various types of assisted living for the most vulnerable populations managed by public institutions and third-sector actors. The neighbourhood was investigated at various times of the day, throughout the week, and across different seasons, in order to capture uses, everyday practices, and both critical and potential spaces. This close-up perspective enabled a field-based validation of the data and brought them into dialogue with the material reality of the space.

The site reveals itself as rich in various types and spatial patterns of facilities and services. These elements are understood as supportive spaces – resources that constitute a significant asset not only for the neighbourhood itself, but also for adjacent areas of the city. Across the district, these spaces are concentrated in three main clusters, with educational, social and health facilities serving as key reference points. Each cluster is surrounded by a range of additional amenities and is enlivened by residents' everyday practices. Specifically, in the northern sector, two school hubs are located next to pedestrian areas. In the central sector, a cluster combines social and health services with a diverse set of educational buildings. Finally, in the southern portion, a network of schools and valuable community spaces – including parish sports facilities and a municipal recreational centre offering after-school and summer programmes for children and young people – is situated between two main groups of council housing (Fig. 10).

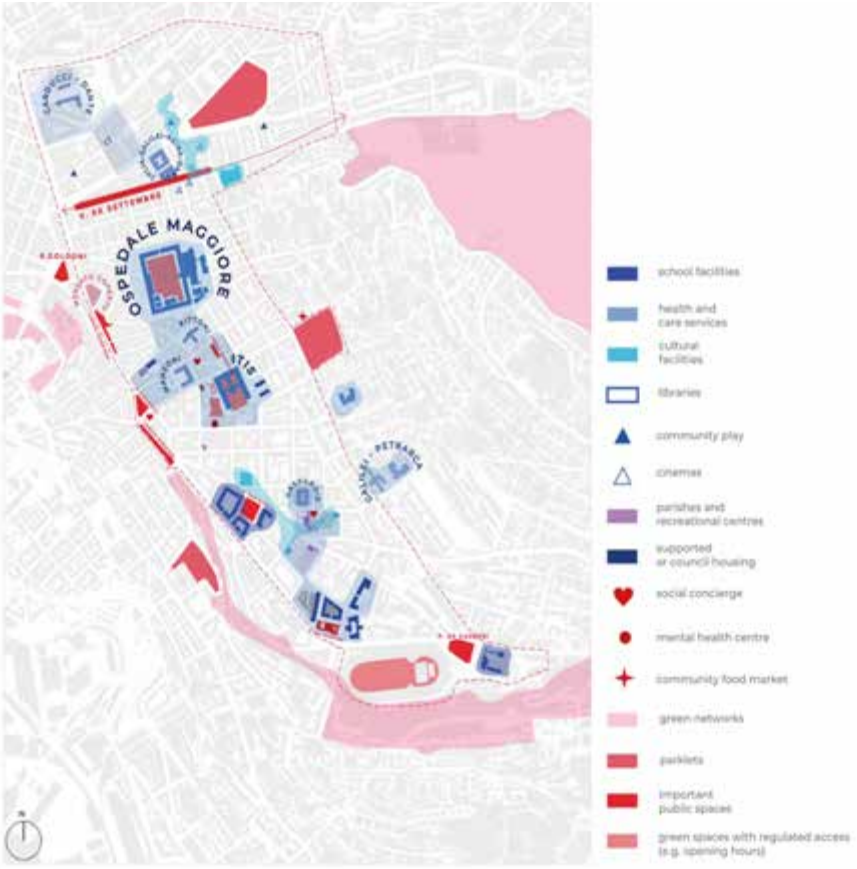

Fig. 10: Supportive spaces. Clusters of facilities and services
(Source: Urban Planning Atelier, the University of Trieste, 2024-25).

However, these well-equipped clusters do not function as integrated systems but rather resemble a *loose constellation of separate buildings and spaces.* Weak and fragmented mobility and environmental networks – comprising scattered tree-lined paths and the peripheral location of major green areas often with restricted access – limit the movement between facilities. In many cases, particularly near heavily trafficked roads or poorly designed spaces, the road infrastructure itself constitutes a physical and perceptual barrier. In parallel, the neighbourhood as a whole is characterised by a lack of squares and meaningful public open spaces, which are largely confined to a few spots along the main road running along the western edge of the site. These areas primarily function as public transport hubs or informal market spaces during limited hours of the day. Indeed, despite the richness of available facilities and services, this part of the city suffers from a pronounced lack of accessible, high-quality public space (Fig. 11). Dominated by car traffic and extensively paved and sealed, the neighbourhood is poor in terms of permeability, environmental comfort, and microclimatic resilience. Consequently, it faces significant limitations both in accessibility and in its capacity to adapt to climate-related challenges, particularly regarding the impacts on the most vulnerable population groups – such as the elderly and children.

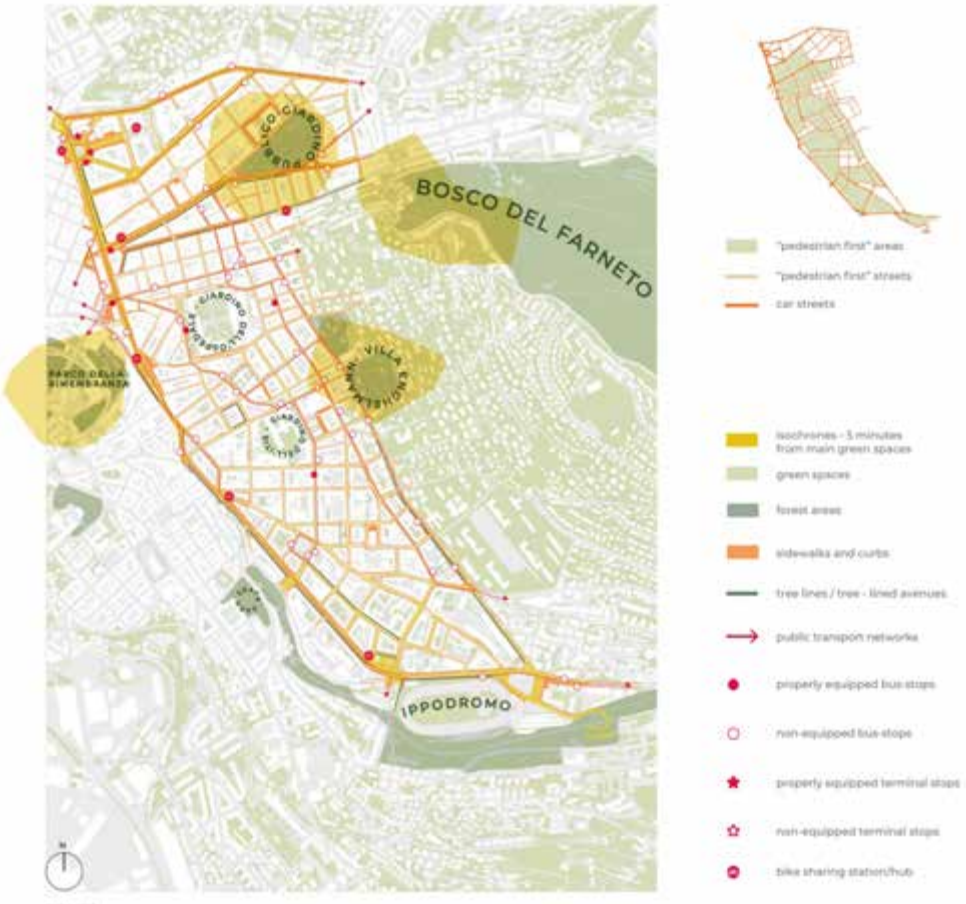

Fig. 11. Roads and green spaces. A poor supply of soft mobility and environmental networks (Source: Urban Planning Atelier, the University of Trieste, 2024-25).

4.3.4. Masterplan: Connections and Insertions

Building upon the key information and issues previously outlined, the masterplan articulates a comprehensive vision that integrates strategic frameworks with localised actions aimed at reducing the neighbourhood's vulnerability (Fig. 12). These spatial systems and interventions are contextualised in relation to two core strategies.

The first strategy centres on *spatial connections*, aiming to transform open areas within the neighbourhood into

a system of genuinely public spaces that promote soft and sustainable mobility, foster relationships between facilities and among residents, and are reimagined as resilient infrastructures capable of mitigating flooding and urban heat island effects. The focus is on the road network and associated urban spaces, currently heavily impacted by car traffic – both from stationary (parked) and circulating vehicles.

The reorganisation of the isotropic street grid into a hierarchical system – distinguishing between major thoroughfares and finer-grained, capillary routes – enables the definition of spatial 'quadrants' (clusters of urban blocks), within which internal areas can be freed from car dominance. Drawing inspiration from Barcelona's *superilla* model (Adjuntament de Barcelona, 2025), this restructuring allows for restricted vehicular access, the creation of pedestrian-only pathways and zones, and the introduction of traffic-calming measures. These interventions are instrumental in reclaiming space for connections between housing and services. Furthermore, mobility corridors and inner courtyards are transformed into porous environments, redesigned with green and permeable elements that also enhance overall environmental comfort. In parallel, the main mobility axis – which defines the western boundary of the study area and links the railway station, historic centre, and the wider Barriera Vecchia neighbourhood with the more porous southern zones (including the racecourse and public housing blocks) – is redesigned. Currently a high-speed and hazardous road, it is reconfigured as a sequence of articulated spaces for both movement and social interaction. Along this axis, existing open areas are transformed into a series of distinct public squares connected to key service hubs within the study area. Meanwhile, underused or poorly conceived spaces – such as vacant lots, oversized car parks, asphalted surfaces, and outdated mobility infrastructures (e.g., a petrol station in the southernmost portion, planned for relocation) – are reorganised and repurposed.

All interventions operate at a *fine-grained, interstitial scale:* reclaiming pedestrian zones and pavements; redesigning public transport stops as elements that support active mobility and function as comfort-enhancing landmarks; and reconfiguring building courtyards — in some cases making them accessible or traversable. These spaces, currently dominated by impermeable surfaces, are reimagined as shared environments for residents, accommodating micro-facilities, areas for play and wellbeing, and green, permeable landscapes.

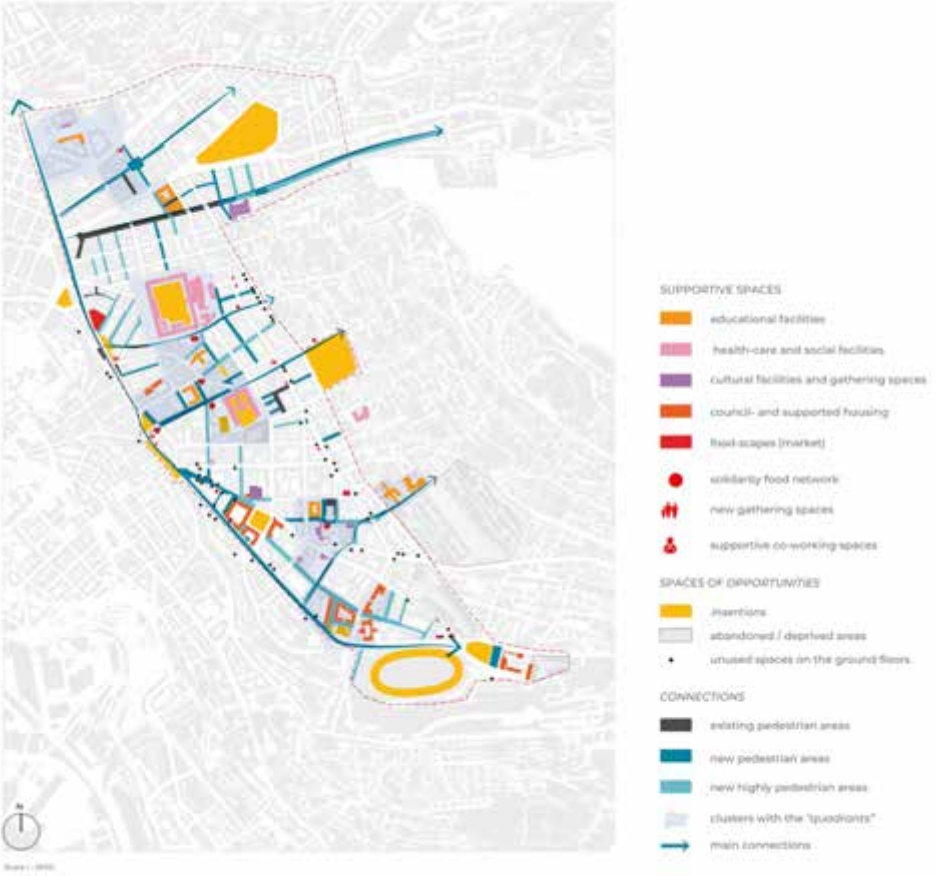

Fig. 12. Masterplan. Connections and intersections: supportive spaces and spaces of opportunities. (Source: Urban Planning Atelier, the University of Trieste, 2024-25).

The second strategy consists of *insertions* of new uses and activities, often through the repurposing of underused or vacant spaces as catalysts for more liveable and enriched urban conditions. It primarily focuses on the reconfiguration of areas situated within or adjacent to public facilities, integrating them and enabling their systemic use through the connections provided by the broader pedestrian mobility system. This approach aims to strengthen the service network and improve its *isotropy* by activating spaces currently perceived as critical (e.g., abandoned stalls inside the food market), and by reorganising functions associated with existing facilities into a 'spatial infrastructure' accessible at different times of the day and by a diverse range of users (e.g., canteens, libraries, gyms, sports equipment, conference rooms).

Specifically, a first type of intervention involves rethinking the spaces adjacent or within the plots of schools and healthcare centres. The redesign of thresholds, entrances, courtyards, and fences aims to better connect buildings with their surroundings, with particular attention to the needs of vulnerable users, especially older adults and children. In parallel, vacant ground-floor areas are conceived as extensions of the domestic sphere and reprogrammed with activities that support residential life (e.g., shared kitchens, self-managed nurseries and after-school services). These indoor and outdoor dimensions are brought into dialogue, fostering spatial and functional integration as well as new activities and social practices.

A second type of intervention – closely linked to the mobility reorganisation – reconfigures key open spaces as inclusive areas designed for diverse uses. One example is the new pedestrian route connecting the hospital, schools, and care facilities in the central sector of the neighbourhood. New uses include temporary markets, play areas, accessible public transport stops, and community-oriented facilities.

Finally, the project envisions new systems of open spaces and an environmental network, connecting to major green areas located on the perimeter of the neighbourhood that are currently segregated or inaccessible due to topographic constraints. Enriched by tree lines, rain gardens, and targeted depaving, these systems are imagined to host micro-functions that also encourage inclusive and intergenerational practices — for example, new sport facilities, playgrounds, and sheltered seating areas.

5. Conclusions

In inner suburbs and semi-central urban contexts, which are vulnerable both to becoming natural areas of expansion for ongoing real estate valorisation processes in the adjacent areas, and to the displacement and filtering up of resident populations, a central issue is how to *avoid regeneration that fosters gentrification*. This should be achieved primarily, if not exclusively, by promoting projects and initiatives with a strong ecological value that specifically address vulnerable groups living in these areas – in terms of housing provision, service typologies, and connections among public spaces (Lanzani, 2024b, p. 177). From this perspective, the masterplan (and the entire process oriented towards its design), developed through the research activities carried out in the Barriera Vecchia district, is conceived as a tool which aims to support "a much stronger public action", "contrary to neoliberal rhetoric and partly also to the more radical ideas of do-it-yourself urbanism" based on the poor resources of even those struggling to independently manage their lives (Ibid.).

Another lesson learned from the iNEST research in Trieste is that, when working in highly sensitive and fragile social and spatial contexts, there is a strong need to integrate analytical surveys, direct observation, and interaction with local institutions, stakeholders, and inhabitants who live and operate in these areas on a daily basis. While general data frameworks and observatories are useful for guiding action at the broader urban system scale, at the local level what is also needed is a closer, design-oriented perspective aimed at defining *unconventional spatial solutions* – solutions capable of responding to emerging social needs, accommodating new collective practices, and fostering a deep integration across diverse urban policy domains, from housing to the wider spectrum of welfare.

Within this process, the existing facilities and services – their further development through new insertions and additions, their connection via spaces capable of ensuring widespread and inclusive accessibility, and the creation of new synergies with interventions aimed at reducing soil sealing and re-vegetating urban surfaces – are of considerable importance. Together, these elements can shape a *framework of spatial and social infrastructures* designed to alleviate the sociodemographic and economic vulnerabilities that increasingly affect large segments of the urban population. These infrastructures – composed of public spaces and amenities – not only respond to social needs arising from the growing and multifaceted vulnerabilities of individuals and families, but also enable and foster new institutional and grassroots practices. At the same time, thinking in terms of infrastructures – understood as continuous and interconnected systems – invites a rethinking of the design process itself: its methods and aims, and particularly its role as a pivotal mechanism for the de-sectorialisation of the many and diverse public policies addressing different forms of vulnerability, ranging from urban planning to public works and mobility, and from education to social and healthcare services.

One final clarification is, however, necessary: the major omission in this narrative is housing itself. Policies aimed at affordable housing – particularly in the rental sector – capable of addressing sociodemographic and economic distress are indispensable. The approach adopted in the development of the masterplan should therefore be understood as one component within broader pathways of public policy innovation, aiming to refocus regeneration efforts on space and people, and encompassing *both the internal and external environments of the dwelling.*

The Old Town of Taranto. Reclaim neglected spaces to challenge narratives of decline

Gabriele Leo
IUAV University of Venice
Email: gleo@iuav.it

Abstract
This paper examines the precarious spatial and social condition of Taranto's Old Town, affected by a radical process of abandonment and subsequent ruination. Part 1 provides a historical overview of Taranto's transformation from a small coastal settlement into a contemporary sacrifice zone for global industrial interests. Part 2 offers an in-depth focus on the Old Town, tracing its enduring condition of spatial injustice across history and analyzing how successive waves of industrial development and demographic shifts have progressively marginalized the area and made it a symbol of socio-economic exclusion and infrastructural decay. Part 3 briefly explores grassroots spatial practices active within the Old Town, which reclaim neglected or underused spaces, generating alternative cultural and social dynamics that contest dominant narratives of abandonment and decline.

Keywords: Taranto, Taranto's Old Town, Sacrifice Zones, Toxic Legacies, Post Disaster

1 - Taranto: ascent and decline of a 'platform city'.

Taranto is a port city in Southern Italy that underwent an extensive modernization and industrialization process in the first half of the 20th century, which radically altered its scale and modes of existence, transforming a small-sized coastal town into a node of heavy production on a global scale.

The industrial turn shaped a parabolic trajectory in the city's urban development — marked by a phase of rapid ascent followed by decline over the course of a century — heavily influenced by state-led projects that deeply affected both the social and spatial composition of the city.

Today, the entire territory is compromised by a stratification of contaminations — inscribed in the sea, air, soil, and subsoil — legitimized by a hegemonic narrative that frames territorial development as inevitably dependent on industrial growth. These legacies extend beyond the physical boundaries and imagined narratives of a specific site or case study, often revealing the ways in which an era is perceived by its actors, both in its continuities and in its ruptures (Brenu, Pessina, Tiganea, 2024). In this sense, Taranto's toxic legacy is closely intertwined with the techno-optimistic imaginary of industrial modernity, which has produced uneasy and often intangible heritages, functioning as collective objects of inquiry, conflict, debate and, at times, denial.

With regard to its spatial structure, Taranto presents itself as a 'platform city', extensively top-down planned, where multiple systems can be identified (Curci, Geroldi, 2020), each operating at very different scales (see Figure 1).

Within the urban system, two distinct types of city can be recognised: the dense, pre-industrial fabric (comprising the Old Town and the nineteenth-century grid) and the post-war expansion, dispersed and fragmented into spatially separate areas and satellite districts.

The system of productive and military infrastructure, on the other hand, consists of the steel industrial area, petrochemical plants, industrial port, naval arsenal, and military bases. These occupy vast portions of the city, forming enclaves entirely inaccessible to its inhabitants.

Figure 1. Taranto, satellite view

1.1 - Historical overview of a radical transformation

The urban development of Taranto is closely linked to the continuous demographic accelerations following the Unification of Italy, radically and rapidly transforming its urban structure. The first of these took place between the late nineteenth and the early decades of the twentieth century, when, following the establishment of the military base and naval arsenal, the city's population doubled, rising from around 30,000 in 1881 — with 80% residing in the Old Town — to approximately 60,000 by 1911. The city's military specialization also led to significant growth during the wartime and interwar periods, with an increase of roughly 100,000 inhabitants between 1911 and 1951. This phase corresponded to an expansion of the city towards the mainland, one of the direct consequences of which was the depopulation of the Old Town. (Curci, Geroldi, 2020)

Following the industrialisation process initiated by the naval arsenal, in the post-war period Taranto was designated as one of the main industrial hubs of Southern Italy within the regional development strategies promoted by the Cassa del Mezzogiorno. The complex programme of industrialisation in the Mezzogiorno represented one of the most extensive public interventions ever undertaken by a state in post-war Europe to reduce internal regional disparities. What appears paradoxical is that, in the long term, these interventions failed to achieve their intended goal of economic convergence. Instead, they ultimately registered a reversal of the trend, bringing the regional gap back to its initial levels[1]. This tendency is not unique to Southern Italy but reflects a broader

1 "Yet, to this day, the economic gap between the North and South of the country has not narrowed and, in some areas, has even widened: in 2019, the GDP (at current prices) of the eight southern regions accounted for 22% of the national total, less than the 24% recorded in 1951. Nor are there improvements in terms of resident population: in 2019, per capita GDP in the South was still just over half (55%) of that of the Centre-North, only slightly higher than the 53% recorded in 1951 (SVIMEZ, 2011; 2020). However, the invariance of these aggregate figures conceals very different trends over time. In the first thirty-five years after World War II, there was a significant reduction in socio-economic disparities between the South and the Centre-North of the country, but from the 1980s onward, this convergence 'came to a halt,' and the gaps began to widen again, in some cases returning to levels seen in the early 1950s." (Martinelli, 2020)

stagnation in regional convergence processes observed in most Western European countries since the 1990s. (Martinelli, 2022)

The construction and expansion of the steel industry, alongside the development of the port, an oil refinery, and a cement factory, produced significant social and territorial impacts, giving rise to conflict between influential state powers and local institutions. (Coppola, D'Ovidio 2018). During this phase, the city continued to grow, gaining approximately 50,000 more inhabitants between 1961 and 1981. However, this demographic growth never halted the depopulation of the Old Town, which became increasingly intense and irreversible.

In 1982, Taranto reached its peak population of 244,798 residents, after which it began to shrink. With an economy based on industrial monoculture, the city was unable to withstand the negative effects of the steel crisis. Today, both unemployment rates[2] and population numbers are returning to the levels of the pre-industrial period (Santa Cruz Grau, 2014).

1.2 - From Techno-optimism to the awareness of sacrifice

At the time of the construction of the steel plant, in the early 1960s, a transformation occurred that was not only spatial and economic, but also cultural: the myth of industry — as the city was being reshaped — took root and gained strength (Leogrande, 2018), supported by an extensive media propaganda campaign.

However, the initial enthusiasm was soon overshadowed by the disproportionate expansion of industrial infrastructure. In 1968, Italsider (the Italian steelmaking company) proposed extending the steelworks from 528 to 1,500 hectares, overriding both the municipal master plan and the 1961 industrial development plan. Prioritizing logistical concerns, the state-owned company advanced plans to expand toward the port and city. The so-called raddoppio — effectively a tripling of the plant's surface area — provoked resistance from parts of the local political establishment. In January 1971, the municipal administration denied Italsider a construction permit for the port works, citing incompatibility with urban planning regulations (Giannì, Migliaccio 2016).
In 1972 the journalist Antonio Cederna used for the first time the word "disaster" to refer to the city of Taranto. In the pages of Corriere della Sera[3], Cederna described what was happening in Taranto as

> a truly barbaric process of industrialisation. A state-participated industrial enterprise, with an investment of almost 2,000 billion lire, which had not yet considered even the most basic anti-pollution measures, nor planted a single tree to protect the poor residents of the downwind working-class neighbourhoods.

Despite this, in the mid-1970s, the expansion was eventually executed (through an injunction decree issued by the Committee of Ministers for the Mezzogiorno) bringing the number of direct employees to an exorbitant 22,000, with a further 14,000 employed in around 400 subcontracting companies[4]. This expansion further increased the size of the factory, laying the foundations for an industrial gigantism that today contributes to making the city a "complex problem" (Balducci, 2020). Indeed, in the following decades, the multiple effects of industrial overloading gradually began to surface, fuelling a multidimensional crisis characterised by the simultaneous presence of environmental and public health issues. In 1990, the Ionian area, together with several neighbouring municipalities, was declared an "area of high environmental risk" by the Italian Ministry of the Environment (at the time, it alone produced 92% of the dioxin emissions in Italy). In 1995, with the privatisation and sale of the steel plant, environmental concerns intensified and became a widely shared social issue. However, it was only in 1998 that official documents acknowledged the existence of a severe environmental and public health crisis. In 2008, the Apulia regional government approved a law establishing emission thresholds for industrial pollutants in the atmosphere, particularly for dioxins, assigning enforcement responsibilities to ARPA (the Regional Environmental Protection Agency) which was obliged to suspend polluting production in the event of violations. Epidemiological

4 data from Istituto Tagliacarne; OECD, 2016

studies revealed that the incidence rates of respiratory, cardiovascular, and cancer-related diseases in the Taranto area were significantly higher than the national average (Greco 2020).

Nowadays, Taranto is un-famous for being one of Italy's most known environmental disasters. On January 2022, a U.N. report on human rights[5] included the city in the list of "sacrifice zones": areas where vulnerable and marginalized communities are exposed to extreme levels of pollution and toxic contamination. The term originated in the cold war era, when it was used to describe areas rendered uninhabitable by nuclear experiments and, according to the report,

> today a sacrifice zone can be understood to be a place where residents suffer devastating physical and mental health consequences and human rights violations as a result of living in pollution hotspots and heavily contaminated areas.

From the perspective of collective awareness, the UN report had a significant impact on the population, as it was an official and formal acknowledgment of such a condition. However, it is important to highlight that, in the preceding decade, several researchers and activists had already been denouncing evidence of a sacrificial process. In 2019, Lidia Greco, Professor of Economic and Labour Sociology at the University of Bari, wrote:

> [...] within the dynamics of capitalism and the industrial division of labour, certain areas and social groups are sacrificed in the name of broader processes that enable and sustain the very possibility of accumulation. In this sense, Taranto constitutes a sacrificial area. Rather than taking shape as a social conflict centred on environmental justice [...] the conflict in Taranto tends to manifest as a post-political issue. Here, the absence of accountability and strategic visions is combined with the search for an almost exclusively technical and scientific solution to the problem, one focused on the physical limits of growth, territorial degradation, and resource scarcity, without questioning the aims and values of the development model affecting the area and the way its costs and benefits are distributed. In Taranto, however, it is not merely a question of creating a world compatible with life and capable of sustaining it; it is also about representing and interpreting reality as a whole, giving it meaning primarily through the creation of bonds among individuals who find in it the reason for their existence.

In the current context, one of the most difficult challenges lies in seeking a balance between health, employment, and the environment. The pursuit of environmental justice must begin with the recognition of the inherently political nature of the issue, which involves not only the workers but also the various social groups that collectively bear the social costs of industrial overloading.

2 - The Old Town: isolated both physically and socially

All the massive transformations induced by the industrial development profoundly reshaped the territory in a very short time, layering new lifestyles and urban practices onto pre-existing ones. In this process, certain parts of the city and groups of inhabitants were left behind, to the extent of becoming sorts of residual wastes produced by the voracity of radical transformation. The most significant case is represented by the island of the Old Town. Commonly referred to as "Città Vecchia" by the inhabitants of Taranto, the Old Town is the original settlement of the city, located on a small, narrow island (approximately 25 hectares) that extends longitudinally along an East-West axis, separating the open sea from a smaller inland lagoon, and connected to the mainland on both sides by two bridges (See Figure 2). The trajectory of its urban history is closely intertwined with the broader impacts that industrialisation — and its subsequent decline — have had on the city's social and spatial organisation (Coppola, D'Ovidio 2018).

5 United Nations, General Assembly, The right to a clean, healthy and sustainable environment: non-toxic environment. Report of the Special Rapporteur on the issue of human rights obligations relating to the enjoyment of a safe, clean, healthy and sustainable environment, 12/01/2022

Figure 2. The island of the Old Town, satellite view

2.1 - Story of an exodus

Due to a particular combination of historical events and geographic configuration, Città Vecchia has always been marked by conditions of social disparity and spatial injustice. For centuries, the island was subjected to extremely high population density, as a result of military regulations that prohibited urban expansion beyond its fortifications. Demographic growth in the 18th and 19th centuries eventually rendered the confines of the Old Town excessively narrow: by the second half of the 19th century, approximately 25,000 inhabitants were concentrated within the island.

Amidst this condition of extreme density — which left no room for open spaces for social interaction — two distinct urban areas can still be identified, both spatially and socially. The upper part overlooks the open sea and is characterised by a more spacious urban fabric, with large residential palaces that once housed the city's wealthier classes. The lower part, also known as la marina, developed along the inland lagoon (the Mar Piccolo) and took the form of a dense maze of small, tightly packed dwellings built on an artificial extension of the island. This part of the Old Town — which, in the pre-industrial period, was mainly inhabited by fishermen and the working class — has long been affected by precarious living conditions, and still today, following the processes of ruination and abandonment of the island, remains the most severely impacted by the city's recent crisis.

The problem of overcrowding in Taranto's Old Town, along with the difficult sanitary and hygienic conditions it entailed, remained a constant feature of the city's history from at least the second half of the eighteenth century until the 1950s (Lapesa 2011). After visiting Taranto at the end of the eighteenth century, the Swiss traveller Carl Ulysses von Salis-Marschlins noted:

> Eighteen thousand inhabitants are crammed onto this small rock, in houses so tall and so tightly packed one against the other that the streets are rendered dark, exceedingly narrow, and uncomfortably windswept. To this, one must add a dreadful paving, especially along the Via della Marina, which [...] is impassable due to its filth and stench. This quarter provides overwhelming evidence that the city is far too

populated for the extent of its territory.

About half a century later, in 1844, Giuseppe Costa, commissioned by the Società Economica di Terra d'Otranto to collect statistical information on the city, observed:

> Given the limited perimeter of the city for the size of its population, the shortage of space is compensated by multiplying the floors of the dwellings. Nevertheless, the number of inhabitants far exceeds the capacity of these homes, and as a result, they live in extremely cramped conditions.

In such a context, it became necessary to adopt an expansion plan aimed also at addressing the island's severe sanitary conditions, which had been further exacerbated by overcrowding. Meanwhile, in 1882, the Italian Parliament approved the construction of what would become the largest naval arsenal in the country, to be located near the newly planned urban expansion, while additional civilian production areas were established on the mainland to the west of the island.
In this phase of urban development, the Old Town played a highly marginal role, while rapid and uncontrolled growth took place in the Borgo Nuovo — beyond the bridge to the east of the island — which first attracted the upper and middle classes (See Figure 3).

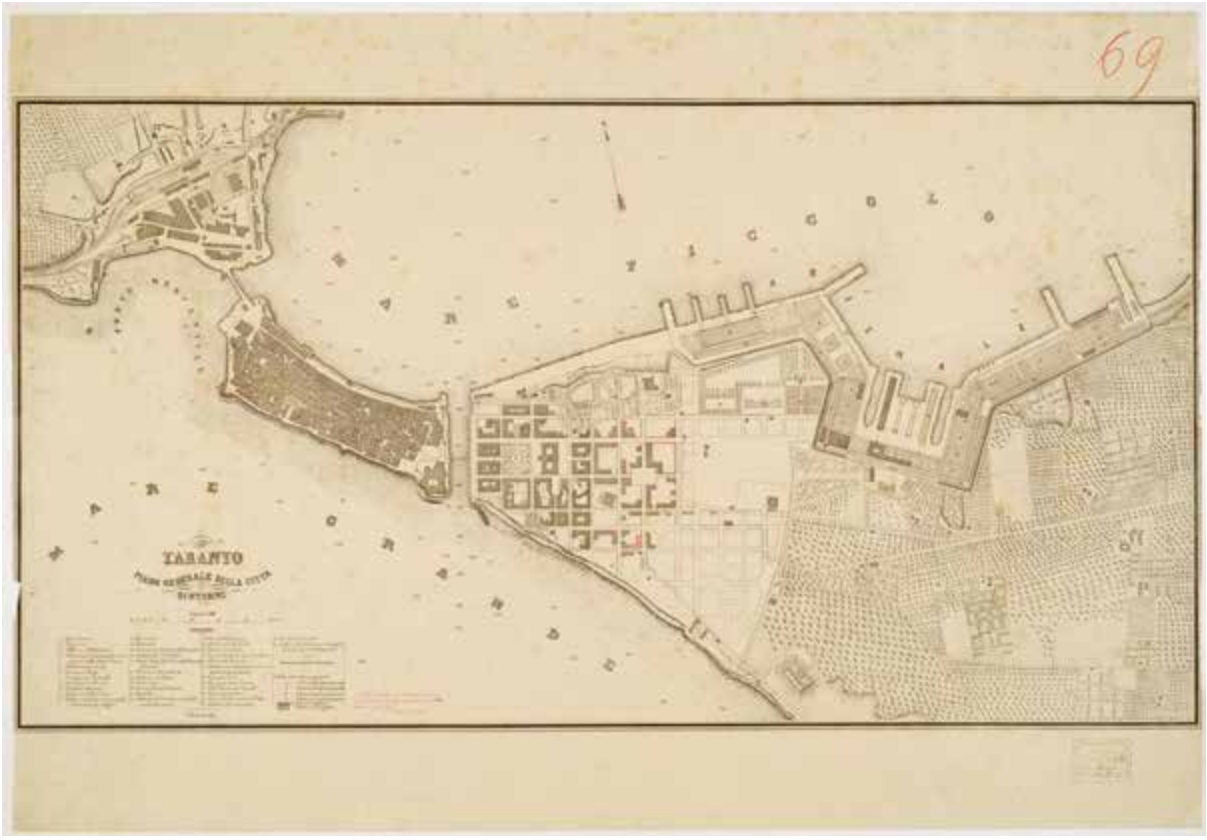

Figure 3. Taranto, general plan of the city. Istituto Geografico Militare, 1889

Finally, in the post-war era, the Old Town experienced a significant diaspora. By 1969, population data already recorded 15,861 residents, the majority of whom were employed in fishing and the construction industry[6]. As the island was gradually abandoned, a large number of new social housing complexes were built on the city's

6 Franco Blandino, Relazione Illustrativa del Piano Particolareggiato per il Risanamento e il Restauro Conservativo della Città Vecchia (Illustrative Report of the Detailed Plan for the Rehabilitation and Conservation Restoration of the Old Town), Municipality of Taranto, 1971.

periphery, fueling the growth of the so-called "Città Nuova" — the modern expansion area, which today is by far the largest both in terms of surface area and population.

Depopulation steadily increased until 1975, the year of the tragic "Vico Reale collapse", when a three-story building fell down, claiming the lives of six people. The incident had a strong emotional impact and was widely covered by the media, contributing to a stigmatizing narrative about the entire neighborhood. At the same time, it triggered a process of structural monitoring of unsafe buildings, whose data were used to justify top-down depopulation policies. A so-called "sanitization" program, promoted by the government, forced the remaining residents to relocate to newly built districts through expropriation procedures. As a result, today the majority of the abandoned — and thus physically deteriorated — housing units, many of which have since collapsed, are publicly owned[7] (see Figures 4, 5).

Figure 4. Taranto, top view of the Via di Mezzo enclosed area. ph. Pierfrancesco Lafratta

Figure 5. Taranto's Old Town. View from a rooftop. ph. Pierfrancesco Lafratta

At present, the Old Town of Taranto counts approximately 2,500 inhabitants. Among the most severe outcomes of the prolonged depopulation process is the structural collapse of abandoned buildings. By 2011, it was estimated that one out of every three structures was no longer suitable for habitation (ANCSA 2017). In this regard, the historic core of Taranto represents one of the most physically compromised urban centers in Italy, second only to L'Aquila following the 2009 earthquake. A substantial portion of the island is now rendered inaccessible due to the deteriorating condition of vacant properties. Over the years, the municipal administration has progressively erected walls to isolate unsafe areas, effectively fragmenting the urban fabric. These enclosures impede free

7 According to data provided by the Municipality of Taranto (Gazzetta Amministrativa), over 1,600 properties in the Old Town are owned by the municipality. Of these, 1,338 are residential buildings.

circulation through the island and oblige remaining residents to navigate around large restricted zones, further exacerbating the spatial and social fragmentation of the area. (see Figures 6, 7).

The walls that partially conceal the perception of urban disaster — together with the steel structures encaging abandoned buildings to prevent their collapse — have become a stable and defining feature of the Old Town's urban landscape for over fifty years. These interventions, rather than representing a coherent risk management strategy, appear to embody a form of institutional disengagement from a condition of structural fragility that has become deeply embedded over time.

This widespread perception of institutional inaction is further reinforced by the fact that not only has the residential architectural heritage been left to a gradual and unchecked process of ruination, but buildings of recognized historical and cultural value have been subjected to the same fate. A clear example of this is the case of the Church of San Paolo, dating back to the 15th century, long abandoned and closed to the public. In February 2011, part of its perimeter wall and a section of the dome collapsed onto the street below, dramatically exposing an advanced state of material decay[8]. (see Figure 8)

2.2 - Informal strategies to deal with social-spatial fragility

This combination of forced abandonment, physical fragmentation, and persistent lack of care in the Old Town is closely connected to the social fragility and fragmentation of its inhabitants. Within such a context, informal and illegal activities found fertile ground, further fueling a stigmatizing narrative that portrayed the Old Town as a criminal ghetto. Over the years, the area gradually came to be perceived as a dangerous and unsafe place.

The Old Town and its problems receive little attention in the national media, overshadowed by the prominent and complex issues surrounding the fate of the steelworks plant, whose implications extend far beyond the local level and the city of Taranto itself. Yet, the Old Town accumulates and stratifies deep contradictions and opportunities, making it a remarkable place — a condenser of unexpected and powerful possibilities to produce a rupture within a dominant narrative, one that today remains narrowly focused on the fate of the steelworks (Pucci, 2020).

Recently, the interweaving of industrial, environmental, and social crises — combined with the site's strategic value — has turned Taranto into the object of nationally scaled policy interventions. Within these frameworks, the regeneration of the Old Town has often assumed a symbolic role in narratives of the city's rebirth[9]. In recent years, the historic centre has experienced a limited flow of investment, primarily linked to the Urban II Initiative, whose implementation nonetheless produced mixed outcomes (Santa Cruz Grau, 2014), with regeneration projects concentrated in areas directly affected by tourist presence and the opening of a few new commercial activities (Coppola, D'Ovidio 2018). It is important to recognise, however, that despite funding schemes and planning initiatives, the Old Town continues to experience persistent demographic stagnation and multidimensional crisis. At present, notwithstanding the numerous building renovation projects currently underway, no policy framework has been established that actively incorporates the involvement of local residents, either in participatory terms or through employment opportunities directly connected to urban regeneration processes. Conversely, one of the most prominent policy measures introduced in recent years has been the so-called "Case a 1 euro" (one-euro homes) programme, which, through a series of public calls, allows private individuals to acquire vacant properties within the Old Town at a symbolic price, conditional upon the demonstration of both the technical and financial feasibility of their restoration projects. This policy mechanism, however, is structurally exclusionary with respect to the existing local population, which remains largely unable to access either the financial capital required or the complex bureaucratic, technical, and administrative procedures necessary for participation.

And yet, within this condition of spatial and social degradation — and in the broader inadequacy of official recovery policies — the Old Town represents an extremely vital context in terms of the diversity of urban practices enacted within it. What might appear as an atmosphere of abandonment and stagnation is, in fact, beneath the surface and largely invisible to institutional scrutiny, a theatre of informal and often submerged spatial practices. These are predominantly forms of spontaneous self-organisation, emerging as necessary strategies to compensate for the persistent absence of institutional care and public services.

In a context marked by widespread physical ruination, where spaces for daily life and social interaction have become scarce and precarious resources, some of the most significant practices involve collective actions that — with different degrees of informality depending on the social groups and needs involved — activate processes of reclaiming and reappropriating residual and unused spaces. At an informal level, a multiplicity of dynamics can be observed, reflecting a specific spatialisation of the local social infrastructure (Lo Re 2023): housing occupations, informal exchanges of public housing units through verbal and trust-based agreements between relatives and acquaintances, mutual support practices targeting the most socially vulnerable, self-managed recuperation of public spaces, and the addition of informal storeys to existing buildings.

In parallel with these practices, which are closely linked to the organisation and social reproduction of the most fragile social groups, examples of social mobilisation and civic activism emerge, aimed at providing responses and alternatives to material and social degradation. These initiatives operate by connecting and enhancing environmental and relational-cultural resources (Berardi, Castronuovo 2017). Through these actions, forms of belonging are constructed and alternative imaginaries shaped, attempting to overcome the recurring rhetoric of disadvantage and marginality.

In the next section, I focus attention — through three examples — on practices of commoning and grassroots regeneration carried out by interdisciplinary groups of inhabitants and cultural workers. These initiatives have

9 "Since 2015, an extraordinary mobilization of state powers and resources has been launched through the establishment of multilevel governance mechanisms. An "Institutional Development Contract" (CIS) was created, managed by a state-controlled agency (Invitalia). Within this broader framework, the city was also asked to develop a "Plan for the recovery, regeneration, and enhancement" of the Old Town, for which an ideas competition was announced in 2015. To implement the measures outlined in this framework, state funds were allocated for port development, environmental remediation, the construction of new services and housing, and the regeneration of the historic center." (Coppola, D'Ovidio 2018)

experimented with models of social and cultural innovation, placing at the centre of their interventions the recovery, participatory management, and re-signification of underused spaces within the Old Town of Taranto.

3 - Collective practices of space reclamation. Three case studies

Within the context of the ongoing environmental, economic, political — and consequently social — permacrisis in which the city of Taranto appears to be 'stuck', the latent potential of abandoned and physically degraded spaces in the Old Town represents an opportunity to imagine and experiment with alternative forms of living, social relations, and work.

The practices discussed here are united by a reclamation of urban space in which the use of the discarded and the residual performs a dialectical function in relation to the imposed economic development model (Lo Re 2023). In this sense, the projects do not merely aim at the functional recovery of underutilised spaces, but contribute to promoting a process of collective emancipation by fostering a renewed imaginary of the Old Town — shifting its image from a stigmatised and marginalised area to a contemporary laboratory of social and cultural innovation.

In the first case, I delve into the spatial practice of the Labuat collective through an in-depth exploration of 'Park Urka!', a project that re-signified a residual urban void by promoting a process of active listening and co-design with the social groups involved in the area.

The second case is the Domus Armenorum project: an attempt — led by a mixed group of residents and cultural practitioners — to consolidate the (already existing) practice of collective management of a deconsecrated church through the institutional recognition of the space as a common good.

The third case is Post Disaster Rooftops, an interdisciplinary project positioned at the intersection of artistic activism and culture-led urban regeneration, which temporarily transforms the rooftops of the Old Town into spaces for conversation and artistic production, fostering a critical debate on the condition of the city.

It is important to note, in analysing these practices, that a significant number of the people involved — in more or less direct ways depending on the specific case — have been part of a regional network supported by a particularly productive period of youth policies implemented by the Apulia Region between 2005 and 2015. This policy context promoted the emergence of an interconnected ecosystem of bottom-up, culturally driven urban regeneration initiatives through public funding, networking platforms, and capacity-building programmes[10].

3.1 - LABuat and the "Park Urka!" project

The first case concerns a series of initiatives carried out by the cultural association LABuat, composed of young architects and cultural practitioners from Taranto. The association was established within the framework of the "Principi Attivi" call (1st edition) promoted by the Apulia Region, "with the aim of redeveloping urban spaces through concrete, collectively significant interventions"[11].

LABuat operates through co-design workshops involving local communities, conceived as tools to trigger tentative transformations, reveal hidden situations, and open up new possible trajectories. The group's statement reads as follows:

10 Since 2005, the Apulia Region has developed a new political strategy focused on local development, culture, and youth. EU structural funds were used innovatively to boost the local economy through tourism and the creative industries. Over the years, a system of sectoral programs and integrated local strategies fostered widespread creativity, cultural centers, and creative enterprises across the region. Initiatives like Principi Attivi and Bollenti Spiriti (from 2008) and Pugliesi Innovativi (from 2015) supported entrepreneurial projects in areas such as natural conservation, knowledge-based local development, social inclusion, and cultural, technological, and social innovation. Funding, training opportunities, mentoring, and public workshops were essential components of these programs, promoting a multifaceted idea of development combining economic growth, community empowerment, self-entrepreneurship, and urban regeneration.

11 from LABuat website - https://labuat.wordpress.com/

LABuat aims to promote a process of citizen participation around the reclaiming and reappropriation of the city and its public spaces. The city should communicate to its inhabitants the joy of inhabiting, the pleasure of belonging to a place and a community, as well as memory and desire. LABuat seeks to disseminate this message through tangible actions related to the regeneration and management of urban spaces, and their improved use through the installation of temporary and/or permanent structures, with the goal of creating new opportunities for encounter and conviviality, and establishing new conditions of livability in otherwise abandoned or underused places.

The group presents itself as a multidisciplinary, non-profit organization whose projects focus on participation, active citizenship, environmental sustainability, and local development, actively involving actors and communities typically positioned at the margins of public discourse and decision-making.

Although primarily concentrated in the Old Town, LABuat's spatial practice has extended to other areas of the city as well. Among its initiatives located within the Old Town, a particularly relevant case study is the Park Urka! project — a spatial transformation process combining grassroots urban regeneration and tactical urbanism. The project is noteworthy for two main reasons. Firstly, for the emphasis placed on relational processes aimed at developing a spatial practice oriented toward a co-design model. Secondly, for the symbolic value of the site itself — an empty space created by the collapse of a building in the very area historically marked by the tragic collapse of Vico Reale. In this sense, the project intervenes in the re-signification of a difficult, or even dark, heritage and proposes the imaginary of a possible "new beginning"[12] (See Figures 9, 10).

Figure 9. Making of the Park Urka! project, 2009

12 translation for "rinascita", used by Labuat in the project description on their website.

Figure 10. Park Urka! opening, 2009

In engaging with the Old Town both spatially and socially, the group deliberately chose to intervene in a marginal, discarded space — an urban void without a defined function, yet informally appropriated in various ways, from a children's play area to a site for illegal waste dumping.

> We believed that the only viable path was to reclaim an abandoned space and turn it into a field for practical and manual experimentation, directly involving local residents and, above all, the youngest members of the community. The aesthetic quality of the final outcome was not our primary concern. What mattered was the process of dialogue, exchange, and collective construction that, for days, kept us working together from morning to evening in those spaces with the residents of Via Cava. In those September days, we had the opportunity to deepen our understanding of the Old Town and grasp some of its underlying issues through the simple observation of everyday habits.
>
> [...]
>
> It was through the children that we learned the first issue to be addressed in that open area was the paving, since the combination of poor cement quality and steep incline made it impossible for them to even play a basic game of football.

As a result of these observations, the intervention consisted in levelling the uneven surface of the "square" and placing playground elements along the edges of the space, in order to allow for football games. Although the wooden playground components were vandalized shortly after installation, the square is still used today by local children, who have renamed it "il Campetto" - the little football pitch (See Figure 11).

Figure 11. "Il Campetto" in 2018 (9 years after Labuat intervention) source: Google Street View

3.2 - Domus Armenorum

The second case of interest - which includes (among others) the Labuat association - is the collective management of the Church of Sant'Andrea degli Armeni, a small deconsecrated church "embedded" among the buildings of Piazza Monteoliveto in the Old Town. The project, named Domus Armenorum, represents a (partially successful) attempt to formalize an existing practice of re-appropriating a disused public asset by citizen committees and cultural activists from the city. On the project's social media pages, it states:

> The project was born out of the spontaneous collaboration of local residents, architects, and cultural heritage professionals. It aims to foster a model of recovery and participatory management of the widespread cultural heritage of Taranto's Old Town, much of which lies in a state of abandonment, with the goal of preventing its loss and promoting its integrated enhancement.

The small church was originally part of a larger complex that included a rectory and a sacristy. These adjacent structures were recently acquired and incorporated into a hospitality facility (the Hotel Residence Sant'Andrea degli Armeni), while the church's main hall—restored with public funds in 2008 and subsequently forsaken—became the focus of a series of initiatives aimed at its valorization, promoted by local residents, neighborhood committees, cultural associations, NGOs, foundations, and individual citizens.

The use of the church, almost exclusively dedicated to public events of community interest, was "regulated" by an informal set of guidelines that spontaneously emerged over time through collective co-management practices. These simple principles included basic rules such as being fully autonomous in organizing the events and cleaning the space after use.

After several years of informal and entirely self-organized co-management—without the involvement of the local administration—a group of activists, including residents and young members of the LABuat association, promoted an attempt to formalize this practice by seeking official recognition of the church as a relational good (Berardi, Castronuovo 2017). In 2014, the association sent a letter addressed to various institutional bodies potentially concerned with the matter, stating:

> LABUAT Association's proposal is to experiment with new forms of preservation, enhancement, and participatory management of the diffused cultural heritage within the island, starting with what we consider a 'good practice' already in place: the 'spontaneous care' undertaken by local residents and qualified cultural

practitioners for the church of Sant'Andrea degli Armeni. This care practice is something the association intends to encourage and support through the DOMUS ARMENORUM project.
[...]
At present, no institution, of any nature, formally claims responsibility for the architectural asset, generating a bureaucratic deadlock and a lack of interlocutors, which limits the feasibility of projects and significantly slows down processes of enhancement. In the meantime, a group of local residents continues to take care of the sixteenth-century church on a voluntary basis, viewing it as an essential component of the quality of the urban space, preserving it from deterioration and informally ensuring its cleanliness, maintenance, and accessibility for both tourism and socio-cultural purposes.

The aim of this initiative was therefore to promote the full and effective public use of the site — while respecting its historical and artistic significance and ensuring its preservation — through the self-training of citizens capable of providing services within a framework of reciprocity. The experience of revitalizing, enhancing, and collectively managing the church of Sant'Andrea degli Armeni generated a process of participatory urban regeneration and contributed to the wider revitalisation of the neighbourhood. Additionally, the LABuat association organised a self-financed construction workshop aimed at providing the church with the necessary furnishings to host community events.

By 2017, the direct management of the site involved ten island residents (six of whom lived in Piazza Monteoliveto) and three local associations, which enabled the site to open for approximately two hundred days a year (Berardi, Castronuovo 2017).

Today, the participatory management of the site continues, albeit with fluctuating intensity depending on the availability of endogenous and exogenous resources, while the Domus Armenorum project has expanded the scope of its actions by integrating the church into a broader network of cultural and natural heritage sites across the territory.

Figure 14. Live arts event at Sant'Andrea degli Armeni

3.3 - Post Disaster Rooftops

The third case, in chronological terms, is Post Disaster Rooftops, a platform for artistic and cultural production set on the rooftops of Taranto's Old Town. The project — which I am personally involved in as a co-founder — was initiated in 2018 by the independent initiative of a group of architects and designers from Taranto and its surrounding areas. All of them had been directly or indirectly involved in practices, projects, and organisations supported by the Puglia Region's youth policies in the previous decade.

The initiative was driven by an urgent need to move beyond a pervasive sense of resignation, which had emerged in the wake of the exhaustion of both these public policies and the bottom-up initiatives that had animated the Old Town in preceding years. That same year, the Italian government had sold the local steel industry to a

foreign corporation, and The New York Times published an article depicting Taranto as a fading city, an emblem of Western political failure[13]. Post Disaster Rooftops arose, in part, as a response to this suffocating narrative that had settled over the city following its intense media exposure in 2012[14].

As suggested by its name, the project rests upon two intertwined notions that together shape and synthesise the format of the practice: one of a critical nature, articulated through the cultural provocation embedded in the idea of the post-disaster; and one of a spatial nature, through the concept of rooftops, understood both as a physical platform and as an elevated, situated vantage point from which to observe and reflect upon global processes.

By creating temporary installations on the rooftops that combine scenographic and functional elements, the collective Post Disaster — which later took its name from the project itself — transforms existing spaces, amplifying their performative and relational potential (see Figures 15, 16, 17). Within these spaces, artists and researchers are invited to develop context-related projects, based on their own media and disciplinary practices, while engaging in dialogue and collaboration with local artists and cultural practitioners.

Each edition of the project addresses distinct yet interconnected themes, all informed by the city's ongoing condition of crisis (e.g., the relationship between nature and culture; territorial subalternity; the notion of monstrosity, etc.). The project's ephemeral nature is compensated by the creation of a multimedia archive that collects and preserves the content produced during the live events in the form of texts, images, videos, and sound recordings.

The rooftops are reimagined as relational spaces within a specific urban context — the Old Town of Taranto — where public space is largely denied by physical barriers of various forms. In contrast, within the hyper-dense urban fabric of the island, rooftops constitute a potential network of visually (and, in some cases, even physically) interconnected spaces offering sites for encounter and sociality, a sort of diffused common.
In the project's statement, it reads:

> PDR interprets rooftops as unconventional urban spaces — suspended between public and private — free from the main hegemonic forms of control. Climbing up onto the roofs of Taranto's Old Town provides an overview of a traumatised city. But it also offers an opportunity for healing, a privileged point of view from which to collectively imagine possible futures, starting from those buildings still standing.

14 In 2012, Taranto's environmental crisis reached a peak of public attention following an investigation by the Public Prosecutor's Office, which led to the seizure of ILVA steel plant's hot area facilities and the arrest of several executives and owners. The charges included environmental disaster, food contamination, manslaughter, and corruption

Figure 17. Post Disaster Rooftops EP05, Taranto, 2025. Ph Cosimo Calabrese

Originally conceived as a fully self-funded initiative, starting 2022 Post Disaster Rooftops progressively evolved into a project supported by national, regional, and European funding. Each edition is articulated through two complementary and interdependent phases.

The first consists of a production phase of spatial and relational nature, aimed at generating the material and social infrastructure necessary for the programme to unfold. This phase establishes a context-specific collaboration with the local communities inhabiting Taranto's Old Town, whose participation is integral to shaping the spatial configurations and relational dynamics of the project.

The second phase takes the form of a live, public programme — composed of site-specific artistic interventions, conversations, and performances — designed to engage both the neighbourhood's residents and a wider urban and regional audience.

Depending on the availability and nature of the spaces hosting the practice, the public programme can vary in both form and duration — ranging from a very dense, week-long sequence of events to a more extended schedule unfolding over several months, featuring individual contributions on a weekly basis. For instance, the fifth edition, recently held in April 2025, concentrated a particularly dense programme within two weeks, including: four artist residencies followed by site-specific live events; two sound performances; a temporary exhibition; a public poster campaign in the city; four thematic talks.

Over the years, Post Disaster Rooftops has experimented with different spatial and organizational models. One particularly significant case concerns the rooftop of the Galilei School gymnasium, a structure built in the late 1970s following the demolition of a decaying building. Although originally conceived as a public space, complete with an external staircase, the rooftop has never been publicly accessible (except for a very brief squat in the 1990s). In 2022, after opening a dialogue with the municipal administration, the collective managed to obtain a

temporary agreement for the use of the space. This allowed for a steady presence and a series of cultural initiatives, briefly transforming the rooftop into a vibrant meeting point for the city's creative community (See Figure 18). However, in 2025, after the mayor's resignation and the appointment of a technical government, the authorization was formally withdrawn, abruptly interrupting the project. This episode exemplifies the structural fragility of cultural practices in geographically and politically marginal contexts, where local administrations often lack the autonomy and stability to support long-term civic initiatives.

Abstract
The North Adriatic coast has been profoundly shaped by centuries of interaction between human activity and natural dynamics, with major transformations accelerating since the 19th century. Today, this territory faces escalating risks, intensified by climate change and decades of extractive development. This paper adopts the lens of mobility justice to analyze the region's vulnerabilities and opportunities, focusing on three river transects: Stella, Corno-Aussa, and Natissa. Combining historical analysis, policy review, fieldwork, and design experimentation, the study explore a transition from rigid, unsustainable models toward adaptive, plural, and regenerative futures. It positions urban and territorial design as strategic tools to redistribute spatial opportunity, restore degraded ecologies, and ensure fair access to mobility and resources. The resulting project scenarios offer site-specific strategies that integrate climate resilience, intermodal connectivity, and ecological restoration, reimagining the North Adriatic as an amphibious, relational landscape shaped by both human and more-than-human agency.

Keywords: Climate Change; Mobility, Mobile Commons; Spatial Justice; Adaptation

Introduction

The North Adriatic coastline has experienced profound transformations since the late 19th century, shaped by the dynamic interplay between human interventions and natural processes. Early land reclamation projects converted wetlands into arable land, while the development of coastal tourism and the expansion of infrastructure for the terrestrial movement of people and goods further reconfigured the region's landscapes and economies. Today, this territory is confronted by multiple, intersecting crises: declining agricultural productivity, the exhaustion of mass beach tourism, and ongoing demographic shrinkage. These challenges are compounded and increasingly intensified by the accelerating impacts of climate change, which will be particularly intense on this low-lying coast, where lagoonal, deltaic, estuarine, and artificially reclaimed landscapes coexist and overlap.

These challenges resonate with the three interrelated crises identified by Mimi Sheller (the climate, the urbanization, and the refugee crisis), which she argues are deeply interconnected and rooted in a shared structural cause, what she terms "the politics and power relations of (im)mobilities" (Sheller, 2018: 1). In response, she calls for a move beyond "sedentary theories of justice", advocating instead for a perspective that treats "injustice as an unstable configuration that moves across scales and realms" (Ibid: 33). Thus, with respect to earlier frameworks of spatial justice (Soja, 2010) and the just city (Fainstein, 2010), themselves grounded in foundational work from the 1960s onward (Lefebvre, 1968; Harvey, 1973), Sheller proposes to use a mobile ontology that allows justice to be understood not as a fixed condition, but as a dynamic process of emerging relationships that re-make spaces and subjects.

Such a reconceptualization requires expanding the very subject of justice to include diachronic processes, different spatial scales, and the interplay of different phenomenons and subjects. As some authors have pointed out, this entails recognizing non-human beings as legitimate agents (Barry, Suliman, 2023; Scott, 2020), as well as acknowledging the intricate interrelations between various types of flows, both human and non-human (Allievi, Bernardi, Vineis, 2023). At the same time, it is important to recall that connectivity has long been a core principle in landscape ecology and a key guideline for maintaining ecosystem health (Brodie et al., 2025), and, by extension, planetary health (Horton, Lo, 2015; Nishi, Hashimoto, 2022).

Drawing on the concept of mobility justice, Sheller (2018) argues that patterns of mobility, unevenly distributed across social and spatial domains, are shaped by both historical and contemporary power relations. Building on this framework, this paper first examines how the territory of the North Adriatic coast has been reshaped over the centuries, with particular attention to the transformations of the last 150 years. We explore how different processes of modernization have significantly altered both local ecosystems and the anthropic use of the land, as well as the movements of human and non-human actors. This analysis is based on a review of existing literature and the interpretation of historical cartographic sources. In the second part of the paper, we turn to current plans and policies concerning mobility and ecology, focusing on three territorial transects that follow the courses of the Stella, Corno-Aussa, and Natissa rivers. This part of the research is based on a combination of qualitative methods, including interviews with local actors, site visits, and a review of regional and local planning documents. Finally, a third section of the paper explores future possibilities for these territories through the lens of urban design and planning. This exploration is based on a series of projective scenarios developed during a design workshop with PhD students in urbanism and urban planning, who envisioned adaptive and just futures for the region through site-specific proposals. Together, these approaches offer a grounded perspective on how mobility justice can inform spatial and environmental planning in a context marked by multiple, overlapping crises.

(Im)mobility of the North Adriatic Coast

The Italian stretch of the North Adriatic coast is characterized by a flat, sandy landscape interspersed with lagoons, estuaries, and low-lying wetlands. However, this present configuration is a relatively recent outcome of centuries of intertwined natural processes and human interventions (Gelichi, Ferri, Moine, 2017; Fontana, Rocchi, 2021). These transformations took place within what is often referred to as the land-sea interaction (LSI): the interplay of biogeochemical processes and socio-economic dynamics (Kidd, Jones & Jay 2019).

Until the Roman period, the coasts and lagoons remained sparsely populated. Major settlements such as Aquileia and Concordia Sagittaria were established just beyond this marshy fringe, on more stable inland terrain. With the decline of the Roman Empire, infrastructure and settlements were gradually abandoned. Populations progressively migrated toward the coastal and lagoon areas, giving rise to a dispersed archipelago of cities, ports, and rural communities sustained by water-based mobility (Auriemma, Maggi, 2013; Gasparri, Gelichi, 2024). The emergence of Venice as a maritime power during the Middle Ages gave centrality to the lagoon system. The Serenissima Republic embarked on major hydraulic interventions, including extensive river diversions, to protect the Venetian lagoon as a vital strategic and commercial asset. Meanwhile, the northern coastal territories became increasingly marginal, often relegated to extractive uses. These transformations imposed a more rigid territorial configuration, at least within the Venetian lagoon, while maintaining its amphibious character (D'Alpaos, 2010; Dorigo, 1994; Fassetta, 1977).

A radical transformation of the region's spatial and ecological configuration began in the 19th century, driven by a series of interconnected modernization processes. Chief among these were the land reclamation projects, which gained significant momentum following Italian unification. Enabled by mechanized pumping systems and sustained public investment, particularly after the enactment of the Baccarini Law in 1882, vast wetlands were drained and converted into productive farmland. These efforts also led to a notable reduction in malaria, an endemic disease that had long afflicted the region (Novello, 2009; Vallerani, 2008).

Much of the reclaimed land lay below sea level, and its productivity increasingly depended on a complex, energy-intensive drainage system. This process, alongside the expansion of agriculture and urbanization, led to the gradual loss of the region's amphibious ecology, which had included spring-fed wetlands, toward the mountains, coastal lagoons and marshes, toward the coast, and a band of forested areas between them. As a result, the historical fluidity that once characterized the region was progressively and rigidly fixed within an artificially regulated landscape.

This "terrestrialization" of the coastal territory unfolded in parallel with the rise of mechanized mobility. The construction of major railway lines reshaped patterns of access and movement across the region. In the following decades, the mass adoption of the automobile spurred the development of an extensive road infrastructure, gradually supplanting the once-vital network of inland waterways. Improved terrestrial accessibility, combined with the eradication of malaria, laid the ground for the explosion of coastal tourism in the 20th century, particularly in the post-WWII economic boom. The coastline was rapidly transformed into a corridor of leisure urbanization. Former fishing villages and dune landscapes were reimagined as tourist enclaves. Lignano, Bibbione and Caorle, among others, saw exponential growth driven by hotel development, second homes, marinas, and camping villages. What began as scattered, informal initiatives soon became systematized through zoning regulations, public incentives, and private investment. However, this urbanization came at the cost of coastal dynamism. Rigid defense structures were built to protect settlements and infrastructure, effectively freezing the coastline and disrupting its natural sedimentary processes (Battigelli, 2007; Fontolan, Bezzi, Pillon, 2011; Perelli, 2005).

Finally, another process of development reshaped the coast: industrial production and port logistics. The most emblematic case is Porto Marghera, which embodied the modernist vision of coastal industrialization. Further east, the area around the Marano-Grado lagoon saw the rise of Torviscosa, a company town established under Fascism for cellulose production, and the development of Porto Nogaro as a regional logistics hub. These sites introduced new forms of mobility, primarily of goods and labor, but also intensified environmental degradation and social transformation. The fragile ecosystems of the lagoons, already under pressure from land reclamation and tourism, were further compromised by pollution, dredging, and the hardening of waterways for navigation. These historical processes have produced a landscape marked by mobility injustice, in which the expansion of land-based mobility for goods, tourism, and other motorized flows has come at the expense of traditional communities, non-motorized forms of transport, and ecological systems, all of which have become increasingly immobilized. Today, the consequences of this historically embedded immobility are becoming ever more apparent. The coastal territory, rendered artificially static and rigid, is now under growing pressure from climate change, facing threats such as sea-level rise, land subsidence, erosion, salt wedge, and storm surges. A region once defined by fluidity and adaptability has become fragile and exposed.

This requires acknowledging that past development paths have unevenly distributed mobility, access, and environmental risk, privileging extractive flows and economic gain over ecological integrity and collective wellbeing, often provided by welfare spaces and policies. The resulting landscape bears multiple layers of injustice: ecological degradation, infrastructural exclusion, socio-economic marginalization, and the erosion of traditional knowledge and relationships with the land. Rethinking its future demands more than technical adaptation; it calls for a fundamental shift in how mobility is understood and distributed, and for a reframing of territorial planning and design through the lens of spatial justice.

Planning coastal futures: climate and mobility policies across three transects in Friuli Venezia Giulia

The Northern Adriatic coast is currently facing crucial challenges related to climate change, encompassing environmental management and sustainable mobility. While institutional awareness of climate risks is growing and several promising initiatives are emerging, policies and plans at the regional, supra-local, and local levels still struggle to integrate these issues in a coherent and coordinated manner. Their translation into concrete actions is further hindered by administrative fragmentation and ongoing institutional changes, which undermine the capacity of local governments to develop and implement effective policies.

In the case of Friuli Venezia Giulia, these dynamics are particularly evident. Hydraulic planning and management, entrusted to the Eastern Alps River Basin Authority (Autorità di Bacino Distrettuale Alpi Orientali) and the regional land reclamation consortia (Consorzi di Bonifica), focus primarily on infrastructure security and efficiency, lacking a systemic approach to climate change. Regional planning consists of a fragmented array of documents, sometimes offering conflicting guidance. Important steps have included the adoption of the FVGreen strategy in 2023, followed by a Regional Strategy for Sustainable Development (Strategia Regionale per lo Sviluppo Sostenibile, SRSvS), and the 2018 approval of a Regional Landscape Plan (Piano Paesaggistico Regionale, PPR), which proposes networks to restore ecological connections, promote sustainable mobility, and enhance cultural heritage. Along these lines, the 2022 Regional Cycling Mobility Plan (Piano Regionale della Mobilità Ciclistica, PREMOCI) focuses on cycling infrastructure and its integration with public and waterborne transport. In contrast, the Regional Infrastructure Plan (Piano Regionale delle Infrastrutture, PRITML, 2011) and the Public Transport Plan (Piano Regionale del Trasporto Pubblico Locale, PRTPL, 2013) promote high-speed mobility, with a strong emphasis on logistics and conventional transport. The region's main urban planning instrument, however, is severely outdated, dating back to 1978, with only partial attempts to update it in recent years (Marchigiani, in press).

At the local level, municipalities in Friuli Venezia Giulia are often small and seldom coordinated by stable supra-local entities. This limits their administrative and planning capacities. The Region has launched initiatives to encourage municipalities to adopt climate action plans, particularly by supporting the drafting of Sustainable Energy and Climate Action Plans (SECAPs or PAESC in Italian). Nonetheless, relatively few municipalities have completed them. Several interesting initiatives have also been launched through European research and territorial cooperation programs, which have enabled experimentation with innovative tools in areas such as integrated coastal and marine zone management, the protection of natural reserves, the valorization of ecosystem services, sustainable tourism, and intermodal water-land mobility. Among these, the Wetland Area Contract for the Marano and Grado Lagoon stands out as a pioneering initiative that brought together local administrations in a collaborative framework to safeguard the lagoon's socio-ecological systems.

To better understand local dynamics of transformation, we carried out an in-depth analysis of three territorial transects along the course of three rivers, extending from their outlets to the sea, passing through the lagoon, and reaching back into the low Friulian plain up to the *risorgive* zone. These transects illuminate emerging challenges linked to climate change, demographic decline, and economic transitions in agriculture, logistics, and tourism. They also reveal how spatial injustices are produced and addressed. Yet, amidst these pressures, some promising local initiatives suggest potential pathways toward more just and sustainable transitions.

The **Stella** River transect navigates a landscape where nature conservation, water governance, and local development intertwine. In its upper reaches between Codroipo and Pocenia, the river retains much of its natural character, flowing through biodiverse wetlands recognized by the European Commission. Since the early 2000s, local governments in Rivignano-Teor have implemented ecological restoration projects, notably the LIFE S.T.A.R. initiative. These efforts enhanced the river corridor's resilience and spurred low-impact tourism: bike paths, canoe access, eco-lodging, and agri-tourism services have flourished. However, downstream, the river enters a rigidly controlled reclamation zone with intensive agriculture and engineered drainage, increasingly vulnerable to climate change. The Foci dello Stella Nature Reserve protects the river mouth, but stronger interventions are needed. In Lignano Sabbiadoro, a major seaside resort, mobility challenges persist due to car dependency and seasonal congestion, despite some green initiatives. This area underscores the urgent need for a new paradigm of mobility justice, one that values ecological integrity, local knowledge, and equitable access to the landscape.

The **Corno** and **Aussa** rivers trace a different path, shaped by industrialization, environmental degradation, and socio-economic decline. In their upper stretches, natural habitats like the Paludi del Corno biotope benefit from conservation projects such as LIFE Friuli Fens. Downstream, however, the rivers become heavily canalized and surrounded by industrial infrastructure. Torviscosa, a legacy of Fascist-era industrial planning, has long been a pollution hotspot. Despite partial closures and its designation as a national contaminated site (Siti di Interesse Nazionale, SIN), remediation remains contested. Porto Nogaro adds complexity: originally a sugar export hub, it

is now a multimodal industrial port. While it sustains employment, it exacerbates congestion, land-use conflicts, and pressure on the lagoon ecosystem.

The **Natissa** transect connects Aquileia and Grado through a corridor of significant archaeological, ecological, and hydrological value. Aquileia has adopted a sustainable planning approach aimed at enhancing and preserving its archaeological heritage while better integrating it into the urban fabric and everyday life. In this context, mobility is treated as a key strategy. Strategic documents, such as the SLOW Aquileia vision, propose rerouting a regional road to create more space for pedestrians and sustainable transport. The Natissa River plays a central role in this strategy, with bank reinforcement projects and the introduction of a public boat service linking Aquileia to Grado, a coastal town situated on an island between the lagoon and the sea. Grado faces serious challenges, ranging from the pressures of mass seasonal tourism to escalating climate risks such as sea-level rise and storm surges. Some measures have been introduced, including Variant No. 34 to the municipal land use plan, which prohibits the construction of underground parking and limits further urban development tied to tourism. Additionally, a recently approved mobility plan promotes sustainable transport and aims to reduce space allocated to private vehicles. However, despite these efforts, the town still lacks a comprehensive and integrated climate adaptation strategy.

In conclusion, while the three transects share overarching challenges, each reveals distinct dynamics: the Stella transect highlights a disconnect between upstream ecological restoration efforts and downstream vulnerabilities linked to mass tourism and industrial agriculture; the Corno-Aussa area exemplifies spatial and environmental injustice shaped by extractive flows and heavy infrastructure; the Natissa corridor demonstrates the potential to integrate cultural heritage, ecological sensitivity, and mobility innovation, while also exposing the limitations of fragmented, small-scale responses to systemic climate threats. Despite these challenges, the research suggests that alternative futures are thinkable and possible. Such futures must be built on a rebalancing of mobility systems, one that values slowness, intermodality, and ecological connectivity alongside speed and efficiency. They must also be grounded in place-based knowledge, empowered by local actors, and attentive to the more-than-human agencies that shape and sustain these landscapes.

Rethinking the North Adriatic through mobility justice: urban design as a tool for adaptive futures

The increasing pressures that affect the North Adriatic lowlands call into question long-standing assumptions about how territories are inhabited, used, and connected. These challenges demand a deeper reconsideration of how spatial justice is conceived and enacted, moving from adaptive transformation to more radical transformative projects (Fedele et al. 2019). The following project-based exploration of the Stella, Corno-Aussa, and Natissa river corridors reflect upon the possibility of an urban and territorial design approach rooted in relational ecologies and integrated mobilities. The projects were built around two main hypotheses. The first is the need to expand sustainable mobility, such as walking, cycling, public transport, and waterborne transit, while increasing intermodality, with the goal of reducing fast mobility, particularly private car use. This draws on Sheller's (2018) interpretation of Illich (1974), who argued that slow mobility is inherently more equitable and sustainable than fast mobility. The second hypothesis is the need to reclaim a more amphibious and adaptive territory, one that gives more space to water and, in doing so, enhances the role of water-based mobility. Such a reconfiguration will not only improve ecological health and connectivity but also increase resilience to the transformations expected under climate change.

The territory along the **Stella** river reveals the essential role of water in sustaining both the ecological life and the cultural memory of this landscape. In recent decades, however, this delicate system has been destabilized and it is further threatened by climate change. The project reimagines the Stella River as an amphibious corridor, capable of absorbing and responding to hydrological fluctuations while supporting new socio-ecological practices. From its springs to its coastal mouth, the Stella becomes an integrated system of ecologies, mobilities, and new circular economies. In the northern stretches, valuable habitats are expanded and connected, reclaiming land from intensive agriculture and restoring the ecological continuity of the river. Toward the mouth, traditional farming is replaced by ecologically adaptive agricultural mosaics, including halophytic cultivation and aquacul-

ture systems, structured to operate within variable water regimes. Mobility, in turn, is reconceptualized as an intermodal, slow, and low-impact network. Cycling infrastructure and intermodal hubs encourage a shift away from car dependency, promoting accessibility while minimizing environmental cost.

The **Corno-Aussa** transect presents a landscape historically shaped by extraction and infrastructural fragmentation, where the pressures of industrial development have left behind damaged ecosystems and marginal communities. Here, the project envisions a phased territorial park aimed at environmental compensation and adaptive climate regeneration. The strategy recognizes the debts owed to both human and non-human communities and proposes spatial repair through ecological restoration and expanded public access. Central to this reimagining is the enhancement of river corridors as vectors of ecological recovery and active mobility. New bicycle and pedestrian paths reconnect fragmented habitats, while soft mobility on land and water is supported by intermodal hubs and equipped landings. This layered infrastructure responds to the needs of local communities, while strengthening ecological connectivity. The final phase of the project envisions the return of amphibious ecosystems and seasonal flooding cycles, thus transforming past damage into future potential.

In the **Natissa** transect the increasing pressure of mass tourism, climate-related risks, and infrastructural congestion demands a new mobility regime capable of mitigating anthropogenic impacts while supporting sustainable livelihoods. In this context, mobility becomes a strategic entry point to imagine and implement an integrated transition. The proposal identifies four amphibious hubs as anchor points in a renewed intermodal network linking buses, bicycles, and ferries. This system would offer a viable alternative to car use, supporting both residents and visitors while alleviating seasonal congestion and pollution. Car traffic in central Grado and Aquileia would be limited to residents, while improved canal networks and a new intermodal node at Cervignano station would enhance regional accessibility. At the same time, the progressive flooding of saline-compromised agricultural areas is proposed to create a new ecological corridor along the Aquileia coast. This would link up with the Anfora canal and surrounding wetland systems, generating ecological value, buffering climate risks, and creating a basis for a new model of sustainable tourism.

Across these three river systems, urban and territorial design serve as tools to operationalize mobility justice, not only by redistributing access to infrastructure and space, but by reconfiguring the relationships among humans, non-humans, water, land, and movement. The goal is not to preserve an existing equilibrium, but to cultivate adaptive, just, and plural futures in a region where stasis is no longer viable.

Conclusions

Viewed through the lens of mobility justice, the North Adriatic emerges as a territory shaped by centuries of profound transformation. Rather than a landscape to be preserved unchanged, it should be understood as a dynamic laboratory for climate resilience, mobility reconfiguration, and ecological renewal, especially in light of the disruptions brought by climate change. Mobility justice serves here as both a diagnostic lens and a generative framework: it reveals how territorial arrangements have produced exclusion and vulnerability, while also opening pathways for spatial practices grounded in care, repair, and cohabitation. Within this perspective, mobility is redefined as a collective resource and a driver of ecological and social regeneration at the territorial scale. The proposed design scenarios outline strategic interventions that redistribute spatial opportunities, prioritizing environmental stewardship and social equity. They emphasize the need to move beyond fragmented or sectoral solutions toward an integrated, multi-scalar approach that weaves together climate adaptation, heritage enhancement, ecological restoration, and infrastructural innovation. The goal is not to preserve an unsustainable status quo, but to embrace transformation, designing for resilience, adaptability, and justice in the face of ongoing change. The scenarios developed along the Stella, Corno-Aussa, and Natissa river corridors are more than speculative proposals; they offer tangible spatial imaginaries and strategic tools for navigating uncertainty and cultivating resilience. By expanding the scope of justice to include more-than-human actors, evolving ecosystems, and historically marginalized places, this approach invites planners, policymakers, and communities to reimagine the North Adriatic not as a fixed coastline to be defended, but as a fluid, amphibious commons.

Importantly, the reflections presented in this text were developed within the framework of a research project funded by the National Recovery and Resilience Plan (PNRR).[1] Our approach interpreted the PNRR's goal of reducing territorial disparities (which brought substantial resources to Italy) through the lens of mobility and access justice. We focused on reducing inequalities not only between north and south, or center and periphery, but also in terms of everyday access to services, infrastructure, housing, and employment. In this view, minimizing mobility injustice in daily practices becomes just as crucial as addressing broader territorial imbalances.

Civic peri-urban: repositioning peri-urban urbanization in new forms of inter-generational co-ownership.

Keywords: peri-urban, civic uses, re-landscaping.

Abstract
The essay investigates the regenerative potential of peri-urban areas by examining the relationship between in-between spaces and civic uses, moving beyond functionalist perspectives toward an ecocentric and collective understanding of space. Reinterpreted as practices of "living uses," collective uses emerge as a lever for establishing metropolitan eco-public networks and reconstructing a public fabric of rights and relationships. Detached from proprietary and extractive logics, the peri-urban is framed as a plural civic space of care and co-production, where common goods are held in diffuse ownership and constitute a form of spatial capital. Through regulated and inclusive practices, a process of "re-landscaping" is envisioned—reassembling existing elements into qualitative relationships—thus countering the commodification of space and advancing access to fundamental rights in both urban and peri-urban contexts.

1. Introduction

Peri-urban territories are complex socio-spatial configurations that challenge the dichotomous theoretical categories of urban and rural inherited from classical urban theory. They represent the local-scale outcome of spatial restructuring processes in which decentralization, deconcentrating, and territorial dispersion are organically intertwined. These phenomena are observable both in the distribution of built functions and densities, as well as in demographic dynamics and extractive processes that subordinate these areas to infrastructures functional to urban performance. This results in spaces where long-term co-evolutionary processes (i.e., landscape) are absent, with specific identities having been dissolved within a few decades, and where the ecological context becomes a tool of the present's transience.

The complex peri-urban geography reflects the emergence of a multipolar spatial organization, where residual space is both a frontier to be shielded from further urbanization and a porous "ecotone" open to new forms of use and sociality. Resisting the externalization processes and extractive urban dynamics implies a reorientation toward redistributing rights, aiming to establish a negotiation space where urbanity is capable of recognizing an ecological context beyond the contingencies of present-day needs. It is an open process with local communities to overcome hierarchical and anthropocentric visions, seeking to build an intergenerational co-ownership rooted in socio-ecological relationships, as also affirmed by Article 9 of the Italian Constitution. This article links the protection of the environment, biodiversity, and ecosystems to the rights of future generations.

This calls for a paradigmatic shift away from the individualistic conception of space, anthropic pressure, and ecological fragmentation, toward new collective rights based on the recognition of shared practices and living uses, capable of overcoming the dualism between city and nature, society and ecology conceived as separate spheres. The reference is to the tradition of civic uses, which, in their original form, share the functional character (space of performance) with the peri-urban fringe. Current legislation replaces this functional nature with the valorization of ecological-environmental protection, in which intergenerational co-ownership is inspired by values of territorial inclusivity (Mangone, 2022).

2. Threshold Territory: Rethinking the Urban-Rural Continuum

For a long time, the city was defined in opposition to the countryside, through a sharp dichotomy that identified spatial and social boundaries as clearly distinct. However, contemporary processes have radically transformed this configuration, making it increasingly difficult to establish where the city ends and where what was once

considered "other" begins.

Recent transformations have dissolved traditional boundaries between urban and rural, center and periphery, local and global scale, giving rise to hybrid, fragmented, operational, and interconnected landscapes—often elusive and hard to define (Brenner, 2014).

It is not just the city that changes, but the very way we conceptualize the urban: no longer as a bounded and delimited spatial entity, but as a set of relations and logics that extend beyond classical morphology. In this context, not everything is urban, but everything is driven by the urban (Brenner, 2009). The city as we knew it dissolves —along with its natural outside— into a complex and multiscalar system of heterogeneous territories, connected through flows, infrastructures, and functions distributed discontinuously (Soja, 2007).

A new urban dimension emerges, a diffuse and polycentric organism that unfolds through diversified forms, roles, and landscapes. Urbanization shifts from the metropolitan model toward regional and planetary processes, reflecting global dynamics but materializing locally in in-between contexts: blurred, liminal territories where urban expansion absorbs and transforms rural space, reducing the city-countryside divide to an increasingly tenuous threshold.

The peri-urban space takes shape as a dynamic and unstable threshold, a hybrid field in which the dichotomies between urban and rural dissolve. In this complex landscape, a geography of atopos emerges —marked by the absence of formal coherence, stable historical ties, and durable future projections— resulting in a precarious, present-oriented dimension (Formato, 2012).

This is a space where the "technical activation" of norms flattens the territory, endowing it with a reality of its own akin to that of a commodity (Capone, 2020), producing spatial forms often detached from any intentional planning (Koolhaas, 2006).

In these once marginal spaces, strategic functions consolidate, demographic gradients re-balance, and lifestyles between center and periphery converge. Peri-urbanization and the hyper-urbanization of flows contribute to the decline of space as an ordering category, increasingly replaced by networked and relational logics (Amin & Thrift, 2002).

Low-density expansions, topological fractures, and infrastructural discontinuities compose a dispersed mosaic stretching beyond the established city limits. This is neither simple suburbanization nor the classic middle-class residential periphery (Fasciano, 2003), but rather a liminal territory where rural, natural, and urban components overlap in continuous tension (Errington, 1994). These zones, described by Mininni (2005) as the "third territory," form a "bridge space" (Ferretto et al., 2013) between urban density and the rarefaction of agricultural landscapes—an emerging figure in the ongoing regionalization of the urban.

Such spaces function as urban ecotones: gradual transitions between different settlement systems that lack clear continuity. These are threshold spaces in a flexible and permeable continuum, where spatial transformations respond to polycentric dynamics, no longer legible through binary categories (Simon et al., 2006). Koolhaas (2006) describes this as a formless proliferation, where urban design dissolves into the casual addition, into the unintentional assemblage of heterogeneous fragments. The result is a landscape where action blurs with outcome, hierarchy with accumulation.

The peri-urban thus becomes symptomatic of a new multipolar territorial organization, in which urban functions tend to decentralize and redistribute unevenly. It is within these territories that extended urbanization (Wandl et al., 2014) begins to unfold—a fragmented spatial configuration that overlays agricultural landscapes, deeply altering their functions.

The privatization of land, the transformation of collective usage rights into exclusive ones, and the enclosure of common resources (Harvey, 2003) act as accumulation by dispossession devices, reshaping forms of living and production. This produces a stark discrepancy between quantitative growth and socio-environmental quality, between urban development and ecological sustainability.

The absence of a coherent institutional framework—one that often continues to classify these areas as merely agricultural—hinders access to services and limits spatial quality, preventing these territories from expressing their potential as sites for alternative living models and emerging practices. Demographic changes, evolving occupational patterns, the conversion of productive activities, and the increasing role of market logics produce a constantly reconfiguring space, where the urban-rural divide loses its analytical relevance (Webster, 2002).

Resource pressure and intensive infrastructuring create growing competition in land use, accelerating territorial marginalization. The scarcity of essential services, lack of public transportation, and dependence on private mobility (Rojas-Caldelas et al., 2008) make these territories structurally subordinate to urban systems. At the same time, they absorb informality and leftovers, hosting residual functions unwanted or unsustainable in the core city (e.g., landfills, recycling centers, shopping malls, peripheral industrial sites).

Here, soil degradation, biodiversity loss, and the breakdown of ecological networks become tangible indicators of an environmental crisis triggered by unregulated urban expansion (Allen, 2006).

Yet peri-urban spatiality is not a void to be filled nor a mere byproduct of urban growth. Rather, it is a space constituted through complex relations—marked by overlapping attachments, by centripetal and centrifugal forces, and by forms of specialization that make it a territory with uncertain vocation (Pareglio, Pozzi, 2013). While some configurations resemble uniform sprawl, others appear as cellular fabrics or linear development corridors along major infrastructures (Simon et al., 2006). In all cases, peri-urban areas are shaped by forces that render them unstable, unequal, and layered.

From this perspective, peri-urbanization dynamics are not simply spatial phenomena but interpretive keys for understanding contemporary territorial restructuring and its social, economic, and ecological implications.

These transitional zones between city and countryside are now actual territorial devices that reflect the evolution of the post-metropolis, where urban space dissolves into networks, flows, and functional fragmentation (Simon et al., 2006). Borders no longer delimit—they articulate, defining new thresholds of interaction among interconnected territories.

Peri-urban areas thus emerge as territorial figures dense with ambiguity—not reducible to traditional spatial categories, but rather to be interrogated for their capacity to shape new geographies of dwelling. Any project must begin with the recognition of their hybrid, ecotonal, and unstable nature.

3. Mapping the Peri-Urban

The peri-urban is configured as a space dense with fragments, the result of stratified sedimentations and transformations, reflecting one of the most emblematic structural conditions of contemporary territories. It expresses, often in ambiguous and unresolved forms, the social, economic, and functional discontinuities that traverse postmodern urban geographies, highlighting the crisis of traditional categories such as centre and periphery.

In an attempt to interpret the tensions that run through these territories — between demolitions and reconstructions, abandonments and reuses — it is useful to recall the two opposing tendencies described by Bernardo Secchi in Prima lezione di urbanistica (2000), which can also be applied to peri-urban spaces. On the one hand, there is a position that seeks to re-establish clear boundaries, separating the city from what is perceived as an indistinct background, restoring order and form, tracing historical arrangements or containment policies. On the other, there is an interpretation that rejects any clear boundary, conceiving space as part of an urban continuum

in which every attempt at formal distinction proves artificial. Both interpretations, however, according to Secchi, reflect a deeper difficulty that we could interpret as the inability to construct interpretative grammar capable of capturing the specificities of the peri-urban as an interstitial territory, structurally hybrid and in constant redefinition.

Minnini (2013) proposes reading the peri-urban space through the categories of transcalarity and proximity, with particular attention to open space, understood as a fundamental element in the emancipation process from modernist models and in the re-foundation of the contemporary city, fragmented and plural. This approach invites us to free urban design from sectoral logics, recognising the landscape as a new infrastructure capable of ensuring greater freedom of movement and autonomy in constructing an individual habitat, while embedding it within a collective idea of territory.

In the Piano Paesaggistico Territoriale Regionale (PPTR) of Puglia, the peri-urban is recognised as the space where recent transformations most visibly reveal the criticalities generated by the contemporary city. These are areas that must be removed from the logic of randomness, from the unlimited availability for use and consumption, and from the dissipation of symbols and resources, to be reinterpreted through an attribution of meanings arising from experience, restoring their role in the ongoing transition. These are spaces to be made useful again, starting from a pact that re-establishes symbolic, alimentary, recreational, hygienic, and experiential exchanges between city and countryside in a multilevel perspective. This vision is based on a strategy of agrourbanisme inspired by Alberto Magnaghi's theories on self-sustainable regional development.

The definition of the field of existence of the peri-urban takes shape through an anthropo-geographical interpretation that constructs a taxonomy of settlement morphologies, positioned between city and countryside, and understood as active components of this pact. The labels campagna abitata, campagna urbanizzata, campagna del ristretto, and campagna profonda express the intention to name things in order to understand their problems. In these contexts, one finds loosely woven fabrics such as public peripheries or allotments lacking a clear relationship with the street; formations in an uncertain state, often artisanal or residential, destined to remain incomplete; linear settlements that urbanise extra-urban roadways; large-scale tourist platforms and dispersed coastal landscapes tied to seasonal use of second homes.

In the Linee guida per le aree della dispersione insediativa e per le aree del periurbano (DiCEM, 2004), developed in 2024 by the Campania Region in collaboration with the Dipartimento delle Culture Europee e del Mediterraneo (DiCEM), the peri-urban space is described as an "orphan of landscape." This definition underscores the inability of such territories to continue representing the cultural and symbolic values that once structured the relationships between space and society. From this, emerges the urgency to elaborate new imaginaries capable of interpreting ongoing transformations and reflecting the culture of our time.

This is a territoriality largely generated by the unintended outcomes of planning — a "territoriality without authorship" that now calls to be rethought and reconfigured through a renewed urban and landscape project. From this perspective, the peri-urban is interpreted as a strategic resource for the city and its inhabitants, particularly where it is managed by active forms of agriculture and by new rural actors who live and produce in the campagna di prossimità, contributing to the challenges of ecological transition.

In these Linee guida, the peri-urban is conceived as a spatial device interposed between the urban periphery, scattered settlements, and adjacent rural spaces: a condition of thirdness — neither city nor countryside — outlining a landscape proposition for the contemporary condition. In this view, a different critical geography is affirmed, one capable of including the hybridised territories of the agrourbano. This is a space that once again becomes available for renegotiating the relationship between city and countryside through the valorisation of open proximity spaces, generated by agriculture which, as in Campania, has not been marginalised with respect to urban fringes, but rather retains a strong productive capacity and a potential regenerative function.

The theoretical perimetral definition structured by the Linee guida per le aree della dispersione insediativa e per le aree del periurbano considers several territorial and demographic factors that define a transition zone between city and countryside, represented by a "geometric band" surrounding urbanised areas. The thickness of this band varies according to the municipal population: 100 metres for municipalities with fewer than 2,000 inhabitants; 200 metres for those between 2,000 and 15,000; and 500 metres for those with more than 15,000 inhabitants. Urbanised areas exclude surfaces smaller than 5 hectares for municipalities under 2,000 inhabitants; 25 hectares for those between 2,000–15,000; and 50 hectares for those above 15,000. These exclusions derive from the fact that such areas do not present sufficient significance in generating the peri-urban.

Thus, in this study, the peri-urban area of Campania is represented by: a 100-metre transition band for municipalities with fewer than 2,000 inhabitants; a 200-metre band for municipalities with between 2,000 and 15,000; and a 500-metre band for municipalities with more than 15,000 inhabitants.

Prior to the study developed for the Linee guida, a further investigation was conducted within the preliminary studies for the Piano Paesaggistico Territoriale Regionale della Campania by the Dipartimento di Architettura (DiARC) of the University of Naples "Federico II" (Attademo et al., 2022). This study, carried out at the regional scale, introduces a set of composite indices that can be replicated in other contexts and applied at more local scales to deepen territorial specificities.

The mapping of peri-urban space is based on three main indicators: the density gradient, anthropic pressure, and ecosystem fragmentation.

The density gradient is the initial indicator, useful for excluding extreme situations by distinguishing what is unequivocally urban from what falls within areas of high ecological value or biodiversity reserves. This indicator allows for the identification of significant thresholds, isolating portions of territory with characteristics attributable to the rural.

Anthropic pressure (Angelini et al., 2018) represents the level of disturbance exerted by human activities on non-urbanised biotopes, within the physiographic landscape units. It is assessed by considering the "biotope constraint," that is, the intensity of disturbance due to proximity to anthropised environments such as intensive agricultural areas, quarries, fallow lands, industrial zones, brownfields, and other artificialised spaces. This index also captures the diversity of land uses typical of peri-urban contexts.

Ecosystem fragmentation describes the process of progressive reduction and isolation of natural and semi-natural environments, largely driven by urban expansion and the growth of infrastructural networks. This phenomenon negatively impacts ecological continuity, reducing the size of patches unaltered by artificial elements and fragmenting them into smaller and more isolated units. Evaluation is conducted using the effective mesh density index (Seff) proposed by Jaeger (2000), which measures the density of ecologically functional meshes interrupted by infrastructural barriers and land artificialisation.

The combined analysis of these three indices, through cartographic overlay techniques, enables a synthetic and integrated representation of the peri-urban interface, highlighting both its criticalities and its potential in terms of ecological and design-based reconfiguration.

4. A New Peri-Urban Civic Space

Exploring the nexus between the peri-urban and civic uses requires a shift away from a utilitarian-functional perspective toward one of meaning—repositioning peri-urban urbanization within a framework of shared land, understood as co-owned in its modes of use and across species, intergenerational in scope, and transcending the temporality of utility. This connection can be critically examined by contrasting the distinctive traits of the peri-urban fringe—as a space of performances—with some fundamental aspects of civic use.

Civic and collective uses, reinterpreted as categories of use of goods functional to the enjoyment of fundamental rights, act as triggers for systemic regeneration processes through spatial concretizations capable of recovering "living uses" (Capone, 2016). These practices reveal the regenerative potential of peri-urban areas and support the formation of eco-public networks at the metropolitan scale as incubators of new urban civic spaces (Formato, 2021).

As contemporary spaces where dichotomies and binaries thin out in extractive processes, in-between territories absorb the full extent of individualism, reflecting the prevailing climate of exaggerated exaltation of private property. This tends to "realize a society entirely governed by private law, one that does not admit exceptions to the primacy of the market, not even for the collective rights of the constitutional state" (Capone, 2016: 622). In this setting, solidarity is replaced by competition over scarce and inadequate resources (Bauman, 2005)—a hallmark of neoliberal society that acts through the decontextualization of relational meaning and territorial specificity.

The erosion of identity traits—understood as values sedimented over time—allows us to observe space as a medium for uncovering customary practices that have historically characterized the collective use of land and resources (Capone, 2020). However, the concept of identity often ties civic use and even temporary enjoyment to select groups of "original communities" and "claimants, falling within, and naturally residing in a specific territory" (Di Genio, 2019). Thus, considering the peri-urban as a space devoid of long-term processes (landscape), or rather as a space where such processes have been dissolved within decades, necessitates a focus on the "practice of use" (Capone, 2016). This practice breaks free from the "straitjacket of exclusive ownership," dissolves the individualistic approach to spatial use, and allows us to "extend the notion of civic uses in the more general form of collective uses, with their recognition in specific usage regulations—of buildings and urban spaces—restoring collective access to goods functional to the exercise of fundamental rights" (Capone, 2016). This perspective emerges when civic uses are viewed as a "convenient expression" extending the legal institution to the entire territory, not only to agricultural and forested areas.

It is therefore necessary not to consider civic uses strictly as a legal institution (as established by Law 1766/1927), which excludes a large number of "living uses"—new forms of collective usage that demand a constitutionally oriented generalization within the very notion of civic use, extending such usage to urban or quasi-urban areas. Moreover, civic and collective uses represent social and fundamental rights—personal, individual, collective, and diffuse—which benefit both the individual and the community (Di Genio, 2019). They are connected to environmental protection (Judgment 156/1995) and landscape preservation (Judgment 310/2006), as well as to the preservation of such uses and the democratic principle of participation in decision-making processes, as expressions of a collective capital that ties land ownership to the community (Di Genio, 2019).

Thus, it is essential to approach this institution from the perspective of "collective rights" (rights of use and enjoyment) that "belong to a community of inhabitants, or to an undifferentiated collective of citizens residing in a given locality" (Capone, 2016). A community of inhabitants is understood as a "plural and complex social reality, constituted through acts of care and the reproduction of common goods" (Capone, 2020).

These collective rights, as a category encompassing both ancient and more recent uses, enable the conceptual generalization and spatial extension of the content of civic uses through specific usage regulations—bringing back to the fore public life and the social function of goods, their public destination, and space itself (solidarity, subsidiarity, and the free development of the individual and social formations).

What emerges is a counterpoint that shifts the understanding of civic use away from its original economic-productive configuration—now superseded by ecological-environmental protection (Mangone, 2022)—and toward a notion of "practice of use" that is not resolved in exclusive ownership, that breaks with the individualistic approach to spatial use, and that challenges processes of spatial irrelevance. It allows for both a conceptual generalization and a spatial extension of the notion/institution of civic use into its broader form of collective uses and their formal recognition.

The resulting project is a space with diffuse ownership of goods, moving beyond identity-based belonging and instead ensuring accessibility, inclusivity, impartiality, and usability—countering the exclusive use driven by the "proprietary-exclusionary paradigm" (Capone, 2016). The aim is to promote "plastic and open communities" (Capone, 2020), rooted in the territory through acts of care and relational production—communities that consider goods within their ecological context and beyond the provisional nature of the present. This perspective overcomes the modernist logic of spatial reproduction, in which "space becomes real only through transformation and commodification" (Viganò, 2023), and instead proposes a form of "spatial capital" understood as a "stock of collective resources." This capital transcends utilitarian and functional dimensions, becoming a collective heritage that accumulates and develops over time as the result of multiple and heterogeneous intentions, held in both intimate and collective dimensions.

The collective use of space constructs relational networks through a doubly creative action: the production of common goods and the generation of their reference communities (Capone, 2020). It allows for a shift from "self-assertive values" (competition, expansion, domination) to "ecocentric values" based on interdependence: from hierarchies to networks (Capra, 2001). This outlines a project of peri-urban "re-landscaping" through spatial practices that counter the "speculative supremacy of the conceived" (Capone, 2020), invoking the social function of space as established by the Constitution. It envisions a peri-urban territory no longer available for extractive processes, but one in which quantitative dimensions have already been exhausted and must now be reassembled into qualitative relations.

This closure becomes an opening toward regenerative potential—configuring metropolitan-scale eco-public networks as incubators of new urban civic spaces (Formato, 2021), and an assemblage of spatial concretizations capable of recovering "living uses" (Capone, 2016: 621). Rebuilding a public fabric of civic and collective rights, practices, and spaces enables the connection between landscape protection (Judgment 310/2006) and the democratic principle of participatory decision-making. It expresses a form of collective capital that ties land ownership to the community (Di Genio, 2019) and removes peri-urban landscapes from any further permanent development or degradation. This "re-landscaping" process transforms already-consumed quantities into new qualitative assemblages through spatial practices that counter the "speculative supremacy of the conceived," ensuring that "technical activation" (Capone, 2020) of regulations does not flatten space into a consumable commodity.

Abstract
Resilience has become a topic of increasing importance, gaining presence in debates on spatial planning. It refers to the capacity to resist, to maintain vital functions and identity, but also the capacity to go forward, to learn, to build back better, to become more efficient and more functional in face of risks or shocks like flooding, which is being experienced in Europe with greater frequency and more impact. From this definition, this paper focuses on two cases of flood risk management at metropolitan level -Eurodelta Megaregion in The Netherlands and the Metropolitan Area of Valencia in Spain- with the aim to show learned lessons and to identify and propose recommendations regarding innovative and more effective planning procedures and frameworks to improve the resilience-related governance across scales, sectors and actors at metropolitan level.

Keywords: Resilience management; Flood risk; Climate-resilient spatial planning; Metropolitan governance.

Introduction

Resilience has become a topic of increasing importance due to the succession of more frequent crisis phenomena and the emergence of future uncertainties, gaining presence in debates on urban and regional policy and planning (Davoudi, 2012; Tasan-Kok et al., 2013; Greiving, 2018; Marom & Shlomo, 2024). According to Pascariu et al. (2022), 'resilience' is not just the capacity to resist, to maintain vital functions and identity, but also the capacity to go forward, to learn, to build back better, to become more efficient and more functional in face of risks or shocks. This resilience is not only innate or given, but can also be trained, for which policies, plans and programs, with the participation of epistemic communities and communities of practice, with a leading role for citizens who become familiar with risk and its management in each living space.

The management of resilience is related thus to a mix of techniques (planning tools) and patterns of governance (stakeholder management) in face of two main types of risks or changes, namely: abrupt "shocks" that disrupt everyday life for a limited period of time (e.g., an earthquake or a pandemic); and enduring "stresses" or crises that put systems under constant pressure (e.g., climate change or aged infrastructures), leading to overloads

that can severely restrict sustainable development in the long term (Coaffee et al., 2018). Among these risks, flooding is being experienced in European countries with greater frequency and more impact. This can be due to different reasons such as climate change; deficiencies in infrastructure and its management and maintenance; the complexity of stakeholder roles and responsibilities; a lack of clarity and willingness to accept responsibility; and a lack of understanding flood risk (Local Government Association[1]). However, risks can be estimated, and the impacts can be significantly mitigated, so response and recovery can be more effective and efficient. In this vein, resilience highlights the need to be prepared to anticipate, react and adapt to changes, especially to those that could produce critical impacts on a territory. As a result, the scale of places, their governance and spatial planning become a crucial issue for managing resilience. Spatial planning at metropolitan level is thus an important basis to make steps forward to an appropriate metropolitan governance in soft spaces but also in formally constituted metropolitan areas. That is asking for collaborative approaches to address complex challenges, redefining governance and planning practices beyond traditional administrative boundaries.

To identify and propose recommendations regarding innovative and more effective planning procedures and frameworks to improve the interplay across scales, sectors and actors, this paper focuses on two cases of flood risk management at metropolitan level in Europe, namely: the Eurodelta Megaregion (Netherlands) and the Metropolitan Area of Valencia (Spain). Both, The Netherlands (in past 2010 decade) and the Valencia region (more recently in past October 2024 but with a long history of centuries on this matter), have heavily suffered the effects of floods due to extraordinary rainfalls intensified by the climate change, causing very important damages at personal, economic, facilities and infrastructure levels. Both are also cases of informal metropolitan areas, where natural events are asking for governance beyond formal borders.

So, the objective of this paper is to highlight the need to strength a territorial culture and to develop institutional capacity to respond in a coordinated manner to these phenomena at metropolitan scale. By shifting the focus toward the changing roles of planners and citizens, the emergence of frameworks of interinstitutional cooperation beyond administrative borders, and of new types of solutions and adaptation measures (e.g., nature-based solutions), the paper sets the basis to spark a dialogue on innovative approaches to resilience.

The paper is structured as follows: in the next section we introduce the case of Eurodelta Megaregion, providing a general description of the area, the main water-related threats and challenges, and of the different measures adopted regarding flooding. The second section provides the same analysis focusing on the case of the Metropolitan Area of Valencia. A comparison of both cases is conducted in section 3 according to the analytical framework proposed, searching for similarities and differences among cases. Finally, the paper ends with a set of recommendations and final conclusions regarding the interplay between spatial planning and metropolitan governance to face flood risk in a new climate change context.

1. The case of Eurodelta Megaregion (the Netherlands)

Eurodelta is a densely urbanised megaregion with approximately 45 million inhabitants, also known as the "Rhine-Scheldt Delta". It is a transnational[2] and a polycentric region spanning parts of the Netherlands, Belgium (Flanders), and Germany (North Rhine-Westphalia), home to major port cities like Rotterdam and Antwerp, acting as a crucial gateway to the continent (Gerretsen et al., 2017). It is shaped by a shared historical background and the socio-economic philosophy referred to as the "Rhineland model" (Braun, 2020). So, strategically embedded within the Trans-European Transport Network (TEN-T), the Eurodelta functions as a key node in the global flow of goods, services, and knowledge. In addition, it positions itself as an innovative, sustainable, and inclusive delta-region, aiming to lead in climate-resilient infrastructure development while improving the quality of life for its

1 See: https://www.local.gov.uk/topics/severe-weather/flooding/flood-and-coastal-erosion-risk-management/flood-risk-and-flood-risk

2 Other transnational megaregions in Europe, such as the Øresund region (Malmö and Copenhagen), the Euregio Maas-Rhine, and the Danube Region, offer comparable cases where cross-border integration presents both challenges and opportunities for collaborative spatial governance.

population (SURE, 2020).

However, within the Eurodelta, there is no single, formal metropolitan region encompassing the entire megaregion. Instead, metropolitan governance operates at multiple scales. It functions as a polycentric network of cities with shared challenges, intensive interactions, and strategic cooperation, rather than as a unified administrative entity (ASSET, 2025; METREX SURE Expert Group, 2019; SURE, 2020). They promote cooperation models capable of managing interdependencies, coordinating cross-border policies, and facilitating effective spatial planning in areas with fluid, overlapping jurisdictions (ESPON Project[3]). Nonetheless, the Eurodelta's potential remains constrained by political fragmentation. Realising its advantages requires a shift toward flexible governance beyond traditional borders and institutional inertia.

1.1. Climate and governance-related challenges at metropolitan scale

Eurodelta is characterised by its low-lying river basins of the Rhine, Meuse, and Scheldt, and its low-lying deltaic landscape through its direct connection to the North Sea. Its strategic location and economic importance have historically driven significant spatial development, often at the expense of natural flood retention areas. This particularly confronts an urgent imperative for climate-resilient spatial planning (METREX SURE Expert Group, 2019). This unique geographical setting, while historically a source of prosperity due to fertile lands and navigable waterways, also presents inherent vulnerabilities, particularly to flooding. Eurodelta's complex administrative fragmentation, socio-economic and cultural values as well as environmental fabric requires a highly integrated and cooperative approach to spatial planning and governance, especially in the face of escalating climate change impacts (Deltametropool[4]).

4 See: https://deltametropool.nl/projecten/a-economic-strong-just-and-climate-proof-eurodelta/

The Eurodelta region has a long and often dramatic history of confronting the threat of flooding, a challenge that has been significantly exacerbated by climate change. Historically, the primary concern stemmed from storm surges from the North Sea and high river discharges. Major flood events throughout history, such as the devastating 1953 North Sea flood in the Netherlands, have profoundly shaped the region's approach towards water management. This event, which caused widespread destruction and loss of life, served as a catalyst for the development of ambitious, large-scale engineering projects like the Delta Works[5], aiming to provide a robust physical defence against the sea.

In climate terms, beyond the immediate threat of flooding, the region grapples with a complex array of climate-induced challenges. Salinisation, the increasing salt content in soil and water, poses a growing problem in low-lying areas, threatening agricultural productivity. Concurrently, increasing drought conditions in higher-lying parts of the Eurodelta impact agriculture and business activities. Land subsidence, the gradual sinking of land, further exacerbates these issues, causing damage to foundations and infrastructure. The increasing frequency of extreme weather events and erratic river discharge patterns introduce new layers of complexity, intensifying the pressure on existing systems (RLI[6]). These environmental shifts are not isolated; they create spatial conflicts, notably between agriculture and nature, as adaptation strategies often require changes in landscape structure and management that lead to competition for land (Blom-Zandstra et al., 2009). The region also faces the challenge of developing new residential areas that are energy-efficient and resilient to drought, heat, and heavy rainfall, alongside integrating renewable energy infrastructure without compromising existing landscapes or public acceptance (Nabielek et al., 2023).

The Eurodelta's aspiration to become a sustainable and globally competitive megaregion is persistently chal-

5 See: Rijkswaterstaat. (n.d.). De Deltawerken. Available at: https://www.rijkswaterstaat.nl/water/waterbeheer/bescherming-tegen-het-water/waterkeringen/deltawerken [Accessed: 29 May 2025].

6 see: https://www.rli.nl/sites/default/files/Rli%202024-02%20Klimaatadaptatie%20ENG%20def%20interactief.pdf

lenged by fragmentation across administrative, sectoral, value-based, and spatial planning dimensions. These divisions obstruct coordinated spatial development and weaken the region's capacity to address shared challenges effectively. Administratively, the Eurodelta spans multiple national jurisdictions, including the Netherlands, Belgium, Germany, and northern France. Each of these territories is governed by distinct legal systems and planning traditions. This institutional diversity hampers policy alignment and reinforces siloed decision-making. Although the European Union promotes a more integrated spatial planning approach, the rigidity of national frameworks and the protection of institutional interests often inhibit genuine cross-border collaboration (ESPON, 2025a; ISOCARP, 2025).

Sectoral fragmentation is equally pronounced. Despite a dense and advanced infrastructure network, the region suffers from disjointed mobility systems and policy mismatches, particularly in transport and energy. These inefficiencies undermine EU climate objectives, as spatial demands from energy transition and circular economy initiatives increasingly compete for limited land (ESPON, 2025b; Blom-Zandstra et al., 2009). Value-based fragmentation further complicates the planning landscape. Divergent stakeholder interests, such as those between private capital and public equity, create tensions in the implementation of shared sustainability goals (Deltametropool, 2022; Mikaelsson & Lager, 2024). Spatial planning and governance fragmentation is also driven by divergent planning systems, regulatory tools, and institutional capacities. The lack of a unified vision or binding cross-border frameworks results in policy misalignment and inconsistent implementation across borders. This hinders coordinated responses to transnational challenges like urbanisation, climate adaptation, and infrastructure modernisation. So, moving forward, flexible but formalised governance mechanisms are essential to foster coherence, enable joint action, and realise the Eurodelta's long-term spatial potential.

Furthermore, the challenges are compounded by interconnected socio-ecological factors. The transition to a circular built environment, for example, demands physical space for new infrastructure such as circular construction hubs and material storage. This adds to existing spatial pressures from climate adaptation and energy transition (INTERREG Europe, 2025[7]). These interdependencies mean that addressing one issue in isolation often creates new conflicts or intensifies others. Success in climate adaptation is therefore inseparable from managing broader societal transitions. Non-climate drivers such as population growth, demographic ageing, and rising inequality further amplify climate vulnerabilities, with at-risk groups disproportionately exposed to heat and other hazards (Ministry of Infrastructure and Water Management, 2023).

Finally, the ongoing housing expansion and energy transition, while vital, can increase exposure to climate risks if not coordinated through integrated spatial planning (Ministry of Infrastructure and Water Management, 2023). Addressing these challenges requires a holistic approach that accounts for trade-offs and co-benefits, moving beyond fragmented planning. The core obstacle is not a lack of recognition or vision, but the limited political and institutional capacity to implement integrated strategies amid competing economic interests and entrenched land-use practices. This necessitates stronger regulatory tools and a cultural shift across authorities, businesses, and the public to prioritise water and soil systems as foundational planning principles (Jaap de Graeff, Agterberg, et al., 2024).

1.2. Climate-resilient spatial planning and governance practices

Deltametropolis Association was established in 1996 as a collaborative initiative by the four mayors responsible for spatial planning in Amsterdam, Rotterdam, The Hague, and Utrecht, collectively known as the Randstad. Its objective was to develop a spatial strategy aimed at transforming the Randstad into an urban complex of international significance: a European Delta Metropolis. Conceived as an informal collaboration, the association operates as a non-profit, non-governmental, and member-based organisation. The concept of spatial planning in the context of Deltametropolis extends beyond its physical dimensions, it represents an ideal and a mode of thinking. It emphasises a focused and reflective approach to metropolitan development, driven by long-term societal interests. This includes addressing pressing contemporary challenges such as the energy transition, urbanisation, and climate adaptation.

7 See: https://www.eurometrex.org/new-interreg-europe-project-announced-for-a-eurodelta-spatial-strategy/

The Dutch Delta Programme was officially launched in 2010 as a long-term national strategy to protect the Netherlands from the growing risks of climate change, including sea-level rise, river flooding, and periods of drought. The programme was initiated following the recommendations of the second Delta Committee, which was established in 2007 in response to increasing scientific evidence of climate-related threats to the country's low-lying and densely populated regions (REF[8]). Since the beginning of the Delta Programme, the indication towards cross-border coastal water management started getting some attention. Since 2015, with the Paris Climate Agreement, Deltametropolis Association, together with METREX and some urban metropolitan regions of the Netherlands, Germany, Belgium, initiated the conversations and possibilities to work together voluntarily on the cross-border Eurodelta scale and named it Strategic Urban Region of Eurodelta (SURE) Network.

Figure 3. Strategic Urban Region of Eurodelta (SURE) Network
Source: Braun, C. (Ed.). (2020, October). Eurodelta - SURE: Strategic Urban Region Eurodelta – Roadmap. METREX, City of The Hague, City of Amsterdam, and Province of South Holland. https://deltametropool.nl/publicaties/roadmap-eurodelta-sure-2020/

The Dutch Delta Programme highlights the critical role of spatial adaptation in ensuring that the Netherlands becomes climate-proof and water-resilient by 2050. It promotes coordinated action among municipalities, water boards, provinces, and the national government to address water-related challenges such as flooding, drought, heat stress, and waterlogging. Spatial planning in the Netherlands has long been deeply intertwined with water management. Historic land reclamation and polder development required a highly coordinated approach to land use, resulting in a planning tradition that integrates flood risk assessment and water infrastructure from the outset. Within the Eurodelta, water governance operates through a multi-level structure involving national, regional, and local authorities.

8 See: https://english.deltaprogramma.nl

The Dutch Water Boards -Waterschappen- are a distinctive example of functional governance. With autonomous taxing authority and direct responsibility for managing dikes, water levels, and water quality, they have cultivated a strong territorial culture of water awareness and shared responsibility. Comparable regional and local bodies exist in Flanders and North Rhine-Westphalia, though typically within broader provincial or state governance frameworks. While differing in institutional autonomy, these entities collectively reflect a commitment to integrated and locally rooted water management across the Eurodelta. Bringing together the many separate authorities and governments, as well as the citizens in the diverse Eurodelta region, can be quite difficult. However, everyone shares common ground due to similar water-related challenges like flood risks.

a) Professional approach and community engagement
Building on the existing formal governance structures and exploring with new informal ways of working, the Eurodelta also relies on "soft spaces"—flexible, non-statutory zones of collaboration that transcend administrative boundaries. These spaces enable actors to address shared challenges, such as flood risk or climate adaptation, where rigid jurisdictions fall short. The Strategic Urban Region Eurodelta (SURE) network exemplifies this approach. It serves as a collaborative platform for urban and spatial planning professionals, facilitating cross-border dialogue and coordination. SURE promotes a vision of a borderless, sustainable megaregion by aligning efforts across mobility, spatial development, climate adaptation, and the circular economy, advancing integrated solutions beyond institutional silos.

In recent years, resilience planning in the Eurodelta has undergone a significant transformation, shaped by lessons from past floods, heightened climate awareness, and the region's spatial dynamics of its transboundary setting. Rather than relying solely on defensive infrastructure, the region is moving toward integrated, adaptive strategies that combine spatial planning, ecological restoration, and stakeholder collaboration. This shift reflects a growing recognition that border regions require flexible, cross-jurisdictional solutions tailored to their layered governance contexts (Maila, 2025). The following initiatives and instruments illustrate this transition, showcasing a range of experimental and institutional efforts aimed at enhancing climate resilience, spatial quality, and cross-border cooperation across the Eurodelta in the field of flood risk management.

For instance, the International Commission for the Protection of the Rhine (ICPR[9]) has been a long-standing initiative facilitating cooperation among Rhine-bordering countries to manage water quality and flood risks. This framework has significantly improved the river's ecological status. Still, climate change and increased industrial activities present new challenges, requiring adaptive management strategies. The ICPR could evolve further by strengthening data sharing, harmonizing regulations, and enhancing stakeholder participation to effectively address contemporary water management issues.

Another example is the NEB Bauhaus of the Seas Sails – Delta Grenspark Groot Saeftinghe project. This New European Bauhaus initiative explores innovative approaches to coastal and estuarine development by integrating nature, culture, and community engagement. The Delta pilot at Grenspark Groot Saeftinghe acts as a testing ground for adaptive strategies that balance ecological restoration with economic activities and connect global perspectives with local needs. The project actively engages local communities, who share knowledge passed down through generations of living with water and brings in practitioners and policymakers to discuss future trends and scenarios for the delta. Young planners, designers, and architects then develop new scenarios, which are presented back to the communities to foster understanding of their future involvement in delta decisions. While this project fosters interdisciplinary collaboration, its long-term success hinges on sustained stakeholder engagement and the ability to scale its solutions, with the complexities of cross-border governance and spatial planning still needing to be addressed.

b) Risk management and interinstitutional cooperation
Given the numerous administrative boundaries, a multi-level collaboration framework is crucial for developing

9 See: International Commission for the Protection of the Rhine (ICPR). (n.d.). Home. Retrieved from https://www.iksr.org/en/

and implementing cohesive strategies. We can see strong examples of this in action with initiatives like the Benelux Union and the EGTC Linieland van Hulst en Waas. The Benelux Union, encompassing Belgium, the Netherlands, and Luxembourg, has a rich history of intergovernmental cooperation spanning over 75 years, often serving as a blueprint for broader European integration. It provides a vital platform for collaborating on shared challenges such as climate change, energy transition, and mobility, leading to policy harmonization and joint projects. However, the Union's effectiveness can sometimes be hampered by differing national interests and administrative complexities. Enhancing its capacity to implement and monitor cross-border initiatives would undoubtedly strengthen its role in fostering regional integration and resilience.

Similarly, the EGTC Linieland van Hulst en Waas demonstrates the practical application of European Groupings of Territorial Cooperation (EGTCs). EGTCs offer a legal framework that empowers regional and local authorities to undertake joint projects. This particular EGTC, situated along the Dutch-Belgian border, is a prime example of how such a framework can facilitate concrete cross-border collaboration within the Eurodelta, working towards a shared spatial strategy and partnership. It focuses on improving spatial quality, preserving cultural heritage, and enhancing housing and liveability in the historically and ecologically significant Linieland region. To fully realize the potential of this pioneering cooperation model, strengthening institutional mandates and ensuring stable financial support are critical.

c) Solutions and adaptation measures
The solutions of water management in the era of climate change require a shift in thinking, robust adaptation measures, moving beyond traditional approaches to embrace more dynamic and ecologically integrated strategies. A prime example of such a paradigm shift is the Netherlands' "Room for the River" program. This initiative redefines flood management by actively creating space for rivers to safely overflow during periods of high water, thereby significantly reducing flood risks. This program moved beyond solely defensive measures to strategically allocate more space for rivers, linking water safety directly to spatial quality, social issues, and broader economic and ecological improvements. Room for the River approach embodies the long-standing Dutch tradition of "making work with work," seizing opportunities presented by the interventions to achieve multiple benefits. However, adapting and replicating this model in other parts of the Eurodelta demands careful consideration of local contexts and existing governance structures.

One major challenge is the difficulty in scaling localized successes to a megaregional level. Furthermore, there is a consistent need for more integrated spatial planning that fully incorporates climate change adaptation. Current planning often remains siloed within national or even sub-national boundaries, leading to fragmented efforts that may not effectively address transboundary water management issues and adaptive decision-making and governance. The harmonization of legal and regulatory frameworks across borders remains a slow process, which can impede the implementation of comprehensive adaptation measures.

2. The case of Valencia metropolitan area (Spain)
The metropolitan area of Valencia is a functional system made up of 44 municipalities with a population of 1.635.239 inhabitants in 2024, that could be enlarged in a second crown up to 66 municipalities and 1.8 inhabitants (Valencia Metropolitan Spatial Plan). The recent catastrophic flooding experienced on October 29, 2024, affected the south part of the metropolitan area, which is called "Horta Sud" county -comarca-. The "Horta Sud" is made up of 20 Valencian municipalities[10] and has a long-standing organizational and cultural history in the region. It is the second most populated county, with 454,668 inhabitants, and the most industrialized of the Valencian region.

It worths noting that traditionally there have been some tensions between the municipalities and the city of Valencia regarding the expansion of power of the capital city over time (Fundació Horta Sud). Only in the period 2015-2023 was a more cooperative approach attempted between the capital city and its surrounding municipal-

10 The 20 municipalities are the following: Alaquàs, Albal, Alcàsser, Aldaia, Alfafar, Benetússer, Beniparrell, Catarroja, Lloc Nou de la Corona, Manises, Massanassa, Mislata, Paiporta, Picanya, Picassent, Quart de Poblet, Sedaví, Silla, Torrent and Xirivella.

ities. Moreover, the general feeling is of a certain failure in terms of metropolitan governance, largely due to the absence of coordination and cooperation mechanisms between administrations and departments in the area (Romero et al., 2023). This is the context to be considered when assessing the consequences and the responses to the recent flooding in the "Horta Sud" within the metropolitan area of Valencia.

2.1. Climate and governance-related challenges at metropolitan scale

The recent flooding had an enormous impact at different levels, namely: emotional (loss of homes and a sense of vulnerability and helplessness), social (228 deaths), economic (between 0.1 and 0.2% of Spanish GDP in the fourth quarter of 2024, according with the Valencian Institute of Economic Research –IVIE), and environmental (landscape disorder and the spread of industrial and urban waste into the natural environment).

Figure 4. Areas affected by the flooding of October 29, 2024 in Valencia and surroundings
Source: Valencian Cartographic Institute.

The natural origin (physical conditions) that caused floods is well known. So is the disorderly way in which the territory has been occupied in a metropolitan space that has been configured around Valencia, connecting the surrounding cities and towns, all of them within a unique agricultural landscape (Farinós Dasí, 2021).

In climate terms, the floods of October 29th coincided with extraordinary rainfall associated with the frequent high-altitude cut-off low -DANA- conditions, typical of autumn in the Valencian Region. However, this time the rainfall was of an unknown nature and intensity, not in terms of total rainfall (there have been higher ones in the past) but rather in terms of the intensity of the rainfall in one hour (184.6 l/m2/h in the municipality of Turís, total 700 mm of rainfall this day). This intense rainfall in one place and within the short span of just one hour was due to a completely extraordinary atmospheric situation: quasi-stationary convective trains were generated, allowing low pressure systems to reactivate without moving, remaining in the same location, vertically above places where these highs accumulated. These depression systems are associated with climate change and the progressive warming of the Mediterranean (>3ºC), which provides energy and humidity to the air masses coming from the Sahara that cross the sea. When they touch land and collide with the first mountain ranges near the coast,

they rise and precipitate, potentially reaching altitudes of 5,500 meters with the high-altitude cut-off low, which triggers their ascent and the precipitation of all water vapor they have accumulated on their journey.

These meteorological conditions combine with coastal geomorphology characterized by the presence of broad alluvial plains that rapidly transition to interspersed wetlands. This area has been intensively exploited for agriculture and transformed into residential, industrial, infrastructure, and tourism uses. This has profoundly transformed the natural drainage system, which, in a layered form, sought its outlet to the sea, using the Albufera lake as a natural drainage area south of the city of Valencia.

However, the floods of October 29th were not due to the rainfall — in many, not a single drop was recorded— but rather to the intense flooding in the pre-coastal mountain ranges. In these extreme events, small rivers, ravines, and dry riverbeds with steep gradients abruptly channel the intense runoff. The high-water speeds (up to 15 km/h) leave very little time for the lower course of the river populations to react to these sudden and ephemeral floods. All of this poses a clear natural threat to the city and the metropolitan area.

This threat has been exacerbated in recent decades by increased exposure due to massive urban and infrastructure growth between 1966 and 2007, which has been carried out in a poorly organized and environmentally integrated manner. These land development processes also include the development of a new artificial channel in the final course of the Turia River, as it comes in the metropolitan area, diverting it away from the city, as reaction to the floods suffered by Valencia in 1957 (Figure 5).

Figure 5. Valencia and its County Urban Master Plan (1966)
Source: https://www.upv.es/contenidos/CAMUNISO/info/U0684629.pdf

Thus, from a hydraulic perspective, the problem shifted to the towns south of this artificial channel; the same areas where most of the new industrial and infrastructure developments are concentrated (westward, toward Madrid, and southward, toward Alicante), according to the Valencia urban master plan approved in 1966. Since then, and even before, there have been a series of urban, territorial, hydrological, and emergency planning instruments that have attempted to give coherence to these growths by integrating flood risk into the equation. However, despite the unsuccessful attempt at the Metropolitan Coordination Standards (1988), neither their ap-

plication nor the practical results have been as necessary, as discussed below.

2.2. Climate-resilient spatial planning and governance practices

The establishment of economic activities is taking shape as a fragmented set of facilities, with significant conurbations along the main road infrastructure and access routes to towns, without supra-municipal coordination or shared structures, and with a strong component of tertiary and service-industrial activity alongside productive companies. In many cases, these areas are constrained by infrastructure or other urban development projects. Moreover, the buildings in these areas did not develop typologies designed to withstand the risks of flooding, both materially and humanly. The increase in artificialized land in all municipalities, including those prone to flooding, has exacerbated the effects of the recent DANA.

The consequences of the floods arise thus in a context of a lack of a supra-municipal coordination body for environmental and urban planning, a situation that leads to the need for a comprehensive planning model between Valencia and the region. Some of the issues that have emerged regarding the management of resilience and the spatial planning approach are presented below:

a) Professional approach and community engagement

The disaster has sparked intense debate and reaction among citizens, the media, and among experts, technicians, and professionals (see the interprofessional manifesto led by FUNDICOT[11]). Proposals and courses of action have begun to be discussed and put forward by these stakeholders, which can be classified into three stages: before a flood (prevention); during the flood (response, related to the established warning systems and planned management and evacuation plans); and post-disaster recovery (reconstruction and rebuilding). In this third stage, it is important to promote adequate communication and understanding among the population of the risks they face, and to promote a so called "territorial culture" to strengthen both the awareness and the relationship between the population and its territory in functional terms, as well as between professionals and decision-makers (last responsible of applied measures).

Before the flood, the work of professionals should be related to the improvement of meteorological and hydrological information systems; while during the flood, and in relation to emergency plans, the work of planning professionals must contribute to a better integration between territorial and urban planning and civil protection. Finally, in the post-recovery period, the work of professionals is clearly related to the development and selection of alternative courses of action. Reality shows that this is much more important in the former than in the latter, where political criteria prevail. This has been the case of the two expert committees organized separately by the Valencian regional government (outsourcing their work to consulting firms, about which little is known today) and the Spanish government after the disaster. In this second case, on May 29, seven months after the floods, the Ministry of Ecological Transition presented its "Plan to Improve Flood Resilience in the Affected Territory" at the Polytechnic University of Valencia. However, the presence of political representatives was predominant during the event compared to the presence of experts, which was reduced to the final roundtable. Moreover, this program includes various types of actions in flood-prone areas of the Júcar-Turia river system, but most of them infrastructure-related and involving public hydraulic works funded by the national government (for an estimated value of €470 million) to minimize the impact of future flooding.

b) Risk management tools and interinstitutional cooperation

Prevention and adaptation aim to anticipate and avoid or reduce impacts. Prevention is more efficient than recovery and mitigation. It is therefore a matter of planning; and of implementing what is planned. This requires a) an appropriate regulatory and instrumental framework (clear definition of tasks, resources and responsibilities); b) political and administrative will and leadership; c) a society and citizens aware of risks and sensitive to the problem; and d) patterns of repeated interaction between actors and smooth channels of communication. Regulating land use according to flood risk is key, integrating urban and hydraulic variables into territorial and

11 See: https://www.fundicot.org/wp-content/uploads/2024/12/MANIFIESTO-Interprofesional-INUNDACIONES-OCTUBRE-2024-revisado-diciembre-1.pdf

hydrological planning documents. To achieve this, collaboration between the three administrations affected is essential: water, land, and civil protection.

Spatial planning is particularly relevant as it goes beyond the strict scope of hydrological planning for potentially floodable areas, encompassing broader areas with important functions of water capture, retention, and use (crops, forested areas, artificial areas, etc.). Once the catastrophic process begins, it is the systems, structures, protocols, and decision-making within Civil Protection that must take action to protect the potentially affected population and assets, in close collaboration with the population at risk. Therefore, it is important that territorial and urban planning identify and regulate evacuation corridors and refuge areas for displaced persons, which must be included in Civil Protection emergency plans.

In the case of the Valencia metropolitan area, although there is no metropolitan spatial plan (now under development), there are urban master plans for all the municipalities within the area, and a flood risk prevention sectoral spatial plan (Plan de Acción Territorial de carácter sectorial sobre prevención del Riesgo de Inundación en la Comunitat Valenciana -PATRICOVA-) at the regional level, approved by the Valencian Government in 2015 (updating its first version from 2003). There is also a Flood Risk Management Plan -PGRI- at national level (from 2016), for which the Spanish Ministry of Ecological Transition is responsible through the Júcar Hydrographic Confederation, which developed it. The PGRI, as well as the obligation to prepare a risk map to define the Areas of Significant Potential Flood Risk (ARPSI), have their origin in the Directive 2007/60/EC of the European Parliament and of the Council, of 23 October 2007, on the assessment and management of flood risks, which was transposed into Spanish legislation by Royal Decree 903/2010, of 9 July, on the assessment and management of flood risks.

The PGRIs are led by the water authority of the Government of Spain, but are developed with the participation of national, regional, and local institutions and territorial authorities, and include several public consultation and participation procedures. In the case of Valencia, the PGRI of the Júcar River (which includes the Turia river) is aligned to all the instruments: PATRICOVA (which incorporates its own mapping of areas classified as at risk of flooding in the Valencia Autonomous Region), the Civil Protection Master Plan of the Valencian Region government, and, at the municipal level, the urban master plans.

At the Spanish level, the 2016 Regulation on the Management of Public Hydraulic Domains -RDPH- incorporates limitations on land uses in flood zones. It also established that all Spanish Autonomous Communities (namely, the regional level of government) must adapt their land use and urban planning laws to the new flood regulations, for which a Technical Guide was prepared by the Ministry. To this end, they had to modify and adapt territorial and municipal planning that planned future urban developments in flood zones or preferential flow zones (defined, respectively, by Articles 14 and 9.2 of the RDPH). In the Valencian case, the former were delimited when the Júcar PGRI defined the aforementioned ARPSI; for the latter, Article 9 bis prohibits building on them on rural land (with some exceptions, which ultimately becomes their Achilles' heel in terms of compliance).

However, coordination between administrations and the adjustment of different instruments did not occur in a region like Valencia, which has had real estate development and tourism as two important pillars of its economy. This is also because, according to the PATRICOVA, risk maps must be done at the municipal level, although its Article 11.4 also opens the possibility, on a secondary basis, of a supra-municipal level.

c) Solutions and adaptation measures

Integrated flood risk management should focus on sustainable water management and measures that strengthen the resilience of nature and society to extreme weather events. However, traditional public works are often the most popular demands immediately after a disaster strikes. They are often effective in the short term, but less so in the medium and long term; they are more expensive than other types of measures and can create a false sense of security among the population.

These demands for mitigation public works at the territorial level (because at the urban level, mitigation actions and the protection of buildings and people are beyond dispute) focus on the construction of dikes and dams,

maintaining the functionality and/or increasing the capacity of existing riverbeds and channels (increasing the space for water in some of the upper or middle sections of the channels), and refurbishing linear transport infrastructure that can act as a barrier and worsen the effects of flooding. In this sense, the new channel of the Turia River has proven efficient in the task for which it was designed, and it protected the city on its right (northern) bank, but its southern wall acted as a dike for overflowing flows from adjacent basins on the left bank (such as the Pozalet-Saleta ravine system), worsening the situation in these areas. Nor can the Poyo Ravine, where intensive work is being done to restore and artificially condition the riverbed (in contrast to its ecological restoration), guarantee sufficient capacity to handle peak runoffs of more than 2,228,904 m3/s.

This leads us to the need to combine Nature-Based Solutions with other more adaptation-focused measures within a metropolitan Green Infrastructure (Muñoz and Doménech, 2011) through coordinated action at the supra-municipal level, of a metropolitan nature and under the hydrological criteria of the river basin authority, in combination with subregional spatial plans (Farinós Dasí et al., 2024). Some of these Nature-Based Solutions suitable for the case of Valencia are:

• Expanding the floodplain, returning (regenerating) more of the riverbed.

• Managing water with vegetation that facilitates infiltration processes: regenerating riparian forests and river headwaters, thus reducing flow and surface runoff speed.

• Controlling erosion and achieving healthy soils through terraced cultivation systems and "temporary" groundcovers, planting fast-growing plants (legumes or grasses) and then incorporating them as organic matter.

• Reserving areas as floodplains in case of emergency: river parks in the city and in built-up areas, flooding productive agricultural spaces in case of emergency (as has traditionally happened in the Valencian orchard within the current metropolitan area of the city), establishing appropriate compensation mechanisms.

• Become fluffy the soil, allowing water retention and infiltration into the subsoil, combining this with water storage facilities on the surface or in the subsoil of the floodplain (reservoirs that can be used in times of scarcity).

3. Results

The comparison of Eurodelta region and the Metropolitan Area of Valencia on climate-resilience and flood risk management revels several similarities and differences at the same time. In order to systematically assess the measures regarding resilience management (focus on flood risk) and spatial planning at metropolitan level, we have conducted a comparative analysis based on the following dimensions: a) Professional approach and community engagement; b) Risk management tools and interinstitutional cooperation; and c) Solutions and adaptation measures. The aim is to learn about governance and planning practices beyond traditional administrative boundaries (metropolitan scale) to face flooding.

a) Professional approach and community engagement

This dimension addresses the role of practitioners and citizens to face flood risk at metropolitan scale. It is worth noting here that the use and management of land to face flooding often implies limiting business activities, infrastructures developments as well as has impact on agricultural activities, and this introducing new layers of complexity. In Valencia, the engagement of the community and practitioners is heavily growing, but still lacking strong influence on final decisions, since the recovery process remains highly politicized (based more on politics than in appropriate policies in the right time). On the contrary, in the Dutch case the adoption of New European Bauhaus initiatives implies an innovative approach to coastal and estuarine development by integrating nature, culture, and community engagement. The Delta pilot at Grenspark Groot Saeftinghe also acts as a testing ground for adaptive strategies that balance ecological restoration with economic activities and connect global perspectives with local needs. Here, local communities share their knowledge achieved through generations regarding living with water and brings in practitioners and policymakers to discuss future trends and scenarios for the

delta.

These initiatives exemplify how knowledge sharing between experts and local communities can lead to stronger, more trusted land and water management plans. However, despite these positive efforts, scaling successful local projects into consistent, joined-up strategies between levels and sectors; e.g. across the entire Eurodelta megaregion remains a significant hurdle.

b) Risk management tools and interinstitutional cooperation
This dimension focuses on the existence of planning tools and partnerships beyond institutional borders to manage resilience and flood risk. Effective risk management and coordinated action across multiple levels of governance are essential for addressing the complex, interconnected challenges, especially those related to water. However, both territories experience fragmentation across administrative, sectoral, value-based, and spatial planning dimensions. On the one hand, the Eurodelta face distinct legal systems and planning traditions from different countries. On the other, the case of Valencia, even if it is circumscribed to one single country, also presents high complexity and institutional resistances because of the very competitive political and territorial dynamics between the different levels of government concerned and reluctance towards the power of the city of Valencia on the part of the metropolitan municipalities when designing and implement policy solutions. As well as between hydrological and spatial planning, respectively in hands, of the Spanish national and Valencian regional governments. This institutional diversity hampers policy alignment and reinforces siloed decision-making; despite the normative, legal fand instrumental framework is very clearly established in the Spanish case. So, main challenge, in this case, are not structural conditions of governance, but procedural ones (governance practices, both institutional coordination and cooperation, but also bottom-up from increasing public participation).

Nonetheless, in the case of Eurodelta resilience planning has undergone a significant transformation, shaped by lessons from past floods, heightened climate awareness, and the region's spatial dynamics of its transboundary setting. The Strategic Urban Region Eurodelta (SURE) network exemplifies this approach, promoting a vision of a borderless, sustainable megaregion by aligning efforts across mobility, spatial development, climate adaptation, and the circular economy, advancing integrated solutions beyond institutional silos. Besides, the creation of the Deltametropolis Association (1996) provides basis for informal collaboration to address pressing contemporary challenges. This is also the case of the Dutch Delta Programme (2010), that promotes coordinated action among municipalities, water boards, provinces, and the national government to address water-related challenges such as flooding, drought, heat stress, and waterlogging.

At formal level, both the Benelux Union and the EGTC Linieland van Hulst en Waas initiatives demonstrates the practical application of European Groupings of Territorial Cooperation (EGTCs), which offer a legal framework that empowers regional and local authorities to undertake joint projects. Both (formal and informal) initiatives are examples of institutional efforts to bring together the many separate authorities and governments and competing public-private interests to make them sharing to some extent common ground due to similar water-related challenges. On the contrary, coordination between administrations and the adjustment of different planning instruments do not occur in Valencia, which has had real estate development and tourism as two important pillars of its economy, ahead of environmental issues.

c) Solutions and adaptation measures
This dimension focuses on the type of interventions or solutions adopted to prevent, react and recover from flooding at metropolitan scale. Due to their great vulnerability to flood risk, both have adopted adaptation measures that have required great investments and additional land for essential infrastructure, including dyke reinforcement, river expansion, and water storage facilities. However, in recent years, resilience planning in the Eurodelta has undergone a significant transformation, shaped by lessons from past floods, heightened climate awareness, and the region's spatial dynamics of its transboundary setting. Rather than relying solely on defensive infrastructure, the region is moving toward integrated, adaptive strategies that combine spatial planning, ecological restoration, and stakeholder collaboration.

In this vein, a prime example of such a paradigm shift is the Netherlands' "Room for the River" program, which redefines flood management by actively creating space for rivers to safely overflow during periods of high water, thereby significantly reducing flood risks. This program moved beyond solely defensive measures to strategically allocate more space for rivers, linking water safety directly to spatial quality, social issues, and broader economic and ecological improvements. Valencia, one step behind, also is moving in this direction, despite today, being so present the catastrophic effects of floods in citizens' memory, the approach to flood risk management is more focused on traditional public works (business as usual, also from an economic model point of view). This type of measures is predominant compared to nature-based solutions to face flooding.

Conclusions

The objective of this paper has been to highlight the need to strength a territorial culture and to develop institutional capacity to respond in a coordinated manner to these phenomena at metropolitan scale. By shifting the focus toward the changing roles of planners and citizens, the emergence of frameworks of interinstitutional cooperation beyond administrative borders, and of new types of solutions and adaptation measures (e.g., nature-based solutions), the paper sets the basis to spark a dialogue on innovative approaches to resilience. Hence, the lessons learned from the cases lead us to elaborate a series of recommendations that are summarised below.

Drawing insights from the case of the Eurodelta and the Dutch Delta model, the following recommendations are put forth for climate-resilient spatial planning in this transnational megaregion:

• A core ambition must be to profoundly integrate water and soil systems as guiding principles for all spatial development. This means placing natural systems at the very heart of land-use decision-making, especially given the Eurodelta's inherent vulnerability to sea-level rise, flooding, and subsidence.

• To overcome "spatial lock-in" is critical to implement robust planning frameworks, clear regulatory tools, and targeted financial instruments that genuinely support adaptive land use. Areas currently designated for housing, logistics, or industry, even with existing development pipelines, must be re-evaluated for climate adaptation to enhance long-term resilience. Incentives, such as compensation for converting vulnerable land to nature-based solutions, can help align long-term resilience goals with economic pressures. Stronger policy support is essential to ensure water and soil systems decisively shape land allocation and development.

The role of spatial planners and citizens within the Eurodelta must fundamentally evolve. They are no longer merely technicians or inhabitants but must become coalition builders, navigators between institutions, and facilitators of multi-stakeholder dialogues. Their capacity to work across administrative and sectoral boundaries, aligning policies and maintaining momentum in long-term planning processes, is paramount (Maila, 2025). Furthermore, social equity must become central to spatial planning. Climate adaptation measures must actively address inequality, ensuring that vulnerable populations are not disproportionately exposed to risks like extreme heat or flooding. Planners need to integrate social analysis and values into their work, guaranteeing that adaptation strategies benefit all communities, particularly those with the least capacity to act independently.

In this evolving landscape, Research by Design (RbD) is increasingly a valuable method for addressing complex spatial challenges. Throughout the Eurodelta, this approach enables planners and stakeholders to explore future scenarios through creative design processes, combining technical, social, and spatial perspectives to imagine alternative land uses and policy solutions. The full potential of RbD, however, will only be realized when supported by institutions capable of translating its innovative ideas into formal decision-making.

Finally, planning within the Eurodelta must explicitly reflect the interconnected and cross-border nature of its challenges. As an integrated system of rivers, transport networks, and economic flows that extend across national lines, planning must be grounded in functional realities rather than rigid administrative boundaries

(Allmendinger & Naughton, 2010). Effective megaregional planning therefore demands long-term coordination, shared political will, and planning frameworks that operate across jurisdictions. "Planning without borders" is not merely necessary but increasingly urgent for building resilience at the scale where impacts are most deeply felt.

In the case of Valencia, the flood shock has sparked a broad public debate among scientific experts, the media, citizens, administrations, decision-makers, and private sector stakeholders about what lessons can be learned from what happened on October 29, 2024. Firstly, having regulations and rules in place to ensure adequate risk management, the following are recommended:

• Improved understanding of natural processes, this mean to give priority to meteorological alerts; have real-time information on the hydrological status of riverbeds during periods of extraordinary rainfall; adopt an updated flood hazard and risk mapping adapted to the new context of Climate Change, which considers future scenarios and is coordinated (better a single system) among the various responsible administrations, paying special attention to metropolitan areas due to the impact of flooding on them; and launch environmental and risk education campaigns.

• Coherence between spatial planning and risk management: controlling land-use changes in accordance with water regulations in a systemic approach, especially for the population and critical infrastructure, which are increasingly located in metropolitan areas. It makes no sense to delimit risk areas at the municipal level when runoff flow behaviour is completely inconsistent and exceeds the boundaries of each city.

• Establish as a priority responsibility of any government the proper coordination of the administrations involved in hydrological, spatial planning and risk management.

• Flood risk management requires effective governance approaches: it is not just a technical matter of building flood defences and developing flood warning systems. This means the need to consider not only political sensitivity, but to maintain open channels of communication between political decision-makers, technical staff, and subject matter experts.

Finally, political scientists identify other reasons for the failure of current democratic systems to adequately respond to the climate crisis, namely:

• The capacity of democratic decision-making to consider the medium and long term.
• Power issues and the influence of well rooted interests on political decisions.
• The extent to which citizens' views and values are considered in democratic decision-making.

As Driessen et al. (2016) point out, social and institutional factors often create strong barriers to the successful implementation of risk management systems.

Decolonial Strategies for Urban Greenery: Insights from Reimagining Planning Through Epistemic Pluralism in Kumasi

Pitkänen, M. & Hollmén, S. H.
Aalto University
meeri.pitkanen@aalto.fi, saija.hollmen@aalto.fi

Abstract
In the context of global crises, the field of urban planning is critiqued for reproducing unsustainable practices and excluding non-Western epistemologies. This paper explores how Indigenous knowledge practices in Kumasi, Ghana, reveal alternative value systems for planning rooted in relationality, reciprocity, and care. The study draws on fieldwork carried out through community engagement activities, foregrounding the voices of local actors who are often marginalised in planning discourses. Conducted within a transnational North-South university research collaboration, the research examines how engaging with epistemic pluralism can inform more just and inclusive planning processes. By framing planning as a cultural and value-laden practice, the paper contributes to the growing call for decolonising planning practices through the recognition of diverse knowledge systems.

Keywords: urban greening, epistemic pluralism, decolonisation, community engagement

Introduction

Addressing global environmental challenges requires a comprehensive, interdisciplinary approach that critically engages with the limitations of Euro-modern frameworks and dominant Western scientific knowledge systems. In the urban planning context, achieving transformative outcomes entails confronting the enduring influence of colonial legacies, which often sustain standardised, unsustainable practices at the expense of context-specific and locally grounded solutions. These structures – manifested in dynamics such as the privileging of dominant knowledge systems, the alignment of decision-making with financial interests, and the marginalisation of alternative epistemologies – have been the subject of critique for their tendency to overlook the inherent complexity of ecosystems. By overlooking this complexity, the structures rest on a separation of human and nature rather than symbiotic coexistence (Watson, 2019). The prevailing constraints of Western epistemology are evidenced by the eviction of Indigenous peoples in the name of modern conservation, despite the symbiotic relationship between Indigenous communities and nature that has been in place for millennia (Watson, 2019; Chilisa, 2017). The marginalisation of traditional ecological knowledge (TEK), particularly as expressed through Indigenous epistemologies, calls for renewed attention to its relevance in addressing environmental challenges. Engaging with knowledge systems beyond the Western scientific tradition can offer valuable insights and contribute to more inclusive and context-sensitive understandings of sustainability (Robinson, 2004). The question arises as to how these insights of epistemic pluralism could be applied in the context of reimagining transformative planning practices in urban environments.

As Escobar (2018) suggests, exploring alternative epistemic frameworks beyond the Western tradition can open up new possibilities for novel thinking. This includes engaging with relational ontologies rooted in communities that resist dominant development models – what Escobar refers to as "worlds in struggle" (p. 68). Relational ontology emphasizes the interconnectedness of all living and non-living entities, shaping understandings of existence and knowledge through relationships rather than separation. In contrast to the Western emphasis on individualism and rational thought – often framed through ideas such as "I think, therefore I am" – relational worldviews view identity as emerging from collective relations and mutual responsibilities (Chilisa, 2017). While Indigenous relational ontologies tend to prioritize holism, process orientation, and community, Western ontologies often focus on atomism, output orientation, and individual agency (Andersen & Gabel, 2023). These comparisons are informative as the contrasts are substantial. Concurrently, the interpretation of binaries is exemplary of Western ontology, in contradistinction to inclusive approaches. As Andersen and Gabel (2023, p. 66) argue, the creation of a binary separates and fixes in time and space systems that can otherwise never be separated or fixed. Among other scholars (e.g. Escobar, 2018), they advocate the recognition of ontological and epistemological pluralism.

A decolonising approach to planning brings the marginalised voices and epistemologies to the centre (Simonds & Christopher 2013; Chilisa & Tsheko, 2014). Ontological design, as referred to by Escobar (2018), facilitates ways of imagining design practices that contribute to restoring and sustaining people's agency in their territories and cultures by incorporating culturally specific practices, worldviews, and values into planning processes and solutions. In the planning process, the decolonising approach is a theoretical positioning that guides the methodologies applied to validate traditional knowledge and practices that have been accumulated over generations but are yet excluded from the discourses (Kovach, 2010; Chilisa, 2017). The integration of social and cognitive justice as a fundamental principle in the planning process requires a substantial reorientation of the prevailing rationalist and modernist cultural framework from which contemporary planning originated and within which it continues to function (Escobar, 2018).

The case study presented in this paper explores a process-oriented approach to urban planning that facilitates a platform for ontological and epistemological pluralism. By examining local knowledge practices in Kumasi, Ghana, the study aims to reveal alternative value systems for planning amid planetary crises. The case study is set in the city of Kumasi, the capital of the Ashanti Kingdom, which is one of the largest Indigenous socio-political entities in sub-Saharan Africa. The Ashanti Kingdom has maintained its authority through both British colonial rule and the post-colonial era of modern Ghana. The Asantehene, the King of the Ashanti people, along with the Asanteman Council, continues to wield significant influence over cultural, spiritual, and political life. These traditional institutions are the subject of profound respect and play a vital role in customary governance, particularly in matters related to land tenure, communal identity, and dispute resolution (Hollmén et al., 2025).

The Ashanti capital, Kumasi, was initially founded in the midst of a tropical forest and given the reputation of the Garden City of West Africa. Since then, it has undergone significant urban expansion and now accommodates approximately four million people. Despite growing developmental pressures, the city continues to reflect a dual governance structure in which customary authority and formal state institutions coexist. This duality has a significant impact on planning practices, offering opportunities for the integration of Indigenous knowledge systems into urban development frameworks. Yet, the rapid expansion of the Kumasi metropolis in recent decades has led to the encroachment of traditional villages and their absorption into the urban fabric (Quagraine, 2011). This transformation has contributed to the systematic marginalisation and erosion of traditional knowledge within the metropolitan area. The erosion of traditional knowledge signifies a gradual disconnection from the collective worldview and cultural heritage that has been accumulated over generations. Traditional ecological knowledge evolves from local context in direct contact with nature and provides solutions to local challenges while fostering a symbiotic relationship between all living and non-living (Chilisa & Tsheko, 2014; Watson, 2019). The knowledge, rooted in the local ecosystem, has been mitigating climate challenges for thousands of years and has the capacity to inform planning for climate resilience (Watson, 2019).

Indigenous knowledge systems are inherently participatory, emphasizing the central role of community engagement in shaping ethical and environmental practices. As Adom (2016) notes, such knowledge has historically provided a foundation for moral behaviour within traditional Ghanaian communities. He links the rapid decline in biodiversity to the erosion of these systems, framing environmental degradation as a fundamentally social issue. By influencing collective behavioural patterns, he argues, traditional ethics can be leveraged to address contemporary ecological challenges. Building on this perspective, the case study examines how participatory planning processes in Kumasi might incorporate Indigenous epistemologies into urban planning practice. In this manner, it seeks to conceptualise the city and its futures by exploring cultural connections that extend beyond the limitations imposed by the colonial legacy. This approach facilitates the identification of the constraints imposed by contemporary Western planning principles and provides a framework for exploring potential directions for transformative planning practices in the context of urban development.

North-South University Collaboration

In recent years, the role of North-South university collaborations has gained increasing recognition as a vital mechanism for fostering mutual understanding, advancing decolonial knowledge production, and promoting

culturally relevant research practices. The case study is set within the framework of a collaborative endeavour between Aalto University in Finland and Kwame Nkrumah University of Science & Technology (KNUST) in Kumasi, Ghana. That collaborative endeavour was initiated in 2022 within the framework of the Interplay of Cultures Studio, a master-level course organised by the World in Transition Research Lab at Aalto University (Hollmén et al., 2025). Rooted in the thematic areas of global sustainability and cultural locality, the collaboration emphasises cultural exchange and seeks to deepen awareness of local urban qualities through intensive fieldwork in Kumasi. At the core of this partnership lies a commitment to transforming traditionally hierarchical North-South relations by establishing spaces for integrating cultural knowledge with global knowledge, thereby ensuring that research outcomes remain relevant and accountable to local communities (Chilisa & Tsheko, 2014). This approach is consistent with the broader calls for co-production methodologies in university partnerships, emphasising the significance of experimentation and adaptability in engaging with local communities (Ferlicca & Pedro, 2024). Moreover, universities are gaining recognition as impartial platforms with the potential to encourage discourse, foster capacity-building, and establish partnerships that promote social justice. This positions academic collaborations as pivotal actors in the realm of transformative urban practices (Ferlicca & Pedro, 2024).

Kumasi Trees – Project of the Hearts

Since 2023, Aalto University and KNUST have been engaged in collaborative efforts in a project entitled 'Kumasi Trees – Project of the Hearts'. The project has been embraced by the Asantehene, the King of the Ashante, since its outset as a celebration of his 25-year reign in 2024. The project is founded on the principle of multistakeholder engagement, with the overarching aims of (1) introducing practices to replant trees in urban areas and re-invigorate the urban trees and greenery, and (2) securing the preservation of the trees for future generations by embedding their maintenance into the cultural habits and practices of the city dwellers and authorities alike (Hollmén et al., 2025).

The concept of the Garden City of West Africa is frequently associated with the terminology that Queen Elizabeth II employed during her visit to Kumasi in 1961. In addition, a connection has been established with the 1945 Master Plan of Kumasi, as designed by Maxwell Fry and June Drew. This plan is widely regarded as being inspired by the Garden City movement, which was developed by the British urban planner Ebenezer Howard (Quagraine, 2011). The title of the Garden City of West Africa has thus acquired a colonial connotation. Nonetheless, the designation 'Garden City' had been attributed to Kumasi for a considerable period prior to the visit by Queen Elizabeth II or the 1945 Master Plan, as evidenced by the writings of John Maxwell in 1928 (Maxwell, 1928). Moreover, a depiction of Kumasi encircled by tropical forest and featuring street trees that provide shade for the residents was already introduced at the beginning of the 19th century (Bowdich, 1819, p. 321-323). This observation, in conjunction with the historical narrative of Kumasi being established 'under a Kum tree' (the meaning of Kumasi in Twi), suggests an Indigenous concept of a Green African City, prior to the introduction of the imported associations with the Garden City movement, laden with colonial connotations. The re-establishment of this concept could facilitate the creation of a decolonising strategy for urban greening in Kumasi.

To foster long-term commitment to the care and maintenance of trees and urban greenery, the Kumasi Trees project seeks to restore and strengthen the Indigenous human-nature relationship rooted in Ashanti traditions (Adom, 2016). This is pursued through a multi-faceted, multi-stakeholder approach involving participatory activities and community engagement. Acknowledging the enduring environmental and structural impacts of colonialism is crucial, as these legacies continue to shape urban landscapes long after formal colonial rule ended (Leanui & Burgess, 2023). Such recognition creates space to imagine Indigenous futures free from colonial influence and to develop alternative concepts that can inspire more inclusive and context-sensitive urban planning. The decolonial approach employed in the Kumasi Trees project is characterised by a seamless integration of knowledge creation and action, emphasising a holistic and inclusive methodology that transcends the conventional divide between theory and practice. The participatory methodology is employed in order to ground the project in the local socio-cultural context and thereby enhance the social and environmental resilience of the area. Subsequent to this process, the project aspires to catalyse local action for enhanced environmental sustainability and social justice. The objective of the project is to illustrate a transformative planning process that

can be adapted and initiated by all levels of society within their own contexts.

Methodology

The Kumasi Trees project facilitates the integration of Western scientific knowledge systems and Indigenous knowledge systems, as well as knowledge production methodologies, within a framework that aims to decolonise research and planning processes. The decolonising model for research process proposed by Simonds and Christopher (2013, p. 2185) involves the conduct of research with Indigenous communities, placing Indigenous voices and epistemologies at the core of the research process. In the process of adapting the model to the context of urban planning, a range of qualitative and experimental methods are proposed. Eurocentric research methods and participatory action research methods have been the subject of critique on account of their exploitative nature and tendency to focus exclusively on identifying the unmet needs of communities without seeking to initiate change in the situation (Chilisa & Tseko, 2014). Furthermore, these methods are criticised for their emphasis on external solutions to challenges, thereby facilitating further colonisation of Indigenous communities (Archibald & Davidson, 2023; Chilisa & Tseko, 2014). In light of this, change-oriented approaches have been proposed that position communities as knowers, aiming to foster self-discovery through the imaginative processes of dreaming and envisioning futures – developed in dialogue with strategies for realisation and action (Chilisa & Tseko, 2014).

The ontological, epistemological, and axiological positionality of the project design has a foundational impact on the methodological choices made in the process of collecting and analysing data (Cyprian, 2023). In the context of Western scientific and academic frameworks, Indigenous knowledge systems have historically been marginalised and overlooked. Consequently, the notion of Indigenous research methodologies has only fairly recently emerged as a subject of academic discourse, particularly within the scope of participatory dialogue (Cyprian, 2023; Chilisa, 2017; Kovach, 2010). Within the discourse, the argument is posited that methodologies which are of benefit to Indigenous nations, communities, and people must be utilised, irrespective of their ontological and epistemological background. Furthermore, it is asserted that the development of an ethical research relationship is of greater importance than the manner in which data is collected. (Andersen & Gabel, 2023) In this case study, the methodological decisions are employed to facilitate the integration of marginalised knowledge systems with dominant knowledge systems through decolonising the process.

Case study: 2025 Fieldwork in Kumasi

The fieldwork, which was organised in March 2025, involved an international and multidisciplinary cohort from Aalto University and KNUST. The Aalto cohort comprised nine international master's students, two teacher/researchers, and a professor. All members of the cohort were from the fields of architecture and landscape architecture. A total of 24 participants and multidisciplinary support from seven faculty members from the fields of architecture, sociology, horticulture, Indigenous art and technology, and African studies, participated in the programme from KNUST. Moreover, the programme benefited from the assistance of the Manhyia Palace of the Asantehene, and Manhyia Palace Museum during the fieldwork.

At the inception of the 2025 fieldwork programme, the cohort was assigned a task of creating a transformative concept plan for a streetscape situated along a primary route extending from the Kumasi International Airport to Manhyia Palace. Notwithstanding the exclusive nature of the assignment, which was to enhance the aesthetic appeal of a given thoroughfare, the approach adopted was designed to emphasise inclusivity, cultural significance, and community commitment, in accordance with the principles of the Kumasi Trees project.

The 1.1 km-long streetscape, which was referred to subsequently as the Manhyia Corridor, was identified as having profound cultural significance, accommodating both commercial and residential areas, and functioning as a heavily trafficked main road that occasionally facilitates royal processions. The corridor functions as a culturally significant locale, embodying the Indigenous leadership and cultural pride within the local social context. The cultural significance provided an entry point for engaging the local small business owners and residents along the corridor in the creation of the transformative concept plan. The transformative concept plan aimed to

integrate climate adaptation initiatives with the strengthening of socio-cultural identity in the urban landscape. At the conceptual level, the Manhyia Corridor was connected to a broader strategy of urban greening, with the objective of extending green spaces to all access roads entering Kumasi, thereby creating a network of green corridors throughout the city. Nevertheless, the focus of the participants' work during the three-week fieldwork period remained on the Manhyia Corridor.

Methods

The Interplay of Cultures studio course at Aalto University commences annually in January. The preliminary phase is oriented towards deepening the understanding of the themes of the prerequisite courses for the studio, including issues of global development, decolonisation, and culturally informed architecture. The objective of this phase is to enable students to develop the conceptual tools required to identify how cultural values and assumptions are embedded within methods and theories, and to recognise the value of non-Western methods and theories (Simonds & Christopher, 2013). The re-orientation and positioning exercises continued upon arrival in Kumasi in March and upon meeting with the local peers. In the initial meetings, a series of exercises were scheduled to promote team cohesion in the context of intercultural relations, facilitating re-orientation, and establishing a shared vision. The preliminary stage of the collaborative fieldwork is of fundamental importance in establishing a shared comprehension of the project's methodology and principles, of ethical partnerships among the Aalto and KNUST participants, as well as in the context of community engagement, and ultimately, the success of the forthcoming weeks of work (Hollmén, 2018; Lenzerini, 2011; Andersen & Gabel, 2023). The participants from Aalto and KNUST were also prepared with academic research ethics, culturally appropriate research methods, and information regarding the project site.

During the site visits to the corridor leading from Manhyia to the airport, the experiences of the residents and users were examined by studying actions and interactions in their naturally occurring setting to gain a deep understanding of the locale. The physical infrastructure along the streetscape was examined by encompassing ethnographic methods, including observations, field notes and diary, photographs, videos, audio recordings, and mapping. A conversational method was employed in order to gather the experiences of 29 residents, employees, and business owners located along the street. A dialogic approach, characterised by open-ended and semi-structured questioning, was employed to encourage storytelling about participants' relationship with the living environment. The conversational interview enabled the interviewee to direct the discussion towards subjects of relevance to their perspective, thereby mitigating the interviewer's capacity to steer the narrative towards issues deemed significant from the interviewer's perspective and own worldview (Kovach 2010; Chilisa, 2017). The emphasis placed on the role of community members as the expert knowers of the local context is a key aspect of the framework, which is designed to facilitate process-oriented research activities. In this framework, community members are engaged to enhance the existing features of the living environment, rather than merely defining primary issues for external resolutions. Depending on the interviewee, the conversations were conducted in English or Twi and subsequently translated to English for further analysis. The utilisation of the native or common language facilitated the employment of terminology and proverbs that are pertinent to the local context, including native plant species, specific occasions, and intangible heritage, which would only be comprehensible to individuals who possessed the culturally specific knowledge. Therefore, the Aalto and KNUST participants were divided into small groups with the objective of fostering intercultural diversity and ensuring that each group contained at least one participant who spoke Twi. The interviews were all recorded, and the transcripts were translated into English for analysis. The possibility of losing culturally specific information during the translation phase was mitigated by having a local expert panel review and supplement the field data during the following fieldwork phase.

Subsequent to the site visits, the collected data was converted into a digital format, systematically organised, and preliminary analyses were conducted within the student groups. The student groups presented and discussed their findings with a board consisting of faculty members from Aalto and KNUST participating in the project and the curator of the Manhyia Palace Museum. The purpose of the presentations was to seek further validation of the data and to gain a deeper cultural and context-specific understanding of the site before moving

to the initial design stage. Prior to the conceptualisation of design interventions, it was fundamental to ensure that these were derived from the culture, traditions, and lived experiences of the local community. This approach was deemed essential to guarantee the relevance and utility of the proposals for the local population, as more comprehensive co-design was not feasible to be organised within the limited time frame of the three-week fieldwork. By the end of the fieldwork, the transformative concept plan of Manhyia Corridor was presented to the leadership of KNUST to seek administrative approval and further processing in the administration. While the field work in Kumasi was brought to a conclusion at this point in time, it should be noted that the project will continue to be pursued in subsequent instances.

The field data collected during the fieldwork constituted the foundation for the analysis conducted for this paper. The findings, which comprised 29 conversational interviews of residents, employees, and business owners located along the street, supported by field notes and observations, were subjected to a thematic analysis through a qualitative coding process. The grouping of the themes that emerged from the interviews into thematic categories resulted in the identification of the six main categories, which are discussed in the following section. Following this, the categories and findings will be discussed in parallel with culturally specific knowledge and global literature.

Results

1. Indigenous Leadership as the embodiment of the culture

"You see, when you come to the Ashanti region, it is a place of culture and Manhyia Palace is the culture itself." Interviewee 7, a local employee

"I believe that when the King gives an order asking people to make sure their animals do not become a threat to the success of the project, the people will obey." Interviewee 2, a local business owner

"Because dignitaries use the Dichemso route, planting trees along the road will provide a beautiful scenery. And will restore Kumasi's reputation as the Garden City." Interviewee 23, a local resident

The interview data revealed a strong connection between Indigenous leadership and a deep sense of cultural pride and dignity within the community. Unlike elected political governance, Indigenous leadership was perceived as less subject to public scrutiny, suggesting a different form of legitimacy rooted in tradition and cultural continuity. In this context, hierarchical structures based on top-down authority appeared inapplicable, with leadership viewed instead as relational and embedded in communal values. In conceptualising alternative futures devoid of colonial influence, the significance of Indigenous leadership remains paramount. Moreover, the shared sense of cultural pride and unity identified through the interviews offers a valuable entry point for fostering community engagement and long-term commitment. Such engagement supports the cultivation of cultural integrity, which is essential for context-appropriate urban development.

2. Abandonment of traditions due to urbanisation

"Yes, they have some rivers in the forest in which they pour libations, and that is why the forests have been so well preserved." Interviewee 7, a local employee

"As you can see the neem tree over there people come and cut it to treat malaria. These trees have some hidden medicinal purposes that is unknown to us as of now." Interviewee 15, a local resident

"The city has become so busy that people don't even pay attention to them [trees]." Interviewee 1, a local business owner

The interview data revealed that urbanisation has impacted many traditional practices and partially lead to the abandonment of traditional practices, knowledge, and epistemics in urban settings. A minority of respondents identified customs that they considered to be covered by traditional knowledge. However, the majority of

respondents indicated that traditional knowledge existed but was ignored. In this regard, the most frequently cited subjects among respondents focused on spirituality and nature. Such practices are indicative of an acknowledgement of spiritual values, including the tradition of having a designated day of the week on which to refrain from entering the forest, and the utilisation of traditional medicine. However, the responses also revealed a disconnection from the natural environment and an unfamiliarity with a holistic understanding of natural processes. The two natural areas within the designated planning area are physically separated from the surrounding environment by high walls, the primary purpose of which is to restrict interaction with the natural area. The walls were referred to as a source of security, as the wooded areas were perceived as dangerous due to the encroachments that had taken place there during the past few years. Secondly, they also function as a preventative measure against the informal spread of business into the area. One interviewee cited a phenomenon that has also been observed in other parts of the city, wherein natural areas are regarded as undeveloped land that could be utilised for urban development purposes.

3. Cleaning up the beauty of the Garden City

"About 20 years ago, when I was young, when we were talking about Kumasi. It was quite a garden city, because it was one of the cleaner cities in Ghana." Interviewee 7, a local employee

"In some places of the city they can claim the title 'The Garden City', but not even the road where the King passes can claim that title." Interviewee 2, a local business owner

The most distinctive feature of the field work site is the pollution of the soil and water bodies, a phenomenon that is also prevalent in much of the city of Kumasi. In the responses to the interviews, littering and environmental pollution were associated with a lack of collective concern and a rejection of traditional practices. The responses further emphasised the correlation between the concept of cleanliness and the beautification of the environment, as well as the perception of the Garden City.

The high volume of waste was also linked to the flooding issues along the streetscape, as the accumulation of refuse in the gutters resulted in overflow of water and waste materials onto the street level. In certain interviews, the construction of a bridge was proposed as a solution to the challenges posed by flooding. The restoration of the natural environment to serve as a non-polluted, flood-prone zone was a consideration in one interview. In accordance with this observation, the interviews revealed that the presence of fallen leaves on the ground was perceived as a stress-inducing factor. This perception has resulted in the decision to remove trees in close proximity to private residences or commercial establishments. These two cases demonstrate a dissociation from natural processes and a tendency to adopt modern urban solutions that prioritise the separation of humans from nature.

4. Urban space as a facilitator of cultural connectivity

"Cultural parks where the children could go and talk to the elders would be useful. The elders would be able to educate them and tell narratives and stories about the culture. - - This would be useful for the parents who are busy at work." Interviewee 3, a local business owner

"It would be good to have intergenerational parks with artworks that depict the Ashante culture. I believe this will help children to learn the culture as well." Interviewee 2, a local business owner

"Green signifies hope, and I am willing to give hope to my community." Interviewee 23, a local resident

The interviews revealed a disconnection within the cultural continuum, raising concerns about the transmission of cultural knowledge to younger generations. In the course of dialogues concerning aspirations for the urban environment, respondents emphasised a framework for the transmission of cultural knowledge through oral tradition between generations. Furthermore, the presence of Ashanti cultural symbols, such as adinkra, in the street scene to spread cultural awareness and create a sense of community was considered important. In addi-

tion to the utilisation of symbols, dance, and movement were identified as significant modes of communication.

5. Urban services for contemporary needs

"I'd love to see trees, but as a businessman, I'm concerned they could affect my business. If the trees are too big or planted too closely together, it could reduce parking space for buyers with cars. I suggest considering this carefully and providing additional lighting too." Interviewee 9, a local business owner

"The problem will be cattle destroying the plants. So, until we solve that issue, plants will hardly survive." Interviewee 3, a local business owner

"Beyond the environmental solutions, the park will provide jobs for the people and revenue for the government. So, I am in full support." Interviewee 10, a local employee

The interview data demonstrated an emphasis on both traditions and cultural practices, as well as modern needs and practicalities. The long distances to parks and other amenities were perceived as challenging in terms of transportation as well as in establishing social connections. Parks were regarded as providing opportunities for households to send their children to learn and spend time in a safe environment while attending to work. A further requirement for urban services identified was for enhanced security measures in the area, with particular reference to street lighting and pedestrian crossings. In addition, there was a need for improvements to public waste management services. In order to ensure the preservation of vegetation, the necessity to implement sheltering structures to protect against the presence of cattle and goats in the street was also discussed.

The primary issue concerning the vegetation is the limited space available for planting and the maintenance of the trees. The interviews revealed a concern regarding the spatial demands of trees, which were considered to be encroaching upon the already confined street layout. This was a particularly pressing concern for small business owners and employees, who expressed apprehension that the trees would compromise their visibility for potential customers or existing parking spaces near their premises. The intense competition to attract customers and the visibility of the formal and informal businesses along the main road have motivated the business owners to place the items for sale on the street for customers to see. During the discussions, there was a certain degree of hesitancy regarding the prospect of sharing the space with a tree; however, this hesitancy was mitigated by the consideration of potential benefits, such as shade, that the tree could offer to the business. The primary concern expressed in the interviews was the potential impact on livelihoods. This was accompanied by a complementary discourse centring on the prospective employment opportunities associated with urban green spaces.

6. A maintenance strategy based on reciprocity

"We care less, because it is not my property. But we have to care about our environment, because if there are any sicknesses, any diseases, we will catch them." Interviewee 7, a local employee

"The previous tree planters did not educate us on what to do. They just planted and left it. I think you should educate us on what to do. Whether we should water it or you will do the watering." Interviewee 12, a local employee

"I'm concerned with maintenance issues. If there should be trees, the community should be engaged to take care of them, they should have a sense of ownership. This would happen by making them feel like they are part of the project or maybe employ them." Interviewee 1, a local business owner

"We used to have a Town Council, 'Tankas', responsible for cleaning gutters and the environment, but that no longer exists." Interviewee 7, a local employee

The subject of previous tree-planting efforts along the road was a recurrent theme in the interviews. The inadequate maintenance and oversight that followed the previous planting initiative by the party responsible for planting the seedlings have resulted in several factors contributing to the mortality of the seedlings. These

factors include dehydration, consumption by goats and cattle herded along the road, and removal by local residents. The discussions revealed a consensus among the local business owners and residents that the most effective strategy for ensuring the success of a tree-planting initiative is to engage or employ community members to take care of the trees. Upon questioning, the majority emphasised their commitment to take care of the trees planted in front of their businesses or accommodations, if they were engaged in the project during the planning stage and received sufficient instructions for doing so. The analysis revealed that the primary concern expressed by respondents was related to the prospect of eviction and subsequent exclusion from the project, suggesting a potential link between these concerns and the reluctance to participate in tree-planting initiatives.

In conclusion, the interview data revealed that the profound link between Indigenous leadership and cultural identity provides an entry point for community engagement in Kumasi, particularly in relation to stimulating cultural connectivity in urban greening initiatives. The deterioration of cultural connectivity and identity is perceived to be due to urbanisation and the urban lifestyle. However, the interview data also show a sense of pride and commitment to strengthening cultural identity. The setting has the potential to facilitate an urban transformation that is deeply rooted in cultural heritage and traditional knowledge. This transformation would respond to the contemporary needs of residents as part of the urban ecosystem and would envision an Indigenous future disconnected from colonial associations. Thus, it cultivates social and spatial justice while restoring the regenerative relationship between humans and nature.

Discussion

Decolonial Strategy for Urban Greening in Kumasi

The historical encounters with the forthcoming colonial ruler, dating back to the 19th century, have had a significant impact on the urban landscape of Kumasi. The colonial administration has leveraged the built environment to demonstrate and maintain its dominance, both physically and psychologically (Yeboah, 2019). The destruction and reconstruction of urban and rural communities in accordance with imperial principles has resulted in the loss of traditional building expertise (Swithenback, 1969), thereby contributing to the discontinuity in the transmission of traditional knowledge. As demonstrated in the results of interviews and observations conducted in the field, the most prominent contradiction with the Indigenous epistemology is the evident absence of symbiotic coexistence with nature. In the field study site, the evidence of this is apparent in the extractive consumption of natural resources, the pollution of the environment, the separation of the natural environment from the human, and the incapacity to perceive the functioning of the ecosystem and the effects of one's own actions as part of the complex system. Yeboah (2019) observes that, in the colonial era, urban and land use planning was primarily oriented towards the economic benefits of the colonial power. Moreover, since the colonial power presented itself as the owner of the land, it was able to instigate invasions on terms of its choosing (Yeboah, 2019). This may have contributed to the erosion of the sense of ownership and connection to the territory felt by local communities. Furthermore, it has resulted in a legacy of overlapping land-use planning structures and exploitative practices in Kumasi.

The objective of the case study is to illustrate how urban planning can function as a decolonising and transformative action that is reflective, restorative, and regenerative. Such action would be characterised by its deep roots in heritage, its strategic leverage of existing resources, and its imaginative vision for unique futures that promote environmental and social justice. This shift in approach, from owners of the land to stewards, necessitates a re-evaluation of the metanarrative that constructs the planning principles and structures. As Salami (2014) notes, to facilitate a change in structure, it is necessary to first alter the existing narrative around that structure. Salami (2014) continues to elaborate that unethical knowledge production only results in the generation of unethical knowledge. In the urban planning context, the exclusion of the voices of Indigenous communities will further marginalise communities through biased practices (Simonds & Christopher, 2013). Planning, when approached as a process-oriented action, has the capacity to employ methodologies that are suitable in the local context. Such methodologies contribute to restoring and sustaining people's sense of agency in their territories and cultures. This is achieved by incorporating culturally specific practices, worldviews, and values into planning

processes and solutions (Escobar, 2018).

The city of Kumasi has an ontological essence that has been shaped by its location in a fertile region surrounded by tropical forest. The landscape was once dominated by large trees, which created a canopy over the city. The notion of a subsequent Garden City is arguably conceptually misguided, as in a Western context, a garden is generally perceived as a constructed and sustained environment, a subordinate to human action. However, in the case of Kumasi, it can be argued that vegetation was an inherent feature of the environment from the outset. This paper outlines a decolonial strategy to urban greening in Kumasi that moves beyond Western epistemics and aims to restore its glamour as a Green African City that stems from the local ecosystem and forms the foundation for traditional knowledge and practices. As previously outlined, the application of traditional ecological knowledge has been instrumental in informing the design of climate-resilient systems for multiple generations (Watson, 2019). Despite being largely overlooked and ignored, it is crucial that the potential is re-evaluated in terms of restoring more symbiotic coexistence with nature, as traditional knowledge has the capacity to evolve with time and adapt to shifting circumstances (Adom, 2016). In light of the contemporary planetary crises, which manifest across all geographical locations, this represents a shared responsibility for universal engagement with local solutions that respond to local context-specific challenges.

As posited by Maldonado-Torres (2016), the decolonial movement is distinguished by a holistic integration of knowledge and action. A decolonial and transformative planning cannot be considered the responsibility of a single individual or entity; rather, it may involve a dynamic interaction between organised communities, social movements, academic institutions, and governmental authorities. This interactive process enables overcoming the dichotomy of bottom-up (autonomy) versus top-down (institutionalisation) and moves towards an understanding of a co-produced urban process as described by Ferlicca & Pedro (2024). This approach to planning is characterised by a process-oriented and change-focused methodology, informed by existing capacities, identities, value systems, and practices in a culturally specific manner. The framework has the capacity to facilitate the revitalisation, restoration, and protection of valued entities and to establish more meaningful connections with other relevant systems (Chilisa, 2017). As Chilisa (2017) asserts, this approach aims to restore dignity and integrity that have been compromised by colonial practices.

In the context of planetary crises, embracing epistemic pluralism is not only an ethical imperative but also a practical one. By foregrounding Indigenous knowledge systems as legitimate sources of planning knowledge - rather than marginal ones - the planning field can begin to dismantle fixed epistemic hierarchies and open itself up to alternative urban futures. As Chilisa (2017) reminds us, methodologies grounded in African knowledge systems can decolonise sustainability science and recalibrate global knowledge relations. In this light, Western planning traditions must approach non-Western urbanisms with humility and curiosity, ready to learn from ways of knowing that challenge dominant assumptions and expand the repertoire of planetary planning possibilities (Robinson, 2004).

Conclusions

This paper has explored how Western-centric knowledge systems in urban planning often marginalise Indigenous epistemologies, reinforcing unjust and extractive practices. Utilising Kumasi as a case study, the research underscored the significance of process-oriented planning founded on epistemic pluralism as a decolonising approach. The findings of the fieldwork conducted in this area demonstrate a considerable erosion of cultural identity and connectivity, which appear to be largely attributable to rapid urbanisation. This transformation has had detrimental effects on the environment and Indigenous knowledge systems alike, which are deeply embedded, place-based forms of knowledge developed in intimate relation with local ecosystems. Despite their marginalisation, these systems offer valuable insights for climate-adaptive planning by providing contextually relevant, socio-culturally attuned solutions. The analysis emphasises the significance of acknowledging planning as a practice that is inherently embedded within and driven by cultural values. The adoption of this alternative approach to urban planning has the potential to create opportunities for transformative action. It facilitates the incorporation of existing socio-cultural structures, addresses local needs, fosters individual and collective

agency, and challenges prevailing colonial structures. Acknowledging the complexities of multi-stakeholder engagement, the study also sheds light on the challenges associated with incorporating diverse epistemologies into mainstream planning processes. Nevertheless, it asserts the critical need for future planning efforts to consciously reflect on the epistemic frameworks that guide methodological choices. The continued exclusion of non-Western ways of knowing risks reinforcing systemic biases and further marginalising already vulnerable communities. This, in turn, further diminishes the shared ownership and exacerbates the environmental destruction of urban areas, thus weakening the liveability of cities. In conclusion, it can be posited that the incorporation of principles inherent to Indigenous knowledge systems – such as process orientation, holism, and collectivism – can catalyse genuinely transformative planning processes. These approaches have the potential to initiate locally grounded action, strengthen community ownership, promote spatial justice, and inspire ecologically regenerative practices. The establishment of a decolonised planning framework that values epistemic diversity is both possible and essential for the fostering of equitable and sustainable urban futures.

Accounting beyond boundaries: Exploring consumption-based carbon approaches in Paris and Gothenburg

Deshayes Eloïse, Brown Will
Universitat Internacional de Catalunya (UIC), Cambridge University
Email: edeshayes@uic.es

Abstract
This article examines how Paris and Gothenburg have integrated Consumption-Based Carbon Accounting (CBCA) into local climate governance. As cities increasingly confront emissions beyond their borders, CBCA offers a framework to address the carbon impacts of urban consumption. Through a comparative qualitative case study, the research identifies 16 enabling conditions for CBCA implementation, organized into four themes: (1) data transparency and accessibility, (2) institutional and technical capacity, (3) political legitimacy and stakeholder engagement, and (4) multi-level and cross-sectoral support. The findings reveal how different governance models - Paris's institutionalized approach and Gothenburg's pioneering model - can both foster CBCA adoption. This study contributes to understanding the political, institutional, and participatory dynamics that enable cities to engage meaningfully with consumption-based emissions.

Keywords: Consumption-based carbon accounting; Carbon neutrality; Climate governance

1. Introduction

As cities around the world increasingly commit to achieving carbon neutrality, they rely on greenhouse gas (GHG) inventories to assess their emissions and guide climate action. These inventories are typically structured around internationally recognized frameworks, such as the Global Protocol for Community-Sc ale Greenhouse Gas Emission Inventories (GPC)[1], that primarily rely on a production-based carbon accounting (PBCA) methodology (Harris et al., 2020). However, a growing body of academic literature and policy discourse has highlighted the limitations of PBCA, arguing that it captures only a partial representation of urban emissions (Balouktsi, 2020; Millward-Hopkins et al., 2017; Pellan et al., 2024). In particular, PBCA overlooks the substantial carbon footprint embedded in goods and services consumed by urban populations but produced outside city boundaries. On the contrary, consumption-based carbon accounting (CBCA) estimates the life-cycle emissions of goods and services consumed within a city's boundaries, regardless of where those emissions occur geographically offering a more comprehensive and equitable framework for addressing urban GHG emissions, incentivizing the adoption of policies that promote less carbon-intensive consumption (Grasso, 2016; Lombardi et al., 2017). The claim for the switch towards a more CBCA-focus framework is especially relevant in high-income cities in Europe and North America, where local production-based emissions have declined due to deindustrialization, while consumption-based emissions continue (Millward-Hopkins et al., 2017).

Despite its appeal, the implementation of CBCA remains limited and uneven. Most existing research focuses on methodological and technical challenges (i.e., data availability, input-output modeling), while the political and governance dimensions are mostly studied at the national level. Therefore, the governance dimensions of CBCA at the city level remain largely underexplored, particularly with regard to the political, institutional, and organizational conditions that enable its operationalization within local governments.

This article seeks to address this gap by asking the following research question:
What are the governance conditions that enable cities to implement consumption-based carbon accounting and associated policies to reduce emissions?

To answer this question, the article conducts a comparative case study of two European frontrunner cities – Paris and Gothenburg - which have formally adopted CBCA approaches and integrated consumption-based targets

1 Global Protocol for Community-Scale Greenhouse Gas Inventories: https://ghgprotocol.org/ghg-protocol-cities

into their climate strategies. By analyzing these two cases, the study identifies key enabling governance conditions, ranging from data systems and institutional capacity to political leadership and stakeholder engagement.

The article is structured as follows. Section 2 reviews the terminology and key concepts. Section 3 outlines the methodological approach, including the case selection and analytical framework. Section 4 presents the empirical findings, identifying five thematic clusters of governance enablers. Finally, Section 5 discusses the broader implications of the findings for climate governance and outlines directions for future research.

2. Definition and key concepts

It is essential to define the key terms used throughout this study, as terminology in the field of urban carbon accounting is often used interchangeably or inconsistently.

Most GHG reporting frameworks currently focus on territorial or production-based emissions (Harris et al., 2020). PCBA is a method for quantifying GHG emissions that attributes all emissions to the country, region, or organization where the emissions physically occur during the production of goods and services (Franzen & Mader, 2018). At city level, these emissions largely correspond to Scope 1 of the GPC – meaning emissions from industrial activity, transportation, energy use in buildings, and waste management (Balouktsi, 2020; Fan & Guan, 2025). However, PBCA overlooks the embodied emissions in imported goods and services, which can be considerable, particularly in high-consumption urban contexts with limited local production.

In contrast, CBCA allocates emissions to the final consumers of goods and services, regardless of where in the world those emissions occur along the supply chain. This approach accounts for all emissions generated throughout the supply chain, including production, transportation, and distribution (Volden, 2018). It closely aligns with what is considered Scope 2 and Scope 3 emissions under the GPC framework.

The GPC categorizes emissions as follows:

- Scope 1: Direct emissions from sources located within the city boundary (e.g., local transport, buildings, industry).
- Scope 2: Indirect emissions from the consumption of grid-supplied electricity, heat, steam, and cooling within the city.
- Scope 3: Other indirect emissions that occur outside the city boundary as a result of activities within the city

While Scope 3 provides the most comprehensive perspective on urban emissions, it remains largely optional and is often excluded from official city-level inventories or only partially addressed. As a result, most cities continue to focus on reducing production-based emissions, leaving a significant portion of their carbon footprint unaccounted for (Millward-Hopkins et al., 2017). This gap has crucial implications for the effectiveness of urban climate strategies, particularly in "consumer cities" such as those in Europe, where a significant share of emissions stems from imported goods and service (Harris et al., 2020). Furthermore, it is argued that integrating consumption-based accounting, and particularly Scope 3 emissions, into local governance is critical for developing more effective and equitable climate mitigation strategies. A full accounting of urban emissions - beyond territorial boundaries - enables better-targeted policies that reflect the real carbon emissions drivers in service-oriented urban economies.

To explore this shift, the article focuses on the governance conditions necessary to support the integration of CBCA into city-level climate policy. Governance here is understood in a broad sense, encompassing formal and informal norms, procedures, institutions, and instruments that structure decision-making and implementation processes (Grasso, 2016). As Grasso underlined in his study on the political feasibility of CBCA, governance mechanisms for consumption-based accounting may not yet be fully established or even conceptualized. In this study, governance will be analyzed as a multidimensional framework - including policies, institutional structures, political will, and administrative practices - that can either enable or hinder the implementation of CBCA.

3. Study framework

This study draws upon data originally collected in a broader comparative research project that analyzed the barriers to implementing consumption-based carbon accounting (CBCA) in 17 European cities. These cities were purposefully selected to ensure diversity in terms of geographical location, size, and climate policy maturity. Within this wider research effort, certain cities stood out as exemplary cases in integrating CBCA into their local climate governance frameworks. Among them, Paris and Gothenburg were identified as particularly progressive to advance CBCA and have been chosen for a more in-depth comparative study case study on the governance conditions. Drawing from the main study, the authors formulated a set of hypotheses regarding the political, institutional, and technical enablers necessary for successful CBCA integration. These hypotheses guided the subsequent research design and data analysis strategy.

3.1 Main hypotheses

Two principal hypotheses shaped the analytical framework of this study. The primary hypothesis argues that the successful implementation of CBCA at the city level is contingent upon a combination of enabling governance conditions. These include high institutional capacity, strong data transparency, stakeholder legitimacy, and effective multi-level coordination. The second hypothesis states that the successful implementation of CBCA at the city level is contingent upon a combination of enabling governance conditions. These include high institutional capacity, strong data transparency, stakeholder legitimacy, and effective multi-level coordination.

Each of these hypotheses is underpinned by theoretical and empirical insights from climate governance literature and were broken down into more specific analytical categories, as described below.

High institutional capacity

It is anticipated that cities advancing CBCA possess robust institutional capacity. This includes not only administrative competence and specialized staff, but also financial resources sufficient to develop and sustain complex policy instruments such as CBCA.

Data availability and transparency

An expected key enabling factor is the presence of mechanisms to gather, estimate, and communicate consumption-based emissions data. This may involve standardized methodologies, collaboration with national statistical agencies or academic institutions, and innovative approaches to address data gaps. Moreover, transparency in how data are collected and what they represent is considered essential for credibility and stakeholder engagement.

Political legitimacy

Successful implementation is also linked to the legitimacy of CBCA within the local governance ecosystem. Two factors are anticipated to support legitimacy, measurable targets and the active engagement of both internal and external stakeholders in shaping and delivering on the policy objectives.

Multi-level coordination and stakeholder engagement

Effective coordination across governance levels; horizontal (within municipal departments), vertical (with regional or national authorities), and cross-sectoral (with businesses and civil society), is assumed to be a central enabler. The engagement of diverse stakeholders is also crucial to reinforcing legitimacy and ensuring long-term policy durability.

3.2 Research design

From the broader dataset of 17 European city case studies, Paris and Gothenburg were selected for deeper qualitative analysis. The selection was guided by their advanced engagement with CBCA defined here as going beyond compliance with national or EU mandates. Another selection criterion was for the city to have a consumption-based emissions reduction goal that does not only encompass organizational emissions (i.e., from the municipality) but also include city-wide emissions in their climate targets.

Semi-structured interviews were conducted with key stakeholders involved in the climate governance of each city. Interviewees were initially identified through the NetZeroCities (NZC) platform and selected based on their role and knowledge of CBCA implementation. Complementary to the interviews, documentary analysis was conducted on municipal climate action plans, technical reports, and official data-sharing agreements. During the initial research, a codebook was developed. As this research was exploratory, an inductive coding approach was preferred to discover unexpected themes and patterns and limit researcher bias. These codes were then refined through an iterative validation process involving a second researcher, ensuring inter-coder reliability and interpretative coherence.

From the results of the coding of the main research data, an initial focus was placed on the codes that reflected governance enablers. This preliminary review made it possible to identify recurring patterns and key governance conditions necessary for the implementation of consumption-based carbon accounting (CBCA). These conditions form the analytical framework presented in the results section. Subsequently, a comparative analysis was conducted by reviewing all codes linked specifically to the interviews from Paris and Gothenburg. This step aims to identify the concrete governance mechanisms present in these two cities, which are considered frontrunners in CBCA. Additional patterns that complemented the initial findings were identified through this city-specific review. Finally, a close re-examination of the interview transcripts for both cities was carried out to validate and deepen the analysis of the governance conditions that have facilitated progress on CBCA at the local level.

Table 1: Summary of Interviews Conducted in Paris and Gothenburg

City	Date	Duration
Paris	19-07-2024	45:58
Gothenburg	07-08-2024	53:28

The transcription of the interviews conducted in Paris and Gothenburg serve as the primary empirical basis for this study and directly inform the analysis of governance conditions for implementing consumption-based carbon accounting (CBCA). In addition to the interviews, several key documents provided by the municipalities were analyzed, including, the Paris Climate City Contract (CCC), the Paris Climate Action Plam, the Gothenburg CCC. Further desk research was also conducted to clarify specific aspects of local governance and policy context not directly covered in the interviews or official documents.

It is worth noting that, throughout the research process, the terms consumption-based carbon accounting (CBCA) and Scope 3 emissions were frequently used interchangeably by stakeholders. While technically distinct, in this context they were often treated as synonymous in practice and discourse.

3.3 Paris and Gothenburg case studies

Paris and Gothenburg were selected as case studies due to their advanced commitments to climate action, particularly regarding the integration of consumption-based carbon accounting (CBCA) into their urban climate strategies.

Table 2: Key Climate Commitments of Paris and Gothenburg

City	Covenant of Mayors adhesion	Date of CCC publication	Consumption based objectives
Paris	2008	2024	Achieve carbon neutrality, including consumption-based emissions, by 2050
Gothenburg	2009	2024	Reduce per capita consumption-based emissions to 1.9 tCO_2e by 2050

Paris emerged early in the research as a leading example, having set an ambitious carbon neutrality target that explicitly includes Scope 3 emissions. Its 2018 Climate Action Plan and subsequent strategies reflect a compre-

hensive approach, integrating both territorial and consumption-based emissions into its monitoring and objectives. As stated in the Plan:

"Through the Climate Plan, the City of Paris has set an ambitious objective to reduce its carbon footprint by 80%. In this way, it is going beyond the legal requirements by integrating indirect emissions that come mainly from aviation, the production of goods, and the food consumed in Paris. To attain this target, the City of Paris plans to encourage the aviation and food industries in particular to make their practices more sustainable" (p.92)

Gothenburg also represents a strong case, albeit with a slightly less integrated approach than Paris. Nevertheless, it has set clear and measurable targets for reducing consumption-based emissions. The city aims to lower per capita consumption-based emissions to 3.3 tonnes by 2030, 3.5 tonnes by 2035, and 1.9 tonnes by 2050. These goals encompass all goods and services consumed by residents, regardless of where the emissions occur, and imply an annual reduction of approximately 7.6%.

4. Results

4.1 Initial Coding Results

The initial coding process based on the original codebook revealed several recurring governance conditions that enable the implementation of Consumption-Based Carbon Accounting (CBCA). This led to the identification of 16 enabling conditions, organized across four overarching themes: (1) Data transparency and accessibility, (2) Institutional and technical capacity, (3) Political legitimacy and stakeholder engagement, and (4) multi-level and cross-sectoral support. These enabling conditions are presented in the framework below:

Table 3: Enabling Governance Conditions for CBCA Implementation

Themes	Enabling Conditions	Explanation
Data transparency and accessibility	Standardized process	The city has established procedures for collecting and/or analyzing consumption-based emissions data
	Innovation	The city uses alternative data collection approaches where direct data is missing
	Data agreements	The municipality has institutional arrangements with external actors (e.g., private companies, agencies) for data sharing
	Open access	When working with an external stakeholder to collect the data, the city has access to the datasets and methodologies used
Institutional and technical capacity	Dedicated expertise	The municipality has in-house staff or department with expertise in CBCA
	Human and financial resources	The department in charge of the carbon accounting has sufficient technical, administrative, and financial resources
	Strategic cross-departmental collaboration	All relevant departments are being included in CBCA implementation
Political legitimacy and stakeholders' engagement	Strong political mandate	The political commitment goes beyond minimal compliance, supporting ambitious CBCA targets
	Clear communication	There are active efforts to explain CBCA logic and relevance to stakeholders
	Historic commitment	The city has a long-standing engagement in climate action
	City wide and multi-sectoral targets	The consumption-based emissions targets address a broad range of emission sources within the scope of the entire city
	Stakeholders' inclusion	The municipal strategy plans for the engagement of external actors (e.g., citizens, business)

	Clear framing of the objective	A numerical objective with a timeframe is set out from the reduction of consumption-based emissions. This objective is written in the Climate Plan.
Multi-level and cross-sectoral support	National level support	The national ecosystem is favourable of the implementation of CBCA
	Horizontal coordination	Formal agreements are being signed with other public or private organisations allows to enlarge the scope of committed actors

The following sections detail how each theme is manifested in the case studies of Paris and Gothenburg, with insights triangulated through case analysis and complementary data sources.

4.2 Data transparency and accessibility

Four factors have been identified as enabling conditions for CBCA implementation: (1) Standardized data collection and analysis, (2) Use of innovative methods to fill data gaps, (3) Existence of formal data-sharing agreements, (4) Open access and transparency in data communication.

Standardized data collection and analysis processes

A standardized data collection and analysis process appeared essential to strengthen the legitimacy of the accounting process. One the one hand, Paris utilizes the nationally standardized Bilan Carbone methodology developed by ADEME[2], ensuring consistency across French cities and reinforcing data legitimacy. The city also relies on INSEE[3] for robust demographic and economic statistics critical to emissions estimation, especially for sectors like food. Paris estimates average daily meal consumption based on residential and commuting populations to approximate food-related emissions. As expressed in the interviews, the existence of national level process allows to strengthen the legitimacy: *"It's good to have in France this "Bilan Carbone" methodology, because then every city would use the same rate for emissions. So, it gives more legitimacy as well for these figures."*

Gothenburg, while lacking standardized local systems, leverages data provided by the Stockholm Environment Institute (SEI), which, for all cities in Sweden, broke down national data to postal code areas, using market segmentation and local adjustments. However, Gothenburg notes this approach is externalized and lacks sufficient clarity. They also work with a state-sponsored research institute to calculate the impact of food consumption. Therefore, Gothenburg relies on externalized processes, carried on by research institutions, and unified at a national level.

Innovative Approaches

Paris uses innovative methods for categories with data gaps. For example, freight emissions are estimated through regional surveys and applying proportional calculations to allocate emissions to the city. The city also calculates material usage based on construction waste data: *"We do the math from the waste to upstream, because we don't know the amount of materials purchased. So we estimate it from construction waste."*

Gothenburg began with a bottom-up approach in 2008, assessing household consumption categories using available data, despite its fragmented nature. As exposed in the interview: "*We used like more of a bottom up approach that we looked at on various consumption categories and which day-to-day had available and tried to see how difficult the households in Gothenburg consumed and what the emissions were from the different groups*". Nowadays, this work still complements SEI's data.

Formal data-sharing agreements

These data sharing agreements appear to be particularly done with the air travel industry. Paris has a formal

2 ADEME (Agence de l'environnment et de la maîtrise de l'énergie) : French Environment and Energy Management Agency

3 INSEE: French National Institute of Statistics and Economic Studies

agreement with Aéroports de Paris (ADP), providing free annual data on air travel by Parisians, including departure and arrival information. On the other hand, Gothenburg previously received local air travel data from the airport, but this was discontinued due to political sensitivities, highlighting the fragility of this type of voluntary agreement.

Open access and transparency
In the case of Paris, getting the data from national institutions guarantees the transparency of the processes and access to the data sets. However, Gothenburg, while benefiting from SEI's mapping tools, notes that the opacity of the underlying model makes it hard to explain variations between areas, illustrating a trade-off between using relying on an external stakeholder and transparency; *"It's a little bit of a black box. It's a bit difficult to explain why some areas are higher in emissions and some are not"*,

4.3 Institutional and technical capacity
The institutional and technical capacity depends on 3 enabling factors: (1) Dedicated expertise within the municipality, (2) Human and financial resources, (3) Cross-departmental collaboration.

Dedicated expertise within the municipality
Paris also works with the Association Bilan Carbone (ABC) association, a national organization that trains professionals on carbon inventories and methodologies, ensuring the upskill process in French municipalities. Furthermore, the city also created a Department for Ecological Transition and Climate in 2022 to oversee its Climate Action Plan. This department monitors actions across administrative departments, conducts greenhouse gas emissions assessments. Gothenburg has a small, dedicated team, with one or two people focusing specifically on carbon accounting, led by a climate strategist responsible for monitoring emissions. *"We have people working with the carbon accounting, but it's not a big team. It's one or two people that are really working with this in detail."*

Cross-departmental collaboration
Both cities are involving a large number of departments into the strategy to reduce consumption-based emissions. **Paris** promotes shared responsibility by involving various departments and external partners. Carbon accounting data is shared internally to build awareness and ownership: "We try to involve all the stakeholders of the municipality. So we have different ways to raise awareness and to discuss with them". **Gothenburg** collaborates with departments like transport and procurement, though it acknowledges that challenges remain: "There is some collaboration with the transport department and with the procurement department, because their decisions have a big impact on emissions." The CBCA strategy is embedded in the normal environmental governance in Gothenburg: *"The City's climate goals are deeply embedded in its ordinary governance structures, notably outlined in the Environmental and Climate Program, backed by a broad political consensus. Central to this program is the aim for near-zero emissions, driving action across all municipal administrations"*.

4.4 Political legitimacy and stakeholders' engagement
Seven enabling conditions emerged: (1) Strong political mandate, (2) Clear communication, (3) Historic climate commitment, (4) City-wide, cross-sectoral scope, (5) Inclusion of external stakeholders, (6) Legitimacy through leadership and continuity.

Strong political mandate
Both cities have a strong political support that goes beyond the mandatory obligations in terms of climate engagements, as highlighted in the interview: "We have a very ambitious climate plan, and the mayor is very committed to including all emissions, not just the ones happening inside the city." Indeed, Paris's commitment to carbon neutrality by 2050 includes scope 3 emissions. The interviewees also highlighted the role of the COP21 Conference in Paris, and the mayor's leadership as a formal president of the C40 network, as key factors explaining Paris high-level commitment.

Gothenburg has robust, cross-party political support for its 2030 goal of near-zero carbon footprint, targeting both territorial and consumption-based emissions. *"The City's climate goal for 2030, 'a carbon footprint close to zero,' has robust support from a broad political majority, and is particularly highlighted by The Environment and Climate Programme for the City of Gothenburg 2021-2030."* However, as underlined by the interviewee, it might be more complicated to get a political consensus about the methods to adopt to reach the emissions reduction objectives: " *It was quite universal support for these kind of goals, and there have been some discussions when it comes to like individual choices when it comes to like food or what politicians should not do when it comes to emissions related to citizens. But the goals in themselves and not so much discussion".*

In both cases, the cities are pushed by what could be called a moral obligation, as expressed by Gothenburg in the following quote: "We thought we also have an obligation to see how we affect the other parts of the world through our consumption".

Clear communication
Paris actively communicates the importance and methodology of CBCA to stakeholders, both inside and outside the municipality, to foster understanding and engagement:
"We explain to them that it's not just about the emissions from buildings or transport in Paris, but also about what we consume, like food, clothing, and electronics."
"We have meetings and workshops to explain the logic of including consumption-based emissions and why it's important for the city's climate goals." Gothenburg supports public participation, but less detail is available regarding structured communication campaigns.

Historic commitment:
The fact that both cities have been leading on climate action and consider as "champion" is perceived as a clear enabler, pushing cities to further extend their actions towards Scope 3 emissions. Paris has demonstrated a long-standing commitment to greenhouse gas accounting and climate action, reflected in the establishment of specialized departments and the use of standardized methodologies. The city began assessing the impact of its activities in terms of greenhouse gases as early as 2004 and published its first comprehensive greenhouse gas assessment in 2006, identifying key emitting sectors and establishing a knowledge base for further action. They were also calculating the carbon footprint of the city since 2004: *"We were already known as a leader on climate for for a long time, and that's what we want to still carry on".*

Gothenburg began measuring consumption-based emissions in 2008, integrating scope 3 in climate policy despite limited data at the time: *"We had our first time goal for the city, we chose to include the consumption emissions also, even though we had very little data or anything on it".* Initially, the city was separating between territorial and consumption-based emissions before adopting the scope 1, 2, 3 framework as part of their involvement with the Covenant of Mayors and other reporting schemes.

City-wide and cross-sectoral focus
Both Paris and Gothenburg have adopted climate strategies that extend well beyond municipal operations, encompassing a wide range of emissions sources, including those linked to citizen behavior, urban infrastructure, and procurement practices.

In Paris, the city's climate policy is explicitly designed to address emissions across all sectors - not just those occurring within city boundaries. This includes emissions from energy, transport, food, construction, and the consumption of goods and services by Parisians. As one official explains, *"The city's climate plan covers all emissions, including those from energy, transport, food, construction, and even the consumption of goods by Parisians."* Another emphasizes the city's broader scope: *"We don't just look at what happens inside the city boundaries. We want to reduce the footprint of everything Parisians consume, even if it happens outside Paris." The ambition is clear and comprehensive: "Our goal is to reduce all emissions by 100%, not just the ones we control directly."*

Similarly, Gothenburg has adopted a wide-ranging climate objective that integrates both territorial and consumption-based emissions. As described by a city representative: *"The climate goal of the City of Gothenburg has a broader scope than required in the Mission. The goal targets emissions from both a territorial and a consumption-based perspective."* At the organizational level, Gothenburg closely monitors emissions associated with municipal procurement. The city has conducted a detailed analysis of all its programmatic requirements, comparing them against a national emissions database that calculates greenhouse gas intensity per monetary unit. This allows the city to assess the carbon impact of everything it purchases: *"We did this analysis on all our programme requirements, checking them against the database that has data on emissions per krona or monetary unit in Sweden."* As one official notes, this gives the municipality considerable influence: *"We have much more say in what we as a city consume and procure, and we can do much more with that."*

At the citizen level, Gothenburg also aims to capture emissions associated with individual consumption. While recognizing limitations in influencing certain areas - such as the embedded emissions in imported goods - the city still exerts significant control through local systems: *"When it comes to what our citizens consume, we still have a lot of say in how our transport system is set up and our energy system within the city, but not so much when it comes to the cost of goods and services.". To operationalize this broad approach, Gothenburg has developed a climate program structured around seven strategic focus areas - or "strategies"* - that require radical transformation.

Stakeholders inclusion:
Both Paris and Gothenburg prioritize inclusive governance by actively engaging a wide range of stakeholders in their climate initiatives - from large corporations and public institutions to local associations and citizens.

In Paris, the city has developed a collaborative framework to bring together stakeholders from across sectors. One key initiative is the Pacte Action-Climat-Biodiversité (Climate Action–Biodiversity Pact), a publicly available charter that outlines stakeholder commitments and reinforces transparency. *"It's like a kind of charter that some actors and stakeholders agree to sign to say that they will work alongside the city to implement measures that have an impact on the carbon footprint of the city."* The pact not only encourages joint action but also provides open access to information about partners and their objectives. Among the participating actors are major energy providers such as **GRDF** and **EDF**. As one official described, *"We have big energy companies like GRDF, EDF... the idea is to embark all of them and to share experience and good practices between all of them."* This approach reflects a deliberate effort to keep institutionalizing cooperation and knowledge exchange across organizational boundaries.

In Gothenburg, a similarly inclusive approach is taken, particularly with local associations and community-based actors. The city provides targeted support mechanisms that encourage grassroots involvement in climate work. For instance, associations, including sports organizations, can apply for municipal grants to fund environmental initiatives. *"You can, as a sports association, ask the city for grants for doing that kind of work, and you can get access to the city's buildings"*, explained one representative. Notably, these programs have been expanded to include organizations working on issues such as circular economy, allowing for greater diversity in the types of projects supported: *"We extended those programmes to associations that want to work with circular economy issues and things like that."*

Clear objectives
The presence of clearly defined goals - particularly those that are quantitative and time-bound - plays a fundamental role in enabling consumption-based climate action (CBCA). These objectives serve not only as guiding principles but also as concrete benchmarks that drive prioritization, mobilize resources, and ensure accountability. In both Paris and Gothenburg, long-term climate ambitions are formally documented in strategic plans, providing an essential foundation for implementing CBCA measures.

In Paris, the city's objectives are explicitly articulated in the Climate Action Plan and the Climate, Air, and Energy

Plan (PCAET). These plans commit Paris to reducing all local emissions - including both territorial and consumption-based - by 100% in the long term. More specifically, the city aims to cut total emissions (including consumption-based ones) by 40% by 2030 and by 80% by 2050, relative to 2004 levels: *"Paris established targets in its Climate Action Plan to decrease territorial and consumption-based emissions (the Paris carbon footprint) to 40% below 2004 levels by 2030 and 80% below 2004 levels by 2050."*[4]

Similarly, Gothenburg has committed to a clear and ambitious consumption-based emissions reduction pathway. Its goals are both quantified and tied to a defined timeline, providing a strong political mandate for CBCA implementation. By 2030, the goal is to reduce consumption-based greenhouse gas emissions to 3.3 tonnes CO_2e per person per year, down from a baseline of 9.25 tonnes in 2017. This requires an annual reduction rate of at least 7.6%. The final goal is to reach 1.9 tonnes CO_2e per person per year by 2050.

4.5. Multi-level and cross-sectoral coordination

The successful implementation of CBCA depends significantly on coordination across multiple levels of government and sectors. This is enabled by two key factors: a supportive national governance system and a horizontal coordination across sectors and stakeholders.

National governance ecosystem

Paris benefits from a strong national framework that provides substantial institutional support for implementing CBCA. National-level entities - including government agencies, research institutions, and statistical offices - supply cities with the methodologies, data, and standards necessary for consumption-based carbon accounting. These tools not only strengthen the technical foundation of Paris's climate policy but also lend political legitimacy and coherence to local actions. In contrast, Gothenburg operates within a more fragmented national governance context. While it receives technical support from organizations such as the Stockholm Environment Institute (SEI) - which plays a crucial role in developing methodologies for CBCA - there is no formal governmental mandate or support at the national level for consumption-based accounting.

Horizontal coordination

Both cities also rely heavily on horizontal coordination, meaning collaboration across sectors and with various public and private stakeholders.

In Paris, this is exemplified by initiatives such as the Pacte Action-Climat-Biodiversité, an open, online charter where stakeholders voluntarily commit to actions aligned with the city's climate goals, as explained above. Similarly, in Gothenburg, CBCA is not the responsibility of a single department but is instead embedded across the city's governance structures. The Environment and Climate Program for 2021–2030 was adopted by a wide political majority and applies to all city departments and city-owned companies. This ensures that the goal of reducing consumption-based emissions is shared across the entire municipal apparatus.

5. Discussion

This study identifies two contrasting yet complementary models of consumption-based carbon accounting (CBCA) governance: Paris's institutionalized model and Gothenburg's pioneering approach. These cases illustrate that there is no singular pathway to implementing CBCA. Instead, diverse strategies - shaped by political cultures, institutional configurations, and external support systems - can all serve as viable routes to operationalizing this ambitious climate accounting framework.

5.1. Two different models: Institutionalized vs. Bottom-up CBCA Approaches

Paris advances CBCA within a highly institutionalized and nationally supported governance environment. It benefits from a structured ecosystem comprising national research institutions (e.g., INSEE, ADEME, ABC), legal mandates, and standardized methodologies, which provide a robust backbone for methodological consistency and policy legitimacy. CBCA is embedded within the city's broader climate strategy, supported by cross-sectoral coordination and formal target-setting. This reflects what Bulkeley and Kern (2006) describe as "governing through

4 Paris Climate Action Plan

enabling," where higher-level institutions provide cities with tools and frameworks for climate action. In contrast, Gothenburg exemplifies a more bottom-up, pioneering approach. Despite the absence of strong national mandates or standardized frameworks, the city has pushed CBCA forward through close partnerships with expert institutions like the Stockholm Environment Institute (SEI), bottom-up data collection, and partnerships with local institutions. The reliance on external actors has enabled methodological innovation and credibility, though it also introduces potential vulnerabilities in terms of continuity, autonomy, and long-term data governance. Studies shows that, while introducing expertise and standardized methods, the reliance on external stakeholders also include challenges in maintaining consistent methodologies over time, risks of data discontinuity if external partnerships dissolve, and potential limitations on local autonomy and data ownership (Fünfgeld & McEvoy, 2012; Turnhout et al., 2016).

5.2 The Role of National Ecosystems

These two cases highlight the enabling role, but not deterministic function, of the national ecosystem. While Paris's success is deeply tied to a supportive national framework, Gothenburg demonstrates that local innovation can substitute for national direction. Paris thrives in an ecosystem with clear national institutions and policies that underpin CBCA, from macroeconomic data (INSEE) to methodological standards (ADEME). The relationship between national frameworks and local climate action is well documented in the literature. National institutions can provide essential data, methodological standards, and legitimacy, enabling cities to develop robust climate policies (Bulkeley & Kern, 2006; Kern & Bulkeley, 2009).

Conversely, research shows that cities can also innovate in the absence of strong national direction by leveraging local academic and technical expertise. For example, Gothenburg does not benefit from national institution data but draws on the academic expertise of the SEI. However, such innovation may be less stable or scalable without institutionalized national support (van der Heijden, 2019; Castán Broto & Bulkeley, 2013).

5.3 Political framing and target settings as a key enabler towards CBCA

A shared enabler in both contexts is the framing of CBCA through clear, time-bound targets embedded in official climate strategies. Paris aims to reduce territorial and consumption-based emissions by 80% from 2004 levels by 2050. Gothenburg targets a per capita reduction to 3.3 tonnes CO_2e by 2030. The literature demonstrates that setting ambitious and specific targets not only structures implementation but also acts as a powerful tool for political mobilization, stakeholder engagement, and accountability (Rogge & Reichardt, 2016; Hsu et al., 2020).

Closely tied to target-setting is the integration of CBCA across departments and sectors. Paris exhibits more formalized coordination through interdepartmental mechanisms and city-wide climate charters. Gothenburg relies on horizontal integration, embedding CBCA objectives across all departments and city-owned companies through its Environmental and Climate Program (2021-2030). This integration ensures that scope 3 data informs procurement, planning, and budgeting processes which are key for mainstreaming beyond symbolic commitments. The mainstreaming of CBCA objectives across municipal departments and city-owned companies, as seen in both Paris and Gothenburg, is also recognized as a best practice for effective climate governance (Bulkeley & Kern, 2006; Reckien et al., 2018).

5.4 The crucial role of stakeholder engagement

Stakeholder engagement is central to the legitimacy, operationalization, and sustainability of CBCA governance. In Paris, structured participation is institutionalized through the Pacte Action-Climat-Biodiversité, a publicly accessible charter that mobilizes actors across sectors, from energy companies to grassroots organizations. This charter formalizes commitments, ensures transparency, and reinforces co-responsibility. It embeds climate action within a network of shared governance, illustrating that a broad societal buy-in is needed in order to carry out actions to counter consumption-based emissions. Gothenburg mainly focus on society organizations, sports associations, and NGOs are encouraged to align with the city's environmental objectives through financial support and access to public infrastructure. This fosters bottom-up engagement and reflects a high-trust model of participatory governance. The city has expanded its collaborative programs to include circular economy initia-

tives, highlighting the dynamic evolution of stakeholder roles in CBCA. Such bottom-up approaches are shown to be effective in mobilizing local actors, fostering innovation, and ensuring that climate actions are contextually relevant and widely supported (Aylett, 2015; Arnouts et al., 2012).

5.4 Normative Framing and Cities as Global Climate Actors

The deliberate inclusion of consumption-based emissions in local climate plans reflects a normative redefinition of urban responsibility. Rather than limiting themselves to territorial emissions under their direct control, both Paris and Gothenburg embrace a broader ethical mandate that connects local governance to global sustainability. This shift positions cities not as passive implementers but as active shapers of post-territorial climate governance. This framing aligns with emerging literature on cities as global actors (van der Heijden, 2019).

Therefore, it can be argued CBCA equips cities with tools to address climate change systemically but also imposes new demands. Cities must negotiate responsibilities beyond their formal jurisdictions, build internal expertise, and ensure accountability for emissions they do not directly control. To succeed in this role, they require enhanced support - access to funding, methodological guidance, and platforms for international collaboration. The cases of Paris and Gothenburg reinforce the view that cities can lead in addressing global challenges when empowered with the right frameworks and coalitions. Their experiences suggest that CBCA is not just a technical exercise but a transformative approach to rethinking urban sustainability and governance in the age of climate crisis.

Conclusion

This article has examined the governance conditions of consumption-based carbon accounting (CBCA) through an in-depth comparison of Paris and Gothenburg, two cities that, despite distinct institutional contexts and levels of national support, each have advanced ambitious and pragmatic CBCA strategies. The findings reveal that while Paris operates within a highly institutionalized, nationally backed model and Gothenburg advances a more bottom-up, normatively driven approach, both demonstrate that local governments can lead on scope 3 emissions governance, even in the absence of a harmonized international framework.

The Paris case illustrates the strengths of a mature governance ecosystem where national institutions provide the methodological and legal infrastructure necessary to support robust CBCA integration. In contrast, Gothenburg shows that municipal innovation, when coupled with collaboration with expert institutions, can pioneer new methodologies and mainstream CBCA into city operations, even with limited national guidance. Across both cases, the success of CBCA governance is tied not only to technical capacity or institutional design, but also to the political and ethical reframing of urban climate responsibility. By choosing to include emissions beyond their direct territorial control, both cities expand the boundaries of local climate governance toward a more globally accountable model. Clear targets, cross-sectoral integration, and meaningful stakeholder engagement emerge as critical levers for embedding CBCA within policy and society. At the same time, the analysis underscores the fragility of such efforts when they rely too heavily on individual champions, external expertise, or voluntary mechanisms. To sustain and scale CBCA, cities need institutional safeguards such as binding mandates, integrated planning processes, and sustained national support. Moreover, the broader governance landscape must evolve to recognize and support cities as global climate actors, providing the financial and technical resources needed to monitor, manage, and reduce consumption-based emissions.

Ultimately, the Paris and Gothenburg experiences show that CBCA is not only a technical tool but a political and ethical project. It calls for reimagining the role of cities in a globally interconnected carbon economy and for crafting governance arrangements that enable urban actors to lead climate action far beyond their borders. CBCA thus offers a vital lens through which to rethink both the responsibilities and the capabilities of cities in the age of planetary crisis.

Acknowledgements

This research was made possible through the valuable support and collaboration of numerous individuals and

institutions. We would like to express our sincere gratitude to the municipal representatives and experts who generously shared their time, insights, and experiences during the interviews. Their openness and critical reflections were instrumental in shaping the findings of this study.

Abstract
The concept of 15-minute cities has gained global attention as a sustainable urban planning model aimed at creating cities where residents can access essential services and amenities within a 15-minute walk or bike ride from their homes. This model emphasizes accessibility, reducing reliance on cars, and fostering more livable and inclusive urban spaces. This study explores the perceived accessibility of two districts in Ankara, Türkiye (Çankaya and Keçiören) through the lens of the 15-minute city framework.

The findings contribute to the growing discourse on sustainable urban mobility and the practical realities of implementing the 15-minute city concept in diverse urban environments.

Key Words: 15-Minute City, Resident Perceptions, Ankara Urban Planning, Çankaya District, Keçiören District

1. INTRODUCTION

The 15-Minute City concept focuses on ensuring that residents can reach key services—such as employment, shopping, healthcare, education, and recreation—within a 15-minute walk or bike ride from their homes (Moreno et al., 2021). Rooted in long-standing urban planning principles, including human-scale development, density,

diversity, adaptability, proximity, digital integration, and connectivity, the model supports social, economic, and environmental sustainability (Khavarian-Garmsir et al., 2023b; Jiang et al., 2024). It seeks to improve urban liveability, resilience, and public health, particularly in the aftermath of the pandemic and in line with Smart and Green Transition goals (Allam et al., 2022; Shoina et al., 2024; Moreno et al., 2021).

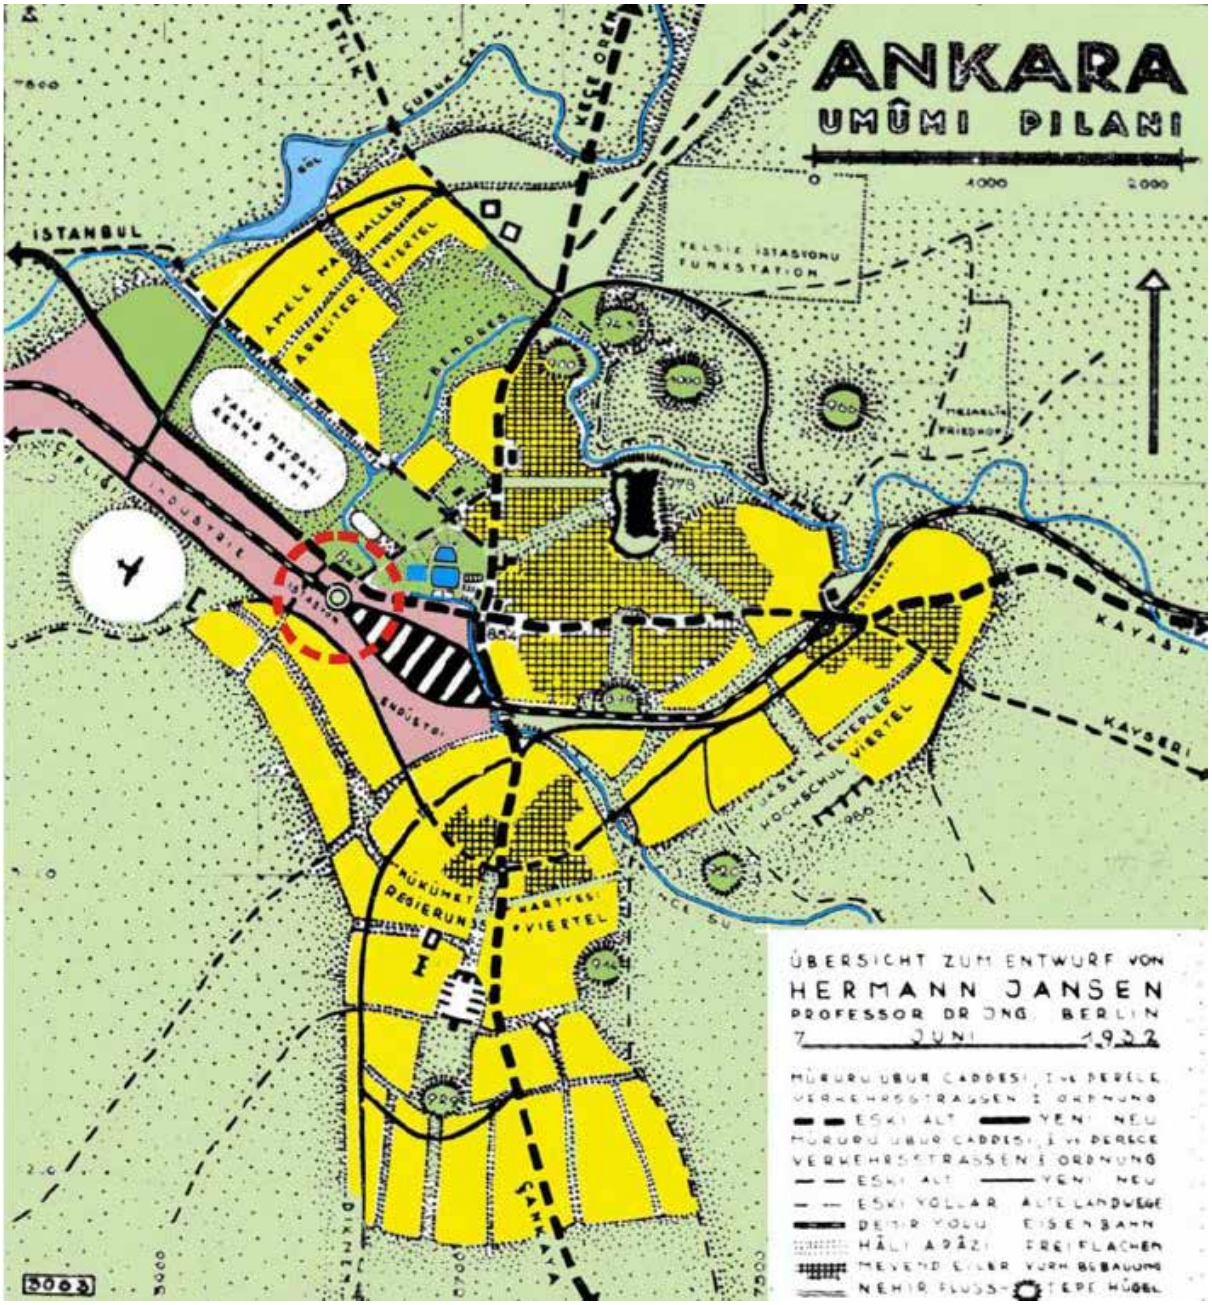
A growing number of cities are embracing the 15-Minute City model, customizing it to align with their specific urban histories and requirements. Case studies emphasize the need for contextual adaptation, highlighting that successful implementation depends on cross-disciplinary collaboration, strategic resource management, and active citizen participation (Pozoukidou & Chatziyiannaki, 2021; Shoina et al., 2024; Di Marino et al., 2022). For instance, cities like Oslo and Lisbon have experimented with integrating flexible workspaces and improving public transport access, although challenges persist in achieving an equitable distribution of services and amenities (Di Marino et al., 2022).

The rest of the paper is organized as follows: In Chapter 2, the applicability and perceived relevance of the 15-Minute City concept within the context of Ankara, Türkiye, focusing on two socio-spatially distinct districts: Çankaya and Keçiören are given. Drawing on historical planning precedents such as the 1927 Jansen Plan, the research examines how the 15-Minute City concept framework—which emphasizes accessibility, proximity, mixed-use neighborhoods, and human-scale development—resonates with Ankara's evolving urban form and contemporary challenges. In Chapter 3, the preliminary resident perceptions in both districts are assessed through a contextual lens where we expect that residents in Çankaya to support the model but raise concerns about affordability and digital expectations, whereas Keçiören's residents are expected to view the 15-Minute City concept as a much-needed strategy for equity, though tempered by skepticism over implementation and accessibility. The paper concludes with the Chapter 4, where reinterpreting the 15-Minute City concept through Ankara's planning history provides an opportunity for inclusive, sustainable, and resilient urban transformation, particularly when guided by neighborhood-specific strategies and participatory approaches.

2. THE 15-MINUTE CITY CONCEPT IN ANKARA'S PLANNING HISTORY

Revisiting the 15-Minute City framework offers an opportunity to reorient Ankara's urban development toward more human-scaled, sustainable, and resilient patterns, particularly through the revitalization of inner-city neighborhoods, integration of transit-oriented development, and promotion of local services. In this way, the concept can serve both as a critique of past deviations and a strategic lens for future planning.

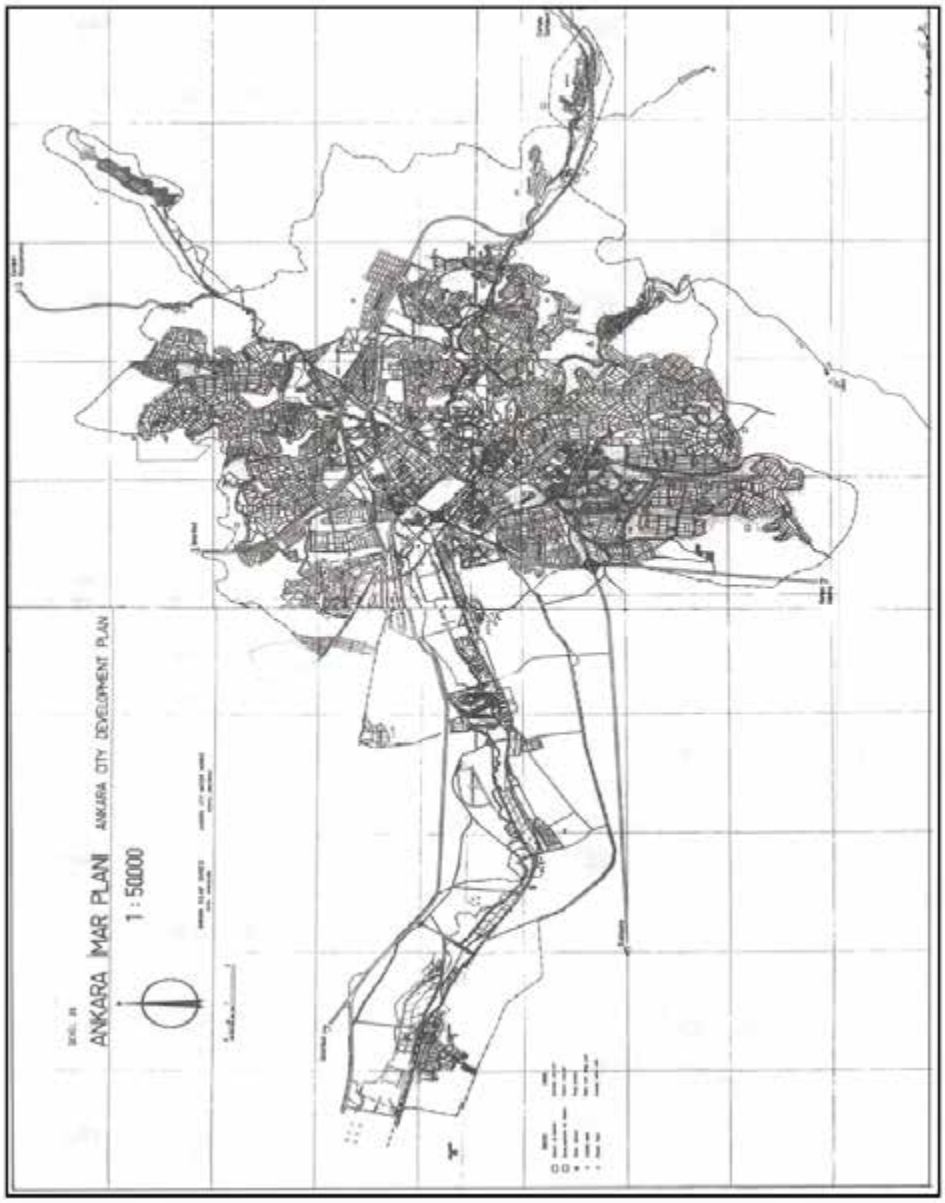
The 15-Minute City concept, with its focus on proximity, accessibility, and mixed-use neighborhoods, resonates with key aspects of Ankara's historical urban planning—particularly the early Republican-era visions that emphasized planned growth, functional zoning, and neighborhood units.



Plan 1. The 1927 Jansen Plan of Ankara (Source: Jansen Plan)

In the 1920s, as the newly founded Republic of Türkiye designated Ankara as its capital, the city was envisioned as a modern, efficient, and rational urban center. The 1927 Jansen Plan exemplified this vision by proposing a well-structured capital featuring green areas, pedestrian-friendly neighborhoods, and accessible public services—an approach that resonates with contemporary 15-minute city principles. As one of Ankara's earliest and most significant planning initiatives, the plan aimed to establish a polycentric layout defined by functional zoning, integrated green networks, and mahalle-based neighborhood units that fostered walkability and community interaction. The foundational ideas behind this plan—particularly the focus on human-scale design, spatial proximity, and public infrastructure—closely align with the core concepts of the 15-Minute City model.

However, despite these promising foundations, Ankara's urban development over the 20th century gradually veered towards mono-functional zoning, and sprawling expansion, leading to increased car dependency. The city's growth was increasingly characterized by automobile-oriented suburbs, fragmented urban patterns, and rising spatial inequality—departing significantly from the original planning vision.

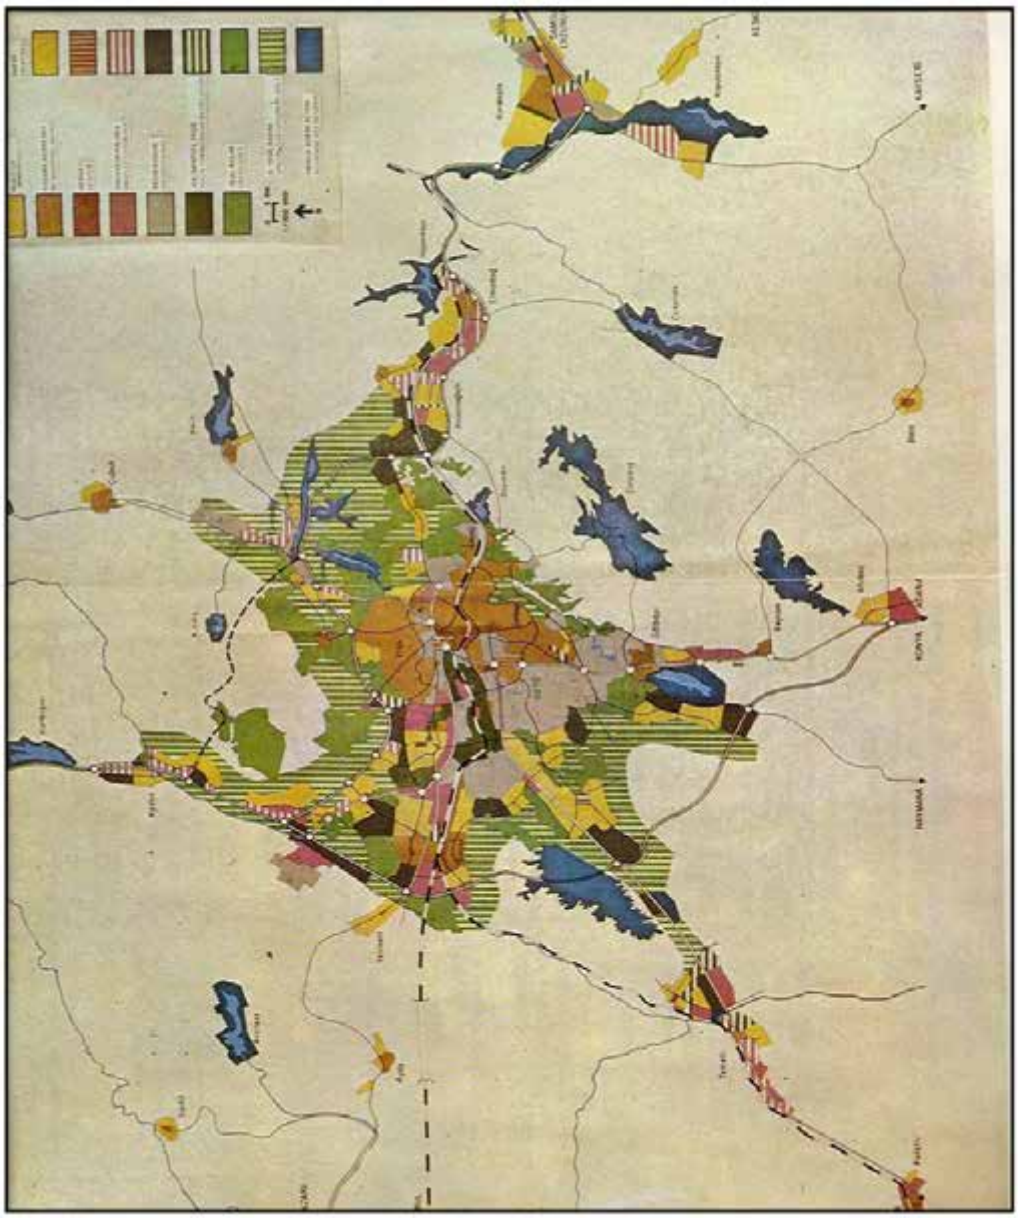


Plan 2. Yucel-Uybadin Plan of Ankara-1950 (Günay, 2012)

The rapid urbanization of Turkey that followed the 1950s, along with speculative land practices and the widespread emergence of gecekondu (informal housing) areas, eroded the initial vision of an integrated and accessible urban fabric.

The third plan sought to preserve the culturalist vision established in the first plan. It aimed to halt further urban growth and densification but ultimately failed by disregarding the underlying societal dynamics, leading to the city's transformation. As a result, the city's dual social structures began to shape its physical form. Apartment buildings in formally planned housing areas and informal, low-rise squatter settlements emerged as the dominant urban patterns, reflecting socio-economic divides. The once-envisioned garden city gave way to a city of

apartment blocks, while the intended green belts were overtaken by informal housing, marking the beginning of a conflict between planned and unplanned development. Over time, this tension led to a complete overhaul of the urban fabric, where the ideal of a modern, orderly city was replaced by a more disordered and chaotic reality. (Günay, 2012).



Plan 3: The structural plan of Ankara-2015 (Günay, 2012)

The Ankara 2015 Structural Plan introduced policies aimed at guiding urban growth toward the city's outskirts. It is notable for its clear definition of the urban center, its recognition and integration of squatter settlements, and its strategy to allocate urban land for the middle class. The Metropolitan Office Plan also sought to address the needs of middle- and lower-income populations by promoting a balance between residential areas and employment opportunities. In contemporary Ankara, however, increasing car dependency, fragmented urban infrastructure, and unequal access to public services have led to pronounced spatial and social disparities—particularly between well-connected central neighborhoods and marginalized peripheral zones. As a result, many residents face long daily commutes, limited access to green space, and a lack of local services—challenges that the 15-Minute City approach is specifically designed to overcome (Günay, 2012).

3. PERCEPTIONS IN CANKAYA AND KECİÖREN DISTRICTS ABOUT 15-MINUTE CITY

We conducted so called Walk-Aong Interviews (WAI) in two districts of Ankara to have a better insight into local perceptions about accessibility and walkability within these districts. WAI are part of are part of the methodological repertoire of empirical social and geographical research which focus on the spatial and social environment. As a mobile method, they allow to gain valuable insights into experiences, perceptions and impressions of different target groups. With an interviewer and one researcher, capturing the observer's perspective, the method of walk-alongs interviews obtain a variety of impressions to analyse perceived accessibility within the framework of the 15-Minute City (Van Hecke et al., 2016; King & Woodroffe 2017; Amaya et al. 2024). Before doing that, some visits to the districts gave some preliminary perceptions about the Çankaya and Keçiören, two of Ankara's most prominent and contrasting districts, are likely to generate different perceptions and responses to the 15-Minute City concept, shaped by their socio-economic characteristics, urban form, topography, accessibility patterns, and service distribution.

In the rest of the study, some preliminary results are presented shortly.

3.1 Çankaya: Supportive but Selective Perceptions

Çankaya is one of the most central and densely populated districts of Ankara, serving as a key administrative, residential, and cultural hub of the city. Characterized by a diverse urban fabric, the district includes a mix of governmental institutions, educational facilities, residential neighborhoods, and commercial zones. While Çankaya offers relatively better access to public services and infrastructure compared to many peripheral districts, the findings of this study reveal that significant barriers to walkability persist, particularly for vulnerable groups such as the elderly and families with children.

The district's varied topography, including steep slopes and elevation changes, presents considerable challenges for pedestrian mobility. Despite its centrality, many neighborhoods within Çankaya exhibit damaged sidewalks, obstructed walking paths, and insufficient pedestrian infrastructure. These issues are further exacerbated by a lack of accessible public amenities—such as parks, rest areas, and recreational spaces—which limits the appeal and practicality of walking, especially for older residents. Families with children also reported concerns regarding safety and comfort when navigating the urban environment on foot, often citing inadequate integration between pedestrian paths and public transportation.

Overall, while Çankaya remains a vital part of Ankara's urban landscape, the district's walkability is hindered by a combination of physical, infrastructural, and planning-related challenges. Addressing these concerns through inclusive urban design and integrated mobility planning is essential for enhancing the quality of life for its diverse population.

The preliminary results for the implementation of 15-min city concept in planning

Lifestyle Compatibility: Many residents — particularly those living in central neighborhoods — already enjoy key features of the 15-Minute City, such as pedestrian-friendly environments, local cafés, bookstores, and cultural venues. As such, the model may be viewed as an affirmation of their existing urban lifestyle and values.

High Awareness and Receptivity: Given the districts highly educated and often progressive demographic, the group tends to support sustainability-focused, human-centered urban strategies.

Concerns Around Gentrification and Affordability: Despite general support, there are reservations that enhancing amenities and public spaces could accelerate gentrification, leading to increased housing costs and reduced affordability for existing residents.

Expectations for Smart Urban Solutions: Within a tech-literate population, there is an expectation that implementation will incorporate digital tools such as mobile mobility platforms, real-time public transit updates, and intelligent urban infrastructure.

Emphasis on Green and Cultural Connectivity: Particular attention may be given to improving access to green spaces and cultural amenities within walking distance — especially in older neighborhoods where such features are unevenly distributed or deteriorating.

3.2 Keçiören: Mixed and Needs-Based Perceptions

Keçiören is one of the most populous and socially diverse districts, with a predominantly residential and conservative profile. Keçiören is one of Ankara's largest and most vibrant residential districts, home to a diverse community with varied mobility needs. The district's topography includes gentle slopes and some elevation changes, which, together with its evolving pedestrian infrastructure, shape residents' everyday walking experiences. While many neighborhoods in Keçiören offer walkable areas, some aspects of the pedestrian environment present opportunities for enhancement to better accommodate all users.

The certain sections of sidewalks could benefit from maintenance and occasional widening to improve accessibility and comfort. The integration of pedestrian pathways with public transportation is an area where further development may support more seamless mobility, especially for families with children. Additionally, while Keçiören offers a range of public spaces, increasing the availability and accessibility of parks, resting areas, and recreational facilities would further enrich the pedestrian experience.

Despite these areas for growth, there is an interest in sustainable transportation options and expressed openness to improvements such as safer cycling routes and pedestrian-friendly crossings. These insights highlight the potential for thoughtful, community-informed planning initiatives to strengthen walkability and enhance quality of life in Keçiören.

The preliminary results for the implementation of 15-min city concept in planning are as follows:

Call for Equitable Service Provision: The 15-Miniute City concept is slowly gaining recognition among citizens.

Skepticism Rooted in Past Experience: Given a history of underinvestment and top-down planning processes, there may be widespread skepticism about the feasibility of implementing the model effectively.

Prioritization of Core Infrastructure: There is a technological innovation center in Keçiören. It helps embracing advanced technological tools. Residents are likely to prioritize tangible improvements in public transport, pedestrian safety, street maintenance, and basic infrastructure.

Need for Accessible Social and Cultural Facilities: There may be a pronounced demand for community-oriented spaces that support family life, youth engagement, and religious or cultural activities —s paces that foster everyday social interaction and cohesion.

Affordability as a Central Concern: A key expectation is that any new amenities or services introduced as part of the 15-Minute City approach remain financially accessible to all residents, avoiding cost-driven exclusion or displacement.

4. CONCLUSION

The study highlights the importance of considering local context and resident perceptions in urban planning, and it calls for a more inclusive approach to designing cities that truly prioritize accessibility for all citizens.

Reintroducing the core principles of the 15-Minute City into Ankara's current urban planning framework presents a valuable opportunity to tackle longstanding urban challenges. Enhancing the function of neighborhood centers as versatile hubs for essential services can help reduce travel distances and stimulate local economic development. Strengthening infrastructure for active transportation — such as pedestrian pathways and cycling routes — and integrating these with public transit systems aligns with both the foundational ideas of the Jansen

Plan and today's sustainability imperatives. Furthermore, leveraging digital technologies, including GIS-based accessibility assessments and participatory planning platforms, can support more responsive, data-informed decision-making that addresses neighborhood-specific needs.

The 15-Minute City also offers timely solutions for Ankara's climate adaptation and post-pandemic recovery efforts. By fostering compact, inclusive, and mixed-use urban forms, the model can help lower carbon emissions, improve public health outcomes, and reinforce social cohesion. In this context, it serves not only to rectify previous shortcomings in urban development but also as a strategic framework in alignment with global priorities such as the Smart and Green Transition and the United Nations Sustainable Development Goals.

At the district level, applying a context-sensitive lens is essential. Planning narratives must reflect the distinct needs, perceptions, and lived realities of each district.

In sum, the 15-Minute City should not be viewed as a novel planning doctrine for Ankara but rather as a contemporary reinterpretation of the city's historical planning aspirations. Grounding this concept in the values of proximity, accessibility, and resilience offers a promising path toward a more just, sustainable, and livable future for Türkiye's capital city.

Abstract
This paper explores how a More-Than-Human approach can reshape storytelling for landscape planning by integrating Artificial Intelligence (AI), as a tool for co-producing multispecies narratives, and Problem Structuring Methods (PSMs), as participatory methods for addressing complex, multidimensional issues. Within this context, the concept of More-Than-Human-Rights offers a legal and ethical framework that supports entanglements between human and non-human agents. To operationalise these theoretical statements, the case study "Mytilus in Fabula" in the Campi Flegrei area is examined, where humans and non-humans co-construct relational landscape narratives. The findings from this theoretical and practical inquiry open a path to the development of more inclusive, equitable, and multispecies planning practices capable of addressing contemporary ecological challenges.

Keywords: More-Than-Human Rights, Interspecies Justice, Ecological Ethics, Situated Knowledge, AI Ethics

Introduction

In recent years, our perception of landscapes has undergone a profound transformation, reflecting shifts in cultural, environmental and scientific paradigms (Antrop, 2014). These paradigms influence the way we interpret and understand our surroundings. Historically, landscapes are valued for the benefits they provide to society, whether these are material or immaterial (e.g. cultural identity, the aesthetics of a place, or recreational opportunities) (Tempesta, 2006). Conventional methods of storytelling and planning in complex landscapes include, among others, Ecosystem Services (ES) (Díaz et al, 2015), Landscape Services (LS) (Termorshuizen & Opdam 2009; Bastian et al. 2014) and Landscape Characteristics Assessment (LCA) (LU et al, 2022), are based on an anthropocentric vision. Although these approaches adopt different logics, they aim to interpret and attribute value to the environmental, cultural, social, perceptual and identity dimensions of a territory. They are characterised by their ability to synthesise and classify the elements that make up a landscape, thus facilitating decision-making processes (Van Eetvelde & Antrop 2009; Haines-Young & Potschin 2011; Vallés-Planells, Galiana & Van Eetvelde, 2014). However, despite their analytical and managerial strengths, they tend to overlook the intrinsic and ecological value of landscapes by focusing primarily on nature's contributions to human well-being. This limited viewpoint neglects the coexistence and interaction of human and non-human entities within territories (Liew & Sundaram, 2009; Cerreta 2010; Montuori, 2013), revealing a need for more integrated, interdisciplinary strategies that embrace multispecies perspectives and promote holistic visions of the human–nature relationship.

In response to the limitations of conventional models, a paradigm shift has been proposed to recognise and integrate the diverse perspectives, memories, and experiences that shape a place's identity. Rather than being considered merely an aesthetic framework, landscapes are now recognised as living, complex entities resulting from the constant interaction between natural and human elements (Council of Europe, 2000). This evolutionary perspective recognises landscapes as continuously evolving systems in which the ecological, social, and cultural dimensions are interconnected and influence each other (Palola, Bailey & Wedding, 2022). Understanding the landscape as a complex, multi-level system enables us to address contemporary environmental and social challenges by promoting an integrated, sustainable approach.

Within this context, the More-Than-Human approach (Haraway, 1985) offers an innovative and critical perspective that challenges the anthropocentric vision. Adopting this approach to landscape planning means recognising

the agency of non-human subjects (e.g. ecosystems, animal and plant species, physical and technological infrastructures) in shaping planning processes (O'Connor & Kenter, 2019). It entails conceiving non-human elements of the landscape as active co-agents in producing environmental, ecological, and social effects (Dürbeck, 2015).

In this context, storytelling (Bulkens, Minca & Muzaini, 2015) emerges as an act of world-making. It uncovers and communicates diverse narratives, values, and relations within the landscape, helping to interpret and actively shape our understanding of landscapes. Recognising storytelling as foundational to planning strategies, this research focuses on its potential to gather and celebrate both individual and collective narratives, not only from institutional actors and experts, but also from those who inhabit and interact with places in their everyday lives, including, in mediated ways, non-human beings. In a More-Than-Human approach, storytelling opens up the planning process to sensitive and relational forms of knowledge (Boros et al, 2024). Storytelling provides a lens through which we can interpret the interdependence between human beings, non-human life forms, and the material elements of a given territory.

Nowadays, storytelling has recently received a powerful boost through the rise of tools like Artificial Intelligence (AI). Among its many capabilities, AI offers innovative ways to represent narratives in more creative, immersive, and dynamic forms. By harnessing its diverse functionalities, AI opens new possibilities for reimagining how stories are told, understood, and shared. In this evolving scenario, the integration of AI with participatory approaches marks a significant shift (Birhane et al., 2022; Delgado et al., 2023; Sacco et al, 2023). New frontiers in AI research emphasise inclusivity, encouraging the integration of diverse perspectives into the design and development of AI systems (Arora, 2024) (Mauri et al, 2024). This fosters an environment that welcomes different voices, counter-narratives, and plural interpretations of complex issues.

Central to this approach is the recognition that identifying the topic, clarifying underlying conflicts, defining relevant data, and determining how to collect and interpret it are all crucial steps in the process. Problem Structuring Methods (PSMs) play a crucial role in this context. These methods are particularly valuable for engaging with the wicked nature of complex, multidimensional issues by supporting the definition of the initial decision problem (Christie 2023; Moallemi et al, 2023). Rather than seeking a single, definitive solution, PSMs aim to deepen our understanding of the problem by incorporating a range of viewpoints (Mingers & Rosenhead, 2004). They help uncover hidden dynamics and encourage the exploration of multiple interpretative lenses. The goal is not simplification, but rather the deliberate complexification of the context, observing it from various angles until the most appropriate framing or action can be chosen based on the specific circumstances (Rosenhead, 2006). At the heart of this study is the intention to explore how PSMs and AI can expand and operationalise a More-Than-Human approach to landscape knowledge and evaluation (Figure 1). Despite their potential, the integration of AI and PSMs remains an underexplored area. Only a limited number of scholars have ventured into this intersection (Sacco & Poli, 2024a), and this research project seeks to contribute to that emerging field.

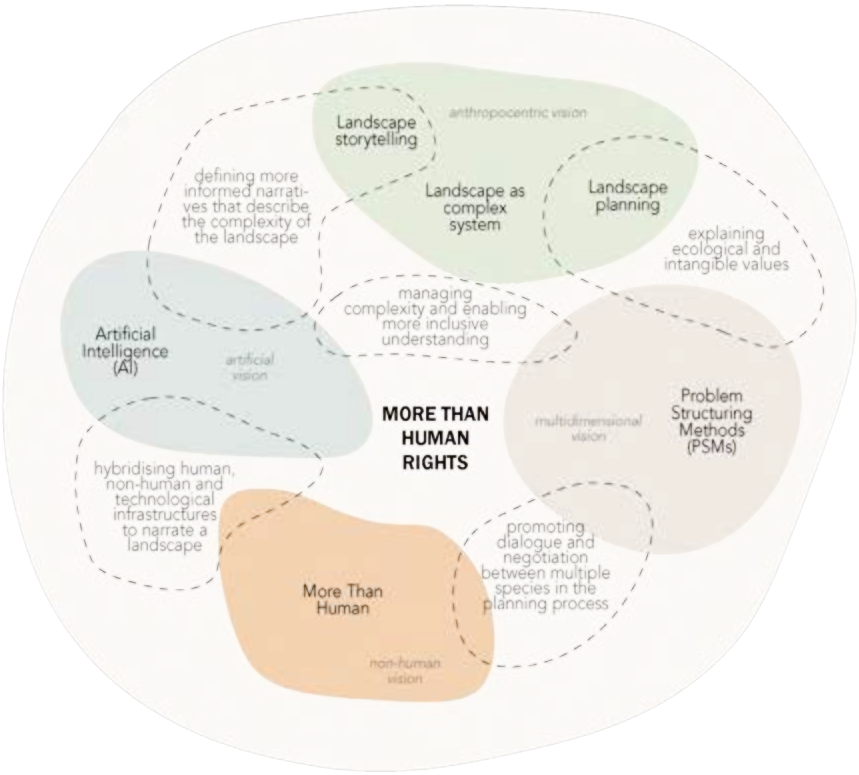

Figure 1: A More-Than-Human-Rights Framework

By doing so, it aspires to lay the foundation for a transformative shift in how landscapes are narrated, interpreted, and assessed, moving beyond anthropocentric paradigms and promoting a more relational and interconnected understanding of landscape complexity.

The concept of More-Than-Human-Rights (César Rodríguez-Garavito, 2024) offers a unifying lens through which to integrate AI, More-Than-Human perspectives, Problem Structuring Methods (PSMs), and landscape storytelling. It proposes a normative stance grounded in spatial justice and recognises the rights of non-human agents, such as ecosystems, species, and material entities, to shape and participate in the configuration of the landscape. This perspective calls for the construction of alternative, inclusive storylines. AI can play a critical role in co-producing these narratives by analysing, visualising, and amplifying overlooked voices and patterns. At the same time, PSMs offer methodological support to define the context: framing the issues, mapping conflicts, identifying actors (human and non-human), and exploring values. Together, AI and PSMs provide a powerful toolkit to foster more equitable and multispecies planning practices that reflect the true complexity of our shared environments.

The contribution is organised as follows: Section 2 delves into the exploration of the More-Than-Human approach and its interactions with AI and PSMs; in Section 3, the concept of More-Than-Human-Rights is introduced, with the aim of enhancing the relational and multispecies dimensions in decision-making processes. Section 4 presents the case study of Mussels Tales, in the Campi Flegrei area, to exemplify the concrete application of the discussed theories. Finally, the last Section envisions some conclusions and future perspectives of the research.

Toward a More-Than-Human Planning Practice

The More-Than-Human paradigm emerges as a critical response to the anthropocentric and dualistic epistemol-

ogies that have long dominated Western thought, particularly those that establish rigid separations between nature and culture, subject and object, human and non-human (Houston et al, 2018). Rooted in the work of Donna Haraway (1985) and developed across a range of interdisciplinary domains, including eco-critical theory, posthumanist philosophy, indigenous cosmologies, and science and technology studies (Daigle, 2022), the More-Than-Human paradigm offers a conceptual and ethical reorientation of how to understand life, agency, and planning. This paradigm should be understood as a pluralistic and generative field of inquiry that brings together a heterogeneous constellation of approaches. These approaches foreground the agency, vitality, and subjectivity of More-Than-Human actors (e.g. animals, plants, fungi, soils, waters, infrastructures, and technologies) as co-constitutive agents in the production of social and ecological realities (Dowling, 2016). Central to More-Than-Human thinking is the rejection of hierarchical ontologies. Posthumanist theorists, such as Manuel DeLanda, advocate for a "flat ontology" (Ash, 2020), in which all entities, regardless of their human or non-human status, possess the capacity to affect and be affected. This ontological flattening challenges landscape planning and design disciplines to reconsider how decisions are made and whose voices are included in the decision-making process. In parallel, Scott Gilbert's work on symbiotic biology (Gilbert, 2024) underscores the interdependent nature of life, highlighting that no organism exists in isolation; all beings are entangled in webs of mutual reliance and co-evolution. Within this expanded panorama, storytelling acquires critical epistemological and political significance (van Hulst, 2012). It is no longer merely a tool of representation, but a situated ecological practice, one that enables the articulation of lifeworlds, affective ties, and embodied knowledges often excluded from formal planning processes. Storytelling becomes an act of care, memory, and resistance (McDowell, 2022). It offers a means of reimagining landscapes through the eyes, experiences, and rhythms of both human and non-human actors. Haraway's (2016) notion of multispecies narratives invites scholars and practitioners to construct narratives that do not centre exclusively on the human subject but instead weave together the perspectives and agencies of other beings. These narrative forms challenge the reductive, technocratic, and often colonial gaze of mainstream spatial planning by foregrounding place-based, experiential, and affective knowledge systems. They contribute to what can be termed ecologies of attention (Ganteau, 2024), practices that cultivate attunement to the complex entanglements that constitute lived environments. These perspectives are deeply resonant with indigenous cosmologies, which have long upheld relational and reciprocal understandings of the world. Unlike the extractive logics of settler-colonial modernity, many indigenous traditions recognise the agency of rivers, mountains, animals, and ancestral territories (Acharibasam et al, 2024). Adopting this viewpoint on landscape means engaging in counter-narrative practices that resist the commodification of nature and promote alternative modes of knowing and dwelling. In this context, situated narrative techniques (Livholts, 2020) offer a means to express values that are often non-monetary and non-quantifiable, such as belonging, spirituality, affective attachment, and intergenerational memory, which are vital to sustaining the vitality of landscapes (Grieco et al, 2024). As such, situated narrative techniques become powerful tools in advancing a More-Than-Human approach to planning. They challenge anthropocentric logics and invite planners to engage with landscapes as relational fields shaped by diverse forms of life. Thus, narrative becomes a situated form of building planning process, capable of informing decision-making processes that are attentive to multispecies justice, grounded in place-based knowledges, and responsive to the complex web of ecological interdependencies. A More-Than-Human-informed planning practice shifts away from a model of designing for communities, implicitly human and often elite, toward a participatory, multispecies co-design process grounded in attentiveness, care, and relational responsibility. This entails not only listening to human voices but also developing methods and sensibilities for interpreting and incorporating the "voices" of rivers, animals, fungi, or even infrastructures. It calls for an expanded notion of participation that moves beyond stakeholder consultation to include More-Than-Human worlds as legitimate agents in shaping futures.

Entangling AI, PSMs, and More-Than-Human Worlds in Landscape Planning

If storytelling can be conceived as a critical method for activating More-Than-Human approaches to landscape planning, then the integration of Artificial Intelligence (AI) and Problem Structuring Methods (PSMs) offers a compelling horizon for expanding these practices. Both AI and PSMs operate at the interface of complexity, uncertainty, and pluralism, and as such, they present valuable tools for designing planning processes capable of acknowledging and engaging More-Than-Human entanglements. AI, broadly understood as the development of

computational systems capable of perceiving and acting upon their environments, has rapidly extended its role in both urban and landscape planning (Son et al, 2023). Applications include land-use optimisation, predictive modelling of urban growth, climate adaptation strategies, and the management of mobility systems (Fernberg & Chamberlain 2023). Advanced forms of AI, such as generative models, Natural Language Processing (NLP), geospatial AI (GeoAI), and computer vision, are increasingly capable of supporting new forms of landscape planning intelligence (Frazier & Song, 2024). These tools enable the extraction of patterns, the integration of heterogeneous data sources, and the simulation of possible futures. NLP allows for the interpretation of narratives embedded in texts, oral histories, and social media, surfacing perceptions, values, and emotions tied to place (Chowdhary, 2020). Generative AI can construct alternative scenario narratives, such as responses to climate-induced disruptions or species extinction. GeoAI and computer vision contribute to interpreting spatial data, landscape imagery, and acoustic biodiversity signals, offering powerful means to analyse cultural ecosystem services and non-human presence (Janowicz et al, 2023).

In parallel, PSMs offer a dialogical and participatory framework for navigating wicked problems, characterised by uncertain knowledge, conflicting values, and the impossibility of linear or optimal solutions. Rooted in systems thinking and operational research, PSMs, developed by Rosenhead (1996), Mingers and White (2010), Ackermann (2012), and Midgley et al. (2013), create space for multiple stakeholders to collectively construct models of shared understanding. PSMs are particularly effective in contexts where data is lacking, variables are multiple and interconnected, and solutions cannot be univocal or linear (Cerreta & De Toro, 2012). In the field of landscape planning, these conditions are commonplace. Particularly in landscape planning, where interests and ontologies often diverge, PSMs help mediate between competing definitions of the problem and facilitate inclusive, negotiated forms of action. When brought together, AI and PSMs can be seen as mutually reinforcing instruments for navigating complexity and enabling inclusive sense-making (Sacco & Poli, 2024b). AI provides analytical depth and the ability to model large-scale dynamics; PSMs ground those insights in situated deliberation, supporting ethical reflexivity and plural value negotiation.

Both have the potential to serve not only human stakeholders but, if reimagined, also More-Than-Human agencies, making visible the values, relations, and entanglements of non-human life forms that have historically been excluded from planning discourses. Nonetheless, both AI and PSMs are developed within anthropocentric knowledge systems and risk reproducing forms of reductionism or instrumentalisation. AI, in particular, can replicate human biases embedded in training data or overlook forms of knowledge that resist quantification (Aquino, 2023). Although PSMs are open to a plurality of perspectives, they are still methods designed by and for humans, which carries the implicit risk of reducing non-human agency to a mere instrument for anthropocentric purposes (Kim, 2020). Addressing these limitations requires a shift in how these tools are conceptualised and used within planning practice. An ethical approach is needed that considers privacy, landscape impacts and shared responsibility between human and non-human actors (Papagiannidis, Mikalef & Conboy, 2025). Reimagining AI through a More-Than-Human lens means going beyond simulation and optimisation toward forms of technological mediation that recognise non-human entities (Hupont et al, 2024), rivers, pollinators, mycelial networks, and atmospheric systems, as agents with communicative potential. AI models could be trained not only to detect ecological changes but to translate them into relational signals that carry meaning within planning processes. Generative AI, for instance, might be employed to construct multispecies narratives, grounded in ecological data and enriched with speculative imagination, to render visible the co-presence and co-dependence of multiple life forms (Arif, et al, 2020). In parallel, PSMs could be extended to facilitate multispecies dialogue, using techniques that map not just human concerns but also the values, needs, and vulnerabilities of non-human actors. Through various and innovative approaches (proxies, sensors, bioindicators, and artistic methods), More-Than-Human entities can be positioned as participants in planning conversations. These adaptations challenge the boundary between knowledge and ethics, opening planning to interspecies negotiation (Lopez et al., 2025).

Advancing toward a More-Than-Human planning paradigm necessitates the development of participatory, hybrid processes that weave together the analytical power of AI with the ethical reflexivity, interpretive depth, and speculative imagination offered by PSMs and narrative methodologies. The objective is to cultivate relational

intelligence and ecological ethics, including values of kinship, responsibility, reciprocity, and care (Tran et al, 2024). This convergence of AI, PSMs, and More-Than-Human thought confronts a profound question: How can planning tools encode and respond to the ethical demands of more-than-human life? What forms of representation, narration, and decision-making can support coexistence and mutual flourishing across species boundaries?

Addressing these questions calls for a radical reorientation of planning imagination, one that acknowledges that landscapes are not passive spaces to be managed, but living, contested, and co-produced territories shaped by many kinds of intelligence.

More-Than-Human-Rights: A Legal-Ecological Framework for AI and PSMs Integration

The concept of More-Than-Human-Rights (Rodríguez-Garavito, 2024) provides a powerful framework for integrating the technical capacities of AI and the deliberative structures of PSMs within a shared ethical and political horizon. While these tools originate from different epistemological traditions, AI from computational logic and automation, PSMs from participatory systems thinking, they can be productively aligned through the lens of More-Than-Human-Rights, which demands new forms of representation, recognition, and responsibility for non-human entities in decision-making processes.

In this light, More-Than-Human-Rights becomes the normative glue that binds AI and PSMs into a shared project of interspecies justice (Celermajer et al, 2021). AI contributes the capacity to sense, model, and simulate More-Than-Human presence, detecting patterns and generating data-rich ecological narratives. PSMs, in turn, provide the scaffolding for structuring dialogue, negotiating values, and legitimising decisions in a pluralistic context. Together, under the umbrella of More-Than-Human-Rights, these approaches constitute a hybrid planning toolkit for the Anthropocene, one in which non-human life is not only ethically acknowledged but legally and methodologically integrated into landscape governance. This shift in perspective responds to a growing recognition in recent decades that dominant legal frameworks, centred on individual rights and anthropocentric assumptions, are insufficient for addressing ecological crises (Fukurai & Krooth, 2021).

As emphasised by environmental scholars and legal theorists (Fensterseifer et al, 2024), there is a pressing need to advance a conception of rights grounded in relational responsibility and ecological interdependence. More-Than-Human-Rights proposes an expansion of legal standing to include non-human entities as subjects of rights. As César Rodríguez-Garavito, founder of the More Than Human Life - MOTH project (Rodríguez-Garavito, 2024), notes, the emphasis must move beyond the static "Rights of Nature" to a more dynamic and reciprocal framework that foregrounds human-nonhuman entanglement (Gilbert et al, 2023).

Several legal developments across the globe reflect this emerging paradigm. Ecuador's 2008 Constitution enshrines the rights of Pachamama to exist, persist, and regenerate its vital cycles (Berros, 2015). Bolivia's Law on the Rights of Mother Earth defines nature as a "collective subject of public interest", establishing legal recognition for ecosystems (International Rights of Nature Tribunal, 2020). In New Zealand, the Te Urewera forest and Whanganui River have been granted legal personhood through bicultural legal arrangements that draw from Māori worldviews, which see these landscapes as living ancestors (Bieluk, 2020). In Europe, Spain's Mar Menor lagoon became the first European ecosystem to receive legal personality, following a citizen-led initiative that involved over 500,000 people (Krämer, 2023). The new law recognises the lagoon's rights to exist, evolve, and be restored, and establishes a participatory governance model involving institutions, civil society, and scientists.

These examples signal a shift in legal consciousness: from viewing the landscape as a passive stage for human activity to acknowledging it as a legal-ecological commons, a co-produced and shared domain of rights, responsibilities, and care (Pelizzon, 2023). This reframing raises critical questions about representation: who is entitled to speak for trees, rivers and mushrooms?

In New Zealand, representation is entrusted to bicultural governance bodies reflecting Indigenous knowledge

(Stewart, 2018). Elsewhere, theorists such as Klaus Bosselmann (Bosselmann, 2021) have advocated for "ecological guardians" or "trustees" to act on behalf of planetary commons, potentially under the auspices of the United Nations. The UN's Harmony with Nature programme (Assembly, 2010), launched in 2009, embodies this ambition by promoting Earth Jurisprudence (Cullinan, 2023) and supporting legal recognition for Nature and the establishment of a new governance system to protect common goods.

In this context, More-Than-Human-Rights opens a conceptual space in which AI and PSMs can converge, encouraging a new interpretative approach to the landscape, leading to alternative and plural descriptions and promoting more inclusive and responsible landscape planning. AI tools can act as mediators of non-human signals, interpreting forest acoustics, soil conditions, or hydrological patterns and translating them into meaningful inputs for governance (Alotaibi & Nassif, 2024). These computational insights, while powerful, gain full relevance when embedded within PSM-based participatory processes that facilitate dialogue, deliberation, and value negotiation across diverse human and non-human actors.

By adopting More-Than-Human-Right as a guiding logic, it is possible to move from purely advocacy-driven approaches to speculative and systemic forms of governance, ones capable of representing not only human interests but also multispecies concerns.

To explore how this framework might unfold in practice, the following section presents an experimental workshop designed to examine whether, and how, such a process can support deliberation on multispecies justice and ecological responsibility. It illustrates how the concept of More-Than-Human Rights can inform the co-design of more inclusive landscape storytelling practices.

Mytilus in Fabula: a More-Than-Human Rights Workshop in Bacoli

The Mussels Tales design research laboratory, part of the PNRR CHANGES project (Cultural Heritage Active Innovation for a Next Generation Sustainable Society), is promoted by the Department of Architecture (DIARC) at the University of Naples Federico II. It aims to develop innovative methodologies for enhancing cultural heritage in the Campi Flegrei area, an ecologically, geologically, and culturally significant landscape. Mussels Tales explores generative, relational, and sustainable approaches to historic productive landscapes. Rather than treating the landscape as a passive backdrop or monument, it is framed as a living, open system shaped by ecological, historical, and design processes.

The project focuses on the Fusaro area, specifically the Borbonico Park, the Casina Vanvitelliana, and the Cassone, an ancient mussel storage facility now in ruins. These sites will be temporarily reactivated through a site-specific artistic installation, conceived as a relational device to host public activities, workshops, and collaborative explorations.

One of the initiatives, part of this laboratory, is an experiential, participatory activity titled Mytilus in Fabula, grounded in a More-Than-Human Rights perspective. This approach recognises landscapes as dynamic ecosystems composed of interdependent human and non-human agents. The activity uses PSMs, such as collective mapping, identity-based role-play, and co-creation, to frame complex territorial issues and stimulate inclusive dialogue. Participants engage in an exploratory walk along Lake Fusaro, designed as a game of impersonation. Each participant receives a character card, generated with the aid of AI, that assigns them the identity of an agent within the ecosystem (e.g., mussels, fish, birds, plants, or even pollutants like plastic). These cards help reveal the relational logic of the environment, encouraging participants to explore the lake's diverse habitats: urban, lakefront, coastal, and woodland, through the eyes of their assigned agent. As they walk from the Casina Vanvitelliana to the Cassone, participants collect signs, traces, and observations tied to their agent's habitat. Without revealing their identity, they contribute clues that support a shared reconstruction of the local ecosystem. This final co-creation moment, held at the Cassone, becomes a decision-support platform, allowing the group to visually and narratively model the network of relationships and tensions at play.

By combining AI-generated identities with participatory PSMs, the activity helps translate the abstract notion of More-Than-Human-Rights into a tangible process of collective sense-making. It foregrounds the perspectives of non-human entities and reframes landscape storytelling as a pluralistic, equitable process. Moreover, the workshop format fosters awareness, empathy, and responsibility toward all forms of life, human and non-human, while broadening civic engagement in environmental governance. In this way, Mytilus in Fabula transforms the More-Than-Human Rights framework into operational practice, opening up space for more inclusive, relational, and responsive ways of caring for contemporary landscapes.

Conclusions

This research highlights the urgent need for a radical transformation in how landscapes are narrated, interpreted, and valued, calling for a shift away from anthropocentric paradigms and towards a more relational, multispecies, and interdependent worldview.

By embedding AI and PSMs into the design of participatory activities, the More-Than-Human-Right framework encourages new modes of representation and imaginative identification with non-human entities, thereby deepening ecological awareness. This complex framework invites planners and researchers to reconsider their practices, not just by integrating more complex data, but by actively listening to the "voices" of multiple beings and by rethinking what counts as knowledge, agency, and justice in territorial governance. Such a framework not only redefines methodological tools; it also demands a new human sensibility, an openness to perceiving and cohabiting change with care.

The Campi Flegrei case study embodies this methodological synthesis: here, human perspectives are intentionally reframed in favour of non-human points of view, paying attention to the relational dynamics that foster collective intelligence across species and material forms. In the Campi Flegrei context, the Mytilus in Fabula initiative provides a concrete case of how participatory and AI-enhanced storytelling can converge to reveal neglected ecological relationships. It proposes an expanded conception of landscape as a site of ecological entanglements, rather than as a neutral or passive backdrop for human activity. The operationalisation of a More-Than-Human Rights framework calls for a rethinking of the planner's role, from that of a neutral technician to an ecological mediator capable of navigating affective, historical, and multispecies relationships. In this view, the landscape is interpreted as a web of memories, conflicts, and co-evolving dynamics.

However, translating this framework into practice faces several significant challenges. One central issue is the representation of non-human entities: how can planners and designers include these agents without reducing them to simplistic symbols or anthropomorphic caricatures? There is also the deeper difficulty of translating this conceptual richness into institutional practice, given that current regulatory and planning frameworks are deeply rooted in human exceptionalism and often lack the cultural and legal tools needed for recognising non-human agency. Moreover, the inclusion of More-Than-Human perspectives raises questions about voice, translation, and legitimacy: how can their needs and rhythms be made legible within decision-making systems structured around human priorities?

Addressing these questions requires a profound recalibration of what participation means in planning. It demands that we go beyond human-centred consultation and representation, instead developing systems that can sense, interpret, and respond to the expressions of non-human life. Here, PSMs offer participatory and iterative frameworks capable of dealing with the messy, uncertain, and pluralistic nature of planning in ecologically entangled worlds. When expanded to incorporate non-human considerations, PSMs can help reframe planning problems to include ecological limits, multispecies dependencies, and non-verbal forms of expression. By synthesising large-scale datasets and simulating potential futures, AI can help planners and communities explore alternative scenarios that centre ecological integrity and multispecies justice. These tools allow for more dynamic storytelling practices, where landscapes are not merely planned or managed but narrated through the interactions, rhythms, and histories of human and non-human actors alike.

Crucially, this shift could reorient global planning frameworks, such as the 2030 Agenda and the Sustainable Development Goals, away from instrumental logics and toward a recognition of non-human entities as co-inhabitants and co-authors of spatial futures. It reframes planning not as a tool for managing nature, but as an ethical and creative process of co-existence, one that acknowledges the agency of all life forms and the entanglement of human wellbeing with planetary vitality.

In conclusion, adopting a More-Than-Human lens invites us to reimagine planning as a cultural and ethical practice of listening, interpreting, and co-creating with the More-Than-Human world. It proposes new politics and poetics of landscape, ones grounded in relationality, care, and multispecies coexistence, and committed to recognising the rights, needs, and contributions of all beings, defining some innovative perspectives on landscape planning.

Acknowledgements
This work is the result of a collaborative effort between the authors. BG developed the theoretical framework related to the More-Than-Human and More-Than-Human Rights paradigm applied to landscape planning and storytelling, while SS focused on the methodological integration of Artificial Intelligence and Problem Structuring Methods within a More-Than-Human perspective. The section on the case study "Mytilus in Fabula" and the final reflections were co-authored by B.G. and S.S. M.C. provided overall supervision and critical guidance throughout the research development. All authors contributed to the final revision of the manuscript.

"Mytilus in Fabula" is an initiative curated by B. Grieco, C. Loffredo, C. Priore, L. La Rocca, S. Sacco and S. Ventre. It was organised as part of the "Mussels Tales - I paesaggi della mitilicoltura a Bacoli" design research laboratory, promoted by the Department of Architecture (DiARC) at the University of Naples Federico II. The event took place in June 2025 in Bacoli, within the framework of Work Package 4 (WP4) of the PNRR CHANGES Spoke 1 - Historical Landscapes, Traditions and Cultural Identities (Scientific Coordinator: M. Russo, Project Code MUR: PE00000020 – CUP E53C22001650006), and was curated by M. Ascolese and F. Casalbordino.

Assessing Climate Change Adaptability and Risk in Italian Territories Using Open Data

Ozge Ogut, Benedetta Cavalieri, Elisa Conticelli, Giulia Marzani, Claudia de Luca
Department of Architecture (DA), University of Bologna (UNIBO)
ozge.ogut2@unibo.it

Abstract
This study evaluates climate adaptability and risk across Italy using two open-data-based indices: the Climate Change Adaptability Index (CCAI) and the Climate Change Risk Index (CCRI). The CCAI measures resilience by balancing climate exposure (e.g., heatwaves, droughts) with adaptive capacity indicators (e.g., tree cover, soil permeability). The CCRI combines similar climate hazards with socio-economic vulnerability. Results reveal strong regional disparities as northern Italy shows greater adaptability, while southern regions face heightened risk. The territorial disparities are visible as well since inner and peripheral areas consistently exhibit lower adaptability and higher risk, while intermediate and metropolitan zones show more mixed profiles. This dual-index approach integrates environmental and socio-economic dimensions, offering a replicable method for territorial assessments. Findings show the value of open data and cross-sectoral governance for guiding sustainable, resilient urban and regional adaptation policies.

Keywords: Climate change adaptability, climate change risk, territorial sustainability, open data, Italy

1. Introduction

1.1. Territorial challenges of climate risk and adaptability

Italy's geographical diversity and socio-economic disparities led to an uneven territorial exposure and responsiveness to climate risks (CMCC and Enel Foundation, 2021). These risks are accelerated by global climate change, particularly within the Mediterranean Basin, identified as one of the most climate-sensitive areas globally (Medri *et al.*, 2013)

Temperature increases and hydrological stress are key climate threats. Projections indicate a potential +5°C rise in average temperature by 2100 under high-emission scenarios (Representative Concentration Pathway, RCP8.5 (Riahi *et al.*, 2007), with corresponding increases in hot and dry days and the intensification of heatwaves and droughts, especially in southern Italy and small islands. Precipitation patterns are expected to become more erratic, but the trend underlines a general increase of the intensity of rainfalls both in the North and South of Italy and seasonal declines more pronounced in central-southern Italy during summer and increased rainfall in northern regions during winter. These changes exacerbate Italy's already stressed water resources, particularly during summer months when demand from agriculture, industry, energy, and tourism peaks (Spano D., 2020).

These changes in the climate conditions also worsen the hydrogeological risks affecting Italy's territory, particularly vulnerable to geo-hydrological instability, including floods, landslides, and soil erosion. Approximately 91% of Italian municipalities are already exposed to this kind of hazards, and 94% are classified as at risk because of both natural and anthropogenic factors (Spano D., 2020). The increasing frequency of short, intense rainfall events makes the instability of fragile areas worse, especially in the Alpine and Apennine regions (CMCC and Enel Foundation, 2021).

Exposure is another key challenge. Italy is one of the most exposed countries in Europe to flood-related hazards with potential infrastructure losses ranging from €1.5 to €15.2 billion annually under high-emission climate scenarios in the period 2071-2100. (Spano D., 2020). Sea-level rise further threatens coastal zones, particularly in the northern Adriatic, while critical sectors such as agriculture and tourism face declining productivity and revenue due to shifting climate conditions (Medri *et al.*, 2013).

The evolving concept of territorial resilience, as proposed by Brunetta et al. (2019), emphasizes a proactive, integrated, and co-evolutionary approach to spatial planning. It advocates for a shift from reactive risk mitigation to adaptive strategies that incorporate socio-ecological and technological systems (SETS), focusing not only on physical robustness but also on institutional capacity, social learning, and cultural assets (Brunetta *et al.*, 2019).

In this context, there is a growing need for more informed planning approaches that integrate data-driven tools to support climate risk mitigation. Such methods are essential for identifying vulnerable areas, prioritizing interventions, and guiding territorial policies that are responsive to evolving environmental pressures.

These territorial and climatic challenges must also be viewed through the lens of vulnerability and risk theory. According to the IPCC (Intergovernmental Panel on Climate Change (IPCC), 2023), vulnerability encompasses exposure, sensitivity, and adaptive capacity, combining both external pressures and internal system characteristics. According to Füssel and Klein (Füssel and Klein, 2006), exposure refers to the extent of hazard contact, while sensitivity and adaptive capacity define a system's ability to respond. Evolving assessment frameworks (Bruno Soares *et al.*, 2012; Peng *et al.*, 2024) increasingly adopt integrated approaches that consider both socio-economic and ecological dimensions. This study aligns with this perspective, emphasizing the need to address both environmental stressors and social fragilities when assessing territorial climate resilience.

1.2. Role of Open Data in climate assessment

Open data plays an increasingly vital role in climate assessment by enhancing the transparency, replicability, and scale of data-driven analyses. In the context of climate change, especially for countries like Italy with strong regional variability, open data enables localized, evidence-based planning while fostering participatory and inclusive decision-making (Grinspan and Worker, 2021).

Beyond their analytical power, open data initiatives support democratic and cross-sectoral engagement. They allow various actors, e.g., planners, researchers, NGOs, and local authorities, to interpret, validate, and reuse the data for both policy and advocacy purposes (Open Governmental Partnership, 2024). Initiatives like OS-Climate, the Net-Zero Data Public Utility, and Dataland have demonstrated how neutral and collaborative data platforms can fill information gaps while reducing reliance on proprietary datasets (United Nations Environment Programme, 2024). This kind of platforms promote integrity, accessibility, and neutrality along with values essential for effective climate governance.

Despite the big potential of open access dataset for describing climate conditions and trends, their accessibility and usability can be lacking for non-experts. Moreover, the comparison of environmental data with other context-related conditions, such as socio-economic and infrastructural ones, may be relevant for taking comprehensive and informed decisions, based on the development of composite indices able to interrelate data from these different domains. Open-access datasets allow for the integration of environmental, socio-economic, and infrastructural information, which is essential for developing composite indices like in this contribution.

1.3. Aims and objectives

This study aims to develop a national-scale, open-data-based framework to assess climate change adaptability and risk across Italian territories. By utilizing datasets that are publicly accessible and easy to use for decision makers, researchers, as well as other professions who takes role in planning, we construct and apply two composite indices i.e., the Climate Change Adaptability Index (CCAI) and the Climate Change Risk Index (CCRI) to support spatialized, evidence-based planning. These indices were developed in a broader study under the framework of the GRINS (Growing Resilient, Inclusive and Sustainable) project, financed by the National Recovery and Resilience Plan (NRRP) in Italy. The objective is to identify regional and territorial patterns of exposure to climate-related hazards and adaptive capacity in order to underline climatic vulnerabilities that also consider other context-re-

lated variables, with the final aim of informing policy responses and prioritize place-based strategies.

More broadly, the study seeks to demonstrate how open data can be effectively operationalized in climate assessment, highlighting both the analytical potential and the structural limitations of this approach. In this framework, the research outcomes contribute to ongoing discussions on transparent, scalable methodologies for climate adaptation and territorial resilience planning.

The paper is structured as follows. Section 2 presents the materials and methods, including the GRINS main features and aims, open data sources, and the construction of the two composite indices i.e., CCAI and CCRI. Section 3 discusses the main results through a territorial lens, highlighting patterns of adaptability and risk across macro and micro typologies. It also includes a cross-index analysis to synthesize findings and identify most vulnerable areas related to climate conditions. The paper concludes by reflecting on the methodological strengths and limitations of the approach, emphasizing the value of open data in supporting spatially informed climate adaptation strategies.

2. Material and Methods

This study adopts a composite index approach to assess climate change adaptability and risk by integrating climate-related and socio-economic indicators. Moving from theoretical and empirical literature (Papathoma-Koehle *et al.*, 2016; Zhao *et al.*, 2020) key variables were identified that reflect either increased fragility (or risk) or adaptive capacity. Indicators such as temperature anomalies, duration of hot periods, and consecutive dry days capture exposure to climate hazards, while permeable soils and vegetation cover represent adaptive assets (Carter, 2018). Socio-economic conditions further influence local vulnerabilities and are embedded in the composite framework. The following subsections detail the taxonomy adopted (Section 2.1), open data sources and indicators (Section 2.2), and the structure of the indices (Sections 2.3 and 2.4).

2.1. Territorial classification developed in GRINS project

The project GRINS (Growing Resilient, Inclusive and Sustainable) (GRINS Foundation, n.d.) is part of an extended partnership funded under the National Recovery and Resilience Plan (Piano Nazionale di Ripresa e Resilienza, PNRR) by the Italian government and the European Union. It aims to create an open-access data platform supporting economic and financial sustainability of territories through research, policy analysis, and evaluation. GRINS is composed by nine spokes, conceived as sub-domains dedicated to address specific topics and produce related data. The present work was developed under Spoke 7 - Territorial sustainability, which aims to investigate and assess territorial disparities, vulnerabilities and gaps to orient more effective policies and actions.

Within Spoke 7 one important analytical output was the development of the "GRINS taxonomy", a methodological approach aimed at classifying Italian territories based on their functional and spatial characteristics. This taxonomy is developed by integrating multiple classification systems, including the National Strategy for Inner Areas (Strategia Nazionale per le Aree Interne,SNAI), the classification of metropolitan areas produced by the National Institute of Statistics (ISTAT), and the OECD Functional Urban Areas (FUAs) framework (Caramaschi *et al.*, 2024). The methodology used the municipal classification dataset of all Italian municipalities provided by ISTAT, which comprises population density and territorial boundaries, for dividing the municipalities into three main macro-classes as follows (see Figure 1a):

1. Inner Italy (Italia Interna), representing peripheral and ultra-peripheral areas identified by elaborating and enriching the National classification of inner areas given by SNAI (2014 and 2020).
2. Intermediate Italy (Italia di Mezzo), which encompasses territories that fall between inner and metropolitan areas. These include medium-sized cities, metropolitan fringes, and urban-rural continua.
3. Metropolitan Italy (Italia Metropolitana), including municipalities that are part of metropolitan areas or classified as Functional Urban Areas (FUAs).

Beyond these three macro-classes, the GRINS taxonomy foresees thirteen distinct sub-classes across the three

macro-classes (see Figure 1b), providing a nuanced understanding of specific territorial differences and dynamics. These include:

- **Inner Italy**: 1.1.1 Inner, remote and sparsely populated area; 1.1.2 Inner and remote area with medium population density; 1.2.1 Sparsely populated inner area closest to a metropolitan area; 1.2.2 Inner area with medium population density closest to a metropolitan area.
- **Intermediate Italy**: 2.1.1.1 Sparsely populated mountain/inland hill urban-rural continuum; 2.1.1.2 Mountain/inland hill urban-rural continuum with medium population density; 2.1.2.1 Sparsely populated coastal and/or lowland urban-rural continuum; 2.1.2.2 Coastal and/or plain urban-rural continuum with medium population density; 2.2 Medium-sized city or non-FUA capital; 2.3 De facto or de jure metropolitan fringe.
- **Metropolitan Italy**: 3.1.1 De facto metropolitan centre; 3.2.1 De jure and de facto metropolitan area (not capital); 3.2.2 Metropolitan capital.

This classification system serves as the foundation for identifying socio-economic and environmental vulnerabilities, including climatic vulnerability, covering the whole Italian territory but providing data at municipal scale and across the different territorial classes. The final goal is to ease the definition of targeted territorial policies and sustainable development strategies.

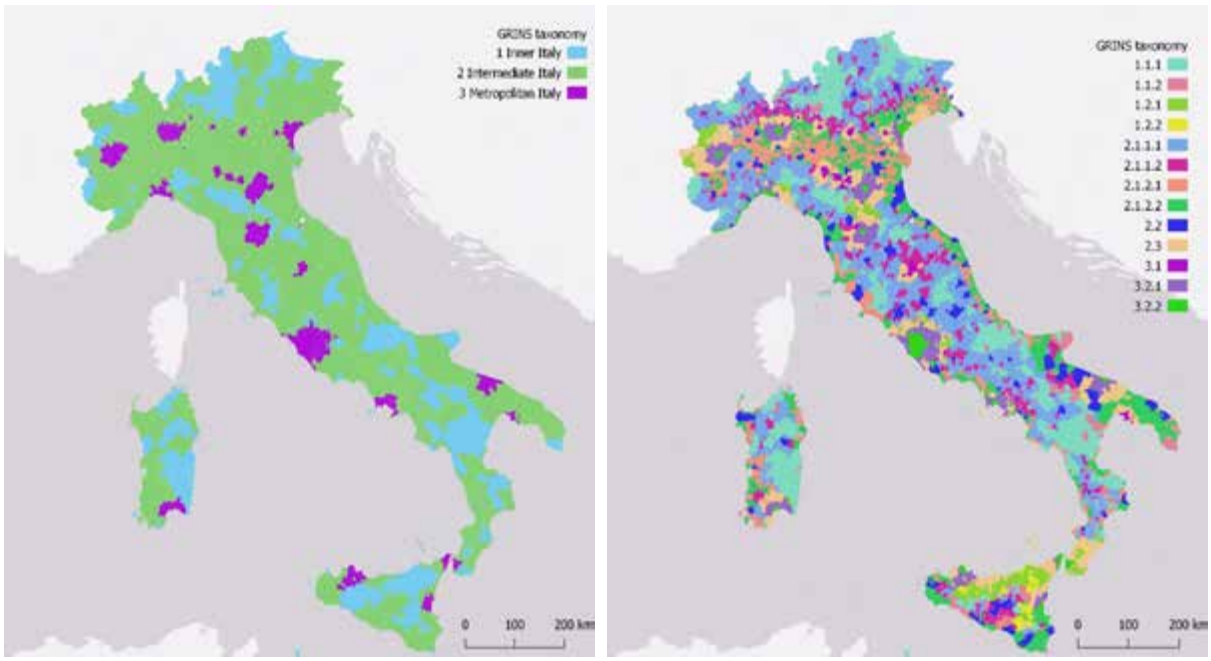

Figure 1. Taxonomy of Italian municipalities, developed within the GRINS project. (a) macro classes and (b) micro-classes. The classification system distinguishes three macro territorial categories (Inner, Intermediate, and Metropolitan Italy) and 13 micro-classes (produced after (Caramaschi *et al.*, 2024))

2.2. **Open Data Sources and indicator Selection**

The construction of both composite indices, i.e., CCAI and CCRI, relied on the selection of key indicators that are accessible, spatially detailed, and relevant to climate-related exposure, adaptive capacity, and socio-economic vulnerability. In order to develop robust and replicable indices, open datasets are prioritized with national coverage and adequate spatial granularity, preferably at the municipal (LAU) or provincial (NUTS3) level.

To ensure consistency and comparability, all data were pre-processed and harmonized. This involved normalization, imputation of missing values, and alignment of temporal and spatial resolutions. While most socio-economic indicators were available at the municipal level through ISTAT (Italian National Institute of Statistics), climate variables required further adaptation, often drawing from higher-resolution grid or provincial-level data.

The initial step was to identify the data needed and seek for the data sources. The most relevant datasets are identified ensuring high spatial and temporal resolution (see Tables 1 and 2) were sourced from national and international open databases including:
- ISTAT (Italian National Institute of Statistics): comprising many datasets for describing socio-economic data, including population density and income levels.
- Copernicus Climate Change Service: Climate-related variables, including temperature trends, heatwave duration, and precipitation data.
- EDJNet (European Data Journalism Network, i.e., a network of media organisations from across Europe, producing and promoting data-driven coverage of European issues, including environmental datasets): Surface temperature map of each municipality.

The sources of each datum, both temporal and territorial coverages, are provided in Tables 1 and 2.

While open data provides a transparent and accessible foundation for territorial analysis, their use introduces certain methodological considerations that required adaptation. The availability and quality of data were not uniform across all indicators and regions. For instance, some datasets, particularly climate variables like temperature trends and heatwave duration, were available at a high spatial resolution (provincial or grid-based), while socio-economic data from ISTAT often had a finer municipal-level granularity.

To address these challenges, the methodology was adapted by employing harmonization techniques to align indicators with differing spatial and temporal resolutions. For variables lacking high-resolution data, provincial-level indicators were aggregated or downscaled as proxies to ensure consistency within the composite indices. Despite these limitations, reliance on open data remains essential for fostering replicable and inclusive research.

2.3. **Climate Change Adaptability Index (CCAI)**

CCAI aims to provide a general measure of the level of response of environmental/anthropogenic factors to climate effects affecting a given territory, by adopting a balanced assessment between factors that are positive for adaptation to climate change and factors that hamper adaptation. The index has been calculated by considering the previous works (i.e., (Assumma *et al.*, 2019; Brunetta *et al.*, 2018) which was transposed in the climate domain, by considering indicators provided by different sources. Basically, the adopted method aims at calculating two synthetic indexes that respectively measure the exposure (E) of the socio-ecological system, and its adaptive capacity (A) by adopting a general perspective. This means considering climatic factors that might influence different spheres, such as the environment as well as the society. The index does not aim at being totally exhaustive in terms of indicators adopted (whose selection is influenced by data availability), however it is a valuable tentative to synthesize any vulnerabilities that can be further investigated.

Table 1. Indicators used to construct the Climate Change Adaptability Index (CCAI), including temporal and territorial coverage, units of measurement, and data sources. The composite index (I.1) is calculated based on five indicators (I.1.1–I.1.5).

Index	Code	Indicator Name	Temporal Coverage	Territorial Coverage	Unit	Data Source
1 CCAI	I.1.1	Consecutive days without rain	2021	Provincial (NUTS3)	n of days	ISTAT
	I.1.2	Duration of hot periods	2021	Provincial (NUTS3)	n of days	ISTAT
	I.1.3	Average temperature increase (1960-2018)	2018	Municipal (LAU)	°C	EDJNet
	I.1.4	Tree canopy density	2018	Municipal (LAU)	%	COPERNICUS
	I.1.5	Permeability	2018	Municipal (LAU)	%	COPERNICUS

The exposure component (E) is derived from the normalized values taking the municipal scale as base to have values between 0 and 1 of following indicators:

- **1.1 Consecutive days without rain**, i.e., maximum number of consecutive days in the year with daily rainfall less than or equal to 1 mm.
- **1.2 Duration of hot periods**, i.e., number of days in the year in which the maximum temperature is above the 90th percentile of the distribution in reference climatological period (1981-2010), for at least six consecutive days.
- **1.3 Average temperature increase from 1960 to 2018**, i.e., temperature variation occurred between the mean temperature values for the two decades considered (1961-1970 and 2009-2018).

The adaptive capacity component (A) is calculated from the normalized values of followings:
- **1.4 Tree canopy density**, i.e., tree cover density represents the percentage of a surface area covered by trees and vegetation in relation to the total surface area.
- **1.5 Permeability mean percentage value of permeable surfaces in a given area**, i.e., calculated by considering the complementary percentage of imperviousness provided by the HRL Copernicus dataset Imperviousness density.

CCAI, is calculated following the Equation through combining these two indexes:

$$CCAI = (A - E) / (A + E)$$

Positive values mean a prevalence of A; negative values mean a prevalence of E. Consequently, the more the negative value, the high the vulnerability.

2.4. **Climate Change Risk Index (CCRI)**
The Climate Change Risk Index (CCRI) captures the intersection of climate hazards and socio-economic vulnerability, highlighting regions where fragile socio-economic conditions are most impacted by increasing climatic extremes. As already anticipated climate risk is a combination of local hazards, exposure, and vulnerability and drought and warming represent the most critical challenges in Italy (Papathoma-Koehle *et al.*, 2016; Zhao *et al.*, 2020).

Therefore, the Climate Change Risk Index (CCRI) integrates exposure to those two climate-related hazards with socio-economic vulnerability to assess the overall risk faced by different territories. While CCAI aims to assess the above-mentioned climate hazards in relation to the adaptation response present in different contexts, CCRI aims to compare the climate hazards with the socio-economic vulnerability, in order to underline how the socioeconomic sphere is at risk in terms of climate change hazards. Therefore, climate change risk index indicates how much climate change hazards impact the socio-economic sphere of the territory, highlighting situations of greater risk and therefore more fragile situations. The index is calculated by averaging the combined exposure indicators with the socio-economic vulnerability index (SEVI), a composite indicator that captures the underlying susceptibility of communities to these hazards.

Table 2. Indicators used to construct the Climate Change Risk Index (CCRI), including temporal and territorial coverage, units of measurement, and data sources. The composite index (I.2) is based on three climatic stress indicators and one socio-economic vulnerability index (SEVI) (I.2.1–I.2.4).

Index	Code	Indicator Name	Temporal Coverage	Territorial Coverage	Unit	Data Source
2 CCRI	I.2.1	Consecutive days without rain	2021	Provincial (NUTS3)	n of days	ISTAT
	I.2.2	Duration of hot periods	2021	Provincial (NUTS3)	n of days	ISTAT
	I.2.3	Average temperature increase from 1960 to 2018	2018	Municipal (LAU)	°C	EDJNet
	I.2.4	Socio-economic vulnerability index (SEVI)	2019/2022	Municipal (LAU)	NA	Authors' elaboration

Formally, the index considers three exposure indicators and the socio-economic vulnerability index:
- **2.1 Consecutive Days Without Rain i.e.,** the maximum number of consecutive days in a year during which daily rainfall is less than or equal to 1 mm. Longer dry spells increase the exposure to drought conditions, impacting water availability and agriculture, and thus elevating climate risk.
- **2.2 Duration of Hot Periods, i.e.,** the number of days in a year where the maximum temperature exceeds the 90th percentile of the baseline climatological period (1981–2010) for at least six consecutive days. Prolonged heatwaves intensify exposure to extreme heat, posing threats to human health, infrastructure, and ecosystems.
- **2.3 Average Temperature Increase from 1960 to 2008, i.e.,** measures the **temperature variation** between two reference decades (1961–1970 and 2009–2018). An increase in average temperature signifies long-term warming trends, contributing to heightened exposure to climate-related hazards such as heat stress and altered precipitation patterns.
2.4 Socio-economic vulnerability index (SEVI), a composite indicator developed by the authors to capture territorial socio-economic fragility. It is calculated as the weighted average of four normalized variables: (1) old-age dependency ratio, (2) gross available income per capita, (3) employment rate (age 20–64), and (4) education level (lower secondary school attainment).

The result provides a comprehensive measure of the overall climate change risk, highlighting areas where climatic extremes intersect with fragile socio-economic conditions.

3. Results and Discussion

3.1. Climate Change Adaptability Index (CCAI)

The Climate Change Adaptability Index (CCAI) provides a measure of territorial resilience by balancing exposure to climate risks with the adaptive capacity. The results reveal significant disparities in adaptability across the national territory, with clear differences between northern and southern Italy, also confirming what was found in another recent study (Medri *et al.*, 2013).

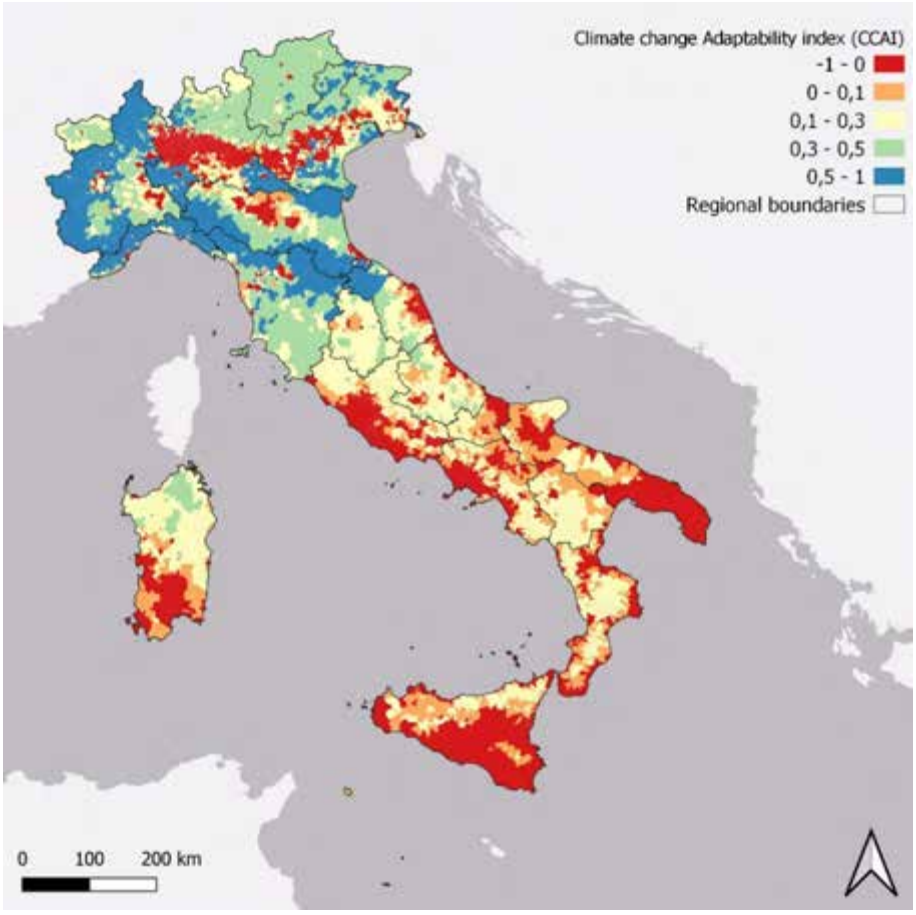

Figure 2. Climate change adaptability index (CCAI) across Italy. Higher index values indicate stronger natural and infrastructural capacity to buffer climate stress, particularly visible in northern and mountainous regions. Lower scores in southern and urbanized areas reflect limited adaptive assets and higher exposure to climatic hazards.

The spatial distribution of the CCAI scores, as presented in Figure 2, shows a clear contrast between northern and southern Italy. On one hand, territories with higher scores, primarily located in northern regions, exhibit favourable conditions such as dense tree canopy coverage and high soil permeability, which enhance natural climate resilience. These areas, including parts of the Alpine and pre-Alpine zones, benefit from robust governance and active climate action strategies, reflected in their positive index values. Conversely, regions in southern Italy and the islands show significantly lower scores due to prolonged droughts, higher exposure to heatwaves, and sparse natural buffers such as vegetation and permeable soils. Municipalities in regions like Sicily and Calabria recorded particularly negative index values, highlighting the urgent need for targeted interventions.

Table 3. Average values of the Climate Change Adaptability Index (CCAI) and its component indicators (1.1 to 1.5) across different territorial typologies in Italy. Values are shown for each typology and sub-typology, including inner, intermediate, and metropolitan areas.

Territorial Typology	1.1	1.2	1.3	1.4	1.5	CCAI
1 INNER ITALY	29	16	2.2	39	39	0.26
1.1.1 – Inner, remote and sparsely populated area	28	16	2.2	99	41	0.34
1.1.2 – Inner and remote area with medium population density	29	19	2.34	95	32	0.07
1.2.1 – Sparsely populated inner area closest to a metropolitan area	31	19	2.1	90	36	0.09

1.2.2 – Inner area with medium population density closest to a metropolitan area	29	15	2.07	73	40	0.05
2 INTERMEDIATE ITALY	25	12	2.07	94	29	0.19
2.1.1.1 – Sparsely populated mountain/inland hill urban-rural continuum	26	14	2.06	98	40	0.34
2.1.1.2 – Mountain/inland hill urban-rural continuum with medium population density	25	12	2.03	84	38	0.16
2.1.2.1 – Sparsely populated coastal and/or lowland urban-rural continuum	25	12	2	96	11	0.26
2.1.2.2 – Coastal and/or plain urban-rural continuum with medium population density	25	13	2.06	90	12	-0.13
2.2 – Medium-sized city or non-FUA capital	28	12	2.06	74	20	-0.11
2.3 – De facto or de jure metropolitan fringe	25	12	2.01	85	16	0.03
3 METROPOLITAN ITALY	28	14	2.2	85	23	-0.17
3.1.1 – De facto metropolitan centre	22	11	2.14	89	25	-0.17
3.2.1 – De jure and de facto metropolitan area (not capital)	24	12	2.21	85	23	-0.16
3.2.2 – Metropolitan capital	33	17	2.06	74	17	-0.44

When analysed through the territorial typologies, Inner Italy shows mixed results as it can be seen in Table 3. Inner, remote, and sparsely populated areas (1.1.1) have a relatively positive score of 0.34, benefiting from natural assets such as forests and low urban density. However, Inner areas with medium population density closest to metropolitan zones (1.2.2) record a score of only 0.05, reflecting challenges tied to urban pressure and limited natural buffers. Similarly, Intermediate Italy demonstrates variability, with sparsely populated coastal and lowland urban-rural continuums (2.1.2.1) scoring 0.26 due to moderate adaptive assets, while urban-rural plains (2.1.2.2) face negative adaptability (-0.13) due to land-use pressures. Metropolitan Italy, while economically strong, exhibits clear vulnerabilities. Metropolitan capitals (3.2.2) report the lowest adaptability scores (-0.44), driven by high exposure and urbanization. Overall, the findings confirm that the adaptive capacity plays a critical role in building territorial resilience to climate risks. Regions with natural assets such as forests and permeable soils demonstrate higher adaptability, while urban and coastal areas, particularly in southern and metropolitan contexts, exhibit negative scores driven by high exposure and limited adaptive measures. Targeted interventions such as reforestation, sustainable land management, and climate governance improvements are essential for reducing vulnerabilities, particularly in areas identified as high-risk zones.

3.2. **Climate Change Risk Index (CCRI)**

The Climate Change Risk Index (CCRI) captures the intersection of climate hazards and socio-economic vulnerability, highlighting regions where fragile socio-economic conditions are most impacted by increasing climatic extremes. Climate risk emerges from a combination of local conditions, including hazards, exposure, and vulnerability. In the Italian context, drought and warming represent the most critical challenges, necessitating the consideration of indicators such as temperature increase, duration of hot periods, and consecutive days without rain to assess both current conditions and future projections (Papathoma-Koehle *et al.*, 2016; Zhao *et al.*, 2020) While the CCAI previously assessed climatic hazards in relation to adaptive capacity, the CCRI focuses on how these hazards intersect with socio-economic vulnerability. This comparison highlights how territorial risks are magnified by fragile socio-economic conditions, such as low income, employment rates, and aging populations. Consequently, the CCRI underscores regions where climate change hazards exert the most significant pressure on the socio-economic sphere, identifying situations of heightened risk and territorial fragility that require urgent intervention.

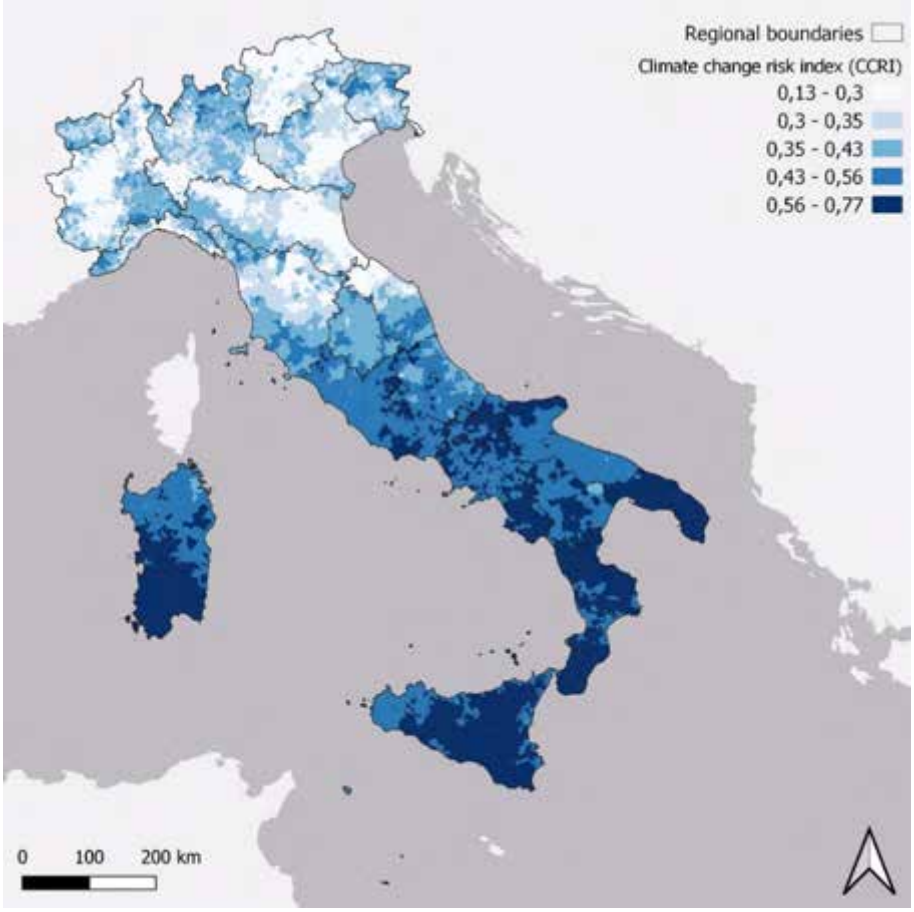

Figure 3. Climate Change Risk Index (CCRI) across Italy. Higher risk scores are concentrated in southern and rural regions, where climatic stressors coincide with fragile socio-economic conditions. Lower risk is observed in more resilient northern and metropolitan areas, though local hotspots remain due to uneven vulnerability patterns.

As Figure 3 shows, the southern regions, particularly Calabria, Sicily, and Apulia, exhibit the highest CCRI scores, exceeding 0.56. This pattern is primarily driven by prolonged exposure to extreme climatic events, such as extended consecutive days without rain (40.60 in inner areas) and duration of hot periods (22.40 days in certain areas). These regions also face socio-economic challenges, such as lower income levels and higher demographic pressures, which further amplify vulnerability. For example, inner remote areas show a SEVI of 0.54, exacerbating the region's inability to cope with climatic stressors. This pattern aligns with findings from another study (Mysiak *et al.*, 2018), which developed a Climate Risk Index for Italy to support national adaptation planning. While their approach relies on high-resolution gridded data and multi-model climate projections from EURO-CORDEX to simulate future scenarios (2021–2100), the present study focuses on recent observational data from open-access national sources to construct two present-day indices. A key methodological distinction lies in the composition of the indices: the Climate Risk Index incorporates a broader set of variables, including manufactured, natural, social, and economic capital, while the present study uses a more streamlined and spatially detailed set of indicators, emphasizing biophysical features (e.g., canopy cover, soil permeability) and socio-economic vulnerability.

Table 4. Average values of the Climate Change Risk Index (CCRI) and its component indicators (2.1 to 2.4) across different territorial typologies in Italy. Values are presented for each typology and sub-typology, including inner, intermediate, and metropolitan areas.

Territorial Typology	2.1	2.2	2.3	2.4	CCRI
1 INNER ITALY	28.97	16.48	2.2	0.52	0.5
1.1.1 – Inner, remote and sparsely populated area	28.27	15.56	2.2	0.54	0.49
1.1.2 – Inner and remote area with medium population density	28.65	19.27	2.34	0.45	0.49
1.2.1 – Sparsely populated inner area closest to a metropolitan area	31.21	18.74	2.1	0.49	0.52
1.2.2 – Inner area with medium population density closest to a metropolitan area	40.6	22.4	2.13	0.45	0.47
2 INTERMEDIATE ITALY	25.1	11.92	2.06	0.49	0.43
2.1.1.1 – Sparsely populated mountain/inland hill urban-rural continuum	25.94	14.29	2.06	0.49	0.43
2.1.1.2 – Mountain/inland hill urban-rural continuum with medium population density	22.54	10.89	2.03	0.38	0.37
2.1.2.1 – Sparsely populated coastal and/or lowland urban-rural continuum	25.29	7.82	1.94	0.34	0.38
2.1.2.2 – Coastal and/or plain urban-rural continuum with medium population density	25.17	12.86	2.15	0.35	0.43
2.2 – Medium-sized city or non-FUA capital	28.2	15.74	2.02	0.42	0.39
2.3 – De facto or de jure metropolitan fringe	25.38	12.1	2.01	0.39	0.36
3 METROPOLITAN ITALY	28.23	14.33	2.2	0.31	0.4
3.1.1 – De facto metropolitan centre	22.18	10.59	2.06	0.3	0.36
3.2.1 – De jure and de facto metropolitan area (not capital)	28.23	14.34	2.21	0.31	0.4
3.2.2 – Metropolitan capital	32.82	16.79	2.06	0.35	0.42

Table 4 summarizes the numerical findings separated by territorial typologies. In inner Italy, sparsely populated areas close to metropolitan regions demonstrate CCRI values of 0.52, driven by a combination of exposure indicators such as 31.21 consecutive dry days and moderate socio-economic vulnerabilities. These results emphasize that rural and remote areas remain disproportionately affected due to limited adaptive capacity, aging populations, and weaker economic conditions.

Conversely, northern and central Italy, particularly in metropolitan areas, show lower levels of climate change risk. Metropolitan regions like Lombardy and Veneto report CCRI scores as low as 0.36–0.40, reflecting favorable conditions, including shorter dry spells (22.18 consecutive days) and stronger economic resilience, evidenced by socio-economic index values as low as 0.31. However, even within metropolitan Italy, capital cities demonstrate slightly higher risk values (0.42), indicating localized challenges associated with urban heat and socio-economic disparities.

The results for intermediate Italy present a nuanced picture. Sparsely populated mountain and inland urban-rural areas report CCRI scores around 0.43, with lower exposure indicators but socio-economic vulnerabilities, such as aging populations and reduced employment rates. Areas with medium-sized cities demonstrate slightly better resilience, but exposure to warming trends still highlights the need for targeted adaptation measures.

Overall, the CCRI underscores the territorial patterns of climate risk across Italy. Southern and rural areas face the most significant challenges, where prolonged dry periods, rising temperatures, and economic fragility combine

to amplify vulnerability. In particular, Calabria region and some parts of Sicily score high both on climate exposure and socio-economic vulnerability with SEVI values exceeding 0.50. In contrast, northern and central metropolitan areas demonstrate lower hazard exposure and stronger socio-economic resilience. Intermediate Italy reflects a mixed picture: while some subtypes benefit from natural buffers, socio-economic fragilities in sparsely populated or mountainous areas contribute substantially to overall risk levels.

Addressing these disparities requires region-specific strategies that improve both adaptive capacity and socio-economic conditions, particularly in high-risk areas, through investments in green infrastructure, economic development, and climate-responsive policies.

Despite lower average CCRI values in several territorial typologies, approximately 27% of municipalities exhibit high climate risk due to socio-economic fragility as well. For example, many are located in urban-rural continuums or sparsely populated inner areas, demonstrate CCRI values above 0.50 and SEVI scores exceeding 0.50, placing them among the most vulnerable within otherwise more resilient typologies. These cases illustrate the importance of disaggregated assessments and reveal "outlier municipalities" (see Figure 4) that may be masked by broader territorial averages, as well as showing the impact of SEVI in CCRI. Recognizing such outliers is critical for ensuring that adaptation strategies are not only regionally targeted but also attentive to intra-regional inequalities.

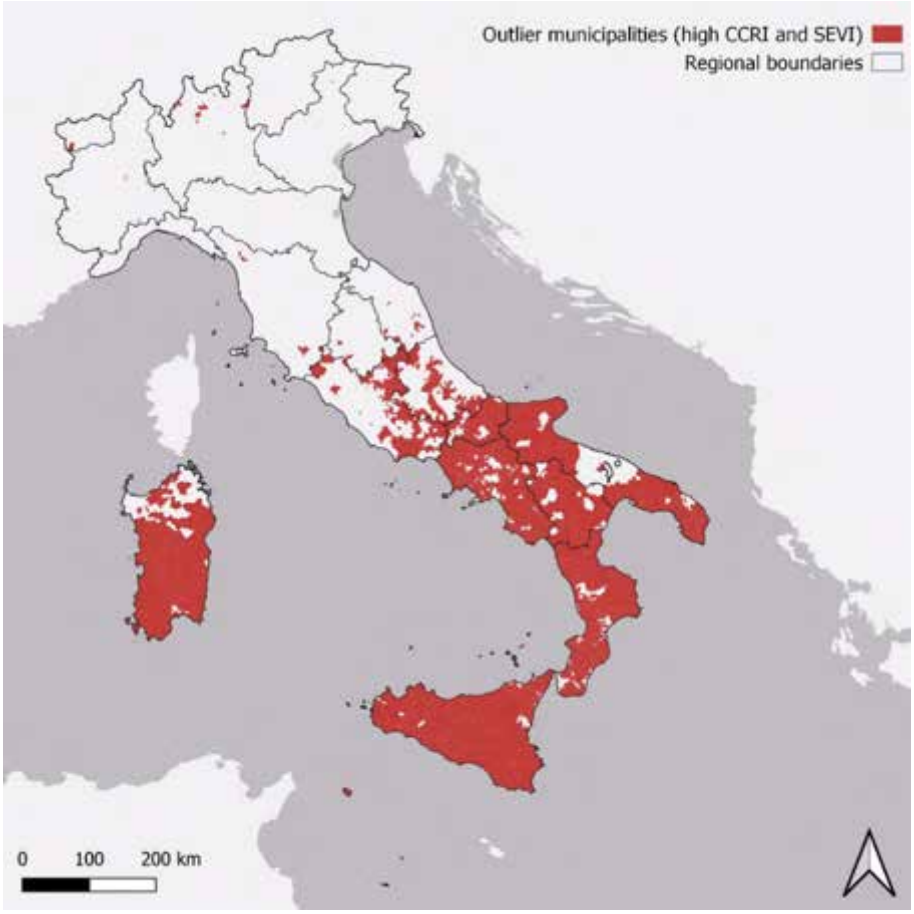

Figure 4. Municipalities with both CCRI and SEVI values above 0.50, identifying territorial climate resilience patterns.

3.3. **Cross-Index Analysis of Adaptability and Risk**

Bringing together the Climate Change Adaptability Index (CCAI) and the Climate Change Risk Index (CCRI) enables a more nuanced understanding of territorial resilience and fragility in Italy. While the CCAI reflects the capacity

of local systems to withstand climatic stress through natural and infrastructural buffers, the CCRI reveals where climate hazards overlap with socio-economic vulnerability. Viewing the indices together highlights critical intersections where resilience strategies are most urgently needed.

Both CCAI and CCRI are unitless composite indices derived from normalized data, which allows their spatial patterns to be jointly visualized.

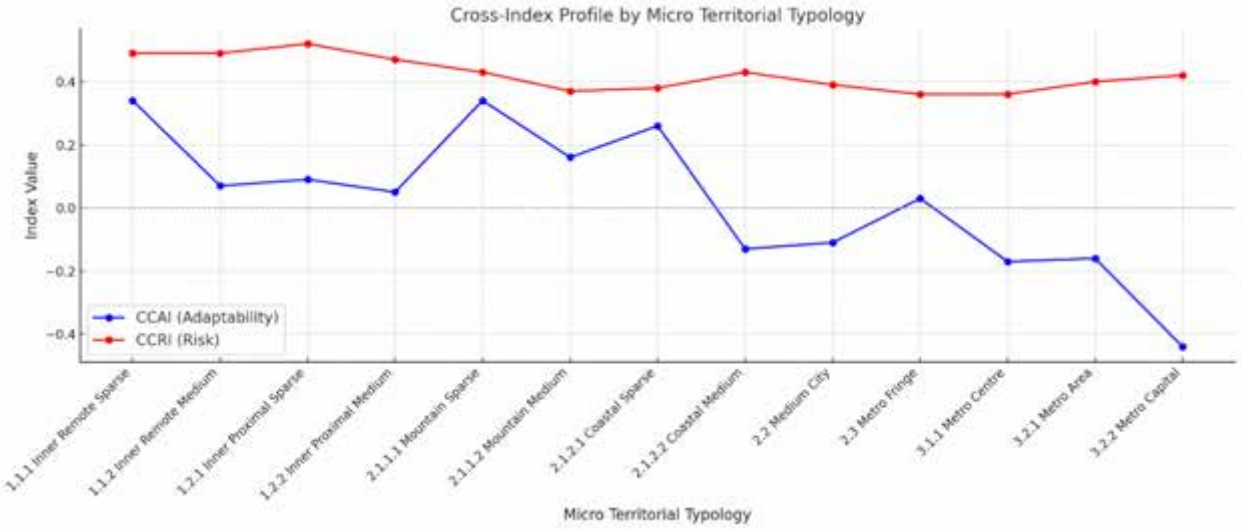

Figure 5. Climate Change Adaptability Index (CCAI) and Climate Change Risk Index (CCRI) across Italian micro territorial typologies. The figure highlights the inverse spatial relationship between adaptability and risk, with notable disparities across inner, intermediate, and metropolitan areas.

Figure 5 illustrates a cross-index plot showing the distribution of scores across micro territorial typologies. A striking feature of the plot is the consistent and steep drop in CCAI scores for metropolitan capitals (3.2.2), which contrasts with their moderate CCRI values—revealing a scenario where high exposure and environmental stress are somewhat offset by socio-economic robustness. Conversely, inner areas (e.g., 1.2.2) show moderate adaptability yet relatively high risk, illustrating the amplifying role of social vulnerability in rural or peri-urban contexts.

This combined perspective reinforces key findings from the previous sections: while natural conditions (e.g., canopy density, soil permeability) offer a degree of climate resilience, socio-economic disparities can override these advantages. At the same time, some urbanized areas with stronger institutions and services demonstrate the capacity to absorb risk, even when ecological adaptability is low.

The cross-index view supports the argument that place-based climate policies should not rely on environmental indicators alone. Instead, they must account for compounded vulnerabilities by aligning ecological investments (e.g., nature-based solutions) with social policy interventions (e.g., education, employment, and health infrastructure). In this way, the combined use of CCAI and CCRI offers a replicable framework for guiding adaptive strategies across diverse territorial contexts.

4. Conclusions

This contribution has presented a national-scale assessment of climate change adaptability and risk in Italy through the development of two open-data-based composite indices: the Climate Change Adaptability Index (CCAI) and the Climate Change Risk Index (CCRI). By integrating environmental and socio-economic indicators across a spatially detailed territorial taxonomy, the analysis reveals stark disparities in both adaptability and risk across Italian territories. The use of open data and a replicable methodological framework enhances the transparency, scalability, and policy relevance of the findings, offering a practical tool for spatialized climate

planning. Such technical foundations are crucial for developing robust composite indicators like the CCAI and CCRI introduced in this study, which depend on integrating open datasets from multiple institutions and spatial scales. Without clear standards and shared conventions, the operationalization of territorial climate assessments becomes fragile, limiting both their analytical reliability and policy relevance.

Despite the strengths mentioned above, the analysis also faces limitations linked to data availability, spatial resolution, and indicator harmonization, which may affect comparability across regions. Despite these constraints, the study demonstrates the potential of open-data-driven approaches for supporting place-based adaptation strategies and guiding informed territorial policy.

The analysis highlights specific regions (e.g., Calabria, Sicily, Apulia) and territorial typologies (particularly inner, remote, and sparsely populated areas) priority zones for climate adaptation. These areas consistently exhibit low adaptability and high climate risk due to limited ecological buffers and compounded socio-economic vulnerability. By contrast, some metropolitan and intermediate areas show greater resilience, yet still face localized pressures that warrant targeted planning. These findings support the need for differentiated place-based strategies tailored to the specific challenges and capacities of each territorial context.

Addressing climate risk and fostering adaptability in Italy requires tools that reflect territorial specificities and local-scale heterogeneity. National-level strategies must be grounded in spatialized assessments capable of identifying not only where risks are highest, but also where adaptive capacity is weakest. This highlights the importance of developing and applying robust, data-driven methodologies that integrate climatic and socio-ecological dimensions at appropriate scales. Such approaches are critical for informing place-based adaptation strategies and ensuring that policy responses are both equitable and effective across diverse territorial contexts.

Abstract
Healthcare has become increasingly relevant for spatial planning - not only due to the Covid-19 pandemic, but also because of growing shortages in skilled labour. Ensuring equal living conditions and basic outpatient care is gaining importance. This article presents a digital decision support system developed within the Carl-Zeiss-Stiftung-funded project Ageing Smart - designing spaces intelligently. The tool includes (1) a data-based analysis of population and healthcare structures, (2) dynamic, intermodal accessibility analyses, (3) a survey on healthcare needs among baby boomers in four municipalities, and (4) a catalogue of analogue and digital options for action. In the future, scenario-based impact visualisation will be added. The system supports evidence-based, participatory decision-making and strengthens spatial planning as a key actor in shaping future-proof healthcare infrastructures.

Keywords: smart region, spatial planning, decision support system, demographic change, public health care

1. Healthcare within the context of demographic change

1.1 Ageing as a key element of demographic change in Germany

In general terms, demographic change describes the change in population in terms of quantity and quality that in Germany has been observed for years. This development can be summarised with the keywords 'older', 'more diverse' and – regionally differentiated – 'fewer or more' (Gans, 2018, p.376). However, closer inspection reveals demographic change to be a multi-faceted process, characterised by the coexistence of shrinking and growing populations, as well as an ageing and increasingly heterogeneous society. Demographic change is therefore accompanied by far-reaching spatial implications, which are also significant in terms of the equivalence of living conditions and the safeguarding of services of general interest (ibid.).

Shrinkage and growth are a reflection of the quantitative aspect of demographic change, which results in a decline in the natural balance. This is due to the persistently low birth rates since the 1970s and the resulting steady reduction in the number of potential parent generations. This is in contrast to the overall positive migration balance (Federal Statistical Office, 2024). However, migration patterns are subject to a variety of influencing factors (e.g. political, economic), which is why they vary from region to region and are not constant. Internal migration within Germany is a key indicator of variations in quality and attractiveness, particularly with regard to the labour market and educational opportunities, as opposed to overall net migration. In contrast, external migration across national borders is influenced by external factors such as humanitarian crises and geopolitical conditions (Fürst & Mäding, 2011, p.29). The outcome of these reciprocal dynamics between natural population development and different migration movements is growth and shrinkage processes that take place side by side in different areas, with equally different spatial characteristics and effects.

Germany's ageing population is defined by an absolute and relative increase in older people. This issue has long been resolved for Germany (Federal Statistical Office, 2024). The population decline in birth rates and shrinking of potential parents generations (also known as 'ageing from below') is counteracted by the steady rise in life expectancy ('ageing from above') (Gans, 2018, p. 379f.). The ageing of the baby-boomer generation is driving this development, as about 25% of the German population was born between 1955-1969 (Federal Statistical Office, 2024;

Stefan et al., 2022: 1ff.). Specifically, the population is getting older as the average age is rising and age groups are shifting. The number of senior citizens and very old people is increasing. The 15th coordinated population projection assumes an increase in the 67-79 age group by 2037, followed by further increases from 2050, while the number of people in the 80+ age group will increase by 2050. The number of people of working age (20-66 years) will decline until the mid-2030s and stabilise from 2037 (depending on immigration).

1.2 Impacts for spatial planning and development

As outlined above, the spatial impacts of demographic change are diverse. They affect e.g. housing markets and settlement density, land use, public infrastructure (including capacity utilisation, costs and replacement needs), traffic flows, economic performance, labour markets, supply and demand structures, public finances, segregation, ethnic and social conflicts, and even public safety. The resulting effects vary in nature and intensity depending on the specific demographic processes and are influenced by various contextual factors. Most of these developments present challenges requiring active engagement from spatial planners and policymakers (Fürst & Mäding, 2011, p. 30).

In quantitative terms, demographic change is particularly evident in the decline of the population in structurally weak, peripheral and rural areas (Maretzke, 2018, p. 32). This is often associated with reduced economic attractiveness and demand for private goods, services, housing and infrastructure. Consequently, these areas face challenges such as vacant buildings, rising per capita costs, infrastructure capacity issues, closures of shops and medical practices, increasing catchment areas, a decline in qualified labour, and a general loss of attractiveness. This is coupled with underprovision of essential public services (Fürst & Mäding, 2011, p. 31; Fina et al., 2018, p. 14). These developments can intensify into self-reinforcing cycles of problems that place significant burdens on municipalities which are already facing declining tax revenues (Fina et al., 2018, p. 14). Internal migration exacerbates these disparities, with young people in particular relocating to economically prosperous metropolitan regions. This widens the gap between shrinking rural areas and growing urban centres (BiB, 2023

Qualitatively, ageing processes, which occur at varying intensities and paces across all German regions, represent the core challenge of demographic change. Those particularly affected include rural, peripheral areas with low population density, as well as urbanised regions and agglomerations with structural economic weaknesses (Gans, 2018, p. 382). While the increase in the old-age dependency ratio primarily challenges the pension system from a macroeconomic perspective, ageing from a regional and local perspective mainly stresses the social infrastructure, especially the provision of adequate healthcare and long-term care. The ongoing decline in the working-age population, combined with an increasing elderly population, exacerbates the imbalance between those in need of care and those able to provide it. The same applies to healthcare provision, where there is an increasing mismatch between the number of patients and the availability of service providers. As society ages, demands on infrastructure also change, affecting healthcare facilities, mobility infrastructure and cultural and recreational services. These needs were clearly identified in internal project workshops held in the seven model municipalities of the Ageing Smart project.

At the same time, an ageing society requires the built environment and public services to be adapted to meet the needs of older people. This involves promoting age-friendly housing and mobility solutions, providing access to healthcare and care services via alternative delivery models (e.g. mobile, digital, hybrid), and designing public spaces that cater to the social and physical requirements of older individuals (e.g. accessibility, seating; Körber Foundation & SRzG, 2020). In shrinking regions, it may also be necessary to reconsider existing infrastructure in light of demographic changes (BBSR, 2020).

1.3 Challenges for healthcare provision

General practitioners (GPs) are important because they're the first point of contact, have a close relationship with patients and coordinate further care and preventative measures. They're particularly important in rural regions, where distances to specialists and hospitals are greater (BBSR, 2025, p. 8). However, structural, demographic and economic conditions pose challenges to ensuring comprehensive, needs-based healthcare (BMWK, 2024, p. 202;

Cramer et al., 2022, p. 2). These areas have lower population density and a lower settlement and travel density (Ried, 2021). On the one hand, the steady ageing of the population is leading to an increasing need for medical care. This is leading to a rising number of elderly people, as well as an increase in multimorbidity and mobility restrictions. Changes in demand for age-specific infrastructure are therefore to be expected, particularly in outpatient, inpatient and nursing care facilities (Cramer et al., 2022, p. 2; Kuhn & Amelung, 2015, pp. 16–17). The effects of climate change on human health are also becoming increasingly noticeable (e.g. in the form of extreme heat events), and are exacerbating the situation (Birkmann & Blätgen, 2018, p. 1102).

This development is countered by declining treatment capacities due partly to population change and partly due to a declining willingness to set up a practice and a decline in full-time employment, alongside a drop in working hours (e.g. German Medical Association, 2023; Zwierlein et al., 2020). Here, too, the baby boomer cohort matters, since doctors aged 50 to 65 work long hours, which younger generations cannot easily cover (German Medical Association, 2023).

Alongside these quantitative challenges, there are also qualitative and spatial issues. There has been a maldistribution of specialists and a shortage of GPs willing to set up a practice. Spatially, there are disparities between affluent urban areas and rural communities where basic care is already at risk (Gerlach et al, 2014, p. 349 ff. and p. 377 ff.). It is hard to fill vacancies in these areas: in 2015-18, 50% of doctors were unwilling to work in rural areas (Zwierlein et al., 2020, p. 2; Jacob et al., 2015, p. 61 f).

Demographic change is putting increasing pressure on outpatient care, particularly in rural areas (Kuhn & Amelung, 2015, p. 18). Securing healthcare provision is therefore necessary, particularly with a view to achieving equality of living conditions (Stiewing & Mangels, 2022, pp. 410–411). Comprehensive measures are required in affected areas to counteract the aforementioned challenges and ensure comprehensive, needs-based healthcare. Local authorities are explicitly urged to establish integrated care and prevention structures, and to develop innovative, sustainable approaches (Böhm & Schönknecht, 2020, p. 1). However, control of the public healthcare system has largely been taken away from municipalities and transferred to statutory health insurance funds and medical service providers. Nevertheless, in the context of demographic change, the question of a stronger role for local authorities in this area arises. How can local authorities be actively involved in shaping local healthcare provision?

1.4 Research approach in the Carl Zeiss project 'Ageing Smart - Designing spaces intelligently'

The effects and challenges outlined in the context of demographic change clearly show that the baby boomer cohort in particular acts as a driver for some of these developments. The research project 'Ageing Smart - designing spaces intelligently', funded by the Carl Zeiss Foundation and the University of Kaiserslautern-Landau with 4.3 million euros over a period of five years, addresses these baby boomers, born between 1955 and 1969, and brings together spatial planning and supply-side approaches, baby boomer needs and local authority requirements and options for action in an integrated approach for the first time. The interdisciplinary research project, which is part of the university's "Region and City" research unit, is divided into ten sub-projects in the disciplines of spatial planning, urban sociology, climatology, computer science and mathematics and is coordinated by the Department of Urban Sociology under Prof Dr Annette Spellerberg.[1]

As the largest patient group, baby boomers are particularly relevant to the healthcare sector. The 'Healthcare' sub-project, coordinated by the Chair of Regional Development and Spatial Planning, focuses on general practitioner, specialist and dental care in four rural-suburban municipalities: Kusel-Altenglan, Nieder-Olm, Geisaer Land and Remshalden. As well as healthcare provision (supply and demand) and transport infrastructure to ensure individual mobility and accessibility to medical facilities, the project focuses on the current housing situation, prospective residential location behaviour, and healthcare behaviour of baby boomers, as well as their requirements in terms of accessibility and medical care design.

1 University of Kaiserslautern-Landau: "Ageing Smart - Designing spaces intelligently", https://www.ageing-smart.de/

The analysis of the preferences and needs of baby boomers serves to answer relevant questions and to derive needs and options for action in healthcare provision in rural-suburban communities. Later in the project, these will be used to feed into the planned decision support system, particularly in view of increasing demand with a simultaneous reduction in available supply. Of particular relevance here is the accessibility of the individual medical locations, which is why the development of a dynamic accessibility model to analyse time-dependent, intermodal accessibility and, in perspective, to optimise the location planning of different services represents an interdisciplinary cross-sectional approach from spatial planning and mathematics, with the aim of harmonising the needs of the ageing population, spatial development and local supply options (Stiewing et al., 2022, p. 132f.).

The objective of the joint project is the development of a data-driven, IT-based, and AI-driven decision support system (DSS) that can be utilised by public stakeholders in their planning and decision-making processes (municipalities ask, the DSS answers). Infrastructure, services and offerings should be developed in a manner that is demand-oriented, sustainable and future-oriented, with a view to ensuring and enhancing the quality of life of baby boomers and, in the long term, the entire population.

B With regard to the baby boomer cohort and the healthcare sector, questions arise concerning the supply of and demand for infrastructure and residential location behaviour, among other things: What are the current and future needs? Which infrastructures are increasingly in demand? How can the quality and accessibility of medical care in rural-suburban areas be improved by incorporating alternative services? What acceptance do digital, mobile and hybrid forms of healthcare provision have among the baby boomer generation? What relevance does the medical care infrastructure have for municipal development? What opportunities are there to influence the location of medical centres? What mobility services will be needed in the future? Where and how will baby boomers live in the future?

Taking demand and supply aspects into account, the role and potential influence of the municipal level in the area of healthcare was analysed and two rural and two suburban municipalities were examined with regard to the provision and accessibility of medical care. In addition, a survey on healthcare provision was conducted among baby boomers in these municipalities in order to generate data on the healthcare and residential location behaviour of baby boomers and the resulting challenges. The findings, e.g. on care structures, demand patterns and needs, residential location and mobility behaviour as well as the acceptance and relevance of digital-mobile forms of medical services, are used to identify specific requirements for action at
and to formulate options for action to ensure healthcare provision and its accessibility. These will also be supplemented by the assessment of experts from politics and administration in the model municipalities, outpatient demand planning and representatives of the leading medical associations.

2. Healthcare as a future task of general interest to municipalities

2.1 Equal living conditions as a guiding principle for services of general interest

Alongside the guiding principle of sustainable spatial development, the provision of equal living conditions is a key objective of German spatial planning policy, which is outlined in the Spatial Planning Act and the Basic Law of the Federal Republic of Germany. This demands comparable opportunities for the population, municipalities and companies in terms of starting, development and funding, as well as access to and accessibility of infrastructures of general interest (Troeger-Weiß, 2023, p. 305). It also means ensuring a comparable quality of life for the population, regardless of regional, social or economic circumstances (Priebs, 2021, pp. 12-13). The task of spatial planning is therefore to organise living conditions throughout Germany in such a way that the population perceives them as equal (Rosenfeld, 2018, p. 838). Ensuring equal living conditions means guaranteeing everyone the basic requirements for a good life. 'Equivalence' refers to fundamental services like education, mobility and healthcare. The guiding principle seeks to minimise disparities between urban centres, rural areas and between federal states (Rosenfeld, 2018, pp. 837-838). The concept of equal living conditions is closely linked to social justice. Regional disparities in infrastructure, education, the economy and healthcare require political intervention (Priebs, 2021, p. 16). However, the concept of equivalence does not imply complete equality. Instead, the desired

equivalence involves defining minimum standards adapted to the regional conditions of individual sub-regions (Rosenfeld, 2018, pp. 841-842).

Equivalent living conditions also include equivalent healthcare. Therefore, ensuring adequate healthcare is considered the responsibility of public services of general interest (Gerlinger, 2021, p. 71), which are embedded in spatial planning and municipal policy as a public mandate (Priebs, 2013, p. 142). This includes outpatient, inpatient and nursing care. However, in addition to providing appropriate healthcare infrastructure, the accessibility of facilities is also important. According to the Federal Government's Equivalence Report, health-related equivalence largely depends on the characteristics and interactions of the following factors:

- the status and development of regional old-age dependency ratios;
- life expectancy and premature mortality;
- the quality and accessibility of medical and nursing care facilities, e.g. the density of care in terms of GPs and access to medical care regardless of place of residence (BMWK, 2024, pp. 42-65).

Significant differences exist between urban and rural districts, particularly regarding accessibility to medical care (BMWK, 2024, pp. 62-64). The number of inhabitants per GP varies considerably, highlighting challenges in rural areas (BMWK, 2024, p. 65). A population survey revealed that 16% of respondents rated good healthcare and nursing care as important for their local area's quality of life (BMWK, 2024, p. 87). Despite efforts to achieve equivalence in healthcare, challenges persist due to spatial disparities and demographic trends. Against this backdrop, minimum standards (basic care) of services of general interest and new concepts in medical care are being discussed (Baumgart & Rüdiger, 2018, p. 831).

2.2 Organisation of healthcare in Germany

In Germany, responsibility for healthcare is not organised by the state, but rather through a self-governing system in which responsibilities are divided between the federal, state and local levels, in accordance with the federal structure of the state. The federal government defines the legal framework in the German Social Code (SGB), among other things, while the federal states and self-governing bodies — the health insurance funds and Associations of Statutory Health Insurance Physicians (KVen) — are responsible for the more precise organisation. The supreme body of this system is the Federal Joint Committee (G-BA), comprising the National Association of Statutory Health Insurance Physicians (KBV), the National Association of Statutory Health Insurance Dentists, the German Hospital Federation, and the National Association of Statutory Health Insurance Funds (G-BA, 2023).

With regard to outpatient healthcare, the responsibility for ensuring sufficient and comprehensive medical care within the framework of statutory health insurance, as set out in § 75 (1) SGB V, lies with the medical service providers (represented by the KVs) and the health insurance funds. The former, in agreement with the respective state associations of health insurance funds, draw up a requirements plan (§ 99 SGB V), which regulates the number and distribution of medical practices based on guidelines issued by the Federal Joint Committee, thereby guaranteeing the provision of care in accordance with this mandate. The demand planning guideline (BPL-RL) establishes nationwide specifications that are implemented at a regional level by the state committees. The BPL-RL describes a comprehensive functional planning system that formulates specifications for care levels, doctor groups and corresponding planning areas, while allowing room for regional deviations. Each group of doctors (e.g. orthopaedists) is assigned to one of four care levels, which are planned at different spatial resolutions: general practitioner care (middle areas), general specialist care (districts), specialised specialist care (regional planning regions), and separate specialist care (state level). The supply situation for each doctor group and region is assessed by comparing the population-physician ratio with the target level (KBV, 2025).

Inpatient care, on the other hand, is primarily the responsibility of the federal states, which must ensure that sufficient hospital services are provided locally. This is financed according to the principle of dual hospital financing by the federal states and health insurance funds. However, most federal states have transferred this responsibility to counties, which often act as hospital operators and are directly and indirectly involved in hospital financing

(Böhm & Schönknecht, 2020, p. 12).

2.3 Municipalities and their role within outpatient healthcare in Germany

Although municipalities are limited in their role within this system, they remain responsible for ensuring public health under constitutional law as part of the state administration (Gerlinger, 2021, p. 16). Effective municipal healthcare also aligns with an overarching health-promoting policy and the 'Health in All Policies' (HiAP) strategy. The latter is a multi-level approach that aims to integrate health into all policy areas and establish societal responsibility for health (Köckler & Geene, 2022). Figure 1 therefore illustrates the role of local authorities with regard to healthcare, health promotion and prevention.

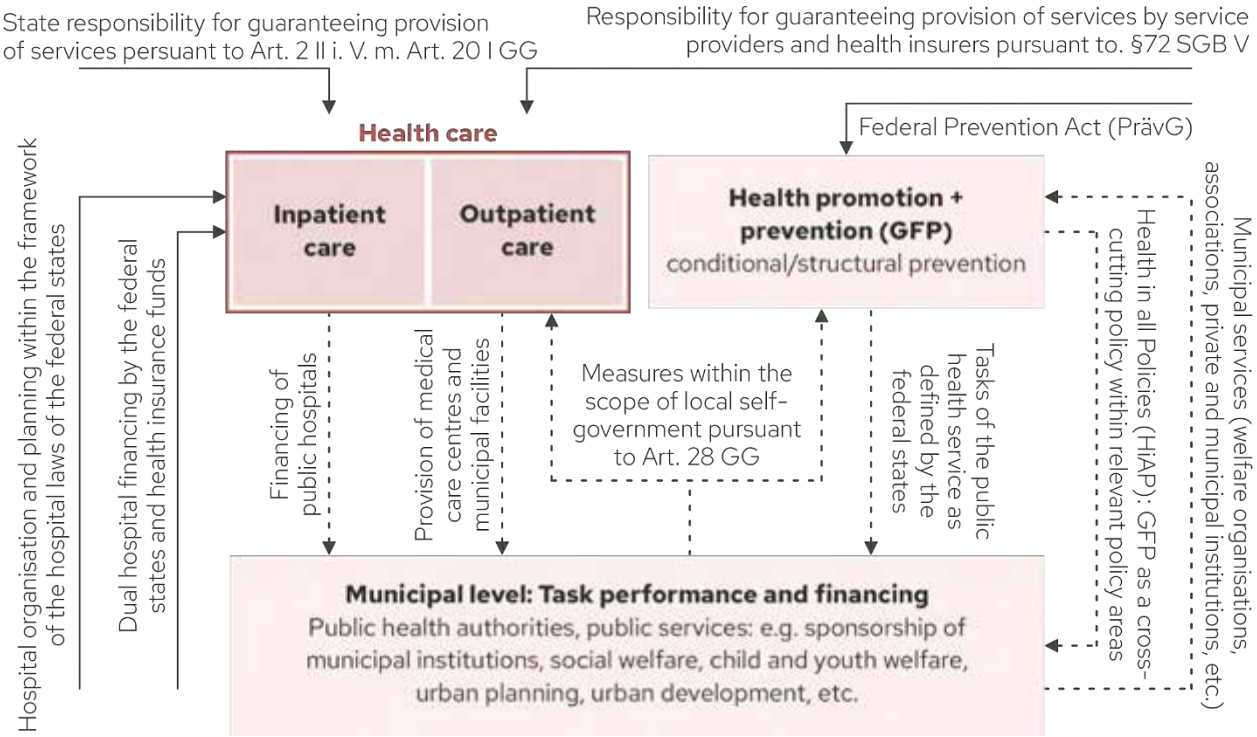

Fig. 1: The role of municipalities in the field of health (Stiewing & Mangels, forthcoming a).

Local authorities can explicitly act as service providers. The legal framework is defined by several acts, including SGB V and the Care Structure Act of 2012. Municipalities can operate their own facilities for direct medical care in justified exceptional cases (§ 105 (5) SGB V). Furthermore, § 95 (1a) SGB V permits the establishment of medical care centres (MVZ) under municipal or inter-municipal ownership, regardless of the approval of the KVs (Gerlinger, 2021, p.70). However, the implementation of this option remains challenging. Studies show that municipal officials are reluctant to establish MVZs, and concerns have been raised about their economic and organisational feasibility (Gerlinger, 2021, p.54; Barthen & Gerlinger, 2016; Kleinschmidt, 2019). The reasons cited include lack of financial resources and expertise. Consequently, the number of MVZs under municipal ownership has been low (Gerlinger, 2021, p.54). Most MVZs are initiated by small municipalities to minimise local supply bottlenecks (Müller, 2020, p.57).

In the context of demographic shifts, the German government passed the Act to Strengthen Healthcare Provision in March 2025. This act aims to enhance outpatient care, including through the simplification of municipal MVZs. While the GVSG is generally welcomed by municipal umbrella organisations, they also express criticism. In particular, they criticise the removal of previously planned opportunities for municipal stakeholders to influence healthcare provision. For instance, the following elements are no longer included: health regions; health kiosks; and primary care centres. Furthermore, the draft document focuses excessively on outpatient care, which means

that the GVSG contradicts the approach of cross-sectoral care. While the expansion of municipal healthcare is a key priority, it is vital to ensure that responsibilities are not significantly transferred to the municipalities, thereby limiting their capacity to deliver services.
Furthermore, municipalities have room for action thanks to the guarantee of municipal self-government enshrined in the German Basic Law (Art. 28 GG). Within this framework, local authorities can influence local healthcare provision through targeted measures such as counselling services, providing practice premises, and offering financial incentives to doctors (Kuhn & Amelung, 2015, p. 18). Furthermore, municipalities can utilise health conferences or inter-municipal and regional networks to encourage collaboration among local stakeholders, thereby addressing gaps in care and ensuring its provision (Böhm & Schönknecht, 2020, pp. 6–10). This is particularly relevant given that demographic change and a shortage of skilled labour are putting increasing pressure on outpatient care in rural and suburban areas (Kuhn & Amelung, 2015, p. 18).
As Böhm and Schönknecht state, municipalities are the lowest administrative unit and have the most direct access to local people. This enables them to align healthcare, health promotion and prevention directly with local needs. As the bodies responsible for the entire local public administration, municipalities have a special role to play in improving health equity and equal opportunities.

3. Decision support for municipalities on healthcare provision
One of the tasks of spatial planning is to record and visualise different developments and their spatial and temporal relationships in a way that is appropriate for the target group as part of spatial observation. Spatial planning thus creates a basis for work and discussion for both political decision-makers and the population, for example for the development of spatial strategies and concepts of various kinds.
In dialogue with municipal stakeholders, including in the context of internal project workshops, networking meetings and conferences, it became clear that there is a need for support, particularly in smaller municipalities with few resources. These tend to have a superficial overview of the local facilities and, from the perspective of the municipal decision-makers, show a rather diffuse awareness of the problem under the keyword "shortage of doctors". Feedback from the workshops held in the model municipalities as part of the project resulted in a multi-stage structure for concrete decision support, which is shown in Fig. 2.

Fig. 2: Components of the ageing smart decision support system in terms of healthcare

In addition to the generally understandable preparation of central trends and framework conditions, which also emphasise the relevance of the topic as a municipal task, the analysis of the current situation in the healthcare sector forms a necessary component for a fact-based decision-making basis. This includes

• general indicators of common spatial structural analyses alongside the requirements and needs of baby boomers surveyed in rural and suburban areas,
• analysis of the medical equipment on a municipal level and
• analysis of the intermodal accessibility of medical facilities.
The aim of this analysis is to describe the current situation of healthcare provision and to derive requirements for action at municipal level as a concrete contribution to decision-making support in municipalities

3.1 Perspective of the baby boomer generation on healthcare and mobility
Compared to previous generations, baby boomers are considered to remain fit and active for longer. However, as they age, this generation will also have greater need for medical care in the medium term. As the largest patient group in the future, baby boomers are therefore highly relevant for securing medical care and thus for municipal development. In this context, the subproject on healthcare conducted a partially standardised survey among baby boomers on healthcare in two rural (Geisaer Land and VG Kusel-Altenglan) and two suburban municipalities (Remshalden and VG Nieder-Olm) in Rhineland-Palatinate, Baden-Württemberg and Thuringia. (Stiewing & Mangels, forthcoming b). Based on e.g. statements on demand behaviour and needs for healthcare, (supra-local) residential location behaviour, mobility behaviour, the aim is to identify the need for action for both political decision-makers and healthcare providers and to formulate options for action to secure healthcare and mobility (Stiewing & Mangels, 2023, p. 403). Among other data, the following data is displayed in the DSS:

• subjective state of health as well as health restrictions, chronic illnesses, risk factors (multimorbidity) and social integration,
• Satisfaction with medical care and mobility at the place of residence,
• Acceptance of mobile and digital forms of healthcare provision,
• Importance of healthcare and mobility as location factors in the choice of residential location (past and anticipated),
• Requirements and wishes for living in old age.

For example, both mobile and digital services provide a flexible alternative to traditional healthcare. The survey therefore asked about acceptance of these types of service for medical consultations or treatments. Table 1 shows the corresponding approval ratings. Two-thirds of respondents can imagine using these services. From the perspective of baby boomers, mobile and digital services can therefore, at least in part, offer an alternative option for consultation or treatment and contribute to securing care, relieving the burden on doctors and improving quality in rural and suburban areas. A higher acceptance of mobile services and counselling is evident among respondents from the suburban model communities. The highest acceptance is among respondents for mobile and digital counselling (Stiewing & Mangels, forthcoming b).

Tab. 1: Acceptance of digital and mobile healthcare services: ('Can you imagine a. being advised/treated by a doctor in an a. online format (n = 279 / 505) / b. in a mobile doctor's office (n = 278 505)?'; percentages refer to the respective answer).

	digital counselling and treatment	digital counselling only	no digital counselling and treatment	mobile counselling and treatment	mobile counselling only	no mobile counselling and treatment
rural	23,3 %	43,4 %	33,3 %	53,8 %	14,7 %	32,1 %
suburban	31,4 %	45,8 %	22,7 %	59,2 %	12,1 %	28,7 %

3.2 Analysis of medical facilities in healthcare provision
In the area of healthcare, the following questions arise at the municipal level: What is the current situation of outpatient healthcare in the district / municipal association / municipality or in the municipal districts? What will the

healthcare situation probably be like in five to ten years' time? Where is there an acute and prospective need for action? A standard data-based inventory and analysis for a specific spatial area (e.g. a district, an association of municipalities) is usually part of a spatial structural analysis. This analysis usually comprises: "spatial structure and settlement development", "development and structure of the population" (including household structure), "development and structure of the economy and the labour market", "accessibility and infrastructure" and, depending on objectives, "trade" or "tourism". Relevant indicators are analysed and assessed using statistical data at municipal level and, where applicable, over time (usually development over the last ten years or so). Forecasts and comparative values can also be used to create a benchmark for assessing the current situation.
Healthcare provision is usually considered as part of the analysis of social infrastructure within the framework of traditional structural analyses. The analysis is usually limited to the location of healthcare facilities (e.g. GP practices and clinics), the number of doctors and the quantitative ratio of doctors to inhabitants in the analysed spatial unit. A more detailed analysis is being carried out as part of the DSS, whereby following data is used:

- Basic data for visualisation, i.e. administrative boundaries (e.g. at district, municipal association and municipal level) as well as settlement areas and buildings,
- Data on spatial structure, in particular spatial types and central locations
- Data on transport infrastructure, i.e. private and public transport, including routes, stops, frequency, distances and accessibility
- Socio-demographic data (e.g. census) to assess quantitative demand, in particular the status and development of the population over the last ten years, population density and population forecast, as well as data on the age structure, e.g. average age, proportion and development of the baby boomer cohort and the over 65/75/85 age groups, life expectancy
- Key data on outpatient demand planning to assess supply in quantitative and qualitative terms, i.e. in particular planning areas, level of care, open seats, ratio of residents per doctor (in the DSS focused on smallest planning areas of outpatient care, i.e. general practitioner, dentist and general specialist care)
- Data on medical facilities at municipal level to assess supply in spatial terms, i.e. in particular address-specific locations of outpatient (individual and group practices, medical care centres) and inpatient care (public and private hospitals) as well as pharmacies and, if applicable, existing mobile, digital and hybrid forms of supply.

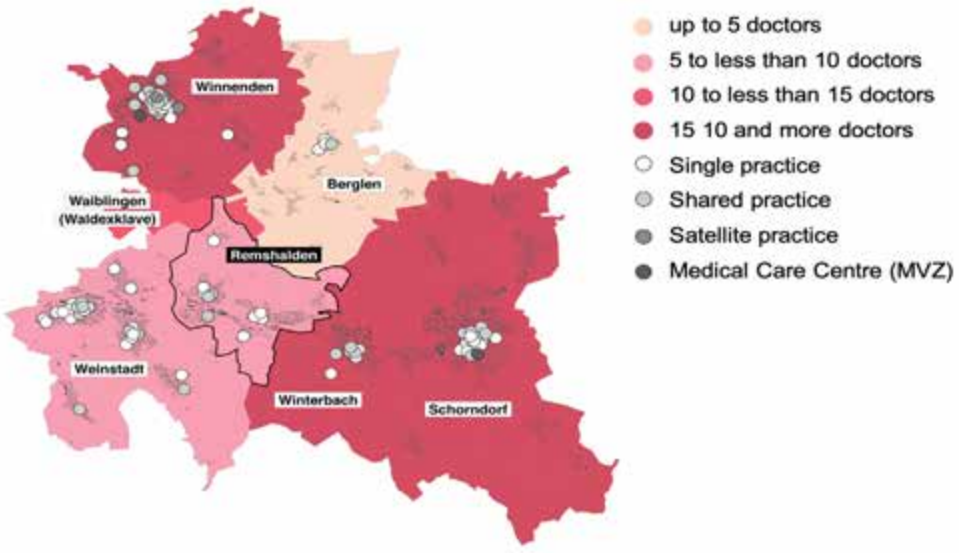

Fig. 3: Outpatient healthcare facilities and doctor-to-resident ratio in the pilote municipality of Remshalden, 2022

3.3 Analysis of intermodal, time-dependent accessibility in an algorithm-based accessibility model
In addition to the provision of medical facilities, accessibility is becoming increasingly important when assessing

medical services in terms of spatial quality, particularly against the backdrop of changing mobility in old age. In rural areas in particular, accessibility is a critical factor due to the sparser infrastructure network and longer distances. Standard structural analyses often depict accessibility by showing the existing transport infrastructure (usually motorised individual transport and public transport) and how long it takes to reach the nearest major or medium-sized centre by car. However, this assumes the availability of a private car, which gradually declines with age (BMVI, 2018, pp. 99–102). Additionally, the activity radius generally shrinks with age, making it more difficult to visit doctors in more distant locations (Stiewing & Mangels, forthcoming a). The analysis of healthcare provision is therefore supplemented by a mathematical accessibility analysis based on cross-sectional spatial planning and mathematical methods.

Accessibility analysis is no longer carried out purely statically in relation to the nearest major or medium-sized centre, or based on linear distance to the nearest infrastructural facility. Instead, it is time-dependent, intermodal and dynamic, in the sense of forward calculation. As part of an intermodal, thematically supported accessibility analysis, different means of transport and their interlinking can be considered, as well as individual mobility. As a component of the DSS, the model provides stakeholders in spatial planning administration (e.g. urban, transport and social planning), political decision-makers, and other stakeholders (e.g. from medical care, research, and demand planning) with an analysis tool. It considers different modes of transport and user profiles, enabling the identification of small-scale accessibility deficits and supply gaps within a planning area (Stiewing et al., 2022, pp. 131–141).

To analyse accessibility in the mathematical model, the locations of the facilities to be included (e.g. outpatient care) are first used as a basis. These locations are characterised by different structural features (e.g. type of practice). In addition, the age of the medical profession can be integrated into the DSS to provide insight into future supply, provided that the facilities remain unchanged. The calculation is also based on the underlying road network and real-time public transport timetable data. Previously defined parameters and ancillary conditions supported by transport planning also form the basis for the calculation (Stiewing et al., 2022, pp. 137–139). To reflect different types of mobility among users, three mobility profiles were configured in collaboration with the optimisation working group and the Chair of Urban Planning at the RPTU. These combine age-specific parameters relating to walking, cycling, public transport, and motorised private transport (MIT), enabling a differentiated analysis of the accessibility of medical services. The preconfigured, customisable 'limited mobility', 'average mobility' and 'above-average mobility' profiles are therefore used to analyse intermodal accessibility in the DSS.

The modelled accessibility is then assessed according to threshold values based on supply-side standards and recommendations for the accessibility of medical facilities. While 15 minutes is assumed for good or adequate general practitioner (GP) care, 30 minutes is used as the corresponding threshold for general specialist care. An exception to this is gynaecological care, which usually involves an annual consultation, so a threshold value of 20 minutes is set here (Stiewing & Mangels, forthcoming a). The same applies to dental care, as an annual consultation is also usually carried out here. Figure 4 shows a possible modelling result and depicts the healthcare situation for general practitioner care in the pilot municipality of Kusel-Altenglan from an accessibility perspective. This illustrates the impact of individual mobility on the quality of small-scale care provision. Analysing intermodal accessibility for the status quo and the anticipated temporal course can reveal areas where action is needed to secure healthcare provision. For example, underserved areas or areas where certain population groups are disadvantaged can be identified, even if the entire central or supply area has a sufficiently high level of supply (Stiewing et al., 2022, pp. 137–139).

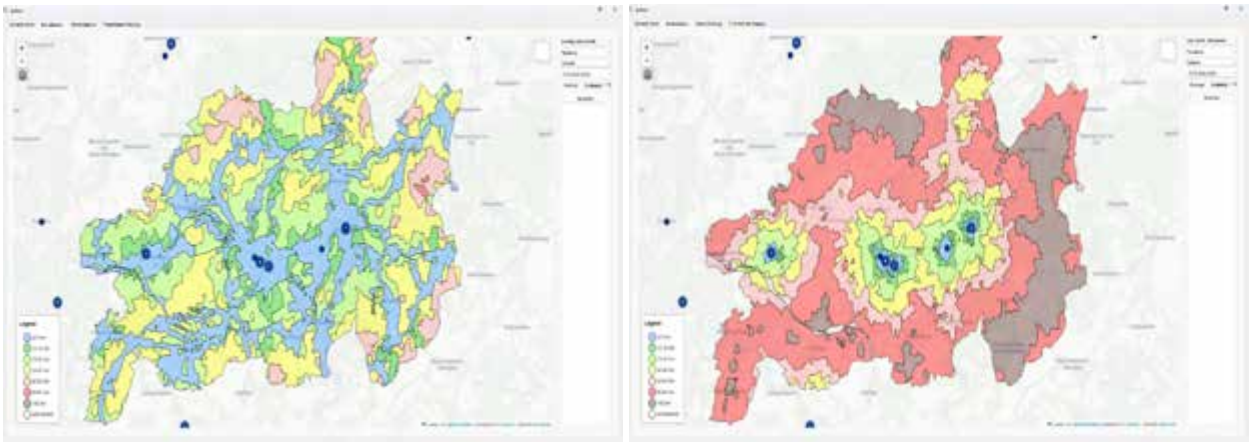

Fig. 4: Accessibility of the general practitioner care in the pilot municipality of Kusel-Altenglan with profile 'average mobility' (left) and 'limited mobility' (right), 2022

3.4 Municipal options for proactively shaping healthcare provision

Based on the described framework conditions and the structural analyses and surveys carried out for the rural and suburban model municipalities in the intermodal accessibility model, action is needed in the municipal provision of healthcare, including ensuring accessibility. Building on this analysis and problem definition, providing possible solutions in the DSS is the second step towards supporting decisions in the healthcare sector. This aims to safeguard the status quo and prevent a deterioration in accessibility, as well as the associated threat of an increase in scale of healthcare provision. The DSS options set out different 'interventions' with corresponding recommendations to support decision-making and, if necessary, alternative futures. They also serve to create scenarios in the decision-making process. As well as planning administrators and municipal decision-makers, the intended audience includes providers of medical services. The following questions take centre stage:

- How can the municipality improve healthcare in the community?
- What opportunities are there for doctors to set up in the community?
- What needs to be done step by step to realise a specific intervention?

As Fig. 5 shows, municipalities can become involved in healthcare to varying degrees. Initially, this commitment involves local authority representatives engaging with the topic and exchanging information with local medical service providers. This can lead to initial action plans, which can be summarised as "counselling", "support" and "mediation". One example is counselling in the context of the branch office. At the second stage, the municipality acts as a partner in searching for and, if necessary, establishing a location. This could include providing or leasing suitable practice premises, or selling real estate or building plots at favourable rates. At the third stage, the municipality becomes active as a moderator or driver by integrating health into its strategies and concepts. In this context, it also makes analysing the status quo and communicating about it the subject of municipal action. This can include inter-municipal strategies and networks. The highest level of municipal involvement is assuming an own care mandate, e.g. sponsoring or participating in a municipal medical care centre. These centres offer the option of employing doctors on a salaried basis, which is particularly popular with younger doctors (Dostal & Partner Management-Beratung GmbH, 2019; BMG, 2024). However, the individual stages do not necessarily build on each other; rather, they represent different organisational approaches that can be combined depending on local circumstances.

Fig. 5: Levels of municipal involvement in healthcare (Stiewing & Mangels, forthcoming b).

The options for action include measures to improve healthcare provision and accessibility in the short term, and health promotion and prevention in the long term. In the 'healthcare' field of action, measures in line with the 'service to people' approach are conceivable. For example, outpatient healthcare services could be provided independently of a location by creating additional services or through mobile and digital provision. In the 'mobility' field of action, the focus can instead be on improving accessibility to medical services through appropriate 'people to service' measures. Development concepts for healthcare or mobility can also be created for both strategies (Troeger-Weiß and Anslinger, 2015, p. 147). Opting for one approach represents an initial political preference decision. The options for action are divided into abstract approaches and measures as well as concrete best practice examples, and are presented in the form of standardised profiles. These profiles are stored in the DSS and contain information on the target group, implementation, challenges, timeframe, costs and the municipality's role.

The options for action can also serve as a basis for alternative scenarios to discuss various possible courses of action and their effects. One example of this is location planning, where the impact of different locations on accessibility can be visualised using the intermodal accessibility model outlined above (Stiewing et al., 2022, pp. 137–139). Examples include the inter-municipal establishment of a medical care centre, providing rooms and spaces for local doctors, and offering consulting services to doctors looking to set up a practice.

4. Outlook

Healthcare is a key aspect in the context of equal living conditions. Factors such as demographic ageing, population loss, the shortage of healthcare professionals and limited resources for the provision of infrastructure have a significant impact on the quality of care. These challenges not only jeopardise the idea of equal living conditions, but also make political and organisational interventions indispensable. Health must therefore be understood as a task for society as a whole, which makes both the active organisation of local authorities and an associated expanded understanding of their role, particularly in securing (outpatient) healthcare, appear sensible.

To date, healthcare has only been included in spatial structural analyses in spatial planning to a limited extent. Existing approaches often fall short, as they are usually limited to infrastructural facilities or the ratio of doctors to the population. These perspectives do not provide a sufficient basis for strategic decisions by planning administrations and politicians. The intermodal accessibility of healthcare facilities, taking individual mobility into account, is becoming increasingly important when analysing the municipal healthcare situation and should be brought into focus.

A data-based DSS can make a decisive contribution to planning and decision-making processes here. In the field of health, for example, it can be used to depict the current supply situation and derive key requirements for action and supplement and specify conventional spatial structural analyses in planning. For example, small- spatial disparities within a care area can be identified. Municipalities and other stakeholders (e.g. KVs, doctors willing to set up practices) in the area of healthcare are thus supported in developing infrastructural offers and services in a needs- and demand-orientated, sustainable and future-oriented manner.

In addition, the DSS enables local authorities to recognise and weigh up options for action in the areas of healthcare, mobility, health promotion and prevention and to implement them within the framework of various roles. Such a DSS can therefore not only be a tool for data exploration, but also an instrument for actively finding and shaping solutions to existing or foreseeable gaps in care. The DSS is initially focussing on the high-birth cohort of baby boomers and accordingly on age-specific infrastructures, offers and services in particular, including the area of healthcare. However, the use cases developed as part of the project are intended to be transferable to other facilities (e.g. local supply, retail, education). In the long term, the DSS can thus make an important contribution to intergenerational urban and spatial development in order to secure and promote the quality of life of both baby boomers and the population as a whole.
