In this complex scenario, the Milanese market stands out as the only nationally relevant example for at least three key reasons. First, although it is not the capital city, Milan accounts for almost 50% of national real estate investment (Banca d'Italia, 2023). Looking solely at the large-scale developments listed in the Atlas published by the Municipality of Milan, investments are estimated to exceed €21 billion (Assolombarda, 2024), some of them like the Milano Innovation District, the Milano Santa Giulia or Milano Sesto are absorbing capital investments exceeding €5 billion euros each. Furthermore, despite the broader European crisis in real estate investment attractiveness, caused by inflation and rising construction costs, the city progressively welcomed an average of 50 new foreign multinational companies every year (Assolombarda, 2024). Also, as Conte & Anselmi (2022) highlighted, flagship projects such as Porta Nuova and CityLife exemplify how financialisation materialises into the urban fabric, channelling capital that, in turn, generated €600 million in investment in the commercial real estate sector alone (office, retail, hospitality) in the past year (Assolombarda, 2024).

Second, despite its size Milan has experienced a level of penetration by international institutional and sovereign wealth funds comparable only to global/globalised cities. This has increased both the reputation and influence of these global actors in the city's governance (Anselmi et al., 2020; Mosciaro, 2021; Conte et al., 2022). In this regard,

Italy's austerity policies and the limited spending capacity of local governments have made financialisation a geostrategic lever through which the Municipality of Milan has enhanced attractiveness, competitiveness, and interdependency (Koelemaij et al., 2023; Derudder et al., 2020; Taylor et al., 2004). The ensemble of such trends massively shaped the investments in urban regeneration, particularly in large brownfields.

Third, the entanglement of trans-scalar financial and geostrategic interests in the real estate market has been enabled by the Municipality of Milan's urban policies over the past decades (Bortolotti, 2023). These policies have involved a variety of fiscal, procedural, and regulatory instruments, including the planning ones. In particular, the mix of interviews and desk analysis on planning documents, permits and agreements revealed that such mechanisms have been made possible, on the one hand by national legal frameworks that favoured the entry of foreign investment funds (Modiano et al., 2023) – as occurred at the European level (Holm et al., 2023) – and, on the other hand, through a certain market-led use of spatial action plans and program agreements already encompassed by the Milanese planning system.

Among the major brownfields unlocked between the 1990s and 2010s—thanks to the privatisation of public companies and Italy's adoption of the euro and, in particular, to the financialisation of real estate, there are the projects of Porta Nuova and City Life: the 34-hectare Porta Nuova district was redeveloped with over €2 billion in investment, attracting prominent international players (Conte et al., 2022), including the Texan global development firm Hines and the Qatar Investment Authority, one of the most relevant institutional investors in the world. Similarly, the 36-hectare CityLife project redeveloped the former trade fair site through a vehicle company led by a consortium of insurance companies headed by Generali and including global financial giants like Allianz and PWC which (together) invested over €1 billion (Conte et al., 2022).

However, the involvement of foreign capital in major urban development and regeneration projects extends beyond these most known examples. The Australian firm Lendlease, alongside Hines, one of the world's largest developers, has announced investment plans for two major districts: the 100-hectare Expo area (MIND), in partnership with the Canadian Pension Plan Investment Board, and the 120-hectare Santa Giulia district (MSG), in partnership with the German fund CTS Eventim. These investments amount to €4.5 billion and approximately €4 billion, respectively (Gervasoni et al., 2024). Hines is also the leading developer of the 150-hectare Milano Sesto mega-project, delivered on the former Falck industrial sites in Sesto San Giovanni, with an initial investment of €1.5 billion in partnership with other national and international actors (Savini et al., 2016).

Parallel to American and Australian investments, some Canadian, Chinese, French, Dutch, Israeli, English and German entities have also attempted to redevelop strategic urban sites, especially for transforming them into retail, education and office locations. Our recognition mapped the intensive activity of qualified institutional investors like, among others, the Dutch pension fund PPGM, the Canadian speculative fund Colliers, the German giant Patrizia, as well as the British fund Savills or the well-known Saudi Arabia Public Investment Fund or the Tel Aviv Investments.

As observed by Briata et al. (2023), Milan is increasingly becoming a destination for luxury tourism elite residential living and customised global investments. This change has been made possible by the alignment of real estate interests of some of the wealthiest Italian families with those of international institutional investors creating unprecedented alliances. Considering 10 pilot flagship projects delivered through significant ad hoc planning and financial tools, our analysis revealed unprecedented partnerships among local and global key investment groups and élites. Moreover, by focusing on a quantitative dimension, the delivery of such urban regenerations apparently caused enormous increases in real estate investments, values and volumes in the respective surrounding areas, in some cases exceeding 100% in comparison to the trends affecting the past ten years.

The sum of these processes reflects how the intertwining of financialisation, real estate management and urban development has generated a 'cascade effect' for magnetising the capital into the city and determining Milan's primacy in the Italian real estate landscape, transforming it into a global node within the urban global network,

despite its relatively small size.

Overall, this research project assumed an interdisciplinary approach, drawing from urban planning, geo-economics, and real estate studies, to provide a comprehensive framework for understanding the financialisation complex in Milano. The insights achieved by observing how global investments are channelled into the Milanese urban market confirm how institutional players strategically deliver capital investments over urban nodes (Holm et al., 2023).

To conclude, the financialisation of real estate assets appears to be designed to establish a form of hegemony within the property sector and urban governance patterns, raising the necessity to pursue policy measures for reinforcing urban sustainability, equity, and resilience. As Jessop (2016) points out, market-oriented strategies represent an incomplete attempt to reconcile social contradictions, often resulting in ambiguity with respect to legitimacy, politicisation, and performativity. In Milan, such ambiguities are reflected in the tension between the attraction of global investment and rising social polarisation, as a growing share of the population is expelled from the city to the wider metropolitan region. These dynamics are caused by multiple phenomena, but local governments can potentially do more to prevent the negative effects of financialisation and further findings of this research will offer practical insights into navigating these challenges in Milano and similar urban contexts worldwide.

The State as an Entrepreneur Who Transforming Public Spaces: The Case of Zeytinburnu Fabrika-i Humayun

Semanur ÖZCAN[1], **Oya AKIN**[2]
1 Yildiz Technical University. ssemanurozcan@gmail.com
2 Yildiz Technical University. oakinster@gmail.com

Abstract
This study explores the privatisation of public lands under neoliberal policies and the evolving role of the state through entrepreneurial approaches, using the Zeytinburnu Fabrika-i Hümayun as a case. Over time, the state has shifted from serving the public good to prioritising capital interests, centralising authority in the process. Institutions like TOKI have transferred public lands to the private sector via opaque procedures and public-oriented discourse. In the examined case, a state-owned factory site was transformed into a luxury housing project by TOKI and its subsidiary Emlak Konut REIT. Although the process followed legal steps, its legitimacy remains questionable. Ultimately, the project restricts public access, serving as an example of dispossession framed as serving collective national interest under neoliberal urban governance.

Keywords: Neoliberal urbanisation, state, privatisation, planning and public interest, Zeytinburnu Fabrika-i Hümayun.

Introduction

The phenomenon experienced worldwide after the 1980s and defined as neoliberalism is based on the reproduction of capital through urban space. In this process, the retreat from the welfare state, privatisation, the intensification of international capital flows, and growing competition among countries, regions, and cities have led to a redefinition of the relationships between institutions, economic actors, nation-states, local governments, and financial capital, initiating a restructuring phase within the capitalist system (Peck, Theodore and Brenner, 2009). In line with the collaboration between the state and capital, land use and construction conditions have been developed to serve the interests of the dominant classes and the groups that benefit directly or indirectly from economic growth. This has triggered the reproduction of the built urban environment (Fainstein, 1994; Sengül, 2009; Uzbek and Dinçer, 2009; Logan and Molotch, 2013; Penpecioğlu, 2013). By enacting the legal regulations required by the neoliberal economic order, the state plays a guiding role in the redistribution of wealth (Bayırbağ and Penpecioğlu, 2017). This process—driven by legislation, fragmented planning decisions, and the expanding powers of central government—has brought forth one of the most striking developments: the commodification of public goods and services. The privatisation of public enterprises and infrastructure, which Sato (2000) defines as dead capital, and their conversion into liquid capital, represents a major obstacle to access to public services for disadvantaged groups, further reinforcing commodification.

In the phenomenon described by Peck and Tickell (2002) not as the neoliberalisation of the city but rather as the urbanisation of neoliberalism, the state and capital reshape the city by producing functionally, socially, and spatially differentiated and privatised areas. Without doubt, the formation of interest networks in the distribution and redistribution of resources, and the generation of multiplier effects, make this process possible. According to regime theory, which explains the reproduction of the urban environment and the role of the state within it, governance is defined by the formation of mutually beneficial networks through which actors pool their resources to act in alignment with their overlapping expectations (Fainstein, 1994; Uzbek and Dinçer, 2009). At this point, urban spatial transformation is financed through state-backed debt, and the state transforms from a social-democratic entity into one that supports capital by providing the necessary infrastructure and financing to enhance capital profitability (Harvey, 2013).

Within the framework of these conceptual assessments, this study focuses on the reflections of neoliberal urbanisation policies in Turkey, particularly in the context of Istanbul, by addressing the privatisation of public lands. The main research questions of the study are: Who are the actors involved in the privatisation of public lands in Istanbul? What is the role of the state in this process? And to what extent does the outcome align with the concept of public interest? Accordingly, the privatisation processes of public lands and their spatial implica-

tions will be examined across Istanbul. The case of the Zeytinburnu Fabrika-i Hümayun will be analyzed in terms of: the privatisation of the site, the legal and planning process, the actors involved, spatial impacts, and the issue of public benefit.

In conclusion, perceiving the city as an investment space leads to the convergence of actors with overlapping expectations. Legal regulations enacted by the state, special planning and construction provisions, and loans and funding provided by public banks give rise to new urban forms on privatised public lands—driven by the private sector's profit expectations. Housing, commercial, office, and accommodation developments, designed to attract high-income groups and foreign investors, generate enclaves that are alienated and disconnected from the urban whole. Meanwhile, the question of what constitutes the public good remains a fundamental dilemma within this process.

Entrepreneurial Intervention and Istanbul in the Context of Neoliberalism

Neoliberalism began to emerge toward the end of the 1970s, following the decline in the profitability of industrial production that had risen during the modernist era and the crisis of Keynesian welfare structures, which emphasised state intervention in the economy (Clarke, 2005; Bahçeci, 2017). According to Brenner and Theodore (2005), neoliberalism represents a market-driven process of social and spatial transformation. In this neoliberal era, the state has moved away from its role as a market regulator and has increasingly become a facilitator of the market, with the notion of public interest being replaced by the logic of capitalist production (Smith, 2002).

Within the scope of neoliberal urban policies, two key concepts emerge depending on the purpose and scale of interventions related to capital-oriented spatial decisions: the entrepreneurial city and the entrepreneurial state (Campbell, Tait and Watkins, 2016). Drawing on Jessop (1997), the distinction between these two can be defined as follows: when urban space is selected as a site of intervention for the flow of capital and local government becomes the primary actor, this reflects the entrepreneurial city; when the central state plays the entrepreneurial role by selecting urban space as a field of intervention to ensure the continuity of capital, this is referred to as the entrepreneurial state. What both concepts share is that space becomes a target of intervention, and capital acts as the driving force behind this intervention (Figure 1).

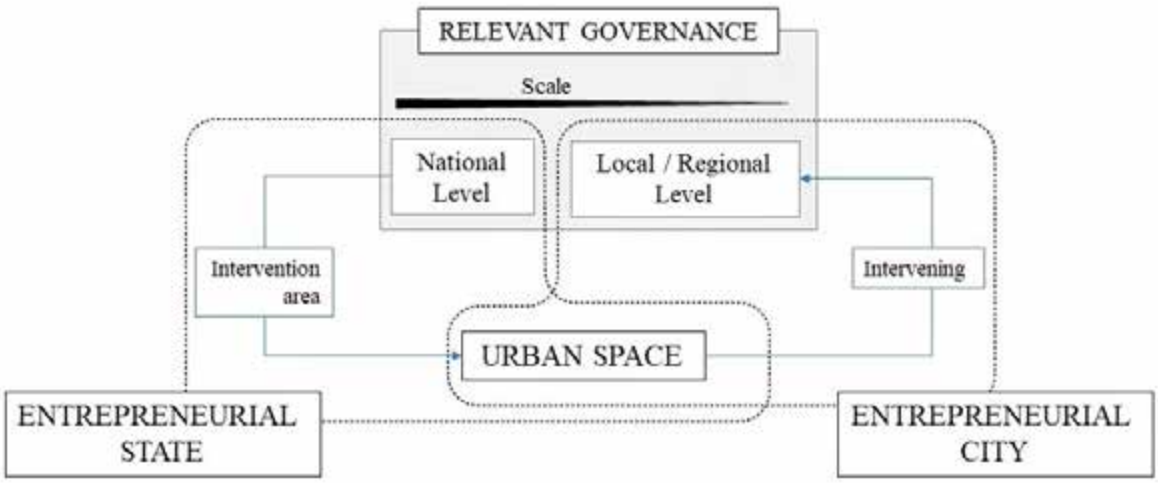

Figure 1 The relationship between the role of the state and spatial transformation (developed by the authors with reference to Jessop, 1997)

In this context, in order to stimulate capital accumulation by enhancing the economic attractiveness of cities (Eraydın and Altay, 2011) and transforming them into investment areas, actors such as real estate developers, local business communities, media institutions, etc., focus on expanding and transforming cities (Logan and Molotch, 1987). This is because investments in metropolitan areas are cyclical. Investments in housing areas attract

further investments in transportation, infrastructure, and new housing, thereby creating multiplier economies (Turok, 1992; Jessop, 2000; Brenner, 2003; Moulaert, Rodriguez and Swyngedouw, 2003).

The state guides the distribution of wealth through three main categories: legislation and legal regulations, fragmented planning decisions, and the expanding powers of the central government.

"The first category is the commodification of public goods and services. This includes the privatisation of public lands under the discourse of national common interest, the steering of investments through infrastructure projects such as highways and airports, and the privatisation of public services (electricity, water, natural gas, etc.) (Smith, 2002; Roy, 2009; Goldman, 2011). The transformation of public enterprises and infrastructure—referred to as 'dead capital' by Sato (2000)—into liquid capital through privatisation constitutes a key aspect of the commodification of public services and poses a significant barrier to disadvantaged groups in accessing these services."

The second category refers to the state's enforcement through market mechanisms, or the creation of new markets through capital's pressure on the state (Harvey, 2017–2020), or the generation of expectations (Aalbers, 2013; Bayırbağ and Penpecioğlu, 2017). This situation, referred to as 'forced marketisation,' takes place through the reproduction of the built urban environment by means of subsidies such as tax reductions and rent support offered by the state to attract entrepreneurs. In this context, the expectation generated—particularly by the middle class—regarding the 'financialisation of the housing market' raises property values and reshapes the rent map of the city, thereby triggering new expectations. This anticipation has altered the real estate landscape within cities, played a key role in the repeated production of space, and in the displacement of social groups and urban functions. Since the 1990s, city centers have thus become arenas where forms of creative destruction have emerged (Kurtuluş, 2006; Peck, Theodore and Brenner, 2009; Günay, 2012; Brenner and Theodore, 2005; Brenner and Keil, 2013; Penpecioğlu, 2013).

The third category consists of state-led practices that result in the displacement of the urban poor in line with renewed and rising land values. This category is defined by dispossession through transformation/displacement rather than improving the living conditions of the population—what Shindler (2017) refers to as 'planetary urbanisation' or Southern urbanisation, and Caldeira (2016) describes as 'peripheral urbanisation' (Akın, 2022).

Although the concepts used in entrepreneurial interventions in space differ, they all share a common feature: the use of space in line with the interests of capital (Jessop, 1997). The role of the state in this context is multifaceted. At times, the state acts as a partner in public-private partnerships focused on investment and economic development (Jessop, 1997), and at other times as a regulator that removes legal barriers such as laws and planning in order to pave the way for capital (Yalçınkaya and Taşçı, 2017). In each of these roles, the state commodifies space, often privatizing publicly owned urban land and infrastructure areas (Serin, Smith and McWilliams, 2020). In doing so, it may establish new institutions or transform existing ones (Yalçınkaya and Taşçı, 2017).

Public lands that are privatised are often used for large-scale commercial projects that do not serve any public function. These projects treat their surroundings as a scenic element while themselves disrupting the integrity of the urban landscape. Such interventions are often made boldly, without consulting the ideas of users living in or around the space, and by displacing them (Ravenhill, 2018). Many of these large-scale projects, often labeled as 'flagship' developments, are justified through public narratives that promote the idea that the place gains recognition and its exchange value increases through urban revitalisation (Harvey, 2015). These projects are thereby legitimised within society (Jessop, 1997; Shin, 2009). Uzbek and Dinçer (2009) interpret these legitimisation efforts through the concept of 'urban politics' in the context of the relationship between governance, capital, and society. According to them, governance has three main objectives: being 'public,' 'voter-based,' and 'entrepreneurial.' In order to legitimise its decisions, governance must focus on both political and economic dynamics and maintain a balance between them. This is because it needs voter support to stay in power politically, and financial backing from the private sector to ensure economic continuity. While one side emphasises the 'use value' of space, the other prioritises its 'exchange value'.

The Changing Role of the State and Governance Mechanism in Entrepreneurial Intervention

The governance model and spatial decisions in entrepreneurial interventions vary depending on scale. In processes involving local governments, particularly in the context of competitive cities, actors representing different collective wills and identities may participate (Jessop, 1997), and the process can proceed in a more transparent and public-oriented manner. However, in cases where the central government acts as an entrepreneur, the state may participate in the process as a parastatal entity (Goldman, 2011), potentially leading to more disruptive outcomes. In other words, the process can vary depending on the intervening party and the underlying dynamics. Goldman (2011) explains the entrepreneurial transformation of cities in two ways: through their engagement in dialogue with international institutions to form transnational policy networks, and through the creation of powerful new 'parastatal' institutions to reduce the bureaucratic hurdles that might otherwise slow the process.

One of the most significant works on the transformation of space is undoubtedly Marx's Labor Theory of Value. According to Marxist urbanism, during the transformation process, either space is produced or commodities are produced from space. When space is produced, use value takes precedence; when space is commodified, exchange value comes to the fore. Use value refers to fulfilling human needs, such as housing use, whereas exchange value focuses not on the social function of the space, but on its market price (Okyay, 2008; Büyükcivelek, 2021). The neoliberal state prioritises exchange value over use value, which ought to be preserved for the public good, thus initiating the commodification of space and, consequently, society's alienation from space. The concept of alienation—defined by Bayırbağ and Penbecioğlu (2017) as both a universal mechanism that facilitates capital accumulation and a tangible outcome with negative psychological/emotional effects on individuals and communities—leads them to propose limiting the privatisation of urban land and public/common spaces in order to protect living environments on a public scale within the urban political system.

The state's attempt to extract value varies depending on the condition of the space. If a space is classified as land, its value is shaped by land use and building regulations; if there is a structure on it, then the characteristics of the building and parcel, as well as its relative locational advantage, become important in generating value (Büyükcivelek, 2021). The privatisation of valuable public lands for projects targeting high-income groups brings about socio-spatial inequality. While the most accessible, central, and scenic areas of the city are allocated to high-income groups, areas lacking these qualities are left to lower-income groups.

Privatisation of Public Lands and Urban Space Debates: The Case of Turkey and Istanbu l

In this context, the subject will first be addressed in terms of legal and institutional structuring after 1980, and then specifically through the case of the Zeytinburnu Fabrika-i Hümayun.

TOKİ, which was established in 1984 under the Prime Ministry to address the housing problems of middle- and low-income groups (Bartu Candan and Kolluoğlu, 2010), was restructured by the central government after the 2000s to become the country's most powerful real estate developer and a key actor in the construction of the neoliberal regime. In addition to establishing a land/housing market for low- and middle-income households, the institution was also tasked with the privatisation of valuable public lands, thanks to its broad regulatory and financial powers (Kuyucu and Ünsal, 2010; 1485). In short, TOKİ also assumed the role of a property transfer instrument by transferring state-owned treasury lands into private ownership. Acting as the flagship in the housing sector, TOKİ and its subsidiary Emlak Konut played a decisive role in the sector—especially after the 2008 crisis—through mega-projects supported by legal and institutional regulations. Particularly through state measures such as VAT reductions, housing mobilisation campaigns, and the provision of low-interest housing loans via public banks (Yeşilbağ, 2020), an artificial economy was created.

Privatisation within the Framework of Legal and Institutional Structuring

In the privatisation processes, numerous legal regulations have been enacted to make lands suitable for capital interests. According to national legislation, the privatisation of public lands is primarily carried out either through the 'Privatisation Administration (PA)' under Law No. 4046 on the Implementation of Privatisation Practices, or through the TOKI under Law No. 1164 on Land Production and Utilisation (Figure 2).

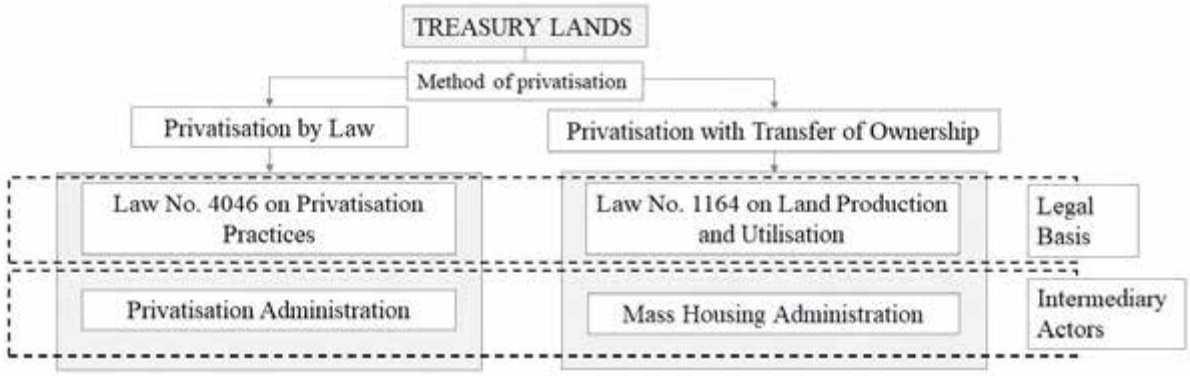

Figure 2 Legal background of the privatisation of Treasury lands

The privatisation of public lands by the PA is carried out under Law No. 4046 and Presidential Decree No. 703. The transfer of treasury lands to TOKI free of charge for investment purposes is conducted under Law No. 1164. According to this law, with the approval of the Presidency, the ownership of immovable properties belonging to the Treasury or to be registered in the name of the Treasury can be transferred to TOKI without charge. Another process that places treasury lands under TOKI's control is the protocols signed between public institutions and TOKI While privatisation decisions made by the Privatisation Administration are published in the Official Gazette, lands transferred to TOKI are not publicly announced.

In 2003, under Law No. 4698, the duties and authorities of the dissolved Housing Undersecretariat were transferred to TOKI. In the same year, amendments were made to the Mass Housing Law through Law No. 4966, and a provision was added allowing TOKI to make profit-oriented investments and establish companies for this purpose. In 2004, with Law No. 5162, TOKI was granted the authority to prepare, have prepared, and amend development plans of all types and scales, provided they do not disrupt environmental and zoning integrity, and to unilaterally implement plans not approved by relevant municipalities. With these powers, it can be interpreted that TOKI, as an extension of the central government, holds authority to plan above local governments (Akın and Özdemir, 2010). In 2005, further amendments were made to Law No. 5018, excluding TOKİ from the Court of Accounts financial oversight (Bahçeci, 2018: 145). This led to a further decline in transparency and limitations on accountability. In 2008, with Law No. 5793, TOKI's powers were expanded again, granting it full authority to prepare and approve all types of plans at all scales and to override the rights of announcement, publication, and objection by local authorities (Bahçeci, 2018: 146). In 2018, with Presidential Decree No. 703, TOKI was removed from the Prime Ministry's jurisdiction and placed under the Ministry of Environment and Urbanisation. The decree also transferred the authority over the sale of all movable and immovable properties belonging to public administrations within the general budget to the Ministry of Environment and Urbanisation.

Emlak Konut, which was established in 1953 to contribute to planned urbaniation and play an active role in housing production, was a subsidiary of Emlak Bank. Following the transfer of Emlak Bank's shares to TOKI and the subsequent closure of the bank, Emlak Konut was transformed into a Real Estate Investment Trust (REIT) in 2002 and became a subsidiary of TOKI (Pınar, 2019; Erdoğan, 2021). One of the duties of Emlak Bank, which was founded in 1949, was to provide affordable housing for citizens without homes (Law No. 4847, Article 2). Today, as a REIT, Emlak Konut's authority is regulated by the Capital Markets Board within the framework of the Capital Markets Law (Pınar, 2019). Emlak Konut REIT holds the highest market value among REIT, with a market value that doubles that of the company ranked second (Erdoğan and Özaslan, 2021).

What Akın and Özdemir (2010) stated about TOKI — that although it was established with the fundamental aim of producing healthy, livable urban environments to meet the housing needs across the country, it acts like a profit-oriented private sector investor by producing housing as an investment tool — also applies to Emlak Konut

REIT. As a result, this indicates that the state's role in the real estate sector has also become centralised and that it operates within the sector as an entrepreneurial actor.

The Transformation Process of the Zeytinburnu Fabrika-i Hümayun

The Zeytinburnu Fabrika-i Hümayun, also known as the 1st Army Zeytinburnu Heavy Maintenance and Repair Factory or the Zeytinburnu Iron Factory, was planned in 1843 (Directorate of State Archives, document no. 1259) and began production in 1846. It was established to meet the basic needs of the military and bureaucracy in line with the industrialisation goals of the period, to reduce dependency on European goods, and to minimise the outflow of resources abroad (Yıldırım, 2015). The factory was used for purposes such as smelting iron ore, casting iron and steel, manufacturing iron cannons, producing new steam engines, or repairing and maintaining existing steam and other types of machinery. The production of cartridges—which gave its name to the area now known as 'Fişekhane'—began in 1881 with the establishment of the Cartridge Manufacturing Plant (Kırlı, 2022).

These buildings, constructed in the mid-19th century, constitute not only a form of production but also an industrial cultural heritage site that includes registered (listed) structures. While the ownership of the land belongs to Emlak Konut REIT, easement rights over the land were granted to the Özak–Yenigün–Zilyan partnership, allowing the construction of new buildings on the site, and the restoration of the registered structures was assigned to Özak REIT. Özak REIT, having undertaken the restoration process of the registered buildings, also acts as a conservation easement stakeholder in the process. The restoration of these listed structures and their repurposing with new commercial functions can be considered an example of Morris's (2015) interpretation of conservation easement rights as a neoliberal instrument.

The factory was established in the Kazlıçeşme area on the shore of the Sea of Marmara, in Istanbul's Zeytinburnu district. This location provided logistical advantages—such as proximity to railways, highways, and seaways—for the transport of raw materials and the shipment of manufactured goods (Figure 3).

Figure 3 Location of the study area

The factory site is located within the tourism center area declared as the Istanbul Ataköy Tourism Center by the Council of Ministers Decision No. 87/11608 in 1987. At the boundary of the study area lies the buffer zone of the Istanbul Land Walls Conservation Area, which was designated as a World Heritage Site in 1985. Due to its proximity to the historic city center and its location within a tourism center area, it has become a site that offers accom-

modation opportunities and is attractive from a touristic perspective (Figure 4).

Figure 4 Study area and its surroundings

Among the registered structures on the site, the fountain was registered on 09.04.1989 under decision number 1043; while the Accounting Office and Gate, Water Tower, Workshops and Warehouses, Turkish Bath, Company Command building, another fountain, and the Armored Vehicle Maintenance Workshop were registered on 25.10. 1989 under decision number 1401 (Real Estate Valuation Report, 2014). Of the seven registered structures, the Water Tower, Bathhouse, Workshops and Warehouses, and the Armored Vehicle Maintenance Workshop are still standing today (Figure 5).

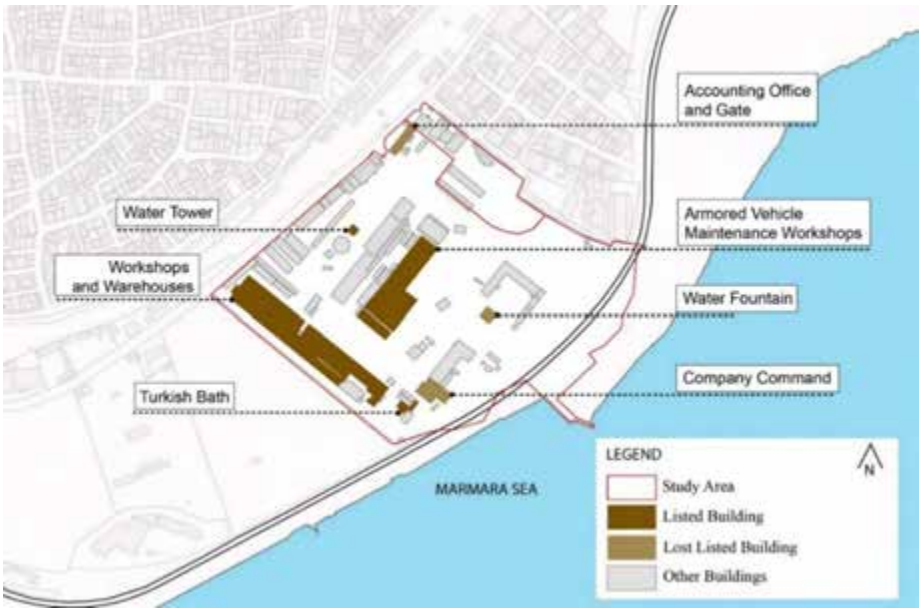

Figure 5 Cultural Heritage Elements in the Area (according to the 2014 site plan)

The Transformation Process from Public Land to Private Housing Project

In the Ataköy Tourism Center, which was designated in 1989, a 1/5000 scale Master Zoning Plan for the Ataköy Tourism Area was prepared by the Ministry of Culture and Tourism in 1998. In this plan, the site was assigned the functions of 'Tourism + Commerce + Accommodation + Recreation,' as well as Vocational High School, PTT (Post Office), and Daily Recreation. The revised plan was republished in 2001, maintaining the same functions; however, the 20-meter-wide road forming the northeastern boundary of the parcels was not shown. In the 2006 Istanbul Ataköy Tourism Center Master Zoning Plan, since the land was registered under the Ministry of National Defense, it was designated as a 'Military Zone' (Ministry of Environment and Urbanisation, 2018).

The first initiative for the transfer of ownership came from the Istanbul Metropolitan Municipality (IMM). According to a protocol signed with the Ministry of National Defense in 1990, the transfer of ownership to IMM was requested, and a letter was sent to the Conservation Board. In the letter, it was requested that the registered structures on the site be excluded from the construction area. In 1991, the Conservation Board stated that it would not be appropriate to predetermine building densities in an area where historical artifacts are heavily concentrated. Subsequently, a preliminary project for the site was submitted to the Conservation Board, and in 1992, the Board approved the project in terms of its principles and construction density (Ministry of Environment and Urbanisation, 2018).

In 2000, the Istanbul No. 1 Directorate of the Board for the Protection of Natural Assets approved the demolition of the 'Company Commande', whose measured drawings had been taken, due to security concerns. In 2008, the Istanbul No. IV Regional Board for the Protection of Cultural and Natural Assets stated that, in terms of Law No. 2863, there was no legal objection to the sale or lease of one of the parcels. In the same year, the Board's letter also requested that the Pay Office Building, which lies on a road according to the plan and is a registered cultural asset, be preserved and the plan be revised to ensure its conservation in situ, without demolition. During construction activities in 2014 and 2015, additional remains were uncovered and registered for protection (Ministry of Environment and Urbanisation, 2018).

In November 2013, a decision was made designating the parcels as residential, commercial, and tourism areas, based on a plan approved by the relevant ministry and later posted by the Provincial Directorate of Environment and Urbanisation in 2014. A lawsuit demanding the annulment of the plan was filed by the Istanbul Branch of the Chamber of City Planners (TMMOB) and the Istanbul Metropolitan Branch of the Chamber of Architects (TMMOB), and the court subsequently annulled the plan (Mimarist, 2017). Following the objection, the 1/5000 and 1/1000 scale zoning plans were revised and re-posted. In 2015, many buildings within the area were declared 'at risk' by Zeytinburnu Municipality in accordance with Law No. 6306. That same year, an application was submitted to the Regional Conservation Board, which approved the demolition of the structures on the condition that the registered heritage buildings would not be damaged.

In the updated Implementation Zoning Plan Report for the relevant parcels in 2018, the area was designated with a Residential + Commercial function, and the building density was reduced. The report states that opinions were obtained from the relevant Cultural Heritage Conservation Board for the relocated registered buildings, and from the Transportation and Traffic Commission for the new road alignment. Following the plan, lawsuits were filed by the Chamber of Architects (TMMOB) and the Chamber of City Planners (TMMOB) against the Ministry of Environment and Urbanisation, after which a new plan was prepared and posted. Although the 2020 plan appears similar to the 2018 plan, a change in ownership among the stakeholders was made.

The Privatisation Process of Public Property

One of the parcels within the study area was allocated to the Land Forces Command in 1955 by the Treasury of Finance for public service purposes. The transfer of ownership of the factory site to TOKI was carried out based on a protocol signed between TOKI and the Ministry of National Defence in 2006 (Ministry of Environment and Urbanisation, 2018). Under this protocol, it was agreed that the immovable properties on the site would be transferred to TOKI in exchange for the construction of a police station (Emlak Kulisi, 2012).

According to the 2013 valuation report, one of the parcels was owned approximately 97% by TOKI and 3% by the Treasury of Finance, while the other parcel was owned 5/8 by the Treasury and 3/8 by TOKI (Nova Real Estate Valuation Report, 2013). The land, which originally belonged to the Turkish Armed Forces / Ministry of National Defence and was later transferred free of charge to TOKİ, was tendered by Emlak Konut REIT and sold to the Özak–Yenigün–Zilyan partnership. Under the revenue-sharing model of the construction project, it was agreed that 37% of the revenue would be allocated to Emlak Konut REIT (Çakıroğlu, 2022).

These two parcels, owned by the Treasury of Finance and TOKI, were divided into eight parcels in 2018, with six of them remaining within the project area. When the ownership status was examined in 2020, it was found that the area, originally consisting of seven parcels, had been subdivided into thirteen parcels, and the ownership distribution had changed (Figure 6).

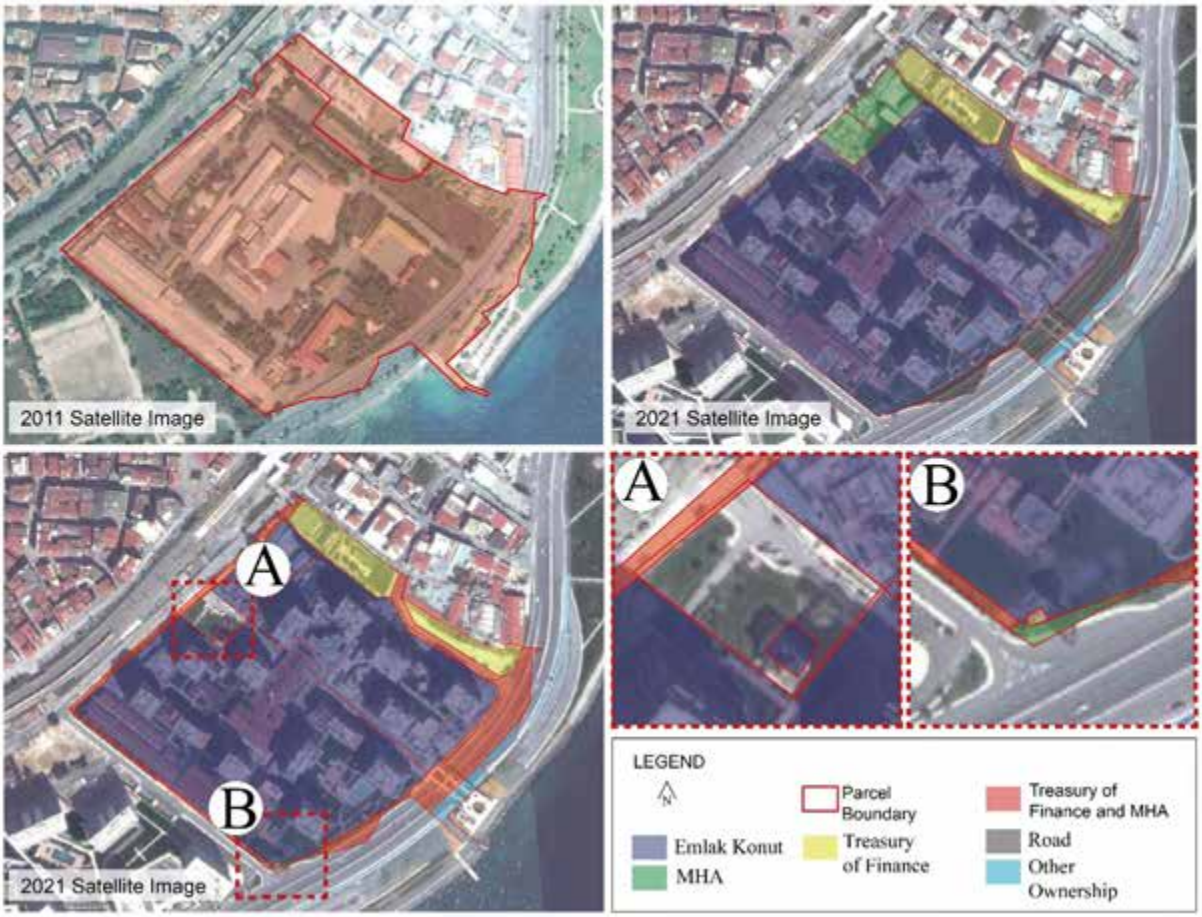

Figure 6 Subdivision of Parcels and Ownership Changes in 2018 and 2020
(Prepared with reference to TKGM, Ministry of Environment and Urbanisation, 2018 and 2020)

An approximate 10% increase was made to the total parcel area in 2018. With this addition, according to the latest ownership records, Emlak Konut's land area was expanded, but its ownership share decreased. In contrast, both the ownership area and share of TOKI and the Treasury of Finance increased. As a result, two parcels belonging to TOKI were transferred to Emlak Konut, while the newly created small and inefficient parcels were allocated to the Treasury of Finance and TOKI (Figure 6; picture A and B).

While the ownership structure involves Emlak Konut REIT, TOKI, and the Treasury of Finance, the project tender was won by the 'Özak – Yenigün – Ziylan Ordinary Partnership,' and the construction process has begun. Özak REIT was established in 1995, and Yenigün in 1973, both being construction firms. Ziylan Real Estate, on the other hand,

was founded in 2014, and the Büyükyalı project is the only joint project of these three companies. The inclusion of Ziylan Real Estate—a newly established firm—in the project suggests that it entered the construction sector with the support of the more established and experienced firms. In other words, this project introduces a new construction company into the sector that aims to make a name for itself. More comprehensively, this is a process in which Özak REIT—ranked 9th in market value—and the other two construction companies utilised publicly owned land to further expand in the sector, following a tender opened by Emlak Konut REIT, the company with the highest market value (Erdoğan and Özaslan, 2021).

Changing Function: From Factory Site to Housing Project

In 2016, when construction of the project began, Özak REIT launched a design competition for the planning of the site, and as a result, the architectural design was awarded to the British architecture firm Chapman Taylor (Karakoç, 2016). It was initially announced that blocks ranging from 5 to 17 storeys would be constructed, not exceeding 55 metres in height so as not to disrupt the silhouette (Karakoç, 2016); however, the final height reached 70 metres. This suggests that the initial narrative may have been constructed merely to avoid public backlash. The same applies to the registered heritage structures. Although it was stated that they would be preserved in situ, four of them were relocated. The registered structures within the study area were restored, but many were moved to other parts of the site. The Company Command Building was relocated near the Accounting Office Building, and its original location was opened to new development. The registered Gate was moved to the northwest of the building, while a fountain structure was reconstructed to its southwest. Artefacts uncovered during construction are now displayed to the west of the Armoured Vehicle Repair Workshop. The remaining registered buildings remain in their original locations (Figure 7).

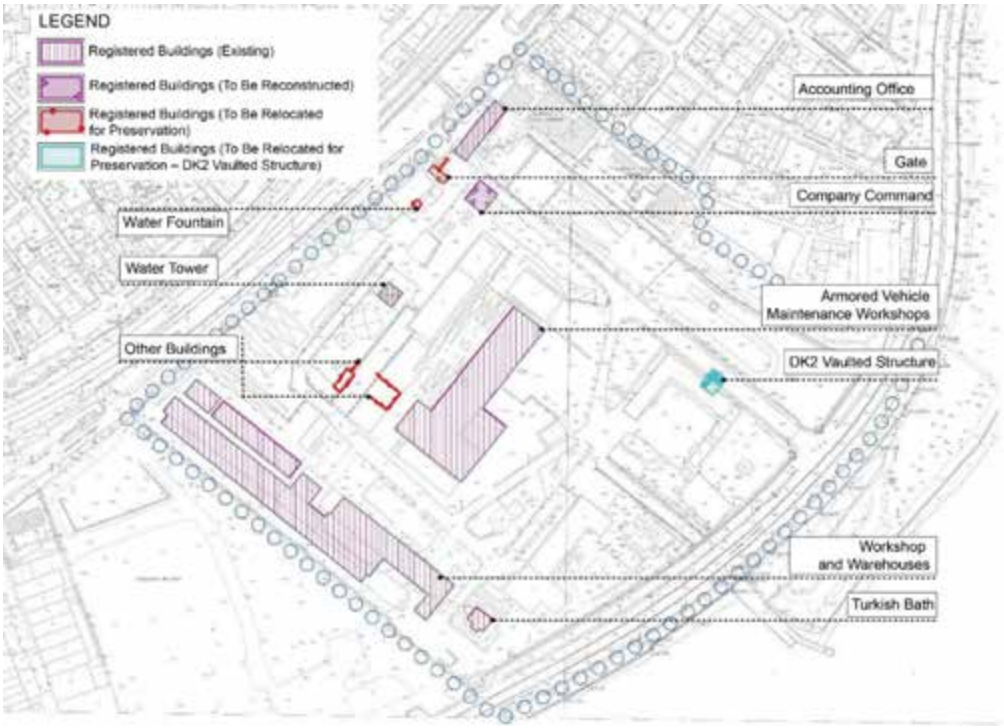

Figure 7 Registered Buildings Sketch (Ministry of Environment and Urbanisation, 2018)

The relocated Company Command was moved to the same parcel as the Accounting Office and is now used for educational purposes on this parcel, which has been designated with an educational function. The Water Tower has been restored and is exhibited, while the other registered remains discovered on-site are displayed in their existing condition. It is understood that two additional underground levels have been constructed beneath the single-storey Armoured Vehicle Maintenance Workshop, and multiple functions such as retail, cafés, restaurants,

exhibitions, and cultural and artistic activities have been added. Similarly, an additional underground level has been added beneath the Workshop and Warehouse building, which is now used as a commercial space. In addition to these, an underground parking facility is also present.

Conclusion

In this study, which examines the changing role of the state under neoliberal policies, the case of the Zeytinburnu Fabrika-i Hümayun is used to illustrate how the state, acting as an entrepreneur, has taken on a role that serves capital interests rather than the public good. As a central authority, the state established the Privatisation Administration and restructured the already existing TOKI to function as parastatal institutions in order to facilitate privatisation. TOKI, as one of the main actors in this process, was granted broad powers by law, enabling the non-transparent and gratuitous transfer of treasury land ownership. By transferring ownership to its subsidiary Emlak Konut REIT and awarding tenders to construction firms, the result has been the development of luxury housing projects and the use of public land for non-public purposes. Except for objections raised by the Chamber of Architects and the Chamber of City Planners (TMMOB), no other formal opposition was made during the transformation of the factory site into a housing project, which is now fully completed.

The area, declared a 'Tourism Center' in 1987, was initially targeted for a housing project by the Istanbul Metropolitan Municipality (IMM), acting as a local state with an entrepreneurial role aiming to transform Istanbul into a global city. However, the housing project was ultimately completed under the initiative of the central government following the centralisation of authority after the 1990s. Decisions regarding the registered heritage structures were made with the approval of the relevant Regional Conservation Board. The process appeared to comply with legal procedures on the surface. This was because the central government played a proactive role by establishing in advance a legal framework that would allow the process to proceed smoothly—resulting in a structure that was not necessarily lawful in spirit, but had legal backing.

The transformation of a publicly owned land, originally used for the public good, was legitimised by promoting the idea that the area would remain publicly accessible under its new function. However, the limited number of shared spaces was equipped with luxury consumption venues. In this process, the public land was used in line with capital interests—despite the public—through the Özak-Yenigün-Ziylan Ordinary Partnership, which won the tender opened by Emlak Konut REIT. This constitutes a clear example of an alienation process through public dispossession.

In 2018, the ownership of the 'Residential + Commercial' and 'Residential + Tourism' zones belonged to Emlak Konut REIT, while the 'Education Area' and 'Religious Facility Area' were under the ownership of TOKI. By 2020, a small portion of the 'Residential + Commercial' area owned by Emlak Konut REIT had fallen outside the parcel boundary, while the 'Education Area' and 'Religious Facility Area' previously owned by TOKI had been transferred to Emlak Konut REIT. Additionally, part of the road area outside the project site was transferred to TOKI. As shown in Figure 6, narrow and inefficient strips of land—publicly used but not functionally viable—were transferred to TOKI's ownership. This way, the proportion of public facilities, which should have been preserved for public use, was maintained on paper.

Originally established as a state institution to provide housing for middle- and low-income groups, TOKI has gradually evolved into a parastatal organisation. Nevertheless, the Keynesian narrative that TOKI continues to build housing for low-income groups is still maintained, which helps preserve its perceived legitimacy in the public eye. On the other hand, TOKI continues to auction off publicly owned treasury lands and real estate, while applying the method of urgent expropriation for social housing projects. In doing so, it relies on Presidential Decrees for legal legitimacy.

While the factory site once held use value on behalf of society, its prestigious location has made its exchange value more significant for capital. Instead of being regarded as part of the industrial heritage that reflects a particular historical period, the registered structures on the site have been transformed into commodities intended

to provide visual pleasure for users and visitors. In a city like Istanbul—where even adequate gathering spaces for earthquakes cannot be designated despite the urgent seismic threat, and where 1.3 million housing units are considered risky and 230,000 buildings are in need of immediate transformation[1]—it is ethically unacceptable for a public space that should serve the common good to be used for capital interests, against the public interest. As long as the growth-oriented approach of neoliberal policies continues, such capital-driven practices that sideline public benefit will also persist. For this reason, the state must recall its public responsibilities, and society must recognise and demand its fundamental human rights through active engagement and resistance.

Dynamic Analysis of Cultivated Area-Food-Population System in Shrinking Rural Areas of Northeast China and Its Planning Strategies

Luanxuan Zang
College of Architecture and Urban Planning, Tongji University
zangluanxuan@163.com

Abstract
Rural population decline, an inevitable outcome of urbanization and socioeconomic progress, critically impacts national food security through interactions within the cultivated area-food-population system. This study examined Northeast China, a region emblematic of rural depopulation, to analyse systemic dynamics using 2000–2020 census data. Spatial shrinkage patterns were mapped and categorized, revealing key trends. Proposed strategies advocate proactive "smart shrinkage" aligned with demographic shifts: enforcing farmland protection, enhancing black soil conservation, optimizing agricultural layouts, and boosting grain productivity. These measures aim to harmonize population-land-grain coordination, balancing strict resource governance with regional integration. Findings provide actionable guidance to advance sustainable rural-urban synergies, ensuring resilient food systems amid demographic transitions in Northeast China.

Keywords: rural population shrinkage; food security; cultivated area-food-population system; Sustainable Food Planning; Northeast China

1. Introduction

The development of urbanisation has facilitated the flow of production factors between urban and rural areas, disrupting the original internal equilibrium mechanism that maintained the mutual adaptation of agriculture, peasant communities, and rural settlements. This transformation has altered the relatively closed, land-dependent traditional rural development model characterised by self-sufficiency, gradually fostering more open urban-rural social relations. However, the conflicts arising from rapid large-scale urbanisation have exacerbated the "agriculture, rural areas, and farmers" issues (Zhang et al., 2022). Since China's reform and opening-up, with pivotal milestones in 1995 (economic system transformation) and 2014 (comprehensive deepening reforms), rural population dynamics have evolved through three distinct phases: gradual development, mass migration, and citizenisation of agricultural migrants (Guo, Zhou and Liu, 2020). Contemporary rural regions now demonstrate persistent population decline, with issues such as rural depopulation and hollowed villages attracting increasing scholarly attention. The outflow and shrinkage of rural populations have become inevitable phenomena in the process of socioeconomic development, leading to a shortage of rural labor and an imbalance in rural economic structures, also serving as key issues for alleviating human-land tensions and achieving high-quality development in rural territorial systems (Guo, Zhou and Liu, 2020; Dong et al., 2023). These changes adversely impact food production and security, emphasizing the need to investigate the effects of population decline on farmland protection and food production, particularly in regions such as Northeast China, which is characterized by vast agricultural land and significant rural population decline, while maintaining exceptional agricultural productivity as a vital grain production base (Zhang et al., 2023). The region shoulders dual strategic responsibilities, such as black soil conservation for sustainable farmland management and safeguarding national food security. Therefore, it is necessary to study the degree of rural population shrinkage and the challenges it brings to the dual tasks of protecting cultivated land and ensuring food security.

Current research on rural population contraction primarily focuses on three dimensions: village hollowing quantification, rural population shrinkage measurement methodologies, and empirical case studies. Some scholars have evaluated rural hollowing patterns across national, provincial, and county-level scales (Long, Li and Liu, 2009; She and Qiu, 2024; Zhang et al., 2024), analysing formation mechanisms and proposing governance strategies. Comparative studies drew lessons from developed nations (e.g., USA, Japan, South Korea, Germany, UK) in addressing ageing, low fertility rates, and rural shrinkage (Xiao, Zhang and Liu, 2022; Zhang, Li and Bai, 2022; Feng

et al., 2022). Other investigations examined spatial-temporal patterns of population outflow rates (Guo, Zhou and Liu, 2020), categorised settlement evolution types, and discussed rural human settlement space planning strategies guided by "smart shrinkage" (Zhao, You and Chen, 2015). Existing methodologies predominantly employed qualitative case analyses or quantitative indices assessing natural, social, and economic dimensions of rural vitality, or referring to the definition of "shrinkage" in the study of shrinking cities (Liu and Yang, 2017; Ma, Li and Zhang, 2021), used indicators such as the rate of change of rural permanent population in a certain period and the average annual change of rural permanent population to characterize the degree of rural population shrinkage (She and Qiu, 2024). However, limited attention had been paid to the interaction between rural demographic contraction and the cultivated area-food system. While human geography research has conceptualised the Cultivated Area-Food-Population Complex System (Bao and Fang, 2007), with subsequent studies applying coupled coordination models to analyse regional system evolution (He et al., 2016; Aimaiti, Tuoheti and Xu, 2020; Yang et al., 2016), the mechanisms linking rural depopulation with land-food system dynamics remain underexplored.

To address this gap, this study focused on Northeast China, a region emblematic of rural population shrinkage, as the research area. Through typological identification of population contraction patterns and systematic analysis of its cultivated area-food-population system dynamics, I discussed planning interventions to support synergistic development of high-quality urbanisation and rural revitalisation in this strategic agricultural zone.

2. Definition of concepts

2.1. Rural Shrinkage

The concept of "rural shrinkage" derives from its urban counterpart, "urban shrinkage" (Dong et al., 2023). In American rural demographic studies, analogous terms include "population decline" (defined as the population in 2010 decreasing by more than 25% compared with the historical peak) and "population loss" (referring to sustained demographic decreases across both 1990–2000 and 2001–2010 periods) (Xiao, Zhang and Liu, 2022). Chinese scholars define shrinking villages as rural settlements experiencing either a permanent resident population smaller than the registered population or persistent population decline during urbanisation and agricultural modernisation, accompanied by vacant or derelict residential buildings (Jiao and Zhang, 2021). Population loss constitutes the most direct and effective measurement indicator of shrinkage phenomena (Ma, Li and Zhang, 2021). Building on the research results of existing scholars on rural shrinkage and China's census-based urban-rural classification criteria, this study operationalised rural shrinkage from a demographic perspective, specifically denoting sustained reductions in permanent rural populations across two consecutive decades: 2000–2010 and 2010–2020.

2.2. Cultivated area-food-population system

The cultivated area-food-population system refers to a complex territorial system grounded in the exploitation and utilisation of cultivated area resources, with grain production, consumption, and circulation as its core processes, and the fulfilment of human dietary needs as its ultimate objective. Within specific regional contexts, both the quantity and quality of cultivated area determine grain output, while the interplay between grain production and population dynamics governs per capita grain availability (Bao and Fang, 2007). Coordinated development of this tripartite system manifests through (Yang et al., 2016):

- Effective regulation of sustained population growth;
- Maintenance of population density on cultivated land within its carrying capacity thresholds;
- Dynamic per capita grain availability consistently exceeding dietary demand;
- Preservation of arable land quality achieved without ecological degradation .

3. Data and method

3.1. Study area and data sources

This study focused on Northeast China's Heilongjiang, Jilin, and Liaoning provinces, with county-level administrative units (counties and county-level cities) as analytical subjects. Based on 2020 administrative boundaries, I integrated historical data from 2000-2020 after accounting for jurisdictional adjustments and data availability constraints. Four newly established counties of Tangwang County, Fenglin County, Daqingshan County and Nan-

cha County in Yichun City, Heilongjiang Province were excluded, resulting in a final dataset of 143 county-level units.

The county-level administrative unit vector data used in this study came from the Third National Land Survey database in 2020. Population data came from county-level demographic statistics from the Fifth (2000), Sixth (2010), and Seventh (2020) National Population Censuses. Cultivated area data came from the cultivated land area of "China Agricultural Statistical Yearbook" (2001), the 2010 data of the Second National Land Survey data (https://gtdc.mnr.gov.cn/Share?UiNMsBTfPrya=1712637735952#/secondSurvey) verified with the China Annual Cultivated Land Dataset (CACD) (https://doi.org/10.5281/zenodo.7936885) released by Dr. Tu Ying in Professor Gong Peng's team at Tsinghua University with a resolution of 30m×30m, and the 2020 data of the Third National Land Survey data (https://gtdc.mnr.gov.cn/Share#/thirdSurvey). The grain production data for 2000 and 2010 were derived from the "China County Statistical Yearbook" (2001, 2011), and the grain production data for 2020 were derived from the statistical yearbooks and the statistical bulletin on national economic and social development of various provinces and cities .

3.2. Method

3.2.1. Rural Shrinkage Measurement

This study firstly identified persistently shrinking rural areas through sustained reductions in permanent rural populations across two decadal intervals (2000-2010 and 2010-2020), using triennial census data, then calculated the average annual change rate of rural permanent population in each county from 2000 to 2020. The population outflow rate of each county was calculated using the permanent population in rural areas and the rural registered population in 2010. The two indicators were combined to characterize the degree of rural shrinkage in Northeast China. The formulas were as follows:

$$= \left(\sqrt{\quad_{2}/\quad_{1}} - 1\right) \times 100\%$$

Where: S_i was the average annual change rate of the rural permanent population of the i county (city) in a certain period, P_{i1} and P_{i2} represented the rural permanent population of the county (city) at the beginning and end of the period respectively, and n was the interval year.

$$= (1 - \quad / \quad) \times 100\%$$

Where: R_i was the population outflow rate of county (city) i, H_i and P_i represented the number of rural registered population and rural permanent population of the county (city) respectively.

3.2.2. Rural Shrinkage Typology

Building on existing literature and Northeast China's demographic trends, county-level rural shrinkage was classified into four types according to dual thresholds of annualised rural population change rate (S_i) and population outflow rate (R_i): In-migration Shrinkage (R_i<0), Moderate Shrinkage (0<R_i≤50%, -3%<S_i≤-1%-,) Severe Shrinkage(0<R_i≤50%, S_i≤-3%), Critical Outflow Shrinkage (R_i>50%).

4. Dynamic analysis of the rural cultivated area-food-population system in Northeast China

4.1. Analysis of changes in total volume

4.1.1. Rural population dynamics

Between 2000 and 2020, Northeast China's county-level rural population declined sharply from 41,450,985 to 25,178,835, a decrease of 39.26% and an average annual growth rate of about -2.46%. This demographic shrinkage exhibited accelerating negative growth trends, with Heilongjiang Province experiencing the most pronounced decline, particularly during 2010-2020, where annualised population loss rates exceeded regional averages.

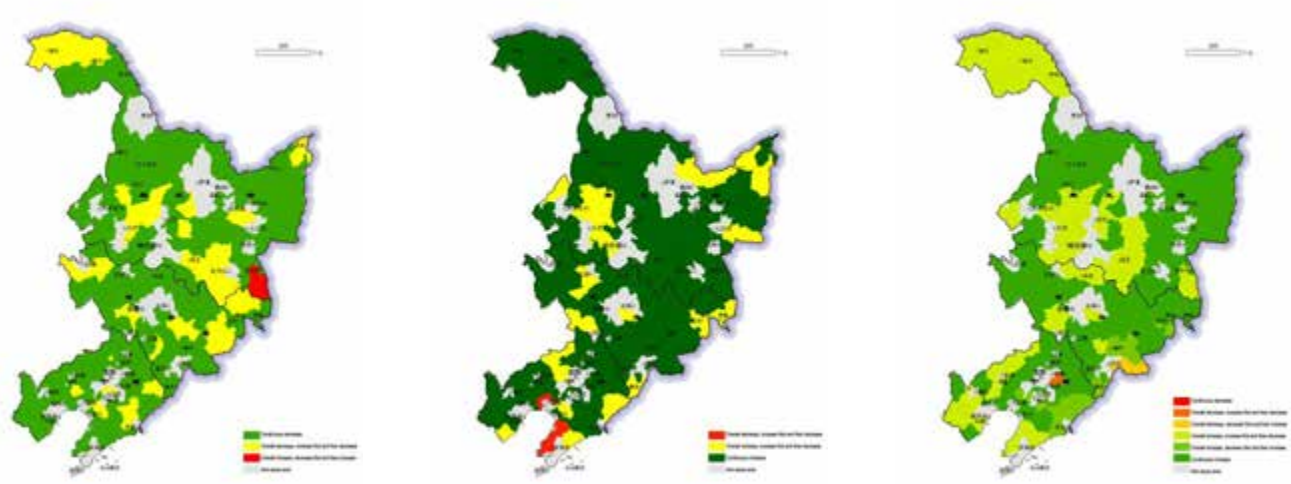
4.1.2. Cultivated land area dynamics

From the perspective of the total scale of cultivated land, the cultivated land area in counties and villages in

Northeast China increased significantly from 2000 to 2020, with a total increase of 106,331 square kilometers, a growth rate of 69.49%. From the perspective of spatial distribution, the cultivated land area of most county units in Northeast China continued to grow, and showed a concentrated and contiguous distribution state. Only the cultivated land area of four county-level units, namely Wafangdian City, Changhai County, Panshan County and Gaizhou City, decreased, and they were concentrated in the Bohai Rim region. Although the total amount of cultivated land in some counties (cities) increased, their cultivated land area decreased in the past decade and was relatively scattered in space. Overall, the protection of cultivated land in Northeast China has achieved good results in terms of quantity and scale.

4.1.3. Grain production dynamics

Grain output in Northeast China surged by 175.57% over the study period, with a relatively large growth rate from 2000 to 2010 and a slowed-down rate from 2010 to 2020, which was related to the reduction of agricultural labor force, the stabilization of cultivated land area and planting structure due to the intensified population loss in Northeast China. In terms of grain production pattern, Heilongjiang Province was the main grain production area in Northeast China, and grain output has basically remained above 50% of the total in the study area. From the perspective of the spatial distribution of changes in grain output, 62.24% of counties continued to increase, and only 5 counties (3.50%) had a decrease in grain output in 2020 compared with 2000, which were scattered around the provincial capital, coastal and border forest areas, attributable to industrial restructuring and topographic constraints.



(a) Rural population (b) Cultivated land area (c) Food production

Figure 1. Changes in the total amount of the rural cultivated area-food-population system in Northeast China

4.2. Per capita/unit analysis

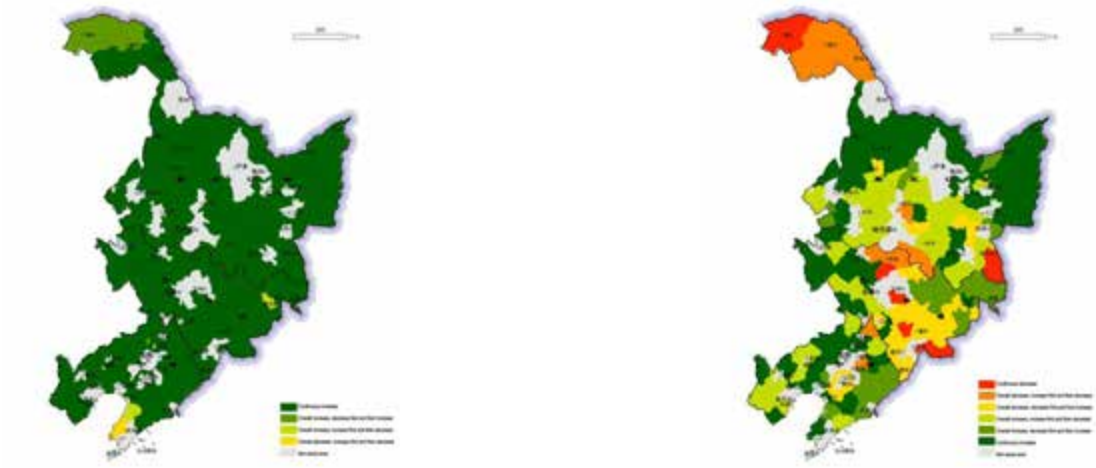
4.2.1. Per capita cultivated land dynamics

Between 2000 and 2020, county-level per capita arable land area in Northeast China exhibited consistent growth, with Heilongjiang Province recording the most pronounced expansion and persistently exceeding the regional average. Spatially, over 95% of counties demonstrated sustained growth in per capita arable land availability, and other counties showed minor volatility, with only the per capita arable land area of Wafangdian City decreasing. This trend reflected the inevitable outcome of rural population contraction coupled with intensified cultivated land conservation measures.

4.2.2. Grain output per cultivated land area dynamics

Grain yield per unit cultivated area across Northeast China increased markedly during 2000-2020, with Heilongjiang Province leading at 90.24% growth, followed by Liaoning Province (72.91%). From the perspective of county

differences, the cultivated land efficiency of 37.76% of counties continued to improve, 37.76% increased with fluctuations, and less than 1/4 of counties decreased, forming two relatively concentrated groups in the Daxing'anling Prefecture and the central-eastern Jilin Province. Spatial patterns revealed optimal productivity concentrated in contiguous agricultural zones consisting of southwestern Heilongjiang Province and western Jilin Province, and plains in northern Liaoning Province and eastern Heilongjiang Province. These high-yield regions benefited from large-scale contiguous farmland conducive to modernised agricultural practices.



(a) Per capita cultivated land area (b) Grain production per land area

Figure 2. Changes in the per capita/unit index of rural cultivated area-food-population system in Northeast China

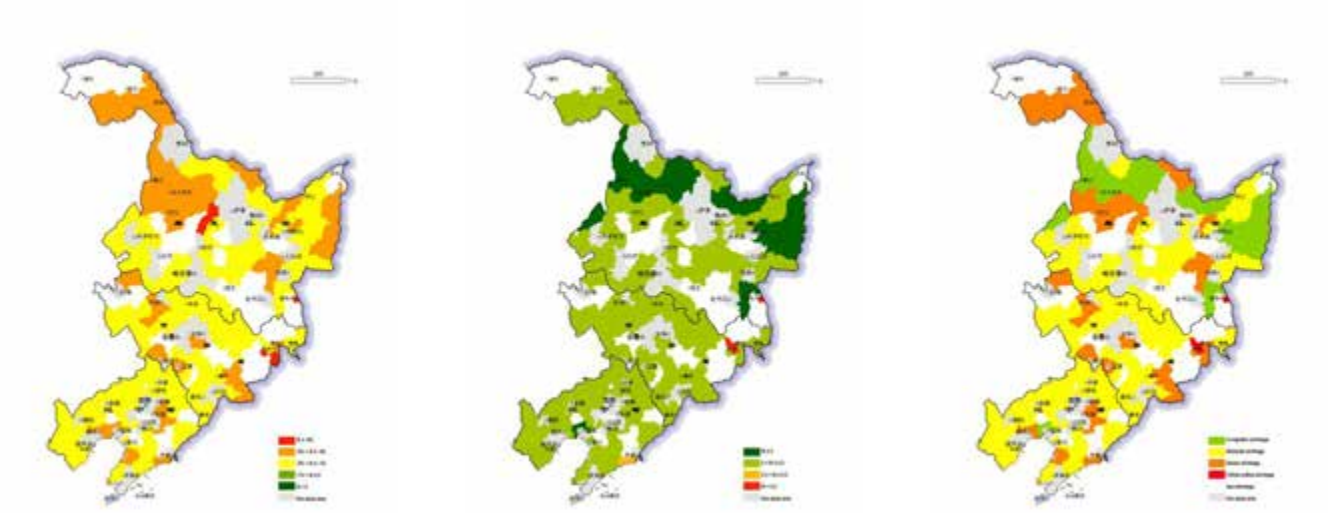
5. Analysis of the types and characteristics of rural population shrinkage in Northeast China

5.1. Identification of the scope of rural population shrinkage

Between 2000 and 2020, 113 county-level units in Northeast China, accounting for 79.02% of the study area, exhibited sustained rural population decline. Among them, there were 35 in Liaoning Province, 31 in Jilin Province, and 47 in Heilongjiang Province, accounting for 85.36%, 79.49% and 74.60% of the total number of study units in each province, respectively. This demonstrated pervasive rural shrinkage across the region, with Heilongjiang Province bearing the largest number of county-level units with rural population shrinkage, and Liaoning Province had the highest proportion of county-level units with rural population shrinkage.

5.2. Classification of rural shrinkage types

Integrating annualised rural population change rate (S_i) and population outflow rate (R_i), four rural shrinkage types emerged, with moderate shrinkage as the main rural shrinkage type in Northeast China, including 73 county-level units, accounting for 64.60% of the total shrinkage units, followed by 25 severe shrinkage units (22.12%), 13 in-migration shrinkage units (11.50%) and 2 critical outflow shrinkage units (1.77%). Spatial patterns showed that, the moderate shrinkage counties were mainly concentrated and contiguous in space, mainly distributed in the southern part of Heilongjiang Province, most of the counties in Jilin Province and Liaoning Province. Besides, the severe shrinkage counties were scattered in the three provinces of Northeast China. The in-migration shrinkage counties were mainly distributed in the northern part of Heilongjiang Province, and there were also scattered points in the eastern part of Heilongjiang Province and the southern part of Liaoning Province. The critical outflow counties were scattered and the number was the smallest, with only two units in Suifenhe City, Heilongjiang Province and Yanji City, Jilin Province. In general, the phenomenon of rural population shrinkage in counties in Northeast China was common, and the rural shrinkage situation in the north part was more severe than that in the south.



(a) Annualised rural population change rate from 2000 to 2020 | (b) Rural population outflow rate in 2010 | (c) Rural shrinkage type

Figure 3. Distribution of rural shrinkage types in Northeast China

5.3. Characteristics of the cultivated area-food-population system in Northeast China's shrinking rural areas

As demonstrated, Northeast China's rural areas exhibited accelerating population shrinkage alongside expansions in cultivated land area, which was changing inversely compared with rural permanent population, and intensifying spatial disparities in grain production efficiency. The dependence of food production on cultivated land resources was increasing. The four identified rural shrinkage typologies (in-migration, moderate, severe, and critical outflow) manifested distinct systemic characteristics within the cultivated area-food-population system, as synthesised in Figure 4.

Figure 4. Table of characteristics of the cultivated area-food-population system in Northeast China's shrinking rural areas

Type	Number of counties	Characteristics of the cultivated area-food-population system	Distribution
In-migration shrinkage	13	• The rural population has decreased, with increased area of cultivated land and improved efficiency of cultivated land. • Food production was less dependent on population and cultivated land resources. • The concentration of cultivated land in plain areas was conducive to large-scale production, and the improvement of agricultural technology level was the key to maintaining system stability.	Plain arable land in the northern-eastern border counties of Heilongjiang Province.

Moderate shrinkage	73	• The rural population has decreased, with increased cultivated land area. • The efficiency of cultivated land has mainly increased, with the efficiency of cultivated land in counties bordering provinces declined in recent years. • Food production was less dependent on the rural population, showing regional differences in the degree of dependence on cultivated land resources, with the main trend being a decrease in dependence.	Plain arable land in southern Heilongjiang Province, and most counties in Jilin Province and Liaoning Province.
Severe shrinkage	25	• The rural population has decreased, and the cultivated land area has increased. • There were large regional differences in cultivated land benefits. • Food production was less dependent on the rural population. • Natural geographical characteristics caused food production to rely more on cultivated land resources. Attention should be paid to the coordination of cultivated land protection and ecological security.	Scattered distribution, mainly in forest areas, mountainous areas and protected areas.
Critical outflow shrinkage	2	• The rural population has decreased, and the cultivated land area has increased. • The dependence of food production on cultivated land resources has decreased. • Non-agricultural counties with scarce cultivated land resources have developed other industries based on their port advantages.	Border port cities, such as Suifenhe City, Heilongjiang Province, and Yanji City, Jilin Province.

6. Planning and regulation strategies for the cultivated area-food-population system in Northeast China's shrinking rural areas

Effective governance of he cultivated area-food-population system necessitates ensuring regional food self-sufficiency, maintaining systemic equilibrium, and coordinating tripartite relationships (Bao and Fang, 2007). As China's primary grain production base, Northeast China secures national food security while requiring targeted interventions to harmonise demographic, land-use, and agricultural dynamics, to acknowledge the inevitable trend of rural population shrinkage, to preserve precious and limited arable land resources, to promote technological progress and enhance food production capacity, so as to achieve the goal of sustainable development.

6.1. Proactive Smart Shrinkage Strategies Aligned with Demographic Trends

Planning should first establish awareness of rural shrinkage, correctly understand the inevitability of rural shrink-

age, abandon the traditional notion of development based on population size, clarify the main theme of "smart shrinkage" (Zhao, You and Chen, 2015), and attach importance to the creation and maintenance of rural vitality (Zhang, 2016). In order to address the coexistence of waste and insufficient supply of public services and generally low quality in rural shrinking areas, it is advised to optimize resource allocation and explore the establishment of a wide-area joint system of local living circles with urban-rural linkage allocation (Zhang, Li and Bai, 2022). The economic function, social structure and spatial evolution of rural areas are deeply influenced by factors such as the natural resource conditions and agricultural foundation of the village itself, the economic location and urbanization development stage, the intensity of interaction between grassroots governance and urban-rural elements, and the level of urban and rural infrastructure and public services (Zhang and Sun, 2019). Therefore, we should respect regional differences and formulate differentiated development paths based on local conditions such as the type of rural shrinkage and natural-economic factors.

6.2. Rigorous cultivated area conservation and black soil enhancement

China's farmland protection has gone through three major stages, from focusing on quantity protection to giving equal weight to quantity and quality, and to the "three-in-one" protection of quantity, quality and ecology. A series of farmland protection systems have been established, including farmland occupation and compensation balance, farmland use control, farmland quality acceptance, permanent basic farmland protection, black soil protection, land development, consolidation and reclamation. Planning should strictly adhere to the awareness of farmland red lines, implement the strictest farmland protection system, and curb the reduction of farmland area. Aiming to improve the quality and benefits of farmland, it is advised to increase the protection of black soil, strengthen agricultural land remediation and high-standard farmland construction, orderly promote rotation and fallow. To strengthen the coordinated protection of farmland and surrounding ecosystems, and to build a healthy and stable farmland ecosystem, are also essential to food and farmland security. By utilising the new generation of information technology to promote the informatization of land and resources, the department of natural resources could timely and effectively track and monitor changes in farmland area and quality.

6.3. Agricultural restructuring for systemic productivity gains

As the national strategic grain base, Northeast China Region needs to build an awareness of serving the implementation of major national strategies, and promote regional agricultural development in a coordinated manner. Planning should adhere to systematic thinking, optimize the agricultural pattern according to the differences in resource endowments in the region, promote cross-county and cross-provincial land resources and grain production coordination, to achieve win-win cooperation. It is also advised to adjust the production structure through reforming the farming system, to establish an ecological agricultural pattern that matches agricultural productivity with resource and environmental carrying capacity, to introduce advanced technology, modern equipment, management concepts, etc. into agricultural production to develop modern large-scale agriculture, so as to achieve the objective of enhancing the overall efficiency of grain production.

7. Conclusion

Rural population contraction constitutes an inevitable urbanisation outcome rather than rural decline. Stabilising the cultivated area-food-population system in rural area, which is an important carrier for ensuring China's food security and sustainable development of land space, remains critical for achieving high-quality development and urban-rural coordination under the general trend of population shrinkage. Northeast China has the dual typicality of rural population shrinkage and cultivated area-food-population system coordination. It is necessary to follow the trend of depopulation to shrink smartly, to strictly protect the stability of the amount of cultivated land and improve its quality, to promote the sustainable development of agricultural production in a regional integrated system, aiming to promote the coordinated development of high-quality new urbanization and rural revitalization in the Northeast China to achieve sustainable development and ensured food security in the face of ongoing demographic and socioeconomic changes.

Abstract
The food system generates one-third of global GHG emissions, with urban regions playing a key role in climate challenges. In Türkiye, the Marmara Region—home to over 25 million people—faces mounting pressure on its food systems due to rapid urbanization, land-use change, and environmental degradation. Despite its agricultural potential, the region experiences declining farmland and water quality. The Play Marmara Food game, developed within the MARUF initiative by Play the City, addresses these challenges through a serious game format. It brings together stakeholders from various sectors to simulate scenarios, visualize data, and co-develop sustainable strategies. This study evaluates the game's role in fostering collaboration and informing food supply chain design to enhance regional sustainability.

Keywords: sustainable regional food systems; food security; supply chains; city gaming; serious game

1. Introduction

The global food system is increasingly recognized as a critical contributor to the climate crisis. According to the Food and Agriculture Organization (FAO), nearly one-third of all human-induced greenhouse gas emissions stem from the production, distribution, and consumption of food (Crippa et al., 2021). However, environmental impact is only one facet of a much broader crisis. Hunger and food insecurity—once on the decline—are rising again worldwide. The FAO reports that the global prevalence of undernourishment (PoU) increased from 8.0% in 2019 to 9.8% in 2021, reversing years of progress and raising doubts about the effectiveness of current food governance models (FAO, 2022a).

This troubling trend signals a deeper systemic problem. Food security depends heavily on access to freshwater, affordable energy, and stable logistics networks- all of which are increasingly vulnerable in a world beset by climate disasters, conflicts, and pandemics (FAO, 2015). Moreover, the inefficiency of current food systems is staggering: nearly 30% of global energy is consumed by food systems, and 38% of that energy is used to produce food that is ultimately wasted (Cuellar & Webber, 2010).

Recognizing this, the United Nations included "Zero Hunger" among its Sustainable Development Goals (SDG 2), acknowledging the need for a multidimensional approach—one that combines food security with social protection, infrastructure investment, and the establishment of sustainable production and distribution systems. The food crisis, fundamentally, is not just about scarcity; it is about the unsustainability embedded within the way we currently produce, distribute, and govern food.

Against this backdrop, regional food systems offer a potential path forward. They can shorten supply chains, promote local resilience, and create opportunities for integrated planning tailored to specific socio-ecological contexts. Yet building such systems requires inclusive governance, data-informed planning, and collaboration across diverse stakeholders- ranging from producers and cooperatives to municipalities, NGOs, and consumers.

Serious game is a structured, interactive method that allows stakeholders to explore real-world challenges in a simulated environment. This paper examines a serious game developed for Türkiye's Marmara Region, *Play Marmara Food*, which seeks to enhance stakeholder dialogue, simulate food system dynamics, and inform strategies for more sustainable regional planning.

The Marmara Region, Türkiye's most populous and industrialized area, plays a dual role as both economic

powerhouse and key agricultural zone. However, it faces mounting challenges related to land-use conflict, environmental degradation, and supply chain fragmentation. This study explores how *Play Marmara Food*, developed by Play the City within the MARUF initiative, facilitates collective problem-solving and knowledge exchange.

The paper proceeds as follows: Section 2 outlines the theoretical foundations of sustainable regional food chains and serious games. Section 3 describes the food system dynamics in Marmara. Section 4 details the game's methodology and design. Section 5 presents the game outcomes and participant insights, as well as discusses the implications for participatory governance and food policy. The final section concludes with recommendations for future applications and research.

2. Theoretical and Methodological Framework

2.1. Sustainable Regional Food Chains

Sustainable regional food chains refer to interconnected systems of food production, processing, distribution, consumption, and waste management that operate within a defined geographical region and are guided by principles of environmental stewardship, social equity, and economic viability. These systems aim to minimize environmental impact while promoting local economic development and food sovereignty (Sonnino et al., 2016).

While the concept of regional food systems offers a sustainable alternative to globalized food chains, their development is constrained by structural and operational challenges, as noted in recent literature and policy frameworks:

- **Land Use Conflicts:** Rapid urbanization often leads to the loss of fertile agricultural land, particularly in peri-urban regions, compromising local food production capacity (FAO, 2023b). This is exacerbated by weak land-use policies and competing economic interests.
- **Governance Fragmentation:** Regional food systems typically span multiple administrative jurisdictions, creating coordination difficulties and regulatory inconsistencies (Moragues-Faus & Morgan, 2015). The absence of integrated food governance hinders systemic change.
- **Logistics and Infrastructure Gaps:** Many regional supply chains lack the infrastructure necessary for efficient and competitive operation, including cold storage, processing facilities, and short distribution networks, coordination issues between transport providers and both small- and large-scale food facilities often result in costly delays and inefficiencies (Day-Farnsworth &Miller, 2014). This limits their scalability and integration into broader markets.
- **Market Access Barriers:** Small-scale producers often face challenges in accessing mainstream markets due to limited bargaining power, lack of certification, and low investment in marketing and technology (Kneafsey et al., 2013). These barriers can reduce the economic viability of regional systems.
- **Environmental Pressures**: The current global food system contributes significantly to climate change, biodiversity loss, and resource depletion. Food production is responsible for approximately one-third of global anthropogenic greenhouse gas emissions (Crippa et al., 2021), with a significant portion attributed to livestock farming and deforestation (Kler et al., 2022; Shabir et al., 2023).
- **Vulnerability**: External shocks such as pandemics and armed conflicts exacerbate food system fragilities. The COVID-19 pandemic and the war in Ukraine, for example, disrupted supply chains, increased food and energy prices, and significantly worsened global hunger and food insecurity (FAO, 2022; Abay, 2022; WFP, 2022). These crises have also emphasized the heavy dependence of food systems on freshwater and affordable energy, heightening their vulnerability (FAO, 2015).
- **Information Deficits:** Data on regional food flows, environmental impacts, and land productivity are often fragmented or outdated, hampering evidence-based planning and policy interventions (FAO, 2023a).
- **Food Waste and Resource Inefficiency:** The energy used to produce the 24.4 billion pounds of dairy products discarded annually in the U.S. alone could meet the world's daily energy needs (Cuellar & Webber, 2010). Reducing such inefficiencies is key to building more sustainable food systems.

To effectively address these multifaceted challenges, integrated and participatory planning approaches have

gained prominence. The City Region Food System (CRFS) framework developed by FAO and RUAF advocates for multilevel, multistakeholder governance to facilitate food system transformation through collaborative and context-specific strategies (FAO, 2023b).

Participatory tools such as serious games provide innovative formats for convening diverse actors, enabling experiential learning, system mapping, and collaborative strategy development (Devisch et al., 2018). By simulating real-world conditions and visualizing complex interdependencies, serious games allow stakeholders to explore alternative futures, test trade-offs, and co-create actionable solutions.

In this context, the Play Marmara Food game exemplifies an applied method that aligns with theoretical and policy frameworks emphasizing collaboration, systems thinking, and integrated governance. By employing serious games as a participatory method, it supports consensus-building and facilitates dialogue across traditionally siloed sectors, making it a relevant methodological tool for informing regional food policy and sustainability planning.

2.2. Serious Games in Planning and Governance

"Serious games" are interactive experiences designed for a primary purpose other than pure entertainment, typically learning, decision-support, or social change (Abt, 1970). Building on Abt's foundational work, later frameworks describe serious games as the fusion of a *serious* dimension (an explicit real-world objective) and a *game* dimension (rules, feedback, voluntary play) (Djaouti et al., 2011).

Across these forms, games share a common structure of *means* (tools, rules), *goals* (desired outcomes) and *feedback* loops that allow iterative experimentation (Parlett, 1999; Crawford, 1983). This structure makes them attractive for planning tasks where complex systems and competing interests must be explored in a "safe-to-fail" environment.

The planning field has a long tradition of using game-based methods to test policies and accelerate stakeholder learning (Mayer, 2009). Notable precedents include:

Urban growth & land-use games: Workshop-based table-top games that let citizens allocate housing, green space and infrastructure, these tools help reveal trade-offs between density, mobility and environmental quality (Sousa et al., 2022).

- **Infrastructure & mobility games**: Metro-planning games in Singapore and transit-oriented-development role-plays in Europe allow transport agencies to co-design route scenarios with residents, balancing capacity, cost and equity. (LTA Connect, 2019; ULI, n.d.)
- **Climate & resource games**: The *World Climate* negotiation game and the *Food Chain Reaction* scenario game engage national delegates, NGOs and private firms in exploring emissions pathways or global food shocks, underscoring supply-chain interdependencies. (Sterman et al., 2015; WWF, 2016)
- **Local food-system games**: Municipal initiatives such as the "City Region Food System Game" (FAO/RUAF pilots) guide diverse actors through sourcing, processing and waste loops to co-create resilient regional strategies. (Cities 2030, n.d.)

These precedents demonstrate that game mechanics—whether as turn-based strategy, real-time simulation or facilitated role-play—can translate technical data into tactile experiences that catalyse dialogue across disciplinary and institutional silos.

Before using serious games in planning, it's important to understand that they have both strengths and weaknesses. The same game elements that help people learn and work together can also make things seem simpler than they really are or lead to biased results. Knowing both the benefits—like testing ideas and learning together and the risks, like depending too much on models or needing a skilled facilitator, helps planners use these games more effectively.

Table 1: Strengths of Serious Games as Tools for Participatory Planning

Strengths	Planning value	Key references
System visualisation & experimentation	Players can rapidly test "what-if" scenarios, seeing consequences of land-use or supply-chain choices without real-world risk.	Mayer (2009); Crawford (1983)
Stakeholder engagement & dialogue	Games level power asymmetries, giving community members, NGOs and officials equal turns and shared visual cues, which improves mutual understanding.	Sousa et al. (2022); Djaouti et al. (2011)
Learning & capacity-building	Embedded feedback, scoring and reflection foster deeper retention of planning principles, logistics constraints and policy trade-offs.	Laamarti et al. (2014)
Data integration	Real-life data (e.g. GIS data, statistics), emissions inventories or cost tables can be encoded as game parameters, turning abstract numbers into tangible decisions.	Abt (1970); Parlett (1999)

Play Marmara Food leverages a table-top game to visualize regional food supply chains, logistics challenges, and policy levers. By embedding Marmara-specific data sets, such as drought and erosion risks, and agricultural land use, into an iterative, multi-round game, it builds on the recognized strengths of serious games, including experimentation and dialogue.

- Co-design with planners and technical experts ensures model accuracy and relevance.
- Transparent rulebooks and debrief sessions uncover assumptions and encourage reflection.
- Scalable, data-driven outputs translate game actions into GIS layers and policy briefs, bridging the gap between play and governance.

As a result, the game acts both as a tool to help participants understand complex food-system dynamics and as a decision-support mechanism that directly informs MARUF23's regional action agenda for "Resilience and Beyond".

3. The Marmara Region Food System: Context and Challenges

3.1 Regional Profile

Located in northwestern Türkiye, the Marmara Region spans approximately 67,000 square kilometers and is home to over 25 million residents, making it the country's most densely populated and industrially developed region. Metropolitan hubs such as Istanbul, Bursa, Kocaeli, and Tekirdağ serve as the primary economic engines, due to their concentration of manufacturing industries, international trade links, and advanced logistics infrastructure (MMU, 2024).

This demographic and industrial intensity has significantly reshaped the urban–rural interface. Rapid urbanization and infrastructure expansion have led to increased competition for land and water resources, placing mounting pressure on regional food systems. Agricultural zones are being converted into residential and industrial areas, resulting in a steady decline in cultivable land and threatening long-term food security.

Despite these challenges, the region retains considerable agricultural potential. Fertile alluvial plains, a temperate climate, and access to river basins and coastal ecosystems make it suitable for cultivating a diverse range of crops, including cereals, fruits, and industrial crops. However, this agricultural base is increasingly at risk. Key threats include industrial pollution, unsustainable groundwater extraction, and climate-related stressors such as droughts and irregular rainfall patterns. These conditions are eroding the region's agroecological resilience and undermining sustainable food production (FAO, 2022b).

3.2. Overview of the Food System in the Marmara Region

The Marmara Region faces a complex set of challenges that threaten the sustainability and safety of its food system. Environmental degradation and food safety concerns are particularly acute. For instance, unregistered fertilizer use and the improper disposal of waste generated during olive production, such as olive black water discharged into the sea, contribute significantly to soil and water pollution, posing serious risks to human and ecosystem health (Ozturk et al., 2021).

In addition to plant-based agricultural risks, livestock farming is a major contributor to nutrient pollution. A recent study by Yaylı, Aydoğdu, and Kılıç (2024) assessed the pollution load from livestock manure across the Marmara Region between 2013 and 2022. The total estimated nutrient load was 25,497.5 tons, with nitrogen constituting 90.6% and phosphorus 9.4% of the total. Balıkesir emerged as the province with the highest contribution, while Yalova recorded the lowest. The study also revealed that cattle farming is the primary source of diffuse nutrient pollution. These findings emphasize the urgent need for improved waste management practices and integrated agri-environmental planning to mitigate the long-term impacts of livestock-based agriculture.

Another pressing issue is the rapid and often unregulated conversion of agricultural land for urban, industrial, and infrastructural development. Between 2000 and 2020, the Marmara Region lost thousands of hectares of productive farmland -particularly in peri-urban areas of Istanbul and along coastal zones- primarily due to urban sprawl (MMU, 2024). This process not only diminishes local food production capacity but also fragments ecological corridors essential for biodiversity, pollination, and microclimatic regulation.

Furthermore, intensive land use and unchecked industrial discharge have contributed to the degradation of soil and contamination of groundwater resources. Excessive application of chemical fertilizers and pesticides, compounded by poor wastewater management, has led to declining soil fertility and polluted aquifers, factors that directly compromise long-term food safety and agricultural productivity. A study by Varol and Tokatlı (2021) in the İpsala district of northwestern Türkiye, an area with a long history of intensive agriculture, found seasonal fluctuations in toxic metal concentrations in groundwater. While contamination levels remained below official drinking water limits, the results underscore the cumulative risks of persistent environmental pressures on regional water quality.

In terms of logistics, the Marmara food system is characterized by a fragmented and inefficient supply chain. Multiple intermediaries, lack of transparency, and weak coordination among actors contribute to post-harvest losses and price volatility, disproportionately affecting small- and medium-scale producers as well as low-income consumers. A regional analysis by the United Nations Development Programme (2021) further supports this observation, identifying rising logistics costs, insufficient technological infrastructure, and limited predictability as key barriers to supply chain efficiency in the region. These issues significantly hinder the ability of local producers to access broader markets and compete with industrial-scale operations.

Given these intertwined challenges, there is a growing recognition of the need for a governance model that is not only integrated but also participatory. International practice points to the City Region Food System (CRFS) perspective put forward by FAO and RUAF, which frames the metropolitan and rural hinterland as a single functional area and emphasizes nested, multi-stakeholder decision-making (FAO, 2023b). As Mäntysalo (2005) argues, effective planning should move beyond interest-based negotiation and aim for mutual understanding and cooperation among stakeholders. Participatory planning processes must be rooted in local realities, beginning at the street

or neighborhood scale and expanding to citywide and regional frameworks. Clearly defining stakeholder roles, decision-making scales, and engagement mechanisms is essential to ensure transparency, accountability, and legitimacy in food system governance.

Building a sustainable and resilient food system in the Marmara Region therefore requires the adoption of multi-scalar, inclusive strategies that address both environmental and socio-economic dimensions, essentially aligning with the integrated agenda championed by the CRFS approach. This includes reducing the environmental burden of agricultural production, improving food safety standards, and enhancing access to nutritious food for vulnerable populations. Ultimately, the transformation of the Marmara food system holds strategic importance not only for regional economic development and public health but also for the broader goal of inclusive and sustainable social development.

4. The Play Marmara Food Game

4.1. Purpose and Development

Play Marmara is a serious game developed through a collaboration between the Marmara Municipalities Union and Play the City, starting in 2018. It debuted at MARUF19 as Turkey's first regional development game. Grounded in real-world data and the methodology of serious gaming, Play Marmara was used as a participatory planning tool to envision sustainable urban and regional futures. The session brought together regional mayors, development agency leaders, practitioners, academics, and university students. This interactive experience at MARUF helped further conversations about the regional development of the Marmara Region.

The most recent comprehensive planning effort for the Istanbul Metropolitan Area dates back to 2005. Given the complexity of managing such a vast urban system, planners and authorities have long acknowledged the need for strategies that operate at both national and regional levels. In recent years, Turkey has been working toward a national spatial planning agenda. Critical regional issues, such as economic development, transportation, ecology, disaster risk, coastal management, and protected areas, demand an integrated planning approach. However, the availability of regional data and the challenge of coordinating across governance levels remain significant obstacles. Play Marmara introduces a novel method to address these issues by allowing key development stakeholders to engage with realistic, data-driven scenarios that simulate multi-level governance processes (MMU, 2019).

The game was first introduced at the Marmara Urban Forum (MARUF) in 2019, focusing on future strategic investments in the region.

Figure 1: Play Marmara 2019 Game Session

The second edition, *Play Marmara 'Sea'*, held in 2021, convened experts from national and local government to collaboratively assess and set priorities for the Marmara Sea Conservation Action Plan.

Figure 2: Play Marmara 'Sea' Game Session

The third edition, *Play Marmara 'Food'*, centers on regional food supply chains, enabling participants to co-design a sustainable food system for the Marmara region.

Figure 3: Play Marmara Food - Mayors Session

4.2. Game Design Methodology

The Play Marmara Food game was designed as a serious game to explore the future of food systems in the Marmara Region through stakeholder collaboration, scenario building, and data-driven decision-making. The game's methodology integrates real-world datasets, stakeholder roles, and interactive tools to support strategic planning for sustainable food systems.

Data collection:
Play Marmara Food was built on a composite geodatabase assembled from seven primary sources: NUTS-2 development-agency strategies; ministry datasets on agriculture, trade, and environment; Copernicus land-use layers; the Greenpeace "How to Feed Istanbul?" inventory; and the Marmara Municipalities Union (MMU) spatial framework. This multi-scalar evidence base captures production volumes, logistics nodes, land-degradation risks, and consumption patterns, providing the empirical boundary conditions that underpin every decision made during play.

Scenario construction and simulation logic
Play Marmara Food unfolds over four iterative rounds, each corresponding to a classic policy cycle stage- diagnosis, strategy design, collaboration, and evaluation. Core parameters (e.g., pollution, energy usage, freight distance) are embedded in *Food-Chain ID* and *Action* cards. Card effects are expressed as additive or multiplicative modifiers on six sustainability indicators -Solidarity, Biodiversity, Technology, Economy, Policy and Healthy Food- mirroring multidimensional evaluation frameworks used in regional planning.

Stakeholder representation and role schema
The stakeholder ecology is reproduced through six Role Cards -local government, producer, cooperative, logistics firm, large-scale retailer/consumer, and NGO- mapped to five sub-regional teams (West Marmara, Istanbul, South Marmara, East Marmara I and II). This taxonomy corresponds to the actor categories observed during field interviews and MARUF participatory sessions, ensuring face validity and role fidelity. Role asymmetries (e.g., fiscal capacity of municipalities, perishability concerns of producers) are encoded as differential starting resources and constraints.

Analogue game components
The material set comprises:

Gameboard a 1 : 125 000 GIS-derived map (240 × 400 cm) printed on a raised table, with GIS data to represent the region's agricultural and urban landscape. It features key land-use types such as orchards, cultivated fields, olive groves, and other agricultural zones, alongside urban settlements marked with logistics centers and wholesale markets. In addition, the map highlights environmentally sensitive areas, including zones with high erosion risk and regions vulnerable to desertification, offering players a realistic spatial context for making decisions related to sustainable land management.

Food-Chain ID Cards offer detailed insights into the supply chains of key agricultural products in the Marmara Region. Covering a variety of crops- including sunflowers, olives, wheat, and grapes- these cards represent the region's most widely produced and consumed items, as well as those grown using different techniques. Each card outlines the technical steps of production and highlights specific challenges associated with both durable and perishable goods, helping players better understand supply chain dynamics.

Action Cards include seventy (70) cards that allow players to express their ideas about the future of food systems. These cards are organized into key categories- production, consumption, logistics, waste, and supply- enabling players to explore different stages of the food chain and propose innovative strategies. Each card is a visual representation of food policies and innovative practices referenced in international reports, turning complex strategies into accessible and actionable game elements.

Collaboration Cards prompts that reward inter-regional alliances with extra actions.

Scoreboard sheets large-format sheets on which facilitators record indicator tallies at the end of each round.

4.3. Game Process
The game session begins with a structured briefing, during which participants are introduced to the regional

food system's core challenges and the sustainability indicators embedded in the game. Participants then select stakeholder roles—such as local government, producer, cooperative, logistics firm, large-scale retailer/consumer, or NGO- based on their professional background and area of interest (MMU, 2024).

The gameplay consist of four rounds (see Figure 4):
(1) Choose Your Team and Product, **(2)** Sustainable Food Chain, **(3)** Collaboration, and **(4)** Evaluation and Expert Review.
1. Choose Your Team and Product: Participants form sub-regional teams and select a key agricultural product, such as wheat, olives, strawberries, based on regional characteristics. Each team locates relevant production clusters on the map and places the corresponding Food-Chain ID Card onto the game board.

2. Sustainable Food Chain: Teams use Action Cards to develop a regional supply chain strategy, selecting interventions like "Organic Fertiliser," "Cold-Chain Logistics," or "Food Literacy Campaigns." Each card influences participants to consider trade-offs and synergies among social, environmental, and economic outcomes.

3. Collaboration: Teams negotiate strategic alliances using *Collaboration Cards*, enabling them to pool infrastructure investments or co-develop solutions such as R&D centers or logistics hubs. These alliances unlock bonus actions, reinforcing the importance of inter-regional cooperation and shared resource planning.

4. Evaluation and Expert Review: At the conclusion of gameplay, indicator scores are transferred on the scoreboard sheets. A panel of food-system experts then reviews the results, offering feedback on the feasibility, equity, and innovation of each team's strategy. These reflections inform subsequent policy briefs and knowledge dissemination efforts.

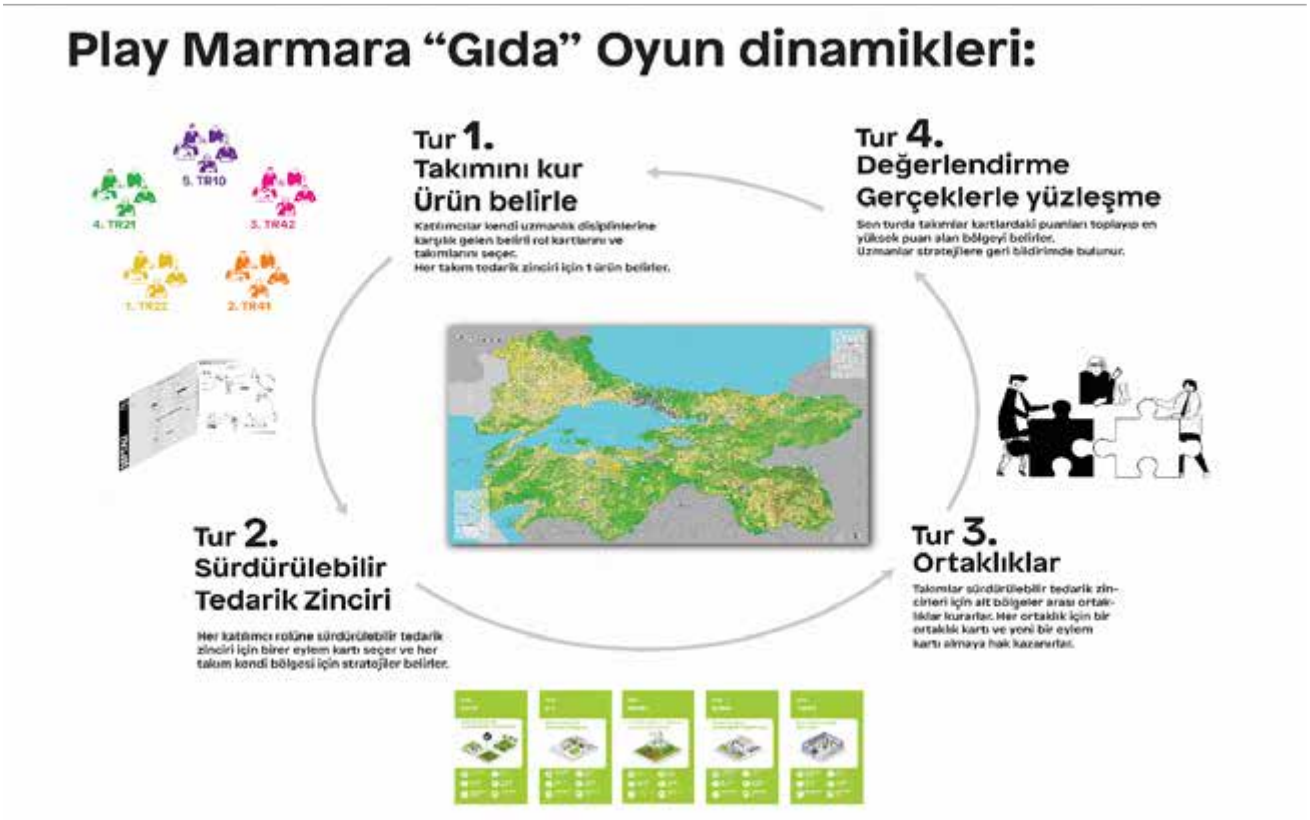

Figure 4: Play Marmara Food Game Dynamics

This four round structure reproduces the iterative nature of strategic planning while keeping total playtime to approximately 90 minutes. This format helps participants explore systemic interdependencies, test decisions, and co-develop actionable insights for regional food planning.

Collectively, the methodology and process position Play Marmara Food as a rigorously grounded, yet highly interactive, decision-support system capable of translating complex agri-food data into shared strategic visioning for the Marmara Region.

4.4 Game Results and Insights

Between 4–5 October 2023 the Play Marmara Food was played in five facilitated, table-top sessions: one *Mayors' Session*, two *Experts' Sessions* and two *Open Sessions* during MARUF23. In total, the exercise convened two metropolitan mayors, food-system specialists, NGO representatives, game designers, academics, and architecture/urban-planning students- a deliberately hybrid audience that mirrored the diversity of the regional food system. (Özdarendeli, 2024)

In each session, participants formed sub-regional teams and selected one agricultural product- such as wheat, olives, or strawberries- based on their sub region . They were asked a common guiding question: *"How can we make the journey of this product from farm to table cleaner, fairer, and more profitable?"* Guided by their regional data, teams selected a range of Action and Collaboration Cards and sketched quick strategic plans for sustainable supply chains.

Across those sessions participants generated more than forty distinct strategy cards and drafted a dozen inter-regional partnerships. Four themes surfaced repeatedly, whatever the product or sub-region:
- smarter logistics and infrastructure (e.g., "Smart Logistics Village");
- circular-economy and waste solutions (compost, biogas, blockchain audits);
- multi-stakeholder governance platforms (food-policy councils, regional regulations);
- youth and community incentives (young-farmer co-operatives, food-literacy programmes).

The exercise also revealed gaps: when teams' strategies were scored against six indicators—Solidarity, Biodiversity, Technology, Economy, Policy, Healthy-Food— most points accumulated in Technology, Economy, and Policy, while Healthy-Food and Biodiversity lagged, signalling issues that merit greater policy attention.

The Table 2 condenses the most prominent strategies that emerged in the final expert/open sessions, showing how different actor constellations tackled distinct products yet converged on similar leverage points; smarter logistics, circular practices, new governance platforms, and community-focused incentives.

Table 2: Sub-Regions, Products and Key Outcomes of Play Marmara Food

Sub-region / Actor	Product	Key actions selected	Impact
Istanbul team	Wheat	*Smart Logistics Village*, *City Farm*, *Food Literacy Training*, *Intl. Trade Networks*	Cut freight emissions, shorten producer–consumer link, boost export value

South Marmara team	Tomato	*National Food-Waste Plan*, *Drought-Resistant Crops*, *Local Incentive Packages*, *Regional Supply-Chain Rules*	Waste minimisation, climate resilience, rural jobs
West Marmara team	Sunflower	*Organic Fertiliser*, *Food Networks*, *Food Policy Council*, *Urban-Ag Zoning*	Regenerative soils, direct marketing, governance hub
East Marmara I & II teams	Strawberry	*Food Incubation Centre*, *Blockchain Waste Audit*, *Young-Farmer Cooperatives*, later paired with *Organic Fertiliser Export* and *Irrigation Optimisation*	Tech-driven transparency, youth entry, nutrient cycling

5. Discussion

Participatory planning has evolved far beyond public hearings and consultation forms. Contemporary approaches- especially those inspired by collaborative planning theory- increasingly emphasize co-creation, experiential learning, and stakeholder empowerment (Innes & Booher, 2004; Sanoff, 2000).

The *Play Marmara Food* game embodies these principles. It provides a "safe-to-fail" environment where actors from different backgrounds negotiate priorities, test scenarios, and reflect on trade-offs. This aligns with Habermasian ideals of deliberative dialogue that seeks understanding, not dominance (Mäntysalo, 2005).

As highlighted by scholars such as Tan (2016) and Hirscher (2017), serious games can serve as generative tools for urban and regional governance. They stimulate creative thinking, foster trust, and visualize complexity in ways traditional methods often cannot. Additionally, they can help resolve participation fatigue by offering more engaging, hands-on formats (Agger, 2012).

The gameplay process yielded actionable insights for regional planning:
- Serious games democratize planning by enabling diverse actors to engage on equal footing.
- The use of real-world data enhances the credibility and policy relevance of the scenarios explored.
- Structuring gameplay into planning-cycle stages reinforces institutional learning.
- It can be used to guide future policy and investment priorities.

These findings point to the broader potential of serious games as complementary instruments within participatory governance frameworks. As cities and regions grapple with climate-driven uncertainty and systemic food insecurity, tools like *Play Marmara Food* offer a promising model for inclusive, data-informed, and collaborative policymaking.

Despite their promise, serious games are not without limitations:
- **Facilitation quality matters:** Outcomes depend on how well facilitators guide discussions and debriefing.
- **Scalability requires adaptation:** Different regions may need contextual reconfiguration of rules, roles, and data.
- **Decision influence is indirect:** While games can inform policy, translating outcomes into formal governance processes remains a challenge.

Nonetheless, *Play Marmara Food* demonstrates that game-based methods can meaningfully contribute to collaborative planning, resilience-building, and sustainable food system design- especially in regions facing the kinds of multidimensional stressors seen in Marmara.

6. Conclusion

Play Marmara Food shows that a data-driven, multi-stakeholder game can support serious regional planning. This paper set out to examine how the Play Marmara Food serious games can inform the design of sustainable food chains in Türkiye's Marmara Region. Three main insights emerged.

1. Game-based dialogue works. Bringing mayors, public officers, NGOs, academics, designers and students to the same table turned abstract policy goals into concrete, crop-specific strategies. Shared priorities- smarter logistics, circular use of waste, new food-governance bodies and youth incentives- surfaced across all five sessions.
2. Data unlocks meaningful dialogue. Because every card and map layer came from lengthy research, participants could see how their choices would play out on the ground, not just in theory. This turned the game into a live testing arena for policies already anchored in regional statistics and GIS layers.
3. Scoreboards expose blind spots. Technology, economy and policy actions scored high, but "Healthy Food" and "Biodiversity" lagged. This highlights the need for future policy cycles and future game iterations to give equal weight to nutrition and ecosystem health.

The draft actions and collaborations produced in the sessions can be translated directly into the Marmara Municipalities Union's forthcoming regional food strategy. Results are context-specific; testing the model in other Turkish regions would show how adaptable the rules and data needs are. Follow-up research should monitor whether game-generated ideas- such as circular compost loops or food-policy councils-are adopted and with what effect.

Comprehensive data did not slow the process; it made meaningful play possible. Future iterations should deepen health and biodiversity metrics, but the current game already offers a tested, evidence-based format that MMU and other regional bodies can adapt when drafting formal food-system strategies.

To conclude, Play Marmara Food demonstrates that serious games can move beyond public engagement and act as practical decision-support tools. By linking real data, diverse actors and clear scoring, the game offers a scalable method for crafting evidence-based, collaborative food policies in regions facing complex agri-food challenges.

Acknowledgements

The authors gratefully acknowledge the Marmara Municipalities Union (MMU) for supplying the spatial data and strategic reports that grounded the game design. Special thanks go to Dr Ekim Tan, founder of Play the City and lead designer of Play Marmara Food, and to the entire Play the City team, whose expertise and commitment were essential throughout the game-development process. Appreciation is also due to the mayors of Kocaeli and Büyükçekmece, the MARUF23 organising committee, and all participants-municipal staff, academics, NGO representatives, designers, and students-whose active engagement enriched the game sessions. This work was supported by the Scientific and Technological Research Council of Türkiye (TÜBİTAK) under the 2224-B National Scientific Events Participation Support Programme.

Abstract
Industrialization and urbanization have profoundly transformed China's county-level population structures, land-use patterns, and food production systems. Variations in natural conditions and urbanization levels have resulted in uneven spatial distributions of population, cultivated land, and food production. Exploring the dynamic evolution of this system in China's counties and formulating targeted planning and regulatory strategies hold significant theoretical and practical value. This study aimed to reveal the internal dynamics of the PCF system through an analysis of its evolution across 1,848 county-level units (excluding urban areas) during 2000, 2010, and 2020. After evaluating system coordination and classifying rural areas into distinct types based on coupling modes though an indicator system, the study proposed targeted planning and regulation strategies for counties with differing coupling modes, emphasizing system coordination.

Keywords: Food Security; Population-Cultivated Land-Food System (PCF System); Urbanization and Rural Development; Planning Strategies

1. Introduction

Food security is related to the national economy, people's livelihood and sustainable development, and is a necessary guarantee for China's modernization. The population-cultivated land-food (PCF) system is a complex system based on the development and utilization of arable land resources within a certain geographical area, with food production, consumption and circulation as the central links, and the ultimate goal of meeting human food needs (Bao and Fang, 2007). As a bridge connecting cities and villages, the dynamic evolution of the population, cultivated land and food system in the county is not only related to the sustainable development of the rural economy, but also directly affects the country's food security and the stable development of society. Therefore, it is of great theoretical value and practical significance to deeply study the evolution characteristics of the rural population - farmland - food system in China's counties and explore the corresponding planning and regulation strategies.

With the continuous development of industrialization and urbanization in China, the population structure, land use and grain production patterns of counties and villages have undergone profound changes. Overall, due to different natural conditions and urbanization levels, the regional distribution of population, cultivated land and grain production in China is uneven. The per capita cultivated land generally shows a distribution characteristic of less in the east and more in the west (Ge, Long and Yang, 2018), and the per capita grain output also shows a characteristic of more in the central and western regions and less in the east. The national grain output and cultivated land area are mainly concentrated in the middle and low-level economic development areas (Wang et al., 2024). Different regions are facing pressure on cultivated land and grain production due to differences in population demand. Rapid urbanization has caused China's rural population to continue to move to cities, resulting in a shortage of rural labor and more unbalanced regional development, which has had a certain impact on agricultural production and food supply (Mu and Lin, 2020). At the same time, the reduction of rural cultivated land resources and the intensification of the "non-grain" and "non-agricultural" trends have also challenged the stability and sustainability of grain production (Zhang et al., 2023). On the one hand, county villages are still an important space for China to carry out grain production functions and rural labor. How to ensure food security and coordinate the relationship between population , cultivated land and food systems? On the other hand, villages in different regions are affected differently by the evolution of urban-rural relations, forming different

development opportunities and conditions (Zhang and Sun, 2019). How to combine past research on rural classification development with the characteristics of county rural economic and social development to carry out more targeted classification planning and regulation of villages has become an urgent problem to be solved.

2. Theoretical basis

This study aimed to reveal the internal laws and dynamic mechanisms of the population-cultivated land-food (PCF) system in Chinese counties and villages through the analysis of its evolutionary characteristics, and to provide corresponding planning, regulation and guidance for rural types with different systemic coordination characteristics. In the semi-open population-cultivated land-food complex system, the cultivated land area and its cultivated land planting structure, grain planting area and multiple cropping index in different regions affect the efficiency of cultivated land, thus determining the grain output. Grain output and the number of permanent residents determine the per capita grain possession. Regions where the per capita grain possession is greater than the per capita grain demand become the main grain production areas, dividing the pattern of grain input and output. The cultivated land area and the number of rural population determine the per capita cultivated land area, reflecting the possibility of large-scale production of cultivated land in the region. In the process of urbanization, the population continues to move and the land use type continues to transform, resulting in the continuous changes in the county's permanent population, rural population and cultivated land area, which are the main driving forces for the dynamic evolution of the population-cultivated land-food system, as shown in Figure 1.

Based on this system, the article firstly sorted out the evolution process of county rural population-cultivated land-food system, and analysed the main factors affecting their evolution. Then the main indicators reflecting the coordination of the PCF system, such as per capita cultivated land area and per land grain output, were adopted to analyse the change coupling model in rural areas of counties across the country. Based on the differences in the types of change coupling patterns, targeted planning and regulation strategies were proposed to provide theoretical support and practical guidance for the sustainable development of county rural economy and national cultivated land and food security.

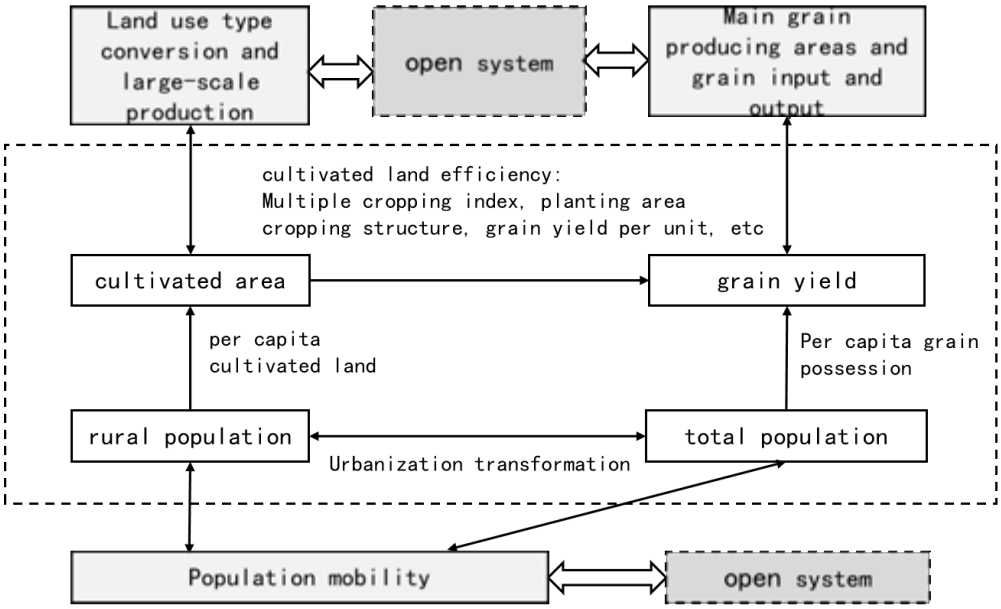

Figure 1 Population-arable land-food system operation mechanism diagram

3. Research Methods

3.1. Study area

The research object consisted of 1,848 county-level units. This study was based on the administrative divisions of 2020, integrating counties and county-level cities. Four prefecture-level cities without county-level administrative regions (Dongguan City and Zhongshan City in Guangdong Province, Danzhou City in Hainan Province, Jiayuguan City in Gansu Province), as well as the Hong Kong Special Administrative Region, the Macao Special Administrative Region, and Taiwan,were were excluded. In addition, due to the missing values of individual variables in some administrative units, the number of samples finally included in the research analysis was 1,848 .

3.2. Data sources

The county-level administrative unit vector data used in this study came from the Third National Land Survey database in 2020. Population data came from county-level demographic statistics from the Fifth (2000), Sixth (2010), and Seventh (2020) National Population Censuses. Cultivated area data came from the cultivated land area of "*China Agricultural Statistical Yearbook*" *(2001)*, the 2010 data of the Second National Land Survey data (https://gtdc.mnr.gov.cn/Share?UiNMsBTfPrya=1712637735952#/secondSurvey) verified with the China Annual Cultivated Land Dataset (CACD) (https://doi.org/10.5281/zenodo.7936885) released by Dr. Tu Ying in Professor Gong Peng's team at Tsinghua University with a resolution of 30m×30m, and the 2020 data of the Third National Land Survey data (https://gtdc.mnr.gov.cn/Share#/thirdSurvey). The grain production data for 2000 and 2010 were derived from the "*China County Statistical Yearbook*" *(2001, 2011)*, and the grain production data for 2020 were derived from the statistical yearbooks and the statistical bulletin on national economic and social development of various provinces and cities .

3.3. Research methods

3.3.1. Standard deviation ellipse

The standard deviation ellipse is a spatial statistical method widely used to describe the spatial distribution characteristics of geographical elements, and it depicts the spatial morphological characteristics of geographical elements such as centrality, spread, and directionality. This study constructed standard deviation ellipses of rural population, cultivated land area, and grain output in counties across the country from 2000 to 2010 and from 2010 to 2020, to analyze the spatial-temporal evolution of rural population, cultivated land area, and grain output.

3.3.2. Variation of coupled mode measurement

This study measured the changing coupling pattern of rural PCF system elements based on the change rate of per capita cultivated land area and per-acre grain output in counties across the country from 2000 to 2010, 2010 to 2020 , and 2000 to 2020.

$$GRit=(Git-Gi0)/Gi0$$

$$LRit=(Lit-Li0)/Li0$$

Where: i represented the county; GRit and LRit represented the change rates of per capita cultivated land area and per-land grain output in county i in year t respectively; Gi0 and Git represented per capita cultivated land area in county i in the base year and year t; Li0 and Lit represented per-land grain output in county i in the base year and year t.

Four coupling types could be divided according to the different changes of per capita cultivated land area and per-land grain output in different stages:

- If GRit>0 and LRit>0, the per capita cultivated land area and per-land grain output of the county were in the "same increase" mode.
- If GRit>0 and LRit<0, the per capita cultivated land area of the county increased and the per-land grain output decreased.
- If GRit<0 and LRit>0, the per capita cultivated land area of the county decreased and the per-land grain output

increased.

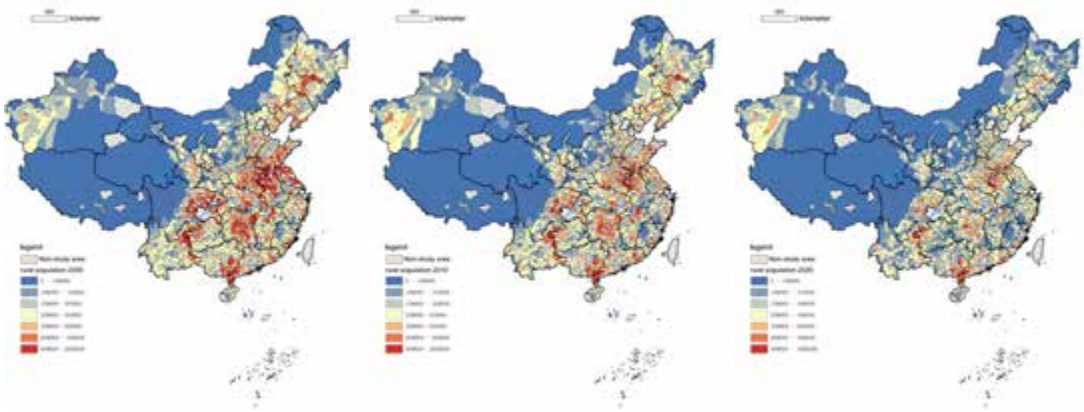
• If GRit<0 and LRit<0, the per capita cultivated land area and per-land grain output of the county were in the "same decrease" mode.

4. Analysis on the spatial-temporal evolution of PCF system in counties

4.1 . Dynamic changes in the total amount

4.1.1. Dynamic characteristics of rural population in counties

In the two decades since 2000, the number of rural populations in all regions of the country has shown a straight-line downward trend. The total rural population has decreased from 6.092×10^{8} to 3.8046×10^{8}, a decrease of 62.45% of the original. Among them, the rural population reduction rate in the central region and the northeast region were relatively high, at 42% and 39% respectively, while the rural population reduction rate in the western and eastern regions was about 34%. From 2000 to 2020, China's urbanization has made great progress, and the central-western regions have become the largest rural population transfer and outflow areas, with significantly decreased rural population. However, due to the geographical location of the western region being farther away from the main inflow areas of the eastern population, the industrial model was more backward, and the rural population base was large. After population mobility, it was still the region with the largest rural population. In addition to being affected by urbanization, the reduction of rural population in the northeast region was also related to the large-scale mechanization transformation of agricultural production. The eastern region was mainly undergoing its own urbanization process, and most of the rural population was converted into urban population on the spot, and the number of rural population continued to decline. While the total population of the country was increasing, the large-scale reduction of rural population has brought challenges to food production.



(a)2000 (b)2010 (c)2020

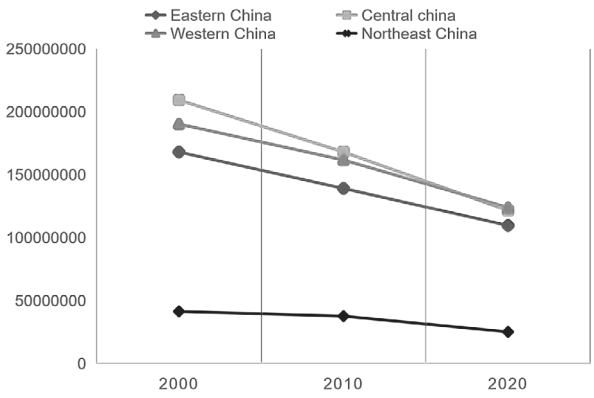


Figure 2 The spatiotemporal evolution of rural population

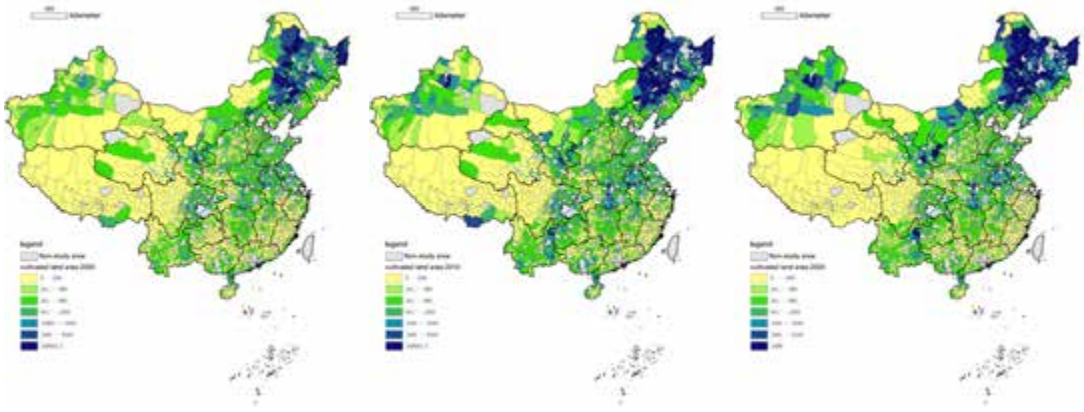
4.1.2. Dynamic characteristics of cultivated land in counties

The changes in cultivated land area in counties in different regions of the country were quite different. Except for the eastern region, the cultivated land area in counties in other regions has increased. Among them, the western region and the northeastern region have shown a continuous growth trend, which was related to the low urbanization level in the western region and the fact that agricultural planting was still the main industry. Affected by the profound impact of the project of returning farmland to forest and grassland since the development of the western region, the growth rate of cultivated land area in the western region has gradually slowed down. Thanks to the good natural farming conditions, the northeastern region has become the most important grain production base in China. With the continuous increase of China's population, the demand for grain has also increased accordingly, and the cultivated land area in the main grain-producing areas of the northeast has increased significantly. The cultivated land area in the central region first increased and then decreased, which was related to the adjustment of the industrial structure in the region and the rapid development of urbanization occupying a large amount of cultivated land. The eastern region has a dense population and a high level of urbanization. The continuous agglomeration of population has generated a greater demand for construction land. At the same time, the rapid economic development has continuously increased the value of land, transformed land use, and continuously reduced the cultivated land area. Although the cultivated land area in the country has increased slightly overall, the distribution of cultivated land has become more unbalanced.



(a)2000 (b)2010 (c)2020

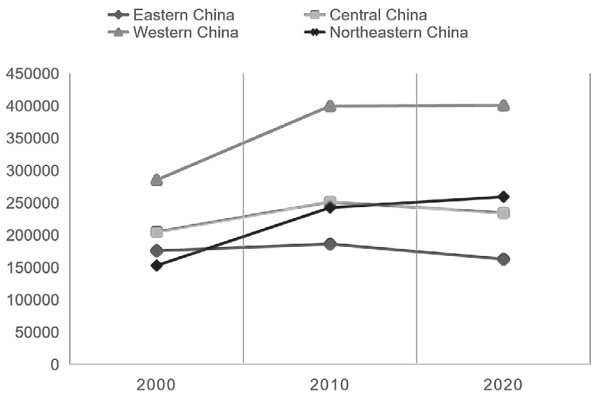


Figure 3 Spatial and temporal evolution of cultivated land area

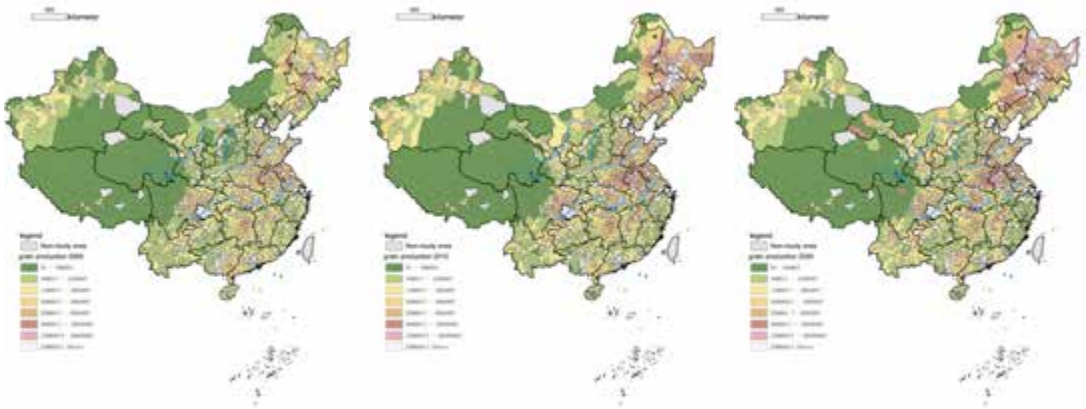
4.1.3. Dynamic characteristics of grain output in counties

The national grain output showed an overall growth trend between 2000 and 2020 (Figure 4). Due to the rapid development of urbanization and the adjustment of industrial structure, the eastern region has insufficient potential for growth in grain output, while the grain output in other regions has increased significantly. The

large-scale increase in grain output under the condition of no significant increase in the overall cultivated land area showed that China had improved the multiple cropping index and grain farming technology level, and the average grain output per land had increased. It was also affected by relevant agricultural benefit policies, and farmers' enthusiasm for growing grain has increased. After 2010, the increase in grain in various regions slowed down simultaneously, which was greatly affected by the change in farming structure. With the development of the economy and the improvement of people's living standards, people's demand for agricultural products has become more diverse, and the development trend of "non-agriculturalization" and "non-grainization" was obvious. It could be seen that both market factors and national policies had a great impact on grain production, and reasonable macro-control by the state was needed to ensure the stability of grain production.



(a)2000 (b)2010 (c)2020

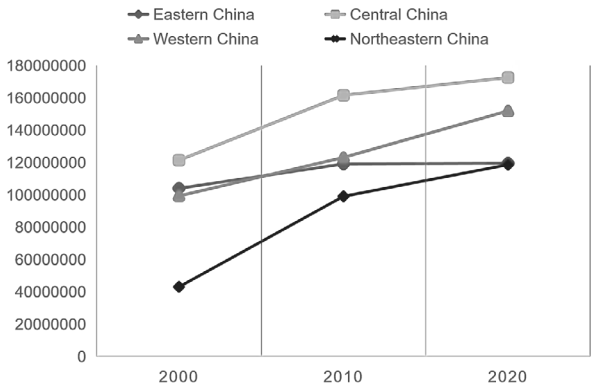


Figure 4 Spatial and temporal evolution of grain production

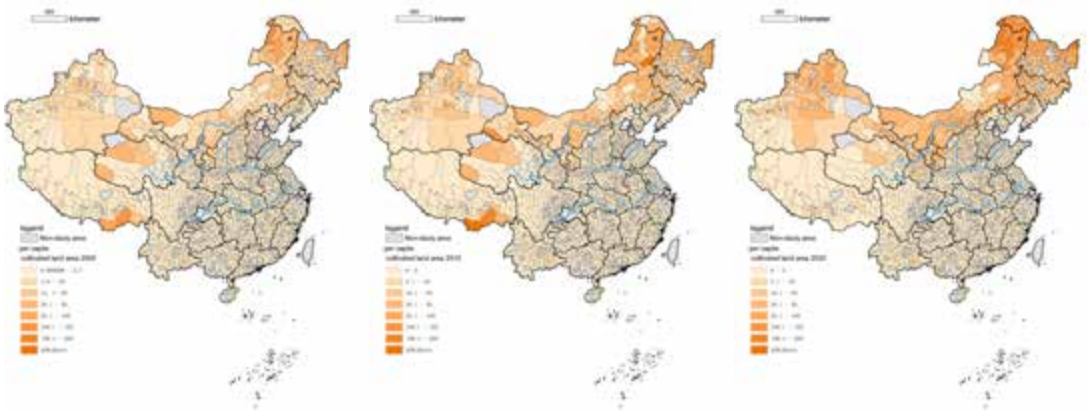
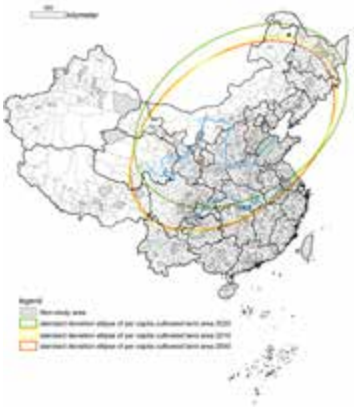
4.2 . Dynamic changes in per capita/unit amount

4.2.1. Changes in per capita cultivated land area

The per capita arable land area of the rural population in counties has increased overall, with the average value increasing from 2.78 mu in 2000 to 6.79 mu in 2020, which was related to the large-scale loss of rural population in the process of urbanization. The center of gravity of per capita arable land area continued to move to the northeast. The northern part of the Northeast, central Inner Mongolia, and the eastern part have vast land and sparse population, good farming conditions, and have always been areas with large per capita arable land area. While Central China, East China, and South China were densely populated, with a high level of urbanization, and arable land was facing great pressure. There was a spatial dislocation between areas with abundant per capita arable land and areas with concentrated populations and developed economies in China.



(a)2000 (b)2010 (c)2020

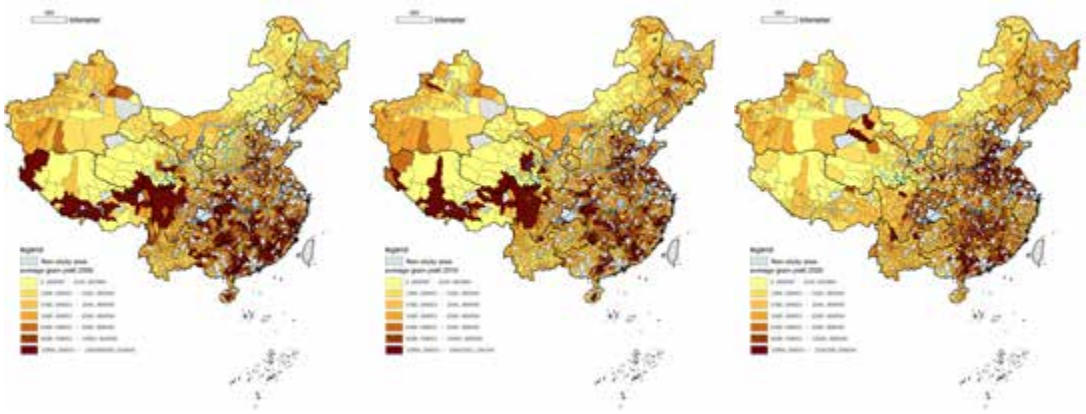


(d)standard deviation ellipse of per captia cultivated land area

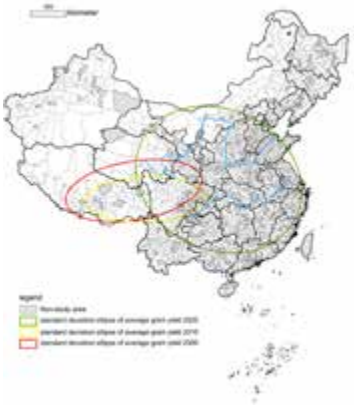
Figure 5 The spatiotemporal evolution of per capita cultivated land area

4.2.2. Changes in grain output per county area

The per capita grain output in counties across the country varied greatly. With the same area of arable land, the grain yield per unit area in the eastern regions such as East China and South China and the middle reaches of the Yangtze River in the central region was relatively high, which was the focus of per capita grain output in China. This was related to the suitable climate and topographic conditions in these regions, the high grain multiple cropping index, the long history of farming, the good economic development, and the advanced agricultural technology. As an important grain export base, the Northeast region had a large total grain output, but due to the cold climate conditions and the vast area of arable land, the per capita grain output was not as good as that in the eastern region. Since different regions had different production characteristics, we should further improve the level of planting technology and increase the per capita grain output so as to ensure food security.



(a)2000 (b)2010 (c)2020



(d)standard deviation ellipse of average grain yield

Figure 6 Spatial and temporal evolution of average grain yield

5. Classification of coupling patterns of PCF system in counties

In the complex system of population-cultivated land-food, population and cultivated land are more important factors of change. The per capita food output and demand in different regions are different, but they can be regulated and redistributed through market operations and national policies. The per capita arable land area of rural population and per-land food output more accurately reflect the development potential and production level of regional food production from the perspectives of "who will cultivate the land", "how much land there is", and "how efficient the cultivated land is", which is related to the national food production security. Therefore, the following focused on analyzing the coupling types of per capita arable land area and per-land food output in counties in different regions across the country, and provided feasible strategic suggestions for the development of food security in the process of new urbanization.

Based on the measurement of the coupling pattern of changes in per capita cultivated land area and per-land grain output in counties across the country, four classifications were produced: the "simultaneous increase" pattern; the "reduction in population, reduction in land, and increase in grain" pattern; the pattern in which per capita cultivated land area in rural areas increased and per-land grain output decreased; and the "simultaneous decrease" pattern.

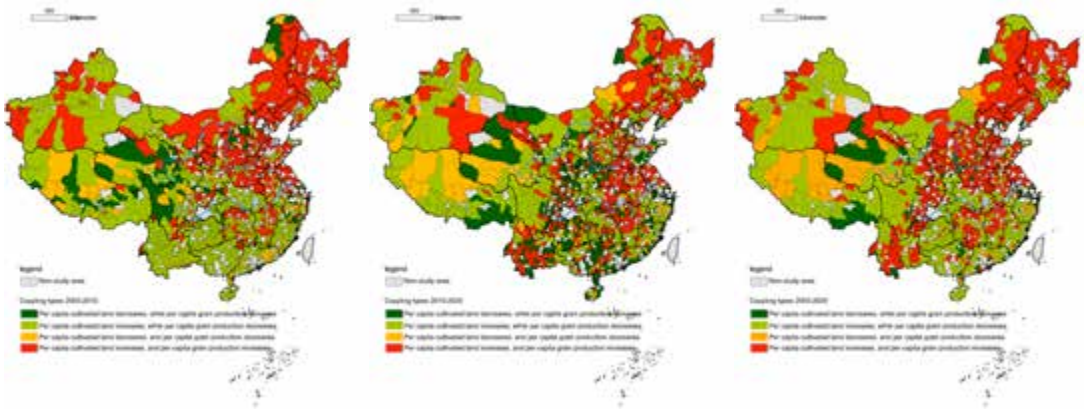
The first is the "simultaneous increase" model of increasing per capita cultivated land area and per-acre grain output in rural areas. From 2010 to 2020, this type of county units accounted for about 38.1% of the total, mainly

concentrated in Northeast China, North China, Jianghuai region, eastern Inner Mongolia, northern Shaanxi, Hunan and parts of Jiangxi Province. These areas were relatively traditional agricultural areas with good natural conditions and a long history of grain farming, and still maintained a certain growth rate of cultivated land area. At the same time, in the process of local urbanization and population flow to neighboring developed eastern regions, the local rural population has continued to decline, resulting in a continuous expansion of per capita cultivated land in rural areas. The advancement of agricultural technology and the use of mechanized production have led to a rapid increase in grain output and a simultaneous increase in per-acre grain output. This type of county should seize the advantages of grain production, make full use of natural conditions, further promote large-scale mechanized grain production, and assume the role of the main force in ensuring national food security and food supply.

The second is the "reduced population, reduced land, and increased grain" model, where the per capita cultivated land area in rural areas decreased and the per-land grain output increased. From 2010 to 2020, this type of county units accounted for about 22.4% of the total, mainly distributed in the middle and upper reaches of the Yellow River and the southwestern regions of Yunnan, Guizhou, Sichuan, and Guangxi. These areas were mainly Gobi deserts and mountains. Desertification and rocky desertification have greatly affected grain planting. In the process of ecological and environmental protection in China in recent years, many low-quality cultivated lands in these areas have been reasonably retired, and the cultivated land area has continued to decrease. Under the condition of generally improved grain planting technology, the per-land grain output has increased. At the same time, due to problems such as transportation and terrain, these areas have lagged behind in social and economic development. There were still a large number of rural population engaged in the primary industry. The speed of land retirement was faster than the speed of rural population loss, and the per capita cultivated land area in rural areas showed a downward trend. This type of county should promote the coordinated development of urbanization and ecological and environmental protection, increase investment in agricultural science and technology, continuously improve the efficiency of cultivated land, and achieve green and efficient development.

The third is the pattern of increasing per capita cultivated land area in rural areas and decreasing per-land grain output. From 2010 to 2020, this type of county unit accounted for about 34.5% of the total, mainly distributed in Northwest Sichuan, Xinjiang and most areas of the southeastern coastal areas. Northwest Sichuan and Xinjiang have turned to the planting and processing of specialty agricultural products in recent years because the ecological environment was not suitable for grain production. While the cultivated land area has increased, the grain output has decreased. In addition, the rapid loss of rural population has led to an increase in per capita cultivated land area in rural areas, but a decrease in per-land grain output. Due to the rapid speed and high level of urbanization in the southeastern coastal areas, while the cultivated land has been transformed into other types of land use and the grain planting area has been reduced , the transformation of rural population into citizens has been more rapid, resulting in an increase in per capita cultivated land area and a decrease in per-land grain output under the condition that the rural population, cultivated land and grain output have decreased in the same direction. Regions with this pattern should vigorously develop intensive agriculture and invest more labor, capital and technical support in limited cultivated land areas.

Fourthly, the "simultaneous reduction" type, where the per capita cultivated land area in rural areas decreases and the per-acre grain output also decreases. This type of county unit had the least number of units, accounting for about 5% of the total from 2010 to 2020, and was scattered in the northeastern part of Zhejiang Province, the southeastern part of Fujian Province, and parts of northern Tibet. These areas were also facing a triple reduction in rural population, cultivated land area and grain output, but due to the rapid urban construction and industrial transformation in recent years, the reduction in cultivated land area and grain output was more obvious. Regions with this model should further optimize the planting structure and increase the grain self-sufficiency rate.



(a)2000-2010 (b)2010-2020 (c)2000-2020

Figure 7 Spatial distribution of coupling types of per capita cultivated land area and per-acre grain output in China

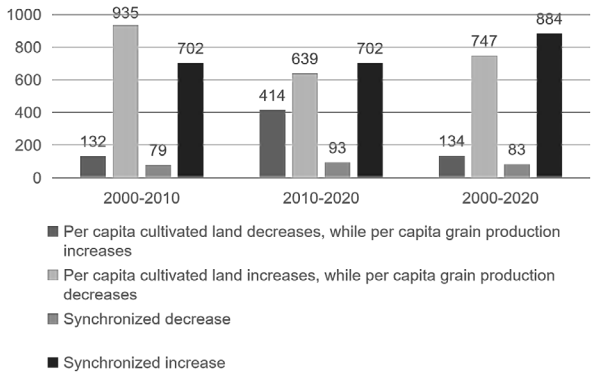


Figure 8 Distribution of coupling types between per capita cultivated land area and per-acre grain output in China

The characteristics and distribution types of the four modes can be summarized as shown in the following table:

Figure 9. Characteristics of coupling types between per capita cultivated land area and per-acre grain output in China

Dynamics of per capita cultivated land area	+	-	+	-
Dynamics of grain output per land area	+	+	-	-
Quantity ratio	38.1%	22.4%	34.5%	5.0%

Distribution	Northeast China, North China, Jianghuai region, eastern Inner Mongolia, northern Shaanxi, Sichuan, Hunan, and parts of Jiangxi Province	Middle and upper reaches of the Yellow River , Sichuan, Yunnan , Guizhou, Guangxi and other regions	Northwest Sichuan, Xinjiang and other areas; Most areas along the southeast coast	Yangtze River Delta and southeast coastal areas
Characteristics and causes	Good natural conditions and a long history of farming made it suitable for large-scale mechanized grain production.	The primary industry was still the main industry, and a large number of rural populations developed agriculture.	The ecological environment was not suitable for food production, so it is advised to turn to the cultivation and breeding of special agricultural products with the decreasing rural population.	The economy was relatively developed, the proportion of cash crops in the planting structure had increased, and the industry has transformed and developed.

Annotations: "+" is for "increase"; "-" is for "decrease".

6. Discussion and conclusion

6.1. Discussion

This study analyzed the dynamic change process and system coordination type of the population-cultivated land-food system in the rural counties of China from the perspective of "spatiotemporal evolution-change coupling-classification regulation", providing a reference for promoting the sustainable development of the rural economy in the counties and the national farmland and food security. Rural areas have important agricultural production functions and ecological product values. In the semi-open complex system of population-cultivated land-food in rural areas, the interaction between various elements promotes agricultural production progress and the balance of food supply and demand, and maintains the dynamic and coordinated evolution of the system, which is of great significance for ensuring national farmland and food security. This study analyzed the dynamic evolution characteristics and change coupling types of the rural population-cultivated land-food system in the rural counties of China, comprehensively considered factors such as natural geographical conditions, resource endowment differences, and county main functions, and proposed differentiated planning strategies for rural areas in counties with different change coupling modes from the perspective of population-cultivated land-food system coordination, including:

(1) The counties, with per capita cultivated land area and per capita grain output in rural areas increasing simultaneously, covered the main grain-producing areas and traditional agricultural areas in China, and were important responsibility areas for ensuring the country's cultivated land and food security. First of all, it is advised to base on the excellent natural resource endowment, strictly adhere to the red line of cultivated land, strictly implement the cultivated land protection system, strengthen soil protection and improvement, so as to achieve the dual guarantee of the quantity and quality of cultivated land resources, and ensure the sustainable

development of grain production. The outflow of rural population and urbanization provide possibilities for large-scale agricultural production. State-owned farms in some areas have the foundation for developing large-scale and mechanized grain production. By strengthening the introduction of agricultural talents and agricultural technology training, the capacity and efficiency of grain production can be enhanced, with the planting structure and grain production structure optimized to cultivate high-quality commercial grain varieties, thereby improving the quality and market competitiveness of grains. At the same time, in response to the trend of rural population decline, efforts should be made to promote the transformation of identity farmers into professional ones, strengthen the introduction and training of agricultural technical labor, improve the professional quality and skills of agricultural practitioners, ensure the supply and stability of technical agricultural labor, and better adapt to the situation of grain production.

(2) For counties where the per capita cultivated land area in rural areas has decreased and the per capita grain output has increased, the contradiction between agricultural resource utilization and the fragile ecological environment is the fundamental factor affecting the high-quality development of agriculture, and it also brings the dual pressure of cultivated land protection and ecological security. Therefore, it is of great importance to solve the problem of coordination between food security and ecological protection, reduce the loss of cultivated land and the destruction of the natural environment, attach importance to the ecological value of cultivated land, and implement the “three-in-one” cultivated land protection strategy of quantity, quality and ecology in the face of rigid resource constraints, so as to promote the sustainable utilization of cultivated land resources and high and stable grain yields. Relying on the long-term traditional agricultural foundation and relatively intensive agricultural labor resources, efforts should be made to improve agricultural technology and farmers’ skills through training and skills support, and improve the efficiency and quality of grain production. In combination with natural geographical characteristics and natural resource endowments, it is advised to optimize the planting structure and adjust the breeding methods according to local conditions, and improve the comprehensive benefits of agricultural production through the development of characteristic agriculture and ecological agriculture, so as to achieve system coordination and economic, social and ecological win-win results.

(3) In counties where the per capita cultivated land area in rural areas has increased and the per capita grain output has decreased, the long-term rapid urbanization of the population has led to a tense relationship between people and land in rural areas, and the trend of cultivated land becoming non-grain is obvious. Therefore, on the basis of keeping the red line of cultivated land to curb resource loss, attention should be paid to the decline in grain output caused by factors such as the loss of agricultural labor and natural conditions. Economically developed regions with special resources are encouraged to adjust appropriate agricultural planting structures, make full use of precious cultivated land resources, develop diversified and efficient characteristic rural industries and intensive agriculture, and optimize the industrial structure in rural areas. It is suggested that through measures such as policy support, industrial assistance, and agricultural services, a better entrepreneurial environment and development opportunities should be provided. Agricultural infrastructure should be strengthened, rural infrastructure and public services improved, and the quality of life and social environment in rural areas enhanced. This will attract urbanized population to return to their hometowns for employment and entrepreneurship, thereby revitalizing rural areas. Meanwhile, other suggestions include actively integrating into the national unified market, promoting the complementary development of grain crops and cash crops, in order to achieve stable cultivated land and sustainable agricultural development.

(4) Counties where the per capita cultivated land area and per-acre grain output decreased simultaneously are mainly in areas with relatively mature urbanization. The primary industry is no longer the main industry in the region, and cultivated land was constantly replaced by other land use types in the process of urbanization. Therefore, in response to the reality of the increasing pressure on cultivated land resources, it is urgent to optimize the allocation of land resources, avoid excessive occupation and destruction of cultivated land resources, further curb the reduction of cultivated land area, and enable the region to maintain a certain grain production capacity and grain self-sufficiency rate. At the same time, it is necessary to improve the urban-rural relationship in the county and surrounding areas , promote the orderly flow and optimal allocation of urban and rural resource

elements, promote urban-rural integration and complementary development, and achieve coordinated and stable regional population-cultivated land-grain systems.

6.2. Conclusion

From 2000 to 2020, the number of rural population in all regions of the country has been declining in a straight line, with the rate of decrease showing a regional pattern of high rate in the central and northeastern regions and relatively low rate in the eastern and western regions. The changes in cultivated land area in counties in different regions of the country varied greatly. Except for the eastern region, the cultivated land area in counties in other regions has increased, and the distribution of cultivated land has become more unbalanced; grain output has shown an overall growth trend, with insufficient growth potential in grain output in the eastern region and significant growth in grain output in other regions. From the perspective of average quantity, the per capita cultivated land area of the rural population in counties across the country has increased overall, and the center of gravity of per capita cultivated land area has continued to move toward the northeast; the per capita grain output of counties varies greatly, with higher grain yields in eastern regions such as East China, South China and the middle reaches of the Yangtze River in the central region, which was the center of gravity of per capita grain output in China.

The coupling patterns of population-cultivated land-food system changes reflected by the per capita cultivated land area and per-land grain output in rural areas were mainly manifested in four types, showing certain differences in spatial pattern distribution. Specifically, the "simultaneous increase" pattern was mainly concentrated in Northeast China, North China, Jianghuai region, eastern Inner Mongolia, northern Shaanxi, Hunan and parts of Jiangxi, mainly in traditional agricultural areas. The "reduced population, reduced land, and increased grain" pattern of reduced per capita cultivated land area and increased per-land grain output in rural areas was mainly distributed in the middle and upper reaches of the Yellow River and Yunnan, Guizhou, Sichuan, Guangxi and other regions in the southwest, which were greatly affected by desertification and rocky desertification. The pattern of increased per capita cultivated land area in rural areas and reduced per-land grain output was mainly distributed in northwest Sichuan, Xinjiang and other regions and most areas of the southeast coastal area, where population urbanization was faster than land urbanization. The "simultaneous reduction" type was scattered in northeastern Zhejiang Province, southeastern Fujian Province, and parts of northern Tibet.

Based on the establishment of a dynamic evolution analysis framework for a semi-open complex system of population, cultivated land and food, this study analyzed the characteristics of changes in total amount and in per capita/unit amount of the population-cultivated land-food system in China's county-level rural areas, and proposed differentiated planning strategies for county-level rural areas with different change coupling patterns from the perspective of population-cultivated land-food system coordination, which could provide theoretical significance and practical reference value for ensuring China's cultivated land and food security, supporting the high-quality promotion of new urbanization and agricultural modernization based on counties.

Exploring the food-climate nexus through a justice lens: insights from urban experimentations.

Alessandra Manganelli
Affiliation: Universitat de Barcelona
Email: ale.manganelli@ub.edu

Abstract
Several cities are adopting re-localized food systems as a vehicle to achieve climate mitigation and adaptation objectives, implementing initiatives like productive nature-based solutions, plant-based food procurement, sustainable food environments, net-zero food waste strategies, and more (IPES Food, 2023). However, despite the potential of these urban experimentations to bridge food and climate sustainability, the urban sustainability literature has largely overlooked the food-climate nexus as a critical arena for achieving place-based sustainability, and for addressing socio-ecological justice. Highlighting this gap, this reflective paper examines how cities are experimenting with a new socio-ecological agenda at the cross-roads between food and climate, positioning themselves as potential agents of transformative change within this nexus. Through theoretical discussions and empirical vignettes, the paper particularly highlights key tensions in combining diverse dimensions of justice through the food-climate nexus.

For a time, we had come to believe that civilization moved in the other direction—making the impossible first possible and then stable and routine. With climate change, we are moving instead toward nature, and chaos, into a new realm unbounded by the analogy of any human experience (David Wallace-Wells, 2020, The Uninhabitable Earth).

Keywords: Urban food planning, urban climate action, food-climate nexus, governance experimentations, justice

Introduction

Climate change is undoubtedly one of the most pressing challenges of our time. Given the increased frequency and impact of socio-ecological crises – and in light of contested discourses around the adequacy of timeframes, scales, and scopes of action (Scoones et al., 2020) –, a sense of urgency and uncertainty permeates perceptions about the future of society and urban areas (Wallace-Wells, 2020). In this context, scientists and experts have been emphasizing the urgent need to act in order to reduce greenhouse gas emissions, given the already devastating effects caused by global warming to our planet (IPCC, 2023). This call for action demands 'deep, rapid, and sustained global greenhouse gas emissions reduction (that) can limit future changes', given that 'adaptation options that are feasible and effective today will become constrained and less effective with increasing global warming' (IPCC, 2023, p.18).

The link among diverse (urbanisation-related) socio-ecological systems – such as land-use, transport, energy, housing, building stock etc. –, and the climate emergency is becoming part of common knowledge, at least in the discourse. Within those socio-ecological systems, food systems are increasingly regarded as major contributors to global anthropogenic greenhouse gas emissions, with food production alone responsible for approximately one-third of global emissions (Garnett, 2011; IPES Food, 2016). To this adds the impact of other food chain activities, not least food waste, given that around one-third of all food produced for human consumption (approximately 1,300 million tons per year) goes to waste all along the food supply chain (FAO, 2022).

Acknowledging this reality of crisis and emergency, since at least three decades, literatures on climate urbanism and urban climate planning have started to highlight the role of cities as providing responses to the climate emergency, through diverse modes of urban climate action. Particularly, this literature recognises how urban areas have become pivotal in governance and planning efforts aimed at meeting the Paris Agreement targets of limiting global warming to below 1.5°C or 2°C (Bulkeley et al., 2012; Busch et al., 2018). To stress this aspect, authors such as Bulkeley (2021) have emphasised a shift in urban climate planning and governance approaches occurring over the past three decades. This passage has brought urban climate action from a sporadic type of intervention based on the voluntary or informal engagement of municipal authorities, to an increasingly 'strategic' approach, where urban climate planning becomes part of the programmatic agenda of cities with respect to priorities of economic and urban development (Bulkeley, 2021, p. 267). Moreover, what distinguishes contemporary modes of approaching urban climate action, according to the author, is the increased accent on the cli-

mate-connected city. Climate-connected urbanism invites to think urban climate action as intrinsically related to issues such as urban consumption of goods and services, wider sustainable development agendas (biodiversity, energy, water, food systems, ...), and issues of social justice.

In this context of enhanced claims for connected action, this paper argues that the food-climate nexus has not received adequate attention. Particularly, urban sustainability scholarship has so far missed to explore the interrelation between food and climate as an arena of urban sustainability governance and planning, and as a testing ground for a connected eco-social justice agenda. Particularly underexplored issues are: a) the key tactics adopted by place-based initiatives to implement and govern sustainability actions at the cross-road of the climate-food domains, and b) the pathways pursued by actors to address different dimensions of justice, including distributive, procedural, recognition and restorative justice (de Bruin et al., 2024). To address these aspects, this paper will draw on insights from literature spanning both the urban food and climate (justice) domains. First, the paper will draw from work on climate urbanism, planning, and mundane innovations (Castán Broto, 2020; Robin and Castán Broto, 2021) to shift the focus from mitigation or adaptation as policy frameworks, to the understanding of the innovative and transformative potential of on-the-ground actions (see section 2). Second, the analysis will argue about the emergence of a recent wave of urban food movements visibly linking food systems to climate action through place-based experiments and higher scale networks (IPES Food, 2023; the Barcelona Climate Challenge) (see section 2.1). Bringing on board critical insights on justice from the urban food and climate literatures (Amorim-Maia et al., 2022; Avelino et al., 2024; de Bruin et al., 2024), the analysis will then sheds light on combing diverse dimensions of justice through the food-climate nexus (section 3). Starting to connect theoretical reflections to empirical evidence, this contribution will briefly illustrate few examples of urban (planning) experiments at the food-climate intersection spanning different sections of the urban food system. Particularly, the paper highlights how these initiatives enact sustainability governance strategies and deal with issues of justice as outlined above (section 4). Based on the analysis, the paper will conclude by highlighting the importance of learning from place-based practices, and understanding justice as a dynamic and continuously negotiated nexus (section 5).

2. Experiments in climate urbanism and planning

Climate governance has typically been shaped by international multilateralism and the leadership of nation-states, reflecting the global nature of climate challenges and the need for coordinated response (Bulkeley et al., 2014). Forums like the United Nations Framework Convention on Climate Change (UNFCCC) have been providing platforms for negotiating agreements such as the Kyoto Protocol and the Paris Agreement, which establish emission reduction targets on a country level. In this context, the year 2015 has constituted a pivotal moment, where through the adoption of the Paris Agreement, national states have come together to commit to limiting the rise in global temperatures to well below 2°C above pre-industrial levels, while also striving to restrict the increase to 1.5°C by the end of the century (see for instance, D' Amico, 2024). The year 2015 also marked a symbolic moment for urban climate action. In fact, the Paris Agreement, including in particular the publications and assessment`s reports that followed, highlighted the specific role that cities can play in deep decarbonisation strategies, by leveraging key urban infrastructures such as the built environment, energy, as well as land and food systems (Babiker et al., 2022; D' Amico, 2024).

To a good extent, urban climate action and experimentation have also emerged to compensate for the lack of clear leadership, responsibility, and institutional commitment of the national level, ushering urban leaders and actors to stand at the forefront of the 'race' against the catastrophic effects of climate change (Bulkeley and Betsill, 2005).

In tandem with these processes, a critical rethinking of concepts and imaginaries such as 'the sustainable city' – along with the urban sustainability agendas that have been emerging in cities – has stimulated a growing body of research on urban climate governance and planning, signing the establishment of 'climate urbanism' as an emerging field of studies (Bulkeley et al., 2012; Castán Broto et al., 2020). Climate urbanism deals with the uptake of the ecological emergency at the city scale through several critical lenses. Among these lenses are the analysis

of drivers and incentives of cities to engage in urban climate governance and planning, mobilizing policy frameworks such as urban climate adaptation or mitigation plans (Bulkeley et al., 2012). Furthermore, early studies in the field have dealt with the engagement of cities in a multi-level climate governance also by means of city networks allowing to experiment within the urban arena, or transfer lessons learned between cities (Bulkeley and Betsill, 2005; Smeds and Acuto, 2018). Furthermore, critical lenses have analysed the entanglement of (neoliberal) urbanization processes with ecological issues, and the social and environmental externalities produced by those dynamics (Long and Rice, 2019).

Yet, particularly in the aftermath of the 2015 Paris Agreement, the climate urbanism scholarship has begun to analyse climate change governance beyond formal political arenas, looking at 'the multiplicity of urban experiments' happening on the ground and analysing their impact in the socio-material and political makeup of the city (Smeds and Acuto, 2018, p 550). As such, the focus has moved from mitigation or adaptation as policy or planning frameworks towards the understanding of the innovative and transformative potential of on-the-ground actions (Castán Broto and Bulkeley, 2013; Castán Broto et al., 2020) This shift has led to the recognition of how, aside from strategic frameworks and grand narratives, climate action is negotiated through place-based sites of experimentation and innovation, where experiments in climate planning could act as catalysts of social and urban change (Robin and Castán Broto, 2021). In this context, the literature has focused on experimentation as both, a planning tactic and a mode of governance that allows to craft adaptive and context-specific solutions that are targeted to local conditions while taking global objectives into account (Castán Broto and Bulkeley, 2013; Smeds and Acuto, 2018). Contrary to overarching planning strategies or policy framework, experimentations target place-specific infrastructures, such as transport, energy, housing, or food, as vehicles for deep decarbonisation dynamics.

It is argued that, what it may appear as a fragmented and piecemeal approach to urban change, constitutes instead a reality in which change is driven by a diversity of actors, sectors, and scales as catalyst of place-based transformations, leveraging concrete sites and specific infrastructure systems (Kivimaa et al., 2017). In this background, pioneer work on mundane innovations has proposed an approach to urban change which goes beyond a modernist understanding of a homogeneously defined urban future, privileging instead a post-colonial conception of transformative innovations as coming from situated practices of actors and communities, which can inspire other agents and scales (Castán Broto, 2020; Robin and Castán Broto, 2021). Recently, prominent scholars within the climate urbanism debate have highlighted the emergence of a new wave of climate change governance, which is increasingly 'climate connected' (Bulkeley, 2021). This means that the connection of climate with other spheres of urban life, with other policy and planning areas, and with pressing issues of social justice is increasingly relevant, as it would allow place-based experiments to gain traction, expand their focus, and increase their impact across policy domains and spatial-institutional scales. These aspects need to be further explored by the climate urbanism and the urban sustainability scholarship at large.

2.1 Building a food and climate partnership through urban-driven experiments

Not dissimilarly to the climate urbanism debate, over the last few decades, literature on urban food governance and planning has also shed light on the numerous urban food 'experiments' that have spread around the world, ranging from urban food strategies, to food policy councils, to multi-city food policy networks, and the like (Sonnino, 2016; Moragues-Faus, 2021). Overall, literature has regarded urban food as a distinct sphere of action where struggles to accelerate food system change towards greater sustainability and justice are negotiated (Moragues-Faus, 2020; Sonnino and Coulson, 2021). On the one hand, urban food movements and scholarly research have been concerned with the challenge to legitimize local food action as a self-standing area (or arena) of urban sustainability, and as a legitimate urban planning domain (Pothukuchi and Kaufman, 2000). On the other hand, the literature has long argued for overcoming silos thinking and moving beyond compartmentalised approaches to the food question. This means considering how food can work in synergy with other urban planning and policy areas, among the most cited being land use, health, social services, education (HLPE, 2024). In fact, due to the multifunctional and multi-layered nature of food, accent has been given to integrated and systemic approaches that could create bridges between actors, municipal departments, and policy areas (Mansfield and Mendes, 2013;

Sonnino, 2019; Sonnino et al., 2019). This integrated work entails not only embedding a food system lens within municipal jurisdictions, but also showing how working on food can help urban actors to address other transition objectives, not least urban resilience and climate adaptation (Ballamingie et al., 2020).

However, due to the often precarious and voluntary nature of food action in cities, experiments with policy integration are still at their infancy in many contexts. Changes in political cycles or socio-economic downturns are among the factors creating challenges to ensure the continuity and survival of food planning and governance structures (see among others, Manganelli, 2025). Furthermore, despite the numerous studies advocating for nexus approaches between food and other socio-ecological systems (Wahl et al., 2021), empirical evidence is lacking concerning concrete challenges and pathways to enable synergies across domains. As a consequence, there are missing opportunities to learn how 'experiments at the nexus' work in place-specific realities, and, more specifically, how interventions enacted in a crucial planning and governance sphere can foster productive externalities in other domains, helping to strengthen key sustainability agendas in the city (Zerbian, 2024). Such a process passes through the reflexivity of actors involved in concrete 'experiments' concerning challenges to surmount and pathways to pursue in order to engender transformative action 'at the nexus'. In short, in light of claims for the climate-connected city or for 'de-siloed' approaches to food, research is needed that provides a deep understanding of how urban food governance and planning can synergise with other urban transition arenas – climate change being particularly key – and, most of all, how this synergistic action can usher from transformative innovations happening on the ground.

I argue that opportunities to make advancements in this direction are already there, emerging, among others, from a recent wave of urban food movements visibly linking food systems to climate action and planetary health objectives. Despite being under-researched in their transformative potential, these movements encompass a diversity of local initiatives, but also scalar processes that, while stemming from food system´s activities, are inherently at the intersection of food and climate, also including interconnected issues of planetary justice and human health (IPES-Food, 2023). Emerging experiments are diverse and involve different activities and areas of the food and urban systems. They range from experiments in using land for agroecological food production, to the scaling out of productive nature-based solutions and biophilic urbanism initiatives, to the movement on plant-based food procurement, work on sustainable food environments and the last food mile, to net-zero food waste strategies, among others. Some of these experiments are enabled by institutionalised planning frameworks at the local level – such as urban food strategies, or urban climate plans (Mahmoud, 2025) – while other initiatives emerge from the outside with the potential to influence institutional frameworks.

In particular, some of the urban areas where these movements occur have joined city networks intersecting both areas: food and climate. These networks include the Milan Urban Food Policy Pact (MUFPP), the Barcelona Challenge for Good Food and Climate, and the latest C40 Network's 'Good Food Cities Declaration', urging city partners to 'deliver sustainable food policies in order to achieve a Planetary Health Diet'. The years 2020-2021 have been particularly crucial in pushing these networks and movements to build coalitions. At that time, around 120 local and regional governments created an alliance in order to shape a common agenda for climate-oriented food system transformation. In 2021 this agenda was officially launched at the global climate conference COP26 in Glasgow (UK). Named as 'the Glasgow Food and Climate Declaration' (GlasgowDeclaration.org), this multi-city pact calls for responsibility in 'reducing greenhouse gas emissions from urban and regional food systems in accordance with the Paris Agreement and the Sustainable Development Goals' (see IPES-Food, 2023, p.10) and invites to shape policy frameworks, governance mechanisms and coordinated action to that purpose. Following the COP26, the 7th Global Forum of the Milan Urban Food Policy Pact was held in Barcelona in 2021, giving place to the so-called 'Barcelona Climate Challenge' (thebcnchallenge.org). The latter is regarded as a step to implement the objectives of the Glasgow declaration. It provides local authorities with support to calibrate and measure their actions at intersection of food and climate. Several actors and networks support the Challenge, including the Barcelona City Council, the Spanish municipal agro-ecology network 'Red de Municipios por la Agroecología' , the Milan Urban Food Policy Pact, C40, the French network 'Terres en villes' and the UK multi-city food policy network 'Sustainable Food Places'.

We could advance the hypothesis that the emergence of these movements – including initiatives such as actors' coalitions, pacts, and declarations around the food-climate nexus – indicates a growing momentum and multi-actor engagement aimed at advancing the climate-food agenda. To build on this momentum, what is needed is a systematic and up-to-date understanding of how these and other initiatives work to overcome siloed actions, create bridges between the sustainability spheres of food and climate, and practically operationalize a multidimensional justice agenda.

3. Informing the food-climate nexus through a justice lens

Socio-ecological theories including work on urban political ecology, environmental justice, but also literature on justice in planning (Fanstein, 2017), have taught us how any initiative seeking to engender meaningful socio-ecological change in complex social and urban settings, has to deal with issues of justice (Manganelli, 2024). Thus, deepening the understanding of the transformative role of on-the-ground 'experiments', work on justice has advanced, intersecting with both, the food and the climate debates (Avelino et al., 2024; de Bruin et al., 2024).

Inspired by civil rights movements and struggles for racial justice in the US, pioneer studies on environmental justice have mainly focused on the analysis of ***distributive justice*** issues, namely the (un)fair distribution of the effects of environmental actions across communities (Schlosberg and Collins, 2014). Early contributions on food justice have advanced a similar focus, understanding justice mostly in terms of 'ensuring that the benefits and risks of where, what, and how food is grown and produced, transported and distributed, and accessed and eaten are shared fairly' (Gottlieb and Joshi, 2010:6). After all, when considering food chains, questions such as how communities get access to food, who is exposed to the greatest disadvantages in access, what are the distributional effects of given food policies, and so on, acquire preeminent attention.

Yet, from the early focus on distribution, the environmental justice debate has over time moved in the direction of embedding multiple dimensions of justice, englobing in particular ***procedural and recognition justice*** (Fraser, 2008; Schlosberg, 2013; Schlosberg et al., 2025), the other two pillars of the environmental justice framework. As scholarly contributions highlight, procedural justice has notoriously been a rather underplayed dimension in the food debate that has long overlooked the importance of politicising decision-making processes (Duncan and Claeys, 2018). Procedural justice, indeed, focuses on how decisions are made and who is included or excluded in decision-making arenas regarding food or climate actions. Recognition justice involves acknowledging who is the real subject of injustices and tackling structural determinants of those actors in disadvantaged positions (De Bruin et al., 2024).

Essentially, the consolidated literature on environmental justice has shown how justice is played out at the intersection of different dimensions. Focusing on the triad distribution, procedural and recognition justice has the value to highlight how actors need to mediate among these different aspects (Schlosberg et al., 2025). Specifically, focusing on distributive issues alone without considering who is included and who is excluded in the first place, risks to induce a reductionist consideration of justice. In the same vein, focusing mainly on establishing procedural arrangements, such as mechanisms for civil society participation, politicisation and control, without attention to how this leads to fairer outcomes, would be a missed opportunity to substantiate justice.

While this literature on justice has put preeminent focus on social aspects, one of the key contributions of the climate urbanism and climate justice debate is to bring to the fore a relational perspective that encompasses ***the ecological*** dimension of justice as linked to the social, but also in possible tension with it (Pineda-Pinto et al., 2021). Based on a relational approach encompassing nature and earth, 'just sustainabilities' perspectives, for instance, have highlighted the need 'to ensure a better quality of life for all, now, and into the future, in a just and equitable manner, while living within the limits of supporting ecosystems' (Agyeman et al., 2016: p. 28). Going deep into diverse relational and ecological perspectives on justice would over-exceed the scope of this paper. However, it is important to highlighting how sub-literatures within environmental justice – such as materialist-feminist perspectives on justice – have acknowledged that, in a world of deep planetary relations and inter-dependencies, theories of justice should be grounded in situated knowledge and practices (Olazabal et al. 2021), specifically ac-

knowledging the place that humans inhabit in the world together with other human and non-human elements. **Ecological justice** then indicates a process of establishing relationships of care with nature and 'the environment', avoiding exclusively anthropocentric perspectives on justice.

These insights could be developed further into an approach to justice at the nexus, nurtured by theories that avoid both dichotomic and universalistic understandings of justice. Nexus justice draws attention to the interconnections between various dimensions of justice and how these unfold within place-specific initiatives. This perspective allows to examine not only how different types of experiments emerge and scale at the intersection of food and climate, but also how, driven by ecological ambitions and environmental targets, they attempt to implement a nexus justice lens. Such a lens connects different policy spheres and multiple dimensions of justice - particularly linking ecological (planetary) justice with social (human) justice.

4. Some empirical examples emerging from cities

What follows constitutes a very explorative illustration of how some of the above insights and concepts can be applied to the analysis of emerging food-climate experiments at the nexus. Without any ambition to provide an exhaustive picture, this section illustrates examples of experiments emerging in different city contexts – i.e. Brussels, New York, and Milan, – and in different sections of the food system, including in particular food production, food procurement, and waste recovery-redistribution.

Data on experiments in these city contexts are mainly retrieved by means of desk research, secondary literature review, personal knowledge networks and, in the case of Brussels, by means of primary research conducted in that context up to the year 2022. These cities were chosen as they belong to some of multi-city networks on food and climate highlighted in section 2.1 (MUFPP, C40, ICLEI..). Furthermore, these cities demonstrate engagement in both climate and food justice action. They show a diversity of food-climate experiments and engage with social and ecological justice dimensions. Each of the following sub-sections illustrates with one city context and experiment.

Vignette 1. The Brussels' Capital-Region: creating an agroecological food hub

The context of Brussels is a rather instructive one from a perspective of food planning innovations and their connection to ecological and climate agendas. Being for several time relatively understudied by the urban food planning scholarship, the Brussels' Region has instead demonstrated a rather good degree of institutional leadership in food issues, combined with a rather dynamic bottom-up engagement in alternative food initiatives (Manganelli, 2020). Particularly, since the official approval of a food strategy in 2015, key institutional actors in the Brussels' Region have been providing steady support for food system's re-localisation. Ecological considerations have been a foundational element in the development of Brussels' food movement. The initial wave of bottom-up mobilization in the early 2000s was largely driven by agroecologically engaged citizens and farmers, as well as by participants in alternative food consumption networks who laid the groundwork for the broader movement (Manganelli, 2020). The key institutional leader of the Brussels' food movement has been the agency of Environment (Bruxelles Environnement), at the forefront of actions related to greening, biodiversity, waste management, public procurement, and responsible consumption in the Region. Several local experiments can be identified in Brussels that connect food and climate agendas, including studies producing evidence on the environmental impact of the food chain in terms of greenhouse gas emissions (see studies connected to the Brussels' Strategie GoodFood). This section, in particular, illustrates an experiment promoting agroecological peri-urban food production and food system re-localisation, called the Boeren Bruxsel Paysans (see Manganelli and Moulaert, 2019). Activated in 2015 thanks to funding received from the European Regional Development Funds, this 'experiment' is a pilot project that involves practices of land restoration and re-conversion to promote agroecological farming activities. It also involves the creation of a re-localised hub for food processing and transformation, refurbishing pre-existing infrastructures. Agroecological farming activities have been implemented in two plots of publicly owned land in the Municipality of Anderlecht, at the outskirts of the Brussels-Capital Region. Since the genesis of the project, the ecological argument related to food system re-localisation, and to the promotion of more resilient and sustainable farming practices, has been rather strong. In this background, the genuine will of public land

owners (i.e. the Municipality of Anderlecht) to use available public land in a different way than urbanisation and soil consumption, was also pivotal to enable the project. Further actors involved in the experiment, including in particular the organisation Terre en Vue, were essential to provide evidence about further accessible and available land for local agroecological producers in the Region.

More than just a project, or experiment, we could argue that through time the Boeren Bruxsel Paysans has constituted an advocacy platform around access to land, agroecological farming practices, and the provision of shorter supply chains. At present, this experiment counts 10,57 hectares of land mobilised for local agriculture; 30 agro-ecological farmers and 25 small processors that were involved in training activities (see Boeren Bruxsel Paysans' documentation). Overall, this coalition of actors has undoubtedly played a role in influencing regional discussions around access to land, and, potentially, in showing a different model of land use and land development for Brussels and its outskirts. One of the key processes initiated by this project is the development of the Municipality of Anderlecht's Climate Action Plan 2023–2030, with a particular focus on reducing greenhouse gas emissions through the promotion and production of low-carbon food.

In summary, this initiative shows how ecological justice arguments related to soil restoration and land reconversion in urban-peri-urban areas, together with the social challenge of supporting small producers, provided a strong narrative to motivate the genesis and role of this experiment. Far from constituting an isolated case, the Boeren Bruxsel Paysans should be regarded in conjunction with similar dynamics going on in Brussels and in other contexts. Given the growing number of urban greening plans and nature-based solutions emerging in response to climate adaptation targets (Mahmoud et al., 2025), there is an opportunity to explore how experiments in re-localized food production can leverage the broader set of frameworks and windows of opportunity created by this expanded climate agenda.

Vignette 2. New York City: combining ecological and social justice objectives through Good Food Purchasing
New York City (NYC) is considered as pioneer in urban food planning, embracing a progressive and systemic vision around food system transformation (Cohen and Ilieva, 2021). Issued in 2010, comprehensive visions and reports such as FoodNYC and FoodWorks show a clear orientation towards a food system approach. Such an approach argues for an integrated food policy that considers the different stages of the food system and examines the ways in which NYC is actually fed (Morgan, 2025). In 2021, the mayor's Office of Food Policy – i.e. the office responsible for food policy-making and for the orchestration of different agencies in the city – launched a food plan called 'Food Forward NYC'. This plan designs a ten-year roadmap aiming 'to reach a more equitable, sustainable, and healthy food system by 2031' (see the Food Forward NYC's plan). In 2023, Mayor Adams also launched the city's climate plan – called PlaNYC, showcasing political engagement in climate action. New York City's leadership has clearly demonstrated its commitment to food and climate goals, notably by joining the Cool Food Pledge in 2021. This global initiative, launched by the World Resources Institute, invites cities and institutions to reduce greenhouse gas emissions from the food they serve by 25% by 2030, using 2015 as the baseline year (Cohen, 2023). This commitment is reinforced in the PlaNYC, which raises the target to 30% emissions reductions by 2030, engaging relevant city agencies such as schools, hospitals, jails, social centres, etc. (IPES-Food 2023, p. 23).

Within this background, City's decision-makers have become conscious about the transformative power that the public sector can leverage thorough sustainable food purchasing (Morgan, 2025). Particularly, this vignette briefly elaborates on the NYC's Good Food Purchasing program as a vehicle for combined food and climate action. The Good Food Purchasing is a public procurement program launched at the local level but responding to a wider national public procurement framework (Morgan, 2025). NYC initially joined the program in 2018, with two agencies participating – the Department of Education and NYC Health and Hospitals. The initiative later expanded to include seven city agencies (Morgan, 2025). In 2022, Mayor Adams reinforced this commitment by signing Executive Order 8, which formally institutionalized the Good Food Purchasing Program (see NYC Food Policy's web sources). Kate MacKenzie, the executive director of the mayor's Office of Food Policy, refers to the food purchasing program as 'an enormous lever for change and critical tool for equity', able to 'deliver higher-quality food and make progress on climate, animal welfare, workers' rights and supporting minority and women owned business'

(Mayor's Office of Food Policy, 2021).

In fact, what is interesting about the Good Food Purchasing program, is the clear orientation towards climate mitigation while also keeping attention to social justice objectives. This is achieved by the set-up of clear ecological and social values, or principles, on which basis establishing a methodology that allows to evaluate the program and track progress through time (Cohen, 2023). Those values and principles draw inspiration from the nationally networked Good Food Purchasing Program. First, the principle of environmental sustainability, which implies establishing a metrics to monitor which food is supplied by public caterers and what is environmental impact of different food types in terms of greenhouse gas emissions. As highlighted by various sources, longitudinal monitoring of this metric enables an assessment of how well food purchasing aligns with climate objectives, and serves to incentivize the adoption of lower-emission, climate-conscious choices (Cohen, 2023; IPES-Food, 2023). Second, the value of supporting local economies while fostering inclusivity. This is achieved by privileging food that is 'grown, processes, manufactured, or distributed' by businesses or enterprises located in the City or in the State of New York (see NYC Food Policy's web sources), while also keeping attention to gender and cultural aspects (by for instance privileging businesses run by women, or people self-identified as indigenous, or minorities). Third, setting quality standards regarding nutrition (e.g. minimum requirements in terms of fruits, vegetables, low-processed plant-based proteins, etc.). Fourth and fifth, the attention to animal welfare (e.g. reporting purchases of animal proteins) and worker's rights (raising transparency and monitoring conditions of food workers and laborers, in all parts of the food chain, in accordance to national laws on labour standards) (see NYC Food Policy's web sources). Finally, a further overarching principle is the one of transparency, i.e. the provision of publicly accessible data concerning monitoring and progress.

The above is a short overview of an 'experiment' whose impact certainly needs deeper evaluation and research. Yet, this experiment provides an inspiring practice of a publicly led program which clearly stands at the nexus of climate and food justice objectives. What needs further deepening are aspects such as the capacity and impact of such a program through time, the challenge of running a clear monitoring framework, and the ways in which this experiment can be further empowered thanks to the connection with the program at the national level. Rather than considered in isolation, this experiment should be regarded within a wider set of practices and movements towards universal and climate-consious public procurement (Morgan, 2025).

Vignette 3. Milan: achieving climate and social targets through the Food Waste Hubs

Having examined experiments in land use and public procurement, this vignette turns to another strategic dimension of the food system with potential to advance both climate and food security objectives: the recovery and redistribution of food waste. Specifically, it focuses on initiatives developed in the context of Milan as illustrative examples. Milan is considered as a further 'best practice' when it comes to leadership in food policy and food governance (Calori et al., 2015). Key institutional steps in food policy development occurred around the year 2014, when the Milan Municipality and the Cariplo Foundation (a key private foundation in the city), launched a study about the Milan urban food system. On this basis, in 2015 actors' consultations led to the development and approval of a food policy for Milan (Food Policy di Milano). In a move comparable to New York City's approach, 2017 saw the establishment of a Food Policy Office (Ufficio Food Policy) within the Deputy Mayor's cabinet, tasked with coordinating and implementing food policy across municipal departments. Among the priority axes of the Food Policy are: ensuring healthy food and sufficient drinking water for all; promoting the sustainability of the food system; Promoting food literacy; tackling food waste; and promoting scientific research in the agro-food sector (see Food Policy's documentation).

In this background, this vignette deals with experiments in food waste as a testing ground for the food-climate nexus, particularly focusing on emerging social and ecological justice aspects. An illustrative case in point is the so called 'Food Waste Hubs' pilot project, activated in Milan a few years ago. Food Waste Hubs is a network of neighbourhood spaces and infrastructures for the collection and storage of surplus food from various retail outlets, including in particular large-scale retail (information retrieved from the Municipality of Milan). Specifically, each hub sources surplus food primarily from supermarkets and workplace canteens, providing it to local NGOs,

community initiatives, and food security organisations that support the neediest members of the community. This experiment started in 2017 as a pilot project, product of the collaboration between the Municipality of Milan, the Cariplo Foundation, the organisation 'Assolombarda' (a consortium of enterprises operating in the Milan Metropolitan area and its province) and the Politecnic University of Milan. The first hub was implemented in 2019 in the 'Isola' district of Milan. In 2021, another hub was established as a sort of consolidation of the experimental phase. From that year on, a father expansion phase occurred, with the creation of other hubs, up to the most recent phase that integrates new actors such as municipal markets (information retrieved from the Municipality of Milan and Polytechnic University of Milan's website sources about the experiment).

The year 2021 was a key moment in the young trajectory of the Food Hubs' experiment. In that year, the city of Milan obtained a reward of 1 million pound (1.17 million euros) in the first edition of the Earthshot price, a global environmental award established in the UK. The Food Hub's project was awarded within the category 'Build a Waste Free World' (see earthshotprize.org). The award could channel further resources that allowed to amplify and further integrate the experiment. In particular, the key actors participating in the project sought not only to create new food hubs and involve more actors; they also pursued the creation of stronger networks among the different actors involved in various food waste hubs, aligning them towards shared ecological and social objectives.

The Food Waste Hubs is one among the several examples of initiatives at the food-climate nexus addressing complex challenge of food sustainability and fight against food waste as an ecological target, while also promoting food equity. Aspects of social justice are addressed by tackling distributive and procedural issues such as improving fragile people´s access to dignified food; scaling out the approach socially and spatially in the city; and by using food as a vehicle for sociability and dignity, by shaping community food infrastructures. At the same time, the experiment could serve as a demonstration platform that put accent on the ecological impact produced by food waste and thus, on the opportunity to take action in this direction. A short account of the impact of this experiment in the year of 2021 tells that across all active Food Hubs at that time, 1,386 tonnes of food waste were recovered, thereby preventing an estimated 3,188 tonnes of CO_2e emissions. According to these data, these efforts facilitated the redistribution of several hundred thousand surplus food items to approximately 27,000 individuals experiencing vulnerability, corresponding to an estimated 1.23 million meals (source: earthprice.org).

There are of course critical questions that can be posed to this experiment. On the one hand, as the NYC's vignette suggests, measuring the impact of this kind of initiative in terms of emissions' savings would require a systematic tracking which measures progress through time. Furthermore, there are questions related to the resourcefulness of this project and its capacity to last in time so as to exercise an impact. Finally, a deeper engagement with the challenge of social justice raises the critical question of the extent to which emerging experiments work in address the underlying determinants that shape access to good and healthy food for individuals in vulnerable situations (HLPE, 2024). Taking these issues into account, one could argue that an experiment of this kind serves to highlight food waste as a critical arena for aligning food and climate objectives, with the potential to synergize with broader urban initiatives such as circular economy strategies and climate action plans.

5. Conclusions: ways forward

This reflective paper has claimed for a deeper account of the interrelation between food and climate as a critical arena for urban sustainability governance and planning. Taking inspiration from the climate urbanism, food governance, food and climate justice debates – but also from real-life movements and practices emerging from cities –, this paper has shown how the climate-food nexus serves as a site for situated experimentations and place-based innovations emerging from the ground-up (Castán Broto, 2020). In this background, this paper has also suggested integrating a nexus-justice approach where aspects of ecological justice could be regarded in synergy (or, sometimes, tension) with social justice dimensions, providing potential arguments for the out-scaling or up-scaling of experiments at the food-climate nexus.

While this contribution has only provided a brief illustration of initiatives in different city contexts and in diverse areas of the food system, there is surely scope for wider theoretical and empirical research. Indeed, further lines

of research could go in the direction of identifying various typologies of food-climate experiments in different contexts, looking at the challenges to connect these sustainability fields and engender systemic and transformative action in both domains. Further research could also explore how city actors and other players are trying to build methodologies in order to track progress and measure achievements in terms of climate objectives and ecological justice targets. Moreover, other studies could mobilise critical lenses that explore the challenges to attend different dimensions of social and ecological justice, and how this justice nexus could create potential contradictions in situated experiments. In conclusion, this paper invites to explore the potential of food as a testing ground for the climate-connected city (Bulkeley, 2021), and of climate as a fertile terrain in which transformative food system goals can be further advanced.

Abstract
Although foodscape planning is increasingly recognized as a critical component of sustainability transitions, it remains an emerging field of research and practice. Existing studies often overlook the multifaceted role that local food planning can play in shaping the physical, economic, and socio-cultural dimensions of foodscapes. This paper examines how recent local food policy initiatives are reconfiguring foodscapes across six Mediterranean sub-regions in France. Using a mixed-methods approach, it combines an analysis of locally implemented policies with survey data on evolving food practices. The findings reveal a growing emphasis by local authorities on socio-cultural and cognitive interventions, which are associated with modest dietary shifts aligned with environmental objectives. These results offer insights into how local food planning can more effectively support the adoption of sustainable diets.

Keywords: Food environment, Urban-rural planning, Climate change, Environmental Food Behaviour Index

1. Introduction

The current food system remains largely unsustainable due to its significant contribution to major 21st-century challenges, including climate change (Mbow et al., 2019) and the rise of diet-related diseases such as diabetes and cancer (Thavarajah, 2018). Transitioning toward more sustainable diets is therefore essential to address the public health crisis and substantially reduce greenhouse gas (GHG) emissions (Poore and Nemecek, 2018). Governments at all levels have the capacity to play a pivotal role in initiating this transition (Temme et al., 2020). Yet, despite the profound implications of food systems for both sustainability and public health, food planning at the local level only emerged as a distinct field in the early 2000s (Pothukuchi and Kaufman, 2000). Since then, numerous cities and regions have intensified their engagement in food system transformation by signing international commitments such as the Milan Urban Food Policy Pact (MUFPP, 2015) and the Glasgow Declaration (2021). These initiatives aim to leverage local food planning as a tool to reduce emissions and offer more sustainable food options to local populations. However, limited research has examined how such policies concretely transform local foodscapes, influence food environments, or shape residents' eating habits.

The High-Level Panel of Experts on Food Security and Nutrition defines food environments as "the physical, economic, political, and socio-cultural context in which consumers engage with the food system to acquire, prepare, and consume food" (HLPE, 2017). In academic research, the term foodscapes is increasingly preferred, as it emphasizes the territorial dimension of food environments and how they are actively shaped by local practices, political institutions, and economic systems (Vonthron et al., 2020). Numerous studies have demonstrated that food choices are shaped less by individual decisions alone than by the surrounding foodscapes, including factors such as retail outlets, urban design, and even walkability (Carrus et al., 2018). However, this literature has predominantly focused on the spatial dimension of foodscapes, mapping retail outlets such as supermarkets or fast-food chains using geospatial methods (McKinnon et al., 2009; Herforth and Ahmed, 2015; Vonthron et al., 2020), and evaluating their public health implications (Adam et al., 2016; Liu et al., 2016; Cooksey-Stowers et al., 2017; Wilkins et al., 2019; Méjean and Recchia, 2022). These studies are often situated in urban contexts (Mattioni, 2021; Méjean and Recchia, 2022) and tend to overlook the broader range of tools through which urban and rural planning can shape foodscapes, not only physically, but also economically, culturally, and cognitively. In contrast, cities and municipalities increasingly mobilize a wider set of instruments that extend beyond spatial accessibility (Morgan and Sonnino, 2010; Morgan and Santo, 2018; Mattioni, 2021). For instance, Barbour et al. (2021) demonstrate, in their review of Milan Urban Food Policy Pact signatories, that the most common measures implemented have focused on public procurement, sustainability guidelines in school meal programs, and the promotion of

urban agriculture. In many of these initiatives, the emphasis on promoting local food stands out as a central objective. However, despite its strong symbolic and political appeal, prioritizing local products has shown limited or ambiguous environmental benefits (Majewski et al., 2020), underlining the need for more ecologically robust and evidence-based local policies.

In the French context, local policymakers have several tools at their disposal to influence foodscapes and dietary behavior. These tools include organizing events focused on sustainable food, regulating food advertising, and managing food waste. They also oversee food procurement for public institutions such as school canteens. Additionally, policymakers work to protect farmland and promote short food supply chains, aiming to improve access to local and sustainable products. To coordinate these actions and align them with sustainability goals, a new policy instrument called Territorial Food Projects (Projets Alimentaires Territoriaux, PAT) was introduced in 2014 (Maréchal et al., 2018). These projects aim to promote local governance over both sustainable food production and consumption. Municipalities involved in PATs are required to consult local stakeholders and develop action plans that address various levers of transformation, including local production and distribution, equitable access to sustainable food, and the reduction of food waste. Environmental objectives are also integrated, with actions targeting reduced food waste, development of agroecology, lower food transport emissions, and the promotion of sustainable practices such as reduced meat consumption and increased procurement of organic products, especially in public canteens. These local policies thus have the potential to promote innovative approaches that address not only the physical aspects of food environments but also their economic, socio-cultural, and cognitive dimensions, thereby encouraging dietary transitions with lower environmental impacts. While several studies have demonstrated that PATs contribute to farmland preservation, the development of urban agriculture, and the expansion of local and organic food procurement, their broader impacts on dietary practices and environmental outcomes remain underexplored (Lulovicova and Bouissou, 2024). Consequently, there is an urgent need to evaluate the impact of such local policies on food behaviors more systematically (Hawkes et al., 2017). Existing studies have primarily focused on emblematic or experimental cases, such as school canteens in Galicia (Perez-Neira et al., 2021) or in Mouans-Sartoux (Lulovicova and Bouissou, 2023), which have shown promising results in terms of both diet and environmental impact. However, these cases are often unrepresentative, thus limiting the generalizability of their findings. This research addresses that gap by examining the evolution of local food planning initiatives, and the dietary changes associated with them in six Mediterranean sub-regions of France. We adopt the concept of foodscape as a heuristic tool to explore the spatial, economic, socio-cultural, and cognitive dimensions of food consumption within the studied territory, and to evaluate how local policies may influence these dimensions. The following sections present the study area, and the methodology used to assess recent food planning initiatives, including the development of a food questionnaire and an Environmental Food Behaviour Index. This is followed by an analysis of the potential of these initiatives to reshape various dimensions of local foodscapes, of dietary changes toward environmental sustainability in the study area, and of territorial differences related to the development of local planning approaches.

2. Methodology

Study area and policy analysis

France is considered a pioneer in the development of local food initiatives, owing to its strong historical and cultural attachment to local agriculture and food products (Bessière, 1998). Since 2014, the expansion of such initiatives has accelerated through the national policy supporting the development of Territorial Food Projects (PATs), which are local food planning tools implemented at the municipal or regional level. Their main objective is to support the relocation of sustainable agriculture and food systems through coordinated action among public and private stakeholders. These developments provide an interesting context for examining how food planning influences foodscapes.

In the Alpes-Maritimes department, located in southeastern France, agricultural activity has declined in recent decades due to urbanisation and the growth of tourism along the French Riviera (Voiron and Liziard, 2008). Nevertheless, the department stands out with a relatively high number of PATs. One PAT operates at the departmental scale, five at the sub-regional level, corresponding to agglomerations or inter-municipal structures, and three at

the municipal level. Some municipal areas are therefore influenced simultaneously by three PATs operating at different territorial levels: municipal, sub-regional, and departmental. Among these, six initiatives are officially recognised as level 2 by the French Ministry of Agriculture, indicating the adoption of an operational action plan. Two additional projects, currently at level 1, are expected to achieve level 2 status shortly. This configuration makes Alpes-Maritimes one of the most advanced departments in France in terms of PAT deployment. However, two sub-regional areas within the department have not yet engaged in any PAT initiative. Geographically, the western part of the department is more actively involved, with full PAT coverage. In this area, four intercommunalities have formed a collective structure known as CAP AZUR, to coordinate ecological transition efforts, including sustainable food systems, in a coherent and integrated manner (Figure 1). In addition, the southern coastal area of the department is highly urbanised, in contrast with the northern area, which is predominantly rural due to the presence of the southern Alps, characterised by high altitudes and steep slopes. These geographical contrasts may influence food access and perceptions.

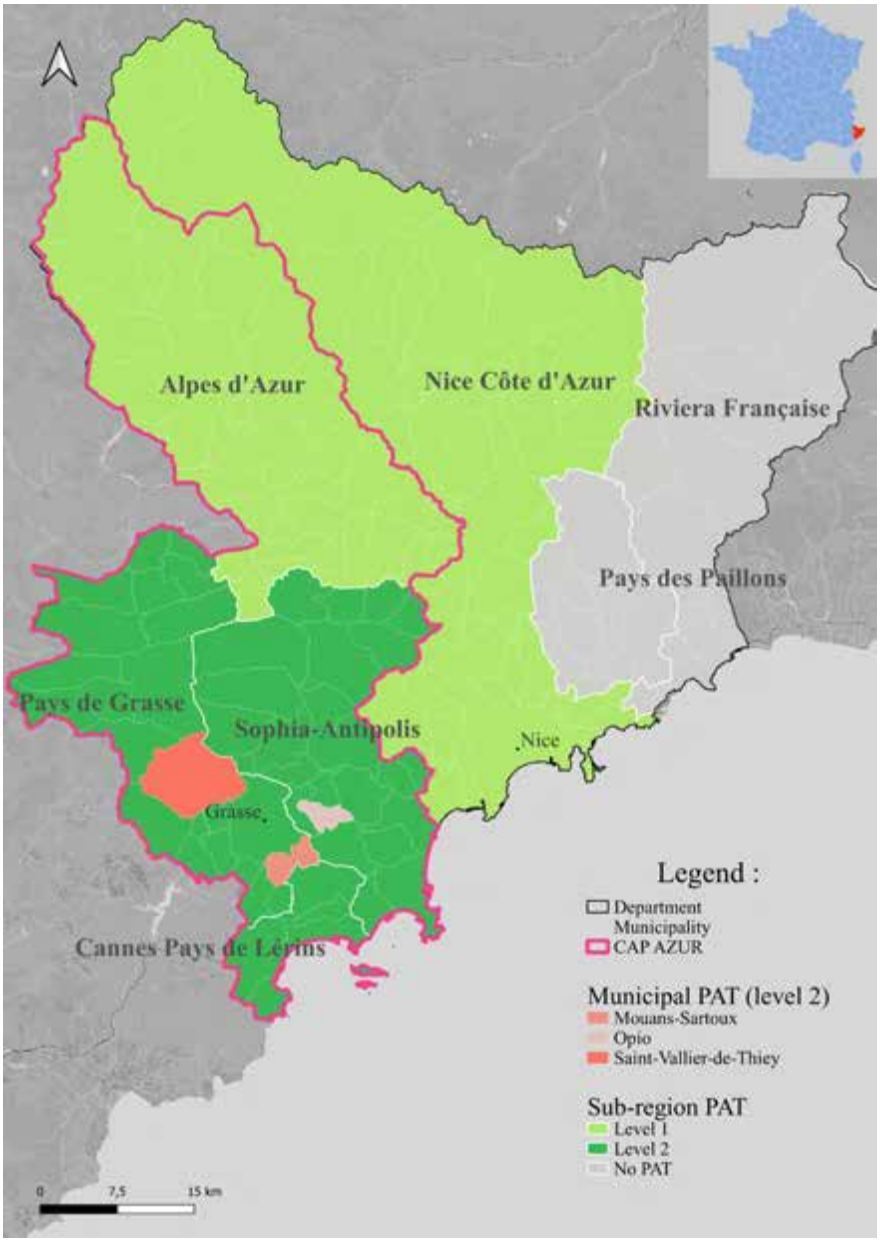

Figure 1. Map of the Department of Alpes-Maritimes and its Food Territorial Projects (PAT).

The scope and nature of food-related initiatives that local decision-makers can undertake through a PAT action plan vary depending on the territorial scale. For example, under French law, municipalities are responsible for public procurement in primary school canteens, while departments manage canteens in high schools. Municipalities also directly oversee local urban planning and are therefore key actors in agricultural land preservation and food retail distribution. Sub-regional authorities typically handle waste management, including food waste, whereas departments are in charge of economic development. Despite these differences, all PATs in the study area share common objectives. They aim to support local, organic, and extensive farming, promote short supply chains, and encourage sustainable dietary practices through educational events, challenges, and policy interventions. For the purpose of the policy analysis, this paper focuses exclusively on territories that are covered by a municipal and/or a sub-regional PAT. The assessment of the departmental PAT is not included, as the objective is to compare the diversity of actions implemented in different local contexts within the same department.

The policy analysis followed a two-step approach. First, a review of existing literature on local food policies was conducted to identify the types of interventions available to local authorities that influence food environments and foodscapes. Key references included works by Morgan and Santo (2018), Sonnino et al. (2019), Barbour et al. (2021), and Brocard and Saujot (2023). This step provided a framework for assessing how local authorities act on the physical dimension of foodscapes, such as market infrastructure or food access, the economic dimension, including subsidies and pricing strategies, and the socio-cultural and cognitive dimensions, through educational campaigns or public food procurement. In the second step, we conducted interviews with local policymakers and analysed the action plans of each PAT. This qualitative investigation aimed to assess the degree of intervention in each of the four foodscape dimensions mentioned above. The findings from this policy analysis are further compared with data on the evolution of local dietary practices in the department, in order to explore any possible links between territory, public action, and dietary change.

Food Questionnaire and Environmental Food Behaviour Index

To examine dietary shifts toward environmentally sustainable practices, we adapted a food behaviour questionnaire developed by Lulovicova and Bouissou (2023). The adapted version collects data on respondents' municipalities, socio-economic characteristics, food purchasing motivations, and self-reported behavioural changes related to environmental sustainability. Evolution is measured over the past five years, corresponding to the launch of most regional PAT interventions. Respondents were asked whether they had participated in locally organised sustainable food events or challenges, frequented municipal farmers' markets, received food aid coordinated by local authorities, or were parents of schoolchildren enrolled in institutions where sustainable food supply initiatives had been implemented.

To evaluate the environmental implications of these reported dietary changes, an Environmental Food Behaviour Index (EFBI) was developed. While numerous studies have documented the environmental impacts of changing food consumption patterns (e.g., Scarborough et al., 2014; Aguiar et al., 2021), no single composite indicator currently captures the full spectrum of food behaviours associated with positive environmental outcomes. Existing indexes tend to focus either on nutritional adequacy or broader notions of sustainability, such as the Comprehensive Diet Quality Index (Toujgani et al., 2024), the Diet Quality Index-International (Tharrey et al., 2024), or adherence scores to specific dietary models like the MEDI-LITE Mediterranean Diet Index (Baudry et al., 2023). The EFBI was constructed to capture behavioural changes that are both likely to be influenced by local foodscape transformations and relevant to reducing environmental degradation, particularly in relation to climate change (Culliford and Bradbury, 2021; Marty et al., 2022). Ten food-related behaviours were selected to build the EFBI, based on their documented environmental significance. These include:

(1) a shift in the types of food retail outlets visited (e.g., from supermarkets to organic shops or fresh markets),
(2) changes in transport modes used for grocery shopping (e.g., switching from motorised to non-motorised transport),
(3) reduction in meat consumption,
(4) reduction in ultra-processed food consumption,
(5) increased consumption of organic products,

(6) increased consumption of seasonal products,
(7) increased consumption of locally sourced products,
(8) reduced reliance on packaged foods,
(9) reduction in household food waste, and
(10) adoption of individual or collective composting practices.

Each behaviour was scored as follows: +1 for a shift toward more sustainable practices, 0 for no change, and –1 for a shift toward less sustainable practices. The final score for each participant therefore ranged from –10 (less sustainable shift across all behaviours) to +10 (more sustainable shift across all behaviours). For example, if a participant switched from using a car to cycling for grocery shopping, but did not change any of the other nine behaviours, they would receive +1 point for the transport indicator, 0 for the others, and a global score of 1. The scoring system does not apply weightings based on the magnitude of environmental impact for each behaviour. Both the composite EFBI and individual behaviour-specific scores were used in subsequent statistical analyses to compare behavioural patterns across territories. The aim was to assess the extent and nature of dietary transformations in relation to sustainability and local context.

The questionnaire was administered between March and May 2025, with distribution coordinated by local authorities. It was disseminated through food-related territorial networks, including urban gardening groups, participants in locally organised food challenges, and parents of school-aged children. It was also shared via social media platforms operated by territorial stakeholders and published in local newspapers. A total of 2,411 fully completed responses were collected. To reduce potential self-selection bias, 60 additional respondents were interviewed in public spaces across the study area. Despite these efforts, the final sample exhibited notable demographic imbalances: women represented 77.8% of respondents (compared to 52% in the general population), individuals aged 35–49 accounted for 38.1% (vs. 22%), and 44.3% held at least a master's degree (vs. 13%). These biases are consistent with prior research showing that women and more educated individuals are more likely to respond to food-related surveys and adopt sustainable food behaviours (Culliford and Bradbury, 2021; Konttinen et al., 2021; Marty et al., 2022). To enhance the representativeness of the descriptive results, raking calibration was applied to adjust sample weights. This statistical method aligns the marginal distributions of gender, age, and education level with those of the local census population, iteratively adjusting the weights to reduce sampling bias (Deville and Särndal, 1992; Deville et al., 1993). Behavioural changes were further analysed by comparing sub-populations across distinct territorial contexts. Comparisons were conducted between participants and non-participants in public sustainable food initiatives (e.g., parents benefitting from sustainable school catering, participants in food- or agriculture-related events, recipients of subsidised sustainable food aid, and regular users of municipal markets), between the western (more intervention-rich) and eastern (less intervention-intensive) parts of the department, and between urban and rural populations, as foodscape accessibility has been shown to influence dietary behaviours (Hawkes et al., 2017; Tharrey et al., 2024). Only changes (positive or negative) in behaviour were included in the analysis; behaviours reported as unchanged were excluded. Due to the non-normal distribution of EFBI scores and the use of independent group comparisons, the Mann–Whitney U test was employed for statistical inference. The statistical analyses were conducted on unweighted data, as the distributions of gender, age, and education level were similar across all sub-populations studied. While these comparisons offer insight into behavioural trends across territories, they do not establish causality. As the data are self-reported and observational, the observed associations should be interpreted with caution and considered indicative rather than conclusive.

3. Results

Systemic Food Planning Assessment

Based on a review of both scientific and grey literature, a list of potential interventions available to local decision-makers was compiled. These interventions target the physical, economic, socio-cultural, and cognitive dimensions of foodscapes. Potential actions on the physical environment include support for local sustainable agriculture, the development of short supply chains, the establishment or improvement of local food markets, organic or environmentally sustainable retail outlets, restaurants, and public canteens, as well as enhanced ac-

cessibility to these infrastructures. Economic interventions encompass measures such as ensuring affordable access to sustainable food products, creating urban gardens to increase the availability of fresh fruits and vegetables, subsidising food aid and community associations, and reducing the cost of higher-quality food in public canteens. Interventions addressing the socio-cultural environment include regulating food advertising, promoting sustainable food offerings, implementing training programs in local institutions, and fostering positive narratives around local, organic, plant-based, and seasonal food consumption. Cognitive interventions, closely linked to the socio-cultural dimension, primarily consist of awareness-raising initiatives and educational campaigns, both within schools and across the broader public sphere.

Within the study area, interventions were identified across six of the seven sub-regions. The sub-region of Pays des Paillons, located in the eastern part of the department, did not exhibit any identifiable policies capable of influencing its foodscape and was therefore excluded from the analysis. Also in the eastern part, the sub-region of Riviera Française, although not engaged in a Territorial Food Project (PAT), introduced some sustainable agriculture-based policies over the past five years, which were included in the assessment. In addition to the analysis of the six sub-regional PATs, three municipalities in the western part of the department that had formally initiated PATs were also examined. In all six sub-regions and the three PAT municipalities, at least one of the potential interventions identified in the literature was implemented over the past five years (Table 1). The most frequently observed actions involved public awareness initiatives related to agriculture and efforts to develop local agricultural production. These were followed by actions aimed at strengthening short supply chains, with the dual goal of reducing both transportation distances and food prices, as well as diverse forms of intervention in school canteens. In the latter, initiatives included educational campaigns targeting pupils, training programs for school catering staff, and sustainability-oriented procurement practices, such as increasing the share of organic and local products and reducing the consumption of ultra-processed and animal-based foods. Urban gardening initiatives were identified in approximately half of the territories studied. These actions involved the allocation of public space and the provision of materials or financial support to local gardening associations. By contrast, interventions in retail environments, such as the regulation of fast-food outlets or food marketing practices, the improvement of food-related infrastructure, and the promotion of affordable food retail options were rare or entirely absent.

Overall, among the various interventions implemented within the PATs and the studied territories, the physical dimension of foodscapes appears to focus more heavily on agricultural production than on consumption spaces, such as food retail outlets. This pattern may reflect both the limited availability of local agricultural supply and the political priority given by local authorities to expanding such supply. Observed economic interventions tend to be indirect, primarily involving the promotion of short supply chains and support for urban gardening. While these efforts contribute to enhancing food system sustainability, they only partially address affordability concerns regarding access to healthy foods. In contrast, the socio-cultural and cognitive dimensions are the most actively developed, with a clear emphasis on information-based strategies designed to raise awareness and reshape food norms. From a geographical perspective, the western part of the department, where most PATs have been implemented, appears to be the most active. These areas displayed a greater diversity of interventions, reflecting a more comprehensive engagement with food system transformation. As nearly all sub-regions include both urban areas in the south and rural zones in the north, no clear distinction could be made between policies implemented in urban versus rural settings.

Table 1. Local government interventions across foodscape dimensions in Alpes-Maritimes. Yellow fields indicate implemented interventions; dimensions are grouped by territorial and geographical level.

Territorial level	Geographical situation	Authority	Physical environment						Economic environment				
			Support local sustainable agriculture	Create or improve local food markets	Promote organic or sustainable retail outlets	Provide sustainable meals in public canteens	Regulate fast-food outlet density	Improve access to food infrastructures	Support affordable and sustainable retail outlets	Establish urban gardens	Subsidise sustainable food for disadvantaged groups	Develop short supply chains	Implement equitable prices of sustainable meals in canteens

Environmental Behaviour Shift and Territorial Differences

The political efforts observed in the department to promote more sustainable food systems appear to have been accompanied by modest behavioural changes among the population. These dynamics are illustrated in Figure 2. According to the weighted sample, 56.7% of respondents reported at least one positive change in their food-related practices, 36.8% reported no change, and fewer than 10% indicated a negative shift across the ten assessed behaviours. The weighted global score, corresponding to the mean number of positive behavioural changes, was 2.02. Most individuals adopted between one and six environmentally beneficial behaviours, although a small number declared improvements across all ten. Negative changes were relatively rare, and no respondent reported more than eight regressions (Figure 2a).

Among the most frequently reported positive changes was a reduction in the consumption of ultra-processed foods, declared by 39.4% of the weighted sample, followed by a decrease in the intake of animal-based products (31.3%). A substantial proportion of respondents (ranging from 19.7% to 30.1%) also reported a shift toward organic, local, and seasonal products, a reduction in the use of food packaging, and the adoption of composting practices. In contrast, changes in mobility practices related to food shopping remained limited: a large majority of respondents (91%) continued to rely primarily on motorised vehicles. Similarly, transitions toward alternative food retail outlets (such as organic stores or fresh markets) were infrequent, with 79.9% of respondents reporting no change in these behaviours. The most common negative shifts involved a reduction in the consumption of seasonal and organic products, observed in 6.4% and 6% of respondents, respectively (Figure 2b)

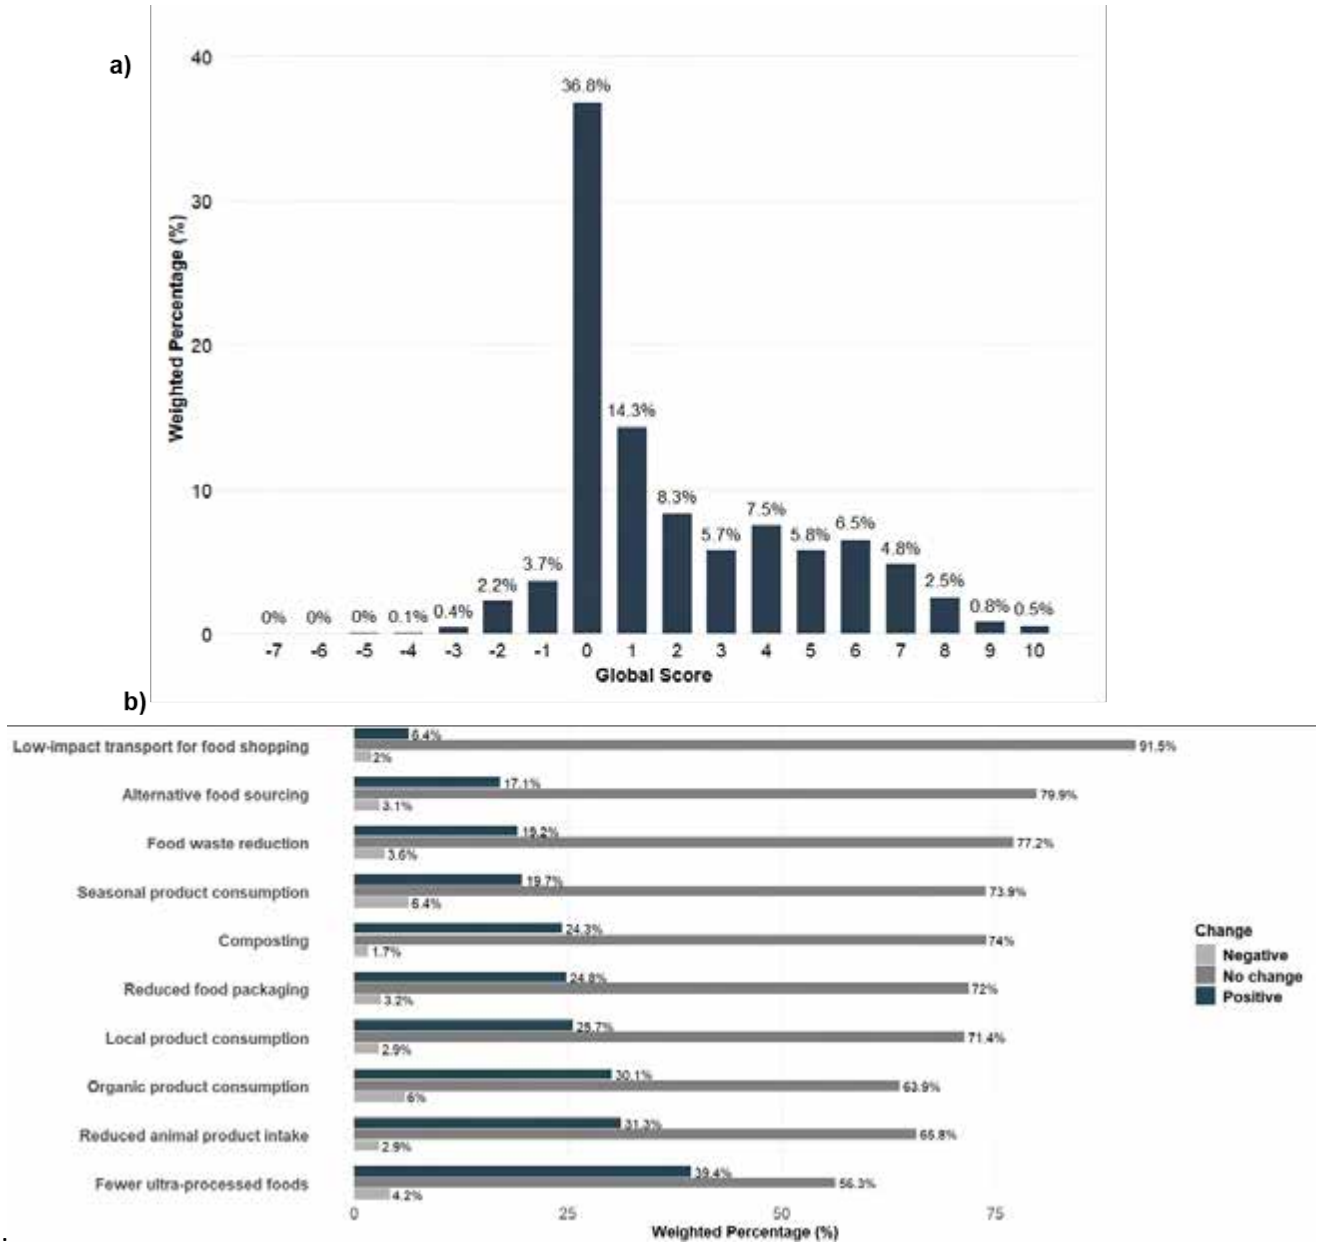

Figure 2. Environmental Food Behaviour Index: (a) Weighted distribution of global scores, with 0 representing no change, and positive or negative values indicating the total number of environmentally beneficial (positive) or detrimental (negative) behavioural changes reported. (b) Weighted percentage of respondents reporting negative, no, or positive changes for each of the ten assessed environmental behaviours.

Statistically significant variations were identified across different sub-populations within the department. As illustrated in Figure 3, the degree of behavioural change differed according to individuals' exposure to local food-related policies and their location within the territory. Three comparative sub-group analyses were conducted:

(a) respondents benefiting directly or indirectly from local interventions (e.g., parents of schoolchildren),
(b) residents of the western sub-regions, characterised by a more dynamic policy environment, versus those in the less advanced eastern sub-regions, and
(c) urban versus rural populations.

The first comparison revealed substantial differences in the evolution of food-related behaviours between individuals benefiting from local food policies and those who were not. Statistically significant differences were observed in seven out of ten behavioural categories, as well as in the global score summarising the total number of positive changes. Although shifts towards low-impact transport for food shopping and increased consumption of organic and seasonal products did not show statistically significant differences, average scores for these behaviours remained consistently higher among policy-exposed respondents. This trend also reflects a lower prevalence of negative or unchanged behaviours, and a higher proportion of positive changes within this group (Figure 3a). In contrast, the west–east comparison revealed minimal differences. Residents of the western sub-regions, where food policies are generally more advanced, exhibited slightly higher average scores across all behaviours, including the global index score. However, these differences were not statistically significant overall. Only two behaviours showed significant variation: greater adoption of low-impact transport in the east, and more widespread composting in the west. Overall, the magnitude of difference between eastern and western regions was notably smaller than that observed in the policy exposure comparison (Figure 3b). Conversely, the comparison between rural and urban populations revealed clear differences in behavioural change patterns. Statistically significant disparities were observed in several areas, including the use of low-impact transport for food shopping, reduced consumption of animal products and ultra-processed foods, increased consumption of organic and seasonal products, and composting practices. For most behaviours and the global index score, urban respondents reported higher levels of positive change, although not all differences reached statistical significance. Among the significant changes, urban residents generally scored better, except for composting, where rural residents reported more substantial improvements (Figure 3c).

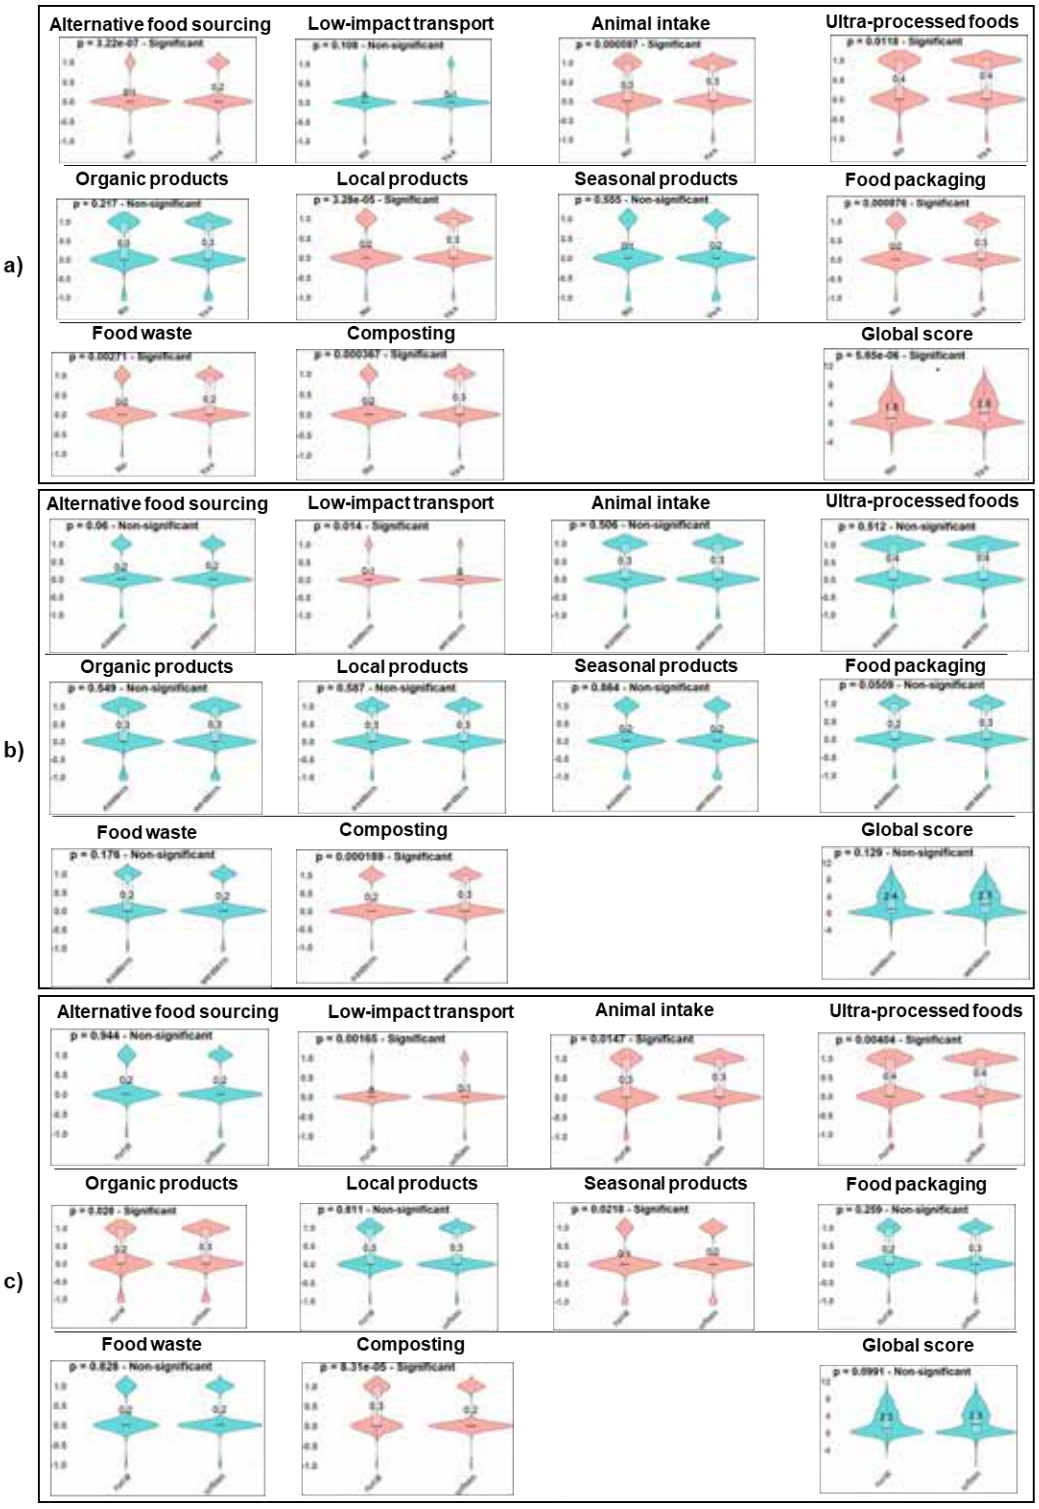

Figure 3. Differences in behavioural change scores across three comparisons: (a) Participants exposed vs. not exposed to local food policy interventions, (b) Residents of western vs. eastern sub-regions, and (c) Urban vs. rural inhabitants. Violin plots show the distribution of individual scores (–1 = negative change, 0 = no change, +1 = positive change) for each behaviour. Plot width reflects response density; mean scores are marked. The global score (ranging from –8 to +10) represents the average number of behavioural changes per respondent within each group. Statistically significant differences ($p < 0.05$) are shown in pink, non-significant ones in blue.

4. Discussion and Conclusion

As revealed in the initial qualitative analysis of local public policies, recent strategies increasingly aim to foster a culture of sustainable eating through awareness campaigns, educational initiatives, school canteen programs, and the development of local food networks. This shift underscores the growing recognition that sustainable food planning cannot rely solely on supply-side measures but must also engage with consumption practices and the social norms that underpin them. Some territories, particularly at the municipal level, appear to be specifically targeted by initiatives designed to construct a positive narrative around sustainable food. This observation is consistent with findings from previous reviews of national public policy interventions (Capacci et al., 2012; Temme et al., 2020; Macura et al., 2022; Ran et al., 2024), which show that informational approaches and educational programs, especially in schools, are the most widespread. Our results are therefore not surprising, given that local initiatives are often embedded within broader national frameworks (Barbour et al., 2021). However, while existing studies on foodscapes predominantly focus on spatial features and the development or transformation of food outlets, the informational and symbolic levers deployed in the studied territories remain relatively underexplored. These interventions tend to rely on non-intrusive, "soft" policy instruments such as informational campaigns, which, although well-intentioned, may not be considered sufficient to trigger substantial behavioural change (Capacci et al., 2012; Mattioni, 2021). By contrast, more tangible, physical foodscape interventions identified in the study area occur at the level of agricultural production, through support for local farming or urban agriculture initiatives. Such changes to the built environment can serve as sources of knowledge and awareness, potentially encouraging healthier and more sustainable food choices (Liu et al., 2016). Nevertheless, like information-based interventions, their broader impact on environmentally relevant consumer behaviours remains largely unexplored and warrants further investigation.

Although the emergence of local sustainable food policies is increasingly well documented, the behavioural transformations associated with them are more difficult to measure. The results of the second step of our analysis demonstrate encouraging signs of behavioural shifts toward greater sustainability in the study area. The most commonly observed changes concern the reduction of ultra-processed and animal-based food consumption, two behaviours with high potential for improving both health and environmental outcomes (Kesse-Guyot et al., 2021). To a lesser extent, significant increases in the consumption of organic, seasonal, and less-packaged products may also contribute to biodiversity preservation, greenhouse gas emission reductions, and natural resource conservation. Despite this, it remains difficult to directly attribute these changes to the expansion of local food planning initiatives. The findings illustrate that behavioural differences are most pronounced among respondents who report having benefited from local policy interventions, primarily parents of schoolchildren, highlighting a potential correlation between policy exposure and behavioural change. It may be hypothesised that recent efforts by local authorities to promote sustainable food publicly are contributing to the emergence of a collective imaginary around environmentally responsible consumption, which, in turn, is helping to shift norms and practices (Robinson et al., 2014). Yet, no substantial differences were found between the western, more policy-active part of the department and the eastern sub-regions, suggesting that positive changes in the overall population may be concentrated within specific social groups. Only two behaviours, low-impact transport and composting, showed significant differences between the west and the east. This can be attributed to the fact that the western sub-sample includes a higher proportion of rural residents, who exhibited lower positive change in transport habits but greater improvements in composting. These patterns are consistent with the rural–urban comparison. Both differences can be explained by spatial inequalities: first, limited access to food retailers in rural areas may reduce the feasibility of low-emission transport modes; second, the greater uptake of composting may reflect increased access to gardens in these areas. Beyond these, our analysis also revealed that an increase in consumption of organic and seasonal foods and reductions in animal and ultra-processed foods, were less frequent in rural areas. These findings corroborate previous research highlighting more pronounced shifts in urban food environments (Hawkes et al., 2017; Tharrey et al., 2024), further underscoring spatial disparities in access to sustainable food transitions. Overall, territorial disparities appear to be non-negligible, suggesting that, beyond known cultural or motivational differences (Guiné et al., 2021), regional and political contexts may also play a significant role in shaping dietary change.

Nonetheless, some behavioural patterns remained consistent across all population segments, regardless of territorial or socio-demographic characteristics. This may reflect broader societal shifts in favour of less processed, more plant-based, and fresher diets, as has been observed in national surveys for parts of the French population (Kesse-Guyot et al., 2021). The absence of clear differences between the policy-rich western sub-regions and the eastern ones also aligns with findings suggesting that informational interventions are only significantly effective when combined with changes in the physical and economic environment, and when implemented in a coordinated, multi-level, and multi-setting approach (Temme et al., 2020; Macura et al., 2022). This level of integration is not yet present in most parts of the studied territory. Consequently, echoing calls from other scholars and practitioners, we argue that to achieve more substantial and widespread progress toward sustainability, local decision-makers must move beyond "soft" informational tools that place the burden of change primarily on individuals. Instead, they should consider implementing more "structural" or "hard" policies that reshape the food environment itself or ideally, a combination of both (Hiller-Brown et al., 2017; Mozaffarian et al., 2018; Mattioni, 2021). These may include regulatory measures (e.g., limits on fast-food outlets and their advertising), economic incentives (e.g., subsidies for sustainable retail infrastructure and improved access to sustainable products for disadvantaged populations), or spatial interventions (e.g., integrating food access considerations into zoning plans). Such actions could complement existing measures and awareness campaigns and make sustainable choices more accessible and default.

It is important to note, however, that our results are based on self-reported data, which may be subject to social desirability bias and intention–action gaps that must be considered when interpreting the findings (Blanke et al., 2022). Although we observed higher positive scores among participants exposed to local food policies, causality cannot be assumed. Individuals already interested in sustainable diets may be more likely to be aware of or benefit from such policies, introducing a potential selection bias. Moreover, food behaviours are shaped by a complex interplay of factors, including socio-demographic variables, personal histories, identities, values, cultural norms, and health events (Furst et al., 1996; Dubuisson-Quellier and Gojard, 2016), and cannot be attributed to policy levers alone. Access to sustainable food is also not evenly distributed, and current interventions may benefit some groups more than others. This is particularly evident in the urban–rural disparities identified in this study. Food planning should therefore be viewed as a means of enabling equal access for all, rather than as a set of prescriptive behavioural instructions. This preliminary assessment thus calls for further research to deepen the analysis of food category-specific changes, explore comparisons across population subgroups, examine underlying motivations, and estimate potential environmental impacts (e.g., GHG emissions). Future research could also compare findings with national or European datasets, such as the NutriNet-Santé cohort (Toujgani et al., 2024). A longitudinal or quasi-experimental design would likewise be valuable in assessing causal relationships and the long-term influence and diffusion of local food policies.

To conclude, this study highlights the central role that local food planning can play in advancing sustainable food systems and contributing to broader climate goals. Our findings show that foodscapes are not static; they are co-produced through public interventions, individual behaviours, and spatial inequalities. Local food planning can serve as a lever to reshape these landscapes over time. While planners and municipalities increasingly recognise the importance of integrating food systems into both urban and rural planning agendas, substantial gaps remain in understanding how to effectively influence food behaviours. Addressing these gaps is essential for achieving long-term environmental, health, and social objectives. Although the concept of the foodscape is still evolving in the literature and the hypotheses emerging from this study require further testing, this research offers novel insights into the complex interrelations between food, place, and people. By examining how regional food policies intersect with environmental goals and behavioural change, it contributes to the growing body of scholarship calling for systemic, place-based approaches to food planning. These findings can help align regional food strategies with broader frameworks such as the EU Green Deal and the Paris Agreement and offer actionable pathways for cities and regions committed to advancing food sustainability in the context of climate change.

Reconfiguring Food Systems in Egypt's Nile Delta An Agroecological Approach to Delta Urbanism

Sophia Arbara
Affiliation: TU Delft
Email: s.arbara@tudelft.nl

Abstract
This paper examines the spatial dynamics of wheat production in Egypt's Nile River Delta, a region vital to national food security yet increasingly threatened by urban expansion and ecological degradation. In response to rising import dependency, the Egyptian government has launched large-scale infrastructural initiatives such as the New Delta project and the world's largest wastewater treatment facility. Using a Delta Urbanism and agroecological planning framework, this study employs layered spatial mapping to analyse land use, irrigation infrastructure, transport networks, and settlement patterns. Findings highlight the limitations of techno-centric desert reclamation strategies and the vulnerabilities of smallholder-based systems. The study advocates for spatially integrated and ecologically adaptive planning approaches, the reintegration of agriculture into urban peripheries and the reconfiguration of food, water, and land systems in deltaic territories.

Keywords: Nile River Delta, food systems, agroecology, Delta Urbanism

Introduction

Wheat is a fundamental crop intricately embedded in the social, political, and spatial fabric of Egypt, particularly within the Nile River Delta. This region, among the most fertile agricultural areas globally, is surrounded by arid landscapes where ancient Egyptians first developed settled agriculture and practiced large-scale farming (Al-Riffai, 2015).

Wheat remains Egypt's most significant crop, with approximately 1.4 million hectares cultivated annually. It is crucial for both household food security and national stability, followed by maize, clover, vegetables, and rice (Molle, 2018). Despite its historical significance and deep cultural roots in the Delta, Egypt has been the world's largest wheat importer since 2007–2008 (Al-Riffai, 2015). The country produces only half of the 20 million tons it consumes, with the remainder imported through a highly resource-intensive supply chain (Asseng et al., 2018). Efforts to expand wheat cultivation in "new lands" have yielded modest increases in production (just 1.9% annually over 2000–2020), insufficient to reduce import dependency below 50% (Gebeltová et al., 2023).

Figure 1: Wheat farmer in the Nile River Delta
source: Baltimore, 2023

Food security and water scarcity remain among Egypt's most pressing challenges. These are exacerbated by saltwater intrusion, uncertain Nile flows, and potential flash floods linked to the Grand Ethiopian Renaissance Dam (Hamada, 2017). Resource scarcity prompts debates on crop reallocation, favoring lower water-demand crops with higher economic value. Simultaneously, recent food crises triggered by the Covid-19 pandemic and the Russia–Ukraine war have reignited discussions on the need for national self-sufficiency in strategic crops like wheat and maize. Egypt's water requirements for wheat under climate change are projected to rise only marginally (2–3% by 2040), yet this increase will not match the escalating demands of a growing population (Hamada, 2017).

In response, Egypt has embarked on ambitious infrastructural strategies, such as reclaiming desert lands and developing the New Delta adjacent to the existing one. While these mega-projects may seem appropriate responses to food insecurity, they have raised scientific concerns about their long-term socio-environmental consequences (Sarant, 2017). This study aims to critically analyze current conditions in the Nile Delta through the lens of wheat cropland distribution, urban expansion, infrastructural development, irrigation, and logistics. It seeks to illuminate pathways for a systemic redesign of the region's agricultural infrastructure as a viable alternative to large-scale reclamation in arid zones. The analysis considers the intertwined dimensions of water, food, mobility, and spatial planning while addressing the ecological, political, and policy contexts influencing wheat cultivation.

Wheat holds strategic and historical importance and, in Fernand Braudel's terms, may be considered Egypt's "crop of civilization" (Braudel, 1979). Egypt follows a tri-seasonal cropping system: winter, summer, and Nili (late summer). Wheat is cultivated as a winter crop, sown between October and December, and harvested by May (Amer, 2017). If wheat was at the center of Egypt's ancient civilization, the deltaic landscape was its spatial foundation. Understanding the interdependencies among water infrastructure, urbanization, cropland allocation, and food transport is central to designing agroecological and spatially adaptive food system reforms.

The Nile Delta is not only Egypt's most fertile region but also its most densely populated. It houses over half of the country's population (Haars et al., 2016), with more than one-fourth living in areas at risk of inundation from a 2-meter sea-level rise. These zones include critical food-producing territories. Even a 0.5-meter sea-level rise would result in the loss of 13% of agricultural land in the Delta. Sea-level rise, increased droughts, and uneven water resource allocation among agriculture, industry, and urban areas pose severe threats to food production in this critical landscape and make it crucial to investigate these territories.

Future transformations and the new Delta project
Recent long term-transformation plans and governmental ambitions to grow strategic crops and particularly wheat include cultivating the arid lands, reclaiming the desert and expanding towards the Sinai Peninsula, west of the Nile Delta (Hegazy & Mohamed, 2023). The project was announced in 2021 by the Egyptian President Abdel Fattah al-Sisi, declaring the expansion of the Nile Delta in a project that involves the reclamation of an area of 9.300 km^2 for agricultural production, cultivation, sorting, packaging and manufacturing. The project aims to re-direct water for irrigation from one of the two branches of the Nile, the Rosetta branch. For this purpose, 50 km long pipes are being constructed along the Mediterranean coast and redirected towards the desert.

"The New Delta is one of the giant projects that will increase the cultivated area in Egypt by more than 1 million feddans.... The new cultivated lands will be planted with strategic crops such as wheat, corn, and vegetables."
El Sayed El Quseir, Minister of Agriculture and Land Reclamation, Egypt

(New Delta, 2025)

Additionally, water will be redirected from upstream to complete the 114 km long waterway that will shape Egypt's largest river (Egypt Independent, 2023). The infrastructural works include 22 kilometers of pipes below ground that transport groundwater, agricultural and drainage water and the river's open part of 92 kilometers.

Wastewater will be treated in what will be the largest treatment plant globally, the Al-Hammam water treatment plant with a capacity of 86.8 m³ per second. In terms of transport infrastructure, the project is located along the Rod El Farag-El Dabaa axis road, a main entrance to Cairo and distributor of food supply (Khatib & Alami, 2024).

Figure 3: The New Delta infrastructure
Source: Khatib & Alami (2024)

This project, called the New Delta, upon completion, will be nearly half of the size of the existing Delta (see Figure 2). There have been doubts that the 1.5 Million Feddan Project of reclaiming the desert will address food crises in Egypt and improve wheat production. Mega Construction Projects (MCPs) represent a strategic option towards achieving sustainable development objectives in developing countries (Othman, 2013).

The narrative of taking over desert land and expanding agriculture and cities in arid lands, has accompanied Egyptian modern history development, although it is questionable how much of the reclaimed land is cultivated. Reclaimed and cultivated land will demand a long period of time to reach a profitable agricultural production with certain impacts on sustainability (Sims, 2014).

Reclaimed desert lands include just a small amount of wheat cultivation of around 11% where large scale and highly mechanized agricultural techniques are being used. Most of the wheat production in Egypt continues to occur in smallholder farms and within the deltaic are of the Nile (Barnes, 2022).

The project comes as a response to the food shortage, increased import prices and reduced available land that the Nile Delta is facing in Egypt. However, it is questionable whether the New Delta Project and other past and future reclamation projects in the desert will address food crises in Egypt and improve wheat production. Experts argue that cultivating the desert is not a sustainable solution but rather an option that comes with high logistical and environmental costs (Luo et al., 2020). Only a small proportion of this newly reclaimed projects in Egypt's desert are located in a place to be irrigated by the Nile River - the remaining area will use water from the Nubian Sandstone Aquifer System, one of the world's largest fossil aquifers lying beneath the Western Desert and parts of Sudan Chad and Libya (Sarant, 2017). Expanding cropland territories towards arid regions comes also with strategies of creating new urban centers in arid regions (water demands will increase). Governments indisputable rationale for food security are used for the implementation and expansion of irrigation projects. The expansion of production on arid lands is rarely contradicted with its ambitions for a high-value, export-oriented agriculture.

Methodological and Conceptual Framework

This paper adopts an agroecological perspective to investigate the spatial, environmental, and infrastructural interrelations shaping the Nile Delta. The methodological foundation is anchored in the framework outlined by Arbara and Hooimeijer (Arbara & Hooimeijer, 2025) which integrates the principles of Delta Urbanism with spatial design and systems analysis. Delta Urbanism offers a transdisciplinary approach that bridges research-by-design with spatial diagnostics to examine productive landscapes within deltaic environments.

The methodology incorporates several interrelated components:

Layered Mapping: Drawing on Meyer and Nijhuis (2010, 2014), this approach visualizes spatial overlaps between wheat cultivation areas, water infrastructure, urban expansion, and climate-related risks. It allows for a nuanced spatial interpretation of current conditions and future trajectories.

Historical trajectories: This traces the long-term development of infrastructural interventions and their environmental implications, from early engineered landscapes to contemporary megaprojects (Braudel, 1996; Hooimeijer et al., 2021). Understanding these historical trajectories is crucial to situating current transformations within a broader socio-ecological continuum.

Agroecological approaches and socio-political landscapes of wheat: By adopting agroecological approaches in urbanism (Molina et al., 2020; Tornaghi & Dehaene, 2021), the study examines socio-political drivers and proposes strategies for integrating food production into multifunctional landscapes. It identifies synergies and trade-offs across variables such as water usage, crop selection, and land suitability, offering pathways for food system transitions rooted in territorial resilience. It also explores the socio-political relevance and importance of wheat for food security touching upon policies of food in the Egyptian context.

By combining these analytical tools, the framework enables a reconceptualization of the Nile Delta not merely as a territory in crisis, but as a dynamic landscape with embedded potential for agroecological transformation. It supports the design of adaptive, spatially integrated strategies that reconcile productivity, equity, and ecological sustainability.

Historical Trajectories of Agricultural and Infrastructural Expansion in the Nile Delta

Human intervention in Egypt's agricultural landscapes has a deep-rooted history, particularly in efforts to extend cultivation into "new lands." Contrary to common perception, the expansion of agricultural areas and establishment of new towns did not begin in the post-1952 era. As Sims outlines, this trend dates back to at least the early 19th century (Sims, 2014). Under the rule of Muhammad Ali, a wave of infrastructure projects and institutional reforms initiated Egypt's modern agricultural transformation, supported by economic and governance frameworks designed to increase cultivable land. By 1820, two million feddans were being cultivated along the Nile, reliant on seasonal flooding. At the time, the population remained below three million. By 1952, cultivated land had increased to over six million feddans, facilitated by the introduction of perennial irrigation, and the population had grown to 19 million (Sims, 2014).

However, the first major engineered interventions in the Nile Delta date even earlier to approximately 1780, when the Ottoman state undertook a series of projects aimed at expanding cultivation into barren or degraded areas. These early efforts mark the onset of large-scale infrastructural manipulation of the delta's hydrology. A pivotal development followed in 1830 with the construction of the Mohamed Ali seawall, designed to safeguard fertile lowland agricultural areas from seawater intrusion (Haars et al., 2016; Warner et al., 2010).

Over the following centuries, infrastructure projects of increasing scale continued to reshape both the physical and socio-spatial fabric of the Nile Basin. The Aswan High Dam, completed in the 20th century, and the Grand Ethiopian Renaissance Dam, nearing completion, exemplify the geopolitical and ecological stakes of river engineering in the region. While Grand Ethiopian Renaissance Dam's primary function is hydroelectric generation, it is expected to impact sediment transport and water availability downstream, contributing to heightened tensions among Ethiopia, Sudan, and Egypt.

Moreover, the modern Nile system is characterized by a vast, human-made waterway network that has severely disrupted natural sediment flows. These modifications have rendered the river virtually sediment-free by the time it reaches the Delta, with significant implications for agriculture, fisheries, and coastal stability (Syvitski & Kettner, 2011).

Taken together, these historical and ongoing infrastructural interventions illustrate a broader transformation of the Nile Basin. Wetlands and coastal dunes have been systematically converted into farmland and urban zones, underscoring the entanglement of environmental engineering, agricultural policy, and transboundary water politics in one of the world's most hydrologically and geopolitically complex regions.

Spatial layers approach

To unravel the contemporary agrarian crisis in Egypt, a spatial layer's approach that considers overlapping geographies of crop cultivation, infrastructure, ecological dynamics and urbanization processes is key to unveil the complexity of interrelated challenges. The map (Figure 4) visualizes four key spatial layers that structure the dynamics of wheat production and land reclamation in Egypt today. Urbanization processes, cropland configuration, deltaic dynamics and transportation systems are the main layers considered and analyzed below.

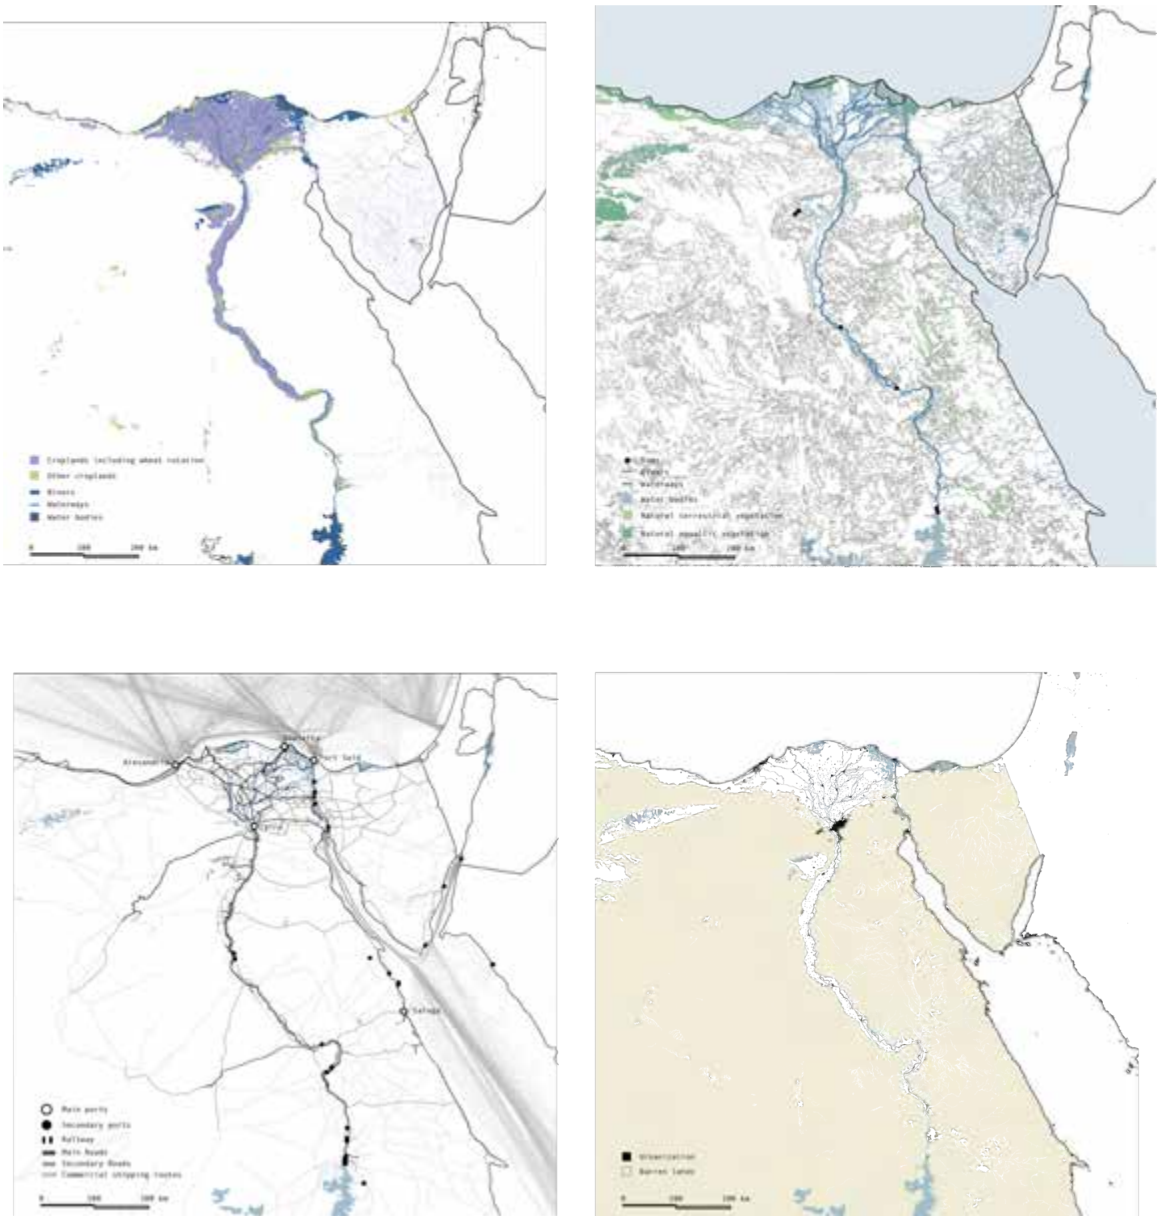

Figure 4: Spatial layers of cropland configuration, deltaic dynamics, transportation and urbanization patterns in the Nile River Delta
source: Arbara & Hooimeijer, 2025

Urbanization
"Due to sea-level rise, out of a total area of 25,000 km^2, between 1,800 and 4,500 km^2 of crop land may be lost by the year 2100. At the same time, urban expansion will claim between 12,500 to 25,000 km2 of the delta." (Rashid, 2023)

The Nile River Delta comprises both the world's longest river as part of one of the oldest deltas with highly fertile and productive agricultural soils while shaping one of the most extensive urban networks and being home to almost half of Egypt's population. In the River Delta, extensive urbanization appears to be over five times more of a challenge to cultivable land than climate change. Looking back, only in the past 50 years population growth along with urban expansion led to a decrease of agricultural land per capita by two-thirds (Sarant, 2017). The massive population increase occurred through formal and informal urbanization. Formal, located mostly in building new communities in the desert and informal, with taking over adjacent land on agricultural areas. The fact that this land was already equipped with water and electricity infrastructure in relation to the high land prices made informal expansion popular amongst poor communities (Salem et al., 2020). Also, the recovery of resettlement land projects to relocate agricultural lands in the past have not been successful, as only half of designated resettlement land has been utilized.

Urban growth occurs in the Nile River Delta either by filling the gaps between urban and rural areas and villages or by following existing road infrastructure. In some cases, even canals of the irrigation infrastructure are being covered by rapid urban expansion (Alfiky et al., 2012).

Cropland configuration: wheat cultivation areas
Agricultural land in the Nile River Delta is a patchwork of small fields, connected by 40.000 kilometers of irrigation canals. Most farmlands range from 0.5 to 2 hectares and farmers may own small parcels of land scattered across different field with the average being around one hectare (Sarant, 2017). Wheat is mostly produced by smallholders in small-scale irrigated farms the "old lands" (Al-Riffai, 2015, Abdalla et al., 2023). In 2015, wheat was grown on 4.3 million small farms (FAO, 2015, Barnes, 2022). Wheat is the crop which takes over the largest surface cultivated during the winter period (around 60%), planted in the months of October to December and harvested from April to May (Nasr, 1955).

Wheat occupies more than half of the cultivated winter area (Negm, 2019). According to an extensive survey taking place in 1998, most wheat farmers where practicing wheat farming as their main activity along with other occupations including work in the public and service sector (Kherallah et al., 1999). Also, part of their yield was dedicated to proper consumption while the remaining one was sold to the government. Agricultural activities in the Nile River Delta follow still low-tech methods, with sowing and harvesting in many farms that lie between the Aswan High Dam and Cairo occurring by hand and in small scale farms (Barnes, 2022).

Over the past years average farm size has decreased significantly; this land parcellation of farms makes design and planning of the water management systems challenging and is a result of rapid population increase and the inheritance system. Farm size has decreased from 6.3 feddan (a feddan is 1.03 acres) in 1950 to 3.2 feddan in 1960 and to 2.1 in 2000 (Negm, 2019).

Also, the small size of the agricultural plots comes with poor economic benefits and increased challenges of management for farmers; consequently, they seek to convert the lands into urban (Salem et al., 2020).

Deltaic dynamics and water infrastructure
In no other country, perhaps, is the identification between water, irrigation, and agriculture as strong as in Egypt (Molle, 2018). As stated in almost every research paper on the Nile River Delta, it is the Nile that, being the source of 96 percent of Egypt's water, allows for life in Egypt to happen (Barnes, 2014). As rainfall is not enough at no part of the Delta to support agriculture, intensive agricultural production is only possible by irrigation (Finch, 1918). Irrigation in the Nile River Delta involves a complex case, both for its size and structural organization (Molle et al., 2019). Its size extends over 20.000 kilometers of a dense network of canals that provide water to croplands of nearly two million farmers (Rap & Dutta, 2013). All types of irrigation technology can be found, from gravity and sprinklers to drip and pivot, using water pressurized by individual pumps or collective pumping stations (Molle, 2018).

The conventional structure of the distribution involves five levels. First, the main feeders (rayah), main canals (primary), branch canals (secondary), mesqa (tertiary) and marwa (quaternary field ditches) (Molle et al., 2019). The structure is not always straightforward, as branch canals may fork out and have subbranches and others might be relatively small, serving 500 feddans. The names are connected to the legal status of the canals: branch canals are public property, whereas mesqas are located on private land, thus owned and maintained by farmers.

Water is traditionally distributed between branch canals based on a rotatory system (5 days on and 5 off in summer, 5 days on and 10 days off in winter). Efficiency, equity, and timing are key issues in water management in understanding how water is distributed upstream (the ministry) and downstream (individuals or groups of farmers) (Molle et al., 2019).

Amongst the main problems of the current irrigation system is the uneven distribution and allocation of water resources between those at the head and end of the canals. Those at the heads of the canal complain not having enough water to grow the crops they would want, those at the end have no water at all and have to cope with an increased uncertainty of water availability (Barnes, 2014).

The management costs and water scarcity led to irrigation reforms in the form of infrastructural improvement

and water management like the Irrigation Improvement Project (IIP) launched in 1987 and expanded to the Integrated Irrigation and Management Project (IIMP) (Molle et al., 2019; Rap & Dutta, 2013). However, the system can still be considered as lacking in using efficient the available resources; research showed that crops only use 47 % of the irrigated water, the rest is lost through the extensive drainage systems. (Haars et al., 2016) "Irrigation improvement projects" aimed at providing a better, more continuous flow and deal with uncertainty of water availability by stabilizing the supply into (secondary) branch canals from where collective pump stations would then deliver water at the tertiary level (mesqa).

For the water demands, also a better monitoring of the crop allocation could turn out to be a useful method to utilize the resources as different crops would require each different amount of water. Crop water needs differ with wheat water needs ranging from 450mm to 650 mm during a growing season. The range for cotton would be 700-1300 mm and 1500-2500 for sugarcane (Amer, 2017).

After rice and sugarcane, maize, wheat and berseem are the highest water consumers per crop in the Nile delta (Amer, 2017). When perennial irrigation was introduced, crop alteration between two crops per year became possible and is the most common strategy while there are three growing seasons: winter from November to May (shitwi), summer from April/May till October (sefi) and the Nili period which goes from July/August to October.

Wheat, similar to maize, is cultivated mostly under surface irrigation with a low application efficiency (ea) of around 60% (Ouda et al., 2014). Changing the irrigation to sprinkler for wheat could increase this application efficiency from currently 60 to 80% under sprinkler irrigation (Ouda et al., 2014). To be able to expand cropland areas, a transition from traditional irrigation systems to modern ones is put in place. Irrigation to drip and sprinkler irrigation has initiated as a pilot project. However, since less water comes through the drainage water (agricultural runoff) it contains higher concentration of salt. Questions on water use efficiency rise: currently there might be a lot of water lost in the actual plot from the irrigation method, but the overall system is quite efficient as higher part runoffs are then being reused in lower parts. With the drip irrigation system there might be less water lost but the loss then may be a lot higher in salt concentration.

"The seasonal rhythm of the delta climate is such that more than one crop can be taken per year provided that adequate water is available; perennial irrigation as a result of the storage of flood waters for gradual dispersal in irrigation rotations made possible the practice of multi-cropping"(Nasr, 1955). Also, more than three-quarters of the land of wheat farmers is irrigated by a pump from a canal (Kherallah et al., 1999). Other strategies of modernizing the irrigation system have been the installation of subsurface drainage in some areas and not in others which has contributed into creating lines of inequality. Farmers not having access to subsurface drainage consider not having access to drainage if only supported by drainage ditches. Having or not access to subsurface drainage is not related to having enough water, but to being able to remove excess water from the system (Barnes, 2014).

"The quantity of water that reaches the Delta depends on how much has been released from the High Aswan Dam (HAD) and how much has been consumed for human and agricultural purposes along the Nile Valley. This second term varies with cropping patterns but is relatively stable since all return flows end up back in the river" (Kebede et al., 2014).

Transportation of wheat and storage

Until the 1950s, Nile and its canals served as a transport route for goods with around 25% of them being transported via the River. The transportation has shifted significantly since then, with the Nile transportation today accounting for 1%, despite the two main inland waterways (Damietta and Rosetta), offering all year-round navigation (Redeker & Kantoush, 2014). Trucks, railway cars, and barges play a vital role in moving wheat (Barnes, 2022). The waterways are used, however, for touristic purposes (with the touristic cruises) and to some extend for the transportation of commodities even though no large-scale transportation with barges is happening. Permission from the government has been stated as part of the reasons (FAO, 2015). Also, no sea transportation from the Nile

abroad is taking place; while there are no wheat exports, large amounts of wheat are imported arriving through sea routes in one of the ports of Damietta, Port Said or Alexandria.

Wheat produced in the Nile River Delta is first transported in sacks to large open areas with dirt floor, known as shonas. These are then gradually transported and stored in silos before being milled into flour (Barnes, 2022). Researchers have pointed out lacunas in the grain storage and transportation infrastructure of Nile River Delta. It is estimated, that due to long distance transportation in unrefrigerated flatbed trucks carrying overflowing crates, more than one third of carried goods does not arrive in healthy conditions at the final destination as trucks often cover distances of more than 900 km. Also, shonas, unlike silos, that offer a better control of atmospheric conditions, storage in shonas often comes with risks of exposure in humidity, increased temperatures and contamination by dirt and stones (Barnes, 2014).

Figure 8: Harvested wheat seeds transport
source: Baltimore sun, 2023

Agroecological approaches and future pathways

Wheat is mainly consumed in Egypt in the form of bread called aish baladi, a staple for its population, as Egyptians obtain approximately one-third of their caloric intake mainly in the form of bread or other wheat-based food. Until the 1970s, Egypt produced most of its wheat having a self-sufficiency ratio of around 70 percent (Chapin Metz, 1990). This declined significantly in the coming years so that by the mid-1980s, only a fifth of the wheat was produced in Egyptian territories (Barnes, 2022). Following the agricultural liberalization in the 1990s and the 1987 reforms on converting a state dominated agricultural sector into a more market oriented economy, domestic wheat production returned into meeting about half of the country's needs (Kherallah et al., 2000). Despite this, population increase is putting pressure in wheat gaps which are facing an increasing trend in Egypt with the government announcing that incentives for farmers would be given in order to increase the country's wheat production (Abdalla et al., 2022). However, so far, while a massive economic budget of the Egyptian state was allocated to subsidize the wheat supply chain, from producers, milling, bakeries and end consumers, smallholder farmers have remained largely neglected in this process.

Wheat is key not only to ensure food security but also political stability in the country; food riots, as a result of a cut on subsidies that were called also "bread riots" were the reason for social unrest in 1977. In the Egyptian revolution of 2011, "Bread, freedom and social justice" was part of the main messages with bread being one of the core demands of the population (Abdalla et al., 2022).

Rising inflation has brought up new policies on providing discounted bread to the majority of the population (more than 70 million) through a food subsidy program starting on January 2023 with prepaid food cards (Henda-

wi, 2023). With Russia and Ukraine being amongst the biggest import suppliers of wheat for the country (85% of wheat imports in 2021 came from there), the Russian Ukraine war has added to the wheat crisis and vulnerability of the food system in Egypt (Abdalla et al., 2022).

Wheat is historically and politically a crucial commodity in Egypt; with future predictions indicating that wheat demand will increase twofold by 2050, wheat becomes a crucial crop to examine within the context of the Nile River Delta. The ministry of Agriculture is responsible for managing the production of this crop which is considered a strategic crop for the country (Barnes, 2022). All cultivated wheat in the Nile River Delta either remains at the farmers household consumed mainly in the form of bread, or returns into being government – subsidized bread, sold across the country's bakeries. Egypt does not export any wheat.

Figure 9: Queuing for subsidized food (Baladi Bread)
source: Sarant, 2017

The challenges facing wheat production and consumption in the Nile Delta necessitate a shift away from techno-centric approaches toward agroecological and spatially integrated planning. Deltaic regions demand tailored strategies that reconcile hydrological processes, land-use pressures, and socio-political objectives. The paper summarizes four main strategies: (1) reintegrating agriculture into urban peripheries to mitigate land loss from sprawl, (2) restoring sediment flows through reassessment of upstream dam operations and the implementation of nature-based solutions, and (3) designing multifunctional infrastructures that simultaneously serve ecological and food security functions (4) re-evaluating the structure of Egypt's food systems, food accessibility and export-import dynamics.

Addressing wheat supply requires a combined approach expanding cultivated areas, enhancing productivity, and minimising food loss, implementing food policies (Yigezu et al., 2021). When considered through the lens of delta ecosystems and long-term sustainability, this approach challenges short-term, human-centred planning paradigms. Large-scale projects like the New Delta may be avoidable if existing food systems, land use, and distribution infrastructures are redesigned. A systemic, cross-sectoral transformation across spatial scales is essential for sustainable food security in the region (see Figure 10).

Figure 10: Spatial impacts and changing dynamics of wheat landscapes across scales in the Nile River Delta
source: Arbara & Hooimeijer, 2025 adopted from Kuzniecow Bacchin (2015)

A first step towards this direction would be to better integrate current hydrological cycle and water dynamics within the built environment. In Egypt, the Nile is considered often as the only valley. Yet, there are a series of wadis which often remain disregarded (Malek & Redeker, 2020). In place of single, large desert reclamation projects, the potential to integrate wadis as cultivated landscapes and propose an alternative design model for desert cities exists (Malek & Redeker, 2020). At the same time, spatial planning and design strategies for the rapid formal and informal urbanization that control unregulated urban expansion shall be set. The National Urban Policy for Egypt to transition towards compact cities with adequate density, services and resource efficiency (Alternative Policy Solutions | Developing a National Urban Policy for Egypt: Towards Compact Cities, Egypt Vision 2030 and the National Strategic Development Plan 2052) are steps towards limiting the unregulated expansion of urbanization. Also, considering the expansion on arid lands, which currently focuses a lot on creating land for cultivation, uses that require less intensive water use could become the prior strategy if developing these areas, keeping the agricultural land in the fertile soils of the delta (Sarant, 2017). Linking back to the initial theoretical framework, research showing that already cultivated land is to a larger extend more fertile and thus should not be reallocated raises again the question of whether ambitions of reclaiming desert land are and to what extend a valid solution
.
Irrigation and drainage infrastructure is another complex, linked to spatial, political and socioeconomic dynamics aspect of food systems. Changes in the irrigation system involve three levels; first, operational (upgrading the infrastructure/technologies in place), second operating on solving inequalities (who has access, how much and when to resources) and third, ensuring that existing water infrastructure will not be impacted by expanding urbanization. On the first, modernizing the Marwa hydraulic system from open canals to pipelines or lined canals is one step which affects also water rights and access to resources. In fact, pilot studies showed an increase in income and cropped feddan and equal access to water resources for all farmers (Modernizing Irrigation Improved Water Security for Farmers in Egypt, 2020). The installation of electric pumps instead of diesel ones and a systematic rotation of irrigation showed that end tailers receive better water flow (85% from 50% before) (Barnes, 2014). Also, modernizing the equipment (pipeline irrigation compared to earth Marwa canals) makes it easier for female farmers to operate and participate in the process. Lastly, ensuring that irrigation canals will be properly maintained and protected by increasing urbanization is another key strategy.

Changing crop sequence from cultivation of one and two crops per year to three crops per year winter, fall then summer crop or winter, early summer then late summer crop can help in solving food gaps problems in Egypt

(Amer, 2017). Climate change impacts will still be present in agricultural production and differ between crops, crop cultivars as well as cropping systems (Nkwasa et al., 2023). Yet, cultivar adaptations into triple-cropping systems instead of single-cropping ones will mitigate crop yield reduction (Nkwasa et al., 2023).

Farm configuration and ownership models play a significant role in how wheat croplands are linked to the social, economic and spatial dynamics of the delta. Over the past years, smallholders have been negatively impacted by long term policies and governmental decisions, leading them to a decreased wheat production (Abdalla et al., 2023). Changes in policies such as the declared by the Ministry of Supply and Internal Trade price, regulations on production costs (pesticides, fertilizers, seeds) which are currently at unaffordable rates for smallholders as well as access to knowledge and information are steps taken to enhance productivity and willingness to grow wheat at a smallholder level (Abdalla et al., 2023). Also, the fact that farmlands are small and fragmented means that selling them for urban is easier and at the same time, that production costs and machinery are more challenging for farmers of a small plot of land. With increasing land fragmentation and decreasing farm size in the old lands, a better monitoring of land conversion from agricultural to urban would be necessary and at the same time, changes in the nature of cultivating wheat productive territories to support ecosystem services should be implemented. Changing wheat cultivation methods from cultivation in basins or on narrow rows to raised beds is another strategy to cope with saving on water resources. Additionally, raised beds cultivation has shown to be more efficient not only in water but also nitrogen and soil quality (Amer, 2017).

At another level, structural changes to synergize wheat cultivation with existing transport and storage infrastructure in the Delta is perhaps amongst the most important steps towards a more sustainable food system. Road infrastructure improvements along with including the water transportation and advances in the current, poorly maintained shona storage system could significantly lessen the gap of food losses in the deltaic area.
Lastly, for structural changes to happen in the wheat production and the food system overall, all of the aforementioned steps will have to be synergized with the deltaic dynamics of the Nile River Delta. Sediment deficit and shortage of freshwater supply along with rising sea levels and salinity are putting great stress on resources, questioning for how long engineering efforts will prevent the disappearing of the Nile River Delta.(Redeker & Kantoush, 2014) Strategies on urbanizing arid lands, outsourcing of agricultural activities, changes in cultivation are amongst future scenarios but as much as the interlinked threads of food scarcity, water scarcity and energy scarcity have to be addressed at the local and territorial dynamics these have to be addressed at a planetary scale.

Conclusion

The transformation of Egypt's wheat landscapes is both a reflection of centuries-old practices and a test of contemporary governance, planning, and sustainability strategies. While mega-infrastructure projects like the New Delta symbolise ambition, they often overlook the nuanced and systemic challenges embedded in food, water, and land management. Rather than defaulting to techno-centric fixes, this study argues for agroecologically grounded planning which recognizes the Nile Delta's spatial, ecological, and cultural fabric. Future strategies must integrate multifunctional land uses, promote urban–agricultural synergy, and ensure that policy and investment support smallholder farmers who form the backbone of Egypt's wheat production. Improving irrigation efficiency, restoring sediment cycles, enhancing local storage and transport infrastructure, and addressing land tenure issues must collectively underpin any meaningful reform. Ultimately, designing resilient delta food systems will require moving beyond short-term self-sufficiency goals to long-term ecological and social sustainability in Egypt's most critical agricultural heartland.

The transformation of Egypt's wheat landscapes is not merely a technical endeavor but a deeply socio-political and ecological challenge. Large-scale infrastructural projects like the New Delta present ambitious visions but fall short in addressing systemic vulnerabilities of water and land use. Adopting agroecological approaches within the framework of Delta Urbanism provides a pathway for designing resilient, adaptive food systems in deltaic regions.

Abstract
Cooperatives are increasingly seen as alternatives to profit-driven food systems, offering economic and social inclusion for disadvantaged groups, particularly women. This study examines women's perceptions and experiences within food production cooperatives in Türkiye, focusing on the Antalya Köy Pazarı Women's Cooperative. Drawing on participant observation and semi-structured interviews, the study explores motivations for participation, daily impacts, and cooperative operations. Findings indicate that economic independence is the primary motivator, but social benefits such as confidence-building, knowledge sharing, and community engagement are equally significant. Women's cooperatives emerge as key mechanisms for fostering empowerment, enhancing well-being, and strengthening women's roles in both family and society. The research highlights the transformative potential of cooperatives as inclusive and sustainable models in food systems.

Key words: Food Production Cooperatives; Gender Equality; Economic Empowerment

1.Introduction

Since the onset of industrialization, the traditional corporate model has dominated food production and distribution, often prioritizing profit over social and environmental concerns. However, in recent years, there has been a growing interest in alternative business models that emphasize community-oriented, environmentally friendly, and socially conscious approaches to food systems. While not a new concept, cooperatives have emerged as prominent alternatives to conventional structures in the food sector (UN, 2023).

By nature, cooperatives aim to support the interests of all members—producers, workers, or consumers. They offer opportunities to empower local communities, promote sustainable agricultural practices, and build a more inclusive and equitable food system. Unlike centralized corporate decision-making, cooperatives operate through democratic processes, positioning them within the scope of social entrepreneurship.

Feminism, as a movement advocating for gender equality and women's empowerment, plays a significant role in women's cooperatives. Emerging in the 19th century, feminism evolved through various phases. Liberal feminism was one of the earliest strands, highlighting women's secondary position in society and calling for equal participation. In contrast, Marxist feminism explains women's oppression through modes of production and patriarchal labor relations, where women's labor is appropriated by male figures (Black, 1984; Taş, 2016).

A core goal of feminism is women's economic independence, which requires equal access to education and skill development. Women's cooperatives serve as platforms where women gain control over their labor, access learning opportunities, and improve their skills. Beyond economic empowerment, these cooperatives enhance women's social participation, self-confidence, and access to networks and resources.

In Türkiye, women's cooperatives operate under the Cooperative Law No. 1163 (KEİG, 2018). However, due to traditional gender roles, they are often treated as a distinct category with a strong emphasis on local development and women's socio-economic inclusion. The Marmara Region hosts the highest number of women's cooperatives (Table1), followed by the Mediterranean, Black Sea, and Central Anatolia regions.

Table1. Geographic Distribution of Women's Cooperatives in Türkiye (Şahankaya Adar et al., 2023).

Geographical Area	Active	Passive
Marmara	182	3
Aegean	130	-
Central Anatolia	157	1
Mediterranean	154	-
Black Sea	155	-
Eastern Anatolia	89	-
Southeast Anatolia	73	-
Total	940	4

An important milestone in this field was the "Empowerment of Women through Cooperatives" project (2021–2024), jointly implemented by the Ministry of Agriculture and Forestry and the General Directorate on the Status of Women. Co-financed by the EU, this initiative led to the formation of the Women's Cooperative Network. Member cooperatives are active in areas such as production, services, marketing, and other sectors. Among them, production cooperatives are most common (Url-1).

This study aims to understand the relationships that women establish with food production cooperatives and the role these organizations play in their lives. The central research question is: "What are the perceptions and experiences of women members of food production cooperatives regarding their cooperatives?" Antalya, one of Turkey's major agricultural cities, was selected as the research site. Of the 22 women's cooperatives operating in Antalya, 15 are engaged in food production, with four located in Kepez, a socioeconomically disadvantaged district. While there is a growing body of literature on women's food production cooperatives, each cooperative and its members have unique experiences and relationships with their organization. This diversity underscores the importance of examining cooperatives within their specific socio-spatial contexts. Accordingly, this research adopts a qualitative, phenomenological design, and selects the Antalya Köy Pazarı Women's Cooperative as a case study. Data were collected through participant observation and semi-structured interviews with cooperative members, and analyzed using content analysis. The experiences of cooperative members are categorized into three main themes: motivation, impact on daily life, and cooperative operation.

2.Methodology

2.1 Research Context and Case Selection

This study adopts a phenomenological qualitative research design to explore the lived experiences of women engaged in a food production cooperative in Antalya, Türkiye. Phenomenology is particularly suitable for understanding how individuals perceive, interpret, and make sense of specific phenomena through their personal experiences (Tekindal & Uğuz Arsu, 2020). The selected case is the Antalya Köy Pazarı Women's Cooperative, established in 2019 in partnership with the Kepez Municipality. This cooperative produce and sells a variety of natural food products, including honey, tahini, molasses, vinegar, and gluten-free flours. The phenomenological approach enables an in-depth exploration of the subjective meanings that cooperative members assign to their roles and involvement in the organization.

2.2 Data Collection

Data were gathered through semi-structured interviews and participant observation. Two interview protocols were designed: one for founding members (management) and one for cooperative workers. The questions were grouped into thematic blocks covering general background, motivations, daily life impact, and roles within the cooperative (Table 2).

Table 2. Semi-Structured Interview Question Groups

Group Code	Question Groups	Focus of Questions
A2	Cooperative foundation, motivation and operation	Reason for founding Why a women's cooperative Challenges during establishment Current problems Decision-making processes How it changed your life Part of daily routine Being a woman Being a female entrepreneur Reactions from others Relationships among members Impact on women's lives Unforgettable memory Future goals Previous life How it changed How she feels Workload Reactions from others Daily routine Decision to join Motivation Why a women's cooperative How she defines it Social relationships with co-workers Responsibilities Cooperation and mutual support What it brought to you Current problems Unforgettable memory Future goals
A3	Impact on daily life	
A4	Role in the cooperative	
B2	Impact on daily life	
B3	Motivation and expectations	
B4	Role in the cooperative	

Three women with varying roles within the cooperative participated in the study: one manager, one producer, and one social media coordinator. Due to scheduling and accessibility constraints, two interviews were conducted by phone and one was conducted in person at the cooperative's production site. Interview durations ranged from 32 minutes to 79 minutes, with an average length of 59 minutes. All interviews were audio recorded with the participants' consent and later transcribed. Informal communication prior to interviews helped establish rapport. To support the interviews, participant observation was conducted at the cooperative's production site. This method allowed the researcher to gain contextual insights into daily operations, interpersonal dynamics, and the physical environment in which the cooperative operates. Field notes were taken during the visit, which enriched the interpretation of the interview data.

2.3 Sampling Strategy

A purposeful sampling strategy was employed to select participants who could provide rich and relevant insights into the cooperative experience. A chain sampling technique was applied, whereby initial contact with a key informant led to the recruitment of additional participants. The sample included individuals with diverse roles

and experiences within the cooperative to ensure a variety of perspectives.

2.4 Validity, Reliability, and Ethical Considerations

To ensure credibility, two qualitative techniques was applied through multiple data sources (interviews, observation). Interview questions were derived from both literature and field knowledge. Member-checking was informally conducted by maintaining open channels with participants for follow-up clarification. Audio recordings were transcribed, and coding consistency was ensured through iterative reading.

Ethical approval was not required for this study. However, verbal consent was obtained from both the cooperative and individual participants. Participants were informed about the study's aims, and interviews were conducted in spaces and times they found comfortable. Audio recordings were made with permission; otherwise, notes were taken during the conversation.

2.5 Data Analysis

Thematic analysis was employed using both inductive and deductive approaches. Transcripts and field notes were coded and categorized using MAXQDA 2024. Codes were grouped into three main themes: Motivations, Impacts on Daily Life (Figure 2), and Cooperative Operation (Figure 3).

•Motivations included both social (e.g., solidarity, socialization, environmental values) and economic drivers (e.g., financial independence, employment) (Figure 1).

Figure 1. Motivation Theme Hierarchical Code Model

•Impacts on Daily Life covered perceived benefits (e.g., personal development, social relationships), responses from family/community, and peer interactions at the workplace.

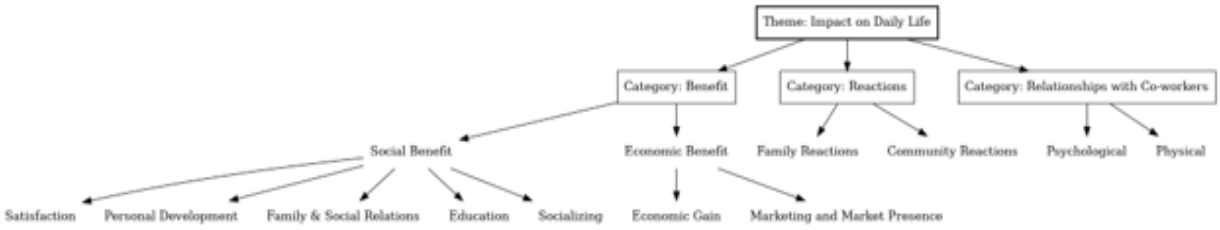

Figure 2. Impacts on Daily Life Theme Hierarchical Code Sub-Code Model

•Cooperative Operation explored internal organization, roles, challenges (e.g., market competition, lack of external support), and collaboration mechanisms.

Figure 3. Cooperative Operation Theme Hierarchical Code Model

These themes reflect the complexity of women's engagement in food production cooperatives, encompassing both personal transformations and institutional constraints.

3.Findings

A word cloud was generated based on the transcripts of the interviews. The visualization was created using MAXQDA, which analyzes all the words in the uploaded document. Accordingly, in the creation of the word cloud, the interviewer's statements were excluded, and only the participants' expressions were considered. Different grammatical forms of the same word were merged. As expected due to the nature of the study, the most prominent words in the cloud are "cooperative" and "woman." Additionally, words such as "production," "market," and "product" also stand out, aligning with the research topic. These are followed by possessive terms like "own," "mine," and "we." Furthermore, words such as "more," "big," "as much as," "included," "a lot," and "now," which imply a forward-looking perspective or comparisons between past and present, are also highlighted. This indicates that participants tend to interpret their relationship with the cooperative through a sense of ownership and temporal comparison (Figure 4).

Figure 4. Word Cloud

The findings of the study were coded under three main themes: Motivation, Impact on Daily Life, and Cooperative Operation, as described in the previous section. A code cloud was created based on the frequency of these codes (Figure 5). In this visualization, green tones represent codes under the Motivation theme, blue tones represent codes under the Impact on Daily Life theme, and red tones represent codes under the Cooperative Operation theme. The most frequently repeated color in the code cloud is blue, indicating that the Impact on Daily Life theme contains more codes and sub-codes compared to the other themes.

Figure 5. Code Cloud

3.1. Motivations

Under the theme of Motivation, the study primarily aims to answer the research sub-questions regarding participants' perceptions of the cooperative and their reasons for joining. The findings are grouped into two main categories: **economic motivation** and **social motivation.**

Although one might expect economic concerns to be the primary reason for joining the cooperative, "solidarity and mutual support" emerged as a crucial underlying factor for women's participation. Within the dimension of economic motivation, the sub-code economic independence was frequently emphasized. For the participants in this study—already engaged in production prior to joining—the concept of economic independence is interpreted as the ability to earn income through their own labor.

Many of the women had previously sold products at the Antalya Village Market but remained financially dependent on their spouses or families. Participation in the cooperative enabled them to achieve economic autonomy. According to Participant 1 (K1), women who previously sold their goods at prices far below market value through informal channels started to sell at market prices through the cooperative. Moreover, the cooperative's policy of purchasing unsold goods provided an additional economic incentive.

Another economic factor mentioned was education and employment. Although not a primary motivation for joining the cooperative, participants acknowledged receiving training as part of state- or municipality-supported initiatives. The fact that all participants were already producers before joining suggests that economic motivation stemmed more from a desire for independence from male-dominated financial structures than from an intent to enter employment from scratch.

The code with the highest number of references under the Motivation theme is solidarity and mutual support, which falls under social motivation. Participants frequently emphasized the significance of producing together and being united. The word cloud (Figure 4) also highlights the prominence of the collective identity expressed through the term "we." While economic concerns were motivating factors for Participants 1 and 2, Participant 3 joined the cooperative solely to support the other members.

Socialization also emerged as a motivational factor. The importance of socialization is partly due to participants already knowing each other through the market setting before the cooperative was formed. During the interviews, participants noted that they also interact outside the cooperative—visiting each other, meeting at the office, and developing close bonds. This suggests that socialization and solidarity are intertwined and mutually reinforcing motivations for participation. The women perceive the cooperative and the village market as an integrated space for social engagement.

3.2. Impact on Daily Life

The theme Impact on Daily Life aims to understand how women cooperative members experience the cooperative and how it is reflected in their daily lives. This theme comprises the categories of Benefit, Relationship with Co-workers, and Reactions. The category Benefit includes two subcategories: Social Benefit and Economic Benefit. The findings suggest that the women's food production cooperative primarily contributes to social benefits in members' lives.

Key codes under social benefits include satisfaction, personal development, and socialization, while education and family and social relations are mentioned less frequently. Participants 1 and 3 stated that being part of the cooperative provides them with a sense of satisfaction. For Participant 1, this satisfaction is related to professional achievements, while for Participant 3, it is rooted in social fulfillment. Participant 2 sees the cooperative, especially the office setting, as a space for socializing and meeting friends. Participants emphasized that the training received during the cooperative's founding phase significantly contributed to their personal development and boosted their self-confidence.

Regarding family and social relations, participants shared stories of other cooperative members. One participant referred to a member with a child with disabilities, stating that the cooperative not only provided economic benefits but also improved family dynamics and the member's self-esteem.

The most prominent code under Economic Benefit is marketing and market presence. Women's cooperatives have enabled producers—who previously sold only within limited, informal networks—to reach broader audiences and gain brand visibility. Participation in the cooperative has also integrated women into the formal economy. Thanks to the cooperative's structure, women no longer worry about selling their products; knowing their products will generate income through the cooperative enhances the significance of earning through one's own production.

Although the relationship between members and their colleagues is categorized under both psychological and physical aspects, the psychological connection cannot be separated from the social benefits. Cooperative members do not view their colleagues merely as coworkers, but as part of a community. This strong bond stems from prior acquaintances and the small size of the group. The challenges faced during the cooperative's founding also reinforced their sense of belonging.

Under the category Reactions, participants reflected on the support (or lack thereof) from their families and communities. Many mentioned that joining the cooperative was a joint family decision. They stated that family support was essential for maintaining membership. Notably, some women who were initially involved had to leave due to lack of support from their husbands. This highlights that family backing—especially spousal support—is crucial for women's continued participation. Participant 1 emphasized that women understood the expenditures required during the cooperative's early phase, but their husbands often lacked patience. Families that were initially skeptical became more supportive once women began generating income, thus increasing the women's influence within the household.

3.3. Cooperative Operation

Under the theme Cooperative Operation, two primary categories were identified: Support and Collaboration, and Challenges. According to the coding, these two categories are distributed relatively equally. This theme covers aspects of the cooperative's internal functioning that do not directly align with the first two themes (Motivation and Impact on Daily Life), thereby addressing more operational and structural dynamics.

Within the Support and Collaboration category, the most prominent code is projects and grants. This is followed by roles within the cooperative and organizational model and personal resources and informal networks. Participants emphasized that receiving government support during the establishment phase made being a woman an advantage rather than a disadvantage. This reflects the structural challenges women often face in society and within their families, positioning external support as a key enabler for women's collective entrepreneurship.

Under the Challenges category, lack of community support emerged as the most frequently mentioned issue. Participants often referred not only to their own experiences, but also to those of former members who left the cooperative during its early stages, highlighting a strong emotional attachment and the social impact of those departures.

Other recurring challenges—market competition, financial support, production space, and consumer profile—are intrinsic to the broader dynamics of cooperatives in general and women's cooperatives in particular. These include limited competitiveness against large brands, financial dependence on internal resources, low consumer awareness, and limited purchasing power in the local market.

Despite these practical barriers, lack of community support stands out as a particularly significant issue for women's cooperatives, indicating the socio-cultural resistance that women face when entering public and economic spaces as independent actors.

4. Conclusion

This study aims to explore the perceptions and experiences of women who are members of food production cooperatives. The findings indicate that women's cooperatives not only contribute to members' economic empowerment but also provide significant social benefits. Participants perceive the cooperative as a major part of their social lives and fulfill their social needs through it. In the case examined—comprising women who were already engaged in production before joining the cooperative—it was observed that those who received family support were more likely to remain in the cooperative, reporting strengthened relationships with their families and communities, along with increased self-confidence. Conversely, members who lacked family support tended to withdraw from the cooperative, highlighting the critical role of the family in shaping women's economic and social engagement.

Overall, the findings reveal that women's food production cooperatives have positive impacts on members' economic, social, and personal well-being. Moreover, for cooperative members, the cooperative and their colleagues hold meaning beyond economic income. Considering women's roles within the family and society, these cooperatives emerge as vital social enterprises that promote women's participation in the economy and strengthen their positions in both familial and societal contexts.

Understanding the role of diverse cities for sustainable food security: a socio-ecological governance framework

Abstract
Amid urgent socio-ecological challenges – including persistent food insecurity and planetary health crises – cities are confronted with the mounting challenge of guaranteeing access to healthy and sustainable food for all (HLPE, 2024). Thousands of urban food initiatives, policies, and strategies have emerged in the last decade to incorporate food related concerns into urban agendas Yet, despite growing calls for integrated and de-siloed approaches, existing conceptual frameworks and practical approaches do not adequately account for the diversity urbanisation processes and related socio-ecological dynamics. Focusing on urban infrastructures and form, networked resource flows, socio-ecological dynamics, and governance dynamics as interconnected 'layers', this paper proposes a socio-ecological approach to urban food system governance which takes the complexity and diversity of urban contexts into serious account.

Keywords: Urban food systems; urban food governance; socio-ecological dynamics; diverse cities

Introduction

Urban food system action is undergoing a critical phase. As currently discussed in scientific and policy circles, the necessity to bring the food system at the center stage of urban sustainability and equity agendas has never been so pressing (Hawkes, 2023). In fact, in an increasingly urbanized world, cities constitute important loci of food consumption, and also active drivers of food system transformations (HLPE, 2024). Urban areas, in particular, account for the highest proportion of global food insecurity, with about 1,7 billion over 2.2 billion of moderate to severe food insecure people living in urban and peri-urban environments (FAO. 2023a; HLPE 2024). As cities are fed by long food supply chains, problems of obesity and bad nutrition are further aggravated by the availability of highly processed food at low costs, often at the expenses of people in precarious socio-economic conditions. In diverse cities, urban food environments are permeated by heterogeneous food infrastructures, where public markets and regional food hubs coexist, compete, or hybridize with conventional food retail and supermarket stores (HLPE, 2024). At the urban margins, the rural-urban interface is continuously negotiated due to dynamics of urban expansion causing land encroachment and undermining prime agricultural areas (López-García et al., 2024). These and other factors hint at the relevance of urbanization processes in both, generating key food systems' problems, but also providing levers to address critical challenges related to sustainable and equitable food production and provisioning.

Recognising the linkages and tensions between urban dynamics and food systems, the urban food literature has underscored the need for policy integration and for adopting systemic approaches to address food systems and urban sustainability problems (Sonnino, 2023). In particular, some authors have set the stage by proposing analytical frameworks tailored to define food systems and describe the interaction among their components, activities, and drivers (Ericksen, 2008; Tefft et al., 2021). Other scholars have focused on how municipal governments attempt to implement a systemic approach, by integrating food system work in the organisational and institutional functioning of the city (Mendes, 2008). More recently, frameworks such as the city-region's food systems have provided further perspectives for an integrated and systemic action (Blay-Palmer et al., 2018). Rather than considering the city as a confined entity, this framework observes how food systems' processes, activities, and flows, dynamically interact with specific urban and peri-urban realities, and rural hinterlands (Krähmer et al., 2024). Additionally, informed by a place-based and socio-ecological perspective, recent contributions in the

debate have argued for an inclusive 'framework for food system transformation that integrates ideas of sustainability co-benefits, spatial linkages, social inclusion and sectoral connectivities' (Sonnino and Milbourne, 2022 p. 915).

While the above contributions offer valuable analytical advancements and propose integrative action-oriented frameworks, very often real-world practices do not align with established principles, or with desirable end-states. In fact, experiments of policy integration are still at their infancy. Local authorities still face challenges to legitimize their action and to exercise a systemic approach, given the precarious status of food governance and policy-making in cities (Doernberg et a., 2019). Furthermore, innovative food governance spaces, such as urban food strategies or food policy councils, that have quickly spread around the globe, face hard times to navigate complex urban dynamics and to deal with the political economy and ecology of cities at different governing scales (Moragues-Faus, 2021). These problems are further aggravated by the current situation of crisis, economic downturn, and geopolitical instability. As a result of these processes, even pioneer cities engaged in urban food system action have been experiencing critical times, as the cases of Toronto in Canada, or Ghent in Europe testify (Manganelli, 2025). Taking this reality into account, we argue that a reflexive step is needed in urban food system action. This reflexive account should take stock of the progress made so far, but also re-evaluate how urban food governance and policy spaces can better deal with contemporary challenges posed by diverse urbanization dynamics. More specifically, we argue that many of the challenges faced by urban food governance and policy actors arise from a persistent neglect of the diverse processes of urbanization - both in the way urban food systems are conceptualized and in the design of city-led responses to food security. By proposing a socio-ecological approach to urban food system governance, this paper aims to take an initial step toward a more integrative analysis that better reflects the complexity and diversity of urban contexts.

To address these issues, the paper is structured as follows. Section 2, after the introduction will provide a socio-ecologically oriented definition of urban food systems' governance, stemming from an understanding of urban food systems as socio-ecological systems that necessarily hybridize with key urban dynamics (the political economy and ecology of the city). This approach allows to identify key layers, or markers, which stand at the intersection of food and urban systems, and can be regarded as strategic points of intervention for an urban food system action. In section 3 these layers will be further broken down into key monitoring indicators, as examples of elements that urban food actors can assess in order to calibrate adapted food security policies, able to tap into key urban dynamics. Some of these dynamics go beyond the food system itself and yet significantly affect food system processes and outcomes in cities. Based on the above insights, section 4 discusses how urban food security governance and policy-making can address key trends characterizing diverse urbanization processes, by prioritizing some of these layers and indicators, or addressing their intersection. Section 5 concludes on how research and action can move ahead towards a better (re)consideration of urban dynamics and trends in urban food system action.

2. Towards a socio-ecological approach to urban food systems' governance

Drawing from a variety of disciplines – including geography, sociology, economics, political science, environmental science, health and community studies, and urban planning, among others –, the food systems' literature has engaged with conceptualizing and analysing the complex interactions among actors, activities, processes, and outputs, that characterize the food system (for a synthesis see, for instance, Battersby and Watson, 2019; Moragues-Faus et al., 2023). At their core, food systems have been defined as including 'the range of activities in the production, processing, distribution, marketing, preparation, consumption and disposal of goods that originate from agriculture, forestry or fisheries, including the inputs needed and the outputs generated' (Tefft et al., 2021, p. 4). In characterizing how the food system works, studies have started to incorporate socio-ecological systems' approaches, which typically look at the ecological and at the social components as interconnected and co-evolving dimensions (Folke et al., 2003; Frank et al., 2017; Hebnick et al., 2021). In particular, focus has been on

delineating the interaction among components (or sub-systems), their activities, inputs and outputs, but also on situating food systems within a broader array of agents, institutions, environmental and social interactions (Ericksen 2008). As Teff et al. (2021) suggest, such interactions involve 'the people and institutions that initiate or inhibit change in the systems as well as the sociopolitical, economic and technological environments in which these activities take place. (...) Urban food systems, specifically, hone in on activities that occur in and/or impact urban and periurban areas' (Tefft et al., 2021, p. 4). As this definition by Teffts et al. (2021) indicates, most (urban) food systems' characterizations treat key socio-ecological dynamics – including socio-economic conditions, socio-cultural dynamics, and biophysical processes –, as external elements affecting or impacting on food systems. On its side, the urban dimension is mostly regarded in locational or spatial terms rather than properly integrated in a socio-ecological account of food system governance (Moragues-Faus and Battersby, 2021, HLPE, 2024). As a result of these tendencies, there is lack of clarity concerning how to properly connect key socio-ecological dynamics and related socio-material flows, to the specificity of urban food systems and their governance constellations.

Recognizing these gaps, the urban food debate has provided further perspectives to embed the characterization of urban food systems within a broader socio-ecological and place-specific approach. Some of these scholarly contributions also address governance or, as highlighted below, suggest useful directions for a socio-ecological governance perspective (Sonnino and Milbourne, 2022). Analyses of urban food flows, for instance, connect food system activities with the metabolism of cities, assessing the potential environmental or social impact of the urban circulation of food production, import-export, processing, distribution, consumption and disposal (Guibrunet et al., 2024). A further perspective is the City Region Food System (CRFS) approach, introduced about a decade ago by the FAO and the RUAF Foundation (REF) (Blay-Palmer et al., 2018; Forster et al., 2015). Specifically, CRFS' frameworks shed particular light on morphological and geographical aspects of the urban, by stressing the need to address specific urban and peri-urban patterns characterizing large or medium-size cities, looking at the interrelation of urban, peri-urban, and rural food system flows (Blay-Palmer et al., 2018). At the same time, the framework suggests going beyond a bounded conception of the city-region, looking at how flows of resources, material, human activities, and non-human elements, connect with wider institutional scales and spatial processes (Krähmer et al., 2024). Underlining the need for a 'more thorough and deeper engagement with the spatial complexity of food systems' (Sonnino and Milbourne, 2022, p.916; see also Vincent and Feola, 2020), further studies have mobilized the notion of place to 'conceptualize and tackle the interwoven socio-ecological issues that affect the food system' (ibid. 2022., p. 915). According to these and other perspectives, adopting a place-based approach would not only allow for a better comprehension of how broader social and ecological dynamics (e.g. socio-economic, cultural, biophysical processes), intersect with food system activities and their material and infrastructural dimensions, in specific urban realities (HLPE, 2024). It would also allow for a better contextual understanding of power dynamics and institutional processes driving urban food systems' governance (Sonnino and Milbourne, 2022). In fact, while socio-ecological system approaches tend to consider governance in normative and abstract terms, as an exogenous force steering food systems, other perspectives such as place-based governance and political ecology, show how governance, power, and institutional dynamics are deeply embedded in metabolic resource flows and in hybrid socio-ecological dynamics characterizing the urban sphere (Moragues Faus and Mardsen, 2017; Heynen et al., 2006).

In synthesis, what we learn from the above analysis is the need for a governance approach that: a) engages with the material, morphological, and infrastructural conditions of cities (space and place, urban infrastructures and form); b) considers the connection of food flows with wider material and immaterial flows (people, ideas, resources); and c) integrates the analysis of key socio-ecological dynamics with the functioning of urban and food systems.

2.1 Depicting key features of a socio-ecological governance approach

Over time, literature on urban food governance has proliferated and a myriad of studies have addressed governance processes or dynamics in a plurality of initiatives, empirical contexts, and types of processes (Doernberg et al., 2019; Haysom, 2015; Moragues-Faus et al., 2022). On a basic level, governance can be defined as 'all modes of governing encompassing activities carried out by different actors to guide, steer, control, or manage the pursuance of food system outcomes in a specific urban area' (Moragues-Faus and Battersby, 2021, p. 5). As food governance studies develop, however, we notice a double tendency, or risk. In particular, on the one hand, when governance is applied to the study of specific initiatives or sectors of the food chain – including urban food production (Ferreira et al., 2018), short food supply chains (Manganelli and Moulaert, 2018), public procurement (Sonnino, Torres and Schneider, 2014), or urban food policies (Moragues-Faus and Morgan, 2015), among others – the risk is to adopt a too narrow focus, which misses a comprehensive, socio-political and socio-ecological understanding of food system processes. On the other hand, food governance studies based on socio-ecological system approaches tend to regard governance in terms of mechanisms, or most appropriate modes of governance such as 'rules, institutions and practices that set limits and govern the behaviour of individuals, CSOs and private sector actors' (Tefft et al., 2020, p. 4). In this case, governance is treated in an abstract, system-focused, and normative way, with poor connection with socio-ecological, socio-political and power dynamics – including conflicts between urban development agendas and interests – related to specific urbanization processes.

In particular, while most of the urban food governance literature addresses governance from within food initiatives or food systems' activities, it is also necessary to draw from perspectives that start from the urban, considering the relation to food. Specifically, drawing from place-based and territorial approaches to governance allows to shed light on how governing actors and institutions relate to the materiality of the city (Latham and McCormack, 2004), and specifically, how they deal with urban infrastructure and its form (McFarlane and Rutherford, 2008; Monstadt et al., 2022; Rutherford, 2014; Tozer, 2019). 'Urban infrastructure and form' encompasses physical elements such as land, built-up and open spaces, parks and green areas, transport networks, but also public markets, food distribution networks, and other relevant food infrastructures (Marsden et al., 2018; Clark et al., 2021). In mediating the everyday life of citizens, urban infrastructures are equally conditioned by wider socio-ecological dynamics (i.e. dynamics related to population movements, urbanization processes, the provision of services, utilities, and economic activities), but also by the politics of urban planning and design institutions in charge of managing growth, deciding on infrastructural investments, channeling development through zoning designations and urban planning guidelines, or allowing for the opening of food markets in urban space (Cabannes and Marocchino, 2018). Therefore, place-based approaches that examine the spatial dynamics of urban infrastructure provision, as well as the politics and governance of the built and unbuilt urban environment – should be integrated as a layer into the analysis and monitoring of urban food system governance.

Urban infrastructures are not just physical entities in urban space. Rather, infrastructures' networks articulate and mediate the dynamic circulation of material and immaterial flows, such as people, ideas, technologies, and material resources (Monstadt, 2009). Governance lenses based on urban metabolism and urban political ecology provide useful insights to disentangle the hybrid socio-ecological flows of food and relevant resources, the connection between food and other flows, and their relation of material flows (resources) with immaterial dynamics (power geometries and governance dynamics) (Heynen et al., 2006; Swyngedouw and Kaika, 2014; Moragues-Faus and Carroll, 2018). At a broad level, urban political ecology allows us to grasp how the interplay of ecological, economic, political, cultural, and social processes – here collectively referred to as socio-ecological dynamics – shapes patterns of access to and distribution of resources within urban areas (Heynen et al., 2006). An illustrative example concerns the interaction between socio-ecological dynamics such as migration patterns and ethnocultural diversity, and global trade mechanisms that govern food imports and exports. These dynamics collectively influence both the types of food available and the characteristics of food environments in specific urban settings. Furthermore, urban political ecology and the politics of urban metabolism allow to grasp the uneven

pattern of distribution and access to key resources – including food –, and how governance institutions relate to the monitoring and provisioning of fair access to resources. Relatedly, while the tendency is to look at flows in a disconnected way, political ecology lenses allow to link food flows with other types of networked resource flows, by for instance observing the relation of public transport provision with food accessibility, or the linkages between energy poverty and food poverty (HLPE, 2024). These considerations allow to integrate a further layer in the socio-ecological governance framework, which can be summarized as 'networked resource flows', i.e. the governance of circulation, provision of, and access to material and immaterial flows such as food, water, waste, energy as well as capital, people, and knowledge.

It is clear how looking at urban infrastructures and form, and networked resource flows allows to shed light on the political economy and ecology of those actors and institutions that are often beyond food-related agendas, and yet have a considerable impact on food system dynamics and the governance of food in the city. What also emerges from the above analysis is how urban infrastructures and form, and networked resource flows, and related governance dynamics, interact with wider socio-ecological dynamics (i.e. biophysical processes related to climate, environment, land and biodiversity; socio-cultural and social dynamics related to population movements, social composition, cultural diversity; the structure of the economy; the access to basic utilities and services). The challenge is to make the depicted socio-ecological governance approach operational. To sketch some directions on this, Section 3 outlines a brief methodological perspective for translating these various 'layers' of the approach into measurable indicators for monitoring urban food systems. Section 4 then discusses how governing actors and institutions can practically apply these indicators in policy and planning processes.

3. Socio-ecological monitoring indicators for food system action

It can be argued that a social ecological characterization of urban food system governance can serve different purposes and can be applied to different contexts. In this paper, we show how the identification of the urban, food system, and governance 'layers` outlined in the above section can serve as a cornerstone for developing an urban food system monitoring framework; an ongoing challenge in urban food system governance processes (Zerbian et al., 2024). In this case, the four layers – socio-ecological dynamics, urban infrastructures and form, networked resource flows and (food) governance dynamics – were used as a guiding structure to identify relevant indicators to develop an assessment framework that operationalizes the evaluation of urban food systems from a socio-ecological and urban perspective. Its overarching aim is characterizing urban food systems whilst measuring the progress of different actions or strategies undertaken to improve the local food system and its governance.

The development of this framework followed a modified Delphi method (Fitch et al., 2001), which involves an initial literature review for potential indicator selection, followed by an iterative survey and consultative process to propose a final indicator set. The process of identifying and outlining these indicators was carried out between 2023 and 2024. It included three steps, outlined as follows.

The first step focused on identifying indicators relevant to a socio-ecological perspective through a structured review of both scientific and grey literature. This included peer-reviewed articles, documents and reports that propose, and/or review indicators sets for urban sustainability and urban food systems sustainability. As outlined above, the identified layers were used as guiding objects to analyse literature sources (38 in total) and extract a first set of potential indicators. After removing duplicates and analysing the suitability of indicators, a total of 266 potential indicators were identified as relevant to operationalise the identified 'layers', organised in relevant dimensions.

In a second step, the identified indicators were tested in the Spanish context, being this context familiar to most of the authors, in order to determine whether issues of data availability would arise in their application, leading

to a first reduction of the indicator set. This meant identifying potential data sources for each indicator using local, national and European databases. This process was conducted for five Spanish cities showing a considerable dynamism in urban food system action, i.e. Madrid, Valencia, Barcelona, Valladolid, Córdoba. Indicators were retained based on criteria such as ease and cost-effectiveness of measurement, availability of a clearly defined methodology, and the capacity to support consistent and comparable data analysis. Preference was given to standardised indicators, or in cases where this was not possible, indicators were normalised to ensure comparability. Indicators for which no reliable data could be obtained were excluded from the list. This process yielded a final set of 88 indicators used in the following step.

The third methodological step was the application of a slightly modified Delphi survey that consisted of sharing with a group of experts, henceforth referred to as panellists, the list of identified indicators for evaluation (Campbell et al., 2002). The aim of such a process is to form a consensus among selected panellists based on their expertise in the field . A total of 33 potential panellists were contacted, composing a heterogeneous panel in terms of professional sectors, including representatives of the public and civil society sector and expertise across food system areas. Twenty-two expert panellists accepted to participate, of which 50% were women and 50% men. Panellists were invited to rate the preliminary indicators throughout two rounds of reviews, based on online questionnaires, with a final face-to-face panel meeting in which the panellists were supposed to discuss and re-rate each indicator. This process led to a final list of 99 indicators, validated and approved by the panel. Table 1, at the end of Section 4, provides examples of core final indicators for each layer and the related dimensions.
While the methodological steps based on the revised Delphi process have been completed, further work is ongoing. This includes testing the indicators in a broader range of European cities, refining the selected indicators, and prioritizing key monitoring elements based on data availability, actionability, and the spatial scale required for observation. Despite the work-in-progress, the following section presents initial insights into the implications for food system action, particularly in relation to governance and policy-making.

4. Dynamizing urban food systems' governance: monitoring indicators as levers for action

Based on the socio-ecological layers delineated above, urban and food system indicators can help to generate knowledge and to indicate pathways for action in different ways, opening up different spaces for reshaping urban food governance. On a first level, each layer of indicators can be analysed independently, as a source of knowledge, and a basis for action on food and urban systems. For instance, the socio-ecological dynamics' indicators are 'more-than-food' indicators that help to understand key dynamics and trends characterizing the city, thus suggesting how food governance and policy-making can leverage them (see also table 1 for a synthetic overview). Within this sub-set, for instance, indicators related to the dimension "economy" are tailored to assess the economic and employment basis of a city; the key sub-sectors, industries, services, driving the urban economy; whether certain sectors or economic trends such as tourism, knowledge economy, financialization, are prevailing over others with potential repercussions on urban food environments, or on import-export relations (HLPE, 2024). Furthermore, the dimensions of "social justice", "demographics", or "health and diet" provide complimentary knowledge about issues such as the level of food insecurity, and data about related determinants of socio-economic inequalities, including gender, level of income, housing insecurity, demographic composition, socio-spatial segregation, and the prevalence of obesity and diabetes across the urban population. This sub-set of socio-ecological indicators are of great importance to both, tailor food security actions, but also bring food action well beyond food and the urban level (Moragues-Faus and Battersby, 2021; Haysom, 2022). In fact, showing the incidence of indicators deriving from those dimensions can allow to build arguments for connecting food with other urban programs and policies, including social welfare programs, public policies and expenditures around health, and so on.

Similarly, indicators related to the layer urban infrastructures and form help to assess the qualities of food and non-food infrastructures (land, green and biodiversity spaces, design and planning, etc.). Specifically, indicators

deriving from the sub-dimension 'design and planning' address issues such as the rate of land consumption over the years (and how this affects urban, peri-urban and regional environments), but also the different uses of land, including for instance what land in the city is scheduled for urban development over the available land. The knowledge generated can allow for establishing dialogue with planning authorities concerning pathways for urban densification, or modes of acting on the urban form to integrate food infrastructures such as community gardens, fruit trees, or urban orchards. It can also suggest pathways for building synergetic action between urban greening and climate adaptation (e.g. through urban greening, nature-based solutions and biodiversity enhancement) and urban agriculture strategies. Moreover, indicators related to the dimension of 'food infrastructure' – including the (lack of) availability and distribution of public markets, food coops, food hubs, food processing and distribution facilities –, shed light on the material basis for calibrating food policy action.

As anticipated in section 2.1, the layer networked resource flows provides further knowledge on the socio-metabolic dimension of food and urban systems. Data on energy consumption for instance can shed light on the carbon footprint of food production, transportation, consumption, and disposal activities, thus helping to identify high-impact areas for decarbonization (IPES-Food, 2023). Indicators on waste – especially those focusing on organic and food waste – can reveal inefficiencies at the consumption level. This can potentially help to link these data to circular policies or programs activated in the city. Data about water flows, such as the amount of water used by (urban) agriculture or other food chain activities, can inform circular and climate adaptation policies, especially in a drought-prone city. Finally, the layer governance dynamics invites to focus on the different actors and agencies shaping urban food governance dynamics, highlighting gaps or missing links concerning existing food governance structures, financing sources, and important issues related to institutionalization and the integration of food in other policies (see table 1).

Yet, as the above analysis suggests, besides working in a standalone manner, the four types of socio-ecological layers, their dimensions, and the related indicators, are more productively analysed in their interrelations. Indeed, functioning like a matrix, key sources of knowledge and levers of action lie at the intersection of various layers and indicators, especially considering their implications for food governance and policy-making, and thus posing particular attention to the connection with governance dynamics (see table 1). Specifically, connecting the layer urban infrastructures and form to the layer governance dynamics raises questions concerning what actors at different levels are driving changes in key urban infrastructures and form and how this is impacting food system outcomes in a specific city. Concretely, indicators such as the distribution of public food markets in the city, the presence of active school food programs per number of inhabitants, or the distribution of producers-consumers networks, could be revelatory of values, actors, modes of community engagement that lie behind the presence and distribution those infrastructures. This source of knowledge allows to calibrate the type of intervention needed in terms of, for instance, public support for food markets or retail stores providing fresh food, sensitization actions, or incentives in terms of distributional patterns. Analogously, actors promoting urban agriculture and greening strategies could consider the availability and quality of the land-infrastructure and the presence of urban planning directions concerning urban expansion or land preservation, in order to propose integrated strategies for the scaling out of food production and greening in the city. Potential synergies between the areas of food and greening could be found especially in a city where greening or climate adaptation strategies are particularly high on the agenda, as recent studies on greening strategies in European cities show (Mahmoud et al., 2025).

Connecting the layer networked resource flows with governance dynamics opens up questions concerning what actors, values, and institutions, at various scales and in different sectors, influence the circulation of capital, human, discursive, and material flows in a specific city, and the implication of this for food governance and policy-making (see table 1). Analysing these aspects means understanding more thoroughly the connections between, for instance, the flow of people in a city (tourists, visitors, temporary workers, minorities, ethnic groups)

and the diffusion of particular food flows and practices such as food away from home, or the creation of particular food environments shaping the city (HLPE, 2024). Furthermore, looking at critical material resources and infrastructures in the city allows to establish connections between apparently unconnected flows and sectors, and their implication for governance (see section 2.1). One illustrative example is the analysis of food system actors and activities that contribute to food waste generation in the city, along with strategies for engaging diverse stakeholders across sectors. In fact, addressing food waste prevention, recovery, and reuse offers a valuable opportunity to connect with multiple actors, infrastructures, and resource flows. For instance, discarded, unsold, or surplus food can be repurposed through community-based initiatives, such as community kitchens. These spaces not only support food redistribution and social assistance, but also foster community building, public awareness, temporary employment opportunities, and intercultural exchange (Gennari and Tornaghi, 2020). Furthermore, composted organic waste can be re-used in urban-peri-urban agriculture activities as soil fertilizer; or it can be recovered for energy generation through anaerobic digestion facilities, producing biogas that contribute to power the built environment.

Finally, highly relevant questions emerge from the connections between socio-ecological dynamics and governance dynamics. In fact, looking at socio-ecological dynamics raises questions concerning what actors and processes (operating in different sectors, spaces and scales) are shaping the socio-ecological dynamics of the city, from its economic basis, to demographics or social justice factors, and how these factors can be leveraged in food governance and policy-making (see table 1). In fact, elements such as food environments, food retail, as well as the price, accessibility, and availability of fresh food options can be highly affected by factors such as demographic composition, population movements, or touristification dynamics, among others (HLPE, 2024). At the same time, tourism can be also a driver of employment, specifically in the food and catering sectors, and a potential lever for sustainable practices involving food (see for instance Bottiglieri et al., 2016, on the example of Turin). Thus, there is space for public actions tailored to understand how touristic facilities (restaurants, canteens etc.) can engage in fair trade and sustainable food practices, including adapting food catering and service facilities to quality labelling standards (see the example of Brussels-Capital Region's GoodFood label). Further examples are interventions in the sphere of tourism and culture that can target the refurbishment and re-valorisation of local farms or food infrastructure facilities for eco-tourism practices. These considerations are particularly relevant for cities and regions that are heavily dependent on tourism, as is the case for many urban areas across Europe (Aguilera et al., 2021). Moreover, socio-ecological dynamics related to social justice factors (food insecurity, socio-economic inequalities) and health factors (prevalence of obesity and diabetes), can provide strong hooks for linking food with other structural programs and policies. Comparative urban analyses revealing a significant prevalence of obesity or diabetes in specific cities can offer robust evidence for positioning food as a strategic entry point in the design of social and public health prevention strategies. Such findings have the potential to mobilize higher levels of governance and institutional support around targeted interventions. Examples are health-related food environment policies at the national or EU level discouraging unhealthy food options and stimulating fresh food environments as a health prevention measure (Schneider et al. 2023).

Table 1. Synthetic overview of key layers, dimensions, and indicators, with resulting priorities and questions for urban food governance and policy-making.

Layer (and dimensions)	Examples of indicators connected to dimensions	Emerging priority areas for food governance and policy-making	Key overarching questions
Socio-ecological dynamics (social justice; demographics; economy; land, environment and biodiversity; health and diet)	*Social justice:* -Population rate at risk of poverty -Percentage of population that are food insecure or hungry -Beneficiaries of food assistance in cash or kind *Demographics:* -Immigration rate; -Demographic composition *Health and diet:* -Prevalence of obesity and overweight in children and adults; -Prevalence of Type 2 diabetes *Land, environment and biodiversity:* -Total GHG emissions per capita (including the food sector) -Areas dedicated to the preservation of agro-ecological diversity *Economy:* -Distribution of Employment by Sector in the Municipality -Employment in the agri-food chain -Relative contribution of tourism to the municipality´s economy (…)	- Understanding how demographic, health, and social justice dynamics intersect with food, and how food can serve as a pivotal element in shaping socio-economic measures and public health prevention policies; -Connecting food with environmental actions especially qualifying cities affected by environmental dynamics and/or engaged in greening / climate adaptation strategies; -Understanding how key economic sectors or dynamics of economic restructuring affect urban food environments, drive food demands and import-export relations, but also provide hooks for creating job opportunities in the food sector and incentivizing food sustainability actions	-What actors and processes (in different sectors, spaces and scales) are shaping the socio-ecological dynamics of the city, from its economic base to demographics or social justice factors and what are the possible implications and hooks for food action?

Urban infrastructure and form (transport network, design and planning, food infrastructure, green spaces and parks)	Transport network: -Access to public transport -Length of the bike network Design and planning: -Population density -Ratio of land consumption rate to population growth rate Food infrastructure: -Total agricultural area per 100,000 inhabitants -Number of community gardens and urban agriculture projects -Number of municipal and collective food processing and distribution infrastructures Green spaces and parks: -Green areas per capita -Proximity to green areas (…)	-Connecting urban agriculture and food interventions to wider urban planning, zoning, and design directions and strategies (including anticipating and influencing those strategies) - Understanding the key actors, values, and factors that affect the availability and expansion of food infrastructures as key to developing targeted types of interventions -Connecting food with the scaling out of greening interventions/ foreseen planning measures on green areas and open spaces	-How do different types of actors and values shape what urban infrastructure and form look like, and, particularly urban food infrastructures? -How can this open up opportunities for targeted interventions through food?
Networked resource flows (energy, waste, food, water)	*Energy:* -Energy consumption -Fuel poverty -GHG emissions in key sectors/ activities of the food chain *Waste:* -Urban solid waste generated; -Municipal waste recycling rate -Number of circular programs and initiatives on food loss and waste *Food*: -Local production and consumption of basic food -Ration of food exports-imports *Water:* -Per capita water consumption -Draught frequency (…)	- Understanding potential connections, synergies, or missing links between food and other metabolic flows -Shaping interventions that provide ground for win-win solutions among different sectors (e.g. food, waste and energy) -Linking food with wider circular economy strategies of the city	-What and how do different actors and processes (operating in different sectors, spaces and scales) influence the circulation of capital, human, discursive, and material flows within cities, including food? -How can this open up opportunities for targeted connecting food to other flows and sectors?

Governance dynamics (actors and networks; policies; participation, transparency, inclusion; finance)	*Actors and networks:* -Presence of an active multi-stakeholder food planning and policy structure - Presence of an active municipal inter-departmental body for food policy and programming *Policies:* -Presence of food as a key pillar of: city sustainability strategy; city planning strategy; municipal health and social welfare strategy; integrated urban strategy -Presence of healthy and sustainable food in the sustainable procurement policy *Participation:* -Representation of specific vulnerable groups in food governance bodies *Finance:* -Municipal budget dedicated to healthy and sustainable food -Commitment to sustainable public procurement (…)	- Understand the degree and modalities through which an integrated food governance and policy-making approach is institutionalized in cities -Envisioning pathways to integrate food in broader urban policies and sectors based on needs and strategic opportunities -Strengthen public engagement in food through key levers (e.g. public procurement; municipal support to markets and retail serving fresh food)	-What are the different actors and agencies shaping urban food governance dynamics within and beyond food?

5. Conclusions: re-considering the urban in urban food system action

When dealing with governance, the use of tools and notions such as 'indicators', or 'food system monitoring' or 'progress' may be perceived as uncomfortable or misleading. In fact, dealing with indicators may appear to divert attention away from deeply qualitative dimensions characterizing governance dynamics and policy actions – including actors' relations, conflictive values and ideologies, power dynamics, institutional processes –, towards the measurement of quantitative aspects such as data, progress, or performance. Yet, our idea is that the process of developing and employing indicators is not solely a matter of data generation; besides, it is a knowledge-building and reflexive process that supports collective action toward the achievement of more sustainable and genuinely transformative urban food systems' outcomes.

More generally, what this paper aimed to convey is the necessity to develop a broader socio-ecological approach to the understanding of food, urban systems, and their governance (Moragues-Faus and Zerbian, 2025, in progress). Drawing from place-based, political economy, and socio-ecological governance approaches was pivotal to identify key layers, connected dimensions, and observable indicators, which could help to envision key governance priorities and areas of intervention at the intersection between food and urban systems. Consequently, embedding urban food action within key urban and socio-ecological dynamics characterizing diverse cities can help local authorities to link food with other sustainability agendas and policy areas at the urban and wider spatial-institutional scales. This is a crucial process that enables food system action to become more inclusive, systematic, and, at the same time, strategically oriented and transformative (Moragues-Faus and Battersby, 2021; Moragues-Faus et al., 2023). We believe that the analysis presented in this paper provides pathways for further research and action on food and urban systems. In particular, questions arising at the intersection of multiple layers offer new opportunities to examine how food system governance is embedded within place-specific urban dynamics, the types of conflicts it may encounter, and the ways in which it can become meaningful and relevant to diverse actors, in-

frastructures, and processes. In conclusion, this paper invites further research into how urban food governance spaces can more effectively engage with the key socio-ecological and economic dynamics that shape diverse urban contexts. This is crucial for advancing food system action beyond its current status as a policy niche, towards a genuinely transformative approach.

Urban Agriculture and Multispecies Commoning in Public Housing Regeneration: Rethinking Ecologies of Care in Scampia

Augusto Fabio Cerqua
University of Naples Federico II, Department of Architecture
augustofabio.cerqua@unina.it

Abstract
In an era of planetary crisis, urban planning must move beyond extractive models toward regenerative approaches grounded in care and multispecies coexistence. This paper explores the contradictions and potential of embedding urban agriculture within public housing regeneration, focusing on Scampia (Naples), a district marked by socio-spatial marginalization. Analyzing the ReStart Scampia project, which proposes a system of cultivated fields, urban forests, and collectively managed green areas, this study reframes urban agriculture as a tool for multispecies commoning rather than a symbolic greening strategy. Drawing on urban political ecology and post-growth theory, the paper interrogates governance structures and asks: can urban agriculture foster socio-ecological justice in marginalized neighborhoods? Can it support post-anthropocentric planning practices through bottom-up land stewardship and care? The case offers insights for rethinking ecologies of care in public housing.

Keywords: urban agriculture; public housing regeneration; open spaces; multispecies commoning; care ecologies

1. Introduction: Beyond Greenwashing in the Age of Crisis

In the context of climate emergency, deepening inequalities, and growing social disconnection, urban planning is increasingly called upon to rethink its tools and paradigms. Recent years have witnessed the proliferation of discourses on care, regeneration, and ecological transition within policy and planning frameworks, yet the operationalization of such principles often remains superficial. In particular, urban greening strategies promoted in public housing neighborhoods tend to instrumentalize ecological rhetoric while maintaining extractive, top-down governance models.

This paper addresses these tensions through a critical reading of urban agriculture as a field of both appropriation and potential resistance within regeneration processes. Focusing on the district of Scampia in Naples, Italy—long stigmatized as a marginal territory yet undergoing a major transformation—the study reflects on the contradictions and opportunities arising when agriculture is mobilized as a tool for regeneration. Drawing on the ReStart Scampia project, it interrogates the extent to which urban agriculture can activate new ecologies of care, enable multispecies forms of commoning, and challenge the growth-oriented logic embedded in redevelopment plans.

To do so, the paper draws from the fields of urban political ecology, post-growth urbanism, and critical planning studies, proposing a situated and relational approach to public housing regeneration. It explores how urban agriculture may contribute to the reconfiguration of urban metabolism and the emergence of regenerative socio-spatial practices—particularly in territories historically marked by structural neglect and speculative planning. The aim is to offer both a critique and a possible reframing of the role of agriculture in post-growth urban transitions.

2. Theoretical framework: Post-growth urbanism and multispecies care

To critically engage with the promises and limits of urban agriculture in regeneration contexts, this paper situates its analysis within the frameworks of post-growth urbanism and urban political ecology. Post-growth thinking calls into question the centrality of economic expansion in urban development, advocating instead for regenerative, care-based alternatives (D'Alisa et al., 2015; Latouche, 2009). This perspective aligns with critiques of mainstream sustainability, which often fail to challenge extractive logics or engage with the socio-political dimensions of ecological transformation.

Urban political ecology offers a complementary lens by foregrounding the power relations embedded in the production of urban nature (Heynen et al., 2006; Swyngedouw, 2004). Within this field, urban agriculture emerges as a site of contested governance, capable of reproducing existing inequalities or opening space for alternative socio-ecological relations.

Building on these perspectives, the paper introduces the notion of multispecies commoning as a critical tool to reframe urban agriculture beyond anthropocentric and managerial paradigms. Drawing from Massimo De Angelis' work on the commons as sites of social cooperation outside capital (De Angelis, 2017) and Laura Centemeri's concept of ecological care as a relational and situated practice (Centemeri, 2015), multispecies commoning foregrounds the entanglements of human and non-human actors in the production and stewardship of shared environments.

This approach resonates with feminist and post-humanist theories of care (Puig de la Bellacasa, 2017; Haraway, 2016), emphasizing interdependence, vulnerability, and the material conditions necessary for living together in damaged worlds. In this sense, urban agriculture can be reimagined not only as a source of food or greenery, but as an infrastructural practice through which ecologies of care and non-extractive relationships are cultivated.
The next section outlines the methodological approach adopted in this research, grounded in situated knowledge, critical engagement, and a commitment to interrogate institutional narratives from within.

3. Methodology: Situated urban political ecology and critical engagement
This research adopts a situated and critically engaged methodology, drawing on the author's direct involvement in the ReStart Scampia project as a researcher and planner. Rather than claiming external objectivity, the study embraces a reflexive stance, recognizing the complexities and tensions of operating within institutional frameworks while maintaining a critical perspective.

Data collection combined ethnographic observation, informal interviews, and document analysis. Fieldwork was conducted intermittently between 2022 and 2024, with particular attention to public meetings, design workshops, and moments of negotiation between planners, local actors, and municipal institutions. As such, the methodology integrates both emic and etic perspectives: it considers the internal logics and aspirations of the project while foregrounding its political and socio-ecological implications.

This embedded approach allows for an analysis that is both grounded in practice and theoretically informed. It also reflects a commitment to what Haraway (1988) terms "situated knowledge": knowledge that is partial, embodied, and accountable. Rather than offering a universal assessment of urban agriculture, the paper focuses on the specific configurations, conflicts, and imaginaries that emerge in the Scampia context—viewing them as entry points to broader questions around commoning, care, and post-growth urbanism.

Beyond its epistemological implications, this methodological positioning can be understood as a political and performative act: a way of "staying with the trouble" (Haraway, 2016) rather than escaping into abstraction. Engaging with urban transformation from within entails embracing uncertainty, ambivalence, and the everyday negotiations that shape socio-ecological realities. In this regard, method becomes more than a tool for knowledge production—it becomes a terrain of situated intervention, echoing Stengers' (2018) call for "slow science" and Shotwell's (2016) invitation to cultivate "imperfect solidarities." By remaining attentive to the frictions, alignments, and silences encountered in the field, the research aims not only to interpret but also to modestly interfere with the conditions of possibility for more just and livable urban futures.

Figure 1 - Schematization of the project by levels.

The ReStart Scampia project, which constitutes the primary empirical basis of this study, is the outcome of a collaboration between the Municipality of Naples and the Department of Architecture (DiARC) at the University of Naples Federico II. The project was developed as a technical and economic feasibility plan for the redevelopment of the "Lotto M" in Scampia, where the last remaining buildings of the infamous Vele complex are located. The DiARC team—led by Enrico Formato and composed of Marianna Ascolese, Eduardo Bassolino, Gilda Berruti, Alberto Calderoni, Pasquale De Toro, Gianluigi Freda, Giuseppina Mari, Federica Palestino, Michelangelo Russo, Ludovica Battista, Luca Boursier, Augusto Fabio Cerqua, Nicola Fierro, and Bruna Vendemmia—proposed a vision that reactivates the area's historical rural identity through a new system of fields and open spaces. This design aims to transform the degraded landscape of the Vele into a more fertile, socially sustainable, and livable environment.

This situated approach also reflects a broader commitment to engage with space not merely as a neutral container but as a terrain of rights that are enacted through embodied practices. As Formato (2023) argues, rights in the city do not pre-exist spatial practices but emerge from them—a process of claiming and shaping space through everyday gestures of care, resistance, and transformation. In this sense, gardening in Scampia is not only ecological but also political: a form of commoning that produces alternative ways of inhabiting and regen-

erating urban territory.

4. Contested Regeneration: Scampia between Ecological Rhetoric and Commoning Practices

Scampia, a district in the northern periphery of Naples, has long epitomized the contradictions of modernist public housing and the socio-spatial marginalization it often engenders. Designed in the 1960s as part of a utopian vision for urban expansion, it became globally infamous for its failed megastructures, institutional abandonment, and stigmatizing media narratives. In recent years, however, Scampia has been at the center of an ambitious regeneration effort, culminating in the ReStart Scampia project, a strategic framework that seeks to transform the area through a combination of demolition, new housing, and ecological requalification.

ReStart Scampia includes a proposal to reconvert open spaces into a system of urban agriculture fields, forestation areas, and collectively managed green commons. While the inclusion of urban agriculture signals a shift toward ecological sensibilities in planning, it also raises important questions about the role of such interventions in shaping new territorial imaginaries. Are these cultivated landscapes meant to function as genuine infrastructures of care and commoning, or do they risk reproducing a sanitized, greenwashed version of redevelopment?

Drawing from direct involvement in the planning process, this section unpacks the internal tensions within ReStart. On one hand, the project attempts to foreground community participation and environmental restoration; on the other, it remains embedded in bureaucratic procedures and aesthetic logics of urban decorum. The agricultural component, in particular, oscillates between symbolic landscaping and the potential for more radical, situated experiments in land stewardship. Design workshops and participatory meetings reveal divergent expectations: while some institutional actors frame agriculture as a beautifying tool or social inclusion device, grassroots groups and informal gardeners express a more grounded interest in autonomy, food production, and environmental justice.

Figure 2 - General project plan.

These frictions expose the limitations of institutional planning when it comes to nurturing regenerative practices from below. ReStart Scampia thus becomes a field of negotiation where the possibilities of multispecies commoning must contend with the constraints of technical planning, fragmented governance, and limited political imagination.

5. From Urban Greening to Commoning: Negotiating Agriculture in Public Housing

Beyond formal plans and institutional frameworks, a multiplicity of informal gardening practices already inhabit the open spaces of Scampia. These gestures—often modest, ephemeral, or spontaneous—enact a relational and situated form of care for the land. They also materialize what Formato (2023) defines as "diritti che si producono nello spazio": rights that are not granted from above but created through embodied, everyday engagements with space. By cultivating small plots, reactivating unused land, or informally organizing green commons, residents perform acts of spatial claim-making that challenge extractive paradigms and articulate a politics of regeneration from below. These practices resonate with the notion of multispecies commoning, as they involve entanglements with plants, animals, and soil in the production of shared ecologies of care.

In the ReStart Scampia project, urban agriculture is framed as a central element of the regeneration strategy. The masterplan envisions the creation of cultivated fields, food forests, and community-managed green areas as tools for activating social inclusion and ecological transition. However, the integration of these elements within a broader institutional framework reveals tensions between symbolic greenwashing and transformative commoning.

On one hand, the agricultural vision embedded in the project is unprecedented for Naples' public housing contexts, signaling an institutional openness to rethinking the urban metabolism and fostering new forms of ecological engagement. The plan explicitly moves beyond ornamental greening, recognizing the productive, relational, and educational potential of cultivated land. It also references concepts such as circularity, biodiversity, and soil regeneration, suggesting a shift from static landscaping to dynamic socio-ecological systems.

Figure 3 - Axonometric design view.

On the other hand, the actual governance model remains largely centralized. While the project mentions participatory management and local stewardship, the mechanisms for such involvement are vague or postponed to future implementation phases. This creates a disjuncture between the transformative narratives surrounding the project and the persistence of technocratic planning logics. The risk is that agriculture, instead of becoming a tool for commoning, is absorbed into a managerial apparatus that maintains control over land and decisions.

These ambiguities have concrete implications. During public meetings and workshops, local actors—residents, associations, informal gardeners—expressed both enthusiasm and skepticism. While some embraced the idea of reconnecting with land through structured initiatives, others questioned the feasibility and sincerity of institutional proposals, especially in light of past failures. Moreover, the spontaneous gardens and informal cultivations already present in the area are largely overlooked in the official design, raising concerns about erasure and displacement.

By situating agriculture within a commoning framework, this paper argues for a more radical rethinking of public housing regeneration. Rather than inserting predefined green infrastructure, urban planning should recognize and support existing ecological practices, enabling a shift from green compensation to collaborative, multispecies stewardship. This implies reworking the planning process itself—its timelines, governance structures, and epistemologies—toward more open-ended, caring, and accountable models.

6. Commoning beyond participation: informal practices of care and cultivation

The promises of participation and community involvement often invoked in regeneration discourses risk being co-opted into top-down planning agendas. In the case of Scampia, while the ReStart project formally integrates participatory components, its institutional framing still reflects the asymmetries of power and expertise characteristic of conventional urban development. However, alongside and beyond these official processes, a range of informal practices has emerged—suggesting alternative ways of inhabiting and cultivating space that do not rely on formal recognition.

Field observations and conversations with local residents revealed a number of grassroots initiatives involving the appropriation, cultivation, and care of small plots of land, often without authorization. These acts—ranging from self-managed gardens to the planting of fruit trees and spontaneous composting—constitute a dispersed but significant ecology of commoning. Although modest in scale, they express relational modes of engagement with the soil and with more-than-human life, offering a quiet but powerful critique of neglect, abandonment, and technocratic planning.

Such practices align with what Centemeri (2015) describes as "ecological care": a form of everyday engagement that emerges from lived experience and local knowledge rather than from formalized sustainability agendas. These gestures may be invisible or illegible to planners, yet they point toward different regimes of value and stewardship. They also reflect what De Angelis (2017) calls the "commons" as a space of social reproduction—where value is generated through cooperation, not extraction.

In this light, urban agriculture becomes a contested terrain, where institutional designs and spontaneous experiments coexist, overlap, or come into tension. By paying attention to these frictions and to the knowledge embedded in informal practices, planners may begin to reimagine regeneration not as the implementation of a predefined plan, but as a process of learning with and from situated forms of communing

7. Conclusions: Toward situated ecologies of post-growth regeneration

This paper has argued for a situated and critical understanding of urban agriculture as a potential catalyst for post-growth regeneration in public housing contexts. Moving beyond the dominant paradigms of greening and participation, the case of Scampia illustrates how agriculture can become a terrain of both conflict and care, institutional design and informal experimentation. Rather than merely implementing green infrastructure, the challenge lies in recognizing and nurturing the situated ecologies—human and more-than-human—that already inhabit these spaces.

By foregrounding the notion of multispecies commoning, the paper has sought to expand the conceptual and practical horizons of urban regeneration. Drawing on local gestures of ecological care, it suggests that alternative forms of value, cooperation, and stewardship may emerge from below, offering a counter-narrative to technocratic or growth-driven approaches. These informal and often invisible practices, while fragile and fragmented, embody a different politics of urban space—one grounded in relation, attention, and interdependence. Planning for post-growth cities demands not only new tools but new sensibilities. It requires planners and institutions to engage with the messy, contested, and affective dimensions of urban life—to see regeneration not as a linear process of improvement, but as a terrain of negotiation, translation, and collective inquiry. In Scampia, the soil tells stories of abandonment and extraction, but also of resilience and imagination. Listening to these stories, and allowing them to inform our practice, may be the first step toward more just and regenerative futures.

Abstract
As planners strive to ensure justice and equity in the long term, they are confronted today with the unprecedented immediate dual challenge to meet the immediate demands posed by associated crises, such as climate change, social inequality, or economic instability. These crises often iterate upon one another, deepening pre-existing inequalities, and thus require planners to engage with ethical principles in a critical way as a guide for transformative action. This paper presents a study of the practical implications of justice in planning, pointing out the particular difficulty when it comes to reconciling varying interests and ideals in urban societies. Following that, he analyzes several of the case studies on postindustrial urban areas and those most immediately impacted by climate change, covering three primary facets: (1) the ethical foundations influencing decision-making in planning, (2) approaches of embedding the values of justice and inclusivity into adaptive planning strategies, and (3) means by which conflicting societal priorities can be mediated. It emphasizes participatory practices, interdisciplinary collaboration, and robust governance as critical mechanisms for aligning ethical commitments with actionable solutions. Distributive, procedural, and recognition-based justice theories offer critical insights into integrating justice into planning efforts at local and systemic levels. It also underscores the importance of fostering resilience and inclusion, particularly for marginalized populations, while tackling broader challenges posed by planetary crises. This analysis ultimately links theory to practice by developing recommendations for planners, policymakers, and other stakeholders who have committed themselves to advancing justice at a time that changes quickly in an ever more uncertain world.

Keywords: Ethical Urban Planning; Adaptive Planning; Climate Justice; Spatial Justice; Participatory Planning

Introduction

The 21st Century brought several crises that have accumulated to a common challenge found in urban planning: climate changes, social inequality, and an unstable economy. The technocratic growth-centric paradigm implied by traditional planning models has proved inadequate in dealing with these multifaceted crises. Thus, there is an urgent need to explore new planning approaches through ethical frameworks that will put issues of justice, equity, and sustainability at the forefront.

The increasing frequency and intensity of climate-related disasters accentuate the urgency of planners adopting ethical frameworks oriented towards justice and equity. Traditional planning models, commonly technocratic and growth-oriented, have proved insufficient in addressing the complex interrelationships of environmental, social, and economic problems. Indeed, the need for a paradigm shift towards more participatory planning approaches has never been so pronounced. The use of ethics in planning practice cannot simply be an intellectual exercise but must develop into a practical necessity. As cities balance immediate needs with long-term sustainability, planners must grapple with embedding justice into urban development strategies so that the voices of the disadvantaged are not merely heard but contribute to shaping the planning process.

This paper seeks justice operationalization within adaptive planning through the investigation of ethical frameworks, which would guide planners in traversing the complex new terrain offered by contemporary urban challenges. The theoretical assumptions, as well as practical applications of a study, aim to undertake the journey of incorporating justice into planning processes, leaving behind hagglers who will be effective and equitable in planetary crisis responses. Furthermore, transforming planners from the direct archetype of top-down models into facilitators of change would change the role of planners, considering that it is a morphing trend. It would

require a deep understanding of the ethical dimensions of planning and a commitment to embedding justice at the core of urban development strategies. The same flow of ideas contributes to the ongoing discourse on how ethics should be tied to planning, highlighting the need for practices not to be disconnected from the broader values of society as well as their meaningful imperative to building resilient, inclusive communities in the face of global challenges.

Theoretical Framework: Dimensions of Justice in Planning
Planning Justice is primarily comprised of three important dimensions: distributive, procedural, and recognition dimensions.

Distributive Justice: Regarding allocation of resources, services, and opportunities. In this sense, planning aims at ensuring equal distribution of benefits and burdens across various communities, especially the marginalized groups (Fainstein, 2010).

Procedural Justice: Pertaining to fairness and inclusiveness in decision-making processes. That means giving emphasis to participatory mechanisms where voices of all stakeholders at different levels could be involved in planning decisions (Healey, 1997).

Recognition-Based Justice: Understanding and respecting the different identities, experiences, and knowledge systems of all individuals in a community. It straightens the way for planners to consider and actively oppose systemic biases and ensure that marginalized voices become not merely spoken but valued (Schlosberg, 2004).

Work to embed these dimensions into the fabric of planning practice calls for an all-encompassing approach that crosses traditional techniques and places ethics at the center of the planning process. Space justice complements the previous dimensions of justice but stands distinctively as one of the concerns of urban planning. Space justice concerns distributing spatial resources equitably and organizing space appropriately so that all people in society have equal access to life-sustaining services and opportunities. This emphasizes the extent to which spatial inequalities often reflect social and economic inequalities. In addition, the multifacetedness of such dimensions clearly emphasizes the challenges involved in operationalizing justice in planning. Thus, while one pursued emancipation through distributive adjectives, there could be need for some reforms in procurement procedures to provide more inclusive participation; while recognition-based justice emphasizes the need for cultural sensitivity and acknowledgment of diverse worldviews as city space is shaped.

Intergenerational justice should be taken into account as well, especially concerning climate change and sustainability. Intergenerational justice recognizes that planning decisions should not infringe upon the ability of future generations to meets their needs. It thus requires thinking ahead to formulate planning policies that balance current development goals with long-term environmental stewardship and resilience. Bringing these dimensions together offers an integrated framework within which planners are most likely to address ethical challenges that may arise with urban development and create environments that function as equitably as inclusive.

Methodology
A qualitative research methodology including case studies, policy analysis, and stakeholder interviews is what the research borrows to understand the application of ethical frameworks to adaptive planning. These case studies include postindustrial urban areas and communities that experience climate changes disproportionately, providing an insight into the challenges and opportunities associated with operationalizing justice in diverse contexts. Additionally, participatory action research (PAR) methods are employed to enhance understanding of ethical frameworks in adaptive planning (Mehan and Mostafavi, 2024). PAR embodies co-learning and power sharing between researchers and other residents, underscoring mutual empowerment. In this way, the research process itself is imprinted with the very principles of justice and inclusion.
Data collection drew on a combination of document analysis-including planning policies, reports-and semi-

structured interviews with planners and policymakers, and community representatives. This approach provides a more comprehensive understanding of ethical influences on planning decisions and their practical implications for justice-oriented programming.

The thematic coding, identifying patterns and themes in relation to the integration of justice in planning processes, guided the analysis. This would allow for the development of best practices, barriers, and facilitators in embedding ethical frameworks into adaptive planning initiatives. Triangulation of data from various sources increases reliability and validity of results from the study that provide nuanced perspectives on operationalization of justice in urban planning. The study also makes use of scenario planning techniques to analyze possible futures and the consequence of alternative planning decisions. It allows them to envisage more informed and ethical decision- making processes in uncertainty and complexity by framing in different assumptions the potential consequences that really could turn out.

Case Studies

1. Urban Regeneration during the Post-Industrial Era

Indeed, city planning institutions that have gone through the transition of industrial economies face new barriers of contradictions in town planning. A case is the restoration of the abandoned areas for more active functionality or for generating other uses. One possibility is using heritage industrial sites to bring together cultural conservation and the development of communities. However, without ethical standards, these actions will put the communities at risk of gentrification and displacement.

From 1986 onwards, it transformed into a cultural and creativity site involving museum facilities and design centers, as well as public spaces, as most adaptations of industrial sites are termed in the successful adaptive reuse of industrial heritage. The redevelopment process emphasized that the community would own the project and, therefore, would ensure that it met local requirements and aspirations.

It would be possible to argue here that the first redevelopment of Docklands in Melbourne purposely ignored community interests in favor of the corporate commercial activities. Because of the result of this kind of treatment-a lack of affordable housing and community facilities-revisions were made in planning approaches to direct attention to inclusive planning processes.

Through distributive and recognition-based justices, regeneration planners guarantee that regeneration initiatives enrich people, set up cultural identities, and spur inclusive economic development within their areas. Such planning processes would lead to gathering local wisdom that, in turn, would lead to increased ownership among the community members on the redeveloped efforts. For instance, adaptive reuse has changed the Zollverein Coal Mine Industrial Complex in Essen, Germany, into a nexus of culture and creativity while economic revitalization stirs. Extensive community engagement ensured that redevelopment efforts tied in well with local needs and aspirations (UNESCO, 2001).

If we relate these situations with the case of Docklands, Melbourne, especially regarding how the place was to undergo development, it can be noticed that some specific exclusion meant for planning is not present. The initial redevelopment plans for Docklands that fell short of including the community were amended or remodeled to fit the centers of importance such as affordable housing, public spaces, and community facilities (City of Melbourne, 2020).

2. Climate Change Adaptation in Vulnerable Communities

Among the communities that suffer the most from climate change effects are poor and disadvantaged groups, as they suffer from low-quality infrastructure and resource constraints. Adaptation planning in such a context shall be prioritized on procedural justice, ensuring that adaptation strategies are co-built with the input of community members.

The planning processes that include local knowledge and experiences into their procedures are more relevant

and effective for adaptive measures. Different ethical frameworks guide planners to redress the systemic inequities that exists with respect to resilience in inclusive and context-sensitive approaches.

In Bangladesh, the traditional practice of floating garden construction, locally known as 'baira', is favored in flood-prone areas for crop cultivation. These gardens consist of aquatic plants like water hyacinth, which make them a sustainable alternative food and income source for climate change-afflicted communities. Community-based adaptation projects in Bangladesh have enabled local people to build and run such climate-resilient practices as floating gardens and the construction of raised houses. All these methods highlight the importance of participatory planning and using indigenous knowledge in strengthening community resilience (Sunder, 2020).

Under the initiative of Rebuild by Design in the United States, since Hurricane Sandy, some communities went into partnership with their peoples to co-create resilient infrastructures. Among the projects that came out of this is the development of New York's "Big U," which is a "superstorm" project that has integrated social, environmental, and economic in addressing climate vulnerabilities (Rebuild by Design, 2014).

Strategies for Operationalizing Justice in Adaptive Planning
To make justice operational in adaptive planning requires diverse approaches, entailing participatory approaches, interdisciplinary collaboration, ethical evaluation, and capacity development. These strategies seek to ensure that processes of planning are equal, inclusive, and attuned to the different needs of communities.

1. Participatory Planning
The first step to developing equitable planning outcomes is to engage all stakeholders in the decision-making process. Participatory planning is used as an umbrella term for a range of tools such as community workshops, participatory mapping, and digital platforms used to carry out inclusive engagement. For example, participatory mapping gifts the people to be planned for with the ability to communicate their own experiences and knowledge toward the planning process, nurturing a sense of ownership and ensuring development in accordance with local needs. Since the advent of such digital tools as interactive mapping platforms and online forums, wider opportunities for community engagement opened up, increasing accessibility and efficiency (Mehan and Stuckemeyer, 2023).

Participatory planning nurtures transparency and accountability in the planning process. Should community members be involved from the start, planners will be able to nipping in the bud potential conflicts that may arise during implementation. And, in this collaborative culture, trust is born, which is indispensable in the long life of any planning activity. In addition, participatory planning can lead to innovative solutions that are highly customized to respond to context. It is often community members who can bring in understanding of local challenges and opportunities that external planners may not pick up on. This local knowledge can then be harnessed for more nuanced planning purposes that respond to the real concerns and aspirations of that community.

2. Interdisciplinary Collaboration
These points address how different disciplinary inputs, such as the sociology, environmental science, economics, and urban planning inputs to the discussions, will help in addressing the difficult issues concerning urbanism. Interdisciplinary collaboration enhances planning approaches by ensuring that both the social, environmental, and economic approaches are included in the discussions as important understandings in the dimensions of urban development. Such collaboration easily defines the development of holistic solutions that are more resilient and adaptable.

In practice, however, collaboration across disciplines improves the effectiveness of both policy making and implementation. Environmental science, for instance, located within the realm of urban planning in broad land-use practices, identifies principles of use in sustainability along with an economic analysis to define the financial viability of the proposed approaches. The sociological viewpoint explains dynamic equity with respect to decisions on planning and further legitimates a just approach in creating such policies (Mostafavi et al., 2024).

Such teams can also spark innovation by coupling different methods and perspectives. This cross-fertilization of ideas may lead to creative approaches not likely to be imagined within a single-discipline framework. Such pluralistic collaboration must be encouraged institutionally, with mechanisms for interdisciplinary training and otherwise facilitating the communication of professionals from different fields.

3. Ethical Impact Assessments

While planning impact assessments may be supplemented with ethical considerations to help planners anticipate and prevent the emergence of injustices from their planning decisions, ethical impact assessments span more than such analyses. Benefits and burdens are to be distributed equally among different community groups. Development should not disproportionately disadvantage marginalized populations, a preventive step towards accountability or transparency, which can see planning practices align with values of social justice.

In fact, ethical impact assessments may serve public engagement because they would draw the stakeholders into the assessment process, while people would be able to learn how different groups of citizens value issues and priorities and even reach equitable results because of their involvement thus adding legitimacy to the planning decision and strengthening its credibility in the eyes of the citizenry.

One more thing is that ethical impact assessments lend themselves to the identification of negative side impacts associated with planning actions-for example, evictions or environmental degradation. Through systematic assessment of these potentials, planners may evolve them into strategies meant to be proactive in handling impacts and ultimately strengthening urban development in sustainability and justice.

4. Capacity Building

Through education and provision of resources, communities are empowered to gain skills for effective participation in planning processes. Capacity building is about training, support, and creating a local leadership structure such that community members engage meaningfully in decision-making. By building the community capacity of planners, procedural justice is advanced, and long-term community resilience is created, enabling communities to adapt to new realities and challenges (Mehan, 2024a; 2024b).

These capacity-building activities could take the form of workshops, mentorships, and technical assistance in the best case. Such activities empower community members with knowledge of planning processes that otherwise may seem too technical to grasp. In addition, capacity building of community-based organizations can give marginalized communities an opportunity to voice themselves and for their perspectives to be considered in planning decisions.

Furthermore, capacity building adds another dimension of sustainability to the processes of planning. Where communities have skills and knowledge to manage and maintain projects, they tend to take ownership of those projects and see to it that these efforts survive. Such ownership can also lead to increased civic engagement, which in turn strengthens social capital within communities.

5. Integration of Technology

Technology can enable better transparency and inclusiveness in the planning processes. GIS, along with other dot offerings, helps communities visualize what planning proposals are about, give feedback, and monitor implementation mechanisms; all these add up to participatory planning. For instance, participatory GIS integrates input from the "community by allowing its members to provide spatial data and local knowledge that led to better-informed and fair decisions."

Through use of technologies, efforts aimed at popularizing community engagement may stretch farther into the reach of individuals who may otherwise not make it to a venue to attend a meeting (Mehan, 2024c). Surveys online, virtual town halls, and interactive mapping are some alternative channels through which diverse voices

can be ensured to be heard.

However, the issue of a digital divide must also be raised when incorporating technology into a process of planning. One way to prevent the exclusion of groups at technological disadvantage is by ensuring equal access to digital tools as well as training on their application (Kozlowski et al., 2020). The planner will have to keep the 'gate' on such disparities wide open for proactivity in bringing forth digital inclusion.

6. Institutional Reforms

Such institutional reforms should also lay the groundworks for planning policies and frameworks that integrate ethical considerations for justice in adaptive planning. These include creating guidelines and standards that would prioritize justice, equity, and sustainability, as well as forming accountability mechanisms that would ensure that such ethics are met.

Changing structures of institutions would involve modifying planning regulations to require equity assessments, creating independent agencies to guarantee compliance with ethical standards, and promoting a culture of continuous learning and reflection among planning organizations. Internalizing these changes would, in fundamental part, awaken in the planning process now-making ethics a part of the pre-institutionalized process.

Further, institutional changes have meant enhanced interagency collaboration as well as coordination, thus mitigating silos often seeming barriers to comprehensive planning. Integrated approach would suffice for institutions in devising effective mechanisms for addressing the complex and interconnected problems of urban communities.

Discussion and Conclusion

The operationalizing process of justice in adaptive planning requires a major shift away from orthodox, top-down outlooks to inclusive, bottom-line practices that rely on ethics. Planners need to grasp the struggle produced by a juxtaposition of competing interests and ideals to balance off efficiency against equity. Ethical frameworks are meant to mediate these conflicts, thereby directing planners to judge their decisions as much by application ability as by justness. Therefore, the operationalization of justice in adaptive planning theory should rather see a practical face-up, as supposed by a variety of real cases.

Take for example the city relocation of Newtok in Alaska following erosion brought on by climate change. It exquisitely demonstrates the interlaced web of issues linked to climate adaptation. Substantial federal funding notwithstanding, the community ended up struggling with issues like substandard infrastructure and interagency coordination problems, which speaks loudly to the requirement of a developed ethical framework in planning methods.

The ACT Initiative in Delhi represents a new approach to urban resilience. ACT strives at making responsive and sustainable urban systems to fight the climate challenge in a collaborative manner with various stakeholders. This goes to show that planning activities aligned with justice could be realized by means of participatory planning and interdisciplinary collaboration.

On the other hand, developing mini-forests in Uttar Pradesh under the Upvan Scheme speaks about integrating natural solutions in urban planning. By promoting green cover, these programs contribute to ameliorating the urban heat island effect that is a real menace for densely populated areas. This kind of program further speaks about distributive justice because it attempts to assure equal benefits from the environment.

In the United States, cities are increasingly integrating justice in climate planning. Several studies have analyzed climate action plans from the 100 largest cities in the United States and found that quite a few justice principles had been incorporated into their climate mitigation strategies, with tools such as equity assessments and community engagement frameworks being used. Such practices point in the direction of increasing awareness

toward the importance of procedural and recognition-based justice considered by urban planners. Moreover, sponge cities in China epitomize cutting-edge urban flood management. Through redevelopment of the green infrastructure, these cities seek to absorb and reuse rainwater, thereby alleviating flooding and enhancing ecological biodiversity. This model exemplifies how ethics in urban design can promote sustainable and resilient communities.

These aforementioned examples show the many sides of justice in adaptive planning. Given their case-study perspectives, they urge the embedding of ethical framework considerations into planning processes to meet the multifaceted challenges posed by climate change and urbanization. Armed with the lessons derived from the real-world instances discussed, planners can formulate strategies that would be workable, fair, and inclusive.

Embedding these ethical frameworks in adaptive planning is certainly given priority to deal with the multifaceted challenges of this century. Set against them, planners could make just, fair, and sustainable strategies that could lead to improved community resilience and recognition of cultural values. The case studies discussed herein shed light on their usefulness in grounding future planning on these principles.

In summary, what this means is the operationalizing of justice in highly adaptive planning needs an abiding set of ethical principles, which includes inclusivity, equity, and sustainability. Planners can embark on the path of participatory planning, interdisciplinary collaboration, and nature-based solutions as they develop strategies that tackle the immediacy of climate change and urbanization, while paving an additional path toward long-lasting resilience and social justice. The experiences of the likes of Newtok, the initiatives from ACT, and the Upvan Scheme will provide invaluable lessons toward that end in seeking equitable and sustainable urban outcomes.

A Study on the Supply–Demand Relationship of Recreational Services Supported by Ecological Public Spaces: A Case Study of Nanjing, Jiangsu Province, China

Jiang Shengbin[1] Lin Roulan[2]
1 : Southeast University , 2 : Xiamen University
Email:1 :13813110308@163.com , 2 : 761683696@qq.com

Abstract
This study explores the supply-demand dynamics of recreational services in Nanjing, China, using 2020 data on land use and population. Key findings include: (1) A spatial mismatch exists between high-demand and high-supply areas. (2) Expanding the accessible radius from 2 km to 10 km improves the supply-demand balance, reducing deficit areas and unmet needs. (3) Nanjing's districts are classified into four types—locally satisfied, medium-distance satisfied, long-distance satisfied, and unsatisfied—with tailored planning recommendations. The study advocates for rational ecological land planning, decentralized management, and enhanced ecological compensation and economic cooperation to ensure fairness in recreational services and promote green development, offering insights for urban planning and ecological civilization.

Keywords: Ecological public space; Supply-demand relationship; Planning and management; Recreational services

I. Introduction

Recreational services, as a vital component of cultural services within ecosystem services, significantly contribute to enhancing human well-being (Li Xiang et al., 2019). However, amid economic development and rapid urbanization, the supply-demand contradiction of regional recreational services has become increasingly pronounced, manifesting distinct temporal and spatial characteristics. To date, research on the evolving supply-demand dynamics of recreational services remains limited, with most studies employing semi-quantitative methods that fail to effectively align regional supply and demand in both time and space. Consequently, there is an urgent need to advance research in this area. This study quantitatively assesses the supply, demand, and balance of recreational services, while leveraging spatial analysis techniques to illustrate the spatial distribution characteristics of the supply-demand relationship within the study area from a geographical perspective. This approach enhances the intuitiveness and comprehensibility of the findings, establishing a foundation for subsequent investigations into the changing patterns of supply-demand balance and offering targeted recommendations to improve these dynamics. Focusing on Nanjing City as a case study, this research examines the supply-demand conditions of recreational services within the ecosystem services of its 11 administrative districts in 2020. By employing methods such as supply-demand measurement assessments and spatial analysis, the study analyzes the supply-demand situation across these districts during this period and explores the spatial distribution characteristics of recreational services in each administrative district in 2020. Investigating the spatial supply-demand features of regional recreational services provides a practical basis for urban land planning and ecological civilization construction, addressing urban residents' aspirations for an improved quality of life and, in turn, elevating their well-being.

II. Theoretical Foundation and Literature Review

Ecosystem Services (ES) refer to the diverse benefits that ecosystems provide to humanity. Since its introduction in the 1990s, this concept has emerged as a research hotspot across disciplines such as ecology, economics, and environmental management. This chapter reviews the literature from four key perspectives—concept definition, supply-demand relationships, types and characteristics, and assessment methods—to establish a theoretical foundation for subsequent research.

2.1 Concept Definition of Ecosystem Services

The concept of ecosystem services was first articulated by Costanza et al. (1997), who defined it as the material and non-material support humans derive from ecosystem functions. This definition gained broad acceptance within the academic community and was further refined by the United Nations Millennium Ecosystem Assessment

(MA, 2005) as "the benefits ecosystems provide to humans," highlighting their direct and indirect contributions to human well-being. Subsequent studies by TEEB (2010) and USEPA (2012) emphasized that ecosystem services encompass a wide range of economic, social, and ecological benefits, underscoring their role as a cornerstone of human welfare.

2.2 Evolution of Supply-Demand Relationships

Research on ecosystem services has progressively evolved from focusing solely on supply to analyzing the balance between supply and demand. Xiao Yu and Xie Gaodi (2003) pioneered the exploration of spatial flows in ecosystem services, elucidating the linkage between supply and utilization. Zhen Lin (2008) defined demand as the consumption and appropriation of ecosystem services in human production and daily life. Li Shuangcheng (2019) proposed a comprehensive service process comprising formation, transportation, and consumption. Wolff (2015) highlighted that service flows connect supply areas to beneficiary regions, transforming ecosystem outputs into usable products for humans. Mou Xuejie and Wang Xiahui (2019) differentiated between direct consumption (e.g., provisioning services) and indirect consumption (e.g., regulating and cultural services), noting that supporting services are indirectly manifested through other service types.

2.3 Types and Characteristics of Ecosystem Services

The classification of ecosystem services provides a critical basis for their assessment. Daily (1997) categorized them into three groups: providing material resources, sustaining life systems, and enhancing life enjoyment. Costanza (2017) expanded this framework, identifying specific services such as food production, climate regulation, waste treatment, nutrient cycling, and recreational activities. Drawing on the MA classification, Wu Xiao and Zhou Zhongxue (2019) classified urban green infrastructure services into regulating, cultural, and supporting categories. Geng Nianzi and Zheng Hua (2023) outlined key characteristics, including quality dependence, spatial heterogeneity, scale correlation, and trade-offs and synergies. Guo Baoxiang and Nie Yuming (2022) observed that service distribution tends toward "spatial homogenization" as scales expand, emphasizing the significance of scale in analysis.

2.4 Development of assessment methods

The development of assessment methods is a core component of research on the supply and demand relationship of ecosystem services, for which scholars have developed a variety of methods. Indicator assessment methods quantify ecosystem services by constructing an indicator system, for example, (Layke et al. 2009) assessed provisioning, regulating, and cultural services, but demand indicators are relatively understudied (Fu Berger et al., 2017). The ecological modeling approach is favored for its ability to reveal ecological processes, and commonly used models include the InVEST model, the SolVES model, and the ARIES model, of which the InVEST model is suitable for water resources and environmental quality assessment due to low data requirements (Ma Lin et al. 2017), but its algorithms are relatively simple and require field data validation (Huang Conghong et al. 2013); The SolVES model focuses on the social value assessment of cultural services, quantifying aesthetic and leisure values through public surveys (Huang Conghong et al., 2013); the ARIES model, on the other hand, is suitable for comprehensively assessing supply and demand, but its application is limited due to its complexity and closed nature (Huang Conghong et al., 2013). The value assessment method quantifies the value of services through monetization, such as the unit area value equivalent factor method proposed by Xie Gao Di et al. (2015), which was pioneered by Costanza et al. (1997) and later optimized to adapt to China's national conditions (Xie Gao Di et al., 2008), and the unit service function price method is divided into the real market method, the alternative market method, and the virtual market method, which are applicable to different types of services (Liu Yao et al. 2017). In addition, the participatory method and empirical statistical modeling method are also important tools, in which the expert assessment matrix method (Burkhard, 2009) assesses supply and demand through expert scoring, which is simple to operate but highly subjective; the questionnaire survey method can accurately reflect the demand, but the cost is high and the scope is limited (Yan Yan et al., 2017); and the empirical statistical modeling method assesses the balance between supply and demand by using socio-economic data, which is easy to get the data but ignores ecological processes (LarondelleN et al., 2016). Each of these methods has its own advantages and disadvantages, and researchers need to choose appropriate assessment tools according to specific objectives and conditions.

III. Overview of the Study Area and Data Sources

3.1 Overview of the Study Area

Nanjing Nanjing City, as the capital of Jiangsu Province, is situated in the southwestern part of Jiangsu and the lower reaches of the Yangtze River. Its geographical coordinates range from 31°14'N to 32°37'N and from 118°22'E to 119°14'E. The city's maximum east-west extent is approximately 70 kilometers, while its maximum north-south extent is about 150 kilometers. On the municipal plane, Nanjing exhibits a pattern of being elongated from north to south and narrow from east to west, with a total area of 6,587.04 square kilometers, encompassing 11 districts and one national-level Jiangbei New Area. In recent years, the Nanjing Municipal Party Committee, Municipal Government, and planning and construction departments have successively announced and implemented a series of highly targeted initiatives to strengthen the development of urban green spaces and ecological infrastructure, thereby enhancing Nanjing's cultural appeal and quality of life.

In 2002, the "Green Nanjing" strategy was implemented, and in 2004, Nanjing launched the "Greening the Old City" campaign (Li Zhong, 2006). By the end of 2021, the city's built-up area achieved a green coverage rate of 44.96%, a green space rate of 40.79%, and a per capita park green space of 16.18 square meters, all ranking among the highest in cities of similar type across China. With the rapid development of the economy and society, residents' living standards have continuously improved, leading to a growing demand for recreational services. Particularly in the context of urban expansion, urban residents have an increasingly urgent need for nearby natural environments, cultural experiences, and other recreational services. However, due to constraints in urban planning and land resources, the supply capacity of recreational services in Nanjing has not kept pace with demand, and in some respects, has even declined. This has resulted in a significant contradiction between supply and demand. Meanwhile, with the improvement of transportation infrastructure, residents' travel options have become more diversified. In addition to traditional modes such as walking and cycling, transportation options like metro, buses, taxis, and ride-hailing services have provided greater convenience to residents. Consequently, as the accessible range of residents' recreational activities has expanded, the spatial layout of the supply and demand for recreational services in Nanjing has adjusted accordingly (Tong Liga et al., 2013).

3.2 Research Data

In this paper, we utilized various data, including land use and population spatial data.
(1) Regarding the 30m land use raster data for Nanjing City in 2020, this information was obtained from the Resource and Environment Science Data Center of the Chinese Academy of Sciences. In the process of creating "China's 20th Century LUCC Spatiotemporal Platform," Liu Jiyuan and his team referenced the LUCC classification system.
Based on the actual conditions of the study area, land use was meticulously categorized into eight distinct types, including paddy fields, dry land, forest land, grassland, water bodies, wetlands, construction land, and bare land.
(2) Regarding population spatial data: These data were based on 1km grid information from the Science and Environment Data Center of the Chinese Academy of Sciences.

3.3 Research Methods

1. Quantifying the Supply of Recreational Services

Past research has primarily focused on areas such as oceans, marine landscapes, urban greening, and forests, with the aim of assessing the potential value of these ecosystems in providing leisure and recreational services. Therefore, this study identifies ecological lands such as forests, grasslands, water bodies, and wetlands as specific areas capable of offering leisure and recreational services.

This research project plans to use a **1km×1km grid structure** as the primary research framework and conduct an in-depth analysis of five different modes of transportation: walking, cycling, electric vehicles, public transportation, and self-driving. During this research, **2 km, 5 km, and 10 km** were selected as the accessible radii for ecological lands, assuming that within a specific grid, ecological lands can provide various leisure and recreational activities to residents within that radius. At the same time, residents within the grid are also eligible to access all ecological lands within that radius (Tao Qin et al., 2021). The calculation process is as follows:

(1) The ecological land within the grid can provide recreational services to each person within the radius.

$$Ai=Si/Pi \quad (1)$$

where Si is the area of ecological land in grid i, Pi is the total population within the reachable radius corresponding to grid i, Ai is the per capita usable area of ecological land in grid i.

(2) In the grid environment, people can experience the services = services provided by all ecological lands within the accessible radius.

$$RSi=\sum kAj \times POPi \quad (2)$$

where RSi is the supply of recreational and leisure services in grid i; j is all the grids within the corresponding buffer radius of grid i; and POPi is the total number of people in grid i. When the reachable distance is not considered, i.e. when the reachable distance is 0km, the supply of recreational and leisure services is the ecological land area of the grid.

2. Quantifying the Demand for Recreational Services

Based on previous studies (Prance GT et al., 2014; Xie Zilai, 1999), this research establishes the per capita ecological land standard as **60 m²/person** and defines the demand for recreational services as:

$$RDi=60 \times POPi \quad (3)$$

where RDi denotes the demand for recreational and leisure services in grid i.

3. Assessment of Supply and Demand of Leisure and Recreation Services

This research program is based on the research method proposed by Zhao et al. (2015), which uses the metric of supply-demand ratio (R) to quantify the supply-demand balance of leisure and recreation services. In the case where the R value exceeds 1, the supply and demand in the study area shows a surplus situation, which means that the supply exceeds the demand, thus making the supply and demand of leisure and recreation services perform quite well; in the case where the R value reaches 1, the supply and demand in the study area reaches equilibrium, which means that the supply and demand are equal; in the case where the R value is lower than 1, the supply and demand show a deficit situation, which represents that the demand exceeds the supply, thus creating an imbalance between the supply and demand for leisure and recreation services.

$$Ri=RSi/RDi \times 100\% \quad (4)$$

where Ri denotes the ratio of supply and demand of leisure and recreation services in grid i.

IV. Research Results and Analysis

4.1 Recreation and leisure service supply in Nanjing under different accessible radius of each administrative district

In 2020, the highest value of leisure and recreation service supply of ecological land in Nanjing is 1.0404km². In terms of spatial distribution, the supply of leisure and recreation services in Nanjing shows different characteristics under different reachable radius, but with the expansion of reachable radius, the distribution of the supply of leisure and recreation services in Nanjing gradually expands and tends to be uniform. Under 0km accessibility radius, the supply of leisure and recreation services in Nanjing shows the characteristics of high in the south and low in the north, and the supply of Gaochun District, Lishui District and Yangtze River Valley in the south is especially high, while the supply of ecological land in the central urban area and Liuhe District is relatively small; under 2km accessibility radius, the supply of leisure and recreation services in Nanjing tends to be scattered, but it is still concentrated in Gaochun District, Lishui District and Yangtze River Valley in the south,

and the supply of Luhe District is still relatively small. The supply is still relatively small; under the 5km and 10km accessibility radius, the supply of leisure and recreation services in Nanjing tends to be uniform, but the supply in Luhe District in the north is still small compared with other administrative districts.

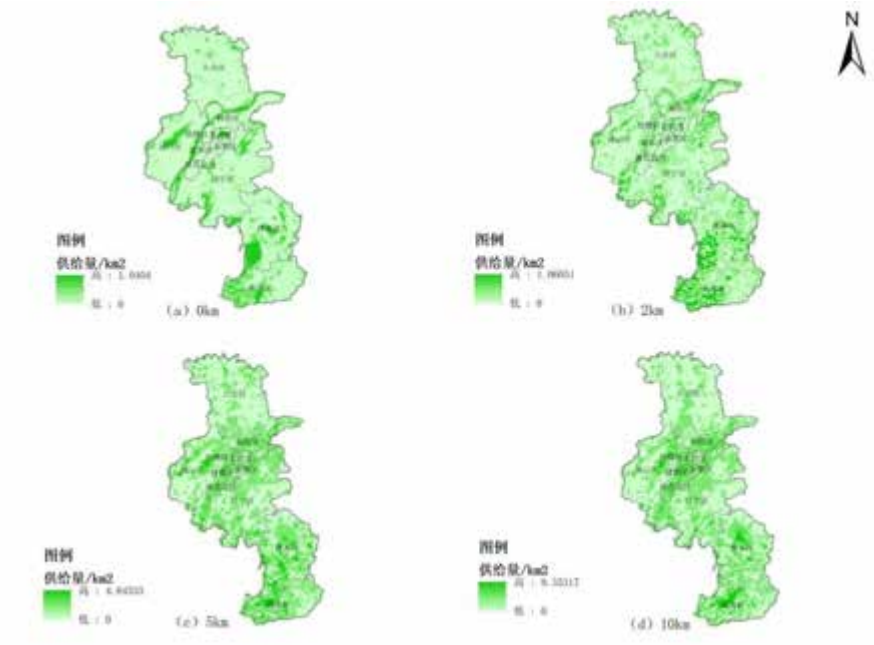

Figure 1 Supply of Leisure and Recreation Services under Different Reachable Radii in Various Administrative Regions of Nanjing City in 2020

4.2 Demand for Leisure and Recreation Services in Various Administrative Districts in Nanjing

In 2020, the highest value of leisure and recreation service demand for ecological land in Nanjing is 1.78503km². In terms of spatial distribution, the demand for recreational and leisure services is higher in the central region and relatively lower in the north and south regions. The core urban areas of Nanjing are the main concentration of high-demand zones, such as Gulou, Qinhuai, and Jianye Districts. These administrative districts have good economic development and convenient transportation, and due to the large proportion of built-up land, this has led to a large increase in the population, and consequently, a rise in the demand for recreation and leisure services. Liuhe District is the main distribution area of low-demand zones, Jiangning District, Lishui District and Gaochun District. These administrative districts are sparsely populated and have low population density, thus the demand for leisure and recreation services is low.

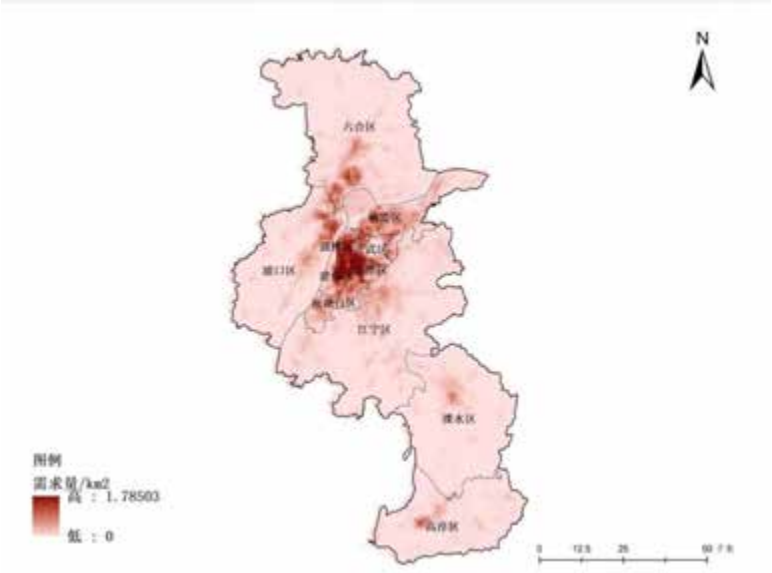

Figure 2 Demand for Leisure and Recreation Services in Various Administrative Regions of Nanjing City in 2020

4.3 Supply and demand of leisure and recreation services in Nanjing administrative districts

In 2020, the supply and demand of recreational and leisure services in Nanjing's ecological land under different accessible radii showed different characteristics, with significant heterogeneity in the spatial distribution of supply and demand, and an obvious mismatch in the location between areas of high supply and high demand, resulting in a serious spatial mismatch problem. Under 0km and 2km reachable radius, the supply of central and northern administrative districts and southern Gaochun district of Nanjing is much smaller than the demand, while the supply of Lishui district is much larger than the demand; under 5km and 10km reachable radius, the supply of central and northern administrative districts of Nanjing is much smaller than the demand, while the supply of southern Jiangning, Lishui and Gaochun districts is much larger than the demand. Overall, when the reachable radius gradually expands from 2km to 10km, the relationship between supply and demand in Nanjing is gradually improving, the deficit area continues to shrink, and the number of people failing to meet the demand for recreation and leisure services is also gradually decreasing. However, the central administrative districts of Gulou, Qinhuai, Jianye and Xuanwu have a small area of ecological land due to the concentration of population, and the number of people with unmet demand for recreation and open space services is decreasing.

However, Gulou District, Qinhuai District, Jianye District and Xuanwu District in the central part of the city have a small area of ecological land due to the concentration of population, so the decrease in the number of people with unmet demand for recreational and leisure services is relatively flat, and the relationship between supply and demand is always in a deficit. Under the 0km reachable radius, the deficit ecological land area for leisure and recreation services in Nanjing is 48.35%, and the deficit population is 82.79%; under the 2km reachable radius, the deficit ecological land area for leisure and recreation services in Nanjing is 65.1%, and the deficit population is 94.67%, which further aggravates the contradiction between supply and demand; under the 5km and 10km reachable radii, the deficit ecological land area for leisure and recreation services in Nanjing is 65.1%, and the deficit population is 94.67%, which further aggravates the contradiction between supply and demand. In 5 and 10km accessible radius, the deficit ecological land area of leisure and recreation services accounted for 24.52% and 21.63% respectively, and the deficit population accounted for 68.12% and 64.11% respectively, the supply and demand relationship improved significantly, and the relationship of leisure and recreation services in Gaochun District turned from deficit to surplus, the overall supply and demand relationship of leisure and recreation services in Nanjing is better, and the leisure and recreation services provided by ecological land basically meet the demand of the people.

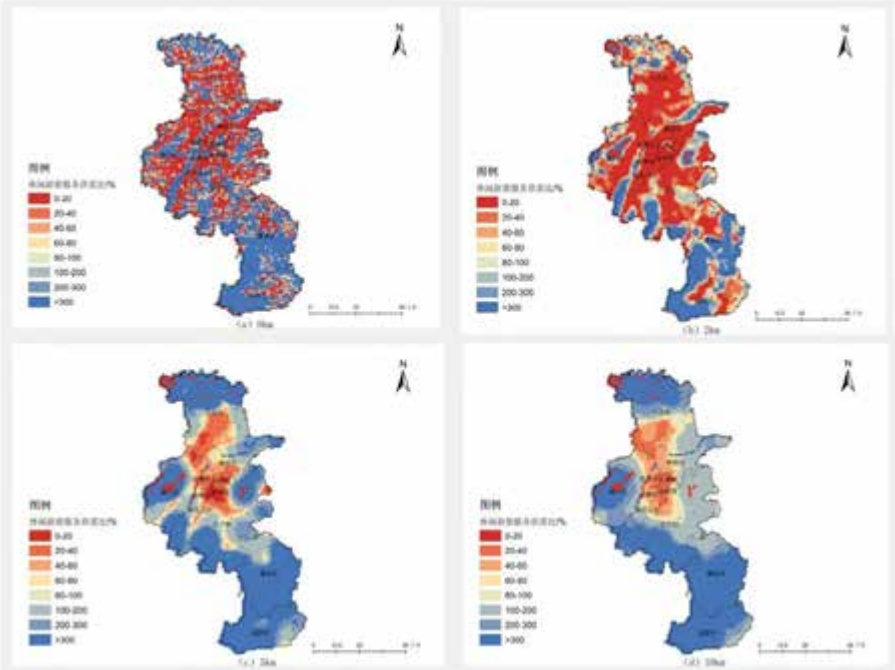

Figure 3 Supply and demand ratio fleisure and recreation services under different reachable radii in various administrative regions of Nanjing in 2020

4.4 Analysis of the changing pattern of supply and demand of recreational and leisure services in Nanjing's administrative districts

The city center is generally the most prosperous area for economic, cultural and transportation development of a city. Under the background of industrialization, the proportion of ecological land has been decreasing, and as the proportion of construction land gradually rises, the number of leisure and recreational services that can be provided by ecological land also decreases accordingly. At the same time, due to the high population density in the urban core area, the residents have a high demand for quality life, which, of course, covers the urgent need for leisure and recreation services. On this basis, the study selects the grids with more than 50% of built-up land in Nanjing as the research objects, and statistically analyzes their supply and demand ratios of leisure and recreation services under different accessible radii, in order to demonstrate the supply and demand situation of leisure and recreation services in various administrative districts in Nanjing. Considering the changing pattern of supply and demand of leisure and recreation services in Nanjing under different conditions of reachable radius, this study divides the administrative districts of Nanjing into four different categories.

Locally satisfied administrative districts refer to the administrative districts with supply and demand ratios close to 100% under the 2km accessibility radius, and there is one such district, i.e. Lishui District. Lishui District has a large area of ecological land and a good relationship between the supply and demand of leisure and recreation services. It should continue to maintain this favorable trend and vigorously develop tourism and ecological industries to meet the increasing demand of residents for leisure and recreation services.

Medium-distance-satisfying administrative districts refer to those administrative districts with balanced supply and demand within a 5km accessibility radius, and there are three of them, mainly located in the suburbs of Nanjing. Some of these administrative districts have a large area of ecological land, but the population density of the area is small, the total demand for recreational and leisure services is low, and the layout of ecological land is unreasonable, so that residents can enjoy the recreational and leisure services provided by ecological land less conveniently, such as in Gaochun District, while some of the area of ecological land is smaller, but the population density of the area is even smaller, such as in Pukou and Jiangning Districts. In the future ecological land use planning, not only should the decentralized layout of green spaces in the administrative districts be

strengthened to enhance the accessibility of the region, but the supply of recreational and leisure services in the deficit areas of the region should also be expanded, e.g., by adding more recreational and leisure venues.

Distance-satisfying administrative districts refer to those administrative districts where a balance between supply and demand exists within a 10-km accessible radius, of which there is one, i.e. Qixia District. The relatively small area of ecological land in Qixia District has resulted in a serious imbalance between supply and demand of leisure and recreational services. Therefore, the construction of pocket parks should be actively promoted and a dedicated tourism line should be established with the geographically close Liuhe District to meet the diversified demand for leisure and recreation services of residents in Qixia District.

Unsatisfiable administrative districts refer to areas where the supply and demand for leisure and recreation services is always below 100% within an arbitrary radius, and there are 6 such districts, which are mainly concentrated in the central urban area of Nanjing, and the leisure and recreation services provided by ecological land in the area are always unable to satisfy the demand of the residents. These districts should develop areas that can provide leisure and recreation services without affecting the city's economic development, create pocket parks and micro-green spaces, expand leisure and recreation spaces within the neighborhoods, and increase the area's green coverage rate, so as to improve the contradiction between the supply and demand of leisure and recreation services in the area and enhance the well-being of the residents.

District Name	0km	2km	5km	10km
Gaochun District	45.92	24.35	504.53	867.11
Gulou District	54.93	3.91	36.3	40.66
Jian YE District	22.63	4.88	45.8	49.41
Jiangning District	82.17	13.75	149.98	154.31
Lishui District	94.05	14.35	288.42	392.65
Liuhe District	44.11	9.68	60.11	65.05
Pukou District	56.71	13.54	146.67	145.14
Qixia District	51.52	11.36	93.57	100.97
Qinhuai District	18.65	1.18	19.22	44.55
Xuanwu District	42.96	3.96	41.01	57.58
Yuhuatai District	25.26	7.93	85.89	91.11

Figure 4 Supply and demand ratio fleisure and recreation services under different reachable radii in Nanjing administrative region in 2020

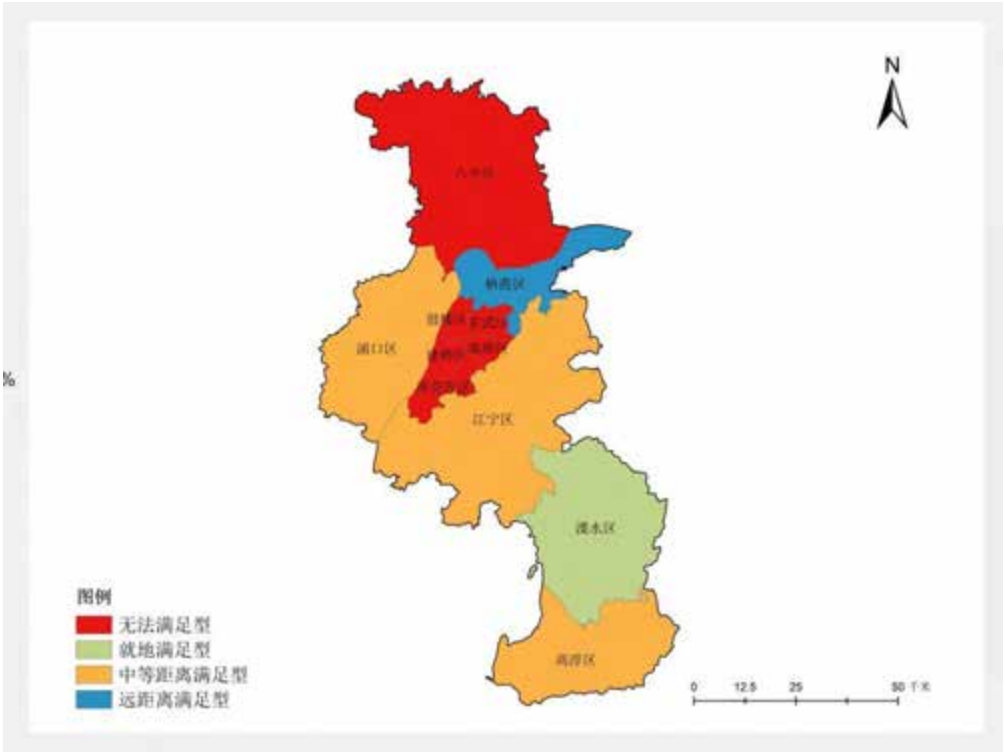

Figure5 Supply and Demand of Leisure and Recreation Services in Various Administrative Regions of Nanjing City in 2020

V. Conclusion and Outlook

This study utilizes land use and demographic data, and utilizes a methodology for assessing the supply and demand relationship of regional recreational and leisure services under different accessibility radii. It also examines the changes in the supply and demand relationship of recreational and leisure services in various administrative districts of Nanjing in 2020, and explores the spatial distribution of the supply and demand relationship under different accessibility radii, and the following are the main findings:

The supply and demand relationship of leisure and recreation services in Nanjing is characterized by very obvious regional characteristics, which is mainly closely related to the geographic location, population density, ecological land layout and urban planning of different regions. Firstly, high demand areas are mainly concentrated in the administrative districts of the city center. These districts are usually the centers of economic, cultural and social activities, attracting a large number of people to gather. Due to the limited nature of land resources, the area of ecological land in these districts is relatively small, and the construction of leisure and recreational facilities is also restricted. As a result, despite the high demand for leisure and recreation services, the supply is relatively low, leading to an imbalance between supply and demand. In contrast, high supply areas are located in the urban outskirts. These areas are less densely populated and relatively rich in land resources, and hence have more space for leisure and open space facilities. However, the layout of ecological land in these areas may not be rationalized. For example, some of the recreational open spaces may be too dispersed or far away from the residential areas, making it inconvenient for residents to use them. In addition, some of the leisure and open spaces may lack the necessary ancillary facilities and services, thus affecting their service quality and attractiveness.

When the reachable radius gradually expands from 2km to 10km, the supply and demand relationship in NJ shows a significant improvement. Such an improvement is mainly manifested in the gradual reduction in the size of the deficit area and the continuous decline in the number of people with unmet demand for leisure and recreation services. Firstly, the expansion of the accessibility radius means that residents can enjoy leisure and

recreation service facilities more conveniently, and service areas that might have been difficult to reach due to long distances are now within reach due to the expansion of the accessibility radius. As a result, the imbalance between supply and demand in the service areas has been effectively alleviated, and the size of the deficit areas will naturally be reduced accordingly. Secondly, with the reduction in the size of the deficit areas, those residents who were originally unable to enjoy leisure and recreation services due to the distance problem are now provided with more choices and their needs are better met, thus the number of people with unmet demand for leisure and recreation services is also decreasing. In addition, the expansion of the radius of accessibility may bring about a series of knock-on effects. For example, as the accessibility of service facilities improves, more people may be willing to visit these facilities for consumption, thus further stimulating the development of related industries. At the same time, the utilization rate of service facilities will also be improved, which will help to achieve optimal allocation of resources.

Based on the spatial distribution characteristics of leisure and recreation services in Nanjing administrative districts under different accessibility radii, we subdivided them into four different categories of areas: locally satisfied, moderately satisfied, distantly satisfied, and unsatisfied, and put forward targeted development proposals respectively. The supply and demand of leisure and recreation services in locally satisfying and moderately satisfying regions are relatively balanced, and can meet the basic leisure and recreation needs of residents, and the creation of urban "green space" should be continuously strengthened to enhance the connection with the city center administrative region, and create a more attractive leisure and recreation brand by combining with the regional characteristics; the long-distance satisfying and unable to satisfy regions should strengthen infrastructure construction and rationalize the distribution of leisure and recreation services. Distance-supporting and non-supporting regions should strengthen infrastructure construction, rationalize the distribution of ecological land, improve connectivity and accessibility between different administrative regions, and at the same time, strengthen ties and cooperation with the outside world, introduce high-quality recreation and leisure resources and technologies, and promote the improvement of the relationship between supply and demand of regional recreation and leisure services.

At the same time, this study is innovative in terms of research perspectives and ideas: on the one hand, it fills the gap of research on the supply and demand relationship of recreation and leisure services at the level of city districts; on the other hand, it systematically analyzes the characteristics of changes in the supply and demand and puts forward suggestions for improvement, which is of practical guidance significance. However, there are some shortcomings in the study: the assessment of supply is only based on area, ignoring the quality of service; road accessibility is not taken into account, which may overestimate the actual supply; the determination of the accessible radius does not adequately reflect the willingness of the residents to travel; and the standard of demand lacks uniformity. Future research should construct a comprehensive supply evaluation system, introduce road accessibility analysis, incorporate residents' willingness to travel surveys, and improve the demand volume standard, in order to enhance the scientific and applicability of the assessment and provide more accurate support for urban planning.

Evaluating Public Space Resilience: an index and a case study

Marichela Sepe
DICEA- Sapienza Università di Roma- ISMed-CNR
marichela.sepe@uniroma1.it

Abstract
Urban resilience is a critical concept in urban planning, yet it often blurs the line between crisis-triggering events and adaptive processes. To address this, the concepts of multiresilience and multiadaptation clarify how public spaces can handle multiple, overlapping risks. Multiresilience focuses on restoring pre-crisis conditions through inclusive, place-specific strategies, while multiadaptation emphasizes adjusting to unforeseen risks by achieving a new, often improved, equilibrium. This study introduces the Multiadaptation Place Index (MPI), a tool developed under the PRIN 2020 SUMMA research project to measure the adaptability of public spaces. The MPI assesses physical, social, and infrastructural factors to guide planners in designing inclusive, flexible interventions. The Hudson River Park in New York serves as a key case study, illustrating how adaptable urban spaces can enhance resilience and liveability under multi-risk scenarios.

Key words: Public space, resilience, liveability, inclusion

Main factors resilient planning

The implementation of resilient planning necessitates a shift from traditional, top-down approaches to more flexible, inclusive, and iterative processes. Key factors in this approach include inclusivity, flexibility, redundancy, diversity, and local knowledge (Banica et Al., 2020; Cutter et Al., 2003; Davoudi et Al., 2012). Inclusivity in planning ensures that all voices are heard, and the needs of marginalized groups are addressed. This can be achieved through participatory planning processes that engage community members in meaningful ways. Workshops, questionnaires, public consultations, and collaborative platforms can facilitate this engagement, allowing stakeholders to contribute their knowledge and perspectives. In areas facing multiple and overlapping risks—such as climate change, economic shocks, and social instability—inclusivity becomes even more critical, as it allows for the identification of vulnerabilities that may otherwise be overlooked and for the co-creation of solutions that are context-specific and equitable.

Flexibility in urban planning involves designing infrastructures and policies that can be easily adapted or modified in response to changing conditions. This might include the use of modular construction techniques, adaptable public spaces, and policies that can be updated based on new information or emerging risks. Flexibility ensures that urban systems remain responsive and resilient in the face of uncertainty. In multi-hazard environments, flexibility is essential to accommodate the dynamic nature of risks, where simultaneous or sequential shocks (such as floods followed by disease outbreaks) demand rapid and coordinated responses.

Redundancy involves creating multiple pathways and backup systems to prevent total system failure. In practice, this might mean designing urban transportation networks with multiple routes and modes of transport, ensuring that critical services like healthcare and communication have backup systems, and developing decentralized energy systems that can operate independently in case of a central grid failure. Redundancy in multi-risk contexts enhances the capacity to absorb disturbances without catastrophic collapse and provides the time needed to implement recovery measures.

Diversity in risk management strategies increases the likelihood that at least some solutions will be effective in any given scenario. This could involve a mix of structural and non-structural measures, such as building flood defences while also enhancing natural floodplains, promoting economic diversification to reduce reliance on a single industry, and fostering social networks that can provide support during crises. Diversity strengthens adaptive capacity by offering a portfolio of responses, reducing the risk of overdependence on any single system or approach (Benedict et Al., 2006; Jabareen, 2013). Local Knowledge and Practices are invaluable resources for urban resilience. Traditional and local knowledge often contain insights into sustainable practices

and risk management that have been developed over generations. Integrating this knowledge with modern technologies and practices can lead to more culturally appropriate and effective solutions. In multi-risk settings, local knowledge can reveal interconnections between hazards that are not always captured by scientific assessments, providing a more holistic understanding of vulnerability and resilience. Furthermore, resilience in multi-risk environments is defined not only by the capacity to withstand individual hazards but also by the ability to navigate the interactions between them. This requires a systemic perspective that accounts for cascading effects, compound risks, and long-term transformations. Adaptation, in this context, entails iterative learning processes, where actors engage in cycles of experimentation, monitoring, and adjustment. Adaptive governance mechanisms—such as flexible regulatory frameworks, polycentric institutional arrangements, and cross-sectoral coordination—play a crucial role in enabling timely and effective responses to complex risk landscapes.

Moreover, building resilience in places exposed to multiple hazards necessitates fostering social resilience, which includes strengthening community networks, enhancing social capital, and promoting inclusive decision-making. Socially resilient communities are better able to mobilize collective resources, disseminate information, and maintain trust in times of crisis (Birkmann, 2013; Bohland et Al., 2019; David, 2006; Folke, et al., 2010; Horton et Al., 2015; Meerow et Al., 2016). To design effectively in these places, an appropriate methodology must be used. This methodology, developed within the framework of the SUMMA research project PRIN2020 #20209F3A37, will be presented below, along with the Multiadaptation Place Index case studies and the core principles for multiadaptation design.

Multiadaptation Place Design

The methodology created to evaluate spaces subject to multiple risks is structured into ten precise phases: six dedicated to analysis and four to strategic planning. Its primary aim is to uncover current or potential hazards—whether separate or interconnected—that may impact public spaces, while also tracing their root causes, assessing users' perceptions, and proposing adaptive interventions to upgrade both resilience and quality. This process produces two detailed mosaics and the Multiadaptation Place Index (MPI). One mosaic consolidates all gathered data on risks, contributing factors, and perceptions; the other offers proposals for adaptation and enhancement. The MPI gauges a site's capacity to cope with multiple hazards while improving its assets.

The opening phase focuses on diagnosing the area to identify present or foreseeable urban hazards, using a standardized observation tool that classifies risks as minor, moderate, or critical. The risks observed may range from physical decline, environmental degradation, socio-cultural threats, human-induced hazards, and seismic dangers to public health issues, poor quality of life, insecurity, and erosion of local identity. The objective is to build a detailed risk profile by systematically mapping and categorizing these aspects.

In the subsequent stage, attention shifts to evaluating the drivers and conditions that shape or might shape these risks. Qualitative observation helps expose underlying factors, such as how mismanaged waste amplifies environmental harm or how fragmented social ties exacerbate insecurity. This phase is key to capturing the intricate relationships within the urban fabric.

The third stage assesses the impacts of risk overlap in a single location, compiling a database that logs each risk, its interplay, and the magnitude of cumulative effects, graded as low, medium, or high. For instance, an area facing both seismic threats and identity loss may struggle to function as a communal space, as insecurity and detachment erode its role. This offers a quantitative grasp of how layered risks undermine urban vitality and shapes targeted remedies.

Step four collects data on risk perception via surveys, exploring how individuals interpret and experience these hazards, whether they consider them transient or entrenched, and how they believe they can contribute to mitigation. The survey covers overall site impressions, evaluations of specific risks, their perceived permanence, and ideas for civic involvement, plus feedback on space quality.
The fifth phase entails reviewing existing plans, strategies, and policy tools relevant to the area, compiling a

mosaic that visualizes ongoing measures across sectors and scales. This informs the orientation of future actions.

The sixth stage identifies key local assets, from heritage landmarks to open areas, parks, and historical urban patterns, blending their presence and functions to evaluate both their value and adaptability. A neglected historic square, for example, may hold potential for revival through targeted upgrades. This produces a mosaic visualizing these quality features and functions as a foundation for future proposals.

Phase seven integrates the entire body of findings—identified risks, drivers, survey outcomes, and quality components—into a composite mosaic, creating a panoramic view of the multi-risk environment and offering a critical reference for planning.

In step eight, the process assesses the adaptability of the space using the composite mosaic, spotlighting zones where flexible transformation is feasible and where urgent action is needed to boost usability and safety. For example, an overlooked green area may be earmarked for community resilience initiatives. This stage leads directly to the formulation of the MPI.

The ninth step devises Multiadaptation interventions tailored to the areas highlighted previously, aiming both to tackle present and future risks and to enrich public space quality. This culminates in a mosaic displaying specific, context-sensitive strategies for urban renewal, ensuring a coherent and comprehensive approach to resilience.

The final phase calculates the Multiadaptation Place Index, which appraises how well urban subareas can respond to concurrent hazards, including unforeseen disruptions.

The MPI is a robust tool to assess the multi-resilience and adaptive capacity of urban settings. It delivers a holistic diagnosis of how effectively different zones manage risks, considering unanticipated changes. The index evaluates key aspects: risk exposure, adaptive capacity, response strategies, recovery potential, and participatory engagement.

Risk exposure gauges how intensely an area faces diverse hazards—natural (earthquakes, floods), socio-economic (poverty, unemployment), or related to urban liveability (health, accessibility, green spaces). Adaptive capacity refers to how social, economic, spatial, and infrastructural systems adjust to changing conditions. A city with dense social ties, varied economies, and resilient infrastructure typically scores high.

Response mechanisms assess the adequacy of risk management plans and grassroots initiatives, measuring their effectiveness across scenarios. Recovery potential captures a place's ability to bounce back and sustain functionality post-shock, influenced by resource availability, institutional strength, and infrastructure resilience, turning crises into opportunities for cultural and social regeneration.

Participation measures how extensively stakeholders—from government bodies and businesses to communities and individuals—engage in resilience strategies. High participation levels point to an inclusive, collaborative mode of adaptation, enhancing co-design with all actors involved.

Accordingly, the MPI is computed using the comparative assessment derived from the composite mosaic in step eight, spotlighting areas with the most significant adaptive potential. Key variables include actual and perceived risks, underused public spaces, streets suitable for pedestrian and cycling routes, tangible and intangible cultural resources, and nearby but connected public spaces.

Each factor is weighted (1–5), and the final score reflects the difference between the risk load and flexibility assets, yielding an index between 1 and 50, where 1 signal minimal potential and 50 maximal potential. For example, an area facing environmental, depopulation, and isolation risks totalling 15, but with 50 points in adaptive resources, scores 35 (50-15). This quantifies a site's capacity for dynamic adaptation and improvement. The MPI can be

applied across contexts to guide resilience strengthening. In a coastal city battling sea-level rise and economic decline, the MPI can help pinpoint vulnerable zones and craft tailored solutions, like coastal defences or economic diversification. In fast-expanding cities, it can highlight gaps in housing, public services, and sustainability, shaping interventions such as affordable housing, vibrant public spaces, and green infrastructure.

Case study

In order to both experiment the method and the relative MPI-Multiadptation Place Index, the case of the renovated Hudson River in New York will be reported.

New York City, in the last years is facing major risks from climate change: rising sea levels, more frequent extreme weather events, and urban heat island effects continually threaten the city. To confront these challenges, New York has crafted and carried out a set of resiliency strategies designed to prepare the city for future climate impacts while safeguarding residents and vital systems. These efforts centre on strengthening infrastructure, enhancing adaptive capacity in neighbourhoods, and embedding sustainability in urban policies.

One of the key approaches for climate resilience in New York City is the "OneNYC" plan, launched in 2015 and updated in 2019. This plan's goal is to make the city fairer, greener, and stronger against climate risks ahead. A critical part of OneNYC (New York City Mayor's Office of Sustainability, 2020) is reducing threats posed by rising sea levels and storm surges. As reported by the New York City Panel on Climate Change (NPCC), sea levels around the city could rise up to 30 inches by 2050. To address this, the city has invested in coastal defence projects, notably the East Side Coastal Resiliency (ESCR) project, a $1.45 billion undertaking to reinforce lower Manhattan against storm surges and rising tides. Besides coastal defences, New York has also prioritized green infrastructure to tackle flooding, heat hazards, and enhance urban quality of life. Green infrastructure includes the use of natural systems like parks, green roofs, and rain gardens to absorb rainfall and lessen pressure on city sewers during storms. This strategy not only limits flooding but also cools areas affected by the urban heat island effect, where dense built environments retain heat and increase temperatures. The Resilient Waterfront initiative in New York City is a cornerstone of the city's wider strategy to confront climate change, guard against sea-level rise, and reduce the effects of extreme weather. With more than 520 miles of shoreline, New York is acutely exposed to climate risks, as highlighted by the destruction caused by Hurricane Sandy in 2012. In response, the city has launched multiple strategies to reinforce its waterfront, improve public access, and sustain economic activity. One of the centrepiece projects is the East Side Coastal Resiliency (ESCR) project, a $1.45 billion investment blending flood defence infrastructure with upgraded public amenities along the waterfront. Spanning East 25th Street to Montgomery Street in Manhattan, the project integrates levees, floodwalls, and deployable barriers engineered to withstand a 100-year flood, aiming to shield at-risk neighbourhoods while maintaining public access to waterfront parks and recreation.

Beyond engineered defences, the city has focused on restoring natural ecosystems, which act as living barriers against storm surges. These ecosystems not only buffer floodwaters but also boost biodiversity and strengthen the city's resilience.

Additionally, the Waterfront Revitalization Program (WRP) embeds climate resilience into land-use planning, ensuring that future developments along the shoreline are designed to endure projected climate stresses. This includes requirements for higher building elevations and the adoption of green infrastructure to better manage stormwater and lower flood risks. Bike lanes also play an essential role in New York's green infrastructure agenda. Expanding the protected bike lane network promotes cycling, cutting car dependency and lowering greenhouse gas emissions. Furthermore, more bike lanes help calm traffic, improving safety for cyclists and pedestrians alike. The use of permeable pavement in some lanes allows rainwater to infiltrate the ground, relieving pressure on the city's drainage system and aiding in flood control. By encouraging cycling as a sustainable transport option, New York not only reduces its carbon footprint but also develops a more resilient transportation system capable of weathering climate disruptions. Indeed, New York's green infrastructure plans extend far beyond traditional parks, encompassing waterfronts and urban spaces like parklets, bike lanes, and pedestrian plazas. The inclusion

of these kind of public spaces constitutes a comprehensive approach to not only manage climate risks but also to enhance the quality of life for the city's residents. These urban design features foster healthier (Sepe, 2023), more liveable communities, while also contributing to New York's long-term sustainability and resilience in the face of increasing climate challenges. By leveraging every available space, whether it's a former parking spot, a small alley, or a city street, New York is leading the way in rethinking how cities can adapt to a changing climate while improving urban life.

This approach not only mitigates flooding but also helps to lower temperatures in areas affected by the urban heat island effect and improve urban health and liveability. A key example is the Green Infrastructure Program, which has already implemented hundreds of green projects across the city, reducing flood risks and improving urban air quality (Horton et Al., 2015; New York City Department of City Planning, 2021; New York City Environmental Protection, 2020; New York City Mayor's Office of Recovery and Resiliency, 2020; New Yorkers for Parks, 2001; Vardı Topal, Franck, 2023).

Hudson River Park

Hudson River Park stretches along the west side of Manhattan, from 59th Street down to Battery Place. Covering 550 acres of land and water, this unique park is the second-largest park in Manhattan after Central Park (New York City Department of City Planning, 2021; Pallarés, 2021).

As regard the first step of the protocol, the identified risks are the following.Hudson River Park, situated directly on the waterfront, is particularly vulnerable to flooding during extreme weather events. The low-lying sections of the park, particularly those close to historic piers, are at a high risk of inundation during storms.

The second identified risk is the urban heat island effect. Surrounding buildings, roads, and other urban infrastructure absorb and retain heat, causing temperatures in the park to rise significantly, especially during summer months. The park's open layout, while ideal for recreational activities, provides little protection from the heat in certain sections.

The third risk is the overcrowding. The park's pathways, particularly the bike lanes and pedestrian paths, is sometimes congested, especially on weekends and during events. This foot traffic could reduce the quality of the visitor experience and put strain on the park's infrastructure, from benches to lawns to waterfront facilities. After identifying the main risks, it is crucial to analyse the factors that contribute to or amplify these risks in Hudson River Park.

Proximity to the Hudson River, while offering opportunities for recreation, is also the primary factor contributing to flooding and coastal erosion. Its location directly exposed to the river makes the park vulnerable to storm surges and rising sea levels.

Global climate change is already having a tangible impact on New York City, and Hudson River Park is no exception. The effects of climate change, particularly rising sea levels and increasing storm intensity, are making coastal flooding more frequent.

Much of the park's infrastructure, including the renovated historic piers and bike paths, is subject to wear and tear due to exposure to natural elements.

Fig.1 New York, Hudson River Park (Source: Marichela Sepe Archive's)

Fig.2 New York, Hudson River Park view (Source: Marichela Sepe Archive's)

Fig.3 New York, Hudson River Park detail (Source: Marichela Sepe Archive's)

Frequent storms and erosion can accelerate the deterioration of structures, making them vulnerable to more significant damage.

In the third step, we analyse how risks might coexist and interact in Hudson River Park, creating potentially more severe effects when occurring simultaneously.

Flooding + Coastal erosion: when flooding and erosion occur simultaneously, they can cause significant damage to the park's infrastructure. Areas along the river, already subject to erosion, become more vulnerable during floods, and storm surges can accelerate the loss of land along the park's coast.

Flooding + Crowding: during extreme weather events like storms, the park may become impassable or dangerous for visitors. Crowding can hinder evacuation and emergency management, making it difficult to protect citizens who use the park as a temporary shelter or escape route.

Extreme heat + Crowding: during summer heatwaves, the risk of heat-related problems increases significantly, especially in crowded areas like Hudson River Park. The lack of shade and the large number of visitors can create no too liveable conditions, particularly for the elderly and children.

In the Risk Perception Questionnaires step, questionnaires were administered to 50 users of the place aging between 30 and 65 years old to assess how visitors to Hudson River Park perceive the risks of flooding, erosion, overcrowding, and extreme heat in the park.

Results of questionnaire showed that visitors are aware of the flooding risks, especially after events like Hurricane Sandy, but awareness of the long-term risks associated with climate change may be less widespread.

Many visitors see crowding as an annoyance rather than a safety risk, underestimating the importance of proper crowd management, especially during emergency events.

Finally, the perception of heat risks is underestimated, with many visitors not fully understanding the dangers of heatwaves, particularly in highly frequented public spaces.

In the step 5, Analysis of Plans, Programs, and Policies were identified. Hudson River Park benefits from several plans and programs designed to improve its resilience, many of which are part of New York's broader coastal

resilience strategy. These include the following. Hudson River Park Trust Initiatives: the Hudson River Park Trust, the entity that manages the park, has implemented various measures to enhance the park's resilience. These include creating flood-resistant infrastructure and protecting natural areas from erosion. The Lower Manhattan Coastal Resiliency Project: as part of the broader Lower Manhattan Coastal Resiliency initiative, this project involves developing flood barriers along the coastline, including parts of Hudson River Park. The goal is to protect both public and private infrastructure from storm surges and rising sea levels. The NYC Climate Resiliency Initiatives: the City of New York has developed a climate resilience plan that includes measures to protect urban green spaces like Hudson River Park from flooding and other extreme weather events. These plans involve improvements in green infrastructure, such as the installation of sustainable drainage systems and the reinforcement of coastal areas (New York City Department of City Planning, 2021; New York City Environmental Protection, 2020; New York City Mayor's Office of Recovery and Resiliency, 2020).

As regard, step 6: Potentialities and Qualities, the Park has many piers of the park and many large public spaces. Furthermore, there is both a beautiful natural environment and a beautiful skyline with the main skyscrapers view. The park's natural areas, such as the wetlands and planted areas along the river, are valuable resources for absorbing rainwater and improving urban biodiversity. There are also many equipment and furniture for free time and sport activities, and off-leash spaces for dogs. Finally, Hudson River Park, with its location and ecological features, is an ideal site for educational programs on climate change and sustainability. Visitors could learn more about environmental challenges through informative installations and educational tours.

In step 7 multi-risks areas are identified, including: coastal flood zones, namely the sections along the lower piers and close to the river would be highlighted as areas subject to more frequent flooding; the crowding areas, namely the high-traffic areas, such as those around recreational piers and bike paths, would be marked as risk zones for crowd management; the erosion hotspots, namely the sections of the park most exposed to coastal erosion would be mapped to identify where structural interventions are needed to prevent future damage.

The multi-adapting areas identified in step 8, include as follows. Multifunctional piers: piers that could be adapted to withstand flooding, with spaces that can be temporarily submerged during storms and used for events and activities during the rest of the year. Adaptive green zones: the park's green areas, particularly the planted sections along the coast, could be transformed into flexible zones, where flood-resistant vegetation and natural drainage interventions can help mitigate flood risks.

Based on the previous steps, the identified multi-adaptation project interventions include measures for water management. This could involve installing systems to collect and manage rainwater along pedestrian paths and bike lanes during storms. Additionally, flood-resistant zones could be created by designing adaptable spaces that can temporarily flood during storms, reducing the risk to surrounding areas. Another intervention is the installation of movable barriers: temporary barriers along the park's coastline that can be raised during storms to protect critical infrastructure and visitors.

The collected information enabled the calculation of the Multiadaptation Place Index (MPI) of step 10 of the protocol, a tool designed to assess the resilience and adaptive capacity of complex urban contexts (Sepe, 2023; Sepe, 2024). This is calculated using the assessment derived from the risks and highlighting the areas with the greatest adaptive potential. The first phase, focused on risk identification, highlights three primary hazards affecting Hudson River Park. These include flooding and sea-level rise, where the low-lying areas and historic piers face particular vulnerability during extreme weather events; the urban heat island effect, driven by surrounding dense infrastructure and a lack of shade in some sections, leading to significant temperature increases during summer months; and overcrowding, where the park's bike and pedestrian paths often experience congestion, particularly on weekends or during events, which strains the park's infrastructure and diminishes visitor experience.

In the second phase, it was observed that the park's proximity to the Hudson River, while offering recreational opportunities, also makes it highly susceptible to flooding and coastal erosion. Moreover, the park's infrastructure

is subject to wear from constant exposure to natural elements, heightening the risk of accelerated structural deterioration.

The risk perception among users revealed widespread awareness of flooding, but an underestimation of the risks linked to crowding and extreme heat, underscoring a gap in public understanding of these hazards.

The park's potentialities and qualities, highlighting multifunctional piers adaptable to controlled flooding, adaptive green zones planted with flood-resistant vegetation and equipped with natural drainage, a wide range of recreational facilities, off-leash areas for dogs, and significant potential for environmental education programs addressing climate change and sustainability.

In phase seven, risk mapping highlights coastal flood zones concentrated around the lower piers, crowding-prone areas along the recreational piers and bike paths, and erosion hotspots located along the waterfront, pinpointing where future structural interventions will be most needed.

Phase eight delineates multi-adaptation areas, such as multifunctional piers that can be submerged temporarily during storms and serve as event spaces in calmer periods, and adaptive green zones designed to absorb excess rainwater through resilient vegetation and natural drainage systems.

The calculation of the MPI results as follows. Risk exposure is rated medium-high due to the combination of flooding, erosion, and heat, with a weight of 10 out of 25. Risk perception is rated medium-low, with a weight of 5 out of 25. The potential, qualities, and flexibility are considered high, reflecting all the existing features, with a score of 50 out of 50.The final score combines the sum of perceived and real risks (15 points) and potential and qualities and flexible areas (50 points), yielding the MPI as 50 (adaptation) minus 15 (risk), equaling 35. This score places Hudson River Park within the high adaptive potential range on a 1–50 scale, signaling its strong capacity to absorb shocks and adapt. This result underscores Hudson River Park's role not merely as a recreational green space but as an emblematic urban site demonstrating how parks can play a pivotal role in metropolitan resilience, helping to mitigate climate risks while enhancing quality of life.

Furthermore, the park's ability to balance social functions—such as sports, leisure, and gathering—with ecological functions—such as biodiversity enhancement and rainwater absorption—positions it as an advanced urban laboratory of multiadaptation, representing a best practice in the design of resilient cities.

Core principles

The diverse case studies used to test this methodology have been instrumental in formulating core principles for multiadaptation planning. These principles are grounded in the notion that risks can be reframed as opportunities to reevaluate and strengthen the qualities of a territory, establishing resilience as a cornerstone of sustainable regeneration. The case studies include Cittaducale and Leonessa in Lazio, alongside Siena, Naples, Paris, Madrid, Copenhagen, and New York. These locations were selected due to the presence of various actual or potential risks: Cittaducale and Leonessa are vulnerable to earthquakes and population decline; Siena, Naples, and Madrid's historic centres grapple with the impacts of mass tourism and globalization; Copenhagen and New York confront flood threats and the erosion of local identity; while Paris faces challenges related to flood and overtourism.

Risk identification should encompass both isolated hazards and combinations of potential simultaneous events. This integrated perspective allows planners to anticipate complex situations where different risks overlap. For example, a city may confront floods, declining liveability, and infrastructure breakdowns all at once. By examining risks holistically, planners can develop more cohesive resilience strategies, using tools like risk matrices and scenario modelling to rank and address threats effectively.

Grasping how people perceive risk is a fundamental aspect of hazard analysis. This requires carefully crafted surveys that capture the subtle differences in how diverse user groups understand and respond to threats.

These instruments should be inclusive, ensuring representation across age, gender, social class, and cultural background. The insights gathered can shape communication strategies and interventions that are more responsive to community concerns and expectations.

Special attention must be paid to vulnerable populations—such as the elderly, children, people with disabilities, and those with chronic health issues—both when assessing risk perception and when designing adaptive measures suited to their needs. These groups typically face heightened exposure and have fewer resources to cope. Adaptation efforts should therefore include provisions like accessible shelters, priority evacuation plans, and tailored healthcare services. Direct engagement with these communities is crucial to understand their needs and to integrate their input into planning.

Surveying urban assets—such as heritage sites, materials, and infrastructure—is essential for designing multi-resilience and adaptation initiatives. These elements should be viewed not as constraints but as opportunities to improve urban liveability. For example, historical buildings can be retrofitted to withstand hazards without sacrificing cultural value, while public parks can double as flood retention areas. Embedding these qualities into resilience planning both preserves local identity and enhances the city's aesthetic and functional appeal.

Continuous monitoring of multi-resilience projects is necessary to anticipate abrupt changes and respond sustainably. This involves deploying advanced technologies—like sensors, satellite monitoring, and data analytics—to observe environmental shifts and urban dynamics in real time. Establishing urban observatories or resilience hubs can help collect and analyse this data, providing early warnings and supporting proactive action. Regular reviews and updates of resilience plans, informed by current data and stakeholder feedback, are also key to maintaining effectiveness.

Flexibility is a fundamental feature of any multi-resilience or adaptation strategy. It must be conceived across scales (from the building to the metropolitan level) and across domains, integrating urban, social, economic, cultural, and ecological dimensions. A flexible urban plan, for example, might include modular housing systems, adaptable green spaces, and policies that permit the swift reallocation of resources during crises. This multi-layered flexibility enhances a city's capacity to adjust to evolving challenges.

The adaptability of public spaces can be greatly strengthened by providing adequate pedestrian and cycling networks. Such infrastructure promotes versatility, accessibility, and broad usability across diverse populations. Encouraging active transportation also advances environmental sustainability by cutting emissions, reducing congestion, and fostering healthier lifestyles. Designing public spaces with these goals in mind helps create dynamic, inclusive environments that support social interaction and improve quality of life.

Accessibility must be prioritized in the design of all public spaces. This means ensuring that every publicly intended area is usable by individuals of all ages and abilities. Eliminating architectural and physical barriers is crucial for enabling access for people with disabilities, seniors, parents with strollers, and others with specific mobility needs. Early-stage design considerations should include ramps, lifts, tactile surfaces, clear signage, and attention to sensory aspects like lighting and acoustics. A strong commitment to inclusivity fosters social participation and integration, creating genuinely open environments.

Multi-resilience and adaptation projects cannot be uniformly applied, even when sites face similar hazards. Each location—whether a historic district, suburban neighbourhood, or redevelopment zone—has distinct features that must be respected. Tailoring interventions to the local context ensures cultural appropriateness, social acceptance, and technical feasibility. For instance, in a historic centre, flood mitigation might focus on preserving architectural heritage, whereas in a suburb, it may emphasize green infrastructure for stormwater management.

Communicating risks, hazards, and resilience plans effectively is essential and should be tailored for audiences of all ages and abilities. Using diverse communication channels—visual materials, interactive media, and clear,

jargon-free language—helps ensure broad accessibility. Public campaigns, educational initiatives, and community workshops can enhance understanding and engagement. Establishing feedback channels is equally important, allowing residents to share concerns and contribute to shaping resilience efforts.

Leveraging emerging technologies is key to improving risk communication. Tools such as Geographic Information Systems (GIS), mobile applications, and social media platforms enable the rapid and precise dissemination of information. For example, GIS can generate interactive hazard maps, mobile apps can deliver real-time alerts, and social media can support two-way communication between authorities and residents, facilitating both outreach and feedback.

Ensuring the transparency and wide dissemination of adopted or planned measures is critical. This can be achieved through dedicated web platforms, mobile apps, social media, sensor networks, and interactive mapping tools. Providing open access to resilience strategies, resources, and emergency protocols builds trust and keeps communities well-informed. Web portals can offer comprehensive documentation; apps can tailor alerts and guidance; and sensors paired with interactive maps can deliver real-time updates on environmental and infrastructure conditions, empowering citizens to make informed decisions during crises.

The integration of a quantitative assessment through the Multiadaptation Place Index (MPI) is crucial. Calculating the MPI enables planners to measure the adaptive capacity of urban areas in the face of multiple risks by synthesizing data on hazards, resources, and flexibility. This index provides an evidence-based foundation for prioritizing interventions and tracking progress over time, supporting more precise and impactful planning decisions.

Redundancy must be embedded into resilience strategies as a core principle. Incorporating overlapping systems and fallback mechanisms—such as multiple transport routes, decentralized energy grids, and backup communication networks—ensures that critical functions are maintained even when one component fails. Redundancy enhances a system's capacity to withstand shocks and reduces the likelihood of cascading failures during crises.

Diversification is essential for strengthening resilience across sectors. Promoting a varied mix of economic activities, social networks, ecosystem services, and infrastructural solutions reduces dependency on single systems and increases the likelihood that some components will continue functioning during disturbances. For example, combining grey and green infrastructure for flood management or fostering economic sectors beyond tourism helps cities better cope with uncertainty and evolving threats (Pelling, 2011; Slovic, 2000; Vale, 2014).

Observation on the MPI

The application of the Multiadaptation Place Index (MPI) to Hudson River Park provides an insightful quantitative and qualitative assessment of the park's resilience and adaptive capacity in the face of multiple risks.

The MPI was developed as part of a comprehensive protocol to evaluate spaces subject to multiple, often overlapping hazards. In the case of Hudson River Park, the assessment followed a sequence of diagnostic phases, beginning with the identification of three primary risks: flooding and sea-level rise, the urban heat island effect, and overcrowding. These hazards not only pose independent threats but also interact, creating compound risks such as flood-induced infrastructure failure or heat-related health crises intensified by crowding. This layered risk landscape underscores the importance of using a tool like the MPI, which integrates diverse data to yield a holistic resilience profile.

A critical observation from the MPI analysis is the park's medium-high risk exposure, rated at 10 out of 25. This score reflects the park's inherent vulnerability to environmental hazards and exposure to storm surges. Additionally, the surrounding dense urban environment amplifies heat retention, while heavy usage patterns contribute to infrastructural wear and crowding-related challenges. Importantly, the MPI framework does not

stop at measuring risks alone; it pairs this evaluation with an analysis of adaptive potential.

One of the most significant findings of the MPI assessment is the high score (50 out of 50) attributed to the park's potential, qualities, and flexibility. These assets not only enhance ecological resilience but also support social well-being, making the park a dynamic site for climate education and public engagement.

The MPI further captures the perceptual dimension of risk, as revealed through user surveys. While park users demonstrated relatively high awareness of flooding risks—likely influenced by collective memory of events like Hurricane Sandy—perceptions of overcrowding and heat risks were considerably lower. This mismatch between actual risks and public awareness highlights the importance of integrating risk perception into resilience assessments. By accounting for both objective hazards and subjective experiences, the MPI enables planners to design interventions that are not only technically effective but also socially meaningful.

The final MPI score for Hudson River Park was calculated by subtracting the combined risk score (15) from the adaptation score (50), yielding a total of 35 on a scale of 1–50. This places the park within the "high adaptive potential" range, signifying its robust capacity to withstand shocks, recover from disturbances, and transform over time. This result positions Hudson River Park as a best-practice model for multifunctional urban spaces that balance environmental, social, and infrastructural resilience.

Another key observation is that the MPI does not merely function as a static measurement tool but as a dynamic guide for future action. By mapping multi-risk zones (such as flood-prone waterfronts, overcrowded pathways, and erosion hotspots) alongside multi-adaptive areas (like flexible piers and green zones), the MPI points to specific spatial priorities for intervention. For Hudson River Park, this means focusing on enhancing flood management systems, expanding shaded and permeable surfaces, improving crowd management strategies, and developing public education initiatives on climate risks.

The MPI also promotes a systemic understanding of resilience, emphasizing not just the park's ability to resist individual hazards, but its capacity to navigate the complex interactions among them. This requires ongoing monitoring, iterative learning, and cross-sectoral collaboration—elements that are embedded within the MPI's multidisciplinary approach. Furthermore, the MPI's integration of ecological, social, and infrastructural variables makes it particularly well-suited for multifunctional spaces like Hudson River Park, where diverse functions coexist and reinforce each other.

The application of the MPI to Hudson River Park demonstrates how this tool can offer a comprehensive resilience assessment that integrates risk exposure, adaptive capacity, flexibility, and public perception. As climate change continues to reshape cities worldwide, tools like the MPI is useful for guiding interventions that are adaptive, inclusive, and forward-looking, transforming public spaces into vital assets for urban resilience.

Conclusion

The case of Hudson River Park in New York City illustrates the importance of adopting a multiadaptation approach in the design and management of urban public spaces exposed to multiple risks. As shown by the analysis, the park faces a complex risk landscape—including coastal flooding, erosion, the urban heat island effect, and overcrowding—which are increasingly intensified by global climate change. However, what emerges most significantly from this study is not only the park's vulnerability but its considerable potential as a resilient and adaptive urban space.

A key conclusion from this research is that resilience planning in urban environments like Hudson River Park requires a shift away from traditional, top-down approaches toward more inclusive, flexible, and iterative processes. This shift is essential to adequately address the dynamic and interconnected nature of risks facing urban areas today. Inclusivity, as underscored in contemporary resilience literature (Banica et al., 2020; Cutter et al., 2003; Davoudi et al., 2012), must become a cornerstone of resilient planning. This means that the engagement

of diverse stakeholders—including local communities, visitors, marginalized groups, and institutional actors—should not be a mere formality but an integral part of decision-making processes. Participatory mechanisms such as surveys, workshops, public consultations, and co-design platforms can help uncover overlooked vulnerabilities and generate locally relevant solutions. Furthermore, Hudson River Park's multifunctional piers, adaptive green zones, and potential for temporary floodable spaces exemplify how flexibility can be translated into physical infrastructure. Policies should similarly allow for adaptability, enabling the park's management to adjust operational strategies as new risks emerge or as conditions change over time. Hudson River Park also benefits from a combination of engineered interventions and nature-based solutions. This portfolio approach reduces dependency on any single measure and improves the park's capacity to respond to a wide range of contingencies.

The methodology employed offers a robust framework for diagnosing complex risk environments and identifying adaptive capacities. The ten-phase protocol—spanning from risk identification and analysis of drivers to perception assessment, quality evaluation, risk mapping, and the formulation of adaptation strategies—provides a holistic approach that balances technical, social, and ecological dimensions. The MPI, by quantifying the difference between risk exposure and adaptive assets, delivers an evidence-based assessment of a site's resilience potential. In the case of Hudson River Park, the final score of 35 out of 50 places the park in the high adaptive potential category.

The broader lessons drawn from this case resonate with international experiences in resilience planning, as seen in the SUMMA research project and other case studies across Europe and North America. Whether in Cittaducale and Leonessa confronting seismic risks, or in Copenhagen and Paris addressing flooding and overtourism, the principles of inclusivity, flexibility, redundancy, diversity, and local knowledge remain central to effective adaptation.

In conclusion, Hudson River Park stands not merely as a green recreational space but as an emblematic case study for urban resilience and adaptive design. It demonstrates how parks and public spaces can move beyond their traditional roles, becoming good practice for sustainability, liveability, and climate adaptation.

Urban Street Space in Planning Transformation: Analyzing and Optimizing the Quality Differences between Subjective and Objective Perspectives—A Case Study of Xi'an

Mengde Zheng & Tianxin Zhang

Abstract
As the most common public spaces, urban streets are not only vital for daily activities but also a direct reflection of the quality of the urban environment and the inclusiveness of society. In the face of multiple challenges such as global climate change, resource crises, and social inequality, enhancing the spatial quality of urban streets has become crucial for improving environmental sustainability, social inclusiveness, and livability. However, most existing research focuses on either objective environmental features or subjective perceptions, often overlooking the systematic differences between these two aspects and their profound impact on spatial design and planning decisions. In the context of rapid urbanization, how to scientifically and quantitatively identify the differences between subjective and objective quality and develop targeted optimization strategies remains a critical issue that needs urgent attention.

In this study, an innovative spatial quality evaluation framework based on multi-label classification is proposed, integrating deep learning technology and semantic analysis methods. Using the MIT Place Pulse dataset, which includes 110,988 street view images, the Microsoft TrueSkill algorithm quantifies six subjective perception scores for streets, including safety, comfort, and richness. Additionally, using the Cityscapes dataset and the Mask2Former algorithm, the objective features of 28,662 streets in the central area of Xi 'an are semantically segmented, and eight landscape element indicators are extracted from four dimensions: safety, comfort, richness, and convenience. The study reveals that (1) the spatial quality of the main urban area of Xi' an exhibits significant spatial heterogeneity and stratification in both subjective perception and objective physical environment dimensions, with higher scores in the core urban area compared to the peripheral areas. (2) There are significant differences in subjective and objective evaluations across different regions, with weak overall correlation between the two, and some administrative districts even showing statistically significant negative correlation. (3) Most streets exhibit inconsistencies between subjective and objective evaluations, particularly those where 'subjective is better than objective' and 'objective is better than subjective,' with a low proportion of streets achieving high consistency in both subjective and objective evaluations. Therefore, improving the quality of urban streets requires not only focusing on the construction of 'hard environments' but also emphasizing the coordinated optimization of subjective experience and social environment. Through quantitative analysis, this study reveals the key deviations and optimization paths of street space from subjective and objective perspectives, which provides practical basis and theoretical enlightenment for street planning and design under the background of rapid urbanization, and helps to build more inclusive and livable urban public space.

Key words: urban street quality, perceptual difference, deep learning

1. Introduction

As urbanization continues to deepen, street spaces, which are the most immediate public areas in residents 'daily lives, have become a key indicator of a city's livability, sustainability, and social inclusiveness. Streets not only serve as transportation hubs but also function as multifaceted spaces that integrate social, cultural, and ecological elements. Their design and management significantly impact residents 'quality of life and the city's image (Jacobs, 2012; Montgomery & John, 1998). In recent years, with the growing emphasis on a 'people-centered' approach, urban planning and design have increasingly recognized the importance of street spaces in enhancing urban vitality and social interaction (Yu, Zhang, & Zeng, 2019).

Although the measurement of street space quality has become a research hotspot, existing studies still face two main limitations: first, methods that focus primarily on physical environments overlook the importance of residents' subjective perceptions; second, perception studies based on questionnaires or expert ratings lack large-scale, efficient quantitative tools, making it difficult to adapt to rapidly changing urban environments (Tang & Long, 2019; M. Wang et al., 2022). Therefore, there is an urgent need to develop a street space evaluation framework that integrates both subjective and objective perspectives, combining scientific rigor with practical applicability, to reveal systematic differences across various dimensions and provide theoretical foundations and practical approaches for optimizing street design.

This study focuses on the main urban area of Xi 'an City as the empirical region, integrating deep learning and semantic segmentation technologies to develop a street space quality evaluation system that combines subjective and objective perspectives. On one hand, it extracts the physical environmental characteristics of streets using street view images and artificial intelligence algorithms; on the other hand, it quantifies residents'

perceptions of the safety, comfort, and richness of streets through a subjective perception model. By comparing the spatial distribution characteristics of the two types of evaluation results, this paper aims to reveal the discrepancies and coupling relationships between the subjective and objective perspectives of urban street spaces, and to propose targeted optimization suggestions, providing new ideas and practical references for the transformation and upgrading of urban street planning.

2. Literature review

2.1 Physical environment measurement method

In recent years, with the advancement of street view imagery and deep learning technologies, significant progress has been made in the objective measurement of street space quality. Researchers commonly use platforms like Google Street View, Baidu Street View, and Tencent Street View to obtain images of neighborhoods and employ deep convolutional neural networks (such as SegNet and DeepLab V3) for semantic segmentation, thereby quantifying physical elements such as green vegetation, openness, and interface transparency (Biljecki & Ito, 2021; Tang & Long, 2019). This automated image recognition and data analysis method has significantly improved measurement efficiency and has shown good accuracy and consistency in multiple empirical studies. Moreover, GIS and spatial network analysis remain crucial tools for assessing the physical characteristics of streets. By quantifying indicators such as building height, road width, street connectivity, and node density, researchers can construct accessibility models to analyze traffic efficiency and spatial organization (Harvey & Aultman-Hall, 2016). Building on this, the integration of multi-source data has become a new trend, including the integration of street view images, 3D building data, POIs, and LBS to establish systematic street quality assessment models (L. Zhang, Ye, Zeng, & Chiaradia, 2019). Data fusion not only enhances the expression ability of indicators, but also enables the dynamic capture of the spatio-temporal evolution characteristics of street space, which provides support for long-term monitoring and optimization.

2.2 Pedestrian subjective perception and multi-dimensional evaluation model

In contrast to the physical environment measurement, the subjective perception of street space has gained increasing attention. Traditional methods often rely on questionnaires and expert ratings, focusing on residents 'psychological perceptions of safety, cleanliness, and human scale. However, sample representativeness and survey costs have become major bottlenecks for their widespread application (Du & Huang, 2022). In recent years, some studies have introduced social media text and sentiment analysis, using big data processing to capture residents' daily expressions of their preferences for the street environment. To integrate both subjective and objective perspectives, Wan et al. proposed the '5D+3S' model, which combines physical indicators such as design, density, diversity, accessibility, and transportation distance with perceptual dimensions like sociality, safety, and state, reflecting both the structural characteristics of street space and the complexity of human experience (Wan, Lu, & Sun, 2022). Technically, some studies have integrated street view image recognition and expert scoring to create semi-automated, multi-dimensional perception rating systems, enhancing the efficiency and reliability of data acquisition. Additionally, research on human-scale urban morphology emphasizes the profound impact of visual continuity, scale sense, and proportional relationships on perceptual experiences (Ye, Zeng, Shen, Zhang, & Lu, 2019). Du and Huang further empirically analyzed the relationship between leisure sports activities of the elderly and street quality, and found that green rate and sidewalk design had a significant positive effect on improving subjective satisfaction, which confirmed the value of environmental perception in the construction of healthy cities (Du & Huang, 2022).

3. Research areas and methods

3.1 Research area

This study focuses on the quality differences between subjective perceptions and objective environments in street spaces within the main urban area of Xi 'an, a city in Northwest China. Xi' an is a key hub for regional economic, cultural, and technological development. In recent years, with the upgrading of urban functions, the implementation of the 'Belt and Road' initiative, and the deepening of the national central city construction, the city's space has rapidly expanded, with the built-up area surpassing 10,000 square kilometers and a permanent population exceeding 12 million. As the population and construction density continue to rise, the urban spatial

structure has shown a clear trend of concentric distribution and functional differentiation (Lin, Xiping, Junyi, Yongyong, & Zhiyuan, 2025).

In the process of urban spatial evolution, old urban areas, constrained by early planning, commonly face issues such as narrow streets, outdated facilities, and enclosed interfaces. In contrast, new urban areas boast higher standards and environmental advantages in street design, greenery configuration, and openness. This structural difference is not only evident in physical space but also profoundly influences residents' subjective experiences and daily behaviors. The growing gap between subjective and objective evaluations has gradually intensified the perception inequality and functional imbalance within cities. To gain a deeper understanding of the multidimensional aspects of street space quality and their optimization directions, this paper focuses on areas with high street density and frequent population activity in the main urban area. By integrating deep learning algorithms and semantic recognition technology, it quantitatively extracts environmental elements of streets and introduces a multi-label perception scoring system to explore the perceptual characteristics and optimization paths of street space at different scales. The aim is to provide theoretical support and practical references for enhancing urban spatial quality and traffic equity (W. Zhang, Chen, & Tian, 2025).

Figure 1. Scope of the study

3.2. Research methods

To support the quantitative assessment of street space quality and the systematic comparative analysis from both subjective and objective perspectives, this paper constructs a multi-source data system that includes built environment characteristics and perception evaluation information. The main data types include road network data, street view images, point of interest (POI) data, administrative division data, and subjective perception evaluation data. The sources, collection times, and processing procedures of each type of data are detailed in Table 1.

Regarding objective variables, the basic road data is sourced from OpenStreetMap (2021 edition). By extracting street centerlines, performing topological repairs, and manually correcting Gaode satellite images, the accuracy and usability of the road network structure are ensured. Street view images are collected from the Baidu Street View Open Platform, with sampling points set at intervals of 50 meters within the study area, resulting in a total of 289,664 images (1024×512 resolution). For sections with missing data, 360 Maps is used to supplement the data. Image processing employs a Mask2Former deep learning semantic segmentation model to extract key visual elements such as sky, greenery, and building interfaces, which form the basis for constructing a visual environment index system for street spaces (Li et al., 2022). POI data is obtained through the Baidu Map API, covering 18 categories of urban functional facilities, including dining, shopping, accommodation, education, and healthcare, to measure the functional mix and service accessibility of streets. Administrative boundary base map data is sourced from the National Basic Geographic Information Public Service Platform, uniformly projected into the WGS_1984 coordinate system using ArcGIS 10.7, ensuring spatial consistency and overlay compatibility across different data sources.

In the construction of subjective perception variables, the study incorporates the Place Pulse 2.0 dataset and its accompanying model developed by the Massachusetts Institute of Technology (MIT) Media Lab (MIT Media Lab). This model constructs a subjective evaluation framework covering six core dimensions: 'sense of security,' 'livability,' 'activity level,' 'wealth,' and 'sense of prosperity' through a paired comparison scoring mechanism. Using the Microsoft Trueskill algorithm, this paper ranks and normalizes image scores, and based on the model's output, it generates six categories of subjective perception scores for street images in Xi' an's main urban area, quantifying residents' emotional experiences and psychological perceptions of the street environment (Wang, Han, He, & Jung, 2022).

In the process of constructing the variable system, this paper integrates existing research findings and urban spatial quality theories to select eight key objective indicators from four dimensions: safety, comfort, richness, and convenience. Additionally, six subjective perception scores generated by the Place Pulse model are introduced, forming a multidimensional quantitative analysis framework for street space (see Table 2). Each indicator clearly defines its meaning, calculation method, and direction, comprehensively covering key factors such as spatial visual characteristics, traffic environment, functional diversity, and human scale. This provides a systematic and logical variable foundation for subsequent empirical analysis (L. Zhang et al., 2019).

Table 1 Multi-source, multi-scale data types, sources and processing

data name	data sources	acquisition time	data handling
Road network data	Open Street Map	December 2024	After the road centerline is simplified and extracted by manual, the topology is checked and verified with reference to the Gaode satellite image
Street View data	Baidu Open Street View Map platform	December 2024	The Baidu Street View API was invoked to collect 289,664 static panoramic images with a spacing of 50 m and a size of 1024 x 512 pixels. Then the Mask2Former semantic segmentation model was used to segment the street view images.
Interest Point (Point of Interest, POI) data	Baidu Map	December 2024	The geographic information interest point (POI) data was obtained from Baidu Map API. According to the research needs, 18 kinds of POI data such as food, hotel and shopping were obtained within the research scope and its surrounding area. The data contained industry categories, names, addresses, administrative areas and other information.
MIT Place Pulse Data set	MIT Media Lab Developed Place Pulse projects	December 2024	The Microsoft Trueskill algorithm was used to calculate the corresponding perception scores of six dimensions, and the model was trained to predict the scores of six perception dimensions on the streets in the central urban area of Xi 'an.

Table 2 Subjective perception indicators and calculation methods

dimension	metric	computational method	weight	direction
safety	sense of security	The "safety" dimension score of street view images is evaluated based on Place Pulse model, and the weighted average of multi-angle image scores is obtained to obtain the perceived safety score of street segments.	0.1717	+
degree of comfort	Sense of oppression	The weighted calculation was carried out based on the negative score results of "livability" and "safety" dimensions of Place Pulse model, and the lower the value was, the stronger the depression was.	0.171741	-
	aesthetic feeling	The "aesthetics" dimension of Place Pulse model is used to score the perception, reflecting residents' subjective evaluation of the visual image of the street. The higher the score is, the stronger the aesthetic sense is.	0.1037	+
rich	Liveliness	The "activity" dimension of Place Pulse model is used to score the perception, which reflects residents' subjective evaluation on the visual image of the street. The higher the score, the higher the activity.	0.3285	+
	Boredom	The perception score of the "boredom" dimension of Place Pulse model reflects residents' subjective evaluation on the visual image of the street. The higher the score, the higher the boredom degree, which is a negative factor.	0.1194	-
convenience	A sense of affluence	Based on the "sense of wealth" dimension score of Place Pulse model, the building material, facade decoration complexity and high-end commercial POI density are taken as auxiliary factors for comprehensive calculation.	0.0759	+

Table 3 Objective environmental indicators and calculation methods

dimension	metric	computational method	weight	direction
safety	Vehicle interference	The degree of influence of motor vehicle traffic on pedestrian activity is measured by the number of vehicles in the unit.	0.0016	-
	Road surveillance	Assess the safety of a street, known as the "eyes on the street," by counting the number of surveillance facilities or pedestrians and shops on either side of the street.	0.1954	+
degree of comfort	Visibility over the sky	The proportion of the visible sky in the street space is calculated to reflect the degree of visual openness. The proportion of the sky in the total pixels is calculated through street view image analysis.	0.1809	+
	High viewership ratings	The proportion of green vegetation in the street view is calculated to reflect the greening degree of the street. The proportion of green pixels in the total pixels is calculated through street view image analysis.	0.0861	+
rich	Interface transparency	Measures the transparency of the facade of buildings on both sides of the street, i.e. the proportion of transparent or translucent parts (such as Windows, porches). Through street view image analysis, the proportion of transparent area to total facade area is calculated.	0.2945	+
	Interface richness	Evaluate the detail and diversity of the facade of buildings on both sides of the street. This can be measured by calculating the types and numbers of facade elements, such as decoration, material changes, etc.	0.0951	+

convenience	Walkable accessibility	Measures how easily pedestrians can get from a street to various facilities (such as stores, public transport stops). It is usually calculated by calculating the number and distance of various facilities within a certain range around the street, combined with the street connectivity index.	0.1449	+
	Function mix	The diversity of land use around the street is evaluated. The information entropy formula is usually used to calculate the proportion and distribution of different functions (such as residential, commercial, office, etc.) land use around the street.	0.0014	+

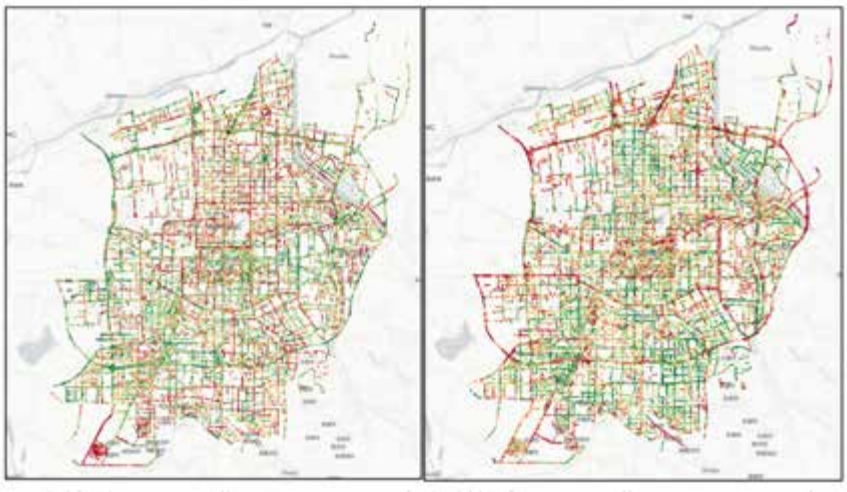
4. Results and analysis

4.1 Spatial distribution characteristics of comprehensive scores

To comprehensively reveal the overall distribution characteristics of the spatial quality of streets in Xi 'an's main urban area from both subjective and objective perspectives, this paper uses multi-source data and entropy value method weights to calculate the subjective and objective comprehensive scores for each street, and conducts spatial visualization analysis. As shown in Figure 2, the left figure (a) presents the subjective street quality measurement results, while the right figure (b) shows the objective street quality measurement results.

From the overall distribution pattern, both subjective and objective scores indicate that the main urban area of Xi 'an exhibits significant spatial heterogeneity and a layered structure. In the city's core areas, such as Beilin District, Lianhu District, and parts of Yanta District, streets generally score high. The high-score segments (primarily green) are concentrated in the city center, indicating that the core urban area offers high spatial quality in terms of both residents 'perceptions and physical environment. In contrast, the outer areas of the city and some newly developed zones have generally lower street scores, with red and yellow sections being more densely distributed. This suggests that these areas need significant improvement in both residents' perceptions and physical environments.

It is worth noting that while the overall trends in subjective and objective distribution are consistent, there are still some differences. For instance, some newly developed peripheral areas have seen improvements in physical space indicators, such as wider roads and better pedestrian accessibility, but the subjective perception scores have not improved accordingly, indicating that residents' subjective experiences of the street environment still need further enhancement. Moreover, some older areas, despite less favorable objective indicators, have relatively higher subjective scores due to their strong historical and cultural atmosphere or community sense of belonging, reflecting the complex spatial characteristics of perceptions and evaluations of street quality from both subjective and objective perspectives.



a. Subjective street quality measurement results b. Objective street quality measurement results

Figure 2 Measurement results of street quality

4.2 Analysis of differences among different administrative regions

To systematically reveal the differences in street spatial quality among different administrative districts in Xi 'an's main urban area, this paper combines the results of both subjective and objective comprehensive scoring (see Table 4). Subjectively, Chang 'an District, Lianhu District, Beilin District, and Weiyang District stand out, with average scores of 0.4282,0.4249,0.4237, and 0.4249, respectively, significantly higher than those of Xincheng District, Baqiao District, and Yanta District. This trend suggests that core urban areas and regions with mature public service facilities and earlier development better meet residents' subjective expectations for safety, aesthetics, and vitality. For instance, Chang 'an District has actively promoted ecological livability and the creation of cultural streets in recent years, significantly enhancing residents' sense of belonging and satisfaction. In contrast, Xincheng District and Baqiao District have lower subjective evaluations, indicating that some emerging areas still face challenges in improving public space quality and have not yet effectively met residents' demands for a high-quality street environment. Notably, the standard deviation of subjective scores across districts is concentrated between 0.03 and 0.04, suggesting that there is still some variation in quality within each district, particularly in Xincheng District and Baqiao District, where internal spatial differences are greater than in core urban areas like Beilin.

From the perspective of objective comprehensive scores, Beilin District, Chang 'an District, and Yanta District rank at the top, with average scores of 0.1294,0.1295, and 0.1274, respectively, higher than peripheral areas such as Xincheng District, Weiyang District, and Baqiao District. These districts excel in physical dimensions like green coverage, street transparency, and pedestrian accessibility, reflecting significant achievements in urban governance and the enhancement of public space environments. Additionally, the standard deviation analysis indicates that the internal fluctuations in the objective scores of Beilin District and Chang' an District are relatively small, suggesting a balanced physical quality of their streets. In contrast, Xincheng District and Baqiao District exhibit higher score dispersion, indicating significant internal differences in spatial development. Some areas still face issues such as strong motor vehicle interference and closed interfaces, requiring urgent intervention and improvement.

Further comparison of the comprehensive scores of subjective and objective indicators reveals a certain degree of synergy and discrepancy between residents 'perceptions and the physical environment in different districts. For instance, Beilin District and Chang' an District have highly aligned subjective and objective scores, indicating that improvements in the physical environment can effectively enhance residents 'spatial satisfaction, making these areas typical examples of successful urban space governance. In contrast, Yanta District shows a situation where objective evaluations lead but subjective experiences are weak, suggesting that merely improving the physical environment is insufficient to significantly enhance residents' sense of gain and happiness. Additional improvements are needed in human-centric aspects and social interaction. Meanwhile, Xincheng District and Baqiao District have low scores in both subjective and objective indicators, indicating that they need to improve in both spatial quality construction and residents' perception.

Table 4 Statistical table of subjective and objective comprehensive scores of each administrative region

canton	Subjective mean	Subjective standard deviation	Objective mean	Objective standard deviation
new city zone	0.4170	0.0360	0.1380	0.0323
Weiyang District	0.4249	0.0394	0.1348	0.0321
Baqiao District	0.4202	0.0366	0.1349	0.0342
Beilin District	0.4237	0.0335	0.1294	0.0287
Lianhu District	0.4249	0.0386	0.1364	0.0335
Chang'an District	0.4282	0.0386	0.1295	0.0288
Yanta District	0.4188	0.0337	0.1274	0.0292

4.3 Subjective and objective coupling and deviation analysis

According to the results of the correlation analysis (see Table 5), there is a weak negative correlation between the subjective and objective comprehensive scores of street spatial quality in the main urban districts of Xi 'an City. Except for Beilin District, the Pearson correlation coefficients for the other districts are all negative and highly statistically significant ($p < 0.001$). Notably, the negative correlation is most pronounced in Weiyang District (-0.290), Xincheng District (-0.220), and Baqiao District (-0.205), with an average correlation coefficient of-0.196 across all districts. This indicates that improvements in the physical environment of streets have not consistently led to an increase in residents' subjective perceptions, suggesting that the subjective and objective evaluation systems exhibit a certain degree of independence in spatial dimensions, and even show a clear divergence trend in some areas.

To further clarify the structure of the discrepancy between subjective and objective evaluations, this paper constructs four coupling types based on subjective and objective scores (see Table 6). The 'subjective superior to objective' type (high-low) has the highest proportion at 29.56%; followed by the 'highly consistent' type (low-low) and the 'objective superior to subjective' type (low-high), with proportions of 27.76% and 25.87%, respectively; only 16.81% of the streets achieve a 'highly consistent' type (high-high). This indicates that less than 20% of the street spaces have seen simultaneous improvements in both subjective perception and objective quality, while most streets exhibit varying degrees of discrepancy between subjective and objective evaluations.

The above results indicate that in the process of enhancing the quality of street space in Xi 'an's main urban area, residents 'perceptions have not fully aligned with the objective improvements. In areas with a strong sense of community or historical and cultural ambiance, despite relatively weaker physical environment indicators, residents' subjective evaluations are more positive, showing a 'high-low' type deviation. Conversely, in newly developed or renovated areas, although the physical environment has significantly improved, residents 'subjective satisfaction has not significantly increased, resulting in a' low-high 'type deviation. This phenomenon suggests that urban spatial governance should not solely rely on the improvement of' hard environment 'indicators but should also focus on the collaborative shaping of' soft environment 'factors, such as residents' emotions, social

interactions, and cultural belonging.

In summary, the interplay between subjective and objective evaluations reveals the intricate mechanisms behind enhancing spatial quality, underscoring the importance of a people-centered approach to governance that focuses on perception. Future strategies for optimizing urban street spaces should focus on a two-way feedback mechanism that integrates 'physical improvements' with 'perceptual responses,' aiming to enhance both functional rationality and emotional experiences, thereby promoting a dual improvement in high-quality public spaces and urban well-being.

Table 5 shows the correlation coefficient and significant p value of subjective and objective comprehensive scores

canton	Pearson correlation	Significant p values
Beilin District	0.025	0.094
Lianhu District	-0.157	<0.001
new city zone	-0.22	<0.001
Weiyang District	-0.29	<0.001
Yanta District	-0.187	<0.001
Chang'an District	-0.143	<0.001
Baqiao District	-0.205	<0.001
The average of the region	-0.196	<0.001

Table 6 Statistical table of subjective and objective comprehensive score deviation types

Type of bias	sample number	percentage
Subjective superiority over objective (high-low)	19351	29.56%
High consistency (Low-Low)	18173	27.76%
Objective superiority over subjective type (low-high)	16938	25.87%
High consistency (4-5)	11003	16.81%

5. Conclusion

This paper focuses on the main urban area of Xi'an City, utilizing multi-source spatial data and deep learning algorithms to develop a street spatial quality evaluation system that integrates subjective perception with objective built environment. It conducts a systematic analysis of the urban street environment from dimensions such as spatial layout, regional differences, and the coupling relationship between subjective and objective perceptions. The main conclusions are as follows:

From an overall spatial perspective, the street space quality in Xi 'an's main urban area exhibits significant spatial heterogeneity and stratification in both subjective and objective dimensions. The core urban areas, such as Beilin District, Lianhu District, and Chang 'an District, stand out with high scores in both subjective and objective evaluations, characterized by a dense concentration of high-quality streets that highlight the spatial advantages of historical urban areas and well-developed public service zones. In contrast, the scores for the city's periphery and some newly developed areas are relatively low, indicating room for improvement in street environment optimization and resident satisfaction.

(2) There are significant differences between different administrative regions. Chang 'an District, Lianhu District, Beilin District, and Weiyang District have performed well in overall subjective comprehensive scores, indicating that these areas have not only improved their spatial environment but also better met residents' psychological expectations for street safety, vitality, and aesthetics. In contrast, Xincheng District, Baqiao District, and parts of Yanta District have performed poorly in both subjective and objective scores and internal balance, suggesting they still face the dual challenges of spatial quality differentiation and insufficient resident perception.

(3) The overall relationship between the subjective and objective evaluation systems is weakly negatively correlated. Pearson Correlation analysis indicates that in most areas, the correlation between subjective and objective scores is low, and in some areas, there is even a significant negative correlation. This suggests that improvements in physical space do not directly enhance residents' subjective satisfaction. Subjective perceptions are significantly influenced by cultural background, social relationships, and individual experiences, indicating a high degree of independence and complex coupling between subjective and objective evaluations.

From the analysis of subjective and objective bias types, only 16.81% of the street samples achieved 'high-high consistency,' while nearly 60% of the streets exhibited inconsistencies between subjective and objective evaluations. Among these, the 'subjective superiority over objective (high-low)' and 'objective superiority over subjective (low-high)' types were more prevalent, reflecting residents 'reliance on soft elements such as cultural environment and community belonging, as well as the disconnect between physical environmental improvements and psychological perceptions. In particular, in some newly developed areas, even with significant improvements in the physical environment, residents' subjective sense of gain remains lagging, highlighting a gap between 'hard environment' and 'soft experience' in current urban spatial governance.

6. Discussion

This study integrates deep learning technology with multi-source spatial data to systematically reveal the spatial distribution patterns, regional differences, and coupling deviation characteristics of urban street spatial quality in both subjective perception and objective environment dimensions. The findings indicate that while the continuous optimization of the physical environment forms the foundation for enhancing urban spatial quality, the transformation of the 'hard environment' alone is insufficient to fully meet the increasingly diverse and personalized subjective needs of residents. Many street samples exhibit a mismatch between subjective and objective evaluations, highlighting that 'soft environment' elements such as social and cultural atmosphere, community belonging, and public participation play a crucial role in influencing residents 'sense of gain and spatial identity. This finding underscores the need for urban spatial governance to shift from a single functional physical perspective to a human-centered approach that integrates perceptual experiences, promoting a systematic transformation of urban renewal from' object-oriented 'to' people-oriented. 'In future urban renewal and spatial optimization processes, it is essential to focus on the coordinated regulation of differences between regions and within areas, driving the dual improvement of the physical environment of streets and the enhancement of residents' subjective experiences, gradually achieving the goal of constructing high-quality, balanced urban public spaces.

However, this study still has certain limitations. Firstly, while the Place Pulse model has improved the efficiency of measuring subjective evaluations, its predictive outcomes are limited by factors such as image acquisition methods, algorithm training biases, and cultural context differences, making it difficult to fully represent

individual perceptions in real-world scenarios. Secondly, the study uses Xi 'an's main urban area as a case for empirical analysis, and its conclusions need further validation and expansion across different city types and social structures.

Future research can expand in two directions: first, by integrating field surveys and online questionnaires with other sources of subjective data to enhance the authenticity and representativeness of the model in perception evaluation; second, by incorporating time-series street view images and dynamic perception data to conduct a longitudinal analysis of urban spatial quality, exploring the temporal evolution mechanisms and influencing factors of both subjective and objective evaluations. This will help develop more precise and actionable strategies for urban spatial optimization, providing a solid theoretical foundation and practical approach to creating fair, efficient, and livable urban public spaces.

Abstract
Urban accessibility construction from a global perspective emphasizes the enhancement of inclusiveness and equity in cities. Community public spaces, as central hubs of daily life, serve as crucial entry points for advancing urban accessibility initiatives. With the aging population and a growing number of individuals with disabilities, the creation of barrier-free environments in the older urban areas of Chinese cities has become a focal issue. This involves analyzing the outdoor activity characteristics (frequency, type, and scope) and variations among individuals with differing mobility levels in these communities, as well as exploring the relationship between outdoor activities and community public spaces. Based on these findings, strategies for enhancing accessibility in public spaces within older urban areas can be developed.

This thesis employs questionnaire surveys and in-depth interviews to examine the accessibility needs of community public spaces for individuals with disabilities and propose targeted design strategies. Specifically, it focuses on the Chengxian Street community. First, 35 valid questionnaires were collected through surveys, behavioral observations, and interviews with all disabled residents in the community. Additionally, 78 travel trajectories were recorded and analyzed, with the temporal and spatial distributions visualized using ArcGIS. Second, the research identifies key patterns based on travel frequency, destinations, and needs, uncovering trends in time-sequenced travel, spatiotemporal circulation, and public space usage behaviors. These findings highlight significant challenges in the accessibility of community public spaces. Finally, the study proposes an inclusive design framework for improving public space accessibility, addressing five dimensions: target orientation, standard setting, spatial siting, spatial layout, and accessibility facilities. By considering the behaviors and needs of vulnerable groups, this framework seeks to advance the construction of inclusive, safe, and sustainable cities and communities.

Ultimately, the thesis revisits the social model of disability studies, offering actionable strategies to enhance the accessibility of public spaces for disabled communities and contributing to the broader goal of fostering equitable urban development.

Key words: Community Public space, Accessibility Strategies, Characteristics of outdoor activities, Disability

1. Introduction

According to United Nations statistics, the global population has exceeded 7 billion. Alongside population aging and the increasing prevalence of functional impairments related to chronic diseases and age-related conditions, over 1 billion people worldwide—approximately one-seventh of the total population—are currently living with some form of disability. This number is projected to rise to over 2 billion by 2050 (United Nations, 2022). In this context, developing sustainable and equitable accessibility systems within urban environments to enhance outdoor participation opportunities for persons with disabilities has become a pressing challenge for social inclusion and sustainable development. Numerous studies have confirmed that moderate outdoor activity offers substantial health benefits for individuals with disabilities. It not only improves cardiorespiratory fitness and physical coordination but also alleviates feelings of isolation and promotes mental well-being (Derakhshan, 2024; Hirvensalo, 2000; Ramlagan, 2013). However, people with disabilities continue to face multiple barriers to outdoor engagement, including environmental, social, and personal constraints (Heath, 2012; Derakhshan, 2024). As a result, their frequency and duration of outdoor activities are significantly lower than those of individuals without disabilities (Shelby, 2025), leading to an infringement on their equal right to outdoor participation (Kapsalis, 2022). In everyday life, persons with disabilities often limit their activities to the vicinity of their residences. Consequently, the 500-meter radius surrounding one's home plays a critical role in determining activity opportunities and overall quality of life (Katayama, 2023).

As the most immediately accessible form of public space, community outdoor areas are pivotal in facilitating social inclusion and improving the quality for people with disabilities. Ward Thompson (2013), through an extensive study on the relationship between outdoor environments and population activity levels, emphasized

that when an environment lacks the necessary functional attributes and appeal for specific user groups, their opportunities for activity diminish accordingly. Therefore, outdoor spaces within communities must be systematically designed and functionally organized to serve the needs of disabled populations. Empirical evidence shows that well-designed community spaces can effectively increase daily walking frequency, enhance physical health, and provide greater opportunities for social interaction and mental wellness among people with disabilities (Sara, 2025). However, in China's older urban neighborhoods, community outdoor spaces often fall short in terms of supply, spatial quality, and functional diversity, thus failing to meet the multifaceted needs of disabled users. Enhancing the accessibility of public spaces in these areas is essential to promoting urban inclusiveness and achieving spatial equity.

Current research predominantly focuses on infrastructure development (Xia, 2019; Chen, 2023), service accessibility, or community participation (Jin, 2023), while insufficient attention has been paid to improving public space inclusiveness through spatial design and environmental creation. To address this gap, this study selects the Chengxian Street community—representative of older residential areas in Nanjing, China—as a case study. Through fieldwork and analysis of the activity patterns of persons with disabilities, the study identifies the types and characteristics of their daily outdoor activities. Based on these findings, it proposes practical and targeted spatial strategies for accessible public space design, aiming to inform the development of more inclusive and equitable community environments.

2. Research Design

2.1 Study Area

This study selects the Chengxian Street community, located in Xuanwu District, Nanjing, as a typical case study (Figure 1). Covering an area of 0.8 square kilometers, the community is rich in historical and cultural heritage. The surrounding eastern ring area, where Chengxian Street is situated, has been designated as one of the key zones for urban renewal in Nanjing. Before the 1990s, the community primarily served residential and educational functions. With the acceleration of urbanization, commercial services gradually emerged along the street.

In recent years, the proportion of elderly and disabled residents in the community has continued to rise. Statistics show that in 2015, residents aged 60 and above accounted for approximately 24.09% of the total population (Li & Li, 2019), indicating a clear trend of population aging. The community is characterized by narrow streets, dense traditional commercial activities, and an aging built environment, lacking basic accessibility infrastructure. These features reflect the typical spatial characteristics of older urban neighborhoods, making Chengxian Street an appropriate and representative subject for this research.

Fig.1. Scope of the study

2.2 Assessment of Mobility Capacity Among Persons with Disability

According to China's Practical Evaluation Standards for Persons with Disabilities and the national standard Classification and Grading of Disabilities for Persons with Disabilities (GB/T26341-2010), China divides the types of disabilities into six categories, namely, visual disability, hearing disability, speech disability, physical disability, intellectual disability, and psychiatric disability; and each category of disability is divided into four grades according to its severity, with Grade 1 being extremely severe disability, Level 2 being severe disability, Level 3 being moderate disability, and Level 4 being mild disability. Disability, Level 3 as moderate disability, and Level 4 as mild disability.

In this study, to explore the activity characteristics of the disabled group in outdoor public space, it is necessary to reclassify the group in combination with the ability to travel, to more clearly identify the differences in their functional needs for spatial services. Based on the above criteria and combined with the results of field research, this paper classifies the traveling ability of disabled people into three categories: the first category is the group of fully autonomous travelers, which has strong spatial perception and mobility and can complete the travel activities independently, mainly including people with hearing disabilities, speech disabilities, and part of the people with mild physical disabilities. The second category is the limited autonomous traveling group, which has some independent traveling ability but needs to rely on auxiliary tools or environmental guidance to travel, typically represented by people with moderate to severe physical disabilities or people with visual impairment. The third category is non-autonomous or accompanied travel groups, which are difficult to complete travel activities on their own, and usually need to be accompanied by family members, caregivers, or volunteers, and mainly include groups of people with multiple disabilities of the first level of intellectual disability and mental disability. For individuals with multiple disabilities, their ability to travel is assessed based on the most severe of their disabilities (Figure 2).

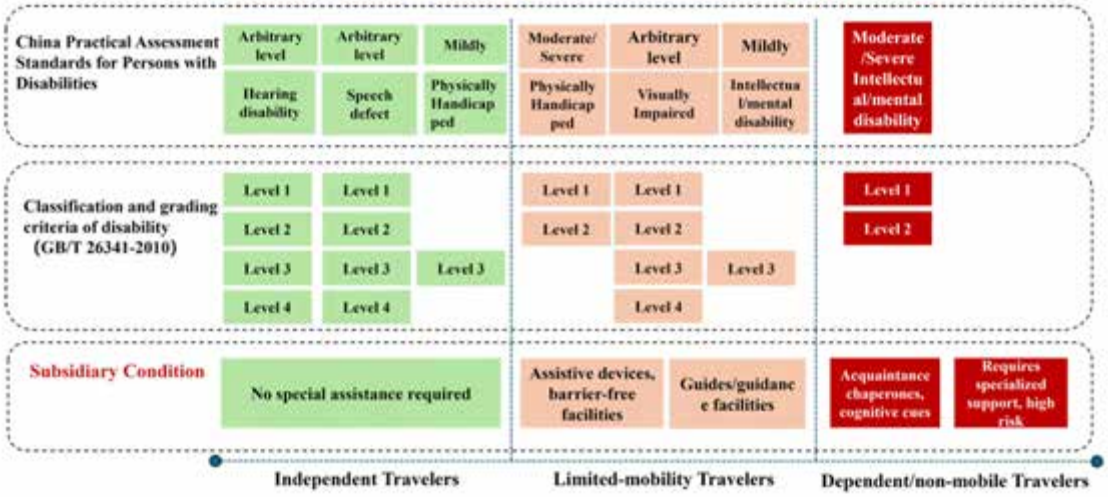

Fig.2. Basis and results of classification of persons with disabilities

First, what are the characteristics (frequency, type, and range of activities) and differences in outdoor activities of people with disabilities with different mobility abilities in old communities in old urban areas? What is the relationship between the outdoor activities of people with different mobility abilities and the accessibility of community public space? Through the systematic analysis of the above questions, this paper aims to reveal the interaction mechanism between community space and the daily behavior of disabled groups and provide empirical evidence for the subsequent proposal of targeted barrier-free space creation strategies.

2.4 Research Program

This study adopts diversified research methods, mainly including field observation, questionnaire research, and semi-structured interviews. Before the formal research, the research team first made several field visits to the

Chengxian Street community in Nanjing to sort out the public spaces within the community where people with disabilities can carry out outdoor activities, and the screening criteria included whether there were basic facilities such as benches and walking paths. A total of 34 representative outdoor public spaces were identified and categorized into three categories based on their spatial form and service radius: unit-port spaces, small activity venues, and centralized activity venues (Figure 3). The study collected information on the outdoor activities of people with disabilities through activity logs, which were used to analyze their activity characteristics and differences. The activity logs cover dimensions such as respondents' basic information, start and end time of the day's outdoor activities, activity content, destination, and mode of travel. The survey was conducted in July and October 2024 under suitable weather conditions (sunny days and 20-30°C). In the activity log survey, this research process is user-centered and guides the respondents to review the previous day's outdoor activity matters, time, and route to restore their life events as much as possible. The researcher supported the recording through notes and audio recordings to enhance the completeness and accuracy of the data. At the community level, with the assistance of the Chengxian Street Community Service Center, the person in charge of this study called 55 people with disabilities in the Chengxian Street community to participate in the research; 55 questionnaires were distributed, with 54 validly recovered, and activity logs were issued to 35 of them who are now living in the Chengxian Street community. After the data collection, the authors analyzed the characteristics of the frequency, type, and scope of outdoor activities of the disabled according to the content of the questionnaires and activity logs.

Fig.3. Distribution of public spaces in the study area

3. Characterization of Outdoor Activities for People with Disabilities

3.1 Social Characteristics of the Disabled Population

This study collected outdoor activity logs from all individuals with disabilities residing in the Chengxian Street community. Among them, 24 individuals belonged to the fully autonomous travel group, 25 to the limited autonomous travel group, and 5 to the non-autonomous or accompanied travel group. Given the difficulty in obtaining analyzable outdoor activity trajectories from individuals who are entirely immobile, this paper focuses on the first two groups—those with some degree of travel capability—for analyzing the behavioral characteristics and patterns of their outdoor activities.

The social profile of the surveyed disabled population is summarized in Table 1. The results indicate a marked aging trend within the disabled community of Chengxian Street, with individuals aged over 60 accounting for more than 60% of the total. Among those under 60, only 16.7% are capable of independent travel, suggesting that even the younger segment of the disabled population includes a considerable proportion of individuals with severe impairments.

In terms of age distribution, individuals aged 60–69 comprise the largest group of those able to travel

independently. Regarding gender, male participants generally demonstrate stronger mobility capabilities than their female counterparts. As for household structure, the majority of persons with disabilities live with their spouses or children—an arrangement associated with higher levels of mobility. Additionally, nearly 80% of respondents have lived in the community for more than eight years, and among them, 38.9% possess the ability to travel independently.

Table 1 Statistics on Social Characteristics of Respondent Population with Disabilities

Classification	Subcategory	All persons with disabilities		Independent Travelers		Limited-mobility Travelers		Dependent/non-mobile Travelers	
		Quantities	proportions	Quantities	proportions	Quantities	proportions	Quantities	proportions
Totally	—	54	100	24	44.4	25	46.3	5	9.3
Age	Below 60	21	38.9	9	16.7	7	13	5	9.3
	60-69	20	37	13	24.1	7	13	0	0
	70-79	10	18.5	2	3.7	8	14.8	0	0
	≥80	3	5.6	0	0	3	5.6	0	0
Gender	Male	34	62.9	14	25.9	16	29.6	4	7.4
	Female	20	37.1	10	18.5	9	16.7	1	1.9
Housing Structure	Living with a partner's son or daughter	43	79.6	19	35.2	19	35.2	5	9.2
	Living alone	6	11.1	4	7.4	2	3.7	0	0
	Other	5	9.3	1	1.9	4	7.4	0	0
Duration of Residence	1-3 years	5	9.3	2	3.7	2	3.7	1	1.9
	4-7 years	6	11.1	1	1.8	5	9.3	0	0
	More than 8 years	43	79.6	21	38.9	18	33.3	4	7.4

3.2 Classification of Outdoor Activities of People with Disabilities

To collect data on outdoor activity patterns, this study adopted and adapted the structure of the Activity Log Questionnaire for Beijing Residents developed by Chai Yanwei et al., supplemented by insights from preliminary observations. Outdoor activities were categorized into three main types, further divided into 12 subcategories. Daily activity logs were compiled accordingly, recording the start and end times, travel locations, and specific content of activities (Table 2).

Analysis of activity duration data for the three major categories reveals a consistent temporal pattern in outdoor activity among persons with disabilities. On average, participants engaged in 2–3 outdoor trips per day, primarily concentrated in three-time windows: 8:00–10:00, 14:00–16:00, and 19:00–21:00. Total daily time spent outdoors typically ranged from 6 to 8 hours, with activities most commonly involving leisure exercise, grocery shopping, and other basic errands (Figure 4). These findings indicate a certain degree of regularity and continuity in the outdoor activity needs of this population.

According to the questionnaire data, most individuals with disabilities rely on family members for accompaniment during outdoor activities, though there are notable individual differences in travel capacity. Among the first group

(fully autonomous travelers), 62.5% reported that they could complete outings independently. Their average duration per trip exceeded two hours, and they went out more than seven times per week. Their activities were relatively diverse, including shopping, walking, and completing daily errands—reflecting a broad range of functional needs for public space.

In contrast, individuals in the second and third groups were more dependent on companions or assistive devices during outings, and their mobility was closely linked to environmental safety, infrastructure accessibility, and community support systems. These contrasts highlight a marked differentiation in how people with varying mobility capacities interact with and rely on community public space services (Figure 5).

Table 2 Classification of behavioral activities of persons with disabilities

Type of activity content	Activity content subcategories
1. Recreational Activities	1-1 Walking
	1-2 Chatting(sunbathing)
	1-3 Playing Chess, Cards, and Mah-jongg
	1-4 Dancing, doing exercises
	1-5 Sports (fitness equipment, hiking)
2. Productive Activities	2-1 Work
	2-2 Go home
3. Life- Service Activities	3-1 Grocery Shopping
	3-2 Shopping and spending, errands
	3-3 Picking up and dropping off children
	3-4 Taking care of parents
	3-5 Hospital Visits

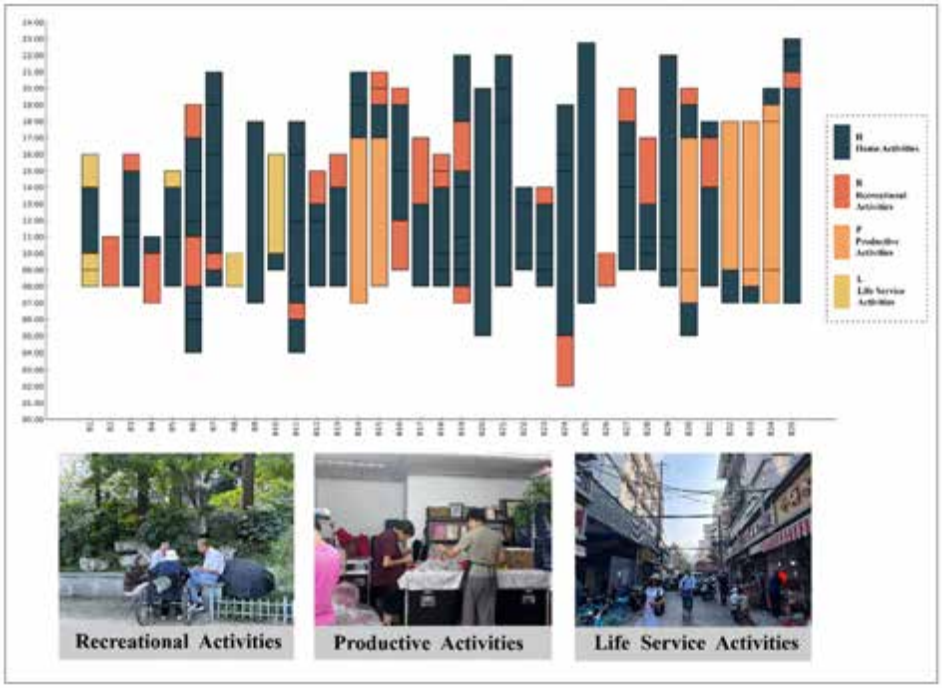

Fig. 4. Schematic diagram of activity sequence statistics for persons with disabilities in residential areas

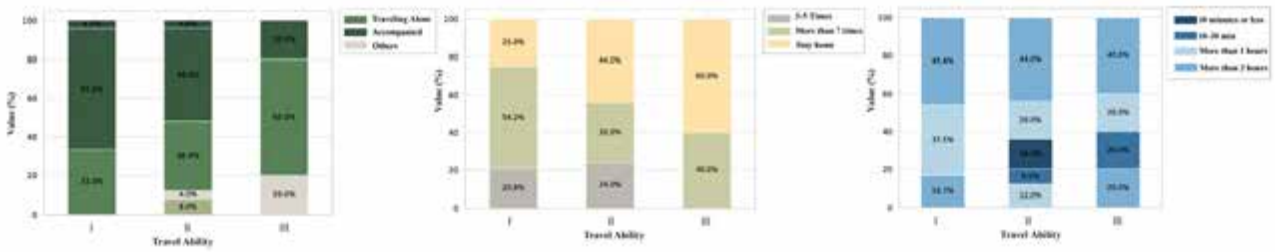

Fig. 5. Characteristics of activities of persons with disabilities of different mobility

3.3 Behavioral Characteristics of Outdoor Activities Across Different Mobility Impairment Groups

To further investigate differences in daily activity patterns among persons with varying levels of mobility impairments, this study selected three representative individuals from the research community and analyzed their behavior across five key dimensions: trip duration, travel destinations, travel modes, types of activities, and whether they traveled alone or with others.

The results reveal significant distinctions in both activity patterns and spatial use among the three mobility groups. Individuals in the first group (fully autonomous travelers) demonstrated high variability and diversity in their daily movements. Their activities primarily included life-related and leisure tasks such as square dancing, walking, chatting, playing cards, or chess. These activities covered a broad spatial range, were highly mobile, and were predominantly carried out on foot. Their preferred activity locations were large public spaces, such as Pearl River Plaza and Heping Park.

In contrast, individuals in the second group (limited autonomous travelers) exhibited more regular and constrained activity patterns. Their activities were largely confined to the community or its immediate surroundings, typically following a fixed routine path between their residence and workplace. Recreational and daily living activities were relatively infrequent. Common activities included light exercise, walking, and sitting, usually conducted along accessible routes near residential areas, such as the banks of the Pearl River.

For the third group (non-autonomous or accompanied travelers), daily activity was markedly limited. Their outings occurred infrequently, usually lasting no more than two hours, and were concentrated during morning or evening hours. Their activity spaces were confined to the immediate vicinity of their buildings—such as the area downstairs or open spaces between buildings. These activities were mostly sedentary, including sunbathing or sitting quietly. The limited spatial mobility and low interaction frequency highlight the significant challenges this group faces in accessing public space and engaging in daily social interaction.

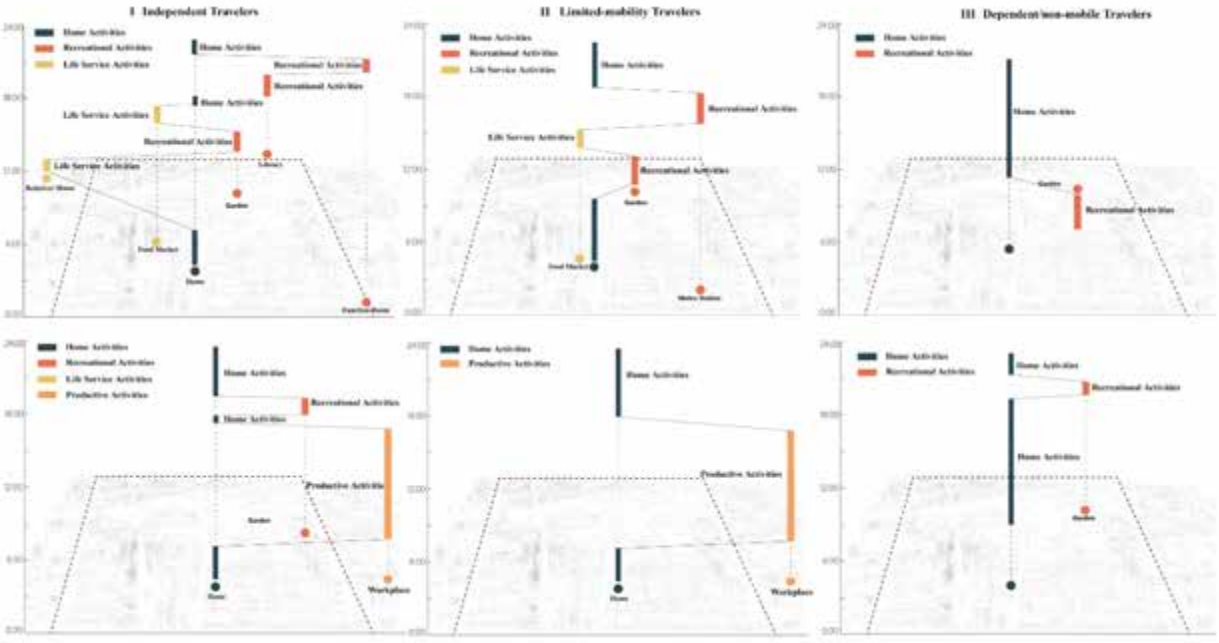

Fig. 6. Schematic diagram of behavioral path analysis for three groups of persons with disabilities

3.4 Public Space Accessibility: Supporting Factors Influencing Outdoor Activities

To further examine how public space accessibility supports or constrains outdoor activity among different categories of people with disabilities, this study combines sample interviews with spatial path analysis to track and document the actual travel trajectories of individuals with disabilities in the Chengxian Street community. By integrating the activity logs of 78 disabled residents and mapping their movement patterns and trajectory densities using ArcGIS, the analysis reveals that travel routes significantly influence the selection of activity destinations. High-frequency paths include Nicco Lane, Tiger Bridge, Xiaosajiao Lane, and Chengxian Street, where adjacent public spaces exhibit a strong capacity to attract activity.

Further analysis highlights clear differences in path selection and activity clustering across mobility groups. Fully autonomous travelers show a wide distribution of paths, with activity points primarily located along the Pearl River and in Heping Park. Limited autonomous travelers tend to cluster around accessible nodes along the Pearl River that are closer to residential areas. Non-autonomous travelers, however, demonstrate low path density, with activities largely confined to the empty spaces beneath or between residential buildings—underscoring their restricted spatial accessibility.

Field observations revealed that one of the main constraints limiting outdoor activity among persons with disabilities is the incomplete and poorly connected system of accessibility infrastructure within the community. On one hand, the Chengxian Street community has implemented some basic barrier-free facilities (Figure 7), including ramps and handrails at entrances to banks, supermarkets, and parks, which generally meet design standards. On the other hand, problems persist, such as irregularly installed ramps, missing or loose handrails in inter-building spaces, and broken pathways that compromise the functionality of the infrastructure. Moreover, blind walkways are often obstructed or discontinuous—affected by parked vehicles, encroachment from non-motorized vehicles, or a complete absence along major thoroughfares—making it difficult for individuals with disabilities to safely and smoothly access public activity spaces within their daily walking range.

Overall, while the Chengxian Street community has made preliminary efforts to establish basic barrier-free infrastructure, the overall connectivity, continuity, and human-centered design of these facilities remain

insufficient. Deficiencies in inter-building links, path integration, and infrastructure usability continue to limit the travel radius and frequency of outdoor activities for certain groups of people with disabilities, adversely affecting their quality of daily life.

Fig.7. Distribution of Barrier-free Facilities in Chengxian Street Community

4. Accessibility Design Strategies for Community Public Spaces in Old Urban Areas

As the primary setting for daily activities among persons with disabilities, the accessibility of community public space is not only a matter of individual well-being but also a critical indicator of spatial inclusiveness and urban equity. In older urban areas, challenges such as limited space, outdated infrastructure, and fragmented layouts often hinder the ability of community public spaces to effectively meet the diverse needs of people with disabilities.

Based on the behavioral analysis of disabled groups with varying mobility capacities in the Chengxian Street community, this study identifies distinct patterns of stratification and spatial circling in outdoor activities. The extent to which individuals are restricted from participating in public space activities varies considerably depending on their level of mobility. Improving accessibility in old urban neighborhoods requires solutions that are feasible under constrained conditions. The design focus should shift from merely providing accessible facilities to establishing a holistic, adaptive relationship among people, activities, and environments.

Targeted and precise design strategies not only serve a wider range of users but also improve the cost-effectiveness of renovation investments, ensuring that the benefits of urban renewal are distributed more equitably among all persons with disabilities. Based on the research findings, this paper proposes a set of strategies for improving accessibility in community public spaces within old urban areas.

4.1 Clarify positioning goals and respond to the needs of special groups

Currently, communities in old urban areas often fail to adequately address the specific needs of persons with disabilities in the planning of outdoor activity spaces. Poor site compatibility and incomplete facilities significantly

limit the feasibility, frequency, and comfort of their daily outdoor activities. For instance, residents are frequently required to bring their tables and chairs for chess and card games, and rehabilitation and exercise equipment is insufficiently provided, which restricts regular participation.

It is recommended that, based on the observed activity types among people with disabilities—and considering the overlapping needs of the elderly—community parks, plazas, fitness corners, and overhead floors of residential buildings should undergo systematic upgrades with barrier-free design principles. Key design considerations include: Installing accessible entrances, ramps, and continuous handrail systems to ensure smooth mobility for wheelchair users and individuals with walkers; Providing appropriate facilities such as seating, shading structures, and level, non-slip surfaces to support the creation of micro-activity spaces that promote rest, interaction, and social engagement.

4.2 Categorize Configuration Standards to Improve Space Suitability

Beyond fitness activities, most daily community activities lack clear spatial allocation standards, leading to a mismatch between facility supply and actual user demand. To address this issue, targeted spatial and facility configuration strategies should be developed based on the nature of different activity types. For space-dependent activities—such as chess, card games, and rehabilitation exercises—the required area can be estimated using the formula: activity unit area × number of participants. Essential equipment (e.g., tables and chairs) should be provided in group-based units to support such interactions.

For activities with high spatial sensitivity but low facility dependency—such as sitting, strolling, and informal leisure—designers should focus on optimizing spatial qualities. Key considerations include: Route continuity, to ensure seamless movement; Microclimatic comfort, such as adequate shading, ventilation, and sunlight exposure; and Visual accessibility, which contributes to safety, comfort, and the psychological ease of navigation for people with disabilities. By categorizing activity types and aligning spatial standards accordingly, the suitability and effectiveness of public space configurations can be significantly enhanced.

4.3 Layered Distribution Strategy to Optimize Spatial Allocation

Findings from this study indicate that outdoor activities among persons with disabilities exhibit distinct spatial circling characteristics. Individuals with full mobility tend to have a wider activity radius and greater spatial mobility, those with limited autonomy are primarily concentrated around the periphery of residential areas, while non-autonomous individuals are largely confined to spaces immediately adjacent to their homes—such as ground-floor areas and inter-building open spaces. In the context of spatial renewal in old urban areas, it is essential to recognize these mobility-based differences and apply layered and circle-based design principles to improve the efficiency and equity of space utilization.

First, high-intensity activity spaces should be preferentially located near community service nodes—such as fresh markets, senior centers, kindergartens, and green areas—to enhance spatial efficiency and encourage shared use across different population groups. Second, for low-mobility groups, micro-space design should be strengthened through targeted improvements in resting spots, including better seating, ground surfacing, and shading systems in frequently used areas like ground-floor terraces and building entrances. Finally, when larger open spaces such as parks and plazas already exist within proximity to the community, spatial resources should be functionally integrated through enhanced pathway accessibility and wayfinding systems. This approach avoids redundant construction while improving the connectivity and coherence of the overall spatial system.

4.4 Optimize the Functional Layout and Enhance Flexibility of Use

Outdoor activities are often accompanied by a variety of behavior combinations, placing higher demands on the multifunctionality and adaptability of public space. Traditional barrier-free design tends to focus solely on the primary activity areas while overlooking the continuity and support of adjacent activity zones and auxiliary facilities. This fragmented approach frequently results in reduced usability and limited participation opportunities. It is recommended that, from a holistic spatial planning perspective, barrier-free design should encompass three

interrelated types of functional spaces: firstly, Primary activity areas – the central spaces where most community activities occur; Secondly, Related activity areas – supporting zones such as spectator seating, resting areas, and access points connected to transportation; and thirdly, Auxiliary function areas – spaces that house public service facilities, such as restrooms, water stations, or information kiosks.

The accessible design of these spaces should be planned as an integrated system to ensure continuity, coherence, and flexibility. Enhancing the interconnection between these functional components will improve spatial usability, especially for persons with disabilities, and foster more inclusive and engaging community environments.

4.5 Improving system integration and enhancing accessibility continuity

As communities in old urban areas are limited by uneven distribution of facilities, narrow scale, spatial fragmentation, and other problems, people with disabilities face the barrier of being accessible but not connected in the process of using public space. To address this problem, the layout of barrier-free facilities should be optimized at the system level to build a continuous and clear barrier-free access network, covering infrastructure such as passages, ramps, and blind corridors; to enhance the accessibility of paths between activity nodes and residential areas, with particular attention to the height of the curb, lighting, and signage systems; and to promote the design of barrier-free transitions between buildings and open spaces, eliminating obstacles such as height differences, steps, and thresholds, to ensure travel Continuity.

5. Conclusion

Taking a typical residential community in the old urban area of Nanjing as a case study, the study focuses on the behavioral characteristics of outdoor activities of the disabled group in the community public space, identifies three main types of activities through a combination of activity logs and questionnaires: leisure activities, productive activities, and living activities, and further explains the differences in the characteristics of outdoor activities of the disabled in terms of the dimensions of demographic attributes, activity time, and spatial distribution. It is found that people with disabilities have a high dependence and sensitivity to the venue environment in the process of participating in outdoor activities and that there are significant deficiencies in the accessibility, comfort, and adaptability of facilities in the existing public spaces in old urban areas. Based on the results of empirical research, this paper proposes accessibility design strategies for community public spaces in old urban areas from five aspects: clarifying the target positioning, formulating configuration standards, optimizing the spatial distribution, improving the flexibility of the functional layout, and reinforcing the integration of the facility system. The strategy emphasizes the starting point of the difference in mobility of people with disabilities and takes into account the needs of other mobility groups such as the elderly, and improves the overall efficiency and fairness of the use of urban space while guaranteeing the right to basic activities. By building a more inclusive community public space system, accurate support for diverse groups can be realized under limited resources, avoiding the waste of resources and management burden brought by exclusive facilities.

This study proposes a preliminary strategy based on a sample of communities in the old city of Nanjing, which is of practical significance for understanding the pattern of outdoor activities of people with disabilities and guiding the renewal of spaces. However, due to the significant differences in the demographics, spatial patterns, and social support systems of people with disabilities in different cities, the characteristics of their outdoor activities may be diverse. In the future, the study can further expand the sample area, pay attention to the dynamic changes of the needs of people with disabilities in different periods, and explore how to acquire the outdoor activity needs of people with disabilities in advance and flexible adaptation strategies, to respond to the needs of diversified groups of people more effectively. Through the construction of an adaptive and sustainable human-centered spatial system, it is expected to promote the transformation of public space from basic barrier-free construction to a higher level of comprehensive inclusion and to realize a more socially equitable and sustainable path of urban renewal.

Abstract
Even though public spaces reshape urban areas and act as sites of hope, we note significant differences in their role in small and big urban areas. Considering the important challenges encountered worldwide, the paper tries to answer the question of how public spaces in small and medium-sized cities could work as agents of inclusive and sustainable urban transformations and thus lead to positive changes in the development of urban areas. The choice of the case study "Xersonisos tis Panagias" in the city of Kavala in Northern Greece was based on the necessity to propose a planning methodology for public spaces which focuses on existing local power dynamics as a means towards an inclusive and equitable living environment for the inhabitants of these areas.

Key words: public spaces, urban areas, sustainable development, inclusion, Kavala (Greece)

Introduction

At the international level public spaces play a key role in the development of urban areas as they act as places for social encounters, political contestations and cultural events (Siláči and Vitková, 2017). Since the ancient times in Greece and in Rome public spaces, in the form of forums and "agora", were areas where people were gathering in order to take decisions about the governance system or to organize cultural events as we can see in examples of medieval cities in Western Europe (Flohr and Zuiderhoek, 2024). At the same time many political contestations take place in streets, squares and parks showing the close connection between grass-root movements and open-air urban spaces where people can easily gather and express their social and political beliefs (Pereira-Zazo and Torres, 2019). In many cases starting from political contestations in the 1950s and 1960s, such as May 1968 in France and the manifestations in USA regarding the War in Vietnam, as well as the more recent manifestations during the period 2010-2020 in several countries of South Europe and Asia (Spain, Greece, Turkey) focusing on economic policies, it is evident that public spaces could reshape cities by bringing together people from different social classes who fight for their own "right to the city" (Harvey, 2008).

Sustainability in all three dimensions (social, economic, environmental) is part of the design of public spaces as they play a key role in cities' transformations in the 21st century. In social sustainability reports and in documents of international organizations such as the Agenda 2030 it is stated that public spaces play a central role in shaping social interactions among cities' inhabitants, foster equity while at the same time environmental sustainability and economic development is linked to their organisation and functions (UN, 2015). It is clear that international organisations such as the United Nations and World Bank are interested in promoting sustainable development conditions worldwide through the design of public spaces, but we should underline the fact that many cities luck funds for the development of such operations or do not have highly experienced executives for the design and implementation of public spaces' policies (El-Kholei and Yassein, 2022). Another concern is about the main focus of public spaces' policies promoted by international organisations, as they often prioritize green washing and gentrification and do not focus on the social dimension of sustainability which could bring social equity and cohesion in all parts of a city and the world (Çetin et al, 2023).

Despite their different form and functions public spaces can reshape urban areas and act as sites of hope, especially in underdeveloped territories where there is need for spaces for recreation and gathering (El-Bardisy, 2024). We should underline the different role of public spaces in small and big urban areas as well as areas of the Global North and Global South (Landman and Mady, 2022). Questions related to climate change and world warming are more evident in big urban areas and thus the planning of public spaces inside these areas and their design are considered as measures for improving environmental conditions (Vukmirovic, Gavrilovic and Stojanovic, 2019). On the contrary, in small urban areas as well as in areas of the Global South the main focus in the planning and design of public spaces is the revitalisation of territories that were neglected or polluted for several years in order to reintegrate them into the urban fabric (Jaszczak et al, 2021). While the main focus of such operations seems to be the well-being of cities' inhabitants it is important to note their high cost and the subsequent gentrification of territories where people with low incomes used to live (Bélanger, 2007). The beautification of neglected territories through the design of public spaces together with the construction of office buildings and commercial centres leads to a swift in the social tissue, by bringing into these areas people with high incomes and leaving behind people that were born and raised there (Gutiérrez, 2024).

Considering the important challenges encountered worldwide in the design and strategic planning of public spaces, the paper focuses on the role of public spaces in small and medium-sized cities, especially to the ones affected by socio-economic and environmental problems. How could public spaces in small and medium-sized cities work as agents of inclusive and sustainable urban transformations and thus lead to positive changes in the development of these urban areas? Small and medium-sized cities often face challenges such as the loss of local population due to the closure of local enterprises, schools and health facilities (Bowns, 2013). In several cases such as deindustrialised cities in West European Countries they lack the necessary funds for their redevelopment based on the three pillars of sustainable development (social equity, environmental protection, economic development) (Atolia et al, 2020). Under these conditions it seems critical to propose redevelopment policies which prioritize the design and planning of public spaces, as public spaces are often combined with the creation of shops and enterprises as well as the construction of housing (Cromwell, 2018). However, we should underline the need to propose redevelopment policies which consider the local characteristics (social, economic, environmental) and avoid green washing and gentrification policies.

The main purpose of the paper is to question the appearance of planning methods and tools for the redevelopment of small and medium-sized urban areas which focus on the design of public spaces while maintaining the characteristics of the local tissue. Which are the characteristics that define the identity of urban areas and need to be considered during the processes of design and planning of public spaces? In our methodology we identified three main categories based on the toolkits of international organisations such as the United Nations (UN, 2015), researchers-practitioners (Gehl, 2010) and groups of academics, "Critical Heritage Studies" (Harrison et al, 2023) in order to analyse the design and planning of public spaces as a process that fosters social equity, protects the environment and cultural heritage and brings economic prosperity in areas facing economic and social difficulties. It is important to mention that the identification and analysis of the special characteristics of urban areas (social, cultural, economic, environmental) alongside the development of planning strategies that focus on these characteristics could potentially enhance social cohesion and economic development as they are retrofitted processes (Urban Initiative, 2024).

Methodology

The research method used was the descriptive-analytic. The descriptive method was used in order to define planning methodologies for the design of public spaces. Our main hypothesis is that the design of public spaces should be the basis for the redevelopment of areas facing socio-economic and environmental difficulties, as usually around public spaces we can find commercial and recreation activities as well as residential and office units. At the same time, in contemporary urban design and city planning policies (urban ecology, environmental urban planning and design) public spaces are designed as spaces that reintegrate nature into the urban fabric. This means that in these spaces we can find a significant number of trees and plants, while in certain cases

polluted natural elements existing in cities, like streams, are restored and re-integrated into the urban fabric.

Neglected urban spaces, such as urban voids usually resulting from deindustrialisation or from the closure of local enterprises are nowadays re-designed as public spaces in order to re-integrate them into the urban fabric. These spaces are also linked to economic recession and environmental degradation especially the former industrial lands. In certain cases, they are occupied by homeless people and immigrants, while contractors, investors and local authorities show a particular interest to build them in order to boost the local economy of cities facing social and economic difficulties. In this context the reconversion and transformation of urban voids into public spaces offers a second life to places that were underdeveloped and neglected for several years due to socio-economic problems. Our hypothesis is that the redevelopment of urban voids as public spaces and their subsequent integration into the urban fabric is not only a measure towards environmental sustainability and resilience, but it can also serve as a measure to solve social conflicts as public spaces in underdeveloped areas are places for social encounters and sports and recreation activities.

Another point to underline in contemporary practices for the design of public spaces, related to "Critical Heritage Studies" and to the protection of urban and cultural landscapes, is the planning of public spaces in areas with a significant number of historical buildings and monuments as a measure that allows the better understanding of the city's landscape. In dense urban areas historical buildings and monuments cannot be usually identified as next to them are built contemporary buildings, while narrow streets block the view towards the buildings. Public spaces like squares and small parks as well as large streets that are easily crossed by pedestrians, which are found in front of historical buildings and monuments, seem to improve the inhabitants and visitors experience in understanding the different historical eras of cities. Taking this into consideration, our third hypothesis is that the planning of public spaces in historical cities' districts, characterised by their unique urban, historical and cultural identities, could act as a measure for a new city-branding as they facilitate urban mobility by foot and bicycle and thus lead to a discovery of the cities' hidden urban past.

The analytic method was used in order to develop our strategy and model for the development of small and medium-sized cities facing socio-economic difficulties based on the design and planning of public spaces in neglected urban voids. The method proposes an experimental approach in the design of public spaces and their relationship with the surrounding urban environment based on the case study of "Xersonisos tis Panagias", a neighbourhood in the city of Kavala in Northern Greece. Our proposal was developed during an urban design studio named 'Public Spaces' at the School of Architecture of Democritus University of Thrace, which emphasises on the design of small public spaces in dense urban areas as measures that lead to urban sustainability and resilience. At the same time semi-structured interviews were conducted with local elected officials and inhabitants in order to take into consideration their needs and expectations for the development of their city. We suggested a development scenario for the city of Kavala, based on the reconversion and transformation of neglected urban voids as public spaces, which focuses on measures such as: 1) the increase of green spaces inside the city, 2) the use of bicycle in urban mobility as well as the mobility by foot, 3) the revalorisation of historical buildings, monuments and landmarks through the design of public spaces, 4) the planning of open-air spaces for recreation and sports activities as well as 5) the connection of the new public spaces in the 'Xersonisos tis Panagias' neighbourhood with the existing ones especially to the ones in strategic areas of the city of Kavala.

For the development of our scenario for the city of Kavala we took into consideration existing power dynamics of the city and the region of East Macedonia and Thrace in which administratively is part the city of Kavala. It is important to mention that the region of East Macedonia and Thrace is among the less developed at national (Greek) level and is characterised by deindustrialisation and the closure of local enterprises. Despite the above weaknesses of the region, the presence of Democritus University of Thrace (DUTH) in six cities of the region (Drama, Kavala, Xanthi, Komotini, Alexandroupoli, Orestiada), including Kavala, is among the strong points of the area as it brings people from other cities in a region affected by deindustrialisation and population decline. The ports in the city of Alexandroupoli and Keramoti, a small town in the outskirts of Kavala, the airports in the city of Alexandroupoli and Xrisoupoli, a small town in the outskirts of Kavala, as well as Egnatia Odos, a highway that

connects the north part of Greece with neighbouring countries create the conditions for the development of the cities of the region based on commercial and retail activities. We should also mention the presence of important natural parks inside the region, including three Natura Zones in Evros, Rodopi and Xanthi, which consist of its internal dynamics, and the presence of the Greek Muslim Community in neighbouring cities of Kavala (Xanthi and Komotini) posing challenges regarding the support of ethnic minorities and the enhancement of social cohesion through the design of public spaces.

The case study: the city of Kavala in Northern Greece and the 'Xersonisos tis Panagias' neighborhood

The city of Kavala is located in the north part of Greece, in the region of East Macedonia and Thrace, with an area of 351.35 square kilometres (Greek Statistical Institute, 2015). It is built near the Aegean Sea, close to the island of Thassos (Figure 1). Based on the 2021 population census, the Municipality of Kavala has 66,376 inhabitants (Greek Statistical Institute, 2021).

Figure 1. Kavala's location on the map of Greece. In detail the cities of the Kavala regional unit, whose capital is the city of Kavala, and the neighboring regional units. Source: Greece-map.net

As most of the Mediterranean cities it is affected during summer by heat waves while during the winter it is often affected by snowstorms originating from the north part of Europe. Kavala is characterised by its dense urban fabric and the absence of open green public spaces especially in the neighbourhoods that were built during the Ottoman era. We can distinguish the old city surrounded by the city's castle (Figure 2), built during the Ottoman Era and where it is located the "Xersonisos tis Panagias" neighbourhood, from the expansions built during the 19th and 20th century which are located near the city's harbour (Figure 3).

Figure 2. Kavala's waterfront. In the photo we can distinguish the city's castle in the back of the picture and city's harbour in the front. Source: www.travel.gr

Figure 3. Kavala's panoramic view. In this panoramic view of the city, we can distinguish in the right and left corner of the photo the contemporary city. At the centre we can see the 'Xersonisos tis Panagias' neighborhood, an urban area built during the Ottoman era, surrounded by a castle in order to keep it safe from pirates' attacks. Source: Alexandros Mpantogias

After the Greek Turkish War of 1919–1922, the city of Kavala entered a new era of prosperity and development due to the industrial and agricultural activities (Karagiannakidis and Likourinos, 2009). Kavala became greatly involved and developed further in the processing and trading of tobacco mainly with European countries (Theodoridou and Moustaka, 2013). Many buildings related to the storage and processing of tobacco from that era are preserved in the city and act as landmarks of the city's past. As most of the Greek cities, especially small and medium-sized, Kavala faces in the 21st century the consequences of deindustrialisation and the closure of local enterprises, despite the fact that the presence of university departments in the area increases the local inhabitants' incomes due to apartments' rentals.

"Xersonisos tis Panagias" neighbourhood is located in the city of Kavala in the region of East Macedonia and Thrace in Northern Greece, an area that maintains its physical and social characteristics since the era of Ottoman Empire and which is nowadays used as a space for recreation and leisure. The limited number of open green public spaces in the city of Kavala as well as the special characteristics of 'Xersonisos tis Panagias' are better represented on the following map (Figure 4) and photos where we can identify the relationship between open and built spaces. The 'Xersonisos tis Panagias' neighbourhood is characterized by its narrow streets, the absence of open green public spaces and the organic and dense urban fabric which better corresponded to the needs of city's inhabitants during the 18th and 19th century (Figure 5).

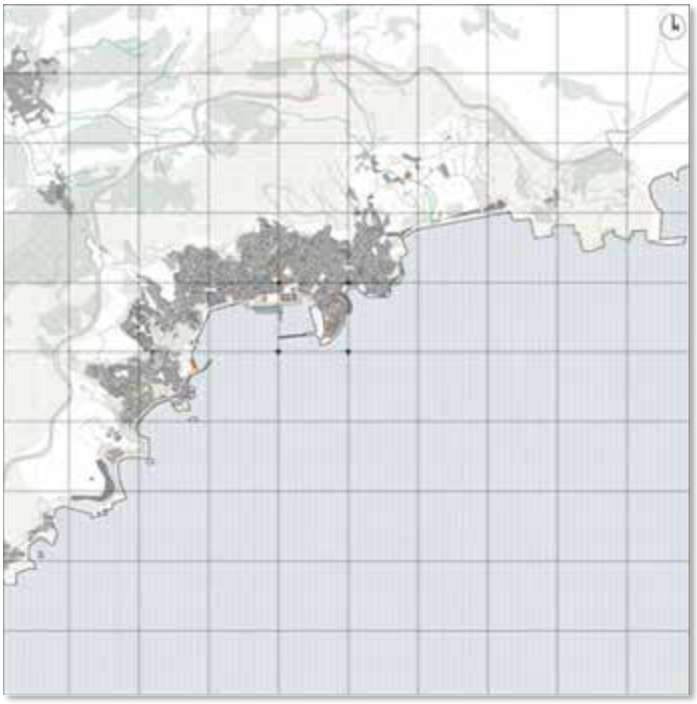

Figure 4. Kavala's built and open spaces. In this map, we can see that most parts of the city of Kavala are built, and the only unbuilt public spaces are around the city's harbour. Source: Alexandros Mpantogias

Figure 5. The 'Xersonisos tis Panagias neighbourhood' in the city of Kavala. In this photocollage, we can see the different urban characteristics of the neighbourhood where it is clear the absence of open green public spaces. Source: Alexandros Mpantogias

During our field research in the city and particularly in the 'Xersonisos tis Panagias' neighbourhood we identified several neglected urban voids, that are nowadays not well integrated into the city fabric, either because they are closed and not accessible, or because they are not well designed in order to accommodate open-air events for the inhabitants and visitors of the city (Figure 6).

Figure 6. Existing urban voids in the 'Xersonisos tis Panagias neighbourhood'. In the photo they are represented neglected urban voids in the 'Xersonisos tis Panagias' neighbourhood which were identified during the field research in the city of Kavala, and which were proposed to inhabitants, local authorities and students at the School of Architecture of DUTH for re-design as public spaces. Source: Varvara Toura

These voids are around the main street of the neighbourhood, Poulidou street, where we can also find small cafés and restaurants, several souvenirs shops for the tourists, monuments such as the Imaret, a building used as an orphanage during the Ottoman era and which is nowadays restored and reconverted into a luxury hotel, schools, small public spaces such as squares and local landmarks such as the lighthouse (Figures 7, 8, 9, 10).

Figure 7. Urban void closed to the Imaret building in the 'Xersonisos tis Panagias neighbourhood'. In the photo we can see a typical use of the unbuilt spaces or the neighbourhood as parking lots. Source: Varvara Toura

Figure 8. Urban void between two housing units in the 'Xersonisos tis Panagias neighbourhood'. In the photo we can see that nature in the form of grass and trees is present in certain urban voids of the neighbourhood. Source: Varvara Toura

Figure 9. Urban void closed to a small café. In this case the urban void is found in an area of the neighbourhood that has designed public spaces such as a small square. It is clear the absence of designed spaces for parking the vehicles and for this reason urban voids, designed public spaces as well as Poulidou street are used as parking lots. Source: Varvara Toura

Figure 10. Urban void closed to Kavala's lighthouse. In our field research in the city, we observed several spaces such as schoolyards, which even if they are designed, they are not used due to their materials (concrete) are their internal organisation and functions. Source: Varvara Toura

The Poulidou street as well as the identified urban voids were part of our development plan for the city of Kavala which is based on the re-design of urban voids as public spaces and their re-integration into the urban fabric.

Outcomes-Results

The urban voids identified inside the 'Xersonisos tis Panagias' neighbourhood have different characteristics. Several of them are relatively big spaces such as the schoolyards, while the unbuilt spaces between existing buildings are considered as small spaces. At the same time in cases where the urban void is a private property there are fences and the space is not accessible. In other cases, such as the Poulidou street and existing small squares and parks which are nowadays not used by inhabitants as they luck urban equipment (benches, pergolas for protection against sun during summer), the spaces are public and accessible. We should also note the different importance of these urban voids, as in several cases they are located close to old buildings dating in the 19th century, which act as living memorials of the city's past, or to monuments such as Imaret, a building dating from the Ottoman era which is unique for its organisation in open and closed spaces. These urban voids are used in different ways. In several cases they are used as places for parking vehicles (they are not designed as parking lots, but they are rather spaces that inhabitants and visitors of the neighbourhood use to park their vehicles). In other cases, they act as small places for social encounters, especially the small squares and schoolyards which are used by young people and children in order to play or to practice sports. From the above spaces we distinguished the designed public spaces such as small squares and schoolyards as they could easily be re-designed and re-integrated into the urban fabric. Still, the analysis of the interviews with local elected officials and inhabitants revealed the necessity to reconsider these spaces according to sustainability and resilience criteria as they are closed spaces or not appropriately designed to accommodate social encounters and for these reasons they are not used by inhabitants and visitors of the neighbourhood.

Our proposal for the re-design of neglected urban voids in the 'Xersonisos tis Panagias' neighbourhood as public spaces included measures to improve the basic problems identified in the area which are measures for the presence of green spaces inside the city, for urban mobility (by bicycle and by foot), for the revalorisation of historical buildings, monuments and landmarks, for the planning of open-air spaces for recreation and sports activities and for the connection of the new public spaces in the 'Xersonisos tis Panagias' neighbourhood with the existing ones especially to the ones located in the harbour of Kavala. The activities and equipment inside the old and new public spaces were decided together with the inhabitants of the neighbourhood in order to foster the dialogue between professionals and citizens and to create the conditions for the public acceptance of our development plan for the city of Kavala. The basic idea was to propose rather simple solutions that could be easily adopted and built by the Municipality of Kavala and to avoid complicated and expensive technical measures. The materials and the vegetation that were proposed (wood, stone, ceramic tiles, pine trees, plane trees) they are all local in order to reduce the cost of the project in an area facing significant socio-economic difficulties.
Concerning mobility measures, we have already mentioned that most of the urban voids of the neighbourhood are used as parking lots for the vehicles of inhabitants and visitors while at the same time the main street of the neighbourhood Poulidou does not have pavements as the neighbourhood was built before 1923, the year of changes in urban planning regulations in Greece (Figure 11).

Figure 11. Existing streets in the 'Xersonisos tis Panagias' neighbourhood. The spaces that are used as informal parking lots are marked in grey colour. We can note that Poulidou street as well as most of the urban voids of the neighbourhood are nowadays used as parking lots and thus do not allow social encounters for the neighbourhood's inhabitants. Source: Alexandros Mpantogias

This means that inhabitants and visitors of the neighbourhood have difficulties crossing streets by bicycle or as pedestrians. Our main strategy was to propose the redesign of several main streets of the neighbourhood as Dutch Woonerfs, including Poulidou street (Figure 12).

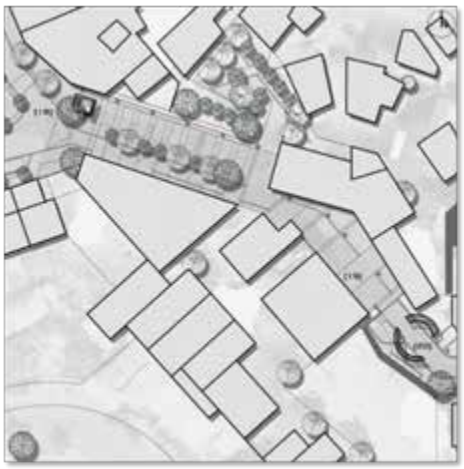

Figure 12. Proposal for the redesign of Poulidou street as a Dutch Woonerf. Trees, pergolas and benches can be found in the new design of the street creating the framework to boost social and environmental sustainability conditions, while small areas of the street are used for parking vehicles. Source: Alexandros Mpantogias

The Woonerf design solves the problems of traffic, pollution and safety by transforming urban streets into shared green spaces (small urban parks) where pedestrians and vehicles can actually co-exist in an optimal balance. Through it, they can be improved local community's quality of living and road safety in the city. The redesign of the main street of the neighbourhood, Poulidou, as a Woonerf allows the expansion of the public spaces on the street level, where vegetation and urban equipment create social and environmental sustainability conditions.

The 'Xersonisos tis Panagias' neighbourhood is among the older neighbourhoods of the city characterised by its buildings which dated on the 19th century. At the same time as the neighbourhood was developed in different

eras (byzantine-ottoman-1923 and onwards), we can find significant monuments such as the Imaret building which was used in the Ottoman era as orphanage and local landmarks as the lighthouse (Figure 13). Nowadays, the main problem in the observation of the city's landscape is the difficult identification of the local landmarks and monuments as they are located too close to contemporary buildings or in closed and not accessible spaces. Several of them, like the local lighthouse, are not accessible to inhabitants and visitors as they are part of closed spaces.

Figure 13. Existing land uses in the 'Xersonisos tis Panagias' neighbourhood. In orange and light brown colour are represented the landmarks and monuments of the area. The organic and dense urban fabric dating on the Ottoman era as well as the construction of new buildings since 1923 does not allow nowadays the observation and identification of landmarks and monuments. Source: Alexandros Mpantogias

In our strategy for the revalorisation of these spaces we considered that the notions of sustainability and resilience are connected to an urban landscape where all phases of the city's history are present and repurposed alongside contemporary needs (small commercial and recreation activities). The redesign of the exterior and interior open spaces of landmarks and monuments (Figure 14) by proposing suitable vegetation (tall trees) and urban equipment (pergolas and benches) highlights the unique historical characteristics of the above spaces and offers a different experience in the discovery of the city.

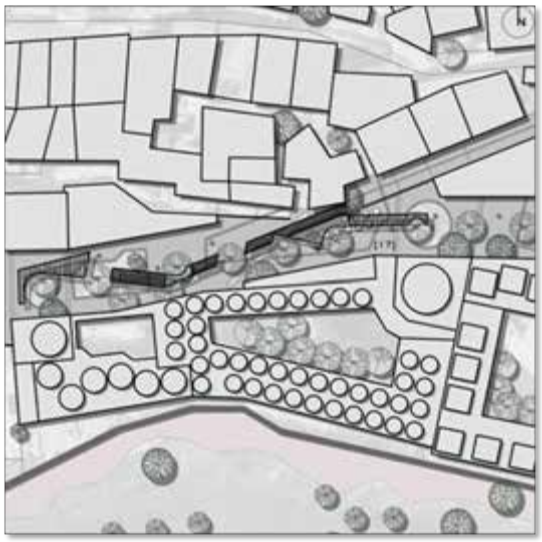

Figure 14. Proposal for the redesign of the exterior open-air spaces of the Imaret Building. Even though Imaret is nowadays restored and transformed into a luxury hotel it is still considered as a landmark of the city and a monument showing the design of public buildings during the Ottoman era. The redesign of the public space outside the building focused on creating a space from which inhabitants and visitors of the neighbourhood would observe the building's main façade while the proposed urban equipment (pergolas and benches) allows the organisation of small festivities by inhabitants. Source: Alexandros Mpantogias

As we have previously mentioned the city of Kavala and particularly the 'Xersonisos tis Panagias' neighbourhood have a limited number of open green urban spaces compared to the city's-built spaces (Figure 15). The city's organisation and the land uses in the 'Xersonisos tis Panagias' neighbourhood resulted from the arrival in the region of East Macedonia and Thrace of refugees from Anatolia region after 1923 (end of Greek-Turkish war) which had as a result the increase of housing needs. In the years following the Second World War and especially in the late 1970s the city expanded in the areas near the harbour affecting also the unbuilt urban spaces in the 'Xersonisos tis Panagias' neighbourhood. The city's limited number of open green urban spaces has as a result the increase in local temperature during summer. We should also note the difficulties that face the inhabitants and visitors of the 'Xersonisos tis Panagias' neighbourhood during summer, regarding the use of the existing open public spaces as there aren't many trees or pergolas in order to lower the temperature.

Figure 15. Existing open green urban spaces and trees in the 'Xersonisos tis Panagias' neighbourhood. The primary note from the analysis of the map of open green urban spaces is that their presence in the 'Xersonisos tis Panagias' neighbourhood is around landmarks and public buildings such as schools and the local lighthouse. On the contrary in areas with private buildings (housing units) we can note only the presence of several trees in streets. Source: Alexandros Mpantogias

During the discussions with local elected officials and inhabitants we noted their willingness to increase the presence of trees and vegetation in the area as they could improve air quality and act as a natural protection during the heat waves in summer and rain and snowstorms in winter. At the same time in Agenda 2030 and in studies of Jahn Gehl it is mentioned that the presence of open green spaces in an urban area could act as measures for improving inhabitants' well-being resulting from the improvement of air and water quality (Gehl, 2010 and UN, 2015). For this reason, it was important to suggest in our development plan the redesign of the public spaces of 'Xersonisos tis Panagias' neighbourhood based on the increase of plants and trees as measures against climate change and extreme weather conditions especially in summer. We should remind that Kavala is located in the Mediterranean region, close to the sea, and is affected in summer by extreme heat. At the same time pergolas were proposed in several areas of the neighbourhood, including the Poulidou street and schoolyards, that are exposed to sunlight in order to lower temperature during summer (Figure 16).

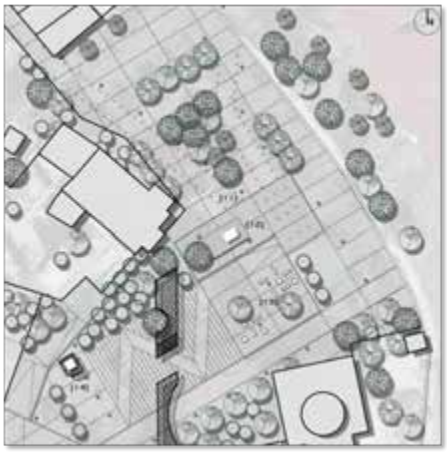

Figure 16. Proposal for the redesign of an existing small square in the 'Xersonisos tis Panagias' neighbourhood. The former design of the square did not include a significant number of tall trees and affected social encounters during summer due to weather conditions. Our proposal included pergolas in areas exposed to sunlight and tall trees in areas that inhabitants use for social encounters. Source: Alexandros Mpantogias

Another problem identified during our field research in the city of Kavala is the disconnection between the different public spaces of the city and especially to the ones located in the peninsula of Kavala which is consisted in its upper part by the 'Xersonisos tis Panagias' neighbourhood and the city's harbour in the lower part. The existing stairs that connect the public spaces of the peninsula were built by the inhabitants in former decades based on their need to have access to the city's harbour and sea. This need was highlighted during the interviews with the inhabitants as well as their thoughts about a safer way to connect the public spaces of the peninsula based on contemporary technical standards. In our development scenario we proposed a vertical connection between the public spaces located in the peninsula of Kavala, the connection is located near the city's lighthouse, in order to facilitate mobility, to increase the number of open public spaces (the vertical connection is a form of public space) and to allow the circulation of air and sunlight in an area (schoolyard) that is nowadays closed (Figure 17).

Figure 17. Proposal for a vertical connection of public spaces of the peninsula of Kavala. The vertical connection is proposed in an area with a significant architectural and historical value and for this reason our basic concern was to propose a solution based on the above special features. The proposal includes the creation of a small balcony in order to increase the area of the public space of the city's lighthouse and a small staircase which will be used by the inhabitants when they want to reach the public spaces in the city's harbour.

Sustainability and resilience are nowadays connected to recreation activities and sports practice as human health and well-being are among the goals of the Agenda 2030 of the United Nations (UN, 2015). The main problem that we identified during our field research was the absence of recreation and sport facilities in the 'Xersonisos tis Panagias' neighbourhood, which could facilitate social interactions and inhabitants' well-being. Inhabitants of the neighbourhood and particularly teenagers and families with young children have expressed during our interviews their need for spaces where they could practice sports or use them in order to organise open-air festivities. During our field research we also noted that inhabitants and visitors of the neighbourhood face difficulties using existing sport facilities, as they are often located in closed spaces (schoolyards) and they are not well maintained. In our development scenario for the 'Xersonisos tis Panagias' neighbourhood and the city of Kavala we considered human health and well-being as key elements of urban sustainability and resilience and for this reason, we suggested the redesign of existing closed (there is a fence around them) open-air spaces like schoolyards as public spaces (Figure 18). This measure, the planning of open-air spaces for recreation and sports activities, could potentially increase social encounters and improve the health and well-being of inhabitants and visitors of the neighbourhood.

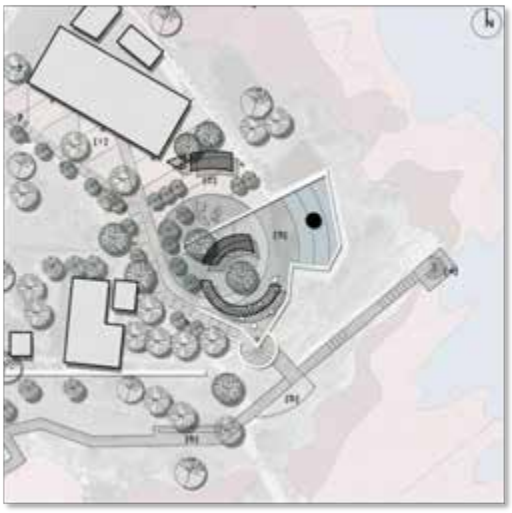

Figure 18. Proposal for the redesign of a schoolyard where it is located Kavala's lighthouse. The existing schoolyard is a closed space not well integrated into the city fabric. The use of concrete in an open-air public space increases temperature during summer, thus not allowing the practice of sports. The schoolyard is designed as a public space for all inhabitants, not only young people, by proposing a small playground for young children and equipment for open-air sports practice. In the same space we can also find pergolas and tired seating which could be used by the inhabitants for organising open-air festivities. We should also note the suggestion for tall trees and plants as natural protection for sunlight and heat during summer.

Discussion

The study of a real-world setting with particular characteristics (socio-economic difficulties, small number of public spaces) revealed the necessity to consider the planning of public spaces in poor small and medium-sized urban areas as a transformative agent which seeks to contribute to a more liveable urban future by combining measures of social and environmental sustainability. Public spaces could act as agents of inclusive and sustainable urban transformations when local elected officials and inhabitants work together with researchers and practitioners in their design processes and try to find solutions that fit not only to technical standards but also to the needs of communities. It is important to mention that this democratic procedure, which can sometimes take the form of co-design and co-production and not only inhabitants' consultation, in small-scale public spaces' projects acts as an urban laboratory for the design and testing of solutions that could later be implemented at city level (the design methodology and planning tools in a small park could also be used in the design of a big park or central square). As we have mentioned in a different section of the paper, the cost of operations in public spaces is an issue to consider when proposing development scenarios in small and medium-sized cities facing socio-economic difficulties. The discussions with local authorities and especially with the inhabitants allow to propose policies and measures that are closer to their expectations and needs, while the socio-economic analysis of the local urban context allows to adjust these policies and measures to the economic dynamics of the city. Good design of public spaces does not mean expensive and complicated technical solutions but rather proposals inscribed in the local social, economic, environmental and cultural urban context.

Another issue to further consider through the design of public spaces and their role in cities' development is urban identity. We saw in the analysis of the case study and the subsequent proposal for 'Xersonisos tis Panagias' public spaces that the particular characteristics of the urban landscape are reflected in the design of public spaces. Historical buildings, monuments and landmarks that have shaped the cities' history are not only living memorials of the different eras of the cities but are also vital elements for contemporary urban life as they are often restored and reused. Their easy identification on urban fabric, achieved through the design of neighbouring public spaces who should be opened and accessible, has as a result a different experience

in cities' discovery by locals, researchers and visitors. Through these planning policies on public spaces, they could be identified significant cities' districts and define around them protection zones in order to protect them from mass-tourism and overscale construction projects that seem to not respond to the cultural and historical characteristics of these urban areas. On the contrary small-scale economic activities such as shops could be found inside these zones as they are necessary for inhabitants (groceries, bakeries). In cases of cities with a high unemployment rate these small-scale economic activities could also serve as measures for facing the difficulties in the local economic context.

To go further on the field of urban sustainability and resilience and the relationship between built spaces and open public spaces we should underline that measures and policies in favor of nature's integration into the urban fabric should be proposed and implemented in dense urban areas based on the local characteristics of each area (urban, environmental, social, economic) to effectively propose solutions that benefit local communities. These measures and policies should put forward the relationship between the built environment and open public spaces and try to find a balance between them in order to improve socio-economic and environmental conditions. At the same time designers, practitioners and local authorities should carefully consider that the integration of the natural element in the design of public spaces, when it is carefully planned, could have positive effects on the temperature inside cities and water and air quality. Public spaces design, organisation and functions based on environmental sustainability criteria could reshape urban areas of the Mediterranean region that are exposed to extreme weather conditions (heat waves) during summer. For this reason, it is important to consider the design and planning of public spaces as a process inscribed in the fields of urban sustainability and resilience as open public spaces like squares and parks serve also as places for social encounters that boost citizens' health and well-being and solve social problems.

In many cases of deindustrialised cities, and especially in small and medium-sized cities of this category where the local economy is primarily based on industrial activities, social problems appear after their deindustrialisation related to the high unemployment rate. This local economic context combined with the loss of local population who moves in other areas in order to find work has as a result the recession of certain urban areas who are trying to find a new identity (social, economic, cultural) in order to increase their population and improve the living conditions of the local population. Public spaces could play a key role in the development strategy of these cities, as we have previously seen in the case study of Kavala a medium-sized city affected by deindustrialisation and the loss of local population. The creation of community conditions (people who have the same goals and needs), in urban districts that are most affected by economic recession, could be achieved through the design of public spaces as these spaces act as places for social encounters where people with different social and ethnic backgrounds gather and spend time with other people. The organisation of festivities and small cultural events in public spaces by the inhabitants of these districts, could serve as a means to bond their relationships and act together in issues related to social, economic and environmental policies of their municipalities. At the same time the design of public spaces in a way that helps the practice of sports (human health) and the organisation of small cultural events by the inhabitants (recreation activities that boost human well-being) are part of the Agenda 2030 (UN, 2015) and should be taken into account by practitioners and local elected officials in order to create inclusive and sustainable urban conditions in areas facing socio-economic difficulties.

Urban mobility is also a question related to the design of public spaces as it affects the form and functions of cities as well as inhabitants' health and well-being. Public spaces and urban mobility are intertwined concepts that significantly impact urban planning and sustainable development. Public spaces, such as parks, streets, and squares, serve not only as gathering places but also as crucial components of the urban mobility landscape. They facilitate movement and connectivity, shaping the daily experiences of city dwellers. The sustainability of urban environments relies heavily on the relationship between mobility and public spaces. Walking and cycling contribute to reducing carbon emissions and congestion, making urban areas more liveable. Integrating green transportation options, such as bike lanes and pedestrians' zones, into the public space design can facilitate this shift towards a sustainable mobility model. Urban planners and researchers often face the challenge of balancing the competing needs of mobility and public space usage. For instance, reducing the traffic of vehicles in

favour of pedestrian-friendly routes can improve the experience of public spaces, but it may also raise concerns about accessibility for those reliant on cars. Measuring the sustainability of public spaces and mobility systems remains a complex task. New and existing sustainability indicators need to account for the multifaceted impacts of urban design in public spaces, such as social engagement, environmental resilience, and economic viability especially for small and medium-sized areas facing socio-economic and environmental difficulties.

Reshaping Urban Spaces: Exploring the Role of Temporary Public Open Spaces in Alleviating Land Pressure in Hong Kong

Ruohan YIN
The Hong Kong Polytechnic University
Email: 24053903r@connect.polyu.hk

Abstract
As urban land scarcity intensifies, Temporary Public Open Spaces (TPOS) offer flexible solutions to meet growing spatial and social demands. This study explores the role of TPOS in addressing the societal impacts of land scarcity in high-density cities, focusing on Hong Kong. Using a qualitative approach, it comprises a literature review, interviews, and comparative analysis of three case studies. The research identifies key characteristics and practices of TPOS, emphasising how different models vary in their social contributions. Findings provide practical insights into optimising TPOS design, governance, and integration into urban planning. The study contributes to a deeper understanding of how TPOS can support inclusive, adaptive public space strategies in dense urban contexts.

Keywords: Public Open Spaces; Temporary Urbanism; Urban Planning

1 Introduction

As urban areas continue to expand and populations increase, the availability of land becomes a scarce resource (Hee & Ooi, 2003; Tang & Wong, 2008). This has significantly changed how urban spaces are designed and utilised (McIntyre, 2009). Temporary uses for public spaces have gained recognition as an essential strategy for revitalising cities and have been widely incorporated into urban policies to address the limited space issue (Fernandez & Mozas, 2021; Andres & Kraftl, 2021). Temporary Public Open Spaces (TPOS) have emerged as a flexible alternative to manage the growing demands on urban areas with limited available land (Bragaglia & Caruso, 2021).

Hong Kong, as a high-density city, exemplifies the growing challenges of providing public open spaces. Initially, the Hong Kong Planning Standards and Guidelines (HKPSG) set a target of 2 square metres of open space per person (DevB, 2015). However, as public demand for quality open spaces has risen, the Hong Kong 2030+ initiative proposed increasing this target to 3.5 square metres per person (DevB, 2021). Despite this aim, a report by Civic Exchange in 2017 shows that the actual provision averages only 2.7 to 2.8 square metres per person.

To alleviate the pressures of urban density, the Planning Department of Hong Kong issued the *Reimagining Public Spaces in Hong Kong – Feasibility Study* (DevB, 2023), which reviews public open space policies in other high-density cities worldwide and summarises emerging global trends in open space planning. The study emphasises the importance of developing innovative, flexible public open spaces, specifically highlighting adaptive strategies like tactical urbanism and time-sharing of space as quick-win solutions to optimise existing spaces. For instance, the study suggests embracing tactical urbanism to create transient open spaces and repurposing underutilised or obsolete spaces. This reflects the Hong Kong government's encouragement of innovative approaches to public open space usage and its commitment to fostering community identity through public participation and flexible spatial solutions (DevB, 2023).

In response to rising public demand and scarce land resources, Hong Kong primarily manages buildable land through permanent grants to the private sector or government allocations for long-term development. Yet before these developments commence, the government often designates specific land parcels for temporary recreational use, maximising available land while addressing supply constraints (Lu, 2023). According to GovHK data (2017), approximately 748 temporary land allocations, covering around 76 hectares, have been established for temporary open spaces.

Despite government efforts to designate temporary public spaces, there are ongoing concerns regarding the quality and sustainability of these spaces (GovHK, 2017). These issues highlight the need for further research into

their design, management, and potential contributions to urban life. This study aims to explore how TPOS can help mitigate land scarcity in high-density cities like Hong Kong.

The research begins with an in-depth theoretical exploration, analysing the definition and main types of temporary use within the framework of temporary urbanism and its role in alleviating land pressure. These insights are integrated with the current state of TPOS in Hong Kong, examining existing policies and measures to summarise the characteristics of TPOS in the unique context of Hong Kong.

Additionally, the study conducts an analysis of three representative cases of temporary public space use in Hong Kong to uncover valuable insights into how these practices inform the design and governance of TPOS. Ultimately, this research aims to refine the theoretical framework of TPOS, offering structured recommendations for their planning and management within Hong Kong's unique urban landscape, and providing guidance for future public open space planning in high-density cities. Specifically, this study focuses on three main research questions:

1. What are the key characteristics and practices of temporary uses of public open spaces in high-density urban areas like Hong Kong?
2. How do different types of TPOS perform in addressing the social impacts of land scarcity in high-density cities?
3. How can insights from temporary uses of public open spaces inform the development of TPOS in Hong Kong?

2 Literature Review

2.1 Temporary Use of Public Open Space under Temporary Urbanism

To address the growing demand for urban public open spaces, the need for cost-effective, rapid, and tailored solutions to repurpose vacant areas has become increasingly urgent, leading to the emergence of the concept of temporary use strategies (Colomb, 2012; Haydn & Temel, 2006; Oswalt et al., 2013). By providing a flexible alternative to traditional development, temporary use offsets the rigidity of long-term formal plans and offers opportunities to experiment with informal, improvisational, and spontaneous innovations (Galdini, 2020), demonstrating significant benefits for social life. As a result, it has become an emerging trend and innovative strategy for reimagining urban spaces, increasingly integrated into urban policies and considered a key feature of urban planning (Andres & Kraftl, 2021; Bragaglia & Rossignolo, 2021; Dubeaux & Cunningham Sabot, 2018).

Temporary use refers to unconventional and informal spatial activities occurring within limited timeframes, differing from the typical urban development cycle (Oswalt et al., 2013; De Smet, 2013). It represents an adaptive, flexible form of urbanisation that aligns spaces with evolving demands and fosters stakeholder consensus (Bishop & Williams, 2012; Bembennek, 2008). As a development-oriented practice, temporary use explores spatial potential while reflecting a gradual integration of grassroots activities into institutional frameworks (Lehtovuori & Ruoppila, 2012; Hou, 2020).

2.1.1 Typologies and Characteristics of Temporary Use

Temporary use, a key practice in temporary urbanism, is defined by temporality and flexibility. While its short-term nature is often seen as a limitation, scholars argue it unlocks unique opportunities unattainable through long-term processes (Madanipour, 2018; Haydn & Temel, 2006). Particularly in high-density cities, temporary use empowers low-cost, low-risk experimentation, providing insights for public open space planning and management.

Andres and Zhang (2020) classify temporary urbanism into bottom-up, top-down, and hybrid modes. Bottom-up approaches, driven by communities, address immediate social needs, enhancing participation and offering ideas for activating TPOS. Top-down strategies, led by governments or institutions, align with broader urban development goals such as cultural industry promotion (Colomb, 2017), providing structured solutions for TPOS requiring rapid deployment and resource optimisation. Hybrid models encourage collaboration among stakeholders, bridging community-driven and institution-led initiatives to mitigate tensions and improve

planning efficiency (Lehtovuori & Ruoppila, 2012). This typological framework highlights temporary use's temporality, flexibility, and collaborative potential, offering a foundation for systematic TPOS policy design.

2.1.2 Alleviating Land Pressure through Temporary Use

Temporary use plays a pivotal role in high-density cities as a cost-effective and flexible spatial strategy, alleviating land pressures through short-term interventions. Its low-cost, low-risk, and time-sensitive nature effectively addresses spatial and temporal gaps in traditional urban planning (Galdini, 2020). By preventing land degradation or unauthorised occupation, temporary use offers transitional solutions for vacant sites awaiting permanent development (Bishop & Williams, 2012; Németh & Langhorst, 2014).

Socially, temporary use fosters inclusivity and enhances the urban quality of life. By responding swiftly to community needs, it strengthens social cohesion, fosters consensus, and reduces barriers for non-profit organisations and grassroots participation (Andres & Kraftl, 2021; Tardiveau & Mallo, 2014). It also encourages citizens to reimagine urban spaces dynamically, inspiring adaptive and innovative uses (Madanipour, 2018).

Economically, temporary use revitalises underutilised land, reducing uncertainties in long-term planning through experimental approaches. This strategy increases land value and attractiveness by allowing iterative feedback for development processes (Ferreri, 2015; Mulgan et al., 2007). Flexible management also optimises land for short-term gains while offering insights for future investments (Florida, 2002).

From a governance perspective, temporary use provides an experimental platform for validating urban policies and strategies. It enables resource optimisation and attracts investors through short-term pilot projects, thus bridging the gap between temporary and long-term urban developments (Stevens & Ambler, 2010; Bragaglia & Rossignolo, 2021).

2.2 Temporary Public Open Spaces in Hong Kong

Hong Kong exhibits highly concentrated urban characteristics, including density, complexity, and verticality (Shelton et al., 2011). However, this level of intensity is often driven by economic motives, with a focus on maximising profits (Tieben, 2016). Under a system of public land ownership, the Hong Kong government's land lease system has constrained the development of public open spaces (Tang & Wong, 2008). For a long time, the government has generated revenue through the transfer of land use rights, making land allocation a significant source of income (Legislative Council Secretariat (LEGCO), 2016). Within this model, dominated by "revenue generation through land management," land-use planning is often regarded as a solution-oriented tool to resolve land disputes among interest groups and local bureaucracies (Bristow, 1984). Public open spaces are seen as additional costs for the government to provide and maintain, which has negatively affected their planning and design (Tang & Wong, 2008).

Over the past few decades, the traditional planning role of public open spaces has gradually diminished, with responsibilities increasingly shifted to the private sector. This has led to the privatisation of public open space functions (Cuthbert & McKinnell, 2001). In the 1980s, the government introduced the "Private Development Public Open Space" (POSPD) policy, encouraging the private sector to provide open spaces for public use within or around their buildings in exchange for higher building density allowances in certain high-density areas. This was intended to compensate for the shortage of public open spaces through private sector participation (GovHK, 2012). However, this incentive mechanism further prioritised economic benefits over community needs, failing to truly address the public's demands (Yu, 2018).

Hong Kong's public open space planning policies are inadequate, and the shortage of facilities has raised social concerns (Siu & Huang, 2015). The availability of public open spaces in many areas falls far below the standard of 2 square metres per person set by the Planning Department (Gilges, 1998; Zhang, 2015). Compared to other Asian metropolises, Hong Kong ranks among the lowest in this regard (Lai, 2017). The government has gradually recognised the important recreational role of public open spaces in high-density urban environments. It has

established HKPSG to provide a fair basis for reserving land for recreational facilities and open spaces, guiding their planning and design (GovHK, 2015). Most public open spaces in Hong Kong are managed by the Leisure and Cultural Services Department (LCSD). Due to limited funding, they often adopt generic approaches to the planning and design of various spaces, prioritising low maintenance costs, which fail to meet residents' comfort needs (Lai, 2017). Under the guidelines of the Hong Kong Public Health and Municipal Services Ordinance, the usage of these spaces is also strictly regulated, limiting the potential for development in the use of public open spaces (Carlow, 2013).

Against this backdrop, TPOS have emerged as an important tool to address land pressures. TPOS in Hong Kong refers to recreational land temporarily allocated by the government before permanent development takes place. Their uses are diverse, including green spaces, playgrounds, and rest gardens (GovHK, 2021). In Hong Kong, developable land is typically allocated through the private sector for permanent projects or managed by government departments (GovHK, 2017). However, this land management approach sometimes results in transitional land being temporarily left idle. This may occur due to issues such as planning, demand, insufficient funding, or land ownership, causing the originally planned permanent development projects to be delayed. To make more effective use of these temporarily vacant land resources, the government tends to allocate them for temporary or short-term uses to ensure the maximisation of land value (Lu, 2023).

According to data from the Development Bureau in 2017, the Lands Department allocated 748 temporary sites, covering a total area of approximately 760,000 square metres, for use as TPOS. Recreational land is often prioritised for temporary use because it aligns with the planning principles of the Outline Zoning Plan (OZP) and is considered a "permitted use" in almost all zoning categories. These spaces not only serve as transitional arrangements during urban land redevelopment but also alleviate the shortage of public open spaces to some extent (GovHK, 2017). When designating temporary recreational land in a particular area, the government considers multiple factors, including the size and timeline of developable land, the surrounding environment, and residents' needs (GovHK, 2017).

The "temporary" nature of TPOS leads to ambiguities in their functions, designs, and user perceptions. In some cases, the lifespan of temporary spaces is comparable to that of permanent open spaces (Lu, 2023). The planning and management of TPOS in Hong Kong have attracted increasing attention, as their usage periods often exceed their intended temporary status. Long-term use has raised concerns about maintenance quality and whether these spaces can adequately meet community needs and expectations (GovHK, 2017).

3 Research Methods

Based on the discussion above, this study examines three specific cases of temporary public space use in Hong Kong: Central Harbourfront Event Space, Sham Shui Po Underbridge Night Market, and Hong Kong Cultural Centre Piazza. These locations were chosen for their diversity in spatial functions, governance models, and user engagement, representing different approaches to temporary public open space utilisation in high-density urban settings.

The case study will rely on existing literature and secondary data analysis, including government documents, official reports, media releases, and news articles. Additionally, 15 brief semi-structured interviews will be conducted with various
stakeholders—five for each site—involving venue managers, event organisers, event staff, security personnel, and regular space users (Figure 1). Thematic analysis will be employed to explore stakeholders' perspectives on the following areas: a) their relationship with the space, b) their views on the temporary use activities and participation processes, and c) their suggestions for improving the facilities and management of temporary activities (Tsiolis, 2017).

By integrating secondary sources with first-hand insights from stakeholders, this study aims to gain a

comprehensive understanding of the opportunities and challenges associated with the temporary use of public open spaces in Hong Kong.

4 Case Study

4.1 Central Harbourfront Event Space

The Central Harbourfront Event Space is a prominent open space located in the Central waterfront area of Hong Kong, widely recognised for hosting temporary public events and activities (Figure 2). It was designated as part of the government's commitment to urban revitalisation and public engagement along Victoria Harbour. As a strategic element of the "Harbourfront City Vision," the site was allocated within the reclamation area of Central Harbourfront to serve as a flexible space for community activities and public interactions (DevB, 2021). Officially established in 2014 under the guidance of the Development Bureau, the site was entrusted to Central Venue Management Limited (CVM) for operational management, becoming one of Hong Kong's most iconic public open spaces for temporary events.

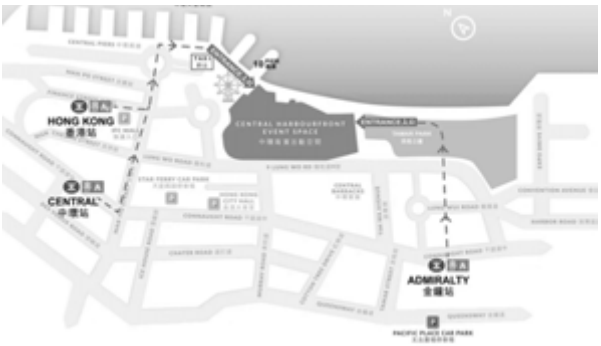

Figure 2. Map of the Central Harbourfront Event Space, CVM 2024
Figure 3. Map of rentable sections, CVM 2024

4.1.1 Operating Model and Stakeholder Relations

The Central Harbourfront Event Space operates under a public–private collaboration model. The Development Bureau serves as the primary government authority, overseeing overall planning and formulating usage policies to ensure the space aligns with public interests and urban development objectives (CVM, 2024). Concurrently, the Hong Kong government has established the Harbourfront Commission as a non-statutory advisory body to

regularly assess and monitor the space's management, ensuring openness and multifunctionality (LEDGO, 2024).

On the private sector side, the operational responsibilities are undertaken by Central Venue Management Limited (CVM), which handles day-to-day operations, event planning, and site maintenance. The event space is divided into four designated areas (Figure 3), catering to public events of various scales. Event organisers can obtain venue rental permits by submitting applications to CVM. CVM operates in accordance with an agreement signed with the Development Bureau and complies with recommendations and public service objectives set by the Harbourfront Commission. It is required to submit regular operational reports to the government (CVM, 2023), ensuring that events held at the venue meet community cultural and economic needs while supporting charitable activities (DevB, 2024).

In this operational framework, government institutions like the Development Bureau and the Harbourfront Commission play policy coordination and advisory roles, while the private company CVM, as the primary operator, collaborates with community groups, non-governmental organisations (NGOs), and commercial entities (Figure 4).

The Central Harbourfront Event Space operates with a structured and efficient management system. During events, security personnel explained that they do not directly interact with venue managers, as arrangements are pre-coordinated by event organisers. "*The process was relatively smooth without major communication issues.*" (Interview, Security Personnel) This indicates that the operational workflow, including venue rental and security coordination, relies on a relatively well-established management system. Clear allocation of resources and responsibilities between the venue managers, event organisers, and security teams facilitates smooth event execution.

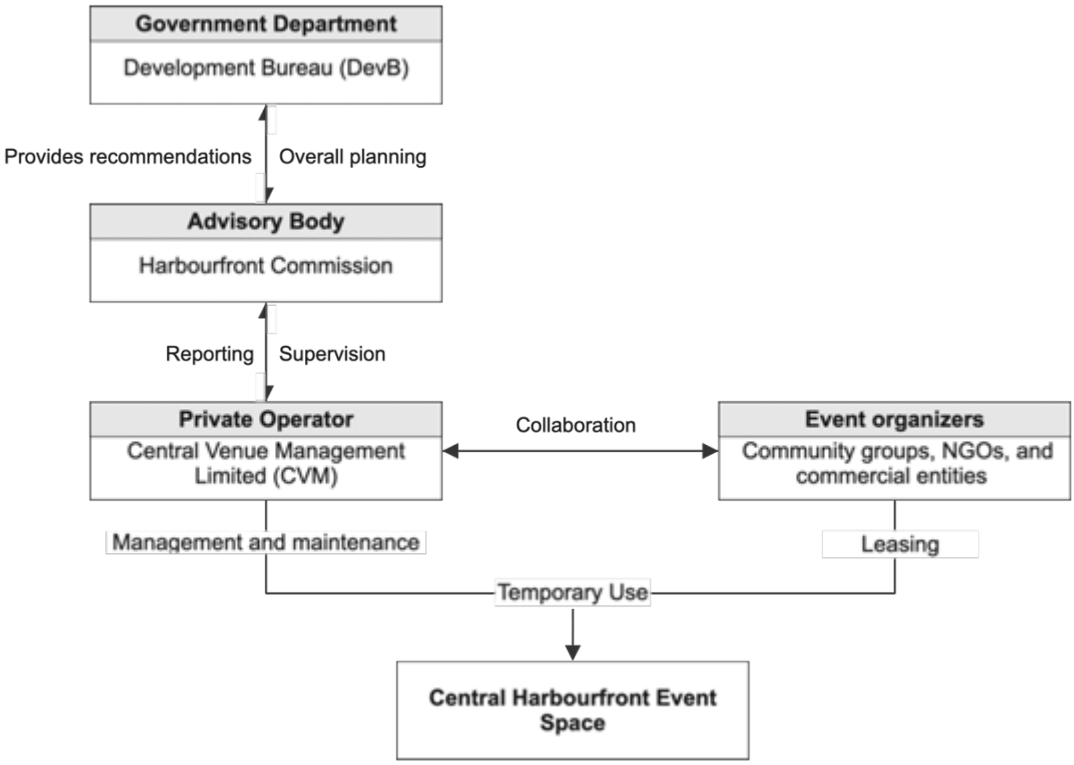

Figure 4. Flowchart of the operating model and stakeholder relationships, own processing

However, the space's operational flexibility reveals gaps in infrastructure that could hinder user experience during adverse conditions. A staff member responsible for maintaining order and ticketing during a temporary event further noted, "*Since the entire area is an open outdoor space, rainy days can be quite troublesome. We can only work in plastic raincoats, which adds challenges to maintaining order. I hope the venue managers can provide temporary rain shelters, such as tents.*" (Interview, Event Staff) While the space's open nature offers flexibility, it also lacks infrastructure to address unforeseen weather conditions.

The space's temporary policies have also been praised for promoting vibrancy and inclusivity, enabling diverse public engagement (Figure 5). A regular visitor who comes almost daily shared, "*The government policies provide considerable freedom. As long as you don't interfere with others, they don't overly restrict spontaneous activities.*" (Interview, Users) This user mentioned witnessing numerous temporary events, which he believes have enriched the space's functionality and attracted more public engagement.

Figure 5. Temporary activities at the Central Harbourfront Event Space, CVM 2024

The Central Harbourfront Event Space has a structured management model with clear delineation of roles and efficient processes from venue rental to event management. However, gaps in spatial planning remain, particularly the lack of adaptive facilities for weather contingencies.

4.2 Hong Kong Cultural Centre Piazza

The Hong Kong Cultural Centre Piazza is located in Tsim Sha Tsui and serves as one of the key venues for cultural and artistic activities in Hong Kong. Originally established alongside the Hong Kong Cultural Centre to provide an open public space for leisure and cultural engagement, the piazza's use has diversified over time due to the growing demand for multifunctional public spaces. Recognising its potential, the government divided it into four sections to host different types of temporary activities to enhance its utility and public engagement (Figure 6). According to the Leisure and Cultural Services Department, the piazza has become a prominent venue supporting diverse cultural, artistic, and community events (LCSD, 2024).

Figure 6. Map of the Hong Kong Cultural Centre Piazza, LCSD 2024

4.2.1 Operating Model and Stakeholder Relations

The Hong Kong Cultural Centre Piazza is managed entirely by LCSD, whose responsibilities include venue rental approvals, daily maintenance, and event management. The use of the piazza primarily involves event organisers, such as community groups, charitable organisations, and private enterprises, who directly apply to LCSD for venue rental. Organisers must submit detailed proposals ensuring compliance with government regulations. LCSD provides a streamlined application process to facilitate efficient approval (LCSD, 2024).

Additionally, LCSD actively organises temporary events in collaboration with charitable associations and community organisations, launching creative markets to provide platforms for young artisans and offering performance spaces for people with disabilities, exemplifying the piazza's inclusivity and diversity as a public space (LCSD, 2024). One organiser noted, *"The open layout and multifunctional design of the piazza greatly facilitate events, particularly as its cultural atmosphere attracts a significant number of participants."* (Interview, Event Organiser) This collaborative model ensures the piazza's cultural vibrancy while allowing LCSD to balance commercialisation with public service needs (Figure 7).

Figure 7. Temporary activities at the Hong Kong Cultural Centre Piazza, LCSD 2024

Temporary activities in the piazza were generally well received by users. Residents living near the piazza stated, *"This space has become part of my daily running route, and the temporary activities held here haven't interfered with my routine. If there were free events, I would make a special trip to participate."* One resident also suggested adding drinking fountains to better serve outdoor exercise enthusiasts (Interview, Users).

While the government's top-down vision emphasises cultural promotion and multi-functionality, feedback from both event organisers and individual users reveals additional layers of consideration. Event organisers highlight the importance of flexible layouts for large-scale cultural events, whereas individual users stress the need for practical amenities like drinking fountains to support everyday activities. Therefore, although the temporary pattern of public open space use in the piazza is well-positioned to meet broad cultural and community goals, challenges remain in aligning the space's offerings with the practical needs of its diverse user base.

4.3 Sham Shui Po Underbridge Night Market

The Sham Shui Po Night Market, located under the Tung Chau Street Flyover, is a three-day temporary market held before the Chinese New Year, representing a grassroots initiative to revitalise underutilised urban spaces in Hong Kong. Emerging naturally in the early 2010s, the night market was initiated by community organisations and street vendors. It is the first Chinese New Year night market in recent years to be driven by grassroots organisations and granted legal operating status, symbolising a new direction in grassroots action and the utilisation of urban public spaces. Without proactive government planning, the night market evolved through collective action and self-organisation, exemplifying a bottom-up approach to temporary public space usage. This process not only heightened public awareness of temporary spaces but also became a significant attempt to reutilise public spaces in land-scarce Hong Kong.

4.3.1 Operating Model and Stakeholder Relations

Figure 8. Flowchart of the operating model, own processing

The operation of the night market involves multiple stakeholders, including government departments, community organisations, and street vendors. The preparation of the night market is typically led by community organisations, which conduct user surveys and draft detailed proposals to assess market demand and feasibility. Following this, vendors need to apply for relevant permits and licences from various government departments, including the Food and Environmental Hygiene Department (FEHD), the Lands Department, and the Environmental Protection Department, which are responsible for examining food safety, land use, and environmental management, respectively (FEHD, 2024). Finally, the legalisation of the night market also requires submission to the district council for discussion and approval (Figure 8). During the operation of the night market, the government does not participate in direct management. Community organisations play a central role, not only coordinating the government's approval process but also overseeing the practical operations of the night market, such as site planning, stall allocation, and communication with vendors.

Although the government has long advocated for transforming underutilised public spaces into marketplaces, including district-led initiatives to establish legal open-air bazaars and night markets, the process remains challenging for vendors (LEGCO, 2015). One organiser stated, "The process for legal operation is complex and lengthy. We had to communicate repeatedly with multiple departments to obtain approval" (Interview, Organiser). Some vendors who considered organising a legal night market ultimately gave up due to the cumbersome application process. *"I once thought about organising a temporary market, but the application process was too complicated, so I abandoned the idea,"* one vendor shared (Interview, Vendors). Another vendor added, *"The government has not provided any policies or assistance to support bottom-up approaches. We are left to navigate in the dark on our own"* (Interview, Vendors).

Compared to Hong Kong's highly commercialised urban spaces, many people appreciate the atmosphere here (Figure 9). During the Chinese New Year holidays, when most shops are closed, such a temporary night market provides convenience for residents. A regular visitor to the night market remarked, *"This is a unique space where you can truly experience Hong Kong's local culture."* (Interview, User)

Figure 9. Sham Shui Po Underbridge Night Market during Chinese New Year, Initium Media 2017

The operating model of the Sham Shui Po Night Market illustrates how bottom-up space utilisation can intersect with the government's top-down regulatory framework. While the legalisation of the night market faces institutional obstacles, the coordination by community organisations and active participation of vendors have made this space a significant example of temporary public open space in Hong Kong. However, despite the government's stated intentions to promote legal night markets, procedural barriers continue to impede progress. The disconnect between the government's top-down regulatory approach and the grassroots needs of vendors underscores ongoing challenges. Without streamlined policies and improved infrastructure support, the long-term sustainability of such initiatives remains uncertain.

5 Discussion

Under the theoretical framework of temporary urbanism, the study of TPOS in Hong Kong reveals a policy-driven and systematic approach to temporary land use. Managed and allocated by the Lands Department, Hong Kong's TPOS aligns with the top-down governance model characteristic of temporary urbanism (Colomb, 2017). This reflects an institutionalised response to land scarcity in high-density urban environments, demonstrating how temporary use can be formalised as part of urban policy to address immediate spatial needs while awaiting long-term development.

The three cases examined in this study represent distinct approaches to the temporary use of public open spaces in Hong Kong. Each case highlights unique operational models that respond to urban land scarcity in specific ways while grappling with contextual challenges.

The Central Harbourfront Event Space operates under a public-private partnership model, managed by a private company under the guidance of the Development Bureau. Transformed from reclaimed land into one of Hong Kong's most prominent public open spaces, its flexible usage enhances urban attractiveness and economic value (Florida, 2002). The structured operational model supports large-scale cultural and recreational events, showcasing efficient event coordination and resource allocation. However, reliance on temporary infrastructure reveals limitations—such as inadequate shelter for inclement weather—restricting its usability for everyday activities.

The Hong Kong Cultural Centre Piazza, fully managed by the Leisure and Cultural Services Department (LCSD), exemplifies a centralised governance model. It integrates temporary activities into cultural infrastructure, offering free venues to disabled individuals and emerging artists, thereby improving urban quality of life and social inclusivity (Andres et al., 2021). The streamlined application process facilitates a range of events, balancing cultural promotion with public service objectives. While organisers value the flexible layout for cultural events, users often highlight practical concerns—such as the need for drinking fountains—demonstrating the ongoing challenge of aligning multifunctional policy ambitions with daily user needs.

In contrast, the Sham Shui Po Night Market represents a grassroots, bottom-up initiative, led by community organisations and vendors. It offers a low-cost platform that enriches dense urban environments and strengthens community cohesion (Németh & Langhorst, 2014). By repurposing underutilised spaces, the night market provides community-centric responses to peak demand periods such as the Lunar New Year, highlighting civic adaptability and collective agency (Tardiveau & Mallo, 2014). Public feedback underscores the value of participation in reshaping urban space; however, long-term sustainability is constrained by fragmented oversight and complex licensing procedures. The lack of institutional support underscores the challenges grassroots TPOS face within Hong Kong's regulatory framework.

Collectively, these cases illustrate the potential of TPOS in responding to urban land scarcity, while underscoring the need for more adaptable infrastructure, simplified regulatory frameworks, and collaborative governance models to maximise their sustainability and inclusivity. Limitations in Central Harbourfront and Cultural Centre Piazza demonstrate the importance of balancing flexibility with practical functionality. Meanwhile, the Night Market reveals a pressing need for institutional mechanisms that better support community-led initiatives. Across all cases, a disconnect between top-down planning visions and ground-level user feedback highlights the necessity of incorporating diverse stakeholder voices into the design and governance of TPOS.

6 Conclusion

This study investigates the role of TPOS in addressing land scarcity in high-density urban environments such as Hong Kong. Through a combination of theoretical research under the framework of temporary urbanism and case studies of three distinct sites, the research identifies how varying governance models and operational approaches influence the performance and challenges of TPOS. The findings highlight a mismatch between the government's planning aspirations and the practical needs of users, pointing to both opportunities and

obstacles in the effective implementation of TPOS strategies.

The study demonstrates that Hong Kong's TPOS policies reflect a structured attempt to incorporate temporary spaces into urban planning. This involves balancing the adaptability required for temporary use with the rigidity of formalised governance systems. By examining the city's approach, key insights emerge: the importance of stakeholder collaboration, the necessity of flexible and inclusive infrastructure, and the value of simplified administrative mechanisms. Acknowledging gaps in public engagement and service provision, this research suggests that the TPOS framework would benefit from enhanced responsiveness to community-driven initiatives that harmonise policy intent with on-the-ground application. Such improvements could improve alignment between centralised planning and the evolving needs of diverse urban users, fostering more sustainable and impactful space management.

The research holds practical implications for refining the TPOS system in Hong Kong, providing insights into how temporary land use can be optimised to address urban pressures. It underscores the potential of TPOS to bridge short-term spatial demands and long-term urban development goals, and calls for a more adaptive, inclusive approach to public space management in high-density cities.

Abstract
This paper introduces a research methodology to investigate the impact of urban green areas on human health, focusing on medium-sized Italian cities. Recognizing the critical link between urban environments and health outcomes, particularly concerning non-communicable diseases exacerbated by urbanization, the study employs concepts of spatial justice, place-based health, and environmental vulnerability. The methodology involves calculating the Normalised Difference Vegetation Index from satellite imagery, determining Pro Capita Green Space, and estimating Real Accessibility to urban parks within a 15-minute walk. Applied to six diverse Italian cities, the analysis reveals varying distributions and accessibility of green spaces, highlighting the influence of historical urban layouts, population density, and natural features on environmental equity. The findings underscore the importance of strategically integrated urban green infrastructure for promoting public health.

Keywords: Green Areas; Public Health; Accessibility; Medium-sized City; Climate Change

Introduction

This paper aims to propose the research methodology developed in the first phase of *Urban green infrastructure, policies on green spaces and health outcomes*, a European Union-Next Generation EU funded research project, which aims to investigate the impact that green areas in urban contexts can potentially have on physical and mental human health.

The relationship between human health and green areas is a dialectical pairing that has always characterized the theoretical and operational interest of urban planning since the formation of the modern discipline. The relentless urbanization processes of recent decades have further prompted the scientific community to explore the relationship between urban areas and citizens' health. On the one hand, urbanization has been shown to facilitate access to health services and offer greater social and employment opportunities. On the other hand, urban environments tend to be less conducive to health, increasing the incidence of chronic diseases, particularly cardiovascular, respiratory, and mental disorders.

Urban environments play a significant role in influencing the risk factors for noncommunicable diseases (NCDs), which include cardiovascular diseases, cancers, chronic respiratory diseases, and diabetes. These conditions are largely driven by behavioral and environmental factors that are often intensified in cities. Air pollution—both indoor and outdoor—is a major environmental risk in urban areas, contributing to millions of NCD-related deaths each year.

In addition, urban settings often promote unhealthy lifestyles, such as poor diets, physical inactivity, tobacco use, and harmful alcohol consumption. These behaviors increase metabolic risk factors like high blood pressure, obesity, elevated blood glucose, and abnormal blood lipids, all of which are linked to a higher incidence of NCDs.

Socioeconomic disparities in cities further exacerbate the problem, as low-income and marginalized populations may have less access to healthcare, healthy food, green spaces, and opportunities for physical activity. To combat the NCD burden in urban areas, it is essential to implement cross-sectoral policies that promote healthy environments, improve access to preventive care, and reduce exposure to risk factors (WHO, 2024).

The idea that space influences well-being is therefore not new, but it has been rediscovered through interdisciplinary research over the past two decades. From a geographical perspective, concepts such as *spatial justice, place-based health, and environmental vulnerability* have made it possible to go beyond an exclusively clinical approach, instead considering health as a shared goal across multiple disciplinary fields (Cummins et al., 2007). A much-discussed and debated concept in the literature, *spatial justice* in this context refers to the equitable distribution of resources and opportunities across different territories. Spatial justice does not merely involve considering social justice *in* space, but rather recognizing the active role that space plays in producing both justice and injustice:

"everything that is social (justice included) is simultaneously and inherently spatial, just as everything spatial, at least with regard to the human world, is simultaneously and inherently socialized" (Soja, 2010, p. 5).

In the specific case of the relationship between territory and health, spatial justice implies that access to healthcare services, green spaces, and infrastructure that promote a better quality of life should not depend on a person's geographic location, as this creates direct injustices and indirect implications for their health. One example is the differing opportunities between rural and urban areas: while both face similar challenges, they respond differently to significant issues such as healthcare access, promoting active mobility policies, and fostering social cohesion. This concept has been explored in recent studies highlighting the role spatial inequalities play in shaping the health of rural populations (Martino et al., 2024).

The concept of *place-based health* supports the connection between people's health and the specific characteristics of the places where they live, work, and interact. This includes factors such as air quality, access to healthy food, neighborhood safety, and the availability of spaces for physical activity. Inequalities in these environmental factors can lead to significant health disparities across different communities. For example, low-income populations often live in areas with less access to health-promoting resources, contributing to poorer health outcomes (Diez Roux, 2016; Boyd et al., 2023).

Another key concept guiding this research is *environmental vulnerability*. This refers to the capacity of territories to suffer harm due to exposure to various types of stress, including environmental and social changes, and conversely, to their lack of capacity to adapt to such changes. This vulnerability is often the result of political decisions and urban planning that fail to consider the needs of territories and their populations, especially the most vulnerable ones. Geographic studies have shown how such decisions contribute to significant disparities in health across different geographic areas (Anderson et al., 2025).

The organization of urban space, the distribution of services, the quality of infrastructure, and the presence of green areas are not neutral elements, but rather determinants of physical and mental health—particularly for older adults (Xu et al., 2023). Cities do not merely host the elderly; they shape their life experiences, either amplifying or mitigating risks. To promote a better quality of life during aging, it is essential to integrate health and psychological dimensions with spatial and environmental ones.

This idea is supported not only by territorial studies but also by the evolving definition of health itself. Since its founding in 1948, the WHO has defined health as "a state of complete physical, mental and social well-being

and not merely the absence of disease or infirmity." This individual-centered definition has given way to the concept of health as *Global Health*, placing strong emphasis on inequalities. The AIDS epidemic in the 1980s highlighted how human health is closely linked to environmental, social, and cultural factors. Since the 2000s, the concept of *One Health* has entered the public health discourse, connecting human health with that of animals and the planet. In recent years, particularly due to the effects of the Anthropocene, a paradigm shift has become necessary to counter a socio-economic system that neglects human, environmental, and planetary well-being—while generating socioeconomic and health inequalities—through the *Planetary Health* approach.

It is also useful to clarify the notion of *health determinants*, particularly within public health: these are elements that, directly or indirectly, significantly impact quality of life and include everything that can contribute to improving or worsening individual health conditions. A highly illustrative and well-known framework (figure 1) was published in 1991 by Dahlgren and Whitehead, which describes the role of social determinants of health, highlighting their cascading influence from general socioeconomic, cultural, and environmental conditions down to the individual, through various layers that also include the urban environment (Capolongo and D'Alessandro, 2017).

Figure 1: the role of social determinants of health. Dahlgren and Whitehead, 1991 (as cited in Dahlgren and Whitehead, 2021)

The work is based on the premise that urban green spaces must be easily accessible to all population groups and equitably distributed throughout the city. The links between urban greenery and health have been demonstrated by numerous scientific publications and reports (Kondo et al., 2018; WHO Regional Office for Europe, 2016). This contribution aims to present an analysis of the distribution and accessibility of urban green spaces in six medium-sized Italian cities, which serve as case studies for the research. This mapping enables reflections on the spatial configuration of urban greenery and its ease of access. It is considered that this aspect should be seen as a priority when addressing the issue of nature in urban contexts and its impact on human health. In particular, these areas are an essential component of outdoor public spaces and services, providing an ideal setting for the equitable and just promotion of health for all members of the community.

Methodology

The methodological approach is divided into three phases. Firstly, the Normalised Difference Vegetation Index is calculated. This index is based on the analysis of satellite images and provides an overview of the greenery within the municipality. In the next stage of the process, the Pro Capita Green Space is calculated, which highlights the surface of green space per inhabitant. Finally, the estimation of real accessibility is provided, indicating the

walking distance to urban green areas.

The Normalised Difference Vegetation Index (NDVI) is an index that facilitates the identification of vegetated areas through the utilisation of multispectral remote sensing images. In this analysis, the images are derived from ESA's Sentinel-2 satellites. Sentinel-2 satellites boast a temporal resolution of five days and are equipped with the MSI (MultiSpectral Instrument). This instrument is capable of acquiring four bands in the visible and near-infrared with a spatial resolution of 10 metres, six bands in the infrared with a spatial resolution of 20 metres, and three bands with a resolution of 60 metres. Two bands (band 4 and band 8) with 10 metres of geometric resolution are utilised in the calculation of the NDVI. The index is derived from the ratio between the difference and the sum of the radiation reflected in the near infrared and red, as outlined in the following formula:

$$NDVI = \frac{(NIR - RED)}{(NIR + RED)}$$

The index has a range of values from -1 to 1: negative values are typically indicative of anthropogenic areas or water, while positive values are indicative of areas with vegetation. The raw images, collected during the period spanning from January to December 2023, have undergone a process of correction to compensate for the presence of clouds or snow. Subsequent to this preliminary processing, the formula for calculating the NDVI is applied to each pixel of each raster image. The final processing of the data is a composite image with aggregated average values.

The NDVI index can be utilised as a foundational metric in the calculation of another indicator, which is instrumental in ascertaining citizens' exposure to green space and acquiring data pertaining to the spatial organisation of the case studies. The index in question is the Pro Capita Green Space (PCGS) index (Aryal et al., 2022), which quantifies the amount of green space (in m2) available per inhabitant. The designated case study areas were subdivided into a hexagonal grid measuring 60 metres. The formula is as follows:

$$PCGSi = \frac{Gi}{PNi}$$

- is the total area of green spaces (m2) in in zone
- is The total population of zone

The number of inhabitants was estimated based on data from the 2021 ISTAT Permanent Population Census. For each hexagon, the resident population was calculated using geoprocessing and proportions.

The initial two index encompass all green areas within municipal boundaries, incorporating agricultural areas, parks, and woodlands, among others. In order to investigate the relationship between population and green areas from the point of view of accessibility, only urban parks were selected in this last phase of the methodology. The methodology for deriving Real Accessibility (RA) catchment areas involves the integration of morphological data with road networks, barriers and population data, and the association of different travel costs depending on the characteristics of the area (Romo et al., 2022). The scenario modelling is based on a maximum distance from green areas of 15 minutes walking (Moreno et al., 2021). Speeds were diversified according to the characteristics of the terrain, starting from a speed considered average, which is strongly influenced by factors such as age, physical condition, etc. (Giuliani et al., 2021). The speeds set are as follows:

• 5 km/h on roads/pavements without obstacles;
• 4 km/h on rural paths and built-up areas where there may be obstacles;
• 2 km/h in rural areas outside and away from roads.
The methodology calculates the distance of 15 minutes, at the speeds indicated above, from the centroid of the

green area. The decision to utilise the centroid was necessitated by the lack of data concerning actual access to the selected urban parks (Giuliani et al., 2021). The following data were utilised in the calculation:

- The centroid of urban parks.
- The 10x10 m Digital Terrain Model (DTM) produced as part of the INGV's TINITALY project (Tarquini et al., 2023).
- The build-up areas obtained from the Lazio Region Land Use Map (2012) and the Tuscany Land Use and Land Cover Map (2019).
- The road network, extracted from the OpenStreetMap (OSM) database.
- The elements that act as barriers to pedestrian movement: motorways, railway lines, lakes and the hydrographic network.
- The census sections of the ISTAT Permanent Population Census of 2021.

The processing was conducted utilising the open-source software GRASS GIS, with particular reference to the r.cost module (Sacchelli et al., 2013; Becker et al., 2017; Cadez et al., 2023). The module facilitates the calculation of cumulative travel costs on the pixel matrix, with the calculation initiated from the centroids and a threshold time of 15 minutes. The matrix calculation is based on an anisotropic friction map that combines morphological data and barriers. The barriers element indicates the designated pedestrian thoroughfares, while the first element modifies walking speed according to gradients (Tobler, 1993). Consequently, the maximum velocity is attainable on level terrain and declines exponentially as the gradient rises, with a threshold limit of 30°. Beyond this limit, crossing is prohibited. The result of the r.cost module is a map with accumulation times commencing from the centroids of the nearest urban parks, as well as a map of the accessibility basins identified for each urban park. The accessibility basins model can be utilised to identify the population residing within a 15-minute radius of green areas.

Case studies

The municipalities of Arezzo, Siena, Grosseto, Latina, Viterbo, and Rieti, located across Tuscany and Lazio, were selected for this research due to their classification as medium-sized cities. Italy is predominantly composed of such cities, which often exhibit complex territorial dynamics while having limited tools to address them. These six cities offer a diverse mosaic of demographic, environmental, and cultural characteristics, with significant differences shaped by geography, history, and economic orientation.

Arezzo, with approximately 99,000 inhabitants, lies in eastern Tuscany, nestled among green hills and along the Arno River. Its historic center is rich in medieval and Renaissance heritage, and the municipal territory features a balance between woodland, agricultural, and urbanized areas. Tourism maintains a steady presence throughout the year, driven by historic events such as the *Giostra del Saracino*.

Siena has around 53,700 residents in its urban core, with a greater metropolitan area exceeding 98,000 inhabitants. It is renowned worldwide for its perfectly preserved medieval historic center, recognized as a UNESCO World Heritage Site. The territory, hilly and relatively small (118 km²), also includes valuable rural and wine-producing areas. Tourism, strongly tied to the *Palio di Siena* and its university tradition, is a key component of the local economy.

Grosseto, home to about 82,000 people, is located on the Tyrrhenian Sea and lies within the Tuscan Maremma region. Its historic center, enclosed by 16th-century hexagonal walls, is entirely pedestrianized. The territory is characterized by a significant presence of protected areas, including the Maremma Natural Park, which features beaches, Mediterranean scrubland, wetlands, and wildlife habitats. Tourism is closely linked to these natural features.

Latina, with approximately 116,000 residents, is a relatively young city, founded in 1932 during the reclamation of the Pontine Marshes. The municipality spans a vast flat and agricultural area, which also includes part of the Circeo National Park, featuring valuable environments such as Lake Fogliano and coastal dunes. Tourism is

growing and focuses on beach destinations (like Capoportiere and Foce Verde), as well as nature-based and food and wine experiences.

Viterbo, with a population of around 67,000, is located in the historical region of Tuscia. Its historic center is one of the largest and best-preserved in Lazio, rich in medieval palaces and Etruscan remains. The surrounding hilly and forested territory includes thermal areas and nature reserves. Tourism is strongly influenced by the *Macchina di Santa Rosa*, a spectacular religious tradition, as well as the thermal baths and wellness-related routes.

Rieti, finally, with about 47,700 inhabitants, is set in the Rieti Plain at the foot of Mount Terminillo. The municipal territory offers a remarkable environmental variety, including mountains, hills, lakes, and nature reserves such as those of the Lungo and Ripasottile Lakes. The *Cammino di Francesco* (Path of Saint Francis), which passes through the so-called Holy Valley, is also of great importance. Tourism is focused on wellness, spirituality, and outdoor activities, particularly hiking and winter sports.

Data analysis and discussion

The NDVI map of Arezzo (figure 2) reveals a landscape predominantly characterised by a high presence of green, particularly in the areas surrounding the primary urban centre. The presence of dark green shades, which are indicative of very healthy and dense vegetation, is pervasive in the areas outside the central built-up area. The green infrastructure is characterised by large continuous blocks of high NDVI surrounding the city, including forests and large agricultural fields. Within the primary urbanised area, the presence of greenery is considerably lower, a reflection of the density of buildings and impervious surfaces. However, there are some linear green areas that penetrate the urban fabric. The primary urbanised area exhibits a distinct and irregular pattern characterised by low NDVI values, suggesting a high concentration of human activity.

The NDVI map for Grosseto (figure 2) reveals a landscape predominantly characterised by moderate to high green in its surroundings, which is indicative of substantial agricultural activity. The chromatic variations in green that characterise the peripheral regions of urban areas tend to exhibit a paler intensity when compared to the verdant shades typically associated with dense forest ecosystems. This phenomenon is particularly evident in the expansive cultivated fields that are commonly present in these peripheral regions. The green infrastructure in the surrounding areas is characterised by a high degree of structuring, exhibiting clear rectangular patterns that are indicative of substantial agricultural plots. Within the confines of the primary urbanised area, the NDVI values are low, creating a pronounced contrast with the rural environment. The transition from urbanised areas to agricultural land is clear. The primary urban centre exhibits minimal green values.

The NDVI map for Latina (figure 2) reveals a landscape predominantly characterised by moderate and widespread greenery in non-urbanised areas, primarily attributable to substantial agricultural activity. The chromatic variations in green exhibited a high degree of uniformity across the expansive rural regions. The green infrastructure in the surrounding areas is characterised by a distinct grid pattern, indicative of highly organised agricultural fields. The urbanised area itself is more extensive and less densely populated than other cities, with a presence of lighter green areas within the urban boundaries. This suggests a more integrated approach to green spaces in residential or public areas. The primary urban zone is distinguished by its low NDVI values. However, the irregular and fragmented nature of its outer boundary, characterised by numerous smaller pockets of low NDVI extending outwards into the rural landscape, suggests a fragmented urban development pattern rather than a single, compact core. The widespread and geometrically organised agricultural patterns in the surrounding areas are a distinctive feature. The presence of lighter green areas interspersed within the urban fabric could imply a design that incorporates more internal green elements than older, more compact cities.

The NDVI map of Rieti (figure 2) demonstrates the city's deep embedding within a lush, topographically complex landscape. Outside the urban boundaries, the predominant colouration is dark green, indicative of elevated NDVI values and dense natural vegetation. The green infrastructure is characterised by extensive, contiguous expanses of forest. Urbanised areas are smaller and more irregular in shape, conforming to the contours of the terrain and

often appearing to be nestled between these large green masses. The built-up areas of the city demonstrate a low NDVI. However, the influence of the rugged morphology is evident, with green areas interspersed with or immediately adjacent to urban areas. The urban footprint is fragmented due to the topography of the surrounding area, which is mountainous and densely vegetated. The pronounced visual contrast between the compact urban settlements and the expansive dark green natural environment is a salient feature. This underscores a context in which the challenge may reside in optimising access to the abundant natural greenery that surrounds the city, whilst concomitantly integrating small accessible green areas within the confines of the urban footprint.

The NDVI map of Siena (figure 2) reveals a city situated within a landscape of considerable diversity, marked by a combination of dense natural vegetation and intensive agricultural activity. The topographical map is characterised by an alternation of dark green areas, indicative of forests, and light green areas representing cultivated land. The green infrastructure encompassing Siena is characterised by an intricate network of wooded areas and agricultural fields, which reflect the undulating topography of the region. The overall vegetation is high in density but heterogeneous in its distribution. The primary urban nucleus is highly distinctive, exhibiting a dense and compact historic core with minimal vegetative cover. The urban profile of Siena is characterised by its irregular and organic nature, with strips of lower vegetation extending outwards into the landscape. This morphology is indicative of development that is closely linked to the natural territory. The transition from high urban density to varied green spaces is evident in the immediate outskirts of the city. The map provides a clear visual representation of the historical compactness of Siena's urban core, where the NDVI highlights a minimal presence of internal greenery.

The NDVI map for Viterbo (figure 2) reveals a landscape that combines the moderate green of agricultural fields with areas of vegetation exhibiting a higher NDVI index. The chromatic variations in green are notable, with a predominance of lighter hues when compared to the darker tones characteristic of densely wooded areas. The green infrastructure in the wider area around Viterbo consists of a combination of defined agricultural plots and darker, less structured patches of green. The primary urbanised area exhibits a low NDVI index, which is characteristic of an urban centre. The presence of several distinct, smaller pockets with low NDVI indices has been identified in the surrounding area, indicative of satellite developments or specific land uses.

Two dominant landscapes can be identified around the case study cities. The municipalities of Arezzo, Rieti and Siena are characterised by a landscape dominated by natural greenery, featuring extensive forests and undulating hills covered with vegetation. The urban form of Rieti and Siena is significantly influenced by the topography of the area, with cities often developed along or within natural green spaces. Arezzo also benefits from a rural fringe rich in vegetation, although its immediate urban surroundings show agricultural patterns rather than dense forests. In contrast, Grosseto, Latina and Viterbo are situated in the plains, which are characterised by their flatter topography and intensive cultivation. The surrounding area is characterised by extensive greenery, predominantly comprising agricultural fields.

There is a correlation between the urban topography and the NDVI index. Arezzo, Grosseto and Siena exhibit a markedly distinct central urban core, characterised by a consistently low surface permeability index (NDVI), indicative of a high concentration of impervious surfaces. This phenomenon is especially evident in Siena, a city with a historically dense and compact urban structure. Despite the presence of green belts in these cities, a paucity of green space within the urban centre is evident. The city of Latina is distinguished by its diffuse urban form and the presence of clearly delineated green areas that appear to be more interspersed within its urban boundaries. This finding indicates a shift towards a more modern approach to urban planning, one that incorporates a greater proportion of green spaces within residential areas.

As previously mentioned, the PCGS (figure 3) is particularly useful for analyzing the spatial distribution of urban greenery, supporting territorial planning, and assessing environmental equity among urban areas. The map presented here applies a similar method for calculating the PCGS, translating NDVI values into a pro capita measure of actual green cover over land and population, in support of ecological and urban planning analyses

at the local scale.

The three maps offer a comparative overview of the distribution of urban green space per capita (PCGS) in the municipalities of Siena, Arezzo, and Grosseto, highlighting both territorial similarities and differences in the per capita availability of green areas.

Siena displays a fairly uniform distribution of green space per capita, with a wide presence of low-density areas (light-colored hexagons) that maintain a decent amount of greenery. However, the urban center appears to have less green space per capita, likely reflecting the demographic concentration in the historic core and the compactness of the medieval urban fabric. Peripheral and hilly zones offer more abundant green space per person but are not always densely populated.

Arezzo, in contrast, presents a more uneven pattern. Areas with a high per capita green space (dark purple tones) emerge in scattered and peripheral locations, while many central areas show medium or low values. The broader and more mixed territorial morphology—urban, agricultural, and hilly—seems to influence the PCGS distribution more significantly, highlighting a certain fragmentation in green space access.

Grosseto stands out for a wider presence of dark-colored hexagons, indicating high green space availability per capita across many areas, especially along the coast and in the southwestern periphery. This is likely linked to low settlement density and the significant presence of natural and protected areas, such as the Maremma Regional Park. However, there are also hexagons with no coloration (indicating no population), revealing vast uninhabited green zones.

In comparative terms:

• Grosseto appears to have the highest per capita green space, due to its large area and low population density in many sectors;
• Siena is more balanced overall but penalized in its central areas by the density of its historic urban structure;
• Arezzo shows greater spatial heterogeneity, reflecting a more fragmented distribution of greenery in relation to population.

In summary, PCGS proves to be an effective tool for capturing spatial inequalities in urban green space provision. The maps reveal how population density, historical urban layout, and the presence of natural areas significantly affect the availability of accessible green space per inhabitant—insights that are highly relevant for urban planning and environmental equity.

As for the cities in Lazio, Viterbo shows a fairly balanced distribution of per capita green space, with numerous dark green hexagons spread across almost the entire territory. This indicates a good availability of green areas per inhabitant, even near the urban center. Both central and peripheral areas display relatively homogeneous levels, suggesting a moderate population density and a significant presence of natural or agricultural spaces. White hexagons, indicating areas with no population, are present but not predominant.

Rieti is characterized by a more fragmented distribution. While some peripheral areas show a high availability of green space, certain central hexagons lack color, pointing to large uninhabited or very sparsely populated zones. Compared to Viterbo, per capita green space is often high but less evenly distributed and more concentrated in specific areas.

Latina presents a more uneven situation, with less green space per capita. A wide presence of light green hexagons suggests lower availability of green areas for inhabitants in many parts of the city. White areas are also relatively widespread, indicating uninhabited zones. Coastal and southern areas appear to be slightly better equipped with green space per capita, possibly due to the presence of natural or agricultural areas. However,

overall, the map shows a lower level of green space compared to Viterbo and Rieti, likely linked to higher urban density or urban planning less focused on green infrastructure.

In conclusion, Viterbo emerges as the area with the best per capita green space, thanks to a more consistent distribution and a good balance between population and green areas. Rieti stands out for its abundant but scattered green spaces, with many uninhabited areas reducing the average impact on the resident population. Latina appears to be the most disadvantaged in terms of PCGS, with a more irregular distribution and generally lower levels of green space per inhabitant.

The Real Accessibility (figure 4) analysis yielded the results presented in Table 1, particularly in the final two rows. A significant proportion of the population in all six cities resides within a 15-minute walking distance of an urban park. Grosseto and Siena demonstrate the highest percentages, at 86% and 84%, respectively, with Arezzo and Viterbo following closely behind at 80%. Latina has the lowest coverage, at 75%, although this still represents a substantial three quarters of its population. Especially in the case of Latina and considering the NDVI results indicating a more spread-out urban layout, it is possible that urban parks are less evenly distributed within the city. The average travel time to reach the nearest urban park is low in all cities, ranging from 8 minutes and 55 seconds (Siena) to 11 minutes and 21 seconds (Viterbo). This finding serves to substantiate the hypothesis that access is efficient for the population within the 15-minute catchment area. Despite its complex topography, as highlighted in the NDVI analysis, Siena shows the fastest average travel time. This finding suggests the hypothesis that the city's urban parks are strategically or historically well integrated into its dense urban core. Viterbo has the longest average travel time, which may be influenced by the greater dispersion of urban parks compared to population centres, as indicated by the substantial non-vegetated area observed in its NDVI map. There is a considerable degree of variability in the absolute number of urban parks, ranging from 41 in Viterbo to 155 in Latina. The average size of these parks is subject to variation. Grosseto has the largest average park size (8,685 m^2), while Siena and Rieti have the smallest average sizes (4,618 m^2 and 4,708 m^2 respectively). A comparison of the number of parks and population coverage reveals certain observations. Latina has the highest number of green areas (155), but the lowest population coverage (75%). This finding suggests that, despite the presence of numerous parks, their distribution or individual size may not be optimally aligned to serve the city's population in an efficient manner. Siena has a modest number of parks (99) with the smallest average size, but achieves excellent demographic coverage and the fastest average travel time. This suggests that the organisation of its parks is highly effective. Grosseto demonstrates a high level of coverage (86%) with an average number of parks (99), yet the largest average size. This suggests a reduced number of parks, but larger ones that are well positioned to serve a significant portion of the population.

Table 1: Real Accessibility data for the six cities

	Arezzo	Grosseto	Latina	Rieti	Siena	Viterbo
Population (total)	96.527	81.412	127.732	45.169	52.991	66.365
Surface (km^2)	385	474	278	206	119	406
n° of green areas	143	99	155	55	99	41
Average surface green areas (m^2)	7.165	8.685	5.421	4.708	4.618	8.186
Population (15 min)	77.206 80%	69.719 86%	96.225 75%	37.794 84%	45.542 86%	52.895 80%
Average time (min)	10' 20''	9' 26''	9' 01''	10' 05''	8' 55''	11' 21''

Conclusion

The study outlines a methodology for evaluating the distribution and accessibility of urban green spaces in medium-sized Italian cities, highlighting their importance for public health and urban planning. Recognising that health is linked to environmental, social and cultural factors, the study adopts a broader approach that embraces concepts such as spatial justice, place-related health and environmental vulnerability, moving beyond a clinical perspective. The growing trend of global urbanisation necessitates a thorough investigation into how urban planning and the provision of green infrastructure can enhance citizens' health.

The methodology includes calculating NDVI, green space per capita (PCGS) and real accessibility estimates to provide information on the spatial configuration and ease of access to urban green spaces in the six cities studied: Arezzo, Siena, Grosseto, Latina, Viterbo and Rieti. NDVI analysis revealed distinct patterns influenced by topography and historical urban development. Cities such as Arezzo, Rieti and Siena are immersed in naturally green landscapes, while Grosseto, Latina and Viterbo are characterised by flatter, predominantly agricultural environments. A correlation was observed between urban topography and NDVI, with densely populated historic centres presenting low green cover. This underlines the need for more integrated green spaces within central urban areas.

The PCGS analysis also revealed disparities in the distribution of green spaces. Grosseto, with its low population density and large protected areas, had the highest amount of green space per capita. Despite its densely populated historic centre, Siena showed a more balanced distribution, although it was penalised in the central areas. Latina, in contrast, appeared to be the most disadvantaged in terms of PCGS, suggesting a lack of integration of green infrastructure in urban planning. Analysis of actual accessibility indicates that a substantial proportion of the population in all six cities has access to urban parks within a 15-minute walk. Despite its complex topography, Siena recorded the shortest average travel time to parks, suggesting effective strategic positioning. Although Latina has the highest number of parks, its lower coverage in terms of population indicates that quantity does not equate to optimal accessibility, suggesting issues with the distribution or size of individual parks. Grosseto, with its larger average park sizes and high coverage, demonstrated an effective balance between park size and strategic positioning.

In conclusion, this research reinforces the idea that urban green spaces are important for physical and mental health, especially for vulnerable groups. The methodologies employed provide policymakers and urban planners with tools to assess existing green infrastructure and inform future development strategies. Understanding the nuances of green space distribution and accessibility in different urban contexts enables cities to progress towards a more equitable and health-friendly environment, in line with the evolving concept of health as a common goal influenced by environmental and social factors. Future research could build on these methodologies by incorporating socio-demographic data at a more detailed level, enabling the identification of specific populations with limited access to green spaces and the development of more targeted interventions.

Fostering Multicultural Integration in Transforming Context: Community Participatory Museum as a Bridge

YAN Xinhang ; HUANG Yi
TongJi University
Email:2330328@tongji.edu.cn, huangyi@tongji.edu.cn

Abstract
To explore how the physical environment, community programs, and Individual Characteristics influence cultural adaptation among Korean immigrants in a transforming district of Qingdao, China. Using a mixed-methods approach combining PLS-SEM modeling and interviews, the research identifies intercultural interaction as a key mediating factor linking space and adaptation. While environmental and programmatic improvements enhance place-based belonging, meaningful integration relies on active engagement across cultural boundaries. To support this, the study proposes the Community Participatory Museum (CPM)—an embedded, co-created public space where residents collaboratively share stories and express cultural identities. This research contributes to urban planning and migration studies by revealing how spatial-social mechanisms can foster intercultural understanding and adaptive inclusion in multicultural communities.

Keywords: Cultural Adaptation; Cross-cultural Communication; Community Participatory Museum; Public Space Design; Community Participation

Introduction

In the context of globalization, the issue of community integration among cross-cultural immigrant groups has attracted growing scholarly and policy attention.An increasing number of foreigners are living, studying, and working in Chinese cities, and their levels of adaptation in language, culture, and social life directly influence the harmonious development of multicultural communities(Li, 2022)(Lo et al., 2005).Qingdao, a coastal city with frequent China–South Korea exchanges, provides a compelling case. Since the establishment of diplomatic relations between China and South Korea in 1992, a substantial influx of South Korean individuals and enterprises has formed distinctive economic and community networks characterized by Korean cultural features(Zhou & Tang, 2023).

For a long time, Korean enclaves in Qingdao have largely exhibited a pattern of “parallel adaptation,” in which immigrant communities are physically embedded in the urban fabric but remain socially and culturally isolated from local society. Daily life among Korean residents is often centered around ethnically bounded commercial systems and language environments, resulting in limited contact with local Chinese residents and restricted cultural identification and emotional attachment(Zhou & Tang, 2023).While this model initially facilitated cultural continuity and living convenience, it also hindered intercultural contact, contributing to misunderstandings and latent tensions.

The 2008 global financial crisis marked a turning point. With the withdrawal of some Korean enterprises and the restructuring of local labor markets, many Chinese residents experienced economic disconnection from the Korean community, which intensified social discontent and ethnic divisions (Fan, 2009). As labor and land costs in Qingdao continued to rise, further business relocations led to a gradual contraction of the Korean population. These changes imposed mounting transformation pressures on the community’s function, population composition, and spatial structure (Sun, 2009).

Under these circumstances, the parallel adaptation model has become increasingly untenable, prompting some Korean residents to undergo “passive integration” and even take the initiative to learn Chinese and participate in local affairs.(Jang, 2012) At the same time, the spatial characteristics of Korean enclaves have evolved into a “hybrid of ethnic commerce, aging residential buildings, and weakly connected neighborhoods.” Public activity spaces in these communities are typically confined to narrow sidewalks, scattered stone tables and benches, or small open areas in front of shops—spaces that lack greenery and fail to support the everyday, spontaneous interactions needed for intercultural engagement. Consequently, they fall short of realizing the community

cohesion and cultural integration potential embedded in public space(Chen and Fang, 2024) .

Amid ongoing urban renewal and growing calls for multicultural inclusion, it remains an open question whether spatial interventions can serve as effective bridges for cultural adaptation.

This study aims to address the following key questions:

To what extent do the physical environment and activity arrangements of community public spaces influence South Korean residents' cultural adaptation to local society?

Does intercultural interaction mediate the relationship between spatial conditions and cultural adaptation?

How can spatial design and planning strategies be leveraged to improve community interaction structures and foster deeper cultural integration between ethnic groups?

1. Literature Review

1.1 Internationalised Communities

Internationalised communities refer to neighbourhoods formed by people from various countries and regions, characterised by multicultural backgrounds and a relative degree of autonomy. They represent micro-units of urban internationalisation and serve as indicators of a city's globalisation level(Völker et al., 2007). With the deepening of China's reform and opening-up and the continuous advancement of urban internationalisation, an increasing number of foreigners have relocated to Chinese cities in recent years, forming distinctive internationalised communities (Lv and Guo, 2019).

However, internationalised communities in China are currently confronted with a range of governance challenges. As Zhao and Qi (n.d.) observe, the degree of participation by foreign residents in local governance remains limited. Moreover, Wang (2011) points out that the shortage of community staff with cross-cultural communication skills, alongside the scarcity of multicultural integration programmes, further exacerbates difficulties in fostering inclusive community environments.

A defining feature of internationalised communities is the achievement of harmony between local and foreign cultures, rather than merely focusing on the number of foreign residents(Chua, 2013) It is essential to respect community differences and foster competitiveness and cohesion by revitalising existing resources and enhancing new elements (Wang and Yang, n.d.).

1.2 Cultural Adaptation

The concept of cultural adaptation, as originally proposed by Robert Redfield and colleagues in 1936, refers to the process through which individuals or groups from different cultural backgrounds undergo changes in their cultural patterns due to sustained and direct intercultural contact and interaction, with reciprocal influence on both sides involved(Redfield et al., 1936). While numerous migration theories—such as the neoclassical theory, the new economics of labour migration, and the world systems theory—have focused on the economic determinants of migration, they often neglect political, cultural, and social dimensions. However, the cultural adaptation trajectories of migrant groups vary significantly due to differences in national cultures, ethnic characteristics, and levels of socio-economic development.

Among the theoretical frameworks that have profoundly influenced the study of immigrant integration, three stand out: assimilation theory, multiculturalism, and the segmented assimilation model. Assimilation theory, argues that immigrants are expected to relinquish their original cultural identities and merge—either actively or passively—into mainstream society(Rudmin, 2003). In contrast, multiculturalism promotes cultural diversity and suggests that immigrants can retain their native cultural traits while simultaneously adapting to the host culture, highlighting the importance of social inclusiveness(Zhou and Li, n.d.) .The segmented assimilation model,

on the other hand, suggests that integration outcomes are shaped by a combination of socio-economic factors, human capital, policy frameworks, and cultural dynamics, resulting in varied modes such as active integration, passive integration, and selective integration (Junger-Tas, 2001).

Further, the bicultural identity integration theory regards cultural adaptation as a dual-dimensional interactive process involving the maintenance of one's heritage culture and the adoption of the host culture. It also emphasises that the host society's receptiveness plays a decisive role in shaping immigrants' adaptive outcomes.

Recent studies on the cultural strategies of transnational migrants have further categorized international communities into typologies such as "self-segregation," "parallel adaptation," and "active integration" (Li, 2022). Notably, "active integration" and "parallel adaptation" are not mutually exclusive; rather, they represent hybrid approaches where certain cultural boundaries are retained while integration is gradually pursued. Robust social interactions have been identified as important catalysts for cultural adaptation (Zhou and Li, n.d.).

Zhou and Tang (2023) indicate that the level of overall integration among South Koreans in China remains limited. Similarly, Sun (2009) examined the cultural adaptation processes among Koreans in Qingdao, identifying their transitional and "floating" adaptation characteristics. However, most existing studies have primarily focused on psychological and sociological mechanisms—such as language proficiency, social support networks, and identity negotiation—while paying relatively little attention to the spatial dimension of adaptation processes (Li, 2003).

Emerging research has started to incorporate public space into the analytical framework of cultural integration. Scholars argue that at the community level, spatial environments and cultural events serve not only as settings for daily life but also as platforms for social interaction, cultural expression, and consensus-building. Particularly in ethnic enclaves, the structure and attributes of community space may constitute critical triggers for fostering intercultural encounters and facilitating psychological adaptation(Binyi and Mwanza, 2014).

1.3 Community Space and Social Interaction

Community space refers to the facilities and spatial configurations designed to facilitate convenience, interaction, and shared use among residents. It embodies both materiality and a complex network of functions and organisational relations, conveying communal values through its spatial characteristics. The configuration and accessibility of such spaces are shaped by natural conditions, social needs, and levels of economic development. Simultaneously, community space is also a socially constructed entity, continually shaped by prevailing beliefs, interests, and aspirations(Theodori, 2005). In essence, community space serves as a locus where the identity of the community is spatially manifested, incorporating both physical and social dimensions.

Previous studies have demonstrated that community public spaces characterised by multifunctionality, inclusiveness, and social accessibility can effectively reduce psychological boundaries between different social groups, enhance the frequency of interpersonal encounters, and promote mutual understanding. For immigrant populations in particular, such spaces represent not only sites of everyday activity but also arenas for emotional attachment and a key pathway for cultural adaptation.

Social interaction comprises both physical and non-physical exchanges between two or more individuals(Hillery Jr., 1955). Empirical evidence indicates that the physical environment and activity programming within community spaces exert a positive influence on patterns of social interaction. By optimising spatial arrangements and offering attractive, participatory programmes, it is possible to foster more frequent and meaningful exchanges among community members (Qi et al., 2024). For instance, (Sirgy et al., 2008)observed that improved community services contribute to higher resident satisfaction.

Despite these insights, several notable gaps remain in current research. First, spatial structure and behavioural interaction are often analysed in isolation, lacking integrative cross-level theoretical frameworks. Second, community-based cultural programmes are frequently treated as informal or supplementary variables, with

limited empirical validation or quantitative modelling. Third, the mechanisms through which place-based interventions—such as participatory cultural initiatives or small-scale community installations—facilitate intercultural integration have yet to be systematically theorised.

Addressing these gaps requires a more holistic and interdisciplinary approach that links spatial design with social practice, and that treats community space not merely as a backdrop, but as an active medium through which inclusion, identity, and integration are co-produced.

2 Research Framework

2.1 Research Background and Case Selection

In response to the increasing need to understand the spatial foundations of intercultural adaptation, this study investigates the relationship between community space and cultural adaptation by focusing on a representative Korean enclave in Qingdao. Employing Partial Least Squares Structural Equation Modelling (PLS-SEM)(Fornell and Bookstein, 1982), the study systematically tests the pathways through which physical environment, community activities, and user characteristics influence intercultural interaction and patterns of cultural adaptation. A spatial integration strategy is proposed, centred on the concept of a "Community Participatory Museum" (CPM). The research aspires to extend existing theoretical models of urban cultural adaptation from a predominantly psychological perspective to a spatial one, while also offering practical guidance for cross-cultural urban governance through spatially grounded interventions.

This study selects the Xianggang Road Community in Qingdao's Shinan District as its empirical case. Administered by the Xianggang Zhonglu Subdistrict Office, the community is located in the core area of Fushan Bay and is designated in the 14th Five-Year Plan and Vision for 2035 of Shinan District as a priority zone for the development of "international-style neighbourhoods." Strategically situated, the community borders the coastline to the east, connects with Qingdao's major commercial centre to the south, and adjoins key administrative zones to the north. Notably, in 2004 the community established China's first Foreign-related Civil Mediation Committee, demonstrating its pioneering role in internationalised community governance.

The Xianggang Road Community covers an area of approximately 1.28 square kilometres, with a population of 12,570 across 4,898 households, of whom 6,500 are registered residents. The community comprises 18 residential compounds, including Panhaimingren Plaza, Luxin Changle Garden, Kaijin Garden, Minjiang Garden, and Yuanyang Garden—all of which reflect a high standard of residential development. Since the early 1990s, Qingdao has maintained robust economic and cultural exchanges with South Korea. The Xianggang Road area has gradually attracted Korean immigrants and enterprises, forming an ethnic landscape centred on Korean schools, churches, restaurants, and beauty salons. Korean residents are predominantly concentrated in the northern residential blocks, where ethnic commercial elements such as Korean restaurants, convenience stores, and salons are prominent. In contrast, the central and southern areas are characterised by a more mixed-use commercial layout with weaker ethnic features, reflecting a spatial gradient in both function and identity.

Comparative analysis of Point of Interest (POI) data from 2012 and 2023, together with field observations, reveals a clear transformation in the spatial structure of commercial areas within the community. The Korean commercial cluster, once concentrated in the northern residential zone, has been gradually displaced by large-scale mixed-use complexes such as AEON Mall and Hisense Plaza. This shift illustrates both diversification in commercial composition and a contraction of ethnic Korean economic influence. The spatial restructuring has important implications for the cultural adaptation of Korean residents: it has reduced dependency on ethnic-specific commercial infrastructures, while simultaneously increasing spatial encounters and opportunities for interaction with local Chinese residents. These evolving spatial conditions provide an empirical basis for shifts in cultural identity formation and behavioural integration.

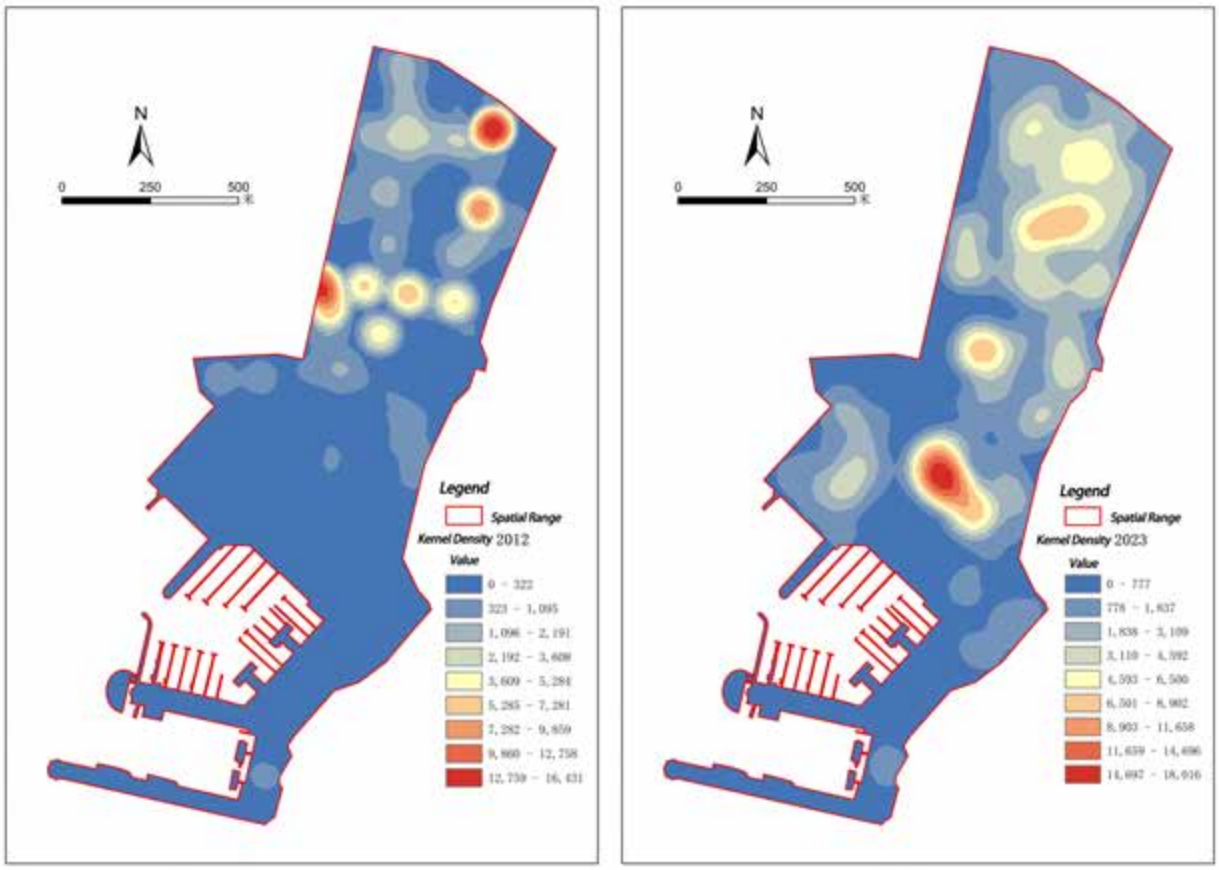

Figure 1. Comparative Kernel Density Maps of POIs in 2012 and 2023 (From Gaode Map)

Given these characteristics, the community—currently undergoing dual processes of social and spatial transformation—constitutes an ideal empirical setting for examining the dynamic interrelations between space, interaction, and adaptation. Its fragmented public space structure, multifunctional and mixed-use commercial corridors, and multiple low-threshold community nodes conducive to everyday encounters collectively render it a naturally occurring laboratory. These spatial features afford unique analytical value for investigating how multicultural integration mechanisms are shaped and negotiated in urban contexts.

2.2 Research Design and Data Collection

This study adopts a mixed-methods approach, integrating GIS spatial analysis, on-site observation, structured interviews, and questionnaire surveys to collect 55 valid samples covering South Korean, Korean-Chinese, Japanese, and Chinese residents. Drawing on existing research variables, the study employs the PLS-SEM method to statistically test the model hypotheses. Data collection was conducted from March to May 2024 and included the following three main components:

Spatial Mapping: GIS tools were used to annotate the distribution of commercial and open spaces and evaluate the accessibility and visibility of community interaction nodes.

Field Observation: Behavioral patterns and social usage in public spaces were recorded across different time periods and user groups.

Structured Questionnaire Survey: To avoid data bias, this study administered questionnaire surveys to community residents over a 12-day period from March 19 to March 30, 2024. The survey employed simple random sampling

and was conducted through both face-to-face and online methods. A five-point Likert scale (1 = strongly disagree, 5 = strongly agree) was used. A total of 55 valid questionnaires were collected, including 33 Chinese residents, 18 South Korean residents, and 2 each from North Korean and Japanese residents. The sample covered youth (18–35 years old, 34.5% of the sample), middle-aged (36–59 years old, 34.5%), and elderly groups (60 years and above, 30.9%). Additionally, statistics showed that over 40% of respondents had lived in the community for more than three years.

Hypotheses and Variables:This study examined multiple independent variables, including the physical environment, community activities, and user characteristics, with the dependent variables being cultural adaptation and cross-cultural social interaction. The selection of dependent variables was based on existing research findings. The independent variables, such as the physical environment, activity programs, and individual characteristics, were derived from relevant literature, field investigations, and interviews with space managers. The dependent variables related to cross-cultural social interaction included "frequency of cross-cultural interaction," "sense of companionship," and "degree of social relationships." Cultural adaptation factors included "cultural assimilation," "cultural integration," and "active participation." These variables were identified through an analysis of previous studies.

Table 1. Latent Constructs and Their Observed Indicators

Latent Variable	Rigorous Definition	Observed Variables (Indicators)
Physical Environment	The physical characteristics and design quality of public spaces in residential communities, including their support for social interaction, multifunctional use, and cultural inclusivity.	INT: Spatial interactivity (whether the space facilitates spontaneous interactions among residents) MULTI: Spatial multifunctionality (whether the space supports leisure, socializing, entertainment, and other functions)
Community Activities	Various public cultural and social activities organized for residents, including local festivals and cross-cultural exchange events, with a focus on frequency and interactivity.	FREQ1: Frequency of traditional festival activities (e.g., Spring Festival, Mid-Autumn Festival) FREQ2: Frequency of cross-cultural exchange activities (e.g., Sino-Korean Cultural Festival)
Individual Characteristics	Residents' participation in community spaces and activities, measured by frequency and duration, reflecting active use and engagement..	UTM: Weekly participation frequency (number of engagements per week) TRM: Duration per visit (time spent in public spaces or activities per session)
Intercultural Social Interaction	The quality of social interactions between Korean and local residents in a cross-cultural community setting, including breadth of social relationships, sense of companionship, and active engagement.	REL: Degree of social relationships (extent of connections with residents from different cultures) CMP: Sense of companionship (belonging and identification within the community) ENG: Frequency of intercultural interaction (willingness and behavior in actively engaging in exchange activities)

Latent Variable	Rigorous Definition	Observed Variables (Indicators)
Cultural Adaptation	The degree of cultural integration and sense of belonging among Korean and local residents in the Qingdao community.	CAI: Cultural assimilation (feeling of adapting to local cultural life) CBI: Cultural integration ("I can maintain my own culture while integrating into the local community") AP: Active participation ("I am willing to participate in cultural activities with local residents")

Based on theoretical review and field observations, the following structural hypotheses are proposed:
H1a: The physical environment has a positive effect on intercultural social interaction.
H1b: The physical environment has a positive effect on cultural adaptation pattern.
H2a: Community activities have a positive effect on intercultural social interaction.
H2b: Community activities have a positive effect on cultural adaptation pattern.
H3a: Individual characteristics has a positive effect on intercultural social interaction.
H3b: Individual characteristics has a positive effect on cultural adaptation pattern.
H4: Intercultural social interaction has a positive effect on cultural adaptation pattern.

Here, intercultural social interaction is set as the key mediating variable, and its mediating pathways between the physical environment, community activities, Individual characteristics, and cultural adaptation are examined.

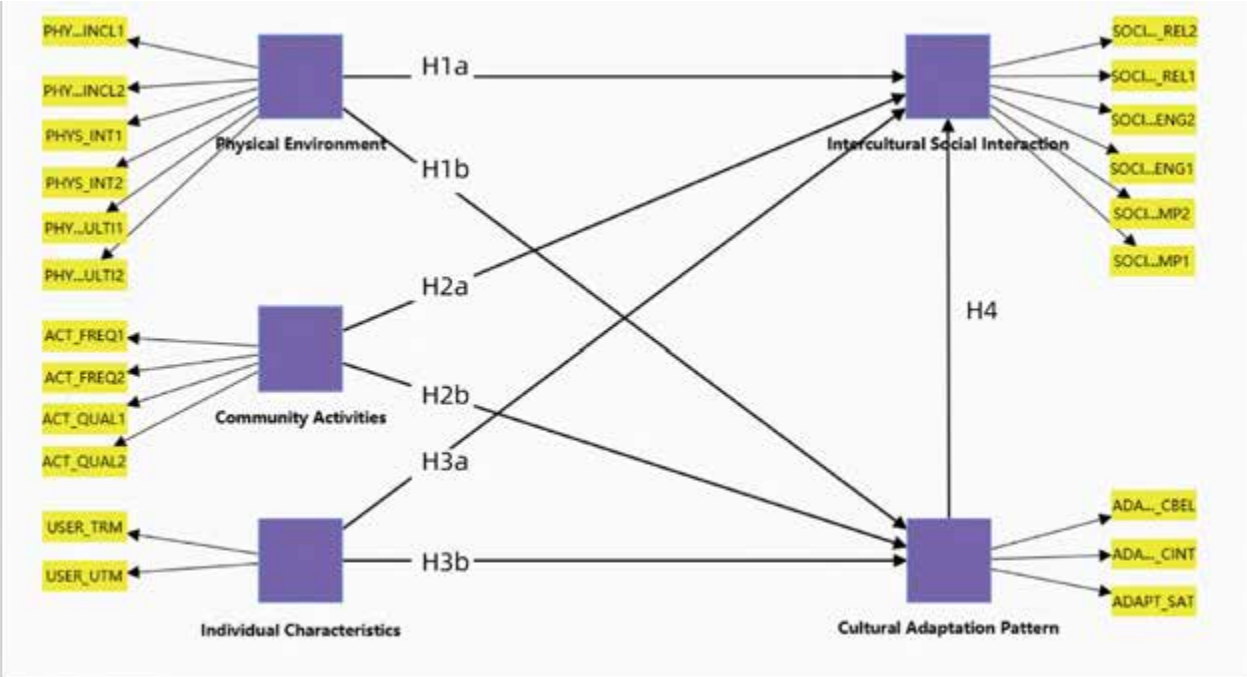

Figure 2. Structural Model of Intercultural Adaptation Pathways

2.3 Analytical Methods and Results

Following the two-step PLS-SEM analytical framework, we sequentially evaluated the measurement model and structural model, with modeling and estimation conducted using SmartPLS 4.09.

Table 2. Reliability and Validity Assessment of Latent Constructs

Latent Variable	Cronbach's Alpha	CR (Composite Reliability)	AVE (Average Variance Extracted)	HTMT (Heterotrait-Monotrait Ratio)
Physical Environment	0.829	0.875	0.591	0.682
Community Activities	0.813	0.874	0.635	0.715
Individual Characteristics	0.744	0.831	0.558	0.647
Intercultural Social Interaction	0.861	0.904	0.703	0.732
Cultural Adaptation Pattern	0.832	0.889	0.627	0.698

Prior to examining the structural paths, we first assessed the reliability and validity of the measurement model. As shown in the table, all latent variables demonstrated composite reliability (CR) values exceeding 0.83 and average variance extracted (AVE) values above 0.55, meeting the convergent validity criteria. Although one indicator loading for Individual characteristics was slightly below 0.7, the overall CR and AVE values satisfied the requirements, justifying its theoretical retention. Furthermore, all heterotrait-monotrait (HTMT) ratios were well below the 0.9 threshold, confirming satisfactory discriminant validity among constructs.

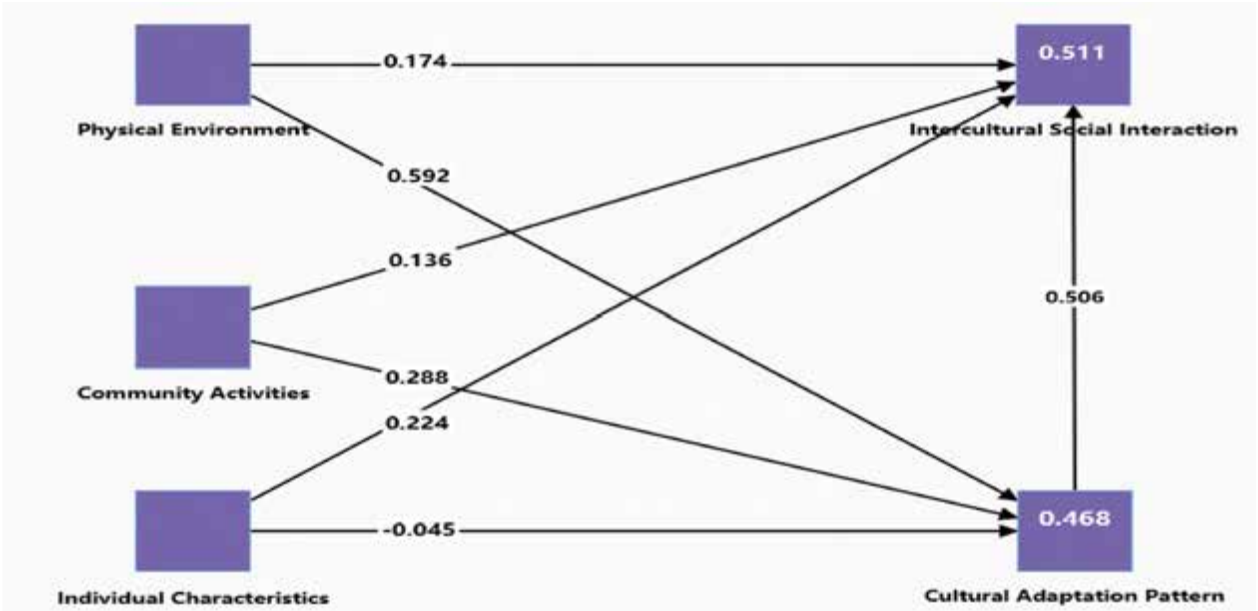

Figure 3. Path coefficient analysis of the model
($p < 0.05$, $t > 1.960$)

Table 3. Path coefficient analysis of the model

Path	Standardized Coefficient (β)	t-value	p-value	Verification
H1a: Physical Environment→ Intercultural Social Interaction	0.174	1.606	0.108	Reject
H1b: Physical Environment→ Cultural Adaptation Pattern	0.592	8.000	<0.001	Accept
H2a:Community Activities→ Intercultural Social Interaction	0.136	1.311	0.190	Reject
H2b: Community Activities→ Cultural Adaptation Pattern	0.288	3.142	0.002	Accept
H3a: Individual Characteristics→ Intercultural Social Interaction	0.224	2.182	0.029	Accept
H3b: Individual Characteristics→ Cultural Adaptation Pattern	-0.045	0.411	0.681	Reject
H4: Intercultural Social Interaction→ Cultural Adaptation Pattern	0.506	4.332	<0.001	Accept

The results indicate that the physical environment has a significant positive effect on cultural adaptation pattern ($\beta = 0.592$, $p < 0.001$) but no significant impact on intercultural social interaction ($\beta = 0.174$, $p = 0.108$). This suggests that high-quality community spatial environments can effectively enhance immigrants' local emotional attachment and life satisfaction, yet they are insufficient on their own to directly catalyze cross-cultural contact behaviors. Particularly under conditions of "parallel adaptation," the physical environment is perceived more as a structural condition ensuring convenience and safety rather than as a social medium fostering interaction.

Similarly, community activities demonstrate a significant positive effect on cultural adaptation pattern ($\beta = 0.288$, $p = 0.002$) but fail to significantly influence intercultural interaction ($\beta = 0.136$, $p = 0.190$). This implies that while activity frequency may be high, deficiencies in cross-cultural orientation, shared participation mechanisms, and language collaboration limit their effectiveness in promoting interaction.

In contrast, Individual characteristics exhibits a significant path effect on intercultural interaction ($\beta = 0.224$, $p = 0.029$) but no direct significant effect on cultural adaptation pattern ($\beta = -0.045$, $p = 0.681$). This indicates that individuals' open behaviors and spatial usage willingness serve as prerequisites for interaction, while the realization of cultural integration still requires psychological internalization through authentic cross-cultural communication processes.

Most crucially, intercultural social interaction significantly influences cultural adaptation pattern ($\beta = 0.506$, $p < 0.001$). Further mediation analysis confirms that intercultural social interaction fully mediates the individual characteristics → intercultural social interaction → cultural adaptation pattern path ($p = 0.044$). The indirect effects of physical environment and community activities on cultural adaptation pattern through intercultural social interaction are marginally significant ($p = 0.075$; $p = 0.067$), suggesting that these external variables partially influence cultural adaptation by facilitating interaction mechanisms that translate into emotional and cognitive cultural integration.

This study further validates the robustness of these findings through model quality assessment metrics. The R^2 values indicate moderate explanatory power for endogenous variables (intercultural social interaction = 0.511; cultural adaptation pattern = 0.468), while the Q^2 values (intercultural social interaction = 0.312; cultural adaptation pattern = 0.395) are all above zero, demonstrating good predictive relevance. Additionally, f^2 effect size analysis reveals that physical environment has a large effect on cultural adaptation pattern, intercultural social interaction a medium effect, and individual characteristics a small effect on intercultural social interaction, underscoring the central role of physical environment and interaction variables in the model.

Building on the quantitative analysis, this study integrates interview data from representative residents to deepen the understanding of the relationship between spatial perception differentiation and cultural adaptation behaviors. For instance, regarding the question of whether "community commercial facilities reflect ethnic elements," residents in different areas exhibit distinct perceptions: those near Fanhai Celebrity Plaza and Minjiang Second Road generally report a decline in "Korean-style" facilities, whereas residents around Zhangzhou Second Road and Zhongshang Plaza note an increase in new Korean-themed stores. This indicates that ethnic spatial elements are not uniformly distributed; their accessibility and visibility are influenced by geographic location and commercial resource clustering.

In interviews, Mr. B, who operates a Korean convenience store, mentioned considering introducing Chinese products due to declining customer traffic, reflecting "cross-cultural adaptation" in business strategies. Ms. C pointed out that an increasing number of Korean residents are proactively seeking language learning and daily interaction opportunities, signaling behavioral willingness shifts. Meanwhile, Mr. T, a local resident, expressed dissatisfaction with late-night operations of some Korean restaurants and a tendency to avoid commercial facilities with prominent Korean signage, highlighting mainstream residents' spatial resistance to overly strong ethnic atmospheres.

Collectively, spatial reconfiguration reflects not merely commercial renewal but a realignment of immigrant cultural strategies, interaction frequency, and psychological belonging. The actual occurrence of intercultural interaction depends not only on space and behavior but also on the interplay of cognition, emotion, and social mechanisms.

In summary, within the Hong Kong Road community, the physical environment and community activities exhibit significant positive effects on cultural adaptation patterns but show no direct influence on intercultural social interaction. This suggests that while spatial and activity-based interventions can foster psychological safety and a sense of belonging, they do not necessarily trigger genuine social engagement.

In contrast, individual characteristics significantly facilitates interaction but lacks a direct path to cultural adaptation, indicating that individual actions are more likely to create contact opportunities, whereas adaptation itself must still be achieved through interaction mechanisms.

Notably, the driving force behind individual characteristics-induced interaction is often not cultural interest or identity-based motivation but rather external factors such as the decline of ethnic commercial facilities and reduced daily convenience. Some Korean residents in the community are compelled to engage with local resource systems to meet daily needs, thereby "passively" opening possibilities for cross-cultural contact. This behavioral restructuring, prompted by structural changes, reveals that the relationship between space, behavior, and identity is not linear but rather marked by friction and transformation.

Therefore, policy and design strategies should not merely focus on "improving spatial quality" or "increasing activity frequency" but must identify genuine behavioral drivers and psychological thresholds. It is recommended to embed low-threshold, co-creative cultural triggers—such as "community participatory museums" or micro-collaborative installations—to reshape interaction pathways among residents. Additionally, language mediation, identity negotiation, and shared narrative platforms should be leveraged to transform "contact" into "meaningful

engagement," ultimately fostering cultural adaptation and emotional integration within a multicultural community.

3 Design Proposal

Based on the aforementioned findings, this study proposes a site-specific spatial intervention strategy grounded in the concept of a community participatory museum. Unlike traditional top-down curated museums, this approach is embedded in daily community life, aiming to empower residents with the agency to "narrate stories, express identities, and co-curate exhibitions." It serves as a cultural infrastructure emphasizing co-creation, sharing, and consensus-building.

3.1 Design Concept

Inspired by the television drama *Reply 1988*, which resonates with both Chinese and Korean residents, and incorporating the local community's memory resources and practical needs, the design is conceived as a "distributed micro-space system" composed of 12 multifunctional nodes. These nodes are strategically positioned at alleyway corners and between commercial blocks, featuring a semi-permanent structure. They are co-built, co-managed, and co-curated by residents, forming a spatial narrative centered around "shared living memories."

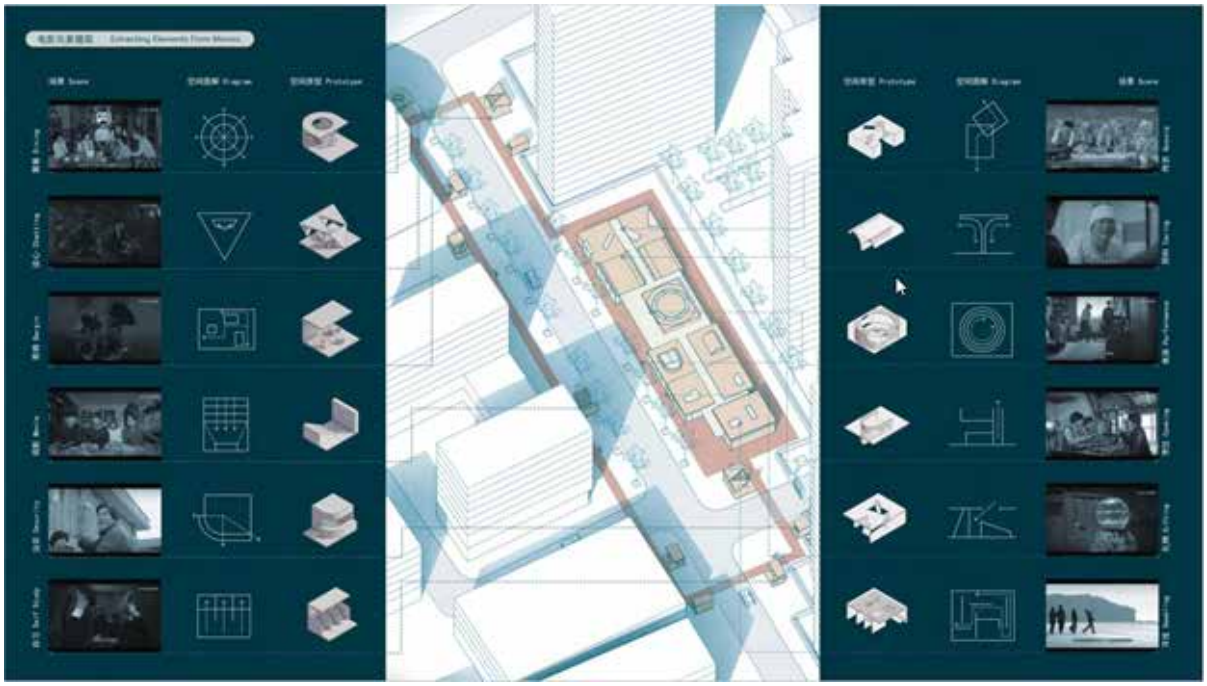

Figure4. Functional Unit Example

3.2 Specific Spatial Combination Logic and Design

The "narrative acupuncture" intervention strategy is adopted to achieve precise activation of community gaps and potential spaces without disrupting the original spatial layout. The design emphasizes mild materials, bilingual signage, human-scale dimensions, and interactive mechanisms.

Figure 7. Exterior Module Design

4 Research Significance and Outlook

This study takes a typical Korean immigrant community in Qingdao as a case study, constructing a structural path model that encompasses the physical environment, community activities, user characteristics, cross-cultural interactions, and cultural adaptation patterns. Through PLS-SEM empirical analysis, it reveals how spatial factors influence cultural integration through social interaction mechanisms. Compared to previous adaptation studies that predominantly focused on psychological dimensions, this research integrates spatial design, behavioral participation, and interaction processes into a unified theoretical framework, expanding the boundaries of urban multicultural governance research.

On a practical level, the study finds that cultural adaptation does not stem directly from physical spaces or activity provision but requires genuine and sustained cross-cultural interactions. This conclusion provides insights for community planning and policy-making, emphasizing the importance of balancing "spatial interventions + interaction mechanisms." The proposed "community participatory museum" strategy further demonstrates how micro-spatial interventions can facilitate identity negotiation and cultural co-creation, offering an actionable design prototype for multi-ethnic cohabitation areas.

Future research could expand in three directions: (1) introducing a temporal dimension to conduct longitudinal tracking analysis of cultural adaptation; (2) comparing mechanism differences across cities and groups to enhance the model's generalizability and flexibility; and (3) incorporating social media data to explore the impact of "digital-spatial" dual interactions on integration pathways, responding to rapidly evolving urban contexts and technological environments.

Abstract
Focusing on the case of a new urban oasis in Belgrade (2024), situated on the site of a Drop in Shelter for the street children, the paper examines a relationship between marginalised group(s), neighbourhood community and multidisciplinary professionals, involved in a project launched by the EUNIC Serbia and the Goethe-Institut. The project involved a group of the second-year undergraduate students of the University of Belgrade - Faculty of Architecture working on a proposal for a unique hub of/for social inclusion, safety and inter-neighbourhood interaction. The selected case is presented through the lenses of educational process, highlighting the synchronisation between the expected environmental and social outcomes, a comprehensive participation of future users (marginalised children and local community) and the estimated/achieved sustainability of the implemented project.

Keywords: Integration, Inclusion, Public Space, Children, Education.

Introduction

The cities exposed to multiple transitional flows have been facing various challenges which especially affect vulnerable and marginalised groups. The strong division between the winners and the losers of the neoliberal mechanisms reflects in urban setting and its public spaces, where the discrepancies between the reality and the globally announced imperatives of sustainability, resilience, equity and justice become extremely visible (World Cities Report, 2024). Belgrade, the capital of Serbia, represents one of the multilayered examples of this practice, fuelling the atmosphere of growing uncertainty, far away from the postulates defined by SDGs, 2030 Agenda or the New European Bauhaus framework.

Highlighting the case of a new urban oases (2024), situated on the site of a Drop in Shelter for the street children, the paper presents a process of a studio project, based on a relationship between marginalised group(s), neighbourhood community and multidisciplinary professionals, all involved in an initiative launched by the EUNIC Serbia (European Union National Institutes for Culture) and the Goethe-Institut. Conducted in cooperation with the Center for Youth Integration, the Belgrade International Week of Architecture (BINA), the Italian Institute of Culture, the Embassy of Portugal, as well as a group of the second-year undergraduate students of the University of Belgrade - Faculty of Architecture, this endeavour triggered the transformation of a small open space into a new hub of/for social inclusion, safety and inter-neighbourhood interaction. Having in mind that street children represent one of the most vulnerable groups, often threaten by socioeconomic inequalities, violence and the lack of any kind of support, their education, safety and healthcare could be challenging or non-existent. Therefore, any action directed toward the improvement of this damaging condition should be based on the set of policies which provide functional support systems, as well as equally accessible resources (Sovacool et al., 2022).

Following these recommendations, the project and its inclusiveness were elaborated through several phases

related to research, design, implementation and the promotion of achieved results. The integrative potential of the upgraded space was emphasised during all organised events - from participatory workshops, lectures, exhibitions, to presentations and public gatherings. The newly created public node was conceptualised and shaped according to the specific needs of identified users, representing a common good for the entire local community. Consequently, the design program stimulates exploration, play and learning through the application of art, ecology, recycling and digitalisation. As a new popular place, the urban oasis should also raise both the environmental awareness and the quality of space while connecting the different groups in their personal experiences.

The important segment of this initiative represented the work of students which was constantly exposed to both professional and public evaluation. Therefore, the educational process and the applied methodological approach had to correspond with expected environmental and social outcomes, while the participation of future users (both the marginalised children and the local community) stimulated a balance between the detected neighbourhood dynamic and the anticipated project sustainability.

The theoretical drivers

Grounded in the concept of social production of space (Lefebvre, 1991) and the concept of social capital (Putnam, 2000), the process conducted within the studio project continuously emphasised the role of integrative potential of public spaces, within the boundaries defined by socio-economic context and the networks of trust, cohesion and exchange within a community (Whyte, 1980; Castells, 2000). The shared development vision, which would stimulate inclusion and transmission of ideas and practices, represented a project necessity leading toward green transition, long-term sustainability and the integration of marginalised children into local community.

The ideas and methods based on tactical urbanism (Lydon and Garcia, 2015), participatory design (Muller and Kuhn, 1993; Bannon and Ehn, 2012) and situated design (Simonsen et al., 2014) were used as a framework for human-centered approach which included affordable, responsive and flexible spatial interventions in order to create engaging public node - an urban oasis which instigates spontaneity and a higher level of accessibility for all interested parties. Both problem- and project-based learning were incorporated into studio curriculum, ensuring a dynamic setting which encouraged students to obtain multidisciplinary knowledge, increase their creative abilities and develop self-esteem and confidence when dealing with real-life problems and challenging situations (Frank and Barzilai, 2006; Barrett and Moore, 2011).

The idea of urban oasis was considered as a multipurpose stage and a medium for both social and environmental themes, acting as an open public space which supports diversity but also provides informality and equality in communication and use (Oldenburg, 1991). Furthermore, the issues of environmental awareness and microclimate quality were considered as an additional level of future cooperation and understanding between local users - from inhabitants and the Shelter beneficiaries to experts and local government. In line with this aspect, the importance of environmental issues was highlighted during the iterative process of studio work, especially the problems of pollution, climate shift and declining biodiversity. The students had an insight into the Value-Belief-Norm (VBN) approach (Stern et al., 1999), the concept of green transition (Mol & Sonnenfeld, 2000; Geels, 2002) and the ecological modernisation theory.

In the direct interaction with street children the students were able to identify a number of challenges which this sensitive group of users has to face every day - from violence and exploitation, to inadequate access to food, education and healthcare. Consequently, the design of a new urban oasis, based on co-creation, co-production and co-benefits, had to address all these issues in local context, overcoming the occasional hostility of neighbours. Social integration with and beyond neighbourhood was stimulated, while the introduction of green spaces was used as a tool for reinforcing the overall sense of belonging through a playful design and various types of activities. These changes could attract new artistic and educational programs, also acting as mediums of inter-institutional cooperation.

Urban oasis: identification, interaction, integration

The project entitled 'Belgrade urban oases' was initiated at the beginning of 2024, by a team of several institutions led by the EUNIC Serbia and the Goethe-Institut. Targeting three typologically diverse sites, which were selected before the application process, the main idea was to increase their spatial comfort, as well as environmental and social sustainability. Characterised by different problems, these (mostly neglected or underdeveloped) open spaces became unique polygons for activation, upgrading and/or renovation which was supposed to improve their condition while increasing a general wellbeing of both immediate beneficiaries and local communities. The project initiative also included the students of two faculties of the University of Belgrade - the Faculty of Architecture and the Faculty of Forestry, which contributed to several phases of the project - from the process of design to implementation.

The site of the Shelter for Street Children (Krfska Street, No. 7a) represented one of these potential urban oases, offering a small open space positioned within the building plot, perpendicular to two parallel streets (Figure 1). Due to its specific position between two public buildings and the lack of any physical barriers which would separate it from the public space of streets, this L-shaped open space represented also a specific corridor (especially during the non-working hours of the Shelter), used as a shortcut between two streets, or a gathering (noisy) spot for local teenagers, often causing official complaints of the neighbourhood. Consequently, the idea was to provide a redesign of this urban pocket, in accordance with a specific set of needs expressed by the direct users - the street children from different age groups (up to 18 years). Additionally, it was necessary to instigate a higher level of social inclusion with(in) neighbourhood, increase the overall safety and decrease the level of hostility, often expressed by local residents. The future urban oasis also anticipated other roles - from the stage for various activities, events and gatherings, a generator of positive identity and pride, to the instrument of ecological and aesthetic transmission, exchange and awareness.

Figure 1. The site of the Shelter for Street Children.

The partners in charge of this oasis were the Center for Youth Integration (as the umbrella organisation coordinating the activities of the Shelter), Belgrade International Week of Architecture (BINA), Goethe-Institut, Italian Institute of Culture, Embassy of Portugal and the University of Belgrade - Faculty of Architecture. The students involved

in the project attended the second year of bachelor studies (2023/24) and their work was conducted within the studio supervised by Professor Dr. Aleksandra Stupar (assistant Aleksandar Grujičić), representing a segment of the course entitled Sustainable Urban Communities (Professor Dr. Ksenija Lalović). Considering the complexity of this project, as well as the number of involved participants, the process was based upon an elaborate timeline, which enabled an intensive collaboration of all partners and involved actors, facilitated participative design and stimulated efficient implementation supported by the immediate users (Figure 2).

Figure 2. The project time-line.

The work on urban oasis used a problem-based approach, which also had an important educational and experiential dimension - both for the students of architecture and the street children/teenagers. It stimulated their mutual bonding, understanding and trust, resulting in a number of creative ideas, later used in the final draft. The theme conditioned the concept of an open-ended project due to a dynamic in-situ context which demanded flexibility and collaboration of all involved parties.

The closer involvement of students started in February 2024, at the beginning of spring semester. Their first task related to the overall topic and the selected site was the analysis of local context which revealed the status of activities, environment, local community and the Shelter beneficiaries - their needs, expectations and mutual interactions. SWAT matrix was used for the classification of results and a further decoding of the ongoing processes in the space, while an elaborated insight into communication flows and existing multileveled networks provided conceptualisation of possible channels of integration, collaboration and exchange. The connection between the direct and the indirect users of space, students and educators was also established, tracing the path for upcoming participative activities. The final outcome of this phase represented a data-base of relevant examples which were assessed according to their specificities and the potential benefits for project context.

The importance of similar experiences, as a possibility for a know-how exchange, was emphasised by a lecture delivered online by Dr. Valentina Talu, a researcher at the University of Sassari (Department of Architecture, Design and Urbanism) and a co-founder and administrator of the spin-off company Tamalacà Srl. Organised by the Italian Institute of Culture in April 2024, the lecture entitled Tactical Urbanism and City Tailored to Children highlighted

the importance of a synergy between theory and practise, local circumstances, available budget and preferred outcomes. It was followed by a discussion which raised issues related to the detected problems of participation process and implementation, legislation drawbacks, funding, sustainability, maintenance, neighbourhood safety, social cohesion and integrative potential (Figure 3). The studio data-base was enriched by the recommended material from the platform Tactical Urbanist's Guide and the e-book The City at the Eye Level for Kids (Danenberg at al., 2018).

Figure 3. The online lecture Tactical Urbanism and City Tailored to Children by Dr. Valentina Talu. Photo: Aleksandar Grujičić.

After this thematic introduction, the students participated in a workshop which was organised on the site of the Shelter and the future urban oasis. The aim of this step was to establish a face-to-face interaction with both the immediate users and their supervising team, while identifying their needs, preferences, dynamic of their daily/seasonal activities and the problems affecting their integration into the neighbourhood (e.g. hostility, prejudice, rejection, segregation). During the workshop, which was also assisted by the BINA representatives, the attention of all participants was directed toward several issues - physical, functional and social limitations of the space, expected/preferred flexibility, environmental upgrading and its sustainability. Students prepared various examples of successful design possibilities as an input (playgrounds and playground equipment, landscape, urban gardens, urban furniture, textures, colours and shapes etc.). Both digital and analogue formats were used as initiators for discussion, creative process and the evaluation of preferred elements and activities. The duration of the workshop was estimated by the supervisors from the Shelter and conditioned by the attention span of involved children and teenagers. The outcomes outlined the possible directions of spatial conceptualisation - urban oasis as a generator, transmitter and display of sustainable and integrative practices and exchange (Figure 4). The collected material and ideas produced by both users and students created a starting point for defining the main goals and design principles.

Figure 4. The first participatory workshop at the Shelter. Photo: Aleksandar Grujičić.

According to the initial findings of the first workshop students developed their conceptual solutions in an iterative process which relied on both the participative and situated design methods. Studio work enabled elaboration of collected ideas and the first public presentation of 23 students' posters, organised in front of the Shelter and in the adjacent park, triggered a positive response from the local community. Children from the neighbourhood and their parents also showed interest in the proposed designs and took part in an informal discussion and interviews. Consequently, the information gathered through the interaction with neighbours, Shelter beneficiaries, supervisors, as well as occasional passers-by, contributed to a common system of values (Figure 5). This public event, partially conducted on the site of the future urban oasis, contributed both to the increased inclusiveness of design process and the further elaboration of exhibited proposals. They were evaluated by simple voting/ rating process (with colourful stickers), not only by Shelter users, but also visitors and observers. As a result, a list of most desirable spatial and functional elements was created, directing the next phase of project elaboration conducted during the last few weeks of spring semester.

Figure 5. Public discussion during open-air exhibition. Photo: Aleksandar Grujičić.

The last phase of design, concluded in the end of May 2024, was presented during the 19th Belgrade International Architecture Week - as the exhibition held on the premises of the Shelter and a public lecture related to all activities within the Belgrade Urban Oases project. The exhibition displayed in June 2024 included a simple voting process and a discussion with users and the neighbourhood which led to the selection of six projects and main design elements (Figure 6). Their authors (students Tamara Šuljagić, Tatjana Paunić, Katarina Rančić, Marko Šepa,

Katarina Nikolić, Đorđe Lazarević) were chosen as a team for project elaboration, coordinated by their supervisor and a BINA representative.

Figure 6. The exhibition during the 19th Belgrade International Architecture Week. Photo: Aleksandar Gazibara

The finalisation of project design was conducted during summer, while the implementation of the project was scheduled for October and November 2024. The selected team described the new urban oasis as a 'place of fun'. Intended for both the Shelter users and the neighbourhood, spatial upgrading enables exploration, learning, relaxation and play, simultaneously increasing environmental awareness, sense of belonging, as well as spatial, social and ecological responsibility.

The outcome

During the implementation, the main construction works were focused on the pedestrian corridor between two buildings which was improved by the ACO drainage system and painted (MAPEI) by the Shelter children, with the support of students and the BINA team. The painted drawings represent a result of a series of creative workshops organised by Dušana Nikolić from the Architecture studio for children La Villette, with the assistance of student Tamara Šuljagić. This activity had an important symbolical significance depicting mutual effort and creativity of all involved children. It also contributed to the evolving identity of urban oasis, open to the Shelter users, but also to the neighbourhood. The oasis was additionally upgraded by the wooden decking with integrated benches and planters, creating a flexible area for different kinds of events, gatherings and concerts. New green walls/ fences were included, as well as a projector and a white board on the outer wall of the Shelter, new trampoline and chairs (Figure 7).

Due to weather conditions and approaching winter months only a part of planting activities was completed. However, the space got new trees and some plants, while the remaining vegetation has been added during

Spring 2025. This intervention also improved the overall atmosphere and comfort, strengthening the link to nature while enriching green infrastructure of the area.

Figure 7. New urban oasis as a node of social interaction, learning, fun and environmental responsibility. Photo: Aleksandar Gazibara.

The activities of the urban oasis, as well as the experiences gained in its space, are regularly shared via digital media. The Shelter users are encouraged to contribute with their own posts which promote activities and features of the space. Due to additional funding from the Ministry of Culture of the Republic of Serbia the online accessibility and digital skills of children have been improved. Consequently, new possibilities for learning, exchange and promotion of successful practices on various digital platforms and social networks have been open, but with a controlled approach, especially important for marginalised children. Additionally, project visibility has been increased enabling more intensive participation of the public, as well as the introduction of numerous environmental themes which could be presented and/or tested within the urban oasis.

In total, the project initiative included about 200 participants, several institutions (Municipality Zvezdara, Beograd put, Public Company - Greenery Belgrade, Ministry of Culture of the Republic of Serbia) and donor companies (MAPEI, ACO). During the active period of 2024 (April to November) many activities were organised and successfully realised, gathering over 840 participants. Students were actively involved until the end of spring semester, while the selected team of students-authors continued their work until November in various capacities.

Conclusion

The problem-based approach used for the conceptualisation and design of a new urban oasis in Krfska street was user-oriented and adjusted to transformative imperatives embedded in the project application of the Belgrade Urban Oases. The studio work with the students of the Faculty of Architecture was structured around several phases and core activities which ensured elaboration, multidisciplinary effort and a high level of collaboration between various actors. The urban co-creation method was applied in order to produce a coherent and sustainable solution based on active user participation, real-time experiences and iterations within a constant design focus (Hertzum, 2014). The importance of situated design - related to context, knowledge and action, was also emphasised as a way toward lasting sustainability of the implemented spatial intervention.

The established node for multiple mutual interaction and integration, conceived as an urban oasis, provides a setting for numerous community activities which could have a positive impact on both the neighbourhood and the Shelter users. Although it is still early to conduct an elaborated evaluation of the achieved results, the event organised during the 20th BINA festival (May 2025) enabled a survey of the current situation. During the annual

celebration of the Center for Youth Integration/Shelter a photo exhibition dedicated to the Oasis was launched, gathering children, employees and other interested guests. They provided their personal insight into several aspects of the established public space commenting its quality (functional, aesthetic and environmental), activity content, (un)fulfilled expectations, frequency of use, ideas for further upgrading and the achieved exchange with neighbourhood.

The feedback is mostly positive, especially from the direct users and participating institutions. According to them, the space of urban oasis has become an attractive outdoor spot, a new feature for positive identification, pride and empowerment of the marginalised Shelter children. They appreciate its flexibility and the vibrant appearance of colourful pedestrian corridor, the wooden decking of the plateau, greenery and new urban furniture with integrated plants and trees. This setting influences their environmental awareness, instigating interest in gardening (planting, watering, cleaning, watering etc.) and overall well-being. The neighbours of the Shelter also noticed better design and maintenance, which attracts local children.

However, some problems were also mentioned, mainly caused by the public character of the place, especially after working hours of the Shelter. Consequently, the problematic evening noise created by various groups of local teenagers (who occupy the wooden deck after school) can be solved by additional enclosures of the space which will be locked during evening, preventing uncontrolled trespassing. This intervention could be realised during 2025, due to the next phase of funding, provided by the Goethe-Institut. In the meantime, it is important to keep the momentum of activities, supporting the social and environmental sustainability of the oasis.

Although the project represents a specific booster for the inclusion of marginalised children into environmental practices, their position in the green transition should be further empowered. Previously detected hostility of the neighbourhood could be diminished through common actions focused on environmental challenges and maintenance of green infrastructure, while the cooperation with students should be developed and eventually directed to similar transformative projects. Their mutual experiences and reflections, as a unique collaborative learning process, could gradually become an example of successful practise and an encouragement for equally sensitive contexts, willing to discover their environmental consciousness.

The Path of Land Use Control for Urban Development and Construction Projects in Germany

Han Tao
College of Architecture and Urban Planning, Tongji University
Email: 2330133@tongji.edu.cn

Abstract
As global urban development transitions from quantitative expansion to qualitative enhancement, land use patterns grow increasingly intricate, necessitating sophisticated regulatory mechanisms. Germany, recognized for its mature development control system, has established an integrated framework combining public construction law, development guidance planning, and permit-based enforcement. Through systematic analysis of Germany's urban land governance evolution, this study examines the synergistic interplay between legislative mandates, planning instruments, and regulatory oversight. It further explores the transferable value of Germany's model through four critical dimensions: clear objectives, robust legal foundations, comprehensive control tools, and refined implementation methodologies, offering actionable insights for achieving sustainable and orderly urban growth worldwide.

Keywords Land use control; German planning system; Zoning; Urban Development

Introduction

As global urban development shifts to a refined phase, land use grows more diverse and complex, with stock development and urban regeneration becoming crucial strategies. Nations face the shared challenge of balancing functional integration with conflict avoidance in urban land use control, while ensuring land use flexibility over its entire life cycle.

Germany, the pioneer in development zoning control, has established a robust system by integrating public construction law, development guidance planning, and construction permits. This system effectively regulates urban construction and use, offering strong support for achieving spatial planning goals and maintaining urban development order.

1. The Evolution of German Land Use Control

1.1 The Origin of Zoning

In the second half of the 19th century, German cities rapidly developed and expanded due to the Industrial Revolution. Municipal authorities started to use spatial planning and legislation to regulate urban growth. The 1862 Berlin City Binding Land-Use Plan and the *1868 Baden Grand Duchy's Road Red Line Law Fluchtliniengesetz* were landmark events in modern urban spatial control. The 1891 Frankfurt *Graded Building Ordinances (Staffelbauordnungen)* marked the birth of German "zoning." It divided cities into residential, industrial, and mixed - use zones, specifying the characteristics, uses, maximum building height, density, and distance between buildings in each zone. Subsequently, the *Graded Building Ordinances* spread rapidly in Germany, with many cities adopting zoning rules. For example, the *1935 Local Construction Ordinance* divided urban land into six functional zones, such as mixed - function and residential areas, guiding the layout of manufacturing, housing, and service functions. It also established ten intensity zones with building density decreasing from 60% to 10% and linked them to functional zones. These regulations embodied the "functional zoning" concept, preventing industrial and residential mixing, controlling development intensity, and ensuring good lighting and ventilation for housing, thereby improving urban living conditions and enhancing public health.

1.2 The Establishment of Development Control Methods and Systems

After World War II, West Germany began national urban construction legislation. The *1960 Federal Building Act (BBauG)* and the *1962 Federal Land Utilization Ordinance (BauNVO)* standardized development plan preparation, marking the establishment of modern German development control. The two laws and the resulting development plans continued the zoning approach of the *Graded Building Ordinances*, forming a refined "land use + building

function" dual - layer mixed - use control system. Under the *Federal Land Utilization Ordinance*, urban development areas are divided into four types: residential (W), mixed (M), industrial (G), and special construction zones (S). Each is further subdivided into several development sites. For instance, industrial zones (G) are split into commercial and industrial zone (GE) and industrial zone (GI). The regulations specify the permissible building functions on each site, guiding their layout. To distinguish primary and supporting functions, permissible construction functions are categorized into "allowable" and "allowable under special circumstances." The restrictions can apply to building types like residential or commercial buildings, or to business types such as retail or catering. They can also limit facility scale, service targets, and external impacts, such as "local - serving" shops or "non - disturbing" handicrafts. Moreover, development plans can set special regulations for specific areas or building parts.

1.3 The Evolution of Development Control Requirements

Over the past five decades, German development control has been continuously optimized based on new planning concepts and has responded to emerging issues. Initially, influenced by the *Athens Charter*'s functional zoning concept, it focused on separating residential and industrial uses to address environmental degradation caused by industrialization. As the service sector grew and vibrant urban life gained recognition, promoting job - housing integration and orderly functional mixing became significant. The *Land Utilization Ordinance* 's evolution reflects this shift. In the 1962 version, only accessory residences like dormitories were allowed in core zone (MK) areas. The 1968 version added "residences above the floors specified in the development plan," and the 1990 version further permitted "other residences meeting the size requirements of the development plan." In 2017, the *Federal Land Utilization Ordinance* introduced the "Urban-Style Zone (MU)" as a new development category, facilitating higher-density, functionally flexible, and spatially coordinated integration of residential and non-residential uses.

2. Development Control Tools and Their Roles

Germany's development control system operates through a coherent regulatory framework integrating public building regulations, development guidance planning, and construction permits Figure 1. This integrated approach ensures comprehensive implementation of development control objectives. Statutory building regulations establish foundational constraints, while development guidance planning translates these requirements into site-specific zoning schemes through adaptive refinement. Construction permits enforce regulatory compliance throughout both construction and operational phases, thus establishing a closed-loop management cycle that maintains system integrity.

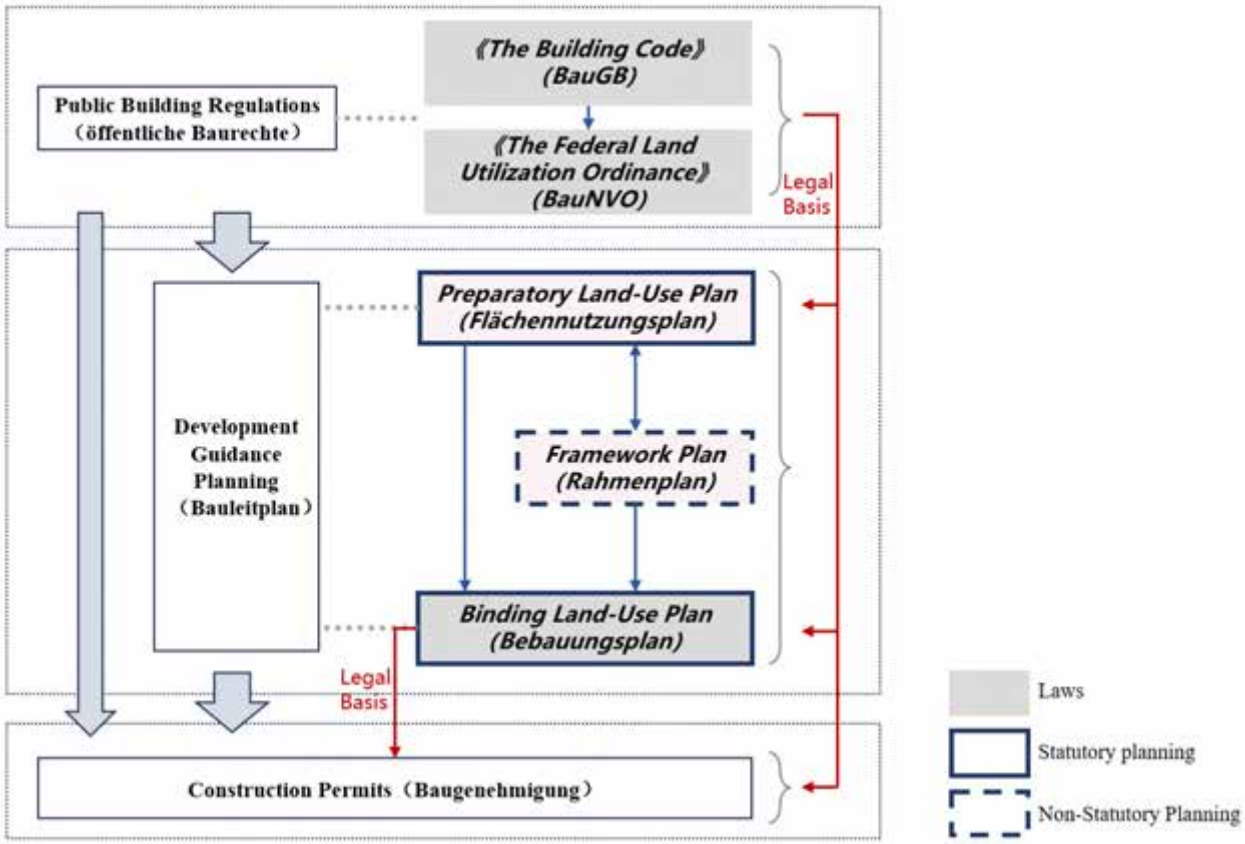

Figure 1: The System of Development Control Tools in Germany

2.1 Public Building Regulations

Public building regulations primarily encompass the *Building Code (Baugesetzbuch, BauGB)* and the *Federal Land Utilization Ordinance (Baunutzungsverordnung, BauNVO)*. These laws provide the overarching framework and general rules for the management of development, construction, and use. In addition to these key regulations, other rules at the federal, state, and municipal levels also play a role in this process.

2.1.1 The Building Code

The Building Code (Baugesetzbuch, BauGB) was established in 1987 through the codification of the *Federal Construction Act (Bundesbaugesetz, BBauG)* and the *1971 Urban Development Promotion Act (Städtebauförderungsgesetz)*. Comprising nearly 300 articles, it provides a comprehensive legal framework for urban development in areas such as spatial planning, land management, planning permission, and renewal measures. The Code defines Preparatory Land-Use Planning (Flächennutzungsplan) and Binding Land-Use Planning (Bebauungsplan) as "development guidance planning" (Bauleitplanung) and specifies their tasks, definitions, purposes, contents, and preparation methods. It serves as the legislative basis for the *Federal Land Utilization Ordinance (Baunutzungsverordnung, BauNVO)* and municipal-level Binding Land-Use Plans. Additionally, the Code clarifies the types of development and construction projects, stating that functional conversion, new construction, and reconstruction all fall under this category. Generally, Binding Land-Use Plans form the fundamental basis for granting construction permits for development and construction projects.

2.1.2 TheFederal Land Utilization Ordinance

The *Federal Land Utilization Ordinance (Baunutzungsverordnung, BauNVO)* is a core legal tool for development control in Germany. The regulations consist of four main chapters, which cover the types of development sites, the scale of construction uses, construction methods and scope, as well as the management transition and

connection before and after regulation revisions. The provisions on development - and - construction - use control are mainly concentrated in the first chapter and include the following three aspects. First, the regulations define the types of development zones and sites. According to these four types of development areas, the *Federal Land Utilization Ordinance* revised in 2021 stipulate 12 types of land zoning Figure 2 . Second, they set out the main uses and permissible buildings for most development sites and clarify these as part of Binding Land-Use Plans Figure 3 . Third, they authorize Binding Land-Use Plans to adaptively adjust the general regulations in the *Federal Land Utilization Ordinance* for specific sites. According to Article 1, Paragraph 7 of these regulations, Binding Land-Use Plans can make special provisions for the use of specific parts of buildings on development sites. For example, they can specify that permissible buildings are only allowed under special circumstances or not allowed at all, and they can restrict the use of specific building facilities to certain locations, all based on special urban - construction reasons.

Main Category	Subcategory	Overview
Residential Area (W)	Small Residential Zone (WS)	Includes residential buildings, private gardens, and small-scale agricultural or horticultural establishments
	Pure Residential Land (WR)	Residential use without disturbance
	General Residential Zone (WA)	Mainly for residential use and regionally oriented local supply
	Special Residential Zone (WB)	Mainly for residential use; in areas of excessive development; may set minimum housing quotas
Mixed Construction Area (M)	Village Zone (MD)	Allows agricultural and forestry enterprises as well as non-intrusive commercial activities
	Village Residential Zone (MDW)	Allows residential and non-intrusive agricultural, forestry, and industrial activities
	Mixed-Use Zone (MI)	Allows residential and non-intrusive commercial activities
	Urban-Type Zone (MU)	Allows residential functions as well as non-intrusive commercial, social, cultural, and other facilities
	Core Zone (MK)	Allows commercial activities and economic, administrative, and cultural center facilities
Industrial Area (G)	Commercial and Industrial Zone (GE)	Allows non-intrusive industrial activities
	Manufacturing Zone (GI)	Allows industrial activities not permitted in other construction areas
Special Construction Area (S)	Special Development Zone (SO)	Areas with special regulations according to Articles 2-10 of the Building Code

Figure 2: The 12 types of land zoning stipulated in the German Building Use Regulations

Development and Construction Areas	Land Zones	Permitted Building Types	Building Types Permitted under Special Conditions
Mixed Area (M)	Mixed-Use Zone (MI)	1. Residential buildings 2. Commercial and office buildings 3. Retail, catering, and hospitality services 4. Other commercial and industrial activities 5. Office, religious, cultural, social, health, and sports facilities 6. Horticulture 7. Gas stations 8. In areas primarily designated for commercial and industrial use, the purpose and scope can extend beyond the core area's entertainment industry	In areas primarily designated for commercial and industrial use, the purpose and scope can extend beyond the core area's entertainment industry
	Urban-Type Zone (MU)	1. Residential buildings 2. Commercial and office buildings 3. Retail, catering, and hospitality services 4. Other commercial and industrial activities 5. Administrative offices, religious, cultural, social, health, and sports facilities	1. Entertainment industry, as well as 2. Gas stations
	Core Zone (MK)	1. Commercial, office, and administrative buildings 2. Retail, catering, hospitality, and entertainment services 3. Other non-disruptive commercial and industrial activities 4. Religious, social, health, and sports facilities 5. Gas stations equipped with parking structures and large parking lots 6. Residences for guards, security personnel, owners, and operational managers 7. Other residences in accordance with the scale specified in the construction plan	1. Gas stations not listed in item 5 of the left column 2. Residences not listed in items 6 and 7 of the left column

Figure 3: Permitted and Specially Permitted Building Types in the Mixed Construction Area (M)

2.2 Development-Guidance Planning and Framework Planning

According to the *Building Code*, development control is a crucial task of both Preparatory Land-Use Planning and Binding Land-Use Planning. Binding Land-Use Planning provides the legal foundation for development control, while the Preparatory Land-Use Plan guides the preparation of Binding Land-Use Plans. In Germany, Framework Plan (Rahmenplan), a non-statutory planning layer, is frequently employed in key areas to integrate Preparatory Land-Use Planning and Binding Land-Use Planning.

2.2.1 Preparatory Land-Use Plan (Flächennutzungsplan)

Pursuant to §5(1-2) of the *Building Code (BauGB)*, the Preparatory Land-Use Plan (Flächennutzungsplan) establishes the land-use framework for municipal development. It articulates municipal authorities' comprehensive development intentions by designating zoning typologies and land-use categories across development sites. While binding on governmental administrative actions, these provisions lack direct enforceability over private development activities.

Municipalities typically adapt land-use categories from the Federal Land Utilization Ordinance (BauNVO) to local contexts. Berlin exemplifies this through its quadripartite residential zoning classification reflecting development intensity gradients (Figure 4). Others like Munich directly specify development-site typologies within their

Preparatory Plans. Select cities including Berlin further prescribe linear spatial configurations for specialized uses, such as primary commercial corridors.

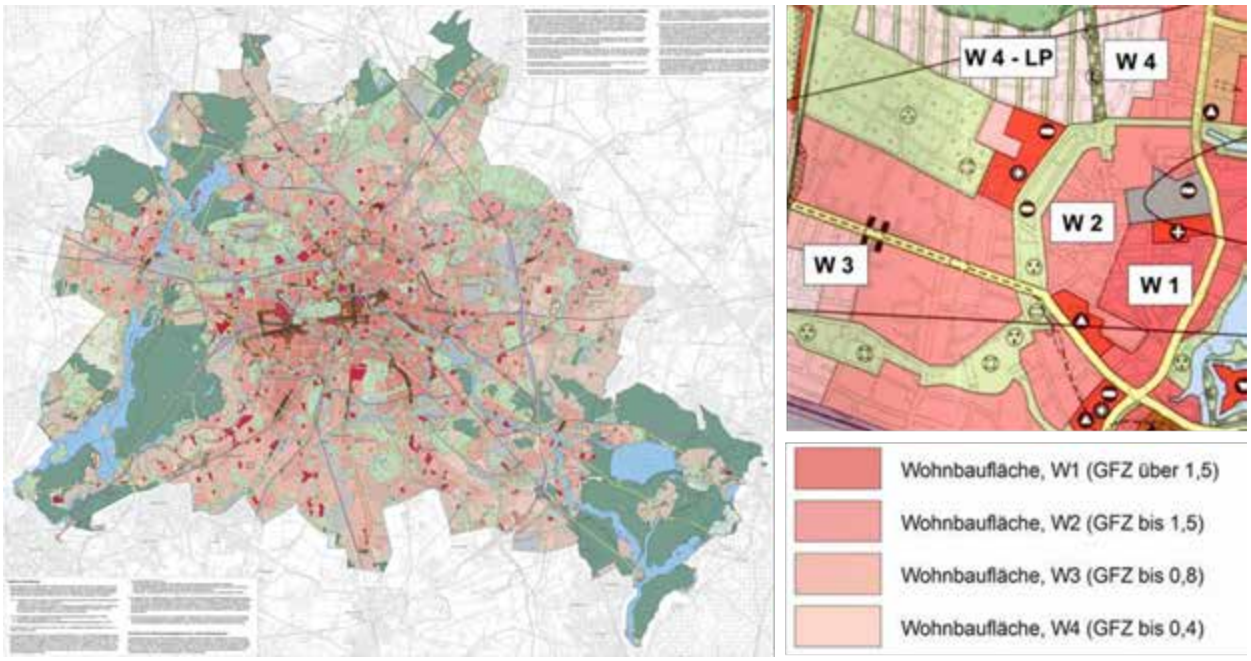

Figure 4: Preparatory Land-Use Plan Flächennutzungsplan of Berlin

During Germany's extensive growth phase, major cities updated Preparatory Plans at 15-20 year intervals. In the current redevelopment era, most municipalities have discontinued comprehensive Preparary Plan revisions. Instead, they implement incremental amendments guided by urban development strategies, key-area framework plans, and neighborhood-scale development concepts responsive to grassroots initiatives.

2.2.2 Framework Plan (Rahmenplan)

Framework Plans operate as flexible non-statutory instruments bridging Preparatory and Binding Land-Use Plans. Their primary function is defining meso-scale development objectives for both greenfield and urban regeneration areas through systematic spatial frameworks. These integrate five core dimensions: spatial configuration, functional organization, building morphology, open-space networks, and transportation systems.

Most Framework Plans prioritize development-site allocation and utilization guidance with methodologies varying according to planning objectives. For new development areas Munich's Riem Conference City emphasizes rational functional zoning while Hamburg's HafenCity focuses on intra-zone functional integration. In renewal contexts Stuttgart's City Core Framework directs controlled functional mixing while enhancing central residential capacity. These outputs support Preparatory Plan adjustments and provide technical guidance for Binding Land-Use Plan preparation.

2.2.3 Binding Land-Use Plan (Bebauungsplan)

The Binding Land-Use Plan (Bebauungsplan) functions as a legally binding local ordinance that specifies land-use parameters for individual plots, ensuring sustainable urban development aligned with public interest and social equity. It constitutes the statutory basis for building construction, renovation, land transactions, management, expropriation, and consolidation. A core mandate involves regulating development and construction by defining the scope and typology of developable sites within the plan area, while adaptively refining building-use provisions stipulated in the *Federal Land Utilization Ordinance (BauNVO)*. All provisions derive authority directly from the *Building Code (BauGB)* and *BauNVO*.

Binding Land-Use Plans are categorized by content and formulation method into three distinct types: Qualified Plans (Qualifizierter Bebauungsplan), which regulate use types and development intensity parameters; Project-Based Plans (Vorhabenbezogener Bebauungsplan), formulated through developer-municipality agreements under Development and Infrastructure Plans (Vorhaben- und Erschließungsplan); and Simplified Plans (Einfacher Bebauungsplan), applied when Qualified Plan criteria remain unmet. Qualified Plans are typically initiated by municipalities without predetermined developers, prioritizing public welfare through market-neutral standards. Project-Based Plans conversely reflect collaborative development between public authorities and private entities, balancing communal interests with market responsiveness. Critically, all plan types incorporate flexible use provisions to accommodate functional conversions and evolving project demands during operational phases.

2.3 Construction Permits

Development projects encompassing new construction, renovation, demolition, or functional conversions require mandatory construction permits under Article 29 of the *Building Code (BauGB)*. Prospective developers must formally submit a construction application (Baugesuch) to the competent authority prior to commencing work. This triggers a comprehensive review of public-law compliance, wherein authorities verify adherence to safety protocols, environmental safeguards, aesthetic coherence, and functional viability standards before granting authorization.

Conformity with designated uses in the Binding Land-Use Plan (Bebauungsplan) constitutes a foundational permit prerequisite, with approval pathways diverging according to plan typology. Qualified Plans necessitate demonstrable alignment between project proposals and both the Binding Land-Use Plan and supplementary construction regulations. For Project-Based Plans, compliance must extend concurrently to the Binding Land-Use Plan and the ratified project infrastructure plan (Vorhaben- und Erschließungsplan). In localities governed by Simplified Plans or entirely lacking Binding Land-Use Plans, Article 34 BauGB enables permit issuance where developments harmonize with neighborhood characteristics.

Critically, the flexible regulatory framework established by the *Federal Land Utilization Ordinance (BauNVO)* and Binding Land-Use Planning allows existing developed sites to secure construction permits without formal plan amendments. This procedural efficiency sustains continuous land-use governance throughout the asset lifecycle while maintaining regulatory integrity.

3. Zoning Control Objectives and Technical Methods

German urban land-use control, particularly the general-use regulations in the *Federal Land Utilization Ordinance (BauNVO)* and the specific-use regulations in Binding Land-Use Plans, is designed to guide rational functional zoning and orderly integration. It divides urban land into functional zones dominated by living, working, and leisure to prevent functional conflicts. Each zone ensures its main function while allowing complementary functions. This enhances the utilization of building facilities in construction and use, meets the needs for functional conversion, and promotes effective functional integration. These features are evident in the differential control requirements for residential, industrial, and service facility-related land-use types, as well as in specific cases.

3.1 Protecting Residential Ambience and Guiding Functional Integration

Residential function is the core of urban areas. Currently, it is crucial to ensure the comfort and privacy of residential communities and buildings while preventing interference from other business types. At the same time, to enhance urban vitality, inclusion, and creativity, it is necessary to reasonably guide the orderly integration of residential and non-residential functions.

Germany has established various use zones through its land - use control system, creating a graded - mixed - use pattern for residential and non - residential functions. This pattern, supported by refined protection measures, achieves balanced development. The residential - and mixed - use construction - land types in Germany exhibit a “graded-mixing” characteristic, with the compatibility of different land - use building functions gradually shifting from strict protection of the residential atmosphere towards promoting functional mixing. Pure residential land

(WR) prioritizes the protection of residential functions, with small - scale local services like commerce requiring special permits. General residential zone (WA) focuses on local service facilities. Urban-type zone (MU) has high functional flexibility with a high proportion of residential functions. Mixed-use zone (MI) requires a rough balance between residential and other uses. Core zone (MK) has a subordinate residential function, ensuring diverse integration through scale - limit regulations and restricting residential layout to avoid interference. For instance, Berlin's I-16 Binding Land-Use Plan stipulates that the residential function around Leipzig Square must account for at least 20% and specifies the minimum vertical elevation for residential placement. The "graded-mixing" of residential and other urban functions creates diverse scenarios, enhancing the habitability of residential environments and promoting the composite utilization of urban spaces.

In Binding Land-Use Planning, supplementary measures are often introduced to coordinate the relationship between residential and non-residential functions and to safeguard the quality of the residential environment. Specifically, certain exclusions for building facilities or limitations on the location of non-residential functions are imposed to prevent interference with residential areas. Meanwhile, horizontal and vertical spatial separation, as well as building protection, are utilized to mitigate the impact of high-intensity activities and traffic noise on residential spaces.

3.2 Internal Combination and External Coordination of Industrial Functions

The industrial function serves as a pivotal driver of urban development. In the realm of industrial land-use control, Germany takes into account a multitude of factors. It caters to the locational and space-environmental requirements of diverse industrial sectors, including manufacturing, storage and transportation, R&D offices, and business offices. Moreover, it coordinates the relationships between different industries and between industrial and urban functions to minimize interference. Additionally, it integrates upstream and downstream industrial chains, jointly plans office, R&D, and manufacturing facilities to foster industrial synergy, and guides the integration of industrial functions with residential and other functions to enhance urban vitality.

To accommodate the needs of industrial clusters, Germany has established two types of industrial-use construction lands: the Commercial and Industrial Zone (GE) and the Industrial Zone (GI). The Commercial and Industrial Zone (GE) is designed for enterprises with minimal environmental impact, such as manufacturing, office operations, warehousing, and utilities. These enterprises typically generate low levels of noise, dust, and odors, allowing them to be situated adjacent to or mixed with residential or mixed-use areas. In contrast, the Industrial Zone (GI) permits all types of enterprises, including heavily polluting ones like chemical plants and power stations. This zone is generally separated from residential or mixed-use areas to mitigate potential environmental and health risks.This zoning strategy, which is based on the environmental impact of enterprises and the local land-use integration needs, effectively balances industrial development with urban environmental quality.

In terms of commercial and office functions, the Mixed-Use Zone (MI), Urban-Type Zone (MU), and Core Zone (MK) all primarily accommodate these uses while also permitting other commercial and industrial facilities. The Core Zone (MK) enforces stricter environmental-impact requirements on enterprises, prohibiting significant interference. In special cases, the General Residential Zone (WA) can host commercial and industrial activities that do not cause significant interference. This use-control framework provides flexible and inclusive spaces for the layout of commercial, office, small manufacturing, and handicraft activities, thereby promoting the integration of industrial functions with other urban functions.

3.3 Hierarchical and Categorical Management of Service-Supporting Functions

Germany employs a hierarchical and categorical approach to manage service-supporting functions, encompassing commercial, social life, and specific service facilities. This approach standardizes these functions in terms of category, scale, and spatial layout, thereby balancing service convenience with the avoidance of use-interference to enhance facility efficiency and sustainable operation capacity.

In the realm of use control, residential, mixed, and industrial zones are assigned different priorities to optimize

functional integration and minimize conflicts. Mixed zones feature relatively flexible regulations to accommodate a diverse array of public service needs. Residential zones, in contrast, are subject to more stringent restrictions to safeguard against potential interference from commercial and industrial activities. Industrial zones, meanwhile, adhere to strict requirements to ensure professionalism and minimize environmental impact.

From a multi-dimensional perspective, Germany enhances planning precision and efficiency by specifying service targets, scales, business types, and adjusting licensing levels. Binding Land-Use Plans focus on the spatial layout of service facilities, often prohibiting residential use on building ground floors to promote orderly distribution along public activity areas. They also consider service radii and market laws to improve residents' lives and community vitality while ensuring facility operation efficiency. Furthermore, plans maintain flexibility to adapt to dynamic construction and operational needs.

4. Insights from Germany's Urban Development Control

Germany's mature urban development control system offers valuable lessons for achieving sustainable and orderly urban growth, characterized by its clear objectives, robust legal foundation, comprehensive toolkit, and refined implementation methods.

4.1 Clear Objectives and Control Principles

As a key mechanism ensuring the orderly development of urban space, Germany's urban development control prioritizes rational functional zoning and promotes functional integration. This approach effectively balances multiple objectives and development needs.

Functional zoning focuses on preventing industrial pollution from impacting other urban functions, strictly protecting residential areas to ensure a high quality of life for residents. Simultaneously, functional integration considers the blending of diverse functions within public activity centers and across different industrial sectors, fostering vibrant and dynamic urban spaces. Germany further enhances this approach through a tiered framework for residential-nonresidential functional integration tailored to specific contexts. This methodology facilitates effective spatial connectivity between functions while preventing mutual interference.

These principles not only meet urban development demands but also create a land use pattern that serves urban residents and other market and societal actors. By doing so, it enhances the efficiency of infrastructure and public services, contributing to the overall sustainability and livability of urban areas.

4.2 Robust Legal Foundation

Germany's urban development control system boasts a robust legal foundation, providing strong support for urban planning and sustainable development. Centered around the *Building Code (Baugesetzbuch)* and supplemented by the *Federal Land Utilization Ordinance (Bundesbaunutzungsverordnung, BauNVO)*, these legal instruments work in tandem to form a well-structured and coordinated legal framework. This framework ensures the scientific nature and effective implementation of urban planning. Other countries can draw on the rigor and coordination of Germany's legal system to enhance the standardization of their own planning controls.

4.3 Comprehensive System of Development Control Tools

Urban development control relies on the close cooperation of diverse instruments including policies, spatial planning, and permits. Germany integrates land use control into these mechanisms, coordinating them through functional zoning and integration principles to form a comprehensive system. This operational framework functions through three interconnected components: First, foundational legislation such as the *Building Code (Baugesetzbuch)* and *Federal Land Utilization Ordinance (Bundesbaunutzungsverordnung, BauNVO)* explicitly defines spatial planning mandates, content parameters, and control objectives. Second, local spatial plans translate these legal requirements into practice while simultaneously providing feedback loops for refining control measures. Third, construction permits enforce regulatory compliance throughout both construction and operational phases, ensuring continuous implementation of control standards.

For nations seeking to enhance their land planning systems, Germany's model demonstrates how synchronizing control instruments through unified objectives, standardized technical approaches, and integrated administrative procedures can significantly elevate the precision, rigor, and normative standardization of regulatory planning controls.

4.4 Refined and Efficient Development Control Methods

Development control regulations and technical methods are crucial for ensuring effective land use control. Germany's sophisticated land use control system incorporates several key features contributing to its success:

1 "Land Use + Building Function" Framework: The system categorizes land into types that permit mixed building functions. This framework defines the suitability and compatibility of uses and specifies primary and accessory functions. This supports appropriate functional zoning and integration while allowing flexible conversion of building uses.

2 "Type of Building Facility + Additional Constraints" Approach: Constraints are specified based on the type of building facility, precisely preventing functional interference. This ensures different uses can coexist without negatively impacting each other.

3 "General Regulations + Specialized Requirements" Method: Combines general rules with specific requirements tailored to particular contexts, guaranteeing both control precision and adaptability. This reduces administrative costs while maintaining flexibility and responsiveness to local needs.

Many countries can learn from Germany's advanced practices in these areas. By adapting these methods to their specific national contexts, they can enhance their control capabilities, refine land use control instruments, achieve efficient urban development, and promote coordinated urban growth.

5. Conclusion

Germany's development control system offers an instructive model for global spatial planning governance. Through rational functional zoning and integrated land-use coordination, it synthesizes statutory frameworks, spatial planning instruments, and permitting mechanisms into a cohesive regulatory ecosystem. This system balances public welfare imperatives, market dynamics, and developmental needs by integrating precise yet adaptable technical methodologies with clear planning directives, thereby enabling effective construction land management. As cities worldwide transition from quantitative expansion to qualitative enhancement—with urban regeneration and stock redevelopment emerging as dominant strategies—Germany's experience delivers actionable insights for international practice.

Comparative Analysis of Legal Frameworks and Reform in Global Urban Planning Systems: Insights from 'Planning Regulation-Constrained' and 'Development Order-Guided' Models in the Stock Era

Han Tao
College of Architecture and Urban Planning, Tongji University
Email: 2330133@tongji.edu.cn

Abstract
This study examines global urban planning systems through a comparative analysis of two governance models: the Planning Regulation-Constrained (Germany, USA, Japan) and Development Order-Guided (UK, Singapore, Hong Kong SAR) approaches. Focusing on six jurisdictions—Germany, USA, UK, Hong Kong SAR, Japan, Singapore—it analyzes their legal frameworks, regulatory tools, and approval mechanisms to assess efficacy in the era of urban stock optimization. Findings reveal inherent tensions between the two models: rigid rules ensure certainty but hinder adaptation, while discretionary systems offer flexibility but risk fairness deficits. Hybridization emerges as imperative, blending as-of-right permissions with contextual discretion. For China's dual system, reforms are proposed—multi-tiered laws, dynamic use packages, streamlined approvals, and collaborative governance—to balance public interest and market dynamism for sustainable urban regeneration.

Keywords Development Control; Planning Systems; Comparative Study; Stock Era

1 Introduction

In this age of accelerated global urbanization, urban planning and land - use management are confronted with increasing challenges. Urban planning systems globally are caught in a fundamental dilemma: achieving legal certainty while allowing adaptive flexibility in development control. These systems generally utilize statutory plans to control land development, but differ significantly in their governance logic. Depending on the relationship between statutory plans and development control, two archetypal models can be identified. The "Planning Regulation - Constrained" Model, as seen in Germany, the US, and Japan, grants as - of - right development permissions via codified rules like zoning ordinances. In contrast, the "Development Order - Guided" Model, pioneered by the UK, Singapore, and Hong Kong SAR, relies on discretionary administrative decisions based on broader policy frameworks.

This study conducted a comparative analysis of six representative countries or regions: New York City (USA), Germany, the United Kingdom, Hong Kong SAR (China), Japan, and Singapore. It concentrates on three key aspects: legal frameworks governing planning hierarchies and authority, regulatory tools enabling land - use control and zoning, and approval mechanisms for development permits. By analyzing the operational logic of each model and assessing their effectiveness in tackling stock - era challenges such as fragmented property rights and the demand for functional hybridity, the study aims to shed light on how global systems balance regulatory certainty and dynamic responsiveness. The insights gained are intended to inform the development of planning governance paradigms that are legally robust yet dynamically adaptive.

2 Dual Models of Urban Planning Systems: Characteristics, Logic, and Evolution

The urban planning system of every country encompasses various forms of planning across multiple top-down levels, all of which include statutory plans for development control. These statutory plans determine the content and procedures that land development and construction projects must follow to obtain planning permission. Based on the relationship between statutory plans and development control, urban planning systems can be divided into two primary models: the "Planning Regulation-Constrained" model and the "Development Order-Guided" model. The Planning Regulation-Constrained model is primarily represented by the zoning systems of Germany (Bebauungsplan), the United States (Zoning), and the Netherlands. Conversely, the Development Order-Guided model is typified by the systems of the United Kingdom and Singapore. Simultaneously, these two traditional models are continuously evolving and refining, gradually incorporating features from each other to form more flexible hybrid models.

Aspect	Planning Regulation-Constrained Model	Development Order-Guided Model
Control System	Strict rule-based control system represented by Zoning.	Due process control system based on case-by-case discretion.
Decision Mechanism	Direct authorization	Administrative licensing
Key Characteristics	Plans act as legal documents, directly authorizing landowners to exercise development rights compliant with zoning regulations. Legitimate development activities are protected by law; compliance automatically grants permission.	Development control is not rigidly tied to plans. Statutory plans serve as *one basis* for development control. Planning permission can even be granted in the absence of a plan.
Representative Countries/Regions	United States, Netherlands, Japan	United Kingdom, Singapore, Hong Kong SAR, China

Figure 1: Comparative analysis of the two modes

2.1 Planning Regulation-Constrained Model: A Strict Rule-Based Control System Represented by Zoning
The Planning Regulation-Constrained regulatory system originated in countries that had developed administrative law or possessed written constitutions defining rights and property rights. Following Napoleon I's conquest of continental Europe, the Napoleonic Code was applied across European nations, establishing administrative legislation and constitutions that explicitly defined powers and corresponding obligations. The defining characteristic of this planning control system is its regulation of development activities through legal statutes. Planning regulations explicitly stipulate the rights and obligations of individuals, as well as the limitations imposed on those rights. The planning systems of most European Union countries, the United States, and Japan derive from this model.

Within the Planning Regulation-Constrained system, development control is based on plans prepared or enacted in advance. The plan itself constitutes a legal document, establishing "As-of-Right" development through regulatory means. It directly authorizes landowners to exercise development rights compliant with zoning regulations via prior authorization. This model emphasizes strict rules and certainty, prioritizing the protection of private property. Development activities conforming to zoning regulations are both protected and constrained by law; compliance automatically grants permission. A local government's refusal of such development constitutes an infringement of private property rights and is subject to appeal. Planners reviewing individual development applications generally possess no discretionary power.

The Planning Regulation-Constrained system is planning-led, extending planning into implementation. Once a plan is approved, it is implemented primarily through building development permits, making development control over land activities relatively straightforward. Plan preparation in this system typically occurs at two levels:1) Strategic Plan at the City-Wide Level: Reflects the municipal government's strategic vision and intent for spatial development and land resource allocation. Examples include Germany's Flächennutzungsplan (Preparatory Land-Use Plan) and the United States' Comprehensive Plan. 2) Statutory Implementation Plan: Legally binding plans for execution, such as Germany's Bebauungsplan (Binding Land-Use Plan, often abbreviated as B-Plan) and the United States' Zoning Ordinance.

Within this system, statutory plans serve as instruments for precisely realizing planning intentions at the legal level. Consequently, they must explicitly specify land-related indicators such as plot boundaries, permitted land uses, floor area ratio (FAR), development density, etc. Statutory plans are enacted through legislative procedures, acquiring legal force and serving as the basis for granting planning permission. Before a plan is finalized, any urban construction activity lacks legal protection. After plan adoption, any necessary adjustments must follow statutory procedures. These procedures vary depending on the nature of the adjustment and are often highly complex, sometimes even identical to the process of statutory enactment itself. Therefore, the Planning

Regulation-Constrained system demands a high standard of plan preparation; plans must be highly operational to serve as the statutory basis for development control.

2.2 Development Order-Guided Model: A Due Process Control System Based on Case-by-Case Discretion

The Development Order-Guided planning system is rooted in the tradition of common law. Its core philosophy recognizes the significant uncertainty inherent in future urban development, arguing that it is impossible to anticipate all potential scenarios for planning applications. Rigid planning would struggle to guide concrete practice effectively. The United Kingdom, along with countries and regions adopting British planning practices, such as Singapore and Hong Kong, originate from this model.

The UK established the foundation for this system with the Town and Country Planning Act 1947. This landmark legislation transferred all future development rights on private land to the state, effectively "nationalizing" development rights and instituting a "development permit" system. Unlike the self-enforcing nature of US zoning, development rules within UK local plans serve as reference points in planning permission decisions. Planning authorities possess discretionary power to consider other material considerations. Concurrently, the UK central government established general development rules (e.g., Permitted Development Rights), granting direct permission for minor development activities and compatible changes of use.

Within the Development Order-Guided system, development control is not rigidly tied to statutory plans. Statutory plans constitute only one basis for development control; planning permission can even be granted in the absence of an adopted plan. In practice, regulating development activities in this model relies more heavily on factors other than the plan itself. Factors influencing planning permission decisions include legislation, regulations, governmental planning policy documents, and local development characteristics. Furthermore, planning departments hold significant discretionary power. When reviewing individual development applications, they can attach specific planning conditions, and, where necessary, even modify certain stipulations of statutory plans.

Compared to statutory plans in the Planning Regulation-Constrained model, those in the Development Order-Guided model offer considerable flexibility. Taking the UK's "Local Development Framework" (LDF) as an example, a key characteristic is its legal establishment of mechanisms enabling plans to react swiftly to unforeseen events and developments. When unexpected circumstances necessitate plan modifications, only the specific paragraphs or sections of the LDF requiring adjustment need amendment, or an "Action Plan" can be prepared – avoiding the need for a comprehensive revision of the entire plan. This functions akin to a folder where new content can be added at any time, embodying its flexible and open nature.

For specific development activities, countries employing the Development Order-Guided model grant greater discretionary power to planning permission approval bodies and officials. This avoids the excessive rigidity and inflexibility often associated with blueprint-style planning. However, extensive discretion also introduces uncertainty. Consequently, such systems necessitate effective oversight and constraint mechanisms. For instance, while UK local planning authorities possess discretionary power over development applications, the existence of the Planning Inspectorate system provides oversight. When disputes arise between local planning authorities, developers, residents, or other stakeholder groups regarding a specific project, a Planning Inspector can intervene in the permission process for that particular development.

Ideally, regions implementing the Development Order-Guided planning system should meet the following conditions:1) Possess a comprehensive urban planning legal framework and related legislation. 2) Establish effective oversight and constraint mechanisms. 3)Employ highly qualified and professional management personnel.

2.3 Convergence and Evolution of the Two Models

The two planning control models each possess distinct characteristics, advantages, and disadvantages. Within

the Planning Regulation-Constrained system, statutory plans constitute the core basis for development control. To safeguard individual rights and ensure planning certainty, this system tends to employ specific regulations, such as density and floor area ratio (FAR), to establish quantifiable development limits, emphasizing regulatory rigidity and legal authority. Conversely, the Development Order-Guided system prefers broadly interpreted principles to maintain planning flexibility, thereby granting the system greater elasticity and adaptability. However, each system has its limitations: overly rigid restrictions can lead to inflexibility, while overly broad policy interpretations may leave policymakers and applicants lacking clear guidance for specific cases. Overall, the Planning Regulation-Constrained system reflects more administrative-level decision-making, whereas the Development Order-Guided system embodies more policy-level considerations. The practical differences between these two systems are significant.

The Planning Regulation-Constrained system excels in transparency and certainty but often lacks flexibility and adaptability. Its stringent restrictions may fail to achieve desired spatial forms, potentially resulting in outcomes misaligned with public expectations or satisfaction. On the other hand, the Development Order-Guided system can adapt to rapidly changing needs and development pressures. However, this system may suffer from insufficient transparency and uncertainty. Its high degree of flexibility and discretionary power can sometimes lead planning authorities to overlook the interests of the state or societal groups during decision-making, raising concerns about the fairness and rationality of planning outcomes.

In practice, both systems have evolved organically, incorporating elements and strengths from one another beyond their traditional foundations. For instance, the United Kingdom, drawing on its administrative law tradition, safeguards procedural rigor through detailed and transparent processes. The United States' zoning system has undergone significant reforms, introducing mechanisms such as Transferable Development Rights (TDR), Form - Based Codes, Zoning Variances, and Incentive Zoning. These additions infuse flexibility into the traditionally rigid zoning framework and offer effective tools for managing public facility provision and historic district preservation. Japan has developed a development control system with inherent flexibility, tailoring the zoning model to its national context. Meanwhile, Singapore, while inheriting the British system, has evolved a dynamic management framework centered on its Master Plan.

Today, the regulatory models in most countries and regions exhibit compatibility with *both* systems. Hong Kong SAR, China, exemplifies this hybrid approach: its land lease system primarily utilizes the Development Order-Guided mode, while its statutory plans operate in a planning-led manner, effectively leveraging the strengths of both models to form a hybrid development control system. For Mainland China, the decision-making mechanism for project development aligns with the Development Order-Guided system, employing an administrative licensing system where planning permission must be sought for authorization. Simultaneously, the *regulatory detailed plan* () adopted in Mainland China draws heavily from the US zoning-based development management system, exhibiting characteristics of the Planning Regulation-Constrained model.

Therefore, selecting New York (USA), Germany, the United Kingdom, Hong Kong SAR (China), Japan, and Singapore as comparative case studies is justified. This selection considers both the similarities these regions share within the spectrum of urban planning systems and their distinctive characteristics. Analyzing these cases offers valuable insights for refining the planning regulatory framework in Mainland China.

3 Comparative Analysis of Legal Frameworks and Regulatory Tools

The planning system generally encompasses three categories of regulatory tools: legislation, zoning regulations, and planning/building permits. These tools work in concert to achieve refined regulatory governance.

3.1 Legal Framework

Given that land development involves the rights and interests of multiple stakeholders—government, market, and society—a fundamental regulatory framework must be established through legislation. Most of the legal systems of the countries/regions all comprise two tiers: "primary legislation" and "secondary legislation".

Primary legislation serves as the core framework governing the overall system, supplemented by multiple pieces of secondary legislation that address specific issues with precision.

Jurisdiction	Primary Legislation & Regulations	Level of Authority
Germany	**Federal Building Code (*Baugesetzbuch - BauGB*)**	**Federal Legislation**
	Land Utilization Ordinance (*Baunutzungsverordnung - BauNVO*)	Federal Regulation
	State Building Code (*Landesbauordnung - LBO*) (e.g., for specific federal states)	State Legislation
	Binding Land-Use Plan (*Bebauungsplan - B-Plan*)	Municipal Regulation
Japan	**City Planning Act (*Toshi Keikaku Hō*)**	**National Legislation**
	Building Standards Act (*Kenchiku Kijun Hō*)	National Legislation
	Land Readjustment Act (*Tochi Kukaku Seiri Hō*)	National Legislation
	Urban Redevelopment Act (*Toshi Saikaihatsu Hō*)	National Legislation
	New Urban Area Development Act (*Shin Jūtakuchi Seibi Hō*)	National Legislation
	Urban Regeneration Special Measures Act (*Toshi Saisei Tokubetsu Sochi Hō*)	National Legislation
	Local City Planning Ordinance (*Chiho Toshi Keikaku Jorei*)	Local Regulation
	Local Construction Ordinance (*Chiho Kenchiku Jorei*)	Local Regulation
New York City, USA	**New York City Zoning Resolution**	**Local Regulation**
	Standard State Zoning Enabling Act (Model Act adopted by NY State)	State Legislation
	Standard City Planning Enabling Act (Model Act adopted by NY State)	State Legislation

Jurisdiction	Primary Legislation & Regulations	Level of Authority
Hong Kong SAR, China	**Town Planning Ordinance (Cap. 131)**	**SAR Legislation**
	Town Planning Regulations	SAR Regulation
	Town Planning (Appeal) Regulations	SAR Regulation
	Town Planning (Compensation) Regulations	SAR Regulation
	Town Planning (Application for Permission to Develop) Regulations	SAR Regulation
Singapore	**Planning Act (Cap. 232, 1998 Rev. Ed.)**	**National Legislation**
	Planning (Master Plan) Rules	National Regulation
	Planning (Development) Rules 2008	National Regulation
	Planning (Use Classes) Rules	National Regulation
	Planning (Development of Land Authorisation) Notification	National Regulation
United Kingdom	**Town and Country Planning Act 1990 (Core legislation; note: 1947 Act was foundational)**	**National Legislation**
	The Town and Country Planning (General Permitted Development) Order (England) [Year] (GDPO)	National Regulation
	The Town and Country Planning (Use Classes) Order [Year] (UCO)	National Regulation
	The Town and Country Planning (Development Management Procedure) (England) Order [Year]	National Regulation
	Local Development Orders (LDOs)	Local Regulation
	Neighbourhood Development Orders (NDOs)	Local Regulation

Figure 2: Primary Legislation and Regulations by Jurisdiction

The primary tasks of legislative tools include authorizing zoning regulations and land-use controls, providing general management rules, and specifying approval requirements.

(1) Authorizing Zoning Regulations and Land-Use Controls

Defining and authorizing zoning regulations is a fundamental task of the legal framework, typically stipulated by primary legislation. Legislation explicitly mandates that land-use control through zoning regulations is conducted according to law. From a global perspective, legislation universally emphasizes the critical role of use-based zoning control in achieving the rational allocation and sustainable utilization of spatial resources for urban development land. Legislation authorizes, often through enabling provisions, the competent authority,

preparation requirements, and content for implementing zoning regulations (see Table X). By establishing mandatory authorizations, legislation ensures the preparation and enforcement of zoning regulations, thereby solidifying the foundation for land-use control.

For example, the United States, through Article 1 and Article 2 of the *Standard State Zoning Enabling Act* (federal model legislation adopted by states), authorizes local governments to undertake zoning. Empowered by this authorization, local governments implement differentiated management based on land use distinctions. Different zones are subject to differentiated development standards, while zones of the same type adhere to uniform control standards. Regulation focuses on core indicators such as building height, total floor area, bulk, location, and permitted uses. Germany's Federal Building Code (*Baugesetzbuch - BauGB*), specifically §1, §5, and §9, establishes that controlling development uses is the core task of both the preparatory land-use plan (*Flächennutzungsplan*) and the binding land-use plan (*Bebauungsplan - B-Plan*). These plans function synergistically: the preparatory plan provides the basis for the binding plan, requiring a comprehensive overview of urban land-use types, while the binding plan focuses on specifying the precise types and scale of permitted development uses.Japan's City Planning Act (*Toshi Keikaku Hō*), under Article 8 and Article 15, stipulates that within City Planning Areas, Urban Plans (*Toshi Keikaku*) can designate various zones and districts, including Use Districts (*Yoto Chiiki*), Special Use Districts (*Tokutei Yoto Chiiki*), Height Districts (*Takasa Chiiki*) or High-Use Districts (*Kodo Riyo Chiiki*), and Special Blocks (*Tokutei Gaiku*). The Urban Plan specifies the types, locations, and boundaries of these zones and districts.

The authorization granted by legislation defines the applicable scope and boundaries of land use, providing precise guidance and clear legal basis for subsequent management.

Jurisdiction	Legal Basis	Plan / Zoning Name	Preparing Body	Key Content Requirements
Germany	Federal Building Code (*Baugesetzbuch*), **§1, §5, §9**	**Building Guidance Plans** (*Bauleitpläne*): - Preparatory Land-Use Plan (*Flächennutzungsplan*) - Binding Land-Use Plan (*Bebauungsplan*)	**Municipal Government** (*Gemeinde*)	- **Preparatory Plan:** Overview of land-use types for urban development across the entire municipal area. - **Binding Plan:** Specification of permitted development uses (type and scale); building methods; permissible/non-permissible development plots; building layout; etc.
Japan	City Planning Act (*Toshi Keikaku Hō*), **Art. 8, Art. 15**	**Zones and Districts** (*Chiiki Kuiki*)	**Municipal Government** (*Shichōson*)	Within City Planning Areas, Urban Plans must designate: - Use Districts (*Yoto Chiiki*) - Special Use Districts (*Tokutei Yoto Chiiki*) - Height Districts (*Takasa Chiiki*) / High-Use Districts (*Kodo Riyo Chiiki*) - Special Blocks (*Tokutei Gaiku*) Plans must specify: **type** (including specific purpose for Special Use Districts), **location**, and **boundary** of each zone.

United States	*Standard State Zoning Enabling Act*, **Sec. 1, Sec. 2** (Adopted by state legislatures)	**Zoning**	**Local Government** (City/County)	Local legislatures may divide territory into districts of appropriate **number, shape, and area** to achieve the Act's purposes. Regulations may control: - Construction/alteration/repair of buildings/structures - Land use Regulations must be **uniform** within each district but may **differ** between districts.
Hong Kong SAR	Town Planning Ordinance (Cap. 131), **Sec. 3, Sec. 4**	**Statutory Plans**	**Town Planning Board** (TPB)	Plans may depict or stipulate: - Streets, railways, major transport facilities - Zones/areas for residential, commercial, industrial, or other specified uses **Any matter** may be expressed via diagrams, illustrations, notes, or descriptive text – all integral to the plan.
Singapore	Planning Act (Cap. 232), **Sec. 5, Sec. 6, Sec. 8**	**Master Plan**	**Urban Redevelopment Authority** (URA)	The approved Master Plan comprises: - Authorized maps - Written statement Proposed revisions may include: - Rezoning - Changes to plot ratios (FAR) - Amendments to written statements - Designation of conservation areas

Figure 3: Authorization of Zoning/Land-Use Plans by Jurisdiction

(2) Providing General Management Rules

Legislation provides unified standards and general management rules for land-use control, establishing clear regulatory guidance. The combined management approach focusing on "Land Use + Building Function" requires stipulation within these general rules. Benchmark countries and regions typically define these within secondary legislation.

For instance, Germany's Land Utilization Ordinance (*Baunutzungsverordnung - BauNVO*), Articles 2 to 9, defines types of development land and the building facility uses permitted (or permitted under exceptional circumstances) within each land-use category.Japan's Building Standards Act (*Kenchiku Kijun Hō*), Article 48, specifies the permissible building scope within the land uses designated under the *City Planning Act*.New York City's Zoning Resolution, notably Chapters 2 (§2), 3 (§2), and 4 (§2), clearly defines permissible building uses and detailed control requirements within each land-use zoning district.

These provisions ensure the standardization and normalization of regulatory activities, provide clear guidance and general principles for urban development, and enhance regulatory efficacy.

(3) Specifying Approval Requirements

Legislation establishes a detailed legal framework for the application and approval of planning permission, ensuring transparency and impartiality in the approval process. Key requirements specified in legislation typically include scope and types of permits, application procedures, procedures for permit modifications, and approval criteria. Examples include Singapore's Planning Act, Part III "Development and Subdivision of Land", which outlines the types of permits and corresponding application procedures. Japan's City Planning Act, Chapter 3, Section 1 "Regulation of Development Activities, etc.", specifies the procedures for permit applications, criteria for development permission, procedures for permit modifications, and requirements for project completion inspections. New York City's Zoning Resolution, Chapter 7 "Administration", details requirements for zoning enforcement, administration and amendments, zoning variances, special permits, authorizations, and certifications. By establishing strict approval procedures, legislation provides clear legal grounding for the approval process, ensuring the effective implementation of land-use controls.

By establishing strict approval procedures, legislation provides clear legal grounding for the approval process, ensuring the effective implementation of land-use controls.

3.2 Zoning Regulations

The primary task of zoning regulation preparation is to guide rational land zoning. As a vital urban planning tool, its universal principle lies in rationally dividing and controlling urban space by explicitly defining land development uses. This aims to optimize urban functions, achieve efficient resource utilization, and foster coordinated social, economic, and environmental development. Both domestically and internationally, the core task of zoning regulation preparation focuses on land-use zoning for urban areas, guiding orderly urban development, safeguarding public interests, accommodating sustainability requirements, and ensuring land-use rationality for the city's long-term healthy development.

The hierarchical structure of zoning regulations falls into two categories: single-tier and multi-tier systems. In Germany, a multi-tier system is used, with the Preparatory Land-Use Plan (Flächennutzungsplan - F-Plan) providing an overview of land uses for urban development across the entire municipality, indicating the overall development intent and guiding the preparation of the Binding Plan. The Binding Land-Use Plan (Bebauungsplan - B-Plan) then regulates the specific development uses for individual plots in the form of local regulations, serving as the direct basis for permit approvals.

Single-tier examples include Japan's Use Districts (Yoto Chiiki), Hong Kong SAR's Use Zones (within Statutory Plans), New York City's Zoning, Singapore's Master Plan, and China Shanghai's three-tier Territorial Spatial Planning System comprising the "Master Plan," "District Plan," and "Regulatory Detailed Plan".

Regarding the legal nature of zoning regulations, they generally fall into two categories, both serving as a basis for permit approvals. Statutory Plans are documents with legal force that guide development control, such as Germany's Preparatory Land-Use Plan (F-Plan), Singapore's Master Plan, and Hong Kong SAR's Statutory Plans. Statutory Plans That Are Also Regulations possess the dual nature of being both the planning document and the legally binding regulatory instrument itself. Examples include Germany's Binding Land-Use Plan (B-Plan) (Municipal Regulation), New York City's Zoning Resolution (Local Regulation), and Japan's Use Districts System (established by the City Planning Act and implemented via local ordinances)

3.3 Planning and Building Permits

(1) Defining Development Activity

Definitions of "development" share common core elements across different countries and regions, specific phrasing and emphases vary according to local contexts and planning management needs. Generally,

"development" encompasses activities such as new construction, renovation, expansion, functional conversion (change of use), and demolition. Internationally, change of use is universally treated as development, requiring planning permission or building permits.

Jurisdiction	Legal Basis	Specific Definition
Germany	Federal Building Code (*Baugesetzbuch - BauGB*), **§29**	Construction of new building facilities; modification or functional conversion (*Funktionsänderung*) of existing buildings; large-scale earthworks (*Erdaufschüttungen*), excavations (*Aushub*); quarrying (*Gewinnung von Bodenschätzen*).
Japan	City Planning Act (*Toshi Keikaku Hō*), **Art. 4**	"Development Activity" (*Kaihatsu Kōi*) refers to changes to the nature of land division (*tochi kukaku-sei no henkō*) undertaken primarily for the construction of buildings or specified structures (*tokutei kōbutsu*).
New York City, USA	Zoning Resolution, **§12-10**	"Development" on a zoning lot or part thereof includes: (a) Construction of a new building or other structure; (b) Relocation of an existing building or other structure to another zoning lot; or (c) Establishment of a new open use (*excluding* accessory uses). Alterations within the scope of §11-23 (Demolition and Replacement) are deemed development.
Hong Kong SAR, China	Town Planning Ordinance (Cap. 131), **Sec. 1A**	"Development" means the carrying out of building, engineering, mining, or other operations in, on, over, or under any land, or the making of any **material change** in the use of any land or buildings. A material change includes the deposit of materials on land, regardless of prior use for deposit, if the deposit increases in area, height, or quantity.
Singapore	Planning Act (Cap. 232), **Sec. 3**	"Development" means the carrying out of any building, engineering, mining, **earthworks**, or other operations in, on, over, or under any land, or the making of any **material change** in the use of any building or land.

Figure 4: Conceptual Definitions of "Development" Across Jurisdictions

In Mainland China, "" (*kāifā* - development) has not been formally established as a statutory term within planning laws, policies, or planning documents. Urban-rural planning management has long centered on the concept of " (*jiànshè* - construction). For instance, within the permit system, the " (Land Use Planning Permit) and " (Construction Engineering Planning Permit) are key statutory documents. Article 40 of China's *Urban-Rural Planning Law* stipulates: "For the construction of buildings, structures, roads, pipelines, and other engineering projects within urban and town planning areas, the construction unit or individual shall apply to the competent urban-rural planning department of the city or county people's government, or the town people's government designated by the people's government of the province, autonomous region, or municipality directly under the Central Government, for a Construction Engineering Planning Permit." This defines the legal scope of "" (*jiànshè* - construction).

However, the concept of "construction" (*jiànshè*) essentially represents only one specific type of activity within the broader scope of "development" (*kāifā*). It has a relatively narrow focus, primarily emphasizing physical building activities. It fails to comprehensively encompass broader development activities such as changes of use or functional conversions. Particularly within the context of territorial spatial planning, where planning objectives are more diverse and management elements more complex, the limitations of the "construction" concept become increasingly apparent. It struggles to meet the demands of multi-objective planning and multi-faceted management.

(2) Permit Types

Regarding permit types, all regions have Building Permits to regulate specific construction proposals. Some countries and cities also have Planning Permits to authorize development proposals from a planning perspective. International experience reveals two primary management process types:

'Building Permit' System (Planning Regulation-Constrained Model - e.g., Germany, New York):Employs blueprint-style planning defining use zones. The plan itself is a legal document, establishing "As-of-Right" development through regulation.Grants landowners the right to develop land compliant with the plan via prior authorization. Legitimate development is protected by law; compliance automatically grants permission.Once the plan is approved, implementation primarily occurs through Building Permits.If development deviates from the plan or necessitates plan adjustments for other reasons, it requires following statutory procedures for zoning variances or special permits.

'Planning Permission + Building Permit' System (Development Order-Guided Model - e.g., UK, Singapore, Hong Kong SAR):Planning control relies on case-by-case administrative discretion. Development control is not rigidly tied to statutory plans.Statutory plans serve as only one basis for control; planning permission can even be granted *in the absence* of an adopted plan.Regulating development relies more heavily on other factors (legislation, regulations, government policy documents, local development characteristics) than the plan itself.Planning authorities hold significant discretionary power. They can attach specific planning conditions to permissions and, where necessary, modify stipulations of statutory plans when reviewing applications.

Mainland China's current system resembles Model 2, employing "Planning Permits + Construction Permits". However, it incorporates localized procedures such as land grant contracts and property rights registration, adding complexity, particularly for functional adjustments.

(3) Permit Categories
Permit requirements can be categorized into Conventional Permits and Exempt Permits. Exempt Permits grant authority for certain development activities with minimal external impacts to proceed without applying for planning permission. Most countries requiring planning permission explicitly define development activities eligible for exemptions.

• **Singapore**: Establishes an "Exemption List" outlining minor developments or construction works that do not require planning approval or a permit from the Urban Redevelopment Authority (URA).

• **Hong Kong SAR**: Beyond Conventional Permits, many changes of use do not require planning permission. Hong Kong classifies all land uses into 18 Broad Use Classes. Once planning permission is granted for a specific Broad Use Class, any use within that class can be changed to another use within the same Broad Use Class without requiring a new planning application.

• **Japan**: Only development activities exceeding a specific scale threshold require a Development Permit. The City Planning Act clearly defines activities subject to Development Permit regulation, primarily including development over 1,000 m² in urbanization promotion areas (UPA). This threshold is lowered to 500 m² in existing built-up areas within the three major metropolitan areas. In principle, all development activities within urbanization promotion areas (UPA) and urbanization control areas (UCA) require a Development Permit. Development activities over 3,000 m² in non-designated city planning areas and quasi-city planning areas also require a permit. Development activities deemed publicly beneficial (e.g., libraries) with no adverse impact on surrounding land use, and those below the specified scale threshold (such as small-scale changes of use), do not require a Development Permit and can proceed as long as they comply with relevant regulations

4 Comparative Analysis and Reform Implications: Towards a Regulatory System Balancing Precision and Adaptability
Within the global urban planning domain, regulatory systems continue to evolve primarily within the dual framework of the "Planning Regulation-Constrained" and "Development Order-Guided" models. However, as urban development enters the stock era, both models face pressures for transformation. This chapter aims to provide a systematic and in-depth comparative analysis of these two models, examining their institutional efficacy, legal tools, and practical challenges. Building on this analysis, it proposes optimization pathways applicable to the

planning regulatory system in Mainland China.

4.1 Re-evaluating Model Efficacy: The Trade-off Between Certainty and Adaptability

The Planning Regulation-Constrained model, exemplified by Germany and the US, demonstrates significant strengths in legal certainty and efficiency. For instance, Germany's *Binding Land-Use Plan (B-Plan)* and the US *Zoning Ordinance*, as direct authorization documents, grant "As-of-Right" development for compliant activities, substantially reducing approval process costs. However, this model has limitations; its rigid rules can lead to spatial governance failures. In New York, zoning proved slow to respond to mixed-use demands, resulting in the redevelopment of old industrial areas becoming trapped in a "compliant yet functionally mismatched" dilemma. In Germany, amending a B-Plan requires complex procedures, including municipal council votes, severely delaying the renewal of historic districts.

The Development Order-Guided model, typified by the UK and Singapore, excels in dynamic adaptability. The UK's paragraph-based amendment mechanism for its *Local Development Framework* allows adjustments only to changed sections. Singapore employs an "Exemption List" to exclude temporary structures and minor alterations from permitting, effectively enhancing responsiveness. Nevertheless, the exercise of discretionary power carries fairness risks. In Hong Kong SAR, the planning permission process has exhibited bias towards high-value commercial uses (e.g., hotels), sparking community protests. In the UK, a lack of transparency in local discretion has exacerbated conflicts between developers and residents. Thus, while both models have merits, a single model struggles with the complexities of the stock era. Consequently, integrating "rule precision" with "procedural adaptability" becomes an imperative choice.

4.2 Core Challenges of the Stock Era

Contemporary global urban regeneration faces significant challenges rooted in fragmented property rights, growing demand for functional mixing, and high institutional costs. In high-density built-up areas, such as Shanghai's Lilong alleyway housing or Tokyo's Shitamachi downtown, traditional zoning struggles to balance compensation standards among numerous stakeholders. Japan's Urban Regeneration Special Measures Act attempts to introduce third-party assessments, but controversies persist. Meanwhile, the dynamic integration trend of living-working-innovation spaces challenges the logic of single-use zoning. New York zoning only began piloting "Work-Live Districts" in Manhattan in 2021, reflecting a lag in responding to mixed-use needs. Additionally, the lengthy and cumbersome procedures for amending zoning regulations create severe misalignment with the market's demand for rapid iteration. For instance, in Mainland China, adjusting a Regulatory Detailed Plan requires an approval period of 6-12 months.

4.3 Lessons Learned and Optimization Pathways

Based on the systematic analysis and comparison of the two models, and taking institutional optimization in Mainland China as an example, the following pathways are proposed for refining urban planning regulation:

Drawing on international experience and adapting to China's context, establishing a four-dimensional reform framework encompassing "Law - Tools - Procedures - Governance" is crucial.

Based on the systematic analysis and comparison of the two models, and taking institutional optimization in Mainland China as an example, the following pathways are proposed for refining urban planning regulation. Drawing on international experience and adapting to China's context, establishing a four-dimensional reform framework encompassing "Law - Tools - Procedures - Governance" is crucial.

(1) Multi-tiered Legal Framework: Enact a national-level Territorial Spatial Planning Law establishing foundational rules. At the local level, introduce supplementary Administrative Technical Regulations featuring a "Negative List + Flexible Conversion" mechanism to enhance legal flexibility and adaptability.

(2) Innovative Regulatory Tools: Introduce Dynamic Use Packages, designating "Innovation Mixed-Use Zones"

allowing flexible configuration of residential, commercial, R&D, etc., based on actual demand. Establish a Refined Exemption Mechanism with a "Minor Renewal List" to fully unleash the vitality of micro-regeneration. Pilot Development Rights Banking, drawing on the US TDR model to balance conservation and development.

(3) Streamlined Approval Procedures: Implement an "Online Permit Platform" to drastically reduce approval cycles to under 30 days. Establish an Independent Planning Inspectorate dedicated to arbitrating property rights disputes, enhancing the fairness and efficiency of approvals.

(4) Governance Model Transformation: Shift from traditional administrative control towards collaborative contracting. Incorporate Public Facility Provision Clauses within land grant contracts. Institute a "Community Planner" system to foster multi-party consensus and synergistic action.

The ultimate goal is to achieve a precise balance between safeguarding public interests and meeting dynamic market demands through an institutional design of "Rigid Bottom Lines + Flexible Space". This will build an urban planning regulatory system that is both nationally appropriate and internationally competitive, providing a robust foundation for sustainable urban development.

Comprehensive Evaluation of Child-Friendly Public Spaces: The Zümrütevler Case as Istanbul's First Permanent Two-Stage Street Transformation

Derya KOÇAŞ, Elif KISAR KORAMAZ
Istanbul Technical University
kocas15@itu.edu.tr, ekoramaz@itu.edu.tr

Abstract
In rapidly urbanizing cities, creating child-friendly public spaces is essential for supporting children's independent mobility, safety, and well-being. Child-centred street transformations, often implemented through phased tactical urbanism approaches, aim to reconfigure vehicle-dominated areas into inclusive, pedestrian-friendly environments. This research critically evaluates the Zümrütevler Square transformation in Istanbul using a multi-scale framework covering process, neighbourhood context, and design details. The study broadens its scope by incorporating user behaviour analysis alongside design criteria, offering deeper insights into the lived experience of the space. Findings highlight successful participatory design and iterative adaptation but reveal limitations in sustaining child-friendly identity post-implementation, constrained child visibility, and institutional fragmentation. The study underscores the importance of integrating flexible, context-sensitive criteria and behavioural observations to enhance long-term child-friendly urban interventions in dense metropolitans.

Keywords: child-friendly; street transformation; public space; design guidelines; user behaviour

Introduction

In today's rapidly evolving urban landscapes, the well-being and development of children are increasingly central to city planning agendas. By 2030, it is estimated that 60% of the global population will be under the age of 18, highlighting the urgent need to consider children's needs in urban development. Urban environments play a pivotal role in shaping childhood experiences, and access to safe, engaging public spaces is essential for their physical, mental, and social well-being. As cities densify and open spaces become more limited, the question of where and how children can play and move safely gains critical importance. Contemporary shifts in neighbourhood dynamics have led to a reduction in outdoor spaces and limited children's independent interactions with their environment. While the value of child-friendly public spaces has long been recognised, creating and sustaining them in densely built environments has become increasingly challenging. For instance, the Welsh Assembly (2002) emphasises that play is fundamental for children's development and that communities should provide environments that support play opportunities.

The concept of a child-friendly city has gained significant attention, representing a broader movement toward creating urban spaces that are not only safe and accessible but also enriching for children's cognitive and social development. Urban designers, architects, and local governments are increasingly recognising children as essential urban actors, advocating for policies and designs that address their unique needs. Krysiak (2020) underlines that when children are ignored in the design process, they are effectively excluded from urban life, limiting their opportunities for growth and participation. One key strategy in advancing child-friendly urbanism is the transformation and pedestrianisation of streets—the very first public spaces children experience. These projects often begin with temporary interventions, using a phased or tactical urbanism approach. This allows cities to pilot changes, observe user reactions, and adapt plans before committing to permanent transformations. In this framework, streets are reimagined as accessible and stimulating spaces for children's daily activities, safe movement, and social interaction.

A prominent example of this strategy is the Zümrütevler Square transformation project in Istanbul, Türkiye. Implemented in two stages, this initiative converted a vehicle-dominated area into a pedestrian-friendly public square. It represents a pioneering case of phased child-friendly urban intervention in Türkiye, particularly significant given the city's high population density and limited open space. Such projects not only provide physical improvements but also aim to shift public perceptions, promote non-motorised mobility, and foster inclusivity, especially for vulnerable groups such as children, the elderly, and those with limited mobility. However, while

phased strategies offer flexibility and encourage public participation, they also present challenges in maintaining the integrity of the original design vision during the transition to permanent implementation. Revisions made for regulatory, political, or budgetary reasons may compromise the child-centred intent, raising questions about the sustainability and long-term effectiveness of such interventions. This study explores whether child-friendly environments created through phased street transformations retain their intended qualities once they are permanently implemented. The primary focus is on assessing both the child-friendliness and sustainability of these transformed spaces. The key research questions are:

- What methods and criteria can be used to measure child-friendliness at different scales?
- How do planning and design decisions at each stage affect the use and perception of space?
- Can spaces temporarily designed to be child-friendly retain their effectiveness after becoming permanent?
- How can sustainability be ensured in long-term child-centred street design?

This research centres on street transformations within metropolitan areas, with Istanbul as the main case context. It examines how car-dominated urban design limits children's mobility, safety, and access to social space, and how phased urban interventions can offer more inclusive alternatives. The study particularly investigates Zümrütevler Square, offering a detailed case analysis to evaluate the design and implementation process, as well as the space's current performance. The scope also includes a review of international urban design guides and case examples from other cities, which inform the evaluation framework used in the fieldwork. The study adopts a case study approach structured across three spatial levels:

- The transformation process (planning, decision-making, and implementation strategy)
- The neighbourhood scale (surrounding land use, accessibility, safety)
- The design detail scale (materials, play elements, inclusivity)

Evaluation criteria are synthesised from five international child-friendly street design guides and adapted to suit the local context. Fieldwork combines qualitative and quantitative methods, including document analysis, stakeholder interviews, field measurements, pedestrian counts, and behavioural mapping. This multiscale and interdisciplinary approach supports a comprehensive evaluation of both the child-friendliness and sustainability of the space, contributing a replicable framework for future urban design research and practice.

Children in Public Spaces

In modern societies, it is commonly believed that children today are more privileged than previous generations due to access to technology and a wide range of leisure activities available after school and on weekends (Freeman & Tranter, 2012). However, this perception raises a critical question: Are today's urban environments truly more beneficial for children, particularly regarding their ability to move freely and independently within the city, or are they still reliant on adult supervision? (Freeman & Tranter, 2012). Understanding how children interact with urban spaces begins with identifying the public environments they use outside the home. Public spaces—such as squares, boulevards, streets, playgrounds, and in-between areas—are more than physical locations; they are social and functional hubs that support daily life, infrastructure, and community interaction (UN-Habitat, 2020). Among these, streets are especially significant, forming the primary network for urban mobility and access, directly influencing how people navigate and connect within cities (GDCI, 2019).

The term "Child-Friendly Cities" was first introduced at the 1996 Habitat II Conference in Istanbul, which led UNICEF to launch the Child-Friendly Cities Initiative (CFCI) in the same year (UNICEF, n.d.). The initiative was designed to help local governments implement the UN Convention on the Rights of the Child by addressing children's needs at the municipal level. Over time, CFCI has evolved into a global platform involving not only local authorities but also NGOs, the private sector, academia, media, and children themselves, promoting collaborative efforts for more inclusive urban environments (UNICEF, n.d.). Although initially targeted at large urban centres, the initiative has extended its influence to smaller towns, encouraging the integration of children's rights into urban policies. The CFCI defines child-friendly cities as those that support children's rights across various domains—including

play, safety, green space, and access to services—many of which are directly linked to urban design (UNICEF, n.d.). Aligned with the UN Sustainable Development Goals, particularly Goal 11, CFCI promotes urban strategies that prioritize inclusivity, safety, and sustainability. Through the provision of playgrounds, green areas, and safe streets, the initiative contributes to making cities healthier and more accessible for children (UNICEF, n.d.).

Cities that provide safe environments, accessible amenities, and pedestrian-oriented infrastructure significantly reduce children's risk of injury. A child's ability to walk or play safely near home reflects a higher urban safety level and contributes to their physical, emotional, and cognitive well-being. Designing cities with children's needs in mind enhances inclusivity and benefits all residents. While inclusivity remains a major challenge in urban planning, prioritizing child-friendly environments—through safe streets, accessible green spaces, and improved public services—offers a promising approach. Thus, child-oriented design should ensure safe mobility, access to play and learning spaces, school routes, and inclusive public areas.

Child-Centred Street Transformation

With the rise of private vehicle use in the mid-20th century, urban residential design began to prioritize drivers' comfort over pedestrian needs (Krysiak, 2021). According to a report by the Gehl Institute and BvLF (2018), streets should not be limited to corridors of movement but reimagined as active public spaces, particularly for young children who often have limited mobility and rely on streets to access public life. Despite growing awareness of the long-term environmental, economic, and health drawbacks of car-centric planning, its impacts on children's daily experiences have only recently gained attention (Krysiak, 2021). The decline in street play has weakened children's relationship with public space, a contrast to previous generations. Moreover, increased car dependency exacerbates inequalities, as not all children have access to private transport or adult accompaniment, limiting their autonomy in traffic-heavy areas.

The restriction of Children's Independent Mobility (CIM), largely due to the dominance of vehicles on urban streets, not only increases the risk of traffic accidents but also reduces children's visibility in public spaces, heightening parental fears such as "stranger danger" (Freeman & Tranter, 2012). This aligns with Jane Jacobs' concept of "eyes on the street," where fewer people—especially children—lead to less natural surveillance and diminished street vitality. Limited street access prevents children from developing road safety skills and disconnects them from urban life. As a result, children miss out on the joys of walking, exploration, and forming a spatial connection with their neighbourhood, fostering a more isolated and sedentary lifestyle (O'Brien, 2003).

Designing streets with children in mind enhances mobility and inclusivity across age groups. Former Bogotá mayor Enrique Peñalosa emphasizes that the presence of children in public spaces is a key indicator of urban liveability, highlighting the importance of predictable and safe traffic environments (Gill, 2017). Transforming streets to allow safe walking and play opportunities empowers children, reduces parents' need to chauffeur them, and strengthens neighbourhood ties through increased social interactions. Krysiak (2021) urges planners and designers to reconsider why urban streets often prioritize vehicle efficiency over children's well-being. Promoting active mobility through thoughtful design not only benefits children but also supports a more cohesive and playful urban fabric by reinforcing community bonds and creating healthier public spaces.

Freeman and Tranter (2012) demonstrate that increased vehicle use over time has led to a decline in children's independent mobility (CIM), reducing opportunities for risk assessment and developmental growth through everyday routines like street crossing. Their findings also indicate a shift in travel modes, with a significant rise in private car use and a corresponding decline in walking and public transport among children (Freeman & Tranter, 2012, pp. 187–188).

The dominance of motor vehicles on urban streets significantly impacts traffic safety for all residents, especially children. Increased vehicle presence and fears of "stranger danger" have reduced children's independent mobility, a critical issue considering that road crashes are the second leading cause of death among children aged 5–14, emphasizing the need for integrating traffic safety into child-friendly urban design (Welle et al., 2015).

Traffic safety concerns extend beyond children, affecting vulnerable populations such as low-income groups, the elderly, and individuals with disabilities, due to insufficient infrastructure and limited mobility options (Welle et al., 2015). The reduction of pedestrians on streets decreases indirect supervision of children, further limiting their street use and independence. Neighbourhoods are generally defined as areas reachable within a 20-minute walk, a benchmark for liveability and equity in urban design (Gürdoğan, Gürdoğan & Thomsen, 2020). To promote pedestrian-friendly neighbourhoods, streets should be redesigned with a focus on walkability, especially in low-traffic areas, using cost-effective interventions (Gürdoğan et al., 2020). The ITDP's "Pedestrian First" project underscores walkability's benefits for equity, resilience, environment, health, economy, and social cohesion (Url-13). Short distances to facilities, notably schools, are vital for children's mobility; walking rates decline sharply beyond 0.5 km, with car use increasing past 1.6 km (Barker, 2006). Policies such as local speed limits and traffic calming can enhance children's independent mobility (Freeman & Tranter, 2012). The "Pedestrian First" initiative also recommends mixed-use development, improved public transport integration, smaller blocks for pedestrian permeability, and expanded car-free zones to support child-friendly neighbourhoods (Url-13). Child-focused street transformations, including temporary closures and permanent design changes, are emerging policy tools worldwide to promote child-friendly cities. Tactical urbanism, defined as low-cost, scalable, short-term interventions with long-term goals, facilitates such transformations by enabling community involvement and testing design possibilities before permanent implementation (Lydon et al., 2011; Yassin, 2019; Silva, 2016). This approach bridges bottom-up and top-down efforts, enhancing governmental and citizen collaboration for successful urban change (Yassin, 2019). Koçaş and Kısar Koramaz (2024), who examined the child-friendly approaches of different administrations, found that involving children and caregivers in the process is a common practice; however, their strategic approaches vary, and this diversity contributes to more inclusive urban designs.

Temporary street transformations gained increased attention during the COVID-19 pandemic, as reduced vehicle traffic and the heightened need for outdoor play spaces near residential areas encouraged the use of streets as playgrounds for children. Tactical urbanism methods facilitate low-cost, temporary street closures that activate public spaces and reprioritize street use. For example, Bristol's "Play Street" initiative exemplifies how such interventions can be implemented with minimal resources (Playing Out, 2014). The concept of play streets, however, dates back to the early 20th century, pioneered by Joseph Lee and gaining legislative support through the 1938 Street Playgrounds Act in the UK. This act permitted local authorities to temporarily close streets to traffic to provide safe play areas for children. Although popularity declined mid-century due to increased car usage and urban transformation, a resurgence has occurred since 2008, driven by community initiatives and government backing, highlighting the social and health benefits of play streets.

Permanent street transformations include the development of "home zones" or 'Woonerf,' a concept originating in the Netherlands and widely adopted in Europe. These shared streets balance the needs of pedestrians, cyclists, children, and drivers by incorporating traffic-calming measures such as reduced speed limits, signage, speed bumps, and street curvature to slow vehicle movement (Lydon, 2011). Woonerfs eliminate curbs to create multifunctional community spaces, with elements like trees and planters serving as natural barriers to maintain low vehicle speeds. Participatory approaches involving residents and children in design activities, such as the Sustrans DIY Streets project, foster greater community ownership and efficacy (Url-2). Signage marking shared zones helps inform drivers of the pedestrian priority (Url-3). A phased design strategy, or "transformation rehearsal," is another approach for permanent street changes that emphasizes gradual implementation and stakeholder involvement. This method allows residents, local authorities, and NGOs to collaboratively refine designs before major investments, facilitating data-driven decision-making and enhancing community participation (Gürdoğan et al., 2020).

Design guidelines serve as critical frameworks for achieving and evaluating child-friendly street designs, facilitating both the design process and the assessment of implemented spaces. Five distinct design guides, developed for various countries and global contexts, provide diverse perspectives on creating child-centred neighbourhoods and public areas. Among these, three guides were prepared with consultancy from the Bernard van Leer Foundation, which supports governments worldwide in enhancing wellbeing for young children and

their caregivers. Additionally, design guides from organizations such as UN-Habitat, ITDP, and WRI contribute further global and regional insights, enabling a comprehensive comparison of child-friendly urban design approaches.

Methodology

Five different child-friendly urban design guides were reviewed, with parameters from three guides selected for direct inclusion in the methodological framework due to their systematic structure and the clarity and measurability of their criteria. All three were developed under the consultancy of the Bernard van Leer Foundation, providing diverse perspectives across different scales, enabling a multi-scalar comparative evaluation. Although the other two guides were not directly included in the methodology, they contributed conceptually by offering complementary insights. The parameters from the three selected guides were compiled, systematically analysed, and grouped, consolidating overlapping or conceptually similar criteria into singular evaluation parameters, while unique parameters were retained individually. Criteria related to the decision-making process were mainly drawn from the NACTO & GDCI (2019) and the Government of India (2019) guides, as no transformation process criteria were found in the Government of Israel (2023) guide. Ultimately, seven key parameters, shown in Table 1, for the decision-making process in creating child-friendly spaces were identified and used as process evaluation criteria within the research methodology.

Table 1 Compilation of the parameters for the decision-making process from the child-centred design guidelines.

NACTO & GDCI (2019)	India (2019)	Israel (2023)	The Parameters for Evaluation
Prepare an action plan.	-	-	Prepare an action plan.
Collaborate with multiple stakeholders.	Collaborative efforts, alliances for public spaces, and self-directed initiatives	-	Fostering inclusive participation through partnerships and collective action
Involve children and caregivers in the process.	-	-	Involve children and caregivers in the process.
Experiment with various analysis and decision-making methods.	A combination of short-term, hands-on action, and long-term strategies	-	Adaptive planning, balancing experimental approaches
Showcase possibilities.	Quick trial-and-error solutions	-	Encourage experimentation through temporary interventions and showcase potential solutions
Temporarily open streets to children.		-	
-	Oversight and coordination of place	-	Oversight and coordination of place
-	Evaluation of expenses and advantages	-	Evaluation of expenses and advantages

Child-focused design guidelines outline parameters for developing child-friendly neighbourhoods, emphasizing both macro-scale elements such as accessibility and land use that address the needs of children and caregivers, as well as micro-scale details like façade treatments and vehicle restriction measures. Neighbourhood-scale criteria support inter-scale evaluation by integrating broader environmental factors—including the quantity and proximity of green spaces, playgrounds, and schools relative to the transformed street area—thereby facilitating

a comprehensive assessment of child-friendliness beyond isolated street interventions. Parameters from three child-focused design guides were compiled, as shown in Table 2, revealing thematic overlaps such as clustering to reduce travel distances and the presence of nearby child-friendly facilities. These overlapping criteria were consolidated into unified parameters, streamlining the evaluation framework and demonstrating how multiple design guides converge on similar priorities for creating child-friendly urban environments. Also, the parameters are categorized into groups such as land use and accessibility, vehicle and pedestrian traffic and activity analysis enabling organized evaluation of related details.

Table 2 Compilation of neighbourhood scale criteria obtained from three different child-centred design guides.

Three distinct design guidelines centred on children and their caregivers provide detailed parameters for creating child-friendly streets. These parameters, synthesized and simplified in this section, culminate in a consolidated list of 36 criteria essential for child-friendly street design, as shown in Table 3. The 36 detailed parameters from child-focused design guides encompass elements like floor materials, borders, and dimensions. These parameters are categorized into groups such as pedestrian crossings, walk paths, urban furniture, play opportunities, green spaces, and design materials, enabling organized evaluation of related details. The analysis reveals that certain details appear across multiple categories; for instance, obstacles are addressed both in pedestrian crossing parameters and in considerations impacting sidewalk comfort and accessibility for disabled users. Furthermore, the guidelines include precise measurements related to seating elements, emphasizing their spatial relationships with surrounding features such as trees and playgrounds. This comprehensive detailing ensures that design elements are evaluated holistically, accounting for their multifunctional impacts within the urban environment. By integrating overlapping criteria, the consolidated parameter list provides a structured framework for assessing and guiding child-friendly street design across multiple facets.

Table 3 Compilation of design scale criteria obtained from three different child-centred design guides.

NACTO & GDCI (2019)	India (2019)	Israel (2023)	The Parameters for Evaluation
Short crossings at least 1.8 m wide, and ideally 2.4 m wide)	-	-	Short crossings at least 1.8 m wide, and ideally 2.4 m wide)
Frequency of crossings (every 50 to 100 m, no more than 200 m)	Crossings with regular intervals	Street-height crosswalks (every 50-100 m)	Pedestrian crossings every 50 to 100 m
Legible crossings (markings should be at least 3 m wide)	Visible and bright colored crossings	-	Visible, wide and bright crossings
At-grade crossings (a rised to match the sidewalk level)	-	Raised crosswalks	Raised crosswalks
Visibility of crossings (No parking within 6 to 8 m of intersections, stop bars at least 3 m from crossings, and minimize visual obstructions within 3 to 5 m of crossings)	No obstruct on crossings	Accessible crosswalks	No parking within 6 to 8 m of intersections, stop bars at least 3 m from crossings, and minimize visual obstructions within 3 to 5 m of crossings
	Parked cars far away		
-	Visible corners	Expanded street corners	Visible corners
Clear walkpath (at least 1.8–2.4 m wide in residential settings, 2.4–4.5 m wide in downtowns, school zones, or commercial areas)	-	Continuous, accessible and obstruct-free pathways	Continuous, accessible and obstruct-free pathways (at least 1.8–2.4 m wide in residential settings, 2.4–4.5 m wide in downtowns, school zones, or commercial areas)
Pedestrian ramps (maximum slope of 10%, ideally 8%)	Inclination ramps	-	Ideal pedestrian ramps (maximum slope of 10%, ideally 8%)

-	Obstacles between different pavements	-	Obstacles between different pavements
-	Low fences	-	Low fences
-	Boulders with min 1.2 m spacing	-	Boulders with min 1.2 m spacing

The study establishes two main objectives: identifying parameters for assessing the processes and design details of child-friendly street transformations, and defining methods for measuring these parameters. The literature review provides a foundation by examining the concepts of child-friendly cities and streets, incorporating various design guidelines focused on children. Methodologically, evaluation criteria are derived by synthesizing common and unique elements from multiple child-centred design guides, despite differences in scale, to suit the research focus. The evaluation approach encompasses three spatial scales: the decision-making process, neighbourhood context, and detailed design implementation. Process evaluation parameters, developed from three design guides, assess the sustainability of the transformation's child-friendly identity, with data gathered via interviews and document analysis. Neighbourhood-scale evaluation considers environmental factors such as green spaces and facilities to contextualize the transformation within a broader child-friendly setting, utilizing land use and accessibility analyses. Design detail evaluation employs 36 criteria grouped into categories like pedestrian crossings and urban furniture, measured through field observations and spatial analysis. Scoring systems are applied across all scales to quantify success, integrating qualitative and quantitative data to comprehensively evaluate the Zümrütevler child-friendly street transformation. In addition to these quantitative measurements and evaluations, a more comprehensive investigation was conducted by incorporating user observations, which provided critical insights into how the design elements function in practice. On January 13, 2025, user behaviour was monitored for 15 minutes between 14:35 and 14:50, followed by a pedestrian flow analysis conducted from 15:00 to 15:15. This period was intentionally selected to coincide with the time students leave school and return home. Data collection methods for this phase included measurement, pedestrian counting, photography, and detailed field notes, enriching the analysis of the design components with direct user interaction data.

Results

The Pedestrian Safety Transformation Trial (Yaya Güvenliği Dönüşüm Provası) was implemented by Maltepe Municipality in partnership with IMM and Superpool, under the guidance of NACTO-GDCI, as part of the Urban95 initiative led by BvLF (Superpool, 2020). This program encourages urban planners and community leaders to reconsider city environments from the viewpoint of a three-year-old child, approximately 95 centimetres tall (BvLF, 2021). The transformation of a chaotic intersection into Zümrütevler Square, a pedestrian-friendly public space, was documented in the report "Zümrütevler Square (2020)." The pilot area was selected due to limited park and open space availability, and the project prioritized redesigning pedestrian crossings and intersections along children's daily routes to school, emphasizing child-centric and pedestrian-friendly design (Superpool, 2020).

Figure 1 Child-friendly street transformation processes in Zümrütevler Neighbourhood: pre-project, rehearsal phase, post-permanent implementation (Superpool, 2022).

The project unfolded in two stages: an interim phase involving temporary measures such as asphalt painting and movable street furniture to allow assessment before permanent interventions, and a final phase with lasting modifications completed in August 2020. The interim implementation began on October 18, 2019, and lasted approximately six months. Differences were observed between pedestrian crossing layouts in the interim and permanent phases, with the total number of crossings reduced from eight to four in the final design (Superpool, 2020).

Figure 2 Comparison of pedestrian crossings after rehearsal and permanent implementation (Superpool, 2020).

Post-transformation data indicated that 1,075 m² of vehicle lanes were converted into pedestrian paths, with 550 m² becoming public spaces. The area gained green spaces and transitioned from a traffic junction to a fully accessible square. Usage increased significantly: the number of people in the square rose by 72%, babies and young children increased by 3.5 times, children aged 5-12 doubled, and the elderly population grew tenfold. Pedestrian crossings increased by 21%, sidewalk use by 30%, and children's independent mobility improved by 43%, with 89% of this occurring in safe zones (Superpool, 2020).

According to the data obtained from open sources and interviews with project coordinators that include detailed explanations of the project process, the transformation process was evaluated according to the parameters determined in the research methodology section. With the two-phased design approach implemented in the Zümrütevler neighbourhood, the street transformation application was one of the actions of a higher scale decision. The decision to transform this area was taken in line with the need and it became the first square of the neighbourhood. When the whole process, including the rehearsal process and the current situation, is considered, the data obtained from open sources and the interviews with the institutions show that other parameters were provided for the transformation process.

A cross-scale evaluation of the neighbourhood surrounding the child-friendly street transformation in Zümrütevler was conducted to assess land use, accessibility, traffic calming measures, and street activity. The land use and accessibility analysis revealed that although the case study area is within walking distance to certain child-related facilities such as open spaces and nurseries, large portions of the neighbourhood lack adequate pedestrian access to kindergartens, health facilities, and open spaces within recommended distances. Primary schools have better coverage due to wider accessibility ranges, but overall, the neighbourhood fails to meet accessibility criteria and does not include local mobility parks or similar child-oriented spaces, resulting in a zero score in the accessibility evaluation.

Traffic calming measures were found to be limited primarily to the immediate vicinity of Zümrütevler Square, with speed limits mostly adhering to the general 50 km/h standard elsewhere. Pavement treatments aimed at increasing driver awareness are scarce, and no additional pedestrian-priority or low-emission zones exist within a 250-meter radius. These findings indicate that traffic interventions are insufficient to support a child-friendly environment beyond the square itself. Conversely, the analysis of street activity indicated a predominance of active frontages supported by mixed-use land and pedestrian presence, fulfilling vitality criteria. Although some residential streets with high garden walls reduce child-friendliness, this issue is limited in extent. Overall, vitality parameters are satisfied. However, when combined, the evaluations demonstrate that the neighbourhood largely fails to meet the comprehensive criteria for a child-friendly environment, with deficiencies in accessibility and traffic calming measures being the main limitations.

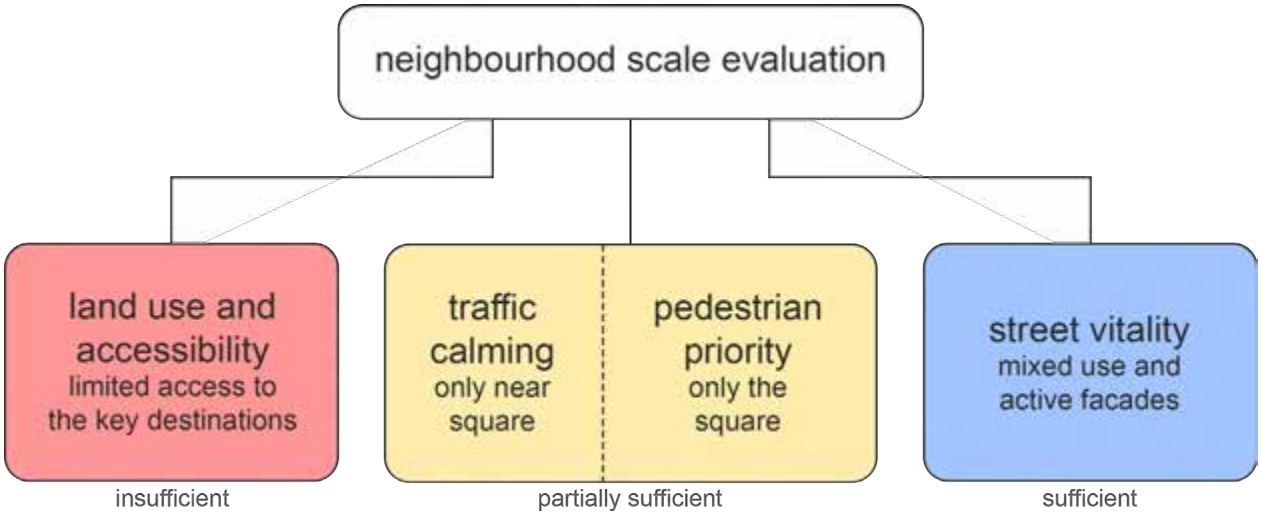

Figure 3 Diagram showing the outcomes of the neighborhood-scale evaluation

The detailed assessment of design elements in the Zümrütevler Square transformation area reveals variable adherence to established child-friendly design standards. Pedestrian crossings comply with minimum width requirements and are adequately spaced within the transformed zone. However, their diminished visibility due to fading and limited presence beyond this immediate area negatively impact pedestrian safety and accessibility. Field observations demonstrate a preference among pedestrians for crossing at informal locations rather than designated crosswalks, exposing a disconnect between intended design and actual user behaviour.

Sidewalks generally offer sufficient width and are mostly unobstructed, with ramp slopes aligning with accessibility norms. Nonetheless, the presence of bollards on ramps hinders ease of use for disabled individuals, marginally reducing overall sidewalk effectiveness. Urban furniture, though limited in quantity, serves its purpose by fostering social interaction through strategically arranged seating. Play opportunities, integrated alongside seating areas and including artistic features, meet all relevant design criteria; however, child usage of these spaces was notably scarce, potentially attributable to parked vehicles affecting perceptions of safety and spatial quality. Green elements demonstrate diversity in plant species and buffer zones. Regarding design materials, bollard placement conforms to standards, yet surface treatments lack child-friendly qualities and do not provide sufficient textural differentiation, fulfilling only half of the evaluated material parameters.

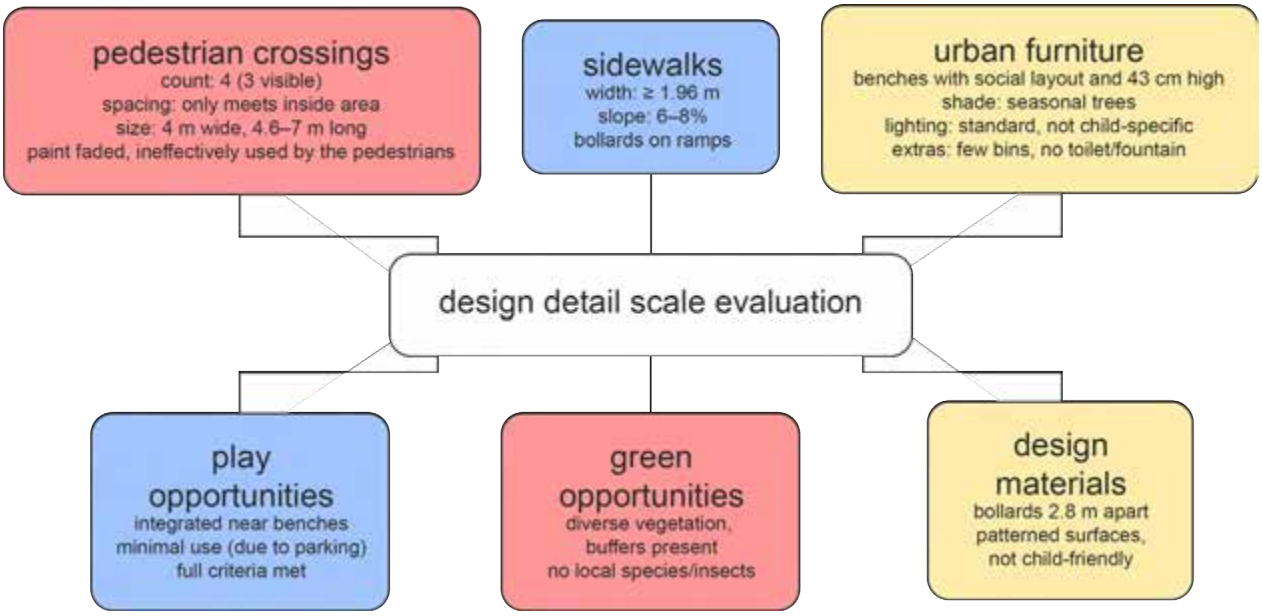

Figure 4 Diagram showing the outcomes of the design detail evaluation

Overall, while the transformation reflects commitment to several child-friendly design principles, significant shortcomings remain in accessibility, material selection, and user-centric functionality. The adequacy of applying all child-friendly parameters universally within the area merits reconsideration, especially considering user behaviour patterns. Although foundational progress toward a child-friendly environment is evident, further enhancements are necessary to fully support independent and safe mobility for children.

In addition to the design criteria evaluations, the interaction between design elements and actual users was examined through field observations. User movement patterns and preferred directions within the area were recorded, with results illustrated in Figure 5, showing frequently used pedestrian routes during the observation period. The majority of users passing through the space were caregivers accompanied by children and individuals returning from shopping. The timing of the observation supports the conclusion that children and their caregivers primarily use the area as a transit route.

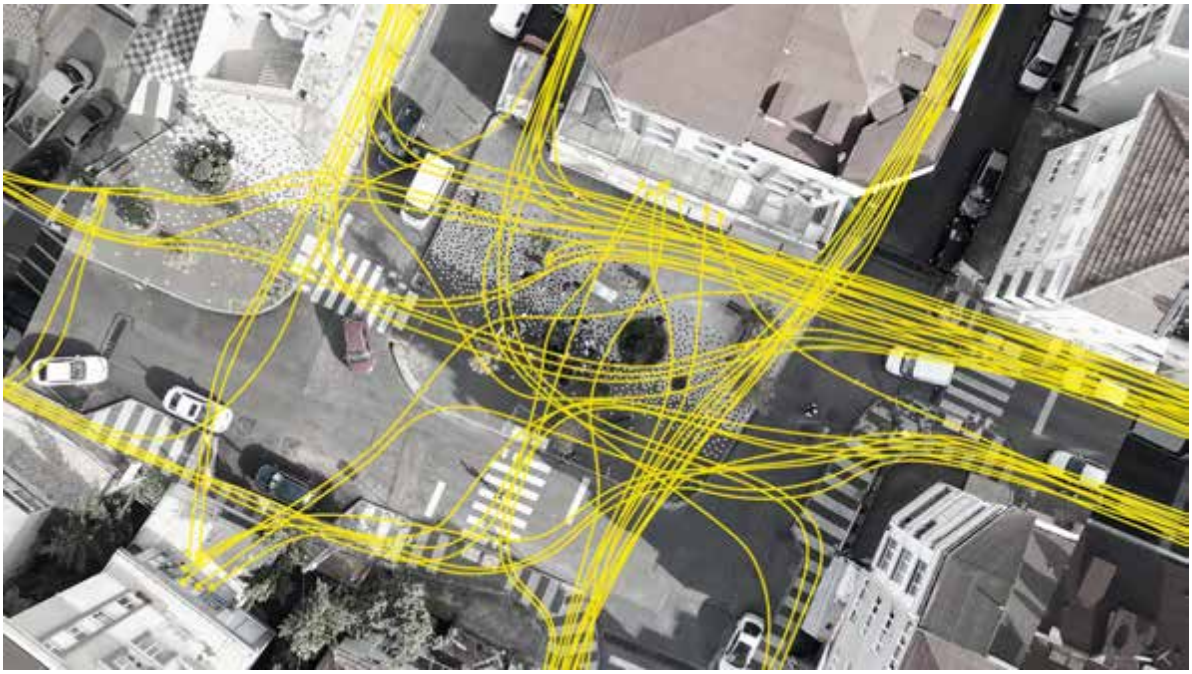

Figure 5 User flow map

Although Figure 5 suggests broad usage of the square, the presence of parked vehicles significantly obstructs pedestrian circulation and undermines the space's child-friendly qualities. As depicted in Figure 6, pedestrians must navigate around parked cars when crossing streets to access the square, reducing comfort and safety.

Figure 6 Users cannot use the area comfortably due to the parked cars

Further photographic evidence gathered outside observation periods indicated that some pedestrians, including those with children, chose to walk along vehicular roads instead of using the open square, as shown in Figure 7. Improper pedestrian crossing behaviours were also documented, highlighting non-compliance with intended pedestrian pathways.

Figure 7 Pedestrians not using the pedestrian crossings

A behavioural map (Figure 8) representing sitting and standing activities during the observation period shows standing users predominantly engaged in socializing near seating elements. These social interactions were primarily carried out by older male individuals, as documented in Figure 9. Notably, these frequent users were not caregivers accompanying children, the primary target group of the child-friendly design.

Figure 8 User behaviour map

Figure 9 Elderly people using the area for rest and chatting

Evaluation of the transformed area from the perspective of children and caregivers revealed that the space functioned almost exclusively as a passageway, as confirmed by measurements and photographic records (Figure 10).

Figure 10 Photographing the use of a passageway by children and caregivers

The combined findings from behavioural observation and pedestrian flow analysis reveal a significant gap between the intended child-friendly design objectives and actual usage patterns. Despite being designed to facilitate stationary, interactive activities for children and caregivers, the space predominantly serves as a transit corridor. Persistent vehicle presence and pedestrian pathway misuse further detract from the space's functionality as a child-friendly public environment. These results indicate a need for additional design interventions to better support and encourage the intended user groups.

Discussion

The child-friendly street transformation in Zümrütevler Neighbourhood was critically examined through a multi-scale lens encompassing the process, neighbourhood context, and detailed design elements, following the evaluation framework outlined in the methodology. The analysis reveals that while the project demonstrated sensitivity to local context and engaged stakeholders actively at the project level, it failed to establish meaningful connections with broader neighbourhood infrastructure and urban policy agendas.

At the process scale, the initiative employed a phased, inclusive, and flexible design strategy that leveraged data insights and fostered collaboration among institutions. Although there was no overarching higher-level planning directive guiding the intervention, the project successfully coordinated diverse stakeholders and ensured the participation of children and caregivers in shaping the outcome. The iterative rehearsal phase was particularly influential, facilitating design adjustments and enhancing community buy-in—highlighting the practical benefits of tactical urbanism approaches in child-focused urban interventions.

In contrast, the neighbourhood-level evaluation exposes significant gaps. Accessibility assessments indicate that most residential areas remain beyond a reasonable walking distance to key child-oriented facilities, while traffic calming measures are confined to the immediate project boundaries. Nonetheless, the presence of relatively active street frontages offers some support for children's independent movement. This juxtaposition reflects a critical disconnect between targeted site-specific improvements and the absence of integrated, systemic planning at the neighbourhood scale.

Regarding design details, the spatial elements only partially meet child-friendly urban design benchmarks.

Although infrastructural components such as sidewalks, ramps, crossings, and urban furniture generally adhere to established technical criteria, observed user behaviour reveals a misalignment between intended design purposes and actual use patterns. The space predominantly functions as a thoroughfare for children and caregivers rather than a place for gathering or play, with frequent informal crossing indicating concerns related to safety and usability. Moreover, the pervasive presence of vehicles and scarcity of playful amenities further restrict children's autonomous engagement. These observations emphasize that adherence to technical standards alone is inadequate; successful child-friendly environments require design approaches that respond meaningfully to lived experience. Ultimately, the findings suggest that enhancing spatial quality must be complemented by coordinated, cross-scale strategies that harmonize physical interventions with everyday behaviours to truly realize child-friendly urban spaces.

Conclusion

The concept of child-friendly cities encompasses multifaceted dimensions and requires comprehensive approaches to effectively promote children's independent mobility and well-being in urban environments. Local governments increasingly pursue child-friendly street transformation projects, underpinned by the prevailing conviction that creating safe, accessible, and health-promoting urban spaces for children contributes to the formation of healthier societies. However, the complexity of sustaining the child-friendly identity beyond initial design stages remains a significant challenge, necessitating critical examination of relevant parameters and practical obstacles throughout the transformation process.

This study contributes to this discourse by conducting a rigorous, multi-scale evaluation of the child-friendly street transformation in Zümrütevler Square, selected as a case study. The research framework incorporated assessment at three interconnected scales: the process level, the neighbourhood context, and the detailed design components. This layered analytical approach not only advances the understanding of child-friendly urban interventions but also foregrounds the necessity of examining interactions across scales to reveal systemic strengths and weaknesses. The development of an original, criteria-based evaluation tool derived from existing design guidelines enabled a nuanced analysis of spatial and procedural aspects of the transformation, while direct incorporation of user behaviour observations ensured that the evaluation extended beyond normative design standards to include lived experience.

A key finding relates to the applicability and relevance of child-friendly design parameters across all scales and contexts. While many criteria are well-established within the literature and provide essential benchmarks, the Zümrütevler case exposes critical tensions regarding their universal applicability. Several parameters, though theoretically sound, proved difficult to implement or maintain consistently throughout the transformation phases, raising important questions about their flexibility and contextual suitability. This insight suggests that future frameworks should incorporate adaptive, context-sensitive criteria that account for diverse urban realities and evolving user behaviours, rather than relying solely on rigid, one-size-fits-all standards.

Regarding the visibility and presence of children within the transformed space, observations revealed a notable deficiency. Despite the project's explicit child-focused intentions, actual child presence and engagement in the area remained limited. The square was predominantly used as a transitional passage by children and caregivers rather than as an interactive, playful environment. This gap between design intention and on-the-ground reality signals a need to critically reconsider not only physical design elements but also socio-environmental factors that influence children's visibility and autonomy in public spaces. Issues such as vehicular dominance, perceived safety concerns, and spatial constraints emerged as significant deterrents to sustained child use, underscoring that child-friendliness must encompass both physical and behavioural dimensions to be truly effective.

The process evaluation further highlighted institutional and procedural complexities that influence project outcomes. The involvement of multiple authorities with overlapping jurisdiction over the site created challenges in coordination, leading to compromises in design cohesion and implementation consistency. This institutional fragmentation underscores the importance of establishing clear governance frameworks and collaborative

mechanisms to streamline decision-making and maintain the integrity of child-friendly objectives. Moreover, the phased approach, which included a rehearsal stage applying tactical urbanism principles, was instrumental in refining the design and fostering public acceptance. However, the research identified a missed opportunity in not conducting a second rehearsal phase, which could have allowed for iterative testing and incorporation of feedback based on revised design alternatives. Evaluating rehearsal phases explicitly within the criteria framework emerges as a critical area for future research and practice, as it holds potential to significantly enhance the adaptability and success of child-friendly transformations.

In sum, this study affirms that multi-scale, integrated evaluations are essential for a holistic understanding of child-friendly urban interventions. Evaluations that combine technical design criteria with empirical user behaviour analysis provide richer insights and more actionable knowledge than those relying solely on normative standards. Furthermore, the findings underscore the necessity to critically assess the feasibility and relevance of design parameters in varied contexts and to maintain child visibility and engagement as central goals. The role of institutional coordination and iterative, participatory design processes—particularly the rehearsal phases—must be emphasized in both research and practice to support sustainable child-friendly environments.

Finally, the transformation of Zümrütevler Square, as one of Turkey's pioneering projects integrating tactical urbanism with permanent implementation in a dense metropolitan context, offers valuable lessons for urban policy and design. It highlights that successful child-friendly street transformations require long-term commitment, cross-sectoral collaboration, and a continuous feedback loop that integrates design adaptation with lived realities. Future studies should expand on the rehearsal phase's role and explore adaptive criteria frameworks to enhance applicability across contexts. Such comprehensive approaches are imperative to advancing child-friendly urbanism and fostering inclusive, healthy cities for all generations.

Abstract
Creating vibrant urban spaces is key for urban renewal. Emotional attachment is also a vital feature of urban vitality. This study quantifies the emotional attachment between people and the built environment as an evaluation index of the dynamic space of small-scale cities. Based on the theory of emotional attachment, an index system was constructed and applied to the five dynamic urban renewal complexes in Beijing and Shanghai. SPSS was used for data analysis, and an improved TOPSIS model combining entropy weight and grey relational analysis for evaluation. Results show the built environment can enhance urban vitality through emotional attachment. Material characteristics deepen emotional experiences, while non - material ones dynamically influence vitality. The study expands the quantitative framework for urban vitality research and offers methodological references for urban space renewal and design.

Keywords: emotional attachment; urban vitality evaluation; EW-GRA-TOPSIS evaluation model

1. Introduction

1.1. Research Background

Urban renewal, as a long-term strategic planning for China's urban development and construction, has gradually become an important topic of study and concern for scholars in recent years (Cheshmehzangi et al., 2023). Specifically, China's urbanization has entered the stage of upgrading existing resources, responding to the development goals of achieving high-quality human life and the development connotation (Pan and Du, 2021), and creating urban vitality spaces is crucial for urban renewal research and practice (Kang, Fan and Jiao, 2021; Guo et al., 2022). By constructing refined urban complexes to renovate the existing architectural environment, it has become an effective way to create these spaces (Wei and Wang, 2024b). Currently, there are many successful cases of transforming old buildings and industrial areas into representative urban vitality complexes in first-tier cities such as Beijing, Shanghai, and in new first-tier cities such as Chengdu, Nanjing, and Chongqing (Zhuang et al., 2019; Du, Du and Wang, 2022). For example, there are the Longfusi Street and Langyuan Station in Beijing, and EKA Art District in Shanghai. In addition, the guiding strategy of "reducing quantity and improving quality" in urban renewal in the 2021-2025 national spatial planning policy of Beijing indicates that small-scale, gradual and decentralized spaces are indispensable components of urban vitality research and design, and further research and development in this regard are needed. At the same time, in the digital era, people's requirements for urban architectural environments have already evolved from basic functional needs to advanced emotional attachments (J, 2022; Zhang, 2023), and the realization of urban vitality also requires considering the emotional interaction between people and the architectural environment (Cao, Deng and Song, 2023; He et al., 2023).

Therefore, it is necessary to establish a small-scale urban vitality space research and evaluation method represented by urban renewal complexes. The theory of emotional attachment provides a theoretical basis for studying the characteristics of emotional attachment between people and the architectural environment and constructing measurement indicators, and the multi-criteria decision-making (MCDM) method represented by TOPSIS provides tools for scientific evaluation of emotional attachment levels. Combining the theoretical basis and method tools can construct an emotional vitality evaluation method for urban renewal complexes. This study selects five representative urban renewal complexes in China's first-tier cities as examples to verify the effectiveness of the above urban vitality emotional attachment evaluation method, including the Longfusi Street and Langyuan Station in Beijing, EKA Art District in Shanghai, Columbia Circle and Raffles City Changning in Shanghai. First, based on the theory of emotional attachment, a scale is constructed to measure the emotional

attachment characteristics of specific built environment characteristics and is used to measure the dimensions and degrees of specific architectural environment space characteristics of the five complexes. Then, based on the constructed attachment evaluation index system, the scale data is processed using SPSS software, and the improved TOPSIS (technique for order preference by similarity to an ideal solution) method, combined with EW (entropy weight) and GRA (grey relationship analysis), ranks the urban vitality levels of the five complexes from the perspective of emotional attachment. Finally, the evaluation results are combined with the correlation analysis results of the scale data to further explore the commonalities and differences in spatial characteristics that promote emotional attachment in the five complexes and obtain method guidance for urban vitality complex renewal design.

1.2. Literature Review

The concept of emotional attachment has been proposed and extensively discussed by scholars across multiple disciplines, including psychology, human geography, architecture, and urban planning. This body of research primarily investigates the interconnections among emotions, cognition, behavior, and spatial entities. Among these discussions, place attachment theory serves as a theoretical framework that systematically examines various influencing factors and constructs an index system to measure different individuals' emotional attachments to specific architectural environments (Ekkekakis, 2013). In the process of developing multidimensional emotional attachment measurement scales, researchers in psychology and human geography have systematically explored the principles and internal mechanisms underlying emotional attachment, emphasizing distinct indicators that enhance such attachment (Manzo et al., 2020; Lewicka, 2011). It is precisely through this multidimensional index system construction that the integration of perspectives from multiple disciplines is highlighted, addressing the current lack of an emotional dimension in urban vitality research and providing a quantitative methodology for assessing emotional attachment between individuals and small-scale architectural environments. In recent years, designers and researchers with multidisciplinary backgrounds have developed a series of emotional attachment scales to evaluate the attachment between people and specific architectural environments, applying these scales to studies on buildings and urban public spaces both domestically and internationally (Zhang & Zhuang, 2017; Birnbaum et al., 2021). These scales encompass physical characteristics of the architectural environment, such as material, form and structure, and color, as well as social and cultural attributes, including sociability, territoriality, and uniqueness. In the digital era, research has further expanded to investigate the interactivity and variability of architectural environments (Zhang et al., 2022). A range of research findings have demonstrated the reliability and validity of these scales, thereby partially addressing the deficiency of quantitative methods for measuring emotional attachment in architectural environment research and offering a methodological framework for assessing emotional attachment in small-scale built environments.

One of the critical factors influencing urban vitality is the comprehensive understanding of the term "vitality," which should be considered in conjunction with emotional attachment. As a prominent theorist and activist in urban studies, Jane Jacobs, an advocate for "urban vitality," defined it as the capacity of a space to attract and accommodate diverse human activities (Dogan and Lee, 2024). She posited that vibrant urban spaces are characterized by physical environments that foster positive emotions among individuals. Maas described urban vitality as the quality of space encompassing people, activities, and the physical environment where these activities occur (Jacobs, 1961). Following extensive scholarly exploration of urban vitality from various perspectives and spatial scales, it has consistently been linked to the built environment and the interactions between users, people, space, and the utilization of spatial places (Mouratidis and Poortinga, 2020; Pan, Zhu, and Zhang, 2023). Consequently, urban complexes have emerged as effective subjects for studying urban vitality. In the digital era, achieving urban vitality necessitates heightened attention to the growing emotional needs of individuals (Zhang and Zhuang, 2017). The development of urban vitality spaces stems from multi-dimensional interactions between people and the built environment, with satisfying people's emotional demands for space constituting one of its core connotations. With advancements in data mining and analysis technologies, research on urban vitality primarily focuses on impact indicators and the construction of corresponding measurement frameworks, along with associated data metrics. Recently, scholars in urban and architectural studies have engaged in in-depth investigations of urban vitality from multiple angles, utilizing geographic big data and urban population

data to explore its manifestations in street networks and population mobility across large-scale spaces (Lan et al., 2020; Fang, He, and Wang, 2021). These studies emphasize broader spatial scopes, and the indicators used in evaluation systems tend to be geographical, social, and economic in nature. Some researchers focus on more human-centric indicators, such as POI data, mobile signal data, road street view images, or audio-related factors, to examine the level of urban space vitality at specific spatial scales (Wu and Niu, 2019; Gomez-Varo et al., 2024; Wei and Wang, 2024a; Duan et al., 2025). Others concentrate on specific functional spaces as indicators of urban vitality and their role in driving positive urban development (Chen et al., 2022). Researchers are gradually shifting their focus toward user-oriented spaces, emphasizing real interaction experiences and emotional connections within urban environments under the current trend of urban vitality research. In conclusion, the study of urban vitality should prioritize the characteristics of small-scale architectural environments while addressing the emotional attachment perspective in urban vitality research.

In order to further evaluate the vitality characteristics and levels of different urban spaces, this study selected the TOPSIS method and its modified version, so as to measure and comprehensively evaluate the urban vitality level based on the requirements of this study. The method adopted in this research belongs to a multi-criteria decision-making method system (MCDM), making the process of evaluating the vitality of urban spaces more scientific, transparent, and participatory (Krohling and de Souza, 2012). The TOPSIS (technique for order preference by similarity to an ideal solution) method was developed by Hwang and Yoon in 1981 and is used to create positive and negative ideal solutions, and then compare the differences between alternative solutions and ideal solutions (Hwang and Yoon, 1981). Since the TOPSIS method can fully utilize the information in the original data and is more understandable and accurate in revealing the detailed advantages and disadvantages of each specific feature, it has been applied in the assessment of urban spaces in multiple dimensions and scales, especially in evaluating various complex urban spaces closely related to user behaviour. For example, the TOPSIS method is widely used in macroscopic urban vitality studies, coupling geographic big data with indicators closely related to human activities to quantify and measure the comprehensive urban vitality index (Zhang, Yang and Wang, 2021). The TOPSIS method is also applied in the research of urban resilience and urban sustainability, by constructing an evaluation system covering multiple dimensions such as economy, transportation, and ecological environment, to comprehensively measure the urban characteristics and their degrees within the regional scope (Xun and Yuan, 2020; Zhao, Ma and Lin, 2022). EW (entropy weight method) and GRA (gray correlation method) are always combined as part of this method to assign weights to indicators and improve the accuracy of the evaluation process (Zhang et al., 2018; Rao and Gao, 2022; (Hu et al., 2022). Besides the above macro-level evaluations of the city, the improved TOPSIS method is also used to evaluate and study the design methods of small-scale built environments, such as landscape performance and the relative performance of community renewal projects (Zhu et al., 2019; Shen et al., 2022). However, in the research on urban vitality, few studies have applied TOPSIS and its improved methods to evaluate the impact of specific architectural environment characteristics on users' emotional experiences. Emotional experience, as one of the indispensable components of urban vitality, this study focuses on people's emotional experiences in the exploration of urban vitality spaces.

1.3. The Main Goal of the Paper

In the context of existing space renewal, the design and research of dynamic spaces need to focus on people's current real needs. Moreover, in the current digital era, people's emotional demands for space have gradually become the key to constructing dynamic spaces, and meeting people's emotional demands for space has become a major goal of creating dynamic spaces. Based on this, this study, at the methodological level, improved the traditional TOPSIS method to an EW-GRA-TOPSIS evaluation method applicable to the small-scale built environment characteristics that the study focuses on, and focused on people's place attachment to small-scale built environment characteristics in urban dynamic spaces. Based on this goal, an index system for evaluating the emotional attachment between people and urban dynamic spaces was constructed. In the theoretical aspect, this study supplements the discussion on the emotional attachment between people and small-scale architectural environment characteristics in urban dynamic research. In the practical aspect, taking five representative urban renewal dynamic complexes in first-tier cities in China as examples, the evaluation index system and EW-GRA-TOPSIS evaluation method constructed in this study were applied to prove their scientific

validity. Based on the above, this study has three corresponding innovation points. The improved TOPSIS method using entropy weight method and combined with grey correlation method increases the scientific validity of the quantitative evaluation method, enabling the methodology to be innovated. Attention is paid to the emotional attachment of small-scale built environment characteristics as an important component of urban dynamic, and in the theoretical aspect, this study supplements the perspective of emotional attachment in urban dynamic research. In addition, the method and theory are applied to the complex assessment of the interaction between people and architectural environment, focusing on how small-scale architectural environment characteristics promote people's emotional attachment to urban dynamic spaces.

2. Materials and Methods

2.1. Study Areas

This study selected five representative and distinctive urban vitality complexes in China's first-tier cities that have been successfully renovated and put into use in recent years. These five research objects are all located in Beijing and Shanghai, namely the Longfusi Street, Langyuan Station in Beijing, EKA Art District, Columbia Circle, and Raffles City Changning in Shanghai. All five complexes were renovated based on the original buildings. Among them, the original built environment of Beijing's Longfusi Street, Shanghai's Columbia Circle, and Raffles City Changning belong to historical districts, while Beijing's Langyuan Station and Shanghai's EKA Art District were transformed from old industrial areas and buildings. Through a series of meticulous architectural and environmental renovations, these five vibrant complexes have presented unique charm in terms of architectural details and space creation. Currently, these five vitality complexes are important urban public spaces that attract people to experience in the city. The carefully crafted various built environments and small-scale architectural environment details play an important role in the emotional interaction with users. More attractive vitality spaces provide various emotional experiences, allowing people to gain more emotional interactions in the real space. It is precisely due to these characteristics that these five complexes become the research objects of this study. The basic conditions and architectural environment characteristics of each complex are as follows.

Table 1. Overview of the basic conditions and characteristics of the five urban renewal complexes.

City	City Level	Name of Complex	Renovation Period	Characteristics of the Original Built Environment	Characteristics of the Redeveloped Built Environment
Beijing	First tier	Longfusi Street	2012-2019	Longfusi Street is an old commercial area with a long history of business and many years of operation, surrounded by hutong residential areas.	Create a cultural architectural complex and a youthful urban dynamic space with complete business facilities, which echoes the historical traditions of the original commercial space.
Beijing	First tier	Langyuan Station	2017-2022	The old warehouse area of the Beijing Textile Factory features a strong industrial architectural complex and a distinct industrial street pattern. The surrounding natural environment is good.	A dynamic complex integrating commercial, office and supporting facilities, with a distinct industrial style. The materials, forms and structures echo the original industrial style.
Shanghai	First tier	EKA Art District	2021-2023	Formerly known as Shanghai Navigation Instrument General Factory, the old factory buildings and industrial area have been well preserved, and the elements of the navigation industry have also been well maintained.	EKA Art District retains the original road network and layout structure of the factory area, transforming it into an international community that integrates experiences, social interaction, consumption and office functions. It also retains many maritime and marine elements.
Shanghai	First tier	Columbia Circle	2016-2024	Located at the junction of the three historical and cultural preservation areas of Hengfu Road, Yuyuan Road and Xinhua Road, it contains many historical buildings and retains the cultural atmosphere.	This urban lifestyle collection includes 3 historical buildings and 11 industrial renovation buildings. The diverse buildings collectively form a unified cultural space.
Shanghai	First tier	Raffles City Changning	2012-2017	Raffles City Changning was formerly the site of Shanghai Saint Mary's Girls' School. Located in the Zhongshan Park business district, the building complex occupies the main space.	With its unique charm that combines historical cultural connotations with the trendy and fashionable atmosphere, the historical buildings of "Four Towers and One Building" complement the modern commercial buildings.

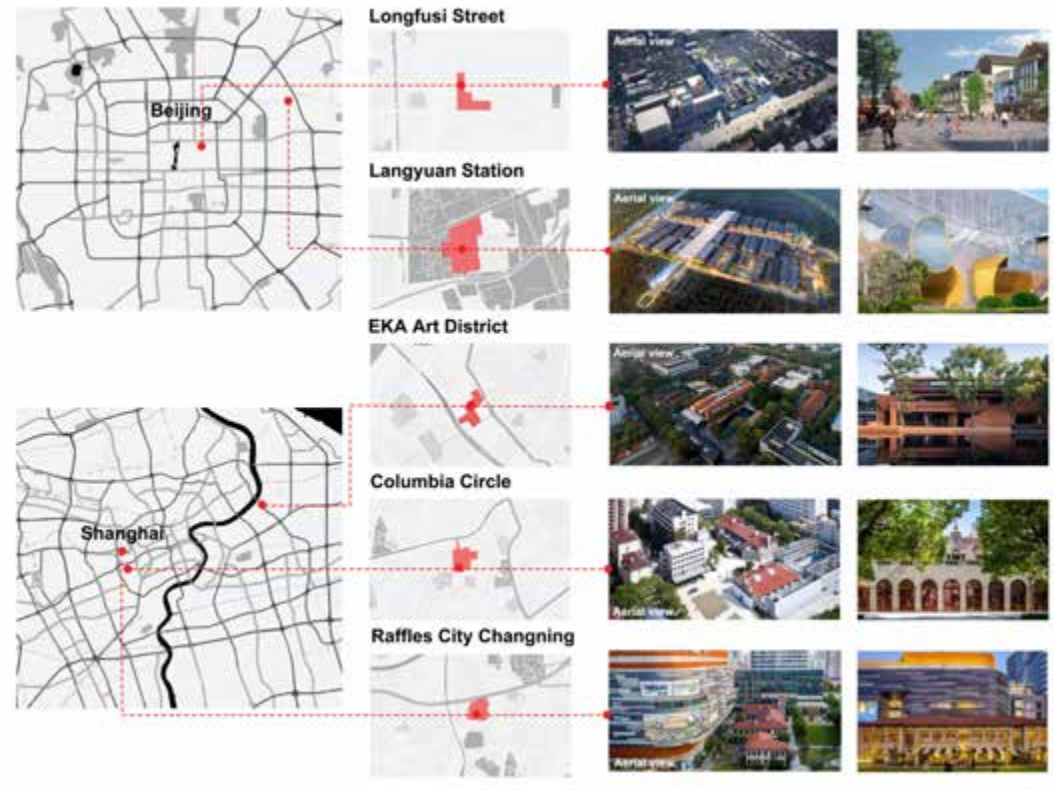

Figure 1. Location and features of the five urban renewal complexes

2.2. Data Sources

In line with the research requirements, the research team selected and developed a scale of emotional attachment in accordance with emotional attachment theories. Through the use of this scale, an assessment of the dimension, degree, and intensity of emotional attachment between individuals and the built environment across the five aforementioned complexes was carried out by the team from July to October 2024. The team members successively conducted on-site research at various research sites in Shanghai and Beijing, ensuring that each team member had a certain level of familiarity with each commercial complex. To ensure the reliability of the data, young people aged 18-35 were randomly selected from the five complexes to participate in the filling of the research scale on-site. Finally, the number of valid scales collected in the five complexes were as follows: 130 in Longfusi Street, 129 in Langyuan Station, 130 in Columbia Circle, 130 in Raffles City Changning, and 130 in EKA Art District.

2.3. Build a Methodology

2.3.1. The Construction of Emotional Attachment Scale and Indicators of Evaluation Index

In order to explore the dimensions, degrees of emotional attachment of people to five urban renewal complexes, as well as the intensity of their attachment to specific built environment characteristic, this study combined the place attachment scale, PANAS scale, and a newly-constructed and tested scale of attachment intensity for specific built environment characteristics to conduct research on the emotional attachment of these five urban renewal complexes. The reliability and validity of this scale have been confirmed by a series of architectural environment researches at home and abroad. Therefore, the indicators in the above scales can also be used as evaluation indicators for the emotional attachment characteristics of the urban renewal complexes to assess them.

In order to explore different emotional attachment characteristics from different perspectives and research needs, multidisciplinary researchers have constructed a series of scales. Among them, Scannell and Gifford, based on previous research, proposed the organizational framework of person-process-place (PPP) to explain the attachment mechanism and constructed the related place attachment scale (Scannell and Gifford, 2010). The PPP PA scale emphasizes the importance of the built environment in the attachment process and is consistent with our research purpose both in content and practicality. Therefore, it was adjusted in the study and used as part of the scale to measure the degree of attachment. In addition, the positive and negative analysis scale (PANAS) was used in the study to explore people's attachment to the five urban renewal complexes. The last part of the scale aims to explore the influence of built environment features and also serves as an indicator in the evaluation process. Based on the characteristics of the five urban renewal complexes and the demands of this study, the evaluation indicators include: material, colour, natural elements, form and structure, privacy, diversity, sociability, territoriality, playability, uniqueness, and changeability. The analysis of scale intensity uses the Likert scale to quantitatively measure the intensity, with a score of 1 indicating almost no emotional attachment to the indicator and a score of 7 indicating a strong emotional attachment. The analysis process uses SPSSPRO and SPSSAU to process the data collected from these scales, including the comprehensive degree and attachment intensity represented by the basic indicators. In addition, SPSS was used for correlation analysis (Spearman) to explore the correlations between attachment, positive and negative emotions, and specific built environment features. The results of each indicator are used in the subsequent evaluation process to rank the five complexes and are analysed and interpreted based on the subsequent correlation analysis results.

2.3.2. The Evaluation Method of Improved TOPSIS Combining Entropy Weight and Grey Relational Analysis

The degree and intensity of people's emotional attachment to the dynamic spaces of a specific city depend on the established scales and evaluation indicators. Although the reliability and validity of the aforementioned scales have been confirmed by relevant research and have mature application experience (Zhang et al., 2022; Zhang et al., 2022), due to certain objective reasons such as the subjectivity of researchers and experimenters and the differences in scale data, the reliability and validity of the aforementioned scales may still be affected, to some extent, affecting the accuracy of the evaluation of people's emotional attachment to the dynamic spaces of the city. To avoid this uncertainty in the evaluation system and its resulting impact, this study uses the entropy

weight (EW) method to assign weights to the aforementioned indicators based on their scores and combines the single evaluation method TOPSIS and the grey relation analysis (GRA) to improve the original single evaluation method (Zu et al., 2021), hoping to enhance the objectivity of the evaluation of the attachment to the urban renewal complex in this study.

1. Entropy Weight Method: Determining the Weight of Indicators
When determining the weights of evaluation indicators, the entropy weight method is adopted instead of the Delphi method or the Analytic Hierarchy Process (AHP) to help improve the subjectivity of the traditional TOPSIS method, making it more objective when simultaneously evaluating interrelated objects. The improvement of this method has been successfully applied by many researchers in urban space evaluation and related studies, avoiding certain degrees of subjective bias in the research. This study needs to assess the emotional attachment of multiple urban vitality complexes in Beijing and Shanghai. The weights of each evaluation indicator are determined through the entropy weight method (EW). The main steps are as follows:

There are mmurban vitality complexes to be evaluated and nn built environmentrelated evaluation indicators for each urban complex in this study, and the nn -th analysis indicator of the mm evaluation objects is marked as $c_{ij}c_{ij}$ (1≤ii≤mm , 1≤jj≤nn), and the judgment matrix $C = (c_{ij})_{m\times n} C = (c_{ij})_{m\times n}$ is expressed as:

$$C = \begin{pmatrix} c_{11} & \cdots & c_{1n} \\ \vdots & \ddots & \vdots \\ c_{m1} & \cdots & c_{mn} \end{pmatrix} C = \begin{pmatrix} c_{11} & \cdots & c_{1n} \\ \vdots & \ddots & \vdots \\ c_{m1} & \cdots & c_{mn} \end{pmatrix} \quad (1)$$

where $c_{ij}c_{ij}$, 1≤ii≤mm , 1≤jj≤nn, mm = 5, nn = 14
The judgment matrix $C = (c_{ij})_{m\times n} C = (c_{ij})_{m\times n}$ is standardized according to the 0-1 transformation, and the standardized matrix $C' = (c'_{ij})_{m\times n} C' = (c'_{ij})_{m\times n}$.

$$C' = \begin{pmatrix} c'_{11} & \cdots & c'_{1n} \\ \vdots & \ddots & \vdots \\ c'_{m1} & \cdots & c'_{mn} \end{pmatrix} \quad C' = \begin{pmatrix} c'_{11} & \cdots & c'_{1n} \\ \vdots & \ddots & \vdots \\ c'_{m1} & \cdots & c'_{mn} \end{pmatrix} \quad (2)$$

In this study, negative affect is regarded as negative indicator, while all other indicators are considered as positive affects. The positive indicators are preprocessed using formula (3), and the negative indicators are preprocessed using formula (4).

$$c'_{ij} = \frac{c_{ij} - \min\limits_i c_{ij}}{\max\limits_i c_{ij} - \min\limits_i c_{ij}} \max_i c_{ij} \neq \min_i c_{ij}$$

$$c'_{ij} = 1 \max_i c_{ij} = \min_i c_{ij} c'_{ij} = 1 \max_i c_{ij} = \min_i c_{ij} \quad (3)$$

$$c'_{ij} = \frac{\max\limits_i c_{ij} - c_{ij}}{\max\limits_i c_{ij} - \min\limits_i c_{ij}} \max_i c_{ij} \neq \min_i c_{ij}$$

$$c'_{ij} = 1 \max_i c_{ij} = \min_i c_{ij} c'_{ij} = 1 \max_i c_{ij} = \min_i c_{ij} \quad (4)$$

Calculate the proportion $q_{ij} q_{ij}$ that the ii-th urban vitality complex occupies in the jj-th indicator. The formula is as follows

$$q_{ij} = \frac{c'_{ij}}{\sum_{i=1}^{m} c'_{ij}}, i = 1,2,\cdots,m; j = 1,2,\cdots,n q_{ij} = \frac{c'_{ij}}{\sum_{i=1}^{m} c'_{ij}}, i = 1,2,\cdots,m; j = 1,2,\cdots,n \quad (5)$$

Calculate the entropy value $E_j E_j$ of each indicator, the formula is as follows:

$$E_j = -k \sum_{i=1}^{m} q_{ij} \ln q_{ij}, j = 1,2 \cdots, n E_j = -k \sum_{i=1}^{m} q_{ij} \ln q_{ij}, j = 1,2 \cdots, n \quad (6)$$

where $k = \frac{1}{\ln m}, 0 \le E_j \le 1 k = \frac{1}{\ln m}, 0 \le E_j \le 1$
Calculate the weight of each indicator. The information entropy redundancy $d_j d_j$ is calculated by the following formula:

$$d_j = 1 - E_j, j = 1,2 \cdots, n d_j = 1 - E_j, j = 1,2 \cdots, n \quad (7)$$

Based on the information entropy redundancy $d_j d_j$, calculate the weight $\omega_j \omega_j$ of the jj-th indicator, and the formula is as follows:

$$\omega_j = \frac{d_j}{\sum_{j=1}^{n} d_j}, j = 1,2 \cdots, n \quad \omega_j = \frac{d_j}{\sum_{j=1}^{n} d_j}, j = 1,2 \cdots, n \quad (8)$$

Based on the index values of 14 evaluation indicators in the emotional attachment evaluation index system for urban renewal vitality complexes in 5 cities of Beijing, this article calculates the weights of each evaluation indicator according to the aforementioned steps.

2. Improved TOPSIS Method with GRA

The calculation process of the improved TOPSIS method is as follows: Firstly, the positive and negative ideal solutions for the emotional attachment of urban renewal complexes are determined through the traditional TOPSIS method. Secondly, the GRA method is used to compare the scores of each evaluation indicator of each complex with the positive and negative ideal solutions. Finally, the grey correlation degree between urban renewal complexes is determined and the intensity of emotional attachment of each urban renewal complex is ranked based on the results. The main steps are as follows:

Standardize the matrix $C = (c_{ij})_{m \times n} C = (c_{ij})_{m \times n}$ to get a standardized matrix $X = (x_{ij})_{m \times n} X = (x_{ij})_{m \times n}$, where $x_{ij} x_{ij}$ is calculated as follows:

$$x_{ij} = \frac{c'_{ij}}{\sqrt{\sum_{i=1}^{m} c'^{\,2}_{ij}}}, 1 \le i \le m, 1 \le j \le n \qquad x_{ij} = \frac{c'_{ij}}{\sqrt{\sum_{i=1}^{m} c'^{\,2}_{ij}}}, 1 \le i \le m, 1 \le j \le n \tag{9}$$

The weight vector $\omega_j\omega_j = (\omega_1,\ \omega_2 \ldots \omega_3 \ldots \omega_n \omega_1,\ \omega_2 \ldots \omega_3 \ldots \omega_n)$ obtained in Equation (8) is multiplied by the standardization matrix $X = (x_{;;}) \qquad X = (x_{;;})$ to get a weighted standardization matrix as follows:

$$Y = \begin{pmatrix} \omega_1 x_{11} & \omega_2 x_{12} & \cdots & \omega_n x_{1n} \\ \omega_1 x_{21} & \omega_2 x_{22} & \cdots & \omega_n x_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \omega_1 x_{m1} & \omega_2 x_{m2} & \cdots & \omega_n x_{mn} \end{pmatrix} = \begin{pmatrix} y_{11} & y_{12} & \cdots & y_{1n} \\ y_{21} & y_{22} & \cdots & y_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ y_{m1} & y_{m2} & \cdots & y_{mn} \end{pmatrix}$$

$$Y = \begin{pmatrix} \omega_1 x_{11} & \omega_2 x_{12} & \cdots & \omega_n x_{1n} \\ \omega_1 x_{21} & \omega_2 x_{22} & \cdots & \omega_n x_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ \omega_1 x_{m1} & \omega_2 x_{m2} & \cdots & \omega_n x_{mn} \end{pmatrix} = \begin{pmatrix} y_{11} & y_{12} & \cdots & y_{1n} \\ y_{21} & y_{22} & \cdots & y_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ y_{m1} & y_{m2} & \cdots & y_{mn} \end{pmatrix} \tag{10}$$

The positive ideal solution $y^+ y^+$ and negative ideal solution $y^- y^-$ is calculated as follows, where $J^+ J^+$ is the set of positive indicators while$J^- J^-$ is the set of negative indicators:

$$y^+ = \left[\left(\max_{1\le i\le m} y_{ij} \ \middle|\ j \in J^+\right), \left(\min_{1\le i\le m} y_{ij} \ \middle|\ j \in J^-\right)\right] = (y_1^+, y_2^+, \cdots, y_n^+)$$
$$y^+ = \left[\left(\max_{1\le i\le m} y_{ij} \ \middle|\ j \in J^+\right), \left(\min_{1\le i\le m} y_{ij} \ \middle|\ j \in J^-\right)\right] = (y_1^+, y_2^+, \cdots, y_n^+) \tag{11}$$

$$y^- = \left[\left(\min_{1\le i\le m} y_{ij} \ \middle|\ j \in J^+\right), \left(\max_{1\le i\le m} y_{ij} \ \middle|\ j \in J^-\right)\right] = (y_1^+, y_2^+, \cdots, y_n^+)$$
$$y^- = \left[\left(\min_{1\le i\le m} y_{ij} \ \middle|\ j \in J^+\right), \left(\max_{1\le i\le m} y_{ij} \ \middle|\ j \in J^-\right)\right] = (y_1^+, y_2^+, \cdots, y_n^+) \tag{12}$$

In this article, the positive ideal solution $y^+ y^+$ refers to a fictional urban renewal complex that has the best ability to foster emotional attachment and the highest level of emotional attachment. The negative ideal solution $y^- y^-$ represents the worst option, which has the poorest ability to foster emotional attachment and the lowest level of emotional attachment.

Calculation of distance between each complex and the positive ideal solution $r_i^+ r_i^+$ and the negative ideal solution r_i^- r_i^-. $r_i^+ r_i^+$ ($r_i^- r_i^-$) is the Euclidean distance, $r_i^+ r_i^+$ ($r_i^- r_i^-$) is lower, indicating that the complex is closer to the positive (negative) ideal solution, while the emotional attachment intensity is higher (lower).

$$r_i^+ = \sqrt{\sum_{j=1}^{n} \left[\left(y_{ij} - y_j^+\right)\right]^2}, 1 \le i \le m, 1 \le j \le n \qquad (13)$$

$$r_i^- = \sqrt{\sum_{j=1}^{n}\left[\left(y_{ij} - y_j^-\right)\right]^2}, 1 \le i \le m, 1 \le j \le n \quad (14)$$

Calculation of the grey relational degree:

$$d_{ij}^+ = \frac{\min\limits_i \min\limits_j \left|y^+ - y_{ij}\right| + \rho \max\limits_i \max\limits_g \left|y^+ - y_{ij}\right|}{\left|y^+ - y_{ij}\right| + \rho \max\limits_i \max\limits_j \left|y^+ - y_{ij}\right|} \quad (15)$$

$$d_{ij}^- = \frac{\min\limits_i \min\limits_j \left|y^- - y_{ij}\right| + \rho \max\limits_i \max\limits_j \left|y^- - y_{ij}\right|}{\left|y^- - y_{ij}\right| + \rho \max\limits_i \max\limits_j \left|y^- - y_{ij}\right|} \quad (16)$$

$$d_i^+ = \frac{1}{n}\sum_{j=1}^{n} d_{ij}^+, 1 \le i \le m \quad (17)$$

$$d_i^- = \frac{1}{n}\sum_{j=1}^{n} d_{ij}^-, 1 \le i \le m \quad (18)$$

where $\rho\rho$ = 0.5, $d_i^+ d_i^+$ is the grey correlation degree between the evaluation indicators and positive ideal solution, $d_i^- d_i^-$ is the grey correlation degree between the evaluation indicators and negative ideal solution.

Dimensionless processing weighted the distances $r_i^+ r_i^+$ and $r_i^- r_i^-$ and the grey correlation d_i^+ and d_i^- d_i^+ and d_i^-:

$$R_i^+ = \frac{\max r_i^+ - r_i^+}{\max r_i^+ - \min r_i^+}, 1 \le i \le m \quad (19)$$

$$R_i^- = \frac{\max r_i^- - r_i^-}{\max r_i^- - \min r_i^-}, 1 \le i \le m \quad (20)$$

$$D_i^+ = \frac{d_i^+ - \min d_i^+}{\max d_i^+ - \min d_i^+}, 1 \le i \le m \quad (21)$$

$$D_i^- = \frac{d_i^- - \min d_i^+}{\max d_i^- - \min d_i^+}, 1 \le i \le m \quad (22)$$

Perform intervaliation processing on the data, where $a = 1,\ b = 2a = 1,\ b = 2$:

$$R_i'^+ = a + \frac{(b-a)(R_i^+ - minR_i^+)}{maxR_i^+ - minR_i^+} \quad (23)$$

$$R_i'^{-} = a + \frac{(b-a)(R_i^- - minR_i^-)}{maxR_i^- - minR_i^-} \quad (24)$$

$$D_i'^{+} = a + \frac{(b-a)(D_i^+ - minD_i^+)}{maxD_i^+ - minD_i^+} \quad (25)$$

$$D_i'^{-} = a + \frac{(b-a)(D_i^- - minD_i^-)}{maxD_i^- - minD_i^-} \quad (26)$$

Integrate the above dimensionless distance and dimensionless grey correlation degree results:

$$S_i^+ = \alpha R_i'^{+} + \beta D_i'^{+} S_i^+ = \alpha R_i'^{+} + \beta D_i'^{+}, 1 \le i \le m, 1 \le i \le m \quad (27)$$

$$S_i^- = \alpha R_i'^{-} + \beta D_i'^{-} S_i^- = \alpha R_i'^{-} + \beta D_i'^{-}, 1 \le i \le m, 1 \le i \le m \quad (28)$$

where S_i^+ (S_i^-) S_i^+ (S_i^-) represents the comprehensive relation between complex C_iC_i and the positive (negative) ideal solution.

$$\alpha + \beta = 1 \alpha + \beta = 1, \alpha\alpha > 0, \beta\beta > 0$$

Calculation of the relative closeness $A_i^+ A_i^+$ of the urban vitality complex

$$A_i^+ = \frac{S_i^+}{S_i^+ + S_i^-}, 1 \le i \le m \quad (29)$$

The higher the $A_i^+ A_i^+$, the closer the urban renewal complex C_iC_i is to the positive ideal solution, indicating that its ability to promote emotional attachment is better, and the intensity of emotional attachment is also higher. By calculating, the comprehensive relative compactness of each urban renewal complex can be obtained, and this indicator can be used to rank the degree of emotional attachment of the urban vitality complexes.

2.3.3. Methodology Framework

This study mainly conducts an analysis and evaluation of the emotional attachment of the small-scale built environment of urban renewal complexes. Based on the measurement of attachment degree, dimension and intensity, it uses the logical path of " criteria establishment-methodology construction-results processing " of the emotional attachment theory to evaluate the emotional attachment of urban renewal complexes. At the same time, it comprehensively analyze the value of specific built environment characteristics by combining the results of scale analysis.

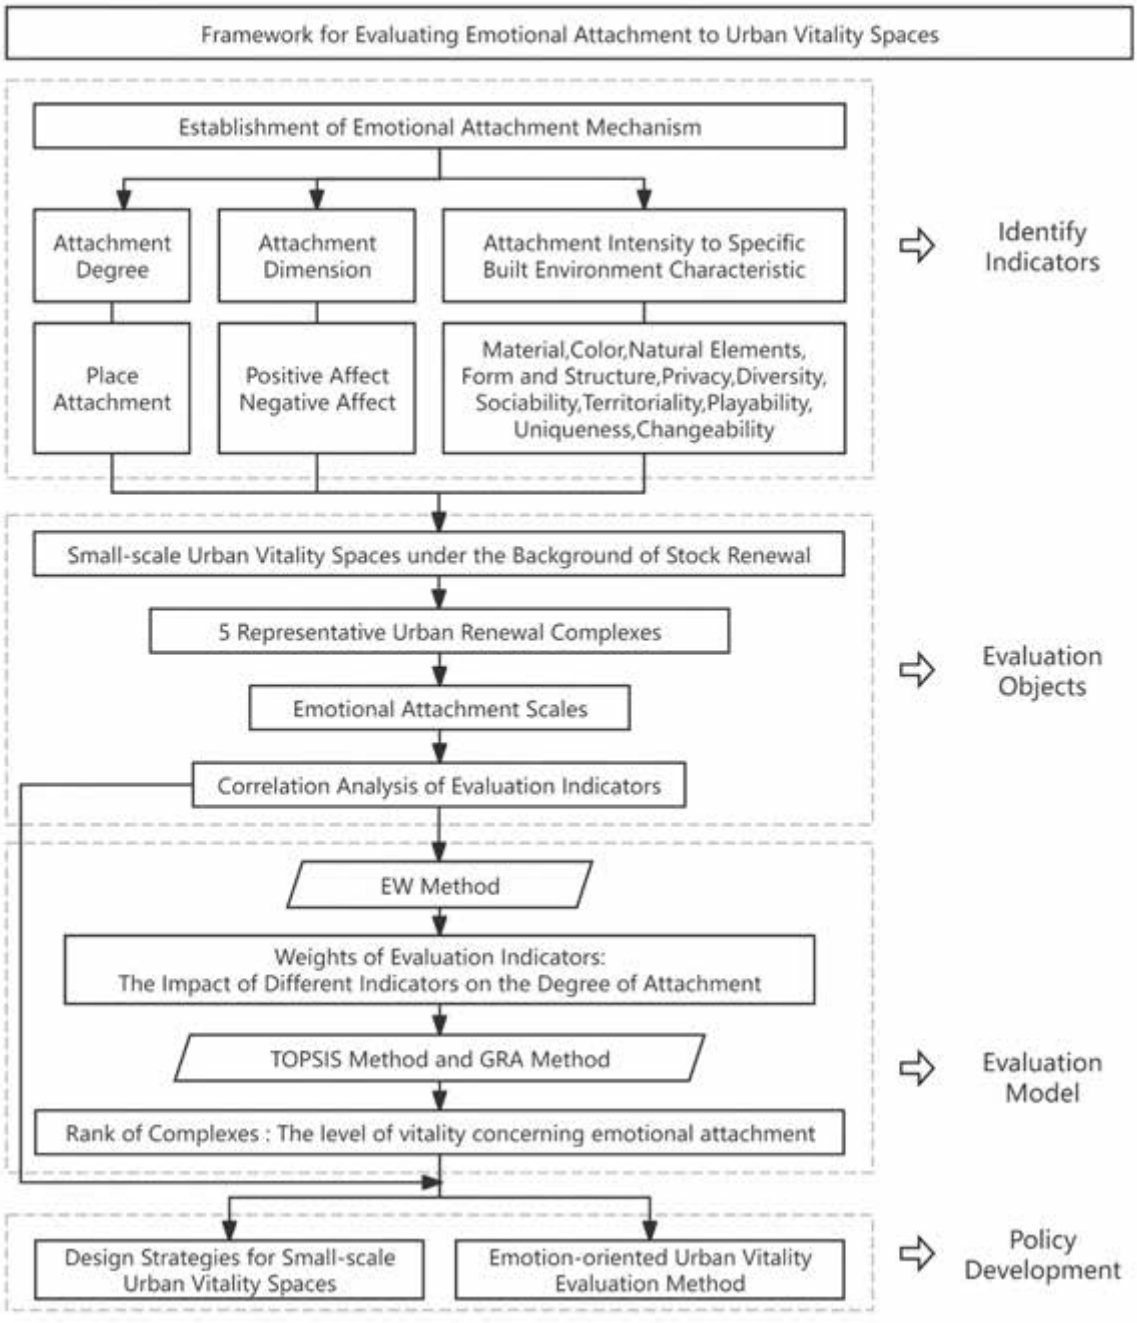

Figure 2. Flowchart of the proposed framework.

3. Results

3.1. The Analysis and Calculation Results of Emotional Attachment Scale and Emotional Attachment Evaluation Indicators

3.1.1. Calculation Results of Emotional Attachment Indicators of the Five Complexes

The overall data of each emotional attachment index for the five complexes are shown in Table 2. The attachment degree scores for these five urban vitality complexes by people all exceeded 3.5, indicating that people have a strong emotional attachment to these complexes, and from the standard deviations, it can be found that the

degree of attachment varies greatly among different people. Regarding the attachment dimensions of the five complexes, from the average values, the score of positive affect is significantly higher than that of negative affect, indicating that the positive affect people receive is more obvious than the negative affect. The value of the standard deviation indicates that people have almost the same feelings in these complexes. As for the intensity of people's attachment to specific architectural environment characteristics, the mean results show that people generally have a strong emotional experience of architectural environment characteristics, which once again proves that specific architectural environment characteristics play an important role in generating people's emotional attachment. Taking the various indicators based on the emotional attachment assessment system dimensions as the indicators of the EW-GRA-TOPSIS method, further demonstrates the urban vitality of the five complexes.

Table 2. Results of emotional attachment indicators of the five complexes.

3.1.2. Calculation Results of Correlation Analysis of Five Complexes

Conducting correlation analysis to further explore the contribution degree of each specific architectural environment characteristic to the degree and dimensions of emotional attachment. The correlation results of the five complexes are shown in Table 3-7. It is obvious that the place attachment of people to the five complexes is positively correlated with positive emotions (0.595 **, 0.595 **, 0.582 **, 0.500 **, 0.558 **). Regarding attachment intensity to specific built environment characteristic, they are positively correlated with the overall emotional attachment in the 5 complexes. The results of describing the architectural environment material characteristics of all five complexes (including material, color, form and structure) are significantly positively correlated with local attachment, because they all have relatively high correlation coefficients, 0.01 (two-tailed). The architectural environment materials of the complexes are elements that people are easy to perceive and build emotional attachment. These coefficients to some extent reflect the value of architectural environment materials' characteristics in emotional attachment. For the social and interactive features of the complexes (including privacy, diversity, sociability, territoriality, playability, uniqueness and changeability), the results are positively correlated with emotional attachment in general, and different indicators reflect the different influences of different complexes on emotional attachment. For example, compared with the other three complexes, the sociability of Langyuan Station and EKA Art District is less correlated with place attachment (0.372 **, 0.355 **), which may be due to the fact that these two complexes are commercial blocks updated from old industrial areas, and compared with the other three complexes, these two complexes have more diverse business types and people's activities with the space are more diverse. It may be because of the richness of the space that the interaction mode here not only stops at interpersonal socialization. The results show that in the five complexes, color is closely related to form and structure (0.675 **, 0.633 **, 0.683 **, 0.571 **, 0.709 **). It indicates that in the design and construction of these urban vitality complexes, the attractive design of form and structure fully utilizes rich colors to express, jointly creating a city vitality space that can evoke people's emotional resonance.

3.2. The Results of the Emotional Attachment Evaluation of Urban Vitality Complexes Using EW-GRA-TOPSIS Method

Based on the index data collected and calculated above for the five complexes, the model for evaluating the emotional attachment to the built environment of urban vitality complexes, which was established in Section 2.3 using the EW-GRA-TOPSIS method, was applied to assess the emotional attachment level of these five complexes.

3.2.1. Calculation of the Weight of Each Indicator

The decision-making matrix CC is constructed, standardized, and normalized in line with Equations (1) – (4). The entropy value E_jE_j and weight $\omega_j\omega_j$ for each indicator of the five complexes are derived through Equations (5) – (8). The detailed outcomes are presented as follows.

Table 8. Weight of each indicator.

Evaluation Index	E_j	ω_j
Place Attachment	0.985	0.066
Positive Affect	0.986	0.062
Negative Affect	0.979	0.092
Material	0.982	0.077
Color	0.985	0.064
Natural Elements	0.985	0.064
Form and Structure	0.985	0.063
Privacy	0.985	0.064
Diversity	0.986	0.062
Sociability	0.981	0.084
Territoriality	0.984	0.068
Playability	0.981	0.082
Uniqueness	0.984	0.070
Changeability	0.981	0.084

3.2.2. Calculation of the Positive and Negative Ideal Solution of Each Indicator

Following the standardization and weighing of matrix CC in accordance with Equations (9) and (10), the ideal positive and negative solutions for each indicator are determined via Equations (11) and (12). The resulting data is outlined below.

Table 9. Positive ideal solution and negative ideal solution of each indicator.

Evaluation Index	Positive Ideal Solution	Negative Ideal Solution
Place Attachment	0.132	0.066
Positive Affect	0.123	0.062
Negative Affect	0.183	0.092
Material	0.154	0.077
Color	0.128	0.064
Natural Elements	0.127	0.064
Form and Structure	0.126	0.063
Privacy	0.127	0.064
Diversity	0.125	0.062
Sociability	0.167	0.084
Territoriality	0.136	0.068
Playability	0.164	0.082
Uniqueness	0.140	0.070
Changeability	0.167	0.084

3.2.3. Calculation of the Distance from the Emotional Attachment of Each Urban Vitality Complex to the Positive and Negative Ideal Solution

After calculating and normalizing the distance between the emotional attachment of each urban vitality complex and the ideal solution using Equations (13), (14), (19), and (20), the results are presented below.

Table 10. Distance from the emotional attachment of each complex to the positive and negative ideal solution.

Urban Vitality Complex	R_i^+	R_i^-
Longfusi Street	0.377	0.460
Langyuan Station	0.426	0.402
EKA Art District	0.236	0.613
Columbia Circle	0.443	0.437
Raffles City Changning	0.651	0.246

3.2.4. Calculation of Grey Relational Degree of Each Urban Vitality Complex

Using the results from the calculation of positive and negative solutions in Section 3.2.2, the grey relational degree of each urban vitality complex is determined and normalized through Equations (17), (18), (21), and (22). The findings are presented below.

Table 11. Grey relational degree of each complex.

Urban Vitality Complex	D_i^+	D_i^-
Longfusi Street	0.433	0.413
Langyuan Station	0.414	0.416
EKA Art District	0.594	0.319
Columbia Circle	0.442	0.420
Raffles City Changning	0.304	0.614

3.2.5. Calculation of the Relative Closeness and the Rank of Each Urban Vitality Complex

Based on Equations (27) and (28), the relative closeness of each complex is calculated by determining $S_i^+ S_i^+$ and $S_i^- S_i^-$. Then, the emotional attachment level of each complex can be ranked. The results are shown below.

Table 12. Relative closeness and the vitality evaluation rank of five complexes.

Urban Vitality Complex	S_i^+	S_i^-	A_i^+	Rank
Longfusi Street	0.446	0.395	0.530	2
Langyuan Station	0.408	0.421	0.492	4
EKA Art District	0.603	0.278	0.685	1
Columbia Circle	0.439	0.432	0.504	3
Raffles City Changning	0.275	0.633	0.303	5

The results show that EKA Art District ranked first among the five complexes, indicating that the level of emotional attachment it established between people and urban complexes was the highest among the five complexes. Longfusi Street and Columbia Circle ranked second and third respectively in the assessment, with their scores being relatively close and both higher than 0.5 (0.530 > 0.504 > 0.5). Raffles City Changning ranked last, indicating that people's emotional attachment to this architectural environment was relatively low. In the next part, we will combine the above correlation analysis and field research results to explore further reasons for this.

4. Discussion

In previous studies, there were not many that focused on the relationship between the built environment at a small scale and the emotional attachment of users. This was due to the relatively difficult acquisition of data. Previous studies on urban vitality usually adopted quantitative data mining and other methods to conduct research, which made it difficult to focus on specific small-scale urban vitality spaces and also difficult to focus on the dimensions and levels of emotional interaction between people and the built environment. Therefore, this study focuses on small-scale urban complexes with representative significance in first-tier cities under the background of urban renewal in China. It conducts research on urban small-scale vitality spaces from the perspective of emotional attachment, and attempts to achieve a scientific and objective study of the emotional attachment dimensions and levels of urban vitality spaces through the construction of quantitative research methods. The research results and the practical process of method construction are as follows.

4.1. The Value of Architectural Environment Characteristics in Establishing Emotional Attachment in Urban Vitality Spaces

The data results show that the built environment characteristics of EKA Art District performed the best in terms of emotional attachment, with the highest score and higher than 0.5 (0.685). EKA Art District is a city complex built on the original industrial factory site through re-design and renovation. It retains the original road network and layout structure of the factory area. Based on the relevant analysis results in Section 3.1.2, the built environment characteristics of this commercial complex play an important role in building the emotional attachment of users. The color, form and structure of the complex, as well as the place attachment, show a significant positive correlation (0.519**, 0.496**, 0.488**), indicating that the original industrial-style spatial forms and structures with industrial characteristics in the industrial-old-site renewal complex have played a role in promoting emotional attachment for this type of urban dynamic space. There is a significant positive correlation between color with form and structure (0.683**), further indicating that the use of industrial-style materials such as rusted steel plates, with their color providing people with deep memories and forming unforgettable emotional experiences. Longfusi Street and Columbia Circle ranked second and third in the assessment, with their scores higher than 0.5 and a certain gap from the first-ranked complex (0.530, 0.504). Based on the correlation results analysis, it can be inferred that the architectural environment characteristics of these two complexes also made significant contributions to promoting emotional attachment. Specifically, the material characteristics of Longfusi Street (including material, color, form and structure) were superior to Columbia Circle (Longfusi Street: 0.626**, 0.524**,

0.526** > Columbia Circle: 0.444**, 0.456**, 0.504**). To a certain extent, it indicates that in the process of renewing a historical district into a complex, the comprehensive application of materials that echo traditional design styles helps people build emotional attachment to this type of complex. Columbia Circle innovatively used new materials, forming a unique style of dynamic complex.

Langyuan Station ranked fourth in the assessment, with a score slightly lower than 0.5 and similar to that of Columbia Circle (0.492). According to the correlation analysis, it can be inferred that the architectural environment characteristics of this complex also made a certain contribution to promoting emotional attachment. Specifically, diversity, natural elements, and form and structure with place attachment show a positive correlation (0.510**, 0.541**, 0.485**). As a city complex built on the original industrial factory site through re-design and renovation, unlike EKA Art District prominent contribution of color and material to the built environment and place attachment, Langyuan Station's application of diversity and natural elements effectively enhanced the spatial vitality of this complex.

Raffles City Changning ranked last among the five complexes in the emotional attachment assessment. Based on the correlation analysis, color, form and structure, as well as uniqueness are positively correlated with place attachment (0.525**, 0.484**, 0.510**), while privacy and playability have the weakest correlation with place attachment (0.328**, 0.305**). This might be related to the unique new architectural enclosure of Raffles City Changning that surrounds the historical buildings in the overall layout of the space. Such a spatial layout is relatively simple, with fewer spatial changes, resulting in insufficient privacy. Compared to other complexes, the transformation of spatial levels in Raffles City Changning is simpler, making the game nature of the complex relatively weak.

Overall, the architectural environment characteristics of the five commercial complexes all play a role in promoting emotional attachment, creating spaces with urban vitality through different design methods. The contribution of specific features to the process of people forming place attachment with different complexes varies, possibly related to the original distinctive style of the complexes.

4.2. The Application of the Emotional Attachment Evaluation Results in the Study of Urban Vitality

Under the background of stock renewal, the design of urban vitality spaces shares many similarities in strategies and techniques with the previous designs that focused on emotional attachment. Previously, we believed that the emotional attachment scale and evaluation results, due to their uniqueness, were difficult to reflect the characteristics of other urban architectural environments such as urban vitality. However, through the above exploration, it can be shown that the newly built small-scale urban vitality spaces significantly promoted the construction of emotional attachment in terms of architectural environment characteristics. Therefore, the specific value research results of this study on the various features of urban vitality spaces not only focus on the exploration of the emotional attachment dimension, but also reflect the degree and characteristics of urban vitality in the process of constructing new urban vitality spaces.

This study innovatively applies the emotional attachment scale to the small-scale assessment of urban vitality spaces and effectively quantifies the emotional attachment data into the assessment results of small-scale and architectural environment characteristics of urban vitality spaces. The attachment scale and evaluation results help reveal the small-scale urban vitality elements that are closer to people's daily lives, and also take into account some aspects of the large-scale urban vitality space assessment. For example, from the perspective of emotional attachment, the material, color, natural elements, as well as the form and structure that people can directly touch and feel are important components of the vibrant urban environment at the small scale. These indicators are rarely used for evaluation in large-scale urban vitality studies. However, the diversity, sociability, and territoriality, which are the overall social interaction characteristics of the environment, can be extended to large-scale urban vitality studies. There is a significant correlation between the diversity and sociability of multiple complexes and their uniqueness, especially in the EKA Art District and Longfusi Street complexes with high attachment levels, which indicates the important role of such emotional attachment measurement

indicators applicable to large-scale spaces in the evaluation system, and proves that such indicators are also important indicators for evaluating urban vitality.

In the future research and design of small-scale urban vitality spaces, the method constructed in this study can not only be repeatedly verified in the research process, but also be quantitatively measured the vitality level of emotional attachment in the evaluation process. It can also further explore the correlation between emotional attachment and architectural environment characteristics. The relevant results of this study can be used as a reference for the design and renovation of small-scale urban complex spaces to create more architectural environments that focus on people's emotional experiences, thereby stimulating the space to exhibit long-term and diverse vitality.

4.3. Promote the Application of Quantitative Methods in the Research and Assessment of the Vibrant spaces in Small-Scale Cities

In current urban research, the quantitative methods for studying urban vitality are mostly manifested as collecting multi-dimensional big data to construct corresponding evaluation systems. Such methods are mainly used to explore large-scale areas within a certain region and the city as a whole. In the context of stock renewal, the small-scale urban vitality space research has more direct significance in enhancing the spatial experience of users compared to the macroscopic regional vitality evaluation. Since the vitality of small-scale spaces comes from the interaction between people and the specific characteristics of the architectural environment, and emotion is one of the core dimensions of vitality formation, the quantitative measurement method of the emotion attachment scale formed by multidisciplinary researchers provides a quantitative approach for the analysis of small-scale vitality spaces. When examining urban vitality in small-scale architectural environments, the emotion attachment method is used both as a theoretical guide and as a quantitative tool. Based on the results of the attachment scale, the improved TOPSIS method is then used to further evaluate the relative levels of emotional attachment in different vibrant complexes. The single TOPSIS model, when calculating scores and standardizing, assumes that the weights of each indicator are the same, which cannot well reflect the objective situation of the data. Therefore, this study selects the EW method to change the weight settings of the indicators in the emotion attachment scale analysis, and assigns different weights to different indicators based on the actual obtained emotion attachment scale data. Additionally, the GRA method is combined to compensate for the inherent shortcomings of the TOPSIS model, making the final constructed EW-GRA-TOPSIS evaluation method more complete. This method has the advantage of combining qualitative and quantitative analysis, considering people's perception of spatial characteristics and emotional needs in the evaluation of small-scale vitality spaces, and using precise mathematical methods for quantification, making the evaluation results clearer. This evaluation system is widely applied to the comparative evaluation of spatial vitality of multiple urban complexes, thereby providing scientific, reasonable, and practical guidance and strategies for urban vitality space design, construction evaluation, and optimization.

5. Conclusion

In the context of stock update, in the existing research fields of urban vitality, there is a lack of design and evaluation methods for small-scale vitality spaces at the research scale. In terms of research dimensions, people lack attention to the advanced needs of people's emotional attachment to specific and vibrant spaces. Therefore, in response to the lack of attention to the emotional dimension and insufficient quantitative research in the study of small-scale urban vitality spaces, this paper proposes a methodology applicable to the exploration and evaluation of small-scale urban vitality spaces, and selects five representative vitality urban complexes in two representative first-tier cities in China as examples to conduct field research and data analysis using this method. Based on the analysis of the experimental process and results, the main results of this study are summarized as follows:

1) In the small-scale spatial dimension, the basic material characteristics of the built environment (including material, color, natural elements, form and structure) play a significant role in stimulating urban vitality. According to the results of this study, their mechanism of promoting urban vitality through emotional attachment is

presented in the following ways. Firstly, based on the manifestation of the basic characteristics of material, such as the texture and color of the material themselves. During the interaction with the vitality complex, people can directly understand the logic of space construction. The cognition of the most basic material characteristics of the complex itself is the foundation for people to establish place attachment and is also a necessary condition for the complex to generate vitality. Secondly, the combination and connection of material elements with the original characteristics of the complex. For example, complexes like EKA Art District and Langyuan Station, which are based on the renovation of industrial buildings, retain the street layout, old materials and original architectural structures. The industrial structure has a certain influence on the re-construction of the vitality space. At the same time, natural elements also have an impact on the vitality level of most complexes. People's affinity for nature makes natural elements crucial in the process of forming emotional attachment.

2) The diversity and frequency of various activities carried out by people in the vitality complex to some extent reveal the social interaction nature of this urban complex, including privacy, diversity, sociability, territoriality, playability, uniqueness, and changeability. The results show that from the perspective of emotional attachment, they play an important role in promoting spatial vitality. At the same time, from the perspective of vitality evaluation, these characteristics have a significant positive correlation with attachment. In the complexes with relatively high vitality evaluation rankings, territoriality and uniqueness have a certain correlation with attachment, indicating that regionalism and uniqueness have an impact on the vitality level of the complex. However, in the complexes with lower rankings, the correlations between privacy and playability and attachment are weaker, indicating that privacy and playability also affect the social interaction nature of the complex and thereby affect the vitality situation of the complex.

With the advancement of emotion measurement and data mining technologies, the acquisition of data on people's emotional attachment to the built environment has become increasingly abundant, and the update of open-source data for various scales of urban spaces has accelerated. The integration and analysis of emotional and spatial data have become more convenient, laying the foundation for the widespread application of this research method. This method can be flexibly replicated to different urban vitality spaces and, through comparative tests, promote continuous improvement. In terms of data collection, in addition to traditional scales, multiple-modal technologies such as wearable physiological monitoring devices, eye trackers, and portable electroencephalogram equipment can be utilized to enhance the accuracy of indicators; when applying this method, the evaluation indicators and weights of the built environment should be dynamically adjusted according to the characteristics of the research area. The research methodology of this method differs from traditional urban vitality assessment methods in terms of perspective and scale, focusing on people's emotional experiences in urban vitality spaces. By leveraging objective data analysis, it aims to explore design and construction strategies for enhancing environmental emotional attachment. The place attachment theory plays a crucial bridging role here, especially in small-scale spaces, effectively converting subjective emotions into quantitative data. Through in-depth analysis of emotional attachment data, this method accurately quantifies the emotional attachment degree and vitality level of complexes and their built environments, and scientifically and objectively analyzes the influence mechanism of architectural environment characteristics on emotional experiences, providing innovative ideas and practical references for the all-round development of future urban vitality spaces with humanistic orientation.

The application of this method in current research has not yet reached a very mature stage. Its depth and breadth need to be expanded. On one hand, with the help of new technologies for collecting and analyzing emotional data, more emotional attachment indicators such as physiological data can be added. In this way, researchers can observe more objectively the impact of indicator changes on the evaluation of urban vitality spaces and architectural environment characteristics. On the other hand, the continuous upgrading of this type of method can be applied to multiple small-scale urban vitality complexes in different cities, widely comparing experimental results and verifying, and upgrading this type of method.

Acknowledgments:
Thanks for Zhe Chang, Zhenzhi Zhou, Hejing Liu and Weiyang Yan for their help of recruiting the team in two cities to help with the scale measurement. Thanks for Xiaoqing Tang, Siya Wang, Ruijie Gong, Peijia Liu, Xinyi Shan and Ziqi Zhang for their help of distributing and collecting scales.

Abstract
Built environment (BE) epidemiologists aim to elucidate the pathways through which BE characteristics are linked to the prevalence of chronic diseases. Our study identifies the direct and indirect effects of urban living environments on overall perceptions of physical health. Our cross-sectional geospatial study involved 4015 residents of Ankara. We fitted multinomial logit models to assess relationships between residents' locations, demographic and socioeconomic statuses (SES), obesity prevalence, PA levels, life satisfaction, and evaluations of urban living environments and overall health perception. We found significant relationships between BE characteristics and health perception, particularly with SES, age groups, green space availability, environmental perception, PA levels, and obesity prevalence. Our findings provide evidence of the relationship between public health policy and urban design and planning.

Keywords: Healthy Neighbourhood Planning, Physical Activity, Public Health

1. Introduction

Cities consist of living environments with different built environment characteristics, which inherently present complex and multidimensional structured environments formed from various processes. While some areas are healthy, safe, and attractive, integrated with urban activities, others are unattractive due to a lack of infrastructure, open and green spaces, and urban services. In developing countries, particularly in fast-growing, high-density cities that receive constant immigration, such areas are more common due to uncontrolled, spontaneous development. Restructuring these areas and transforming them into sustainable, livable, walkable, high-quality, and healthy environments is gaining importance both in Türkiye and worldwide. This study aims to link the overall health assessment of individuals with built environment characteristics, physical activity levels, and obesity prevalence, while controlling for the confounding variables of demographic and socioeconomic status.

The built environment characteristics should enable individuals to prioritize a healthy and active lifestyle while meeting their basic needs, such as shelter and nutrition. Thus, the importance of the relationship between city planning, urban design, and public health is revealed. Although central and local governments have existing practices, producing new approaches that are more comprehensive, location-specific, multi-level, multi-sectoral, participatory, and community-oriented should be the priority. To have a healthy city that supports physical activity, citizens do not need high-cost residential projects; public interventions to increase the presence of walkable, mixed-use, and accessible green areas in living environments will increase overall health perception along with physical activity and contribute to reducing NCDs in society.

The promotion of physical activity — walking, cycling, sports participation, and the broader dissemination of active recreational pursuits — is recognized as a critical component within the framework of the United Nations Sustainable Development Goals (SDGs). This emphasis reflects not only its profound health implications but also its substantial social and economic benefits. Specifically, it aligns with and advances the objectives of SDG 3 (Good Health and Well-Being), SDG 11 (Sustainable Cities and Communities), SDG 13 (Climate Action), and SDG 17 (Partnerships for the Goals).

In this context, the research questions are as follows:
- How do built environment characteristics, socioeconomic statuses, physical activity, and BMI levels influence

overall health perception?
- What are the significant urban planning policies that enhance the perceived health of individuals?

2. Literature Review

Scientific studies have shown that the characteristics of a built environment significantly influence the lifestyle and preferences of its inhabitants and effective urban public health policies can effectively manage these factors (Bennett et al., 2024; Sarkar and Webster, 2017). Cities are composed of neighbourhoods with various built environments and geographical characteristics developed and controlled by city plans. These environments are complex and multidimensional, forming different morphologies and plan periods.

Increased population growth, extensive migration from rural areas to cities, rapid urbanization, and the close relationship between social welfare and neighbourhood quality have heightened the significance of health for societies. Among the Sustainable Development Goals (SDGs) of the United Nations, SDG3 Healthy Individuals and SDG11 Sustainable City and Living Spaces are the two goals that cities have to adopt along with the quality they provide to support 'health' and 'well-being' (Ramirez-Rubio et al., 2019; WHO, 2023). In particular, following the COVID-19 pandemic, the quality of neighbourhoods has become increasingly important, and guidelines have been established to plan and design them through city plans and design (Mouratidis and Yiannakou, 2022). Healthy cities have become the focus of urban planning, and built environment characteristics have gained importance.

Walkable, accessible, mixed-use neighbourhoods supported by robust urban infrastructure are essential for physically active and healthy living (Cerin et al., 2018), and therefore require a new examination of the specifics of socio-spatial attributes of urban living. The physical setup of the neighbourhoods, including residential density, land use diversity, accessibility, centrality, availability of health infrastructure, and sufficiency of green spaces, define the level of physical activity (PA) and health (Sarkar et al., 2014; Ho et al., 2023; Lai et al., 2023; Italia, 2001). A city should offer walkable urban areas and ample spaces supporting mobility; the built environment appears to decrease physical inactivity, thus eliminating the risk factors of NCDs (Haskell et al., 2009). In this context, the planning and design strategies of neighbourhoods ensure the control of the demographic structure and socio-economic and environmental elements and will be effective in promoting health and mitigating the risks, such as physical inactivity (Haskell et al., 2009) that underlie non-communicable diseases (NCDs).

NCDs are responsible for 74% of the death rates in the world (WHO, 2023) and 90% of deaths in Europe (EEA, 2020). NCDs are increasingly responsible for 70-80% of European health costs (EC, 2020). For example, worldwide, adult obesity has more than doubled since 1990, and adolescent obesity has quadrupled; in 2022, 1 in 8 people in the world were living with obesity (WHO, 2024). The environmental relationship between inactivity and obesity has been discussed elsewhere (Gray et al., 2018), but in this paper, we aim to focus on a method to differentiate the neighbourhoods according to the factors known to be associated with PA.

This study shows that some characteristics, in particular land use diversity, health facility infrastructure, and green space size, play a significant role in identifying an urban pattern and are the products of different plan periods, which can influence the physical activity levels of its inhabitants.

Adequate housing involves evaluating the living unit as a physical entity within its environment and as a qualitative, complex formation that encompasses social, economic, and psychological aspects. In this context, the neighbourhood becomes a priority for investment to meet the needs of its residents. It has a fundamental impact on determining the quality of life for an individual (Pacione, 2003). Urban living conditions affect both their physical and mental health (Handy et al., 2002). For example, to promote healthy aging, public housing neighbourhoods should include more accessible spaces and community facilities along walking paths to support PAs and daily needs (Ho et al., 2023).

In transportation and built environment research, some scholars have classified how the physical attributes of neighbourhoods can be evaluated (Ewing and Cervero, 2010; Handy et al., 2002). Initially, they specified these

attributes as density, diversity, and design (Cervero and Kockelman, 1997), and this has been expanded by adding destination accessibility and distance to transit features (Ewing and Cervero, 2001). Next, the affiliation of these attributes with physical activity, walking, and mobility has been specified. It was found that physical activity is directly related to land use diversity, density of road network intersections, presence of urban green areas, distance to public transportation stops, and the number of destinations within walking distance (Ewing and Cervero, 2010; Zhang et al., 2022). In addition, green space size and its accessibility, the presence of green areas, opportunities and land use variability in a neighbourhood, and urban sprawl are specified as other influential factors on physical activity and physical and mental health (Carmona, 2019).

In a recent study, when examined in terms of urban health, eleven dimensions appear: i) housing and land use diversity (mixed-use), ii) accessibility, iii) access by public transportation, iv) design of movement networks, v) attractiveness of active transportation modes, vi) density, vii) distribution of labor force, viii) management of demand for urban services, ix) destination proximity, x) disaster mitigation, xi) distributed interventions and resources (Giles-Corti et al., 2022).

Physical activity is one of the most prominent healthy lifestyle behaviors in preventing both physical and mental diseases, including reducing the risk factors for NCDs, including obesity and type II diabetes, and one of WHO's main strategy recommendations for 'Healthy Cities' is to create a physical and social environment that supports physically active life (WHO, 2018). Neighbourhoods that support physical activity will enhance healthy living and should be accessible to all segments of society, particularly women, children, individuals aged 65 and above, and those in special needs groups who are considered disadvantaged. In settlements where all segments of society have equitable access to high-quality neighbourhoods and where individual and social interests are balanced, the sense of belonging towards the living environment will increase, and the quality of life will be high. In our analysis, the neighbourhood characteristics that support physical activity have been identified through variables derived from the literature review.

3. Methodology

The survey took place between 21 December 2021 and 15 March 2022, and 4015 interviews were reported to be valid. They are distributed across 76 neighbourhoods in Ankara. The research employed a spatial sampling strategy, where neighbourhoods were classified by specific factors linked to physical activity and well-recognized in the literature. The clustering criteria covered key variables: Built Environment Variables (Residential Density, Average Building Height, Average Building Volume, Green Space per Capita (km²/person), Green Area Ratio (green area / total area)), Street Network / Accessibility Variables (FAR (Floor Area Ratio), MAD1000 (Mean Angular Distance within 1000 m), MAD5000 (Mean Angular Distance within 5000 m), TPBtA1000 (Total Pedestrian Betweenness within 1000 m), TPBtA5000 (Total Pedestrian Betweenness within 5000 m)), Local Health Services Variables (Number of Physicians (per 1000 inhabitants), Number of Family Health Centers (FHCs) (per 1000 inhabitants)), Centrality Variables (Number of Chain Markets (per 1000 inhabitants), Number of Food & Beverage Establishments (per 1000 inhabitants), Number of Pharmacies (per 1000 inhabitants)), Land Price (TRY). We used clustering techniques – the Elbow method and specified 7 clusters. The total population, the share of population, the sample size, and the actual distribution of the interviews across clusters are shown in Table 1.

Table 1. Population (2020), Share of Population, Sample Size, Actual Distribution of Interviews by Clusters

Cluster	Population 2020	Share of Population	Sample Size		Actual Distribution of Interviews	
			Number	%	Number	%
1	1,393,621	0.28	929	23.23	953	23.74

4	1,112,234	0.22	830	20.75	828	20.62
5	1,217,823	0.24	869	21.73	878	21.87

6	898,796	0.18	746	18.65	759	18.90
Toplam	4,988,358	1.00	4000	100.00	4015	100.00

* The clusters are merged due to the size and proximity of cluster 3 and 7.

Figure 1 illustrates the locations of the selected neighbourhoods in the Ankara study area. These neighbourhoods are selected based on their cluster and socioeconomic (SES) status. The sample included households from across all neighbourhoods.

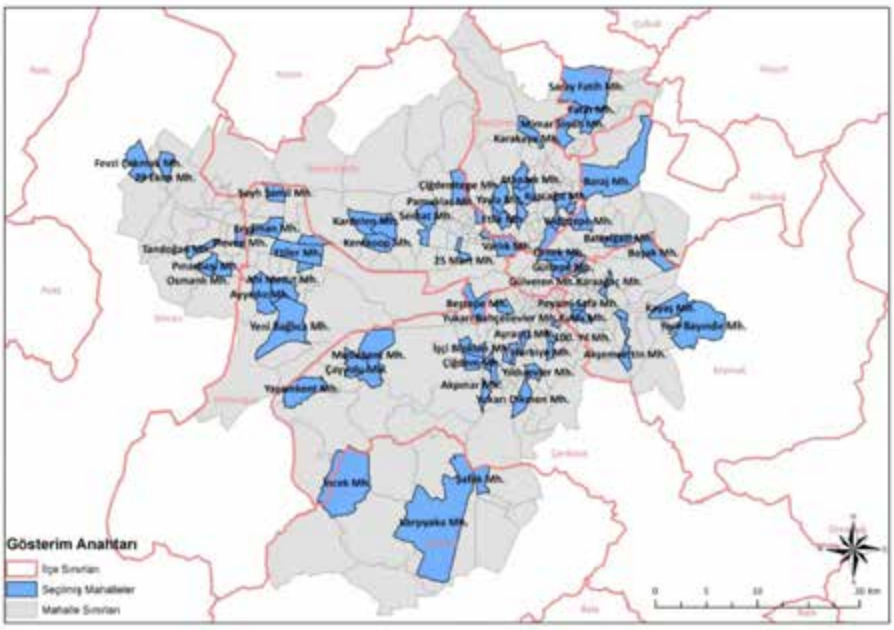

Figure 1. Selected Neighbourhoods in the Study Area

The dependent variable (overall health perception) was classified into three nominal categories ("good and very good", "moderate", and "bad and very bad"). The analysis required the relational statistical assessment of independent variables (built environment characteristics, physical activity levels, obesity prevalence (assessed by BMI) along with confounding factors of demographic and socioeconomic statuses. The model estimates the probability of each category relative to a reference category, based on the independent variables. In our analysis, we chose "bad and very bad condition" as the baseline.

4. Multinomial Logistics Model Results: Health Perception

Tables 2 and 3 show the output of a multinomial logistic regression model (MNL) where the dependent variable, overall health assessment, has three levels: bad/very bad (the reference category), moderate, and good/very good. In the model, the independent variables explain how and whether built environment characteristics, socioeconomic status (SES), age, physical activity level, green space, environmental attitude, obesity prevalence (assessed by Body Mass Index), and life satisfaction are related to perceived overall health assessment.

Table 2 illustrates how the selected independent variables affect individuals' probability of health assessment in the moderate category compared to the reference category, which is the perception of "bad and very bad". For example, individuals' SES and age groups affect their overall health assessment. Individuals with lower SES are 16% less likely to have moderate level health assessment (B=-0.175, p<0.001, Exp(B)=0.840); individuals of higher age groups are 21.6% less likely to have moderate level health assessment (B=-0.244, p<0.001, Exp(B)=0.784). Individuals with moderate levels of physical activity have 2.7 times the odds of being in the moderate health assessment category compared to the reference group (B=0.955, p<0.001, Exp(B)=2.705). Similarly, individuals who perceive their urban living environments negatively are 55% less likely to perceive their health as medium

compared to the "bad" and "very bad" perception categories (B = -0.796, p < 0.001, Exp(B) = 0.450). This suggests that individuals who perceive their urban living environments positively are more likely to have a more favorable perception of their overall health status. The Body Mass Index (BMI) significantly shows that people with low BMI (18-24.99-underweight and normal weight) have 2.9 times the odds to have moderate level health perception (B = 1.072, Exp(B)=2.922, p<0.001) and surprisingly, individuals with higher BMI (25-29.99-overweight) also have 2.2 times the odds to have moderate level health perception (B = -0.777, Exp(B)=2.175, p<0.001).

Table 2. Multinomial Model Results (Overall Health Assessment is at Moderate Level)

	[LifeSatisfaction=3.00]	0[b]			0				

a. The reference category is: bad/very bad.

b. This parameter is set to zero because it is redundant.

Table 3 shows that individuals with a health perception have a higher probability of being in the "good" and "very good" categories compared to those with "bad" and "very bad" perceptions. The results show that, across age groups, individuals' overall health assessment is 50% times less likely to be in the "good/very good" category (B = -0.690, p < 0.001, Exp(B) = 0.502). Individuals who do not have green space in their urban living environments are 52.8% times less likely to be in "good/very good" category (B=-0.750, p<0.001, Exp(B)=0.472). Individuals who perceive their urban living environments negatively and at moderate level are less likely (81% and 37.4% times respectively) to perceive their health at "good/very good" level compared to "bad" and "very bad" assessment categories (B=-1.662, p<0.001, Exp(B)=0.190; B=-0.469, p<0.001, Exp(B)=0.626).

Table 3. Multinomial Model Results (Overall Health Assessment is at Good/Very Good Level)

	[EnvironmentAttitude=3.00]	0[b]			0				
	[PhysicalActivityLevel=1.00]	**0.841**	**0.176**	**22.940**	**1**	**0.000**	**2.320**	**1.644**	**3.273**
	[PhysicalActivityLevel=2.00]	**1.041**	**0.267**	**15.166**	**1**	**0.000**	**2.832**	**1.677**	**4.782**
	[PhysicalActivityLevel=3.00]	0[b]			0				
	[BMI=1]	**0.910**	**0.218**	**17.437**	**1**	**0.000**	**2.484**	**1.621**	**3.808**
	[BMI=2]	**0.458**	**0.200**	**5.218**	**1**	**0.022**	**1.580**	**1.067**	**2.340**
	[BMI=3]	0[b]			0				
	[LifeSatisfaction=1.00]	0.166	0.304	0.297	1	0.586	1.180	0.650	2.144
	[LifeSatisfaction=2.00]	**-1.321**	**0.291**	**20.602**	**1**	**0.000**	**0.267**	**0.151**	**0.472**
	[LifeSatisfaction=3.00]	0[b]			0				

a. The reference category is: bad/very bad.

b. This parameter is set to zero because it is redundant.

Individuals who do not have green space (Greenspaceref=2) in their urban living environments are 70.7% less likely to have "bad" and "very bad" health status (B= -0.750, Exp(B)=0.293, p<0.001). Individuals with negative life satisfaction are 73.2% less likely to have good or very good health perceptions (B= -1.321, Exp(B) = 0.267, p<0.001).

5. Discussion: Potentials and Challenges for Urban Living Environments

Built environment characteristics and socioeconomic factors (such as education, socioeconomic status), lifestyle preferences (physical activity levels, BMI) have a significant impact on overall health assessment. Individuals with SES levels times higher perceptions of good and very good health. Individuals with lower BMI have a significant relationship with health perception. Similarly, physically active individuals are more likely to have moderate to "good" or "very good" health perceptions. Individuals with lower life happiness also have a similar effect on health perception.

These findings, in line with the World Health Organization's health determinants (WHO, 2018) and the "Health in All Policies" approach, demonstrate that health outcomes cannot be attributed solely to the health sector; instead, socioeconomic and physical environmental factors play critical roles. Similarly, the social determinants framework, as emphasized by Wilkinson and Marmot (2003), has highlighted the significant impact of education, income, environmental quality, and social support mechanisms on health. The findings of this study also support the propositions in the literature, indicating that urban planning, education, and social welfare policies should be addressed together in health improvement strategies, particularly in urban areas.

This evidence-based research supports a holistic framework that enables the development of healthier societies by transforming the social and physical environments in which individuals live. The focus should be at the community level rather than solely on individual behavioral change.

This holistic approach will enable the construction of healthier societies by transforming the social and physical environments in which individuals live, rather than focusing solely on individual behavioral change. Some of the significant policies can be listed as follows:

- Increasing investments in education, supporting programs for lifelong learning, and improving individuals' health literacy
- Prioritizing physical environmental criteria such as walkability ease of access and proximity to green areas in urban planning,
- Developing mechanisms to strengthen life satisfaction and social connectedness through community-based interventions,
- Establishing multi-sectoral collaborations to promote healthy weight management and physical activity.

Abstract
This paper explores the role of artistic practices in rural transformation, regarding their influence on rural gentrification and spatial dynamics in particular. Urladam, an art space located in Urla, is examined as a threshold where rural and urban, public and private, and artistic and communal dimensions intersect. Through a hybrid methodology, including archival review, spatial analysis, mapping, and interviews, the study evaluates Urladam's architectural setting and public presence.

Findings suggest that Urladam operates as a transitional zone where artistic engagement contributes to reconfiguring rural identity. The paper underscores the potential of art spaces in re-shaping inclusive rural development, and question their role in socio-spatial change and inequality.

It illustrates how art mediates spatial transition and fosters dialogue between contrasting rural-urban identities.

Keywords: Rural Gentrification, Art Spaces, Threshold, UrlaDam

1. Introduction

Rural areas, once viewed primarily as peripheral, low-density agricultural zones, have increasingly become central sites in global economic and spatial transformations. Far from being passive landscapes, these regions now host complex networks shaped by cultural, economic, and political dynamics. Across the globe, including Türkiye, rural territories are being reshaped by processes such as counter-urbanization, real estate speculation, and the cultural industries, prompting new forms of investment, lifestyle migration, and cultural production. As rural gentrification intensifies, rural spaces have become contested terrains where traditional identities, market forces, and new socio-spatial imaginaries intersect.

The district of Urla, located along the Aegean coastline of İzmir-Türkiye, exemplifies this rural transformation. Originally characterized by its agricultural and coastal heritage, Urla has increasingly attracted white-collar professionals and cultural entrepreneurs seeking alternatives to metropolitan living. The COVID-19 pandemic further accelerated this shift, amplifying desires for proximity to nature, flexible spatiality, and cultural immersion. In this context, cultural venues such as art spaces have proliferated, transforming not only the aesthetic landscape, but also the social and symbolic dynamics of rural life.

This paper examines Urladam, a contemporary art space situated in Urla, through the conceptual lens of the "threshold." Drawing from Stavros Stavrides' theoretical framework, thresholds are understood not merely as transitional boundaries, but as spaces of encounter, where distinct social, cultural, and spatial domains are negotiated. Urladam, in this regard, operates as a site where the rural and the urban, the traditional and the contemporary, the private and the public come into contact. The study explores how such an art space mediates socio-spatial dynamics associated with rural gentrification, contributes to community engagement, and influences cultural identity within its locale.

Rather than presenting a data-driven case analysis, this paper offers a theoretical and conceptual reflection grounded in broader research. It investigates how contemporary art spaces in rural contexts may function as semi-public environments, shaping new modes of visibility, participation, and cultural production. By focusing on Urladam, the study asks: To what extent can an art space act as a transformative public realm within a rural gentrification process? What forms of publicness does it enable, and for whom?

These questions are addressed through an interpretive reading of the literature and field experience, while empirical data and detailed case analysis are reserved for forthcoming academic publications. This methodological choice enables a focus on the theoretical relevance of the process, drawing from the recently completed master's thesis *"URLADAM: Investigation into Emerging Rural Artification"* (Izmir Institute of Technology, 2025). The study contributes to broader debates on public space, cultural production, and rural transformation, offering insights into how art can intervene in the redefinition of the rural as a lived and represented space.

In order to explore how such an art space navigates its role within rural gentrification, the next section outlines the conceptual lens of "threshold spaces." This framework draws from interdisciplinary literature on spatial theory and cultural production, offering a foundation for analyzing Urladam's positioning at the intersection of rural identity and contemporary artistic practices. To investigate how an art institution like Urladam navigates its role within ongoing processes of rural change, the next section elaborates the concept of "threshold spaces." This framework unveils interdisciplinary literature on spatial theory and cultural production, including the spatial triad of Keith Halfacree (2006), Henri Lefebvre's (1991) concept of lived space, and Nancy Fraser's (1990) idea of subaltern counterpublics. Together, these insights provide a foundation for a deeper understanding of how contemporary art engages with rural gentrification and socio-spatial reconfiguration.

2. Conceptual Framework: Threshold Spaces and Publicness

This section explores the conceptual framing of "threshold spaces" to analyze the transformative role of art institutions, particularly Urladam, within the processes of rural gentrification and socio-spatial transformation. Art spaces, when situated in rural contexts, not only function as platforms for cultural production but also operate as mediating environments that engage with local identities, economies, and spatial configurations. Building upon the insights of scholars such as Stavros Stavrides (2010, 2016), Henri Lefebvre (1991), and Keith Halfacree (2006), this study positions Urladam as a spatial threshold that connects traditional rural character with emerging dynamics of urban cultural production. Within this framework, the concept of "threshold" is employed to describe spaces of transition, sites that simultaneously separate and connect divergent socio-spatial domains. The threshold is thus not a fixed border but a dynamic zone of interaction, negotiation, and transformation. The integration of art spaces into rural environments contributes to the redefinition of these locales, a process often catalyzed by counter-urbanization and rural gentrification. This dual dynamic migration from urban centers and the attraction of investment, alters the cultural, social, and spatial fabric of rural areas. In this sense, art spaces are not passive reflections of change but active agents in producing new meanings, practices, and representations of rural life.

In Urladam's case, its architectural flexibility, hybrid programming, and public accessibility position it as a site of both cultural production and social engagement. Through exhibitions, community events, and participatory practices, Urladam facilitates encounters between diverse user groups and fosters the visibility of emergent identities and narratives. Its existence exemplifies Nancy Duxbury's (2011, 2020) argument that rural cultural practices are not merely residual or traditional but actively shape new forms of localized resilience and identity.

Furthermore, this conceptual framing draws upon Adorno and Horkheimer's (2002) critique of the culture industry to interrogate how art spaces participate in commodification processes. Urladam's hybrid model, balancing between market pressures and inclusive cultural production, enables a more nuanced understanding of how rural art institutions negotiate their roles within capitalist dynamics without fully succumbing to them. The tension between artistic autonomy and market integration becomes particularly significant in rural contexts

where economic infrastructures are fragile.

This study also considers how Urladam diverges from the "White Cube" paradigm (O'Doherty 1986) by resisting spatial and ideological neutrality. Instead of isolating artworks within sterilized environments, Urladam incorporates contextual references, local materials, and flexible spatial arrangements that reflect its embeddedness within the community. This spatial strategy enhances its function as a threshold, allowing for site-responsive engagements and multi-directional flows between the institution and its surroundings.

Through this conceptual lens, Urladam is analyzed as a site of spatial negotiation, socio-cultural interaction, and economic integration. It serves as a node in wider artistic and cultural networks while remaining grounded in its immediate rural environment. By operating within this threshold zone, it becomes a space where urban desires, rural traditions, and contemporary cultural practices converge.

In doing so, this section lays the groundwork for section 3, where Urladam's spatial configuration, public representation, and everyday interactions will be analyzed through a three-fold methodological lens. The goal is to trace how the conceptual framework of "threshold" becomes materially and experientially embodied in Urladam's architecture, programming, and role within Urla's evolving socio-spatial context.

3. Rural Context and the Rise of Contemporary Art in Urla

Urla is located 38 km from the city center of Izmir and plays a significant role in the province's urban Situated on the western edge of İzmir and covering 728 square kilometers, Urla has become a focal point of rural transformation in Türkiye. Its strategic location, Mediterranean climate, and historical depth have long shaped its identity; however, recent demographic and socio-spatial shifts have redefined its role within the regional context. According to the Turkish Statistical Institute (TUIK), Urla's population grew from 62,439 in 2016 to 77,599 by 2023, a 24.5% increase reflecting broader post-COVID trends of urban-to-rural migration.

Figure 3.1. Location of Urla District
(Source: Google Earth Software and QGIS).

Traditionally rooted in agriculture and coastal trade, Urla's economy and spatial configuration evolved through various historical layers, from Ionian settlements to Ottoman-era migrations. This multi-layered heritage is visible in its built environment and agrarian practices, particularly olive oil and wine production. The contemporary restructuring of Urla's identity is not only material but also symbolic, shaped by shifting class dynamics and cultural investments.

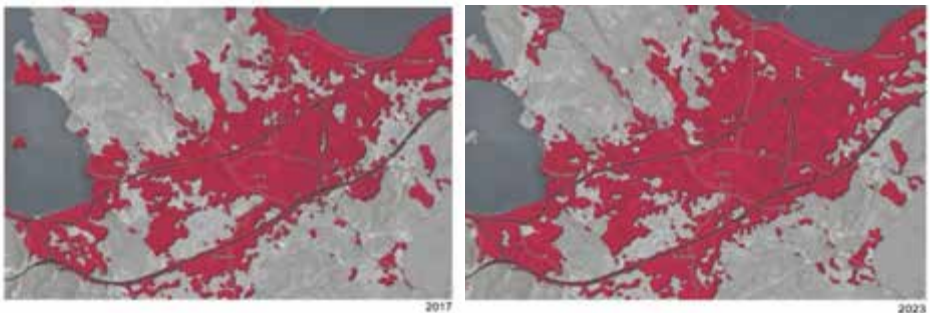

Figure 3.2. Population Change between 2017 and 2023
(Source: TUIK).

In recent years, Urla has attracted cultural entrepreneurs, artists, and white-collar migrants seeking alternatives to urban life. This transformation is particularly evident in the rise of gastronomic tourism, art venues, and boutique accommodations. Initiatives such as the Urla Vineyard Route (Urla Bağ Rotası), organic food markets, and Michelin-starred restaurants reflect a shift toward curated rural lifestyles. Yet, these developments have also fueled property speculation and displaced traditional communities, an unmistakable marker of rural gentrification.

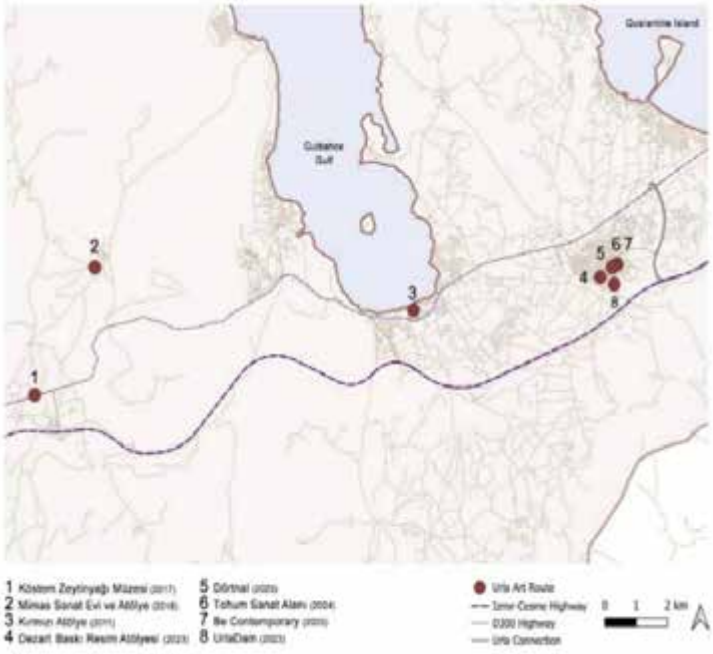

Figure 3.3. Location of Urla Art Spaces
(Source: Google Earth Software and QGIS).

Urla's emerging cultural infrastructure includes a network of decentralized art spaces that engage with both local heritage and contemporary practices. Institutions such as Köstem Olive Oil Museum, Mimas Art House, and UrlaDam contribute to a multi-layered cultural ecosystem. These venues not only support artistic production but also play a role in spatial redefinition, shaping new patterns of cultural participation and visibility.

UrlaDam, in particular, represents a large-scale intervention into the rural cultural landscape. Founded in 2023, the venue integrates performance spaces, workshops, and accommodation facilities within a single compound.

Positioned at the intersection of rural heritage and contemporary cultural production, it exemplifies the duality of cultural revitalization and exclusivity. While offering opportunities for creative engagement, UrlaDam also underscores key tensions around publicness, commodification, and social inclusion.

This evolving cultural scene calls for a nuanced assessment of how creative industries reshape rural space, not just economically, but socially and symbolically. The next section delves deeper into UrlaDam's representational strategies and everyday practices, exploring how its operations reflect and negotiate broader dynamics of rural transformation.

4. UrlaDam and the Everyday: Threshold Public Space in a Cultural Campus

This section examines Urladam as a lived and represented rural cultural public space, drawing upon Keith Halfacree's (2006) triadic model of rural space, which comprises material practices, representations, and everyday experiences. Rather than serving as a neutral space for artistic display, Urladam functions as a site where cultural identity, publicness, and rural transformation intersect.

From Henri Lefebvre's (1991) perspective of "lived space," Urladam's spatial organization and programming generate opportunities for encounter and interaction. Open-air stages such as Ağaçlı Sahne and modular venues like Hangardam promote flexible and accessible forms of engagement, allowing artistic practices to merge with the rhythms of everyday rural life. Events such as exhibitions, concerts, workshops, and children's programs support this integration of art into daily experience. Brian O'Doherty's (1986) critique of the "white cube" further contextualizes Urladam's rejection of traditional gallery neutrality.

Founded in 2023 by renowned Turkish actors Ercan Kesal and Nazan Kesal, Urladam emerged from the couple's vision of establishing an independent arts space rooted in Urla's unique cultural and ecological landscape. While Ercan Kesal is primarily known for his appearances in television and cinema, Nazan Kesal is a prominent figure in Turkish theater. During interviews conducted with Ercan Kesal on August 14, 2024, as part of this study, the founder emphasized the significance of İzmir and Urla as places of cultural inspiration and personal renewal (Kesal Ercan 2024). He noted that the couple began spending more time in Urla during the COVID-19 pandemic, which eventually led to the idea of creating a cultural campus in the region (Kesal Ercan 2024). This direct engagement enabled a deeper understanding of the intentions behind the formation and spatial design of the space. As a private enterprise, Urladam was established with the aim, in Ercan Kesal's words, of creating a place where people can spend time freely, relax, and engage in artistic production (Kesal Ercan 2024). Its design highlights the connection to the rural environment through the use of natural materials and open spaces, promoting local participation. This contributes to a more open, locally grounded mode of artistic production.

Architectural and symbolic choices, such as the naming of spaces like the Sabit Kemal Bayıldıran Library, shape the venue's identity and suggest links to specific cultural narratives. While these associations enrich the space's meaning, they may also reflect selective curatorial visions shaped by personal or philanthropic influence.

The semi-private nature of Urladam introduces tensions between accessibility and exclusivity. Although many events are free of charge, features such as a luxury cafe and on-site accommodation imply a dual audience: one that is local and community-focused, and another that is more affluent and mobile. This dynamic raises important questions about who participates in cultural life, and under what conditions.

Figure 4.1. View of UrlaDam from above
(Source: Izmir.Art, 2024).

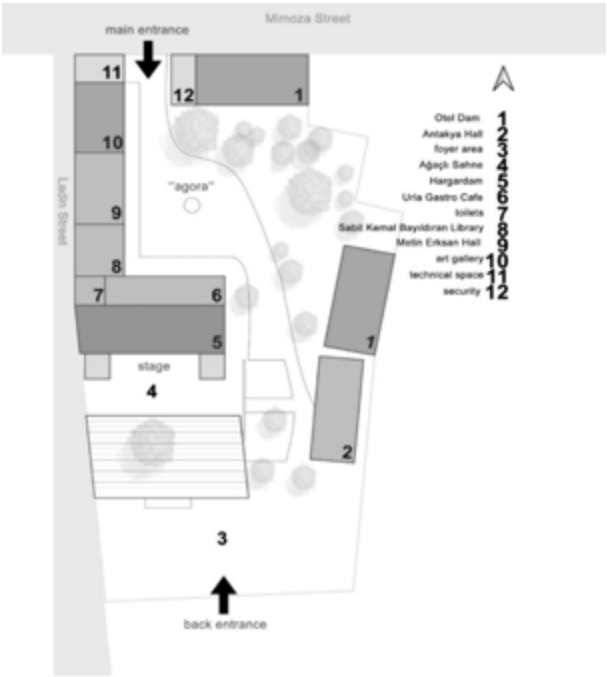

Figure 4.2. Non-scaled Plan Indicating Functional Areas.
(Source: Created by the author).

In spatial terms, Urladam's design contributes significantly to its threshold character. The site is anchored by two main entrances, one facing Mimoza Street and the other connected to a secondary parking area, linked by a clearly defined circulation axis that organizes access and movement. These physical boundaries demarcate the internal campus from its surroundings, generating a sense of both inclusion and separation. Upon entering through the main gate, visitors encounter a central plaza organized around a decorative fountain and red basalt paving stones. Surrounded by multifunctional structures, this semi-enclosed space functions as an informal gathering point and transitional zone.

The spatial configuration reflects various embedded thresholds: the Art Gallery, a single-story exhibition space with a skylit steel roof that echoes the "white cube" typology, establishes a zone of aesthetic focus. Nearby structures such as the Metin Erksan Hall (a small-capacity venue used for talks, screenings, and workshops) and the Sabit Kemal Bayıldıran Library (a poetry-focused library and intimate reading space) provide more dialogic and discursive environments. Gradual elevation changes across the site, especially from the Hangardam (a large, single-story multipurpose indoor hall with a stage used for fairs and screenings) toward the open-air Ağaçlı Sahne (an outdoor stage integrated into the sloped landscape, with seating organized around a preserved tree for concerts and performances) support fluid yet layered experiences of movement and encounter. Notably, the arched stone entrance leading into Ağaçlı Sahne physically marks a passage from the public plaza to the event space, reinforcing spatial symbolism.

The Antakya Hall (a single-story venue with a stage located near the exit and accommodation area) and the adjacent foyer area (a grass-covered transitional space used for pre-event gatherings and sponsor installations) further exemplify how function and spatial sequencing contribute to the condition of threshold. Material choices also reinforce this layered threshold quality. The reuse of local stone, red basalt pavement, and wrought iron details evoke vernacular aesthetics while reinforcing site-specificity. Meanwhile, preserved trees integrated into the design, such as those embedded within the seating rows of Ağaçlı Sahne, blur the boundary between natural and constructed environments.

These design strategies enhance both the temporal and social dimensions of threshold space: while visitors may arrive for a scheduled performance, they often linger—perhaps spending time at the Urla Gastro Cafe (a semi-open cafe overlooking the central plaza), interacting with artists staying at the Otel Dam (a two-story accommodation unit serving both resident artists and guests), or browsing a book fair between concerts. Events such as the D&R Book Festival or children's painting workshops utilize different segments of the site simultaneously, expanding the experiential depth of the venue. Additional infrastructural spaces such as the technical area (a support zone for logistical and technical needs) and security (the main controlled access point at the Mimoza Street entrance) define the operational thresholds of the site, balancing openness with necessary regulation.

In sum, Urladam exemplifies the evolving character of rural public spaces, neither entirely open nor wholly exclusive, but shaped by spatial design, curatorial decisions, and patterns of social access.

Beyond its spatial configuration and material articulation, Urladam's threshold character is further reinforced by its intensive and diverse programming. Throughout the year, the venue hosts a remarkable number of events, from exhibitions and concerts to workshops, film screenings, and literary festivals. This consistent density of cultural programming not only activates physical spaces but also cultivates a dynamic temporality, one in which the site is continuously reanimated by diverse publics and practices.

Figure 4.3. D&R – UrlaDam Book Festival

Between July and October 2024 alone, Urladam hosted 9 exhibitions, 10 theater and performing arts events, 16 concerts, and 12 distinct types of workshops, amounting to a total of 46 sessions. Additionally, 25 festivals and film screenings and 17 author talks and book signing events were organized across various venues. These events were not always sequential; some took place simultaneously in different spaces across the site. This simultaneity is made possible by Urladam's spatial configuration, which accommodates diverse programming capacities, while one visitor may attend a workshop at Metin Erksan Hall, another might enjoy a concert at Ağaçlı Sahne, and a third may simply have coffee at the cafe. This diverse and continuous event calendar exemplifies the multiplicity and layered temporality of Urladam's cultural life. Its role in Urla's cultural ecosystem reflects both the potentials and contradictions of art-led rural transformation, operating as a threshold that bridges the everyday and the exceptional, the local and the curated, the physical and the symbolic.

The data gathered was further visualized through a spatial circulation analysis, highlighting patterns of movement and interaction across Urladam's venues. This analysis also incorporated insights derived from user feedback and field observations, particularly regarding the frequency of visits to shared spaces like the cafe. It was found that the cafe emerged as one of the most frequently used and crowded spaces, due to its proximity to major event venues and its social function. Visitors often used the cafe after attending exhibitions, concerts, and theater performances, turning it into a central hub for informal interaction. Moreover, due to parking challenges in Urla, Urladam has increasingly functioned as a public site for external visitors, offering both a parking solution and access to its cafe, reinforcing its spatial and social utility. A graphic representation of this circulation analysis is provided below to more clearly illustrate these spatial dynamics.

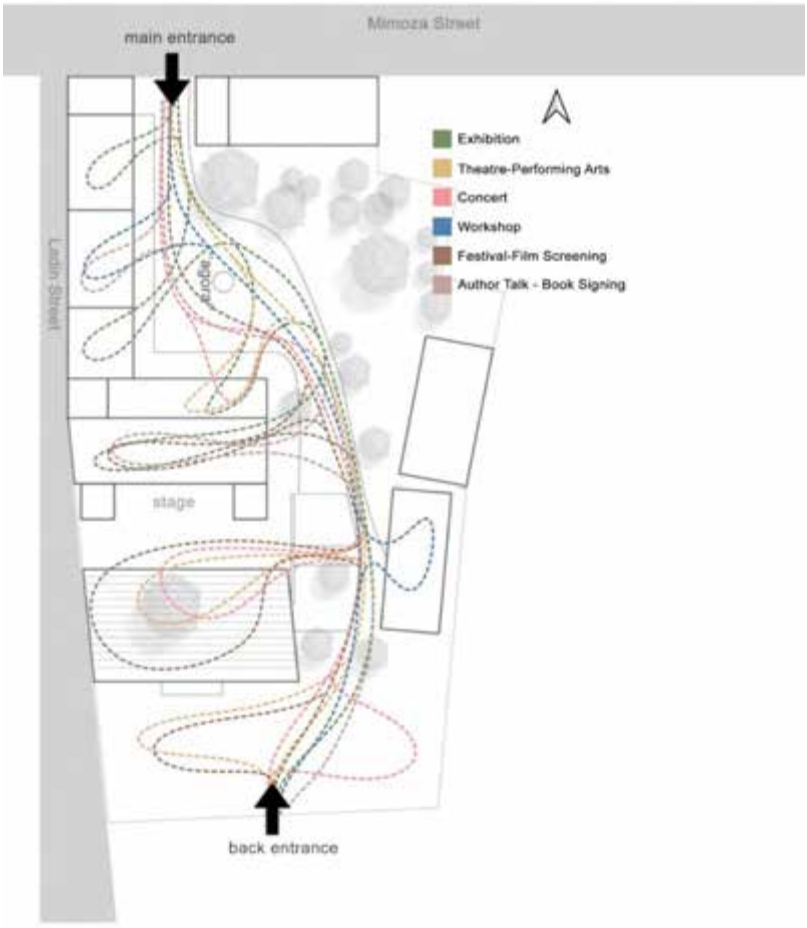

Figure 4.4. Circulation Analysis Based on Spatial Usage Analysis (Source: Created by the author).

In parallel with its spatial circulation and architectural organization, UrlaDam also pursues an aggressive strategy in terms of media visibility. Although in interviews Ercan Kesal emphasized that their primary goal was to let UrlaDam be known through word-of-mouth, the venue actively utilizes platforms such as Instagram, YouTube, and its official website to promote upcoming events, share interviews, and foster audience engagement. These digital platforms serve not only as tools of communication but also as extensions of the venue's publicness in the virtual realm, reinforcing its threshold status by broadening access to its content.

UrlaDam's Instagram account functions as a visual archive, documenting the rhythm of its artistic life through curated photographs and stories, while its YouTube channel hosts interviews, event footage, and commentary, enabling asynchronous participation for geographically distant audiences. This constant digital activity contributes to the emergence of a hybrid public sphere, where physical presence is no longer a prerequisite for participation. In 2023 and 2024, UrlaDam was featured in 22 newspaper articles across local and national media outlets such as Sabah, Milliyet, Karar, HaberEkspres, and GazeteDuvar. This strong media presence demonstrates that UrlaDam aims not only to function as a local cultural center but also to establish itself as a national point of interest within Turkey's cultural scene. Media coverage was particularly amplified during large-scale events like the D&R Book Festival and Urla Jazz Festival, further solidifying the venue's image as a hub of cultural activity.

The strategic integration of both traditional and digital media illustrates how UrlaDam cultivates a multifaceted presence, merging physical, symbolic, and digital thresholds and offering multiple points of access to a diverse audience. This strong media visibility reinforces UrlaDam's role not merely as an event venue, but as a producer

of cultural practices that permeate everyday life. Its presence across both digital and traditional media platforms extends beyond physical events, making visible the intersections between art and daily routines. In doing so, UrlaDam's impact evolves into a deeper "lived space" experience, not limited to a static cultural calendar.

UrlaDam's influence on everyday life in Urla can thus be interpreted through the lens of lived experience and everyday practice. Its diverse programming, ranging from art exhibitions and literary talks to concerts and workshops, establishes a recurring rhythm of public engagement, integrating artistic expression into the routines of local residents and visitors alike. Rather than remaining isolated as cultural spectacles, these activities become woven into the fabric of the town's everyday life, creating shared moments of reflection and participation. In line with this vision, Urladam's owner Ercan Kesal has emphasized that Urladam was intended not only to contribute to cultural enrichment, but also to strengthen social cohesion by functioning as a permeable and inclusive space (Kesal Ercan 2024). This section explores how such experiences resonate with broader debates on rural transformation and the redefinition of public space in contemporary Türkiye.

5. Discussion: Publicness at the Edge of Rural Gentrification

This section critically engages with the concept of publicness within the framework of rural gentrification, drawing upon the theoretical concepts introduced earlier and building on the observations and in-depth interview discussed in the previous section.

Publicness is traditionally associated with accessibility, inclusivity, and collective use. However, in gentrifying rural contexts such as Urla, it becomes a layered construct shaped by economic, cultural, and symbolic power. Rural gentrification initiates spatial and social restructuring through the influx of upper-middle-class populations, leading to rising property values, aesthetic curation, and cultural displacement.

Urladam exemplifies this paradox. As explored in section 4, it functions as a "threshold space" neither fully public nor entirely private, inviting wide participation while embedding selective forms of access. Its architectural configuration, diverse programming, and curatorial framing reflect a model of selective inclusivity: outwardly open, yet subtly aligned with the preferences of culturally privileged groups.

The venue's simultaneous hosting of multiple events, such as workshops, concerts, and literary talks, demonstrates an impressive cultural density. Yet this density does not automatically translate into egalitarian access. While many events are nominally open to the public, their aesthetic, linguistic, and symbolic framing often appeals to urban-educated, mobile demographics. As emphasized by Ercan Kesal in interviews, Urladam was intended to be a space "where one can breathe, create, and rest." But who can afford to breathe there, and who feels invited, remains a socially mediated question.

This duality aligns with Nancy Fraser's (1990) notion of "subaltern counterpublics," where alternative publics emerge within dominant cultural frameworks but remain structurally marginalized. Urladam creates moments for new voices, especially during festivals and workshops, yet it simultaneously participates in hierarchies of taste, access, and legitimacy. Spatial-symbolic elements further complicate the idea of publicness. Open-air stages and features like the preserved tree at Ağaçlı Sahne signal inclusivity, while donor naming, selective cultural references, and visual branding introduce soft exclusions. The spatial circulation study also highlighted the cafe as a central informal gathering point, but its pricing and ambiance arguably cater more to a visitor profile shaped by lifestyle migration than local everyday life. As a whole, Urladam exemplifies how cultural infrastructures can operate as subtle engines of rural gentrification. These spaces do more than host artistic programs, they contribute to shaping cultural legitimacy, aesthetic norms, and everyday rhythms. In doing so, they influence who feels welcome, who belongs, and under what conditions participation becomes possible.

In sum, publicness at the edge of rural gentrification is not a static attribute but a continuously negotiated and contested process. Urladam, as a threshold cultural space, reflects this ambivalence: open yet selective, dialogic yet curated, inclusive in rhetoric yet exclusive in effect. Recognizing this ambivalence is crucial, not to

dismiss such initiatives, but to reframe future strategies in rural cultural development toward equity, grounded participation, and spatial justice.

6. Conclusion

This study set out to explore UrlaDam as a cultural infrastructure embedded in the shifting terrain of rural transformation, offering a nuanced examination of public space, artistic engagement, and social stratification. Through the analysis of spatial, representational, and everyday practices, it has been shown that UrlaDam functions as more than a venue for cultural programming, it is a site where the complexities of publicness, artistic identity, and rural gentrification converge.

Rather than offering final answers, the findings encourage deeper interrogation of the paradoxes within contemporary rural public spaces. While UrlaDam aspires to inclusivity through its programming and open-access philosophy, in practice, the socio-economic and spatial filters embedded in its structure and operation reveal selective modes of participation. Its dual identity as both a public space and a private cultural institution reflects broader tensions in the cultural field, where autonomy, accessibility, and aesthetic value are constantly negotiated.

By operating as a threshold space, between urban and rural, private and public, exclusive and inclusive, UrlaDam highlights the symbolic and material ambiguities of contemporary cultural development. Its visibility in digital media and participation in global cultural networks situates it within a broader system of artification, where aesthetic and institutional logics reshape not only space but also social relations. This contributes to rural gentrification, not merely as a material process of displacement but as a symbolic restructuring of belonging and identity.

In sum, publicness at the edge of rural gentrification is not a static attribute but a continuously negotiated and contested process. Urladam, as a threshold cultural space, reflects this ambivalence: open yet selective, dialogic yet curated, inclusive in rhetoric yet exclusive in effect. Recognizing this ambivalence is crucial, not to dismiss such initiatives, but to reframe future strategies in rural cultural development toward equity, grounded participation, and spatial justice.

As a result, this research underscores the need to approach rural cultural infrastructures with a critical lens, recognizing their potential to generate both engagement and exclusion. The findings suggest that the presence of art in rural areas should not be taken as inherently democratic or transformative, but must be evaluated in terms of who participates, who benefits, and how these dynamics shape rural futures. Ultimately, the case of UrlaDam invites reconsideration of what constitutes a public art space in a rural setting. It raises critical questions about how cultural venues can navigate the fine line between creative autonomy and social responsibility, between curatorial vision and inclusive participation. While the site may offer moments of artistic encounter and cultural dialogue, these are shaped—and at times constrained, by economic, spatial, and symbolic forces.

Rather than concluding the conversation, this paper proposes new lines of inquiry, particularly for future academic work that seeks to align cultural production with principles of spatial justice and social equity. UrlaDam is not simply a site of cultural production, it is a node in the broader reconfiguration of rural space, offering both inspiration and caution in thinking about the future of art, community, and territory.

Community Reading Spaces as Social Infrastructure: A Case Study of Nanjing

Xinkai Yang, Li Bao*
Southeast University, School of Architecture
Email: 572802938@qq.com

Abstract
This study conceptualises community reading spaces as essential social infrastructure that promotes spatial justice and social capital. Drawing on case studies from Nanjing, it proposes a three-dimensional interactive framework integrating physical, institutional, and social perspectives to analyse the mechanisms underlying their social functions. Through comparative analysis of three governance models—leading, co-operative, and autonomous—the study explores how different operational logics affect the dual social functions of reading spaces. The findings highlight the complementary logic among governance types and offer theoretical and practical insights into enhancing the inclusivity and relational capacity of urban cultural services.

Keywords: Community reading spaces; Urban governance; Social infrastructure; Spatial justice; Social capital

1. Introduction: Urban Transformation, Community Needs, and the Multifaceted Value of Reading Spaces

Despite the rapid development of modern cities, they face persistent challenges such as social atomisation, weakened neighborhood ties, and the erosion of public life (Putnam, 2000; Giddens, 1991). In this context, reshaping the urban public sphere, fostering community belonging, and strengthening social cohesion have become critical concerns in contemporary urban governance.

In response, the concept of *social infrastructure* has garnered increasing attention from both scholars. It refers to "soft" facilities such as libraries, parks, and community centers that support daily life, promote social interaction, and maintain community networks (Klinenberg, 2018; Latham & Layton, 2019). These spaces serve not only as service providers but also as foundational elements of urban public life (Amin, 2002) and "key sites" for building trust and fostering interaction. Amin (2014) emphasised that "micro-public spheres" and informal everyday interactions are crucial for sustaining urban vitality. Accordingly, the effective functioning of social infrastructure is regarded as a vital mechanism for enhancing community resilience and promoting social equity.

Following rapid urbanisation, Chinese urban communities have increasingly become essential units of social management and public service provision. Concurrently, residents' demands for cultural engagement and public communication spaces have significantly intensified. In response, the government has been actively promoting the construction of a public cultural service system, and initiatives such as *National Reading* have been elevated to strategic national priorities (General Office of the CPC Central Committee & General Office of the State Council, 2015), aiming to enhance national literacy and cultural engagement. Within this framework, *community reading spaces* have emerged as significant focal points, presenting new opportunities for development.

In this paper, *community reading spaces* refer to public-interest venues established by government bodies or civil society organisations within specific localities. These venues provide access to literary and digital resources and offer a range of reading-centered services and activities. They include public libraries, cultural centers, bookstores, airports, cafes, hotels, and other publicly accessible spaces. These spaces prioritise openness and service provision to the general public. Therefore, institutional libraries (e.g., university or school libraries) and private reading spaces are not within the scope of this study.

From traditional grassroots libraries to contemporary "urban study rooms," independent bookstores, and private reading clubs, a diverse and evolving network of community reading services has taken shape. These spaces are entrusted with multiple social functions, including knowledge dissemination, cultural consumption, neighborhood interaction, and community cultural development (Wang Zizhou, 2017). However, the practical mechanism of such spaces remains more complex than anticipated. Challenges such as underutilisation, operational inefficiencies,

and significant disparities in service models, target groups, and social impact persist. These issues highlight the need for in-depth exploration of the material, institutional, and social foundations of these spaces and their interrelations.

In light of these challenges, this study conceptualises community reading spaces as a critical form of social infrastructure and seeks to investigate their underlying mechanisms. By integrating material, institutional, and social perspectives, this research addresses the following core questions: In the context of China's rapid urbanisation and the evolving public cultural service system, how should community reading spaces be understood as urban social infrastructure? What kinds of interaction mechanisms exist among their physical, institutional, and social elements? How do these mechanisms influence their overall social functions? Moreover, how do community reading spaces operating under different governance models differ in achieving these social functions?

2. Literature Review: Fragmented Perspectives and the Need for Integration

Community reading spaces, as integral components of urban social structures and public life, have garnered increasing scholarly attention concerning their planning, spatial construction, institutional governance, and social impact. While research from various disciplinary perspectives has explored their physical configuration, governance mechanisms, and social functions, most studies tend to focus on a single dimension. This narrow focus often fails to uncover the complex interrelations among physical environments, institutional frameworks, and social practices that define their overall effectiveness.

This chapter presents a systematic review of existing literature on community reading spaces and libraries, critically evaluating the contributions and limitations of different analytical perspectives. It highlights the fragmented nature of current research and advocates for the construction of an integrative framework. This theoretical basis informs the subsequent case-based analysis of community reading spaces in Nanjing.

2.1 Physical Perspective: Reading Spaces as Public Service Facilities

As a key aspect of social infrastructure, the physical characteristics of public reading spaces play a fundamental role in determining the fairness of resource allocation and the quality of user experience. Earlier research—particularly in the fields of library science and urban planning—focused on the quantitative assessment of spatial distribution of cultural facilities. Common methodologies included Geographic Information System (GIS) analysis based on service radius, population coverage, and per capita usage area (Cervero, 1998; Johnson, 2010). For example, studies in the UK and Nordic countries have used spatial models to assess alignment between library networks and residential distribution in order to achieve equitable access. In China, Dai Yanqing (2021) used network analysis to assess the accessibility of newly constructed public reading spaces in Changsha and proposed strategies for site selection and coverage optimisation.

In the context of China's push toward standardizing and equalizing public cultural services, researchers have drawn attention to the persistent "reading facility gap" between urban and rural areas and across regions. Ke Ping (2020) discussed fragmentation in the Co-operative governance of urban and rural library systems, advocating for a more integrated service network. Wang Zizhou (2020) examined how spatial restructuring and cultural drivers have facilitated the rise of "urban study rooms."

As the research has evolved, scholars have recognised that spatial accessibility alone is insufficient. The quality of the physical environment also significantly influences readers' usage behavior, spatial attraction, and cultural engagement. Design features—such as interior layout, ambiance, lighting, and functional zoning—shape user experience and the symbolic meaning of space (Aabø & Audunson, 2012; Hille, 2019). Bao Yaming (2021) emphasised that the experiential quality of cultural spaces determines whether they are genuinely "perceived" and "claimed" by users. In response, many contemporary reading spaces are designed with aesthetic appeal, human-centered layouts, and multifunctional facilities (e.g., leisure areas, parent-child corners, cafés) to enhance spatial engagement.

Nonetheless, the physical perspective has its limitations. First, conflating physical proximity with actual accessibility and benefit is misleading. As Wang Xuexi (2023) noted, user experience may still be hampered by barriers such as rigid service rules, exclusionary attitudes, or poor information access. Vulnerable groups may be marginalised due to digital illiteracy or cultural unfamiliarity. Second, this perspective often relies on static indicators, overlooking how space is dynamically occupied, contested, and redefined in daily use. Space should be seen not only as a physical site but also as a platform for social practice and meaning-making. Therefore, evaluating the social functions of social infrastructure requires integration with institutional and user-centered perspectives.

2.2 Institutional Perspective: Reading Spaces as Governance Instruments

The institutional perspective foregrounds the idea that community reading spaces are not merely spatial constructs but institutionalised entities embedded within governance systems, policy frameworks, and resource allocation logics. From this vantage point, their construction and operation are reflections of broader power structures and governance models (Harvey, 1989; Smith, 2002). Key considerations include policy goal-setting, fiscal distribution, inter-agency coordination, and the adaptability of implementation processes.

In China, community reading spaces have predominantly followed a state-led governance logic. National initiatives, such as the *Regulations on Promoting National Reading* and the *14th Five-Year Plan for Public Cultural Service System Development*, advocate for the equalisation of cultural services and emphasise building urban–rural reading networks centered around public libraries. While this model guarantees baseline resource provision, it also faces limitations such as homogeneous services and administrative inefficiency (Ke Ping, 2018; Li Guoxin, 2018). Some local institutions fail to align services with user needs, resulting in "visible spaces with invisible services."

With the rise of "governance modernisation," hybrid governance models featuring multi-stakeholder collaboration have emerged. These include government contracting, NGO operations, and public–private partnerships (He Ze, 2023; Xu Yibo, 2022). For instance, Nanjing Library collaborates with nonprofits and bookstores to operate "urban study rooms," blending public missions with market flexibility via negotiated governance. Similar international examples include Dutch libraries repositioned as social innovation hubs emphasizing local autonomy (Van Melik & Merry, 2022).

This perspective also exposes structural inequalities. Resources are often disproportionately allocated to city centers, leaving peripheral or disadvantaged communities underserved (Wang Hui, 2021). Additionally, vulnerable populations such as seniors, persons with disabilities, and new migrants may lack representation in service planning and policy dialogues (Wang Sufang, 2020; Klinenberg, 2018). Without mechanisms that prioritise equity, community reading spaces risk exacerbating existing cultural disparities (Pateman & Vincent, 2010).

Institutional studies also draw attention to informal implementation dynamics. While policies establish macro-level frameworks, grassroots execution often requires adaptive practices and negotiated coordination by librarians, community workers, and partner organisations (Wang Ting, 2023). Audunson et al. (2020) described how tensions between formal institutions and everyday practices catalyze service innovation—a pattern that also applies to China's evolving reading spaces.

Nevertheless, the institutional lens has its own shortcomings. It tends to prioritise structural analysis at the expense of understanding lived experiences and micro-level interactions. While it highlights power and governance, it may not fully explain how institutions are reinterpreted through everyday practice. Thus, integrating institutional analysis with physical and social perspectives is essential for a more holistic understanding of the social functions of community reading spaces.

2.3 Social Perspective: Reading Spaces as Relational Infrastructure

The social perspective centers on how community reading spaces function as relational infrastructure—facilitating social interactions, fostering community identity, and enabling public cultural participation. This approach shifts attention from static configurations to the dynamic processes through which space fosters relationships and generates social capital.

Klinenberg (2018), in *Palaces for the People*, emphasised that social infrastructure such as libraries and community centers forms essential networks that sustain everyday social life and community resilience. Oldenburg's (1999) theory of "third places" further underscores their role as informal social venues where civic life unfolds beyond home and work. Svendsen (2013), studying Danish libraries, categorised them as incubators of social capital by fostering bonding (in-group trust), bridging (cross-group communication), and linking (institutional trust). Similarly, Aabø and Audunson (2012) found that Oslo libraries served as inclusive platforms for intergenerational and intercultural dialogue.

In China, empirical studies offer localised insights. Wang Sufang (2020) highlighted the inclusive practices of libraries for elderly users, showing how reading spaces enhance their social engagement and well-being. Xiao Qunzhong (2019) used interviews and ethnographic observations to document emotional exchanges and identity formation in "urban study rooms," emphasizing their role in cultivating a sense of place and local belonging.

Viewed through this lens, community reading spaces also contribute to civic cultivation and co-construction of cultural life. Pateman and Vincent (2010) argued that libraries should be sites of participatory democracy—facilitating not just access to knowledge but also critical discourse and civic engagement. Latham and Layton (2019) noted that the cultural value of social infrastructure relies on the "everyday social labor" of users, which requires deliberate planning and continuous support.

However, this perspective is not without its limitations. Some studies idealise the integrative potential of space while downplaying conflicts, exclusions, and underlying power dynamics. Hall et al. (2021) cautioned that even seemingly open spaces may reinforce social boundaries related to class, race, and age. Moreover, while rich in qualitative detail, many studies fail to analyze how social interactions are shaped by spatial and institutional conditions.

More critically, the realisation of the social functions of social infrastructure often hinges on overlooked forms of "emotional labor" and maintenance. As Schloffel-Armstrong (2024) noted, the sustainability of these spaces depends on invisible infrastructures—volunteer networks, emotional support mechanisms, and managerial coordination—that are rarely acknowledged in mainstream analyses. Without considering these support systems, it is difficult to fully understand how reading spaces sustain their social relevance over time.

2.4 Summary and Research Direction

A review of the literature from physical, institutional, and social perspectives reveals that each offers unique theoretical insights into the spatial attributes, governance dynamics, and social functions of community reading spaces. However, their fragmented application results in an incomplete understanding of the multifaceted role of these spaces as social infrastructure. The compartmentalisation of perspectives risks producing reductive conclusions that overlook the complex interactions among constituent dimensions.

This paper therefore proposes an integrated analytical framework centered on the three-dimensional interaction among physical, institutional, and social elements. Inspired by Schloffel-Armstrong et al.'s (2021) model of "library institution–architecture–interaction," this framework conceptualises community reading spaces as dynamic systems. Their social functions are seen as outcomes of the co-evolution of institutional logic (e.g., governance models, policy execution), material infrastructure (e.g., spatial design, accessibility), and social practices (e.g., relationship-building, community embedding).

This study applies the proposed framework to a set of representative community reading spaces in Nanjing, aiming to analyze how different governance models mediate the interplay among space, institutions, and society. The goal is to uncover the mechanisms through which these spaces, as social infrastructure, realise their social value in the context of rapid urbanisation, and to provide theoretical insights and practical recommendations for policy design and implementation.

3. Case Study of Community Reading Spaces

3.1 Theoretical and Analytical Framework

• Three-Dimensional Interaction Mechanism

This paper proposes and utilises the "physicality-institutionality-sociality" three-dimensional interactive mechanism as the core framework for analyzing the operational logic of community reading spaces. This framework transcends the static classification of spatial constituent elements, emphasizing that community reading spaces are not isolated physical facilities constructed in a vacuum. Instead, they are processual fields continuously generated, adjusted, and embedded in residents' daily lives against specific governance and social practice backgrounds. These three dimensions are intertwined, dynamically providing feedback to each other, and collectively shaping the operational logic and social value of community reading spaces as social infrastructure.

Physical Dimension (Physical Environment): Refers to the spatial attributes of community reading spaces, including geographical location, architectural form, internal structure, facility layout, and environmental atmosphere. These material foundations not only determine the accessibility and functional adaptability of the space (Gehl, 2011; Carmona, 2010) but also influence its attractiveness and receptiveness to specific groups (Bao Yaming, 2008).

Institutional Dimension (Institutional Governance): Encompasses institutional elements such as management mechanisms, policy systems, financial support, service models, and responsibility allocation. This dimension determines how spatial resources are deployed, how governing bodies participate, and the degree of user participation and voice (Bovaird & Löffler, 2015; Ostrom, 1990).

Social Dimension (Social Practice): Emphasises practical activities occurring within the space, such as community building, knowledge exchange, cultural participation, and daily interactions. Through these social behaviors, the space is endowed with cultural meaning and transformed into a key field for community interaction and social capital generation (Oldenburg, 1989; Klinenberg, 2018).

The relationship between the three dimensions is not a linear causal chain but a multi-directional, dynamically coupled feedback loop. For example, flexible and diverse physical design can stimulate daily interactive behaviors (Gehl, 2011); open and inclusive institutional arrangements can enhance residents' willingness to participate and sense of belonging (Larsen et al., 2021); and active social practices, in turn, may promote institutional innovation and spatial renewal (Hall, 2020). It is precisely this multi-level, bidirectional interactive mechanism that enables community reading spaces to continuously adapt to social changes and generate lasting social value.

• Dual Social Functions of Community Reading Spaces

As embedded social infrastructure serving public life, community reading spaces carry important social functions and values. This study believes that its core social objectives are mainly reflected in two closely related dimensions: the practice of spatial justice and the promotion of social capital.

Firstly, proceeding from its public attribute as "infrastructure," community reading spaces must respond to the issue of Spatial Justice. As critical geography theory emphasises (Harvey, 1973, 1989; Soja, 2010), space is not neutral but a field where social relations and inequalities are reproduced. Therefore, social infrastructure should aim to eliminate spatial injustice. Drawing on Nancy Fraser's (2008) theory of justice, the practice of spatial justice covers three levels: Distributive, Procedural, and Recognitive. In the context of community reading spaces, this means ensuring fair accessibility of resources (distributive justice), guaranteeing users a voice in

space management and decision-making (procedural justice), and recognizing and accommodating groups with different backgrounds and needs (recognitive justice).

Secondly, from its core attribute of "sociality," the key value of community reading spaces lies in promoting the generation and accumulation of Social Capital. Social capital is regarded as a social resource that connects individuals, enhances trust, and promotes collective action (Putnam, 2000). Community reading spaces, as "social places," contribute to the formation and strengthening of different types of social connections by providing interactive platforms and activity opportunities. According to the classification by scholars such as Putnam and Woolcock (2001), social capital can be divided into three forms: Bonding, Bridging, and Linking, corresponding respectively to connections within homogeneous groups, connections between heterogeneous groups, and connections between individuals/communities and external institutional resources. Community reading spaces enhance the cohesion, inclusiveness, and vitality of communities by promoting these connections.

The practice of spatial justice and the cultivation of social capital are two core social values pursued and generated by community reading spaces as social infrastructure. They are interrelated and together constitute an important perspective for measuring their social functions.

• Realizing Social Functions through Interactive Mechanisms

Community reading spaces, as a type of small-scale social infrastructure deeply embedded in everyday life, possess unique characteristics that make them ideal cases for analyzing how the three-dimensional interactive mechanism contributes to the realisation of the dual functions of social infrastructure: the promotion of spatial justice and the generation of social capital (Klinenberg, 2018; Hall, 2020). The mapping framework constructed in this study aims to reveal how the dynamic interaction among the physical, institutional, and social dimensions drives and shapes the pathways of these two core social values (Schloffel-Armstrong et al., 2021). This analysis adopts a deductive approach to understanding the mechanism, rather than treating spatial justice and social capital as directly quantifiable indicators. By examining how spaces operating under different governance models integrate physical environments, institutional arrangements, and social practices, their differentiated processes of social value generation can be clearly delineated (Fraser, 2008; Putnam, 2000).

The relationship between the three-dimensional interactive mechanism and the practice of spatial justice can be illustrated as follows (Figure1): this mapping highlights the relative emphasis and specific contribution methods of each dimension in advancing the three sub-dimensions of spatial justice.

The physical dimension, especially given the characteristics of community reading spaces being close to residential areas and limited in scale, contributes to distributive justice through site selection (e.g., located at the center of neighborhoods or on street corners) and inclusive design (e.g., age-friendly, child-friendly, and barrier-free features). These micro-level spatial elements directly influence whether different groups can equitably access and utilise public resources (Carmona, 2010; Gehl, 2011).

The institutional dimension supports procedural justice by establishing flattened feedback channels (e.g., online communities, regular exchange meetings) and mechanisms that empower community organisations and residents to co-govern (e.g., resident-led activities, participation in management committees). Pluralistic governance models effectively enhance the capacity for user voice and participatory decision-making in space operation and service planning (Bovaird & Löffler, 2015; Ostrom, 1990).

The social dimension, grounded in the localness and everydayness of community reading spaces, fosters recognitive justice by organizing context-specific activities (e.g., neighborhood storytelling sessions, community cultural salons) and facilitating informal interactions among neighbors. These practices enhance visibility and acknowledgment of diverse cultural expressions and community identities, thereby directly advancing the realisation of recognitive justice (Oldenburg, 1989; Fraser, 2008).

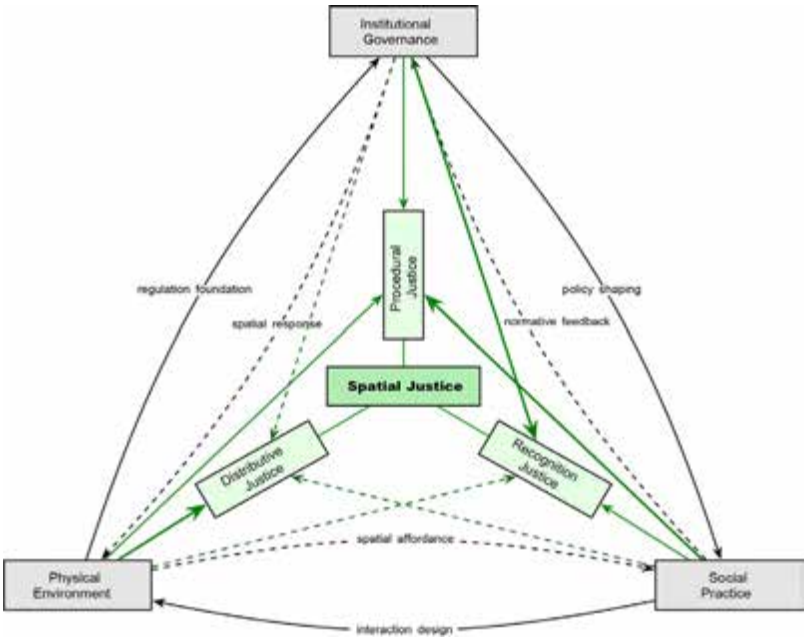

Fig.1. Pathways to Social Functions: Spatial Justice Practice

The relationship between the three-dimensional interactive mechanism and the generation of social capital can be illustrated as follows (Fig.2): this mapping outlines how the interaction across dimensions collectively shapes the formation of bonding, bridging, and linking social capital, with an emphasis on their respective pathways and dynamic mechanisms (Putnam, 2000; Woolcock & Narayan, 2000).

Practices in the social dimension—particularly service activities and community interactions that target specific interests or groups and encourage deep engagement (e.g., regular community reading groups, parent-child co-reading sessions, professional knowledge-sharing events)—serve as key drivers of bonding and bridging social capital. Rooted in shared interests and daily exchanges, these activities create relational platforms for interpersonal connection and mutual trust.

The physical dimension (e.g., open and flexible spatial designs that support informal encounters, such as shared long tables and lounge areas) and the institutional dimension (e.g., low-threshold access policies, institutional support for community-led events, flexible space-use regulations) offer critical yet indirect support for social capital formation. For instance, a welcoming communication corner can spark spontaneous interactions, while inclusive institutional arrangements lower barriers to participation (Gehl, 2011; Gilchrist, 2004).

Furthermore, the institutional dimension—particularly through collaborative operational mechanisms with external community institutions (e.g., local schools, social work stations, non-profit organisations, sub-district offices)—establishes concrete channels for generating linking social capital (Woolcock, 2001). These localised institutional linkages enable community reading spaces to attract external resources and help residents connect to broader networks, thereby strengthening their social connectivity and outward engagement capacity.

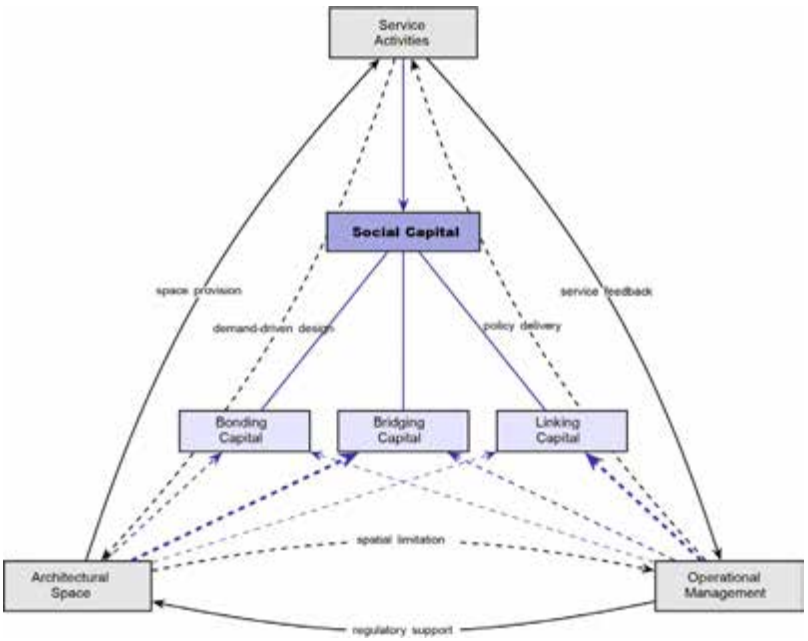

Fig. 2. Pathways to Social Functions: Social Capital Generation

3.2 Case Analysis

To investigate the differentiated realisation paths of the social functions of social infrastructure across various types of community reading spaces, this study adopted the principles of typicality, diversity, and research feasibility in case selection (Flyvbjerg, 2006; Shi Lei, 2016). Drawing on a preliminary investigation into the development status of community reading spaces in Nanjing and informed by the typological analysis of governance models in the literature review, the study constructed a typology framework based on three key dimensions: the level of government support, the degree of integration with the library system, and the extent of collaboration with social actors. These dimensions correspond to distinct institutional driving forces and resource coupling strategies (Bovaird & Löffler, 2003; Zhang Qian, 2021), which shape the institutional characteristics of each case and influence their patterns of interaction with the physical and social dimensions (Ostrom, 1990; Yan Fei, 2017).

Based on this typological framework—and taking into account the representativeness, operational features, and data accessibility of candidate cases—this study selected three representative community reading spaces in Nanjing for in-depth analysis: Jiangsu Writers' Works Hall, Yunji Study, and Wanxiang Study (Table 1). These three cases represent distinct interactive Operational Managements associated with different governance types: government-led (leading type), government–social collaboration (co-operative type), and socially-led (autonomous type). Their significant variation across the three screening dimensions provides a robust foundation for multi-dimensional comparison of interaction mechanisms and the dual functions of social infrastructure—namely, the practice of spatial justice and the generation of social capital.

Table 1. Cases Selection Analysis

Cases	Government Support	Library System Participation	Depth of Social Force Cooperation	Typologies
Jiangsu Writers' Works Hall	Financial + Venue	Nanjing Library Cooperation	Writers' Association Participation	Leading Type
Yunji Study Xuanwumen Store	Policy Guidance	Jinling Library Resource Access	Commercial Brand Led	Co-operative Type
Wanxiang Study	Initial Venue Support	Completely Independent	Brand Independent Operation	Autonomous Type

Case 1: Jiangsu Writers' Works Hall (Leading Type)
•Interactive Dimensions
Architectural Environment: As a thematic venue located within Nanjing Library, the Jiangsu Writers' Works Hall occupies 638 square meters and benefits from the library's prime location and central urban infrastructure (Fig.3 & Fig.4). The interior adopts a "large study room" layout, combining exhibition, reading, and interactive functions. It includes a manuscript exhibition hall, a themed reading zone, and an interactive experience area, displaying over 3,800 works by more than 800 Jiangsu-born authors. Although the space lacks an independent lecture hall, it accommodates large-scale events by utilizing the main library's lecture facility on a rotating basis. Medium-sized events are held by reconfiguring the main hall, while regular small book clubs and new book launches take place in a dedicated conference room. The spatial layout is tailored to serve the pavilion's thematic orientation and activity needs.

Fig.3. Urban Location& Exterior Picture of Case 1

Fig.4. Floor Plan of Case 1

Operational Management: The hall operates under a typical administrative coordination model. Initiated by the Jiangsu Provincial Writers' Association with thematic input, the project was executed through governmental resource coordination and ultimately implemented within Nanjing Library, which handles its daily management. This model, marked by clearly delineated responsibilities and reliance on public funding, ensures stable financial support—its operational costs are embedded in the Nanjing Library's budget system, contributing to long-term sustainability. However, this highly bureaucratic model limits market-oriented flexibility. Resource integration is predominantly achieved through Nanjing Library's local literature system, systematically collecting official literary resources; channels for collaboration with social actors remain relatively limited.

Service Activities: The services are centered on literary materials related to Jiangsu-born writers, emphasizing a regional cultural collection. Its primary audience consists of literary scholars and local culture enthusiasts, particularly middle-aged and senior readers. In addition to permanent exhibitions, it hosts annual public service-oriented cultural events such as literary lectures, book launches, and author meet-and-greets. While weekend events draw more diverse participants, the overall service approach remains rooted in public welfare. Activity formats—typically one-way in nature—are led by the Writers' Association or organised by Nanjing Library. To broaden outreach, a tiered strategy has been adopted, incorporating youth-targeted programming on weekends and holidays while maintaining professional depth in core activities.

Fig.5. Interior Pictures of Case1

• Dual Functions

The leading-type institutional mechanism of this case (government-led, stable finance, library system) directly ensures a superior physical space and rich thematic resources. At a macro level, this contributes to a high degree of distributive justice—the accessibility of specific public cultural resources (Jiangsu writers' works) is guaranteed. However, the interaction between the institutionally set thematic positioning, the limitations of the physical space (insufficient informal communication areas, event venue constraints), and social practices (primarily serving specific groups, one-way output activities) collectively restrict the inclusiveness of resource distribution. For non-literature enthusiasts and residents living relatively far away, its distributive justice is insufficient.

In terms of procedural justice, the highly administrative institutional dimension results in a long decision-making chain for operations, with limited channels for ordinary readers to participate in operational and service content setting, leading to weak user voice. Although collaboration with the Writers' Association and Nanjing Library reflects institutional-level consultation, the lack of a bottom-up user interaction mechanism means that the practice of procedural justice is insufficient.

The presentation of recognitive justice is mainly reflected in the institutional dimension's high recognition of the needs of specific cultural groups (literary researchers, Writers' Association members), providing professional resources and space (physical dimension), and thematic services (social dimension). In recent years, attempts have been made to expand inclusiveness by adjusting physical space (adding a popular reading area) and social practices (holding cross-disciplinary activities), somewhat enhancing the recognition of different groups' needs, but the core positioning still leans towards specific cultural groups.

Regarding social capital, the interaction between the institutionally set public welfare orientation, the social dimension's service content (thematic literature, regular activities), and the target group positioning effectively bonding local literary communities, strengthening the potential for generating bonding social capital. However, the interaction between the physical space design (solemn atmosphere, insufficient informal communication areas) and social practices (daily one-way output primarily) limits the occurrence of spontaneous daily social interactions. Natural interaction among readers from different backgrounds is constrained, and the ability to generate bridging social capital is moderate to weak. The institutional dimension's close ties with academia and the Writers' Association system, as well as the digital resources available through the Nanjing Library platform, construct specific linking social capital. However, due to the administrative nature of the Operational Management, interaction with broader social forces is limited, and linking primarily occurs as structural connections in specific fields.

• Case Summary

Overall, under a leading-type institutional drive, the Jiangsu Writers' Works Hall, with its stable physical and institutional resources, performs outstandingly in ensuring the distributive justice of specific public cultural resources and the bonding capital of specific communities. However, its administrative operation and insufficient social interaction constrain the comprehensive practice of procedural and recognitive justice, as well as the broader generation of bridging and linking social capital. (Table 2)

Table 2. Analysis Summary of Case 1

Dimension	Sub-Aspect	Characteristics	Implications for Spatial Justice	Implications for Social Capital
Institutional	Governance Structure	Government-led; administered by Nanjing Library	Ensures public cultural resource accessibility	Supports bonding within literary institutions
	Resource Integration	Stable public funding; reliance on library systems for official collections	Strengthens distribution of cultural knowledge	Weak external linkage; limited connection to other networks
	User Participation & Co-Governance	Top-down decisions; weak reader engagement mechanisms	Weak procedural justice	Lacks participatory co-governance culture
Physical	Location & Spatial Accessibility	Located in city center; shares main library's spatial advantages	High accessibility for literary users	Excludes residents in non-central areas
	Spatial Layout & Design Features	Thematic, formal layout; lacks flexible or multifunctional spaces	Narrow inclusiveness (recognitive justice)	Hinders adaptation to diverse community needs
	Informal Interaction Capacity	Minimal casual zones; solemn, institutional atmosphere	Constrains interactive use	Weak bridging and linking capital generation
Social	Target Groups	Literary researchers, Writers' Association members, older readers	Recognises needs of cultural niche	Strengthens bonding capital
	Activity Design	One-way activities: lectures, book launches, exhibitions	Weak user engagement; limited feedback inclusion	Inhibits cross-group interaction
	Social Interaction & Inclusion	Occasional outreach efforts; limited informal engagement	Attempts recognitive improvement, but core remains exclusive	Linking capital restricted to institutional domains

Case 2: Yunji Study (Co-operative Type)

• Interactive Dimensions

Architectural Space: Yunji Study Xuanwumen Store is located within the Hengji Center commercial district on Changjiang Road in Xuanwu District, Nanjing. It is situated in a core area along Nanjing's traditional cultural axis, boasting an excellent location and convenient transportation. The Xuanwumen store has a total area of

approximately 400 square meters, arranged in a long rectangular layout (Fig. 6 & Fig. 7). The space is divided into a reading area, a coffee and dining area, a cultural product display area, and an independent small activity space. Some areas feature floor-to-ceiling windows, bookshelf-enclosed seating, and green plant decorations, creating a reading environment that is both quiet and imbued with an urban atmosphere. Its physical space emphasises the integration of "aesthetic experience" and "life scenes," reflecting how new reading spaces accurately respond to the aesthetic and social needs of young consumer groups.

Fig.6. Urban Location& Exterior Picture of Case 2

Fig.7. Floor Plan of Case 2

Operational Management: The Operational Management of Yunji Study can be classified as a "co-operative" path, embodying Co-operative governance characteristics involving local government cultural departments and market entities. The store is operated by Nanjing Yunji Culture Company, with Jinling Library as a partner providing some book resources and lending services. The government is not directly involved in operations but indirectly participates in the public cultural service system through brand co-construction and the embedding of book resources. The source of the venue and the rent mechanism have not been clearly disclosed, but the commercial embeddedness of the study is strong. Relying on the matrix of multiple Yunji Study stores in Nanjing, it constructs an overall operational system through branded service projects. However, most front-desk operational staff are concurrently catering service personnel, with limited public service capabilities. Book lending and reading guidance primarily rely on the books provided by Jinling Library. The space places more emphasis on parent-

child companionship, urban leisure, and cultural consumption, with its public cultural attributes being relatively weaker.

Service Activities: In terms of literature resource allocation, Yunji Study focuses mainly on children's picture books and English original books, also stocking a certain proportion of books about Nanjing city. This is closely related to its core user group positioning: parent-child families (accounting for over 60%) and tourists (reaching over 30% during peak season). In terms of activity model, the study is predominantly venue rental-led, with about 85% of activities hosted by external organisations. The frequency of self-organised activities is low, and activity themes are mostly parent-child reading sessions, etc., with themes being diversified due to external determination. Although the physical separation of the children's area provides a dedicated space for specific groups, the fragmented service characteristic resulting from its scenic area location poses challenges to cultivating reader loyalty.

Fig.8. Interior Pictures of Case 2

• Dual Functions

The physical environment of Yunji Study (scenic area location, commercial aesthetic design) brings high accessibility and attractiveness. Coupled with the institutional co-operative with Jinling Library (providing free book resources), it has, to a certain extent, expanded the breadth of distribution, unexpectedly serving a large number of out-of-town tourists. However, the institutionally set consumption-for-seating policy essentially creates an economic barrier, constraining distributive justice for low-income groups. Simultaneously, the lack of dedicated event space, requiring temporary adjustment of business areas (physical dimension), may also affect the user experience of non-consuming readers.

In terms of procedural justice, the institutional priority of commercial operational logic means that reader demand feedback is mostly conveyed indirectly through consumption behavior, lacking direct mechanisms for participation in operational decision-making. Daily operations are handled by non-professional staff (institutional dimension), which may affect the efficiency of processing professional feedback, leading to a weaker presentation of procedural justice.

The presentation of recognitive justice is strong for specific groups (parent-child families), mainly reflected in the physical space design (physical separation of the children's area) and the service configuration of the social dimension (abundant children's books, frequent parent-child activities) highly matching their needs, providing targeted space and services. However, due to its commercial attributes and focus on specific service targets, the recognition and response to the needs of academic readers, in-depth readers, and other groups are insufficient.

Regarding social capital, the interaction between social dimension services for parent-child families and the physical dimension's children's area design helps attract and form temporary parent-child activity groups. However, there is a lack of sustained institutional support for in-depth community cultivation, limiting the ability

to generate bonding social capital. The physical dimension's scenic location and composite functional design, along with the institutional dimension-led venue rental model that introduces external activities and diverse participants, facilitate chance encounters among readers from different regions and with different purposes. This provides opportunities for establishing weak connections, resulting in a moderate to strong ability to generate bridging social capital. The promotion of linking social capital mainly relies on the institutional co-operative with Jinling Library, enjoying basic resource connections, and establishing Co-operative relationships with external activity organisers. However, this is more of an institutional-level resource connection rather than directly helping ordinary users connect to external high-end cultural or social resources.

• **Case Summary**

Through a government-social co-operative institutional model, Yunji Study leverages the locational and aesthetic advantages of its physical space and introduces market vitality. This effectively expands the physical accessibility of resources (partial distributive justice) and promotes superficial communication among readers from different backgrounds (bridging capital), performing prominently in the recognitive justice for specific groups (parent-child). However, its commercial logic and limited institutional user participation constrain the practice of procedural justice and the generation of bonding capital within in-depth communities. (Table 3)

Table 3. Analysis Summary of Case 2

Dimension	Sub-Aspect	Characteristics	Implications for Spatial Justice	Implications for Social capital
Institutional	Governance Structure	Commercial-led; cooperative with Jinling Library	Enhances distribution range via public-private resource sharing	Enables formal collaboration for resource supply
	Resource Integration	Free book resources from library; consumption-for-seating model	Creates economic thresholds; limits access for low-income users	Institutional support favors event organizers, not individuals
	User Participation & Co-Governance	User needs inferred via consumption; no explicit feedback or decision channels	Weak procedural justice; lacks participatory governance	Limited institutional responsiveness to diverse reader groups
Physical	Location & Spatial Accessibility	Scenic location; commercial aesthetic; highly attractive	High visual/ spatial appeal; broad distribution coverage	Attracts diverse transient users; supports weak tie formation
	Spatial Layout & Design Features	No dedicated event space; flexible use of café areas	Affects reader experience, especially for non-consumers	Restricts bonding via regular, fixed group activities
	Informal Interaction Capacity	Composite functions; adaptable but commerce-oriented layout	Partially inclusive; constrained by business logic	Supports bridging via shared, open use; lacks bonding anchors

Social	Target Groups	Parent-child families are primary audience	Strong recognitive match for select users	Weak toward academic/in-depth users
	Activity Design	Rich parent-child activities; frequent events	Event accessibility high for core groups	High turnover; limited long-term relational development
	Social Interaction & Inclusion	Short-term group cohesion; lacks deep community cultivation	Partial recognitive justice; segment-specific engagement	Weak bonding; moderate bridging; structural linking only

Case 3: Wanxiang Study (Autonomous Type)

• Interactive Dimensions

Architectural Space: Wanxiang Study enjoys a significant locational advantage next to Nanjing University, effectively targeting its core customer group. The interior space is meticulously divided into multiple functional areas, including a shared self-study area, a book lending area (which also functions as a bookstore), a coffee area, an exhibition gallery, a screening room, and an independent space rented out to an external art studio. (Fig.12 & Fig.13) This composite design greatly enhances space utilisation efficiency and provides a physical carrier for different types of reading, learning, leisure, artistic activities, and informal interactions. Its spatial design is full of personality and curatorial sense, aiming to create a unique atmosphere that aligns with its cultural propositions. It is noteworthy that the gallery area is open to the public free of charge, providing a limited point of free public cultural contact.

Fig.9. Urban Location& Exterior Picture of Case 3

Operational Management: Nanjing University Press acts only as the venue provider, while the Wanxiang Study brand is fully responsible for core functions such as book procurement, operational services, and activity planning. This clear division of labor grants the brand high operational autonomy, enabling it to make flexible decisions and quickly respond to market and community needs. Its operation is guided by a distinct cultural philosophy, balancing operational costs through a diverse commercial portfolio including book sales, coffee consumption, membership fees, crowdfunding, and art studio rental, thereby reducing reliance on a single funding source.

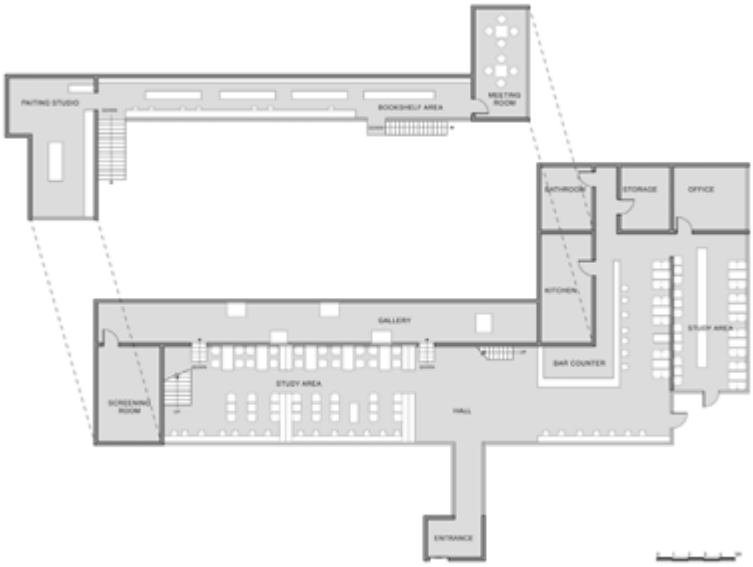

Fig.10. Floor Plan of Case 3

Service Activities: In the social dimension, Wanxiang Study' service configuration reflects a high degree of professionalism and community orientation. Literature resources focus on humanities, social sciences, and independent publications, precisely catering to the interest preferences of its core user group. Its core users are primarily faculty and

Fig. 11. Interior Pictures of Case 3

students from Nanjing University and Southeast University, and activity design is highly diversified and deeply connected with the community. Although many events involve providing venue rental services with content determined externally, Wanxiang Study, through holding activities and curating its own themes, has formed a unique and rich sequence of activities, including book clubs, sharing sessions, small exhibitions, workshops, and film screenings. These activities are not only frequent but also emphasise in-depth interaction and community co-creation, effectively cultivating close-knit communities based on shared values and interests.

• **Dual Functions**

Wanxiang Study' presentation of spatial justice reflects a coexistence of high benefits for specific communities and relatively insufficient inclusiveness. In terms of distributive justice, limited by the physical space volume and the

institutionally set consumption-for-seating policy, the accessibility and coverage of physical space and literature resources are relatively limited, making it difficult to guarantee resource fairness in a universal sense, especially for non-core communities and low-income groups (although the free gallery offers limited compensation). However, its high degree of autonomy under the institutional dimension and user co-construction fostered by the social dimension have built a deeply participatory governance structure, granting users extremely high voice and decision-making power in space operation and activity planning, thereby maximizing procedural justice.

Simultaneously, through highly curated physical space design and service configurations in the social dimension that closely match the needs of the core user group, Wanxiang Study highly recognises and satisfies the needs and identity of specific cultural groups (such as Nanjing University faculty and students, literary communities), providing them with a field where they are highly seen and accepted. Therefore, recognitive justice is very strong. Overall, Wanxiang Study' spatial justice is more manifested in the procedural and recognitive justice constructed by its institutional and social dimensions, rather than in the inclusiveness based on equitable distribution of physical resources.

Wanxiang Study, based on social dimension service activities driven by common cultural concepts, interests, and in-depth interaction, as well as an institutional dimension user co-creation community model, jointly foster an extremely strong capacity for generating bonding social capital, forming high identity and mutual aid networks. Its physical space's composite business format design (such as coffee areas, galleries) and high-frequency, issue-oriented social dimension activities with diverse themes introduced externally attract participants from different backgrounds and professions. This provides a unique platform for intellectual exchange and establishing weak connections, resulting in a strong ability to generate bridging social capital.

Furthermore, relying on the background of Nanjing University Press, the founder's connections, and institutional cooperation with media, academia, and other independent cultural institutions—especially by directly introducing external resources and organisers through the model where activity content is externally determined—Wanxiang Study has built rich external connections. This provides community members with opportunities to connect to higher-level resources and networks, also showing a strong ability to generate linking social capital.

• **Case Summary**
Driven by an autonomous institutional model, Wanxiang Study, with its physical space and social practices highly aligned with community needs, excels in promoting in-depth user participation (procedural justice, recognitive justice) and generating different types of social capital (especially bonding and linking). Its main drawback lies in the resource limitations under its autonomous model, which restricts its performance in inclusive resource allocation (distributive justice). (Table 4)

Table 4. Analysis Summary of Case 3

Dimension	Sub-Aspect	Characteristics	Implications for Spatial Justice	Implications for Social capital
Institutional	Governance Structure	User-led governance; institutional autonomy; community co-construction	Maximises procedural justice; strong user voice	Strong bonding through participatory operation
	Resource Integration	Limited government support; relies on private funding and social networks	Limited distributive justice; access constraints remain	Enables flexible linking with media and cultural institutions
	User Participation & Co-Governance	Users involved in planning and decision-making	Strong bottom-up engagement; highly participatory governance	Fosters deep user ownership and relational commitment
Physical	Location & Spatial Accessibility	Small-scale space; consumption-for-seating policy; free gallery partially compensates	Restricted space access for broader users and low-income groups	Limited inclusiveness; tailored access for core users
	Spatial Layout & Design Features	Curated environment; tailored for university/ literary users	High cultural specificity supports recognitive justice	Reinforces shared identity and cultural cohesion
	Informal Interaction Capacity	Multifunctional layout: café, gallery, book lounge	Encourages spontaneous interaction for targeted groups	Supports both bonding and bridging through semi-public settings
Social	Target Groups	Literary community, university scholars	Strong identity alignment; highly responsive to user profiles	Strong bonding among culturally cohesive groups
	Activity Design	Issue-driven events; external organizer cooperation; diverse cultural themes	Recognises and amplifies cultural plurality; active programming	Bridges communities; deepens trust and reciprocal ties
	Social Interaction & Inclusion	Open platform for dialogue; multi-background participation	Rich recognitive justice; cultural responsiveness	Strong bridging (diverse participants) and linking (external ties)

5. Conclusion and Prospects

5.1 Case Comparison: Complementary Logic of Multiple Types

The three governance models represent distinct institutional configurations that profoundly influence resource allocation, operational logic, and managerial approaches. These institutional differences shape the development of physical space and the structuring of service activities, thereby producing varying strengths and weaknesses in

fulfilling the dual functions of social infrastructure—namely, the realisation of spatial justice and the generation of social capital. Table 778 summarizes the core characteristics of each governance model and their corresponding performance in key dimensions.

The leading type, marked by high institutional centralisation, ensures stable resource input and standardized operational mechanisms. This is reflected in its prime physical location, robust infrastructural support, and a systematic cultural resource collection system. These features significantly enhance distributive justice, ensuring access to public cultural resources and safeguarding the basic cultural rights of specific user groups. However, this model lacks institutional channels for user participation and relies on administratively led, top-down service delivery. The physical environment, while functional, is insufficiently configured to support informal social interaction or diverse engagement, resulting in weaker performance in procedural and recognitive justice. This governance model represents a "top-down" social infrastructure paradigm, with a primary focus on resource provision and institutional order maintenance.

The co-operative type reflects a collaborative governance structure involving both public and private sectors. It typically operates through parallel mechanisms of resource integration, brand co-construction, and service outsourcing. Market participation enhances the spatial design by introducing aesthetic considerations and multifunctional layouts, thereby improving spatial attractiveness and user accessibility. Social practices in this model exhibit higher service diversity and activity frequency, which strengthens recognitive justice and facilitates the generation of bridging social capital. Institutional partnerships with public libraries also partially mitigate deficiencies in cultural coverage and professionalism. However, the dominance of commercial logic may dilute the public-oriented mission, and mechanisms for procedural justice remain limited. This model exemplifies an "embedded" institutional design that seeks to balance resource collaboration with responsiveness to user demand.

The autonomous type is characterized by decentralized governance and strong user agency. This model emphasizes participatory management and community co-creation, with service design closely aligned to the interests and needs of its core user base. Consequently, it demonstrates the strongest performance in procedural and recognitive justice. Moreover, curatorial spatial design and issue-driven programming foster the formation of bonding and linking social capital. However, the lack of institutional support from governmental or library systems constrains its physical space capacity and limits its distributive inclusiveness. This governance path represents a "bottom-up" model driven by community mobilisation and shared cultural identity.

Collectively, these governance models do not exist in isolation but demonstrate a complementary logic in their institutional objectives and operational strategies. The leading type offers broad coverage and foundational guarantees; the co-operative type enhances service diversity and spatial appeal, broadening the potential for superficial social interactions; and the autonomous type prioritizes deep community engagement and user participation, activating the cultural functions of intensive interaction. This complementary interplay is also echoed in international scholarship, such as Tonkiss's (2013) and Mehta's (2014) discussions on "institutional diversity" and "community-negotiated spaces."

Accordingly, the future optimisation of institutional frameworks for community reading spaces should avoid rigid adherence to any single governance logic. Instead, it should strategically combine the strengths of each model: enhancing institutional flexibility and user participation mechanisms within government-led frameworks; integrating public service attributes and professional resources into market-led models; and providing foundational policy support and external resource channels for community-initiated efforts. Through the synergistic coordination of institutional structure, physical space, and social practices, community reading spaces can more effectively fulfill their dual social functions, advancing both spatial justice and the generation of social capital as essential components of new social infrastructure.

5.2 Research Conclusions

• Dual Functions of Social Infrastructure and Three-Dimensional Interactive Mechanism

This research finds that community reading spaces, as a form of social infrastructure, embody the dual functions of providing fundamental public services and fostering social relationship networks. These spaces serve not only as platforms for physical and institutional delivery—guaranteeing daily cultural rights and access to knowledge—but also as relational fields that facilitate neighborhood interaction, collective identity, and trust-building. This dual embeddedness positions them as urban social apparatuses with communicative capacity, organisational capability, and normative orientation.

The realisation of these functions is rooted in the dynamic and synergistic interaction among three dimensions: physical space, institutional arrangements (particularly context-specific governance models in China), and social practices. Case analysis reveals that different institutional logics—such as administrative dominance in the leading type, government–society collaboration in the co-oping type, and community autonomy in the autonomous type—directly shape the accessibility and inclusiveness of physical spaces and guide the design of social practices, thereby determining the specific pathways and performance levels of each model in achieving these dual functions.

• The Synergisation of Spatial Justice and Social capital

The core value of community reading spaces as social infrastructure lies in promoting spatial justice and cultivating social capital. The research emphasises that spatial justice does not solely depend on the balanced distribution of physical space (distributive justice) but must be embedded with dimensions of institutional participability (procedural justice) and responsiveness to cultural identity (recognitive justice).

The Nanjing case analysis (e.g., the autonomous type maximised procedural and recognitive justice, while the leading type focused on the foundation of distributive justice) confirms this. Simultaneously, social capital is not a passive construction of social scenarios but a network of relationships (bonding, bridging, linking capital) dynamically stimulated by physical space forms, institutional arrangements, and user behaviors. Different governance models promote the generation of different types of social capital in differentiated ways by shaping the openness of physical space, institutional openness, and the diversity of social practices (e.g., the co-operative type promotes bridging capital, while the autonomous type strengthens bonding and linking capital). This indicates that spatial justice and social capital, as the two core objectives of infrastructure, are interrelated and synergistically achieved under different practical paths. Their effect depends on whether the three-dimensional elements can be effectively coupled and balance and promote the diverse facets of these two objectives.

• Complementary Logic of China's Pluralistic Governance Models

The Nanjing case study further reveals that against the policy backdrop of China actively promoting pluralistic governance in public cultural services, different governance models such as leading, co-operative, and autonomous types exhibit significant complementary logic. The leading type provides an inclusive foundation, the co-operative type introduces vitality to expand boundaries, and the autonomous type stimulates the deep vitality of communities. This co-existence of multiple paths and complementary patterns provides possibilities for addressing China's diverse community needs. Theoretically, the "three-dimensional interaction—dual functions" analytical framework proposed in this paper offers a new perspective for understanding how social infrastructure plays a composite function at the micro-scale.

At the policy level, it is necessary to move beyond indicator-based assessments and focus on the mechanism design for institutional openness and social embeddedness, and encouraging mixed governance, flexible spaces, and pluralistic participation. Through synergistic complementarity, the value of community reading spaces, as important social infrastructure, can be more comprehensively enhanced to address "spatial injustice" and "social alienation" in urban development. Concurrently, the theoretical perspective and mechanism analysis methods provided by this study can also offer references for research on other types of social infrastructure.

5.3 Research Prospects

This study, based on the "physical-institutional-social" framework, has conducted a preliminary exploration of the interactive mechanism behind community reading spaces. However, the current case selection (only three cases in Nanjing) is limited in quantity and type, failing to fully cover model variations or potential sub-types, and lacks quantitative analysis of the dynamic process of social capital. Based on this, future research needs to expand the breadth and depth of cases, deepen the study of governance models, and strengthen theoretical dialogue. This includes geographical expansion to different cities and regions, inclusion of different community types, identification of more diversified governance practices (such as mixed operations, transformation cases), and more detailed typological research on existing models. At the same time, placing community reading spaces within theoretical dialogues on public space, community governance, etc., aims to construct a more comprehensive and refined classification system of governance models and to verify and improve the theoretical framework.

Secondly, future research should deepen the dynamic process and quantitative analysis of efficacy, and closely connect with practice. The efficacy of community reading spaces evolves dynamically over time, requiring a tracking design to examine the long-term interaction of physical space, institutions, and social practices and their impact on community structure and changes in social capital. Introducing quantitative methods such as social network analysis can systematically depict the composition and dynamics of social capital. At the practical level, research results should be actively connected with departments of urban planning, cultural policy formulation, and community management to provide decision-making support for site selection, design, operation, resource allocation, and efficacy assessment. This will help promote the construction of more vibrant, equitable, and inclusive urban communities and enhance the overall effectiveness of public cultural services.

The Role of Urban Green Spaces Attributes in Enhancing Leisure Opportunities and Psychological Well-Being Among Older Residents

LEUNG Lik Fong, JIAN Yi Izzy, Wen Zhuoyi Vincent
Department of Social Sciences and Policy Studies; The Education University of Hong Kong, Hong Kong (SAR)
Email: s1141747@s.eduhk.hk; izzyjian@eduhk.hk; zwen@eduhk.hk

Abstract
This study investigates how urban green space (UGS) attributes influence leisure opportunities and psychological well-being among older adults in Hong Kong. Using surveys (n=80) and interviews (n=25) conducted in Morse Park and Fung Tak Park, the research applies the Recreationist-Environment Fit (R-E Fit) model to assess the alignment between park features, older users' needs and psychological well-being. Quantitative findings indicate that accessibility, safety and maintenance significantly contribute to both perceived fit and emotional well-being. Qualitative results further underscore the importance of elderly-friendly facilities, shaded seating, and social functionality. Together, the findings highlight how well-designed UGS can meet both functional and affective needs, supporting active aging in high-density cities.

Keywords: urban green spaces, aging population, psychological well-being, leisure opportunities, Recreationist-Environment Fit

1. Introduction

The world is undergoing a significant demographic shift, with a rapidly increasing number of people entering older age. The United Nations (2023) projects this demographic – often termed the "urban aging" phenomenon due to its concentration in cities – to double by 2050, posing significant challenges for urban planners worldwide. Urban Green Spaces (UGS), such as parks, gardens, and greenways, have long been recognised for their potential to enhance the quality of life for urban residents. For older residents, these spaces are especially vital, often serving as primary venues for immediate recreational opportunities. Studies have long shown that access to green space is tied to better mental health, reduced stress, and sharper cognitive function (Kaplan and Kaplan, 1989). Physical activity in green settings can ease fatigue and lift mood (Bowler et al., 2010; Coon et al., 2011). These spaces are also places of encounter, which help ease loneliness and build a sense of belonging (Jennings and Bamkole, 2019).

Mirroring global trends, Hong Kong is grappling with the implications of a rapidly aging society. Projections from the Census and Statistics Department (2023b) indicate that by 2046, more than one-third of the city's population will be aged 65 or above. This demographic shift brings with it greater demand for healthcare and social services, as well as a need to rethink how public spaces can support later life. Despite the growing body of research on urban green spaces and aging populations globally (Tzoulas et al., 2007; Lee and Maheswaran, 2010; Artmann et al., 2017; Xu, Nordin and Aini, 2022), there remains a critical void in understanding how elderly residents in Hong Kong specifically perceive and utilise these spaces for leisure and well-being. An urgent need exists for a thorough and structured examination of their preferences, limitations, and ways they interact with these environments.

This study focuses on two parks in the Wong Tai Sin district: Fung Tak Park and Morse Park, aiming to address the gap by exploring how urban green space attributes influence the leisure opportunities and well-being of elderly residents. The objectives are threefold:

1. To assess how specific park features relate to physical activity, mental health, and social engagement among older adults.
2. To compare user preferences and usage patterns between the two parks, highlighting both shared needs and site-specific distinctions.
3. To provide evidence-based recommendations for improving the design and management of UGS in high-density urban settings, with a view to supporting aging-in-place and promoting health equity in the context of rapid urban demographic change.

This study is expected to make several contributions to the field of urban planning and gerontology. First, it provides empirical insights into the UGS attributes most valued by elderly residents in a unique high-density context like Hong Kong, informing the design and management of future green spaces to better serve an aging population. Second, the study contributes to the broader understanding of the relationship between urban green spaces, leisure opportunities and well-being among older adults, particularly in the context of a rapidly urbanising and aging society. Finally, the findings offer practical recommendations for policymakers, urban planners, and park managers to create more age-friendly environments that promote active aging and improve the quality of life for older residents.

2. Literature Review

Urbanisation has led to an increasing number of people living in urban environments. By 2014, 54% of the global population lived in urban areas, and this proportion is projected to rise to 66% by 2050 (United Nations, 2014). While urban areas offer many advantages, they also present unique challenges for the psychological well-being of elderly populations. Research has identified several key psychological challenges faced by older adults in urban settings. Among the elderly population, loneliness and social isolation are common issues, with approximately one in four older individuals experiencing social isolation (World Health Organisation, 2021). Major life transitions, such as retirement, illness, the death of a spouse or close friends, can drastically weaken an individual's social network (Nicolaisen and Thorsen, 2016). These events are not merely emotional turning points; they carry long-term health implications. Studies have linked social isolation in later life to a higher risk of cardiovascular disease, depression, and cognitive impairment (National Institute on Aging, 2024).

UGS have become an essential component in addressing the psychological challenges commonly experienced by aging populations. For older adults, psychological well-being is shaped by multiple, interrelated factors—social support, meaningful engagement, and exposure to restorative environments all play a role (Huxhold et al., 2013; Tung et al., 2022; Li et al., 2025). Among the theoretical frameworks that illuminate these restorative processes, two remain foundational: Kaplan's Attention Restoration Theory (ART) and Ulrich's Stress Reduction Theory (SRT). Each offers a distinct lens: ART from a cognitive perspective ; SRT from an affective one. Together, they explain how natural landscapes support mental recovery and emotional balance. Physiologically, exposure to natural environments has been shown to reduce stress responses such as elevated blood pressure and cortisol levels (Ulrich et al., 1991). Psychologically, it alleviates attention fatigue by allowing the brain's directed attention system to rest, while simultaneously fostering a sense of calm and positive affect (Kaplan and Kaplan, 1989).

Importantly, the benefits of UGS extend beyond the psychological. Access to green spaces promotes physical activity, supports informal leisure, and facilitates social encounters. Physically, green spaces provide essential opportunities for walking, jogging, and other exercises, and engaging in such green exercise offers numerous well-being benefits and has been proven through various studies to positively impact both mental and physical health (Pretty et al., 2005; Lahart et al., 2019; Aristi Tsokani et al., 2024). Specifically, green exercise can reduce negative emotions such as anxiety, tension, anger, depression, and fatigue, while also enhancing positive moods and feelings like vigor, comfort, a sense of connection with nature, and relaxation (Li et al., 2022). These spaces also provide opportunities for relaxation, socialising, and participating in recreational activities, which can effectively reduce stress and depressive symptoms while promoting feelings of happiness in later life (Godbey, 1981; Coleman and Iso-Ahola, 1993).

Findings indicate that leisure activities serve as a bridge connecting social relationships and health outcomes among older adults (Chang et al., 2014). Importantly, social connections and relationships are vital for the life satisfaction of older individuals (Chokkanathan and Mohanty, 2017). In particular, engaging in leisure activities fosters involvement, instills purpose, and helps individuals derive meaning from everyday experiences (Yen et al., 2023). Parks, gardens, and other shared green areas serve as informal yet essential sites for interaction among older adults; provide opportunities for community participation, encourage regular contact with peers, and mitigate the risks of social isolation and loneliness (Villeneuve et al., 2023). Scholarly investigations have reliably indicated that senior citizens living in more verdant residential areas are inclined to express more robust social

bonds and lower degrees of loneliness (Maas et al., 2009; Teig et al., 2009). When considered collectively, these outcomes highlight the multifarious benefits of UGS for the well-being of the older adults.

2.3 Theoretical Framework

Person–environment fit (P-E fit) is a foundational concept that is extensively utilised in the field of organizational management. It explains the relationship between individuals and their surrounding environment. A high level of P-E fit is associated with positive outcomes for individuals (Kristof, 1996). Extending this concept to the leisure and recreational domain, Tsaur, Liang, and Lin (2012) pioneered the Recreationist-Environment Fit (R-E Fit) framework. They highlight three distinct types of fit: (1) Supplementary fit refers to the compatibility that arises when recreationists and administrators hold similar values; (2) Demand-Ability fit occurs when the demands of the environment align with the abilities of the recreationists; and (3) Need-Supply fit is achieved when the environment can meet the needs of the recreationists. In the context of parks discussed in this article, the need-supply fit is being assessed. It is achieved when the park environment can meet the needs of the recreationists.

In order to better understand how parks can achieve this need-supply fit, it is essential to examine the attributes of recreational settings that contribute to the overall experience of visitors. Noe and Uysal (1997) introduced a dual-dimensional lens for understanding recreational spaces: instrumental and expressive attributes. In urban parks, instrumental attributes refer to concrete and functional, including elements, such as birdsong, artificial water features, and cultivated vegetation, that create a calming atmosphere conducive to rest and relaxation. Functional infrastructure, for instance, benches, restrooms, and sports equipment, further enhances usability by facilitating physical activity and prolonged stays. Collectively, these features provide the physical conditions through which visitors can achieve specific recreational goals.

Expressive attributes, on the other hand, relate to social interaction and psychological well-being. Parks act as informal social arenas where visitors engage in casual conversations or form spontaneous bonds. As for psychological dimensions, parks allow individuals to temporarily disconnect from daily stressors and reconnect with a slower, more reflective pace of life. In doing so, they promote emotional regulation and mental clarity. A well-functioning park, therefore, is not defined solely by its physical structure but by its capacity to offer a needs-supplies fit. When instrumental and expressive attributes align with users' expectations and preferences, the park becomes more than a physical space.

3. Research Design

This study employs a comparative case study approach to examine how the quality of urban green spaces influences leisure opportunities and psychological well-being among older adults. The research is conducted in Wong Tai Sin District, which has a population of approximately 425,235 as of 2023, comprising 5.4% of Hong Kong's total population (Social Welfare Department, 2021). According to the latest census, 24.5% of the district's population is aged 65 or above, higher than the Hong Kong average of 21% (Census and Statistics Department, 2024). Given its significant elderly population, the district provides an ideal setting for this investigation. The results can function as an essential reference for developing age-friendly communities in other areas.

Two sites in the district were selected: Fung Tak Park and Morse Park. Fung Tak Park, located near a dense residential cluster and historical sites, is a mid-sized park known for its Journey to the West-themed cultural design. Morse Park, in contrast, is one of Kowloon's largest public parks, offering a variety of sports and recreational facilities and broader open spaces. This contrast offers an opportunity to explore how different configurations of park attributes affect user experiences.

Figure 1. Different areas in Fung Tak Park: (a) chess area, (b) exercise zone I, (c) exercise zone II, and (d) a map of the park

Figure 2. Different areas in Morse Park: (e) walking path, (f) seating area, (g) jogging track, and (h) a map of the park

Semi-structured interviews were conducted to explore elderly park users' subjective perceptions of park attributes, whether the park fits their needs and their relation to emotional and psychological well-being. Participants were selected based on the following criteria: (1) aged 65 or above, (2) regular users of either Fung Tak Park or Morse Park (at least once per week), and (3) cognitively able to communicate and provide consent. A total of 25 interviews were conducted, with 13 in Fung Tak Park and 12 in Morse Park. Each interview lasted approximately half an hour and was guided by open-ended questions covering themes such as tranquility, spatial comfort, social interaction, and facility adequacy.

A structured questionnaire was developed to quantitatively measure perceptions of park quality, whether the park fits surveyees' needs and its relationship with leisure opportunities and psychological well-being. Psychological well-being was measured using the validated WHO-5 Well-Being Index (Appendix I) and two questions related to social aspects. The survey was distributed via face-to-face paper forms and was assisted with filling out at both parks in May 2025, targeting elderly users who consented to participate. A total of 80 valid responses were collected through convenience sampling, with an equal distribution between genders: 50% male (n=40) and 50% female (n=40). This balanced gender representation supports the reliability of findings and ensures perspectives from both genders are equally reflected in the analysis.

Interview data were transcribed verbatim, translated from Chinese to English and analysed using thematic analysis. Themes were inductively generated and then categorised under the R-E Fit theory, focusing on how the compatibility between an individual's recreational preferences and environmental characteristics influences their internal states and psychological outcomes.

Survey data were analysed using SPSS. Descriptive statistics summarised demographic profiles and key variables. Independent-samples T-tests compared perceived park quality and well-being scores between Fung Tak Park and Morse Park users. Pearson correlation assessed the relationships between park attributes, R-E Fit and well-being indicators. Where applicable, multiple regression analysis was employed to identify the influence of park attributes and FIT on emotional outcomes.

4. Results

4.1 Demographic information and Usage pattern

Table 1 provides demographic information of respondents from Morse Park and Fung Tak Park. In terms of gender, the respondents are evenly split between male and female, with each group comprising 40 individuals (50% each). The age distribution reveals that the largest group is aged 70-79 years (43.8%), followed by those aged 80-89 years (32.5%), while respondents aged 65-69 years make up 20.0% and those aged 90 years and above account for 3.8%. Regarding living arrangements, 63.8% of respondents live with family, 28.8% live alone, and 7.5% have other living arrangements. In terms of self-rated health status, 43.8% of respondents rate their health as "Fair," 35.0% as "Good," while only 3.8% rate it as "Excellent" and 17.5% as "Poor." Overall, the data highlights a balanced gender distribution, a predominantly older age group, a majority living with family, and a general perception of moderate health status among the respondents. However, the two parks show little difference in the above aspects.

Table 1 Demographic information of the respondents

Characteristics	Group	Morse Park(N=40)	Fung Tak Park(N=40)	Total(N=80)	Percentage (%)
Gender	Male	20	20	40	50.00
	Female	20	20	40	50.00
Age	65-69	10	6	16	20.00
	70-79	17	18	35	43.80
	80-89	11	15	26	32.50
	>/=90	2	1	3	3.80
Living Arrangement	Living alone	12	11	23	28.80
	With family	27	24	51	63.80
	Others	1	5	6	7.50
Self-rated Health Status	Excellent	1	2	3	3.80
	Good	16	12	28	35.00
	Fair	16	19	35	17.50
	Poor	7	7	14	17.50

Table 2 presents the usage patterns of respondents regarding Morse Park and Fung Tak Park. In terms of visit frequency, the most common category is "Very Often (every day or more than 6 times)," accounting for 30.0% of respondents, followed by "Often (5–6 times a week)" at 28.8%. Regarding the duration of stay, the majority of respondents stay for "one to three hours" (55.0%), followed by "four to six hours" (36.3%). In terms of usual activities, "Walking" and "Chatting" are the most popular, each accounting for 21.8% of respondents. "Sitting and resting" is also common at 24.2%, while "Exercise" accounts for 16.1%, "Playing chess/cards" for 8.9%, and "Others" for 7.3%. Overall, the data indicates high visit frequency, longer durations of stay, and a diverse range of activities among park users.

Table 2 Usage pattern of the respondents

Question	Option	Morse Park (N=40)	Fung Tak Park (N=40)	Total (N=80)	Percentage(%)

Average Visits per Week	Rarely (1–2 times a week)	4	6	10	12.50%
	Sometimes (3–4 times a week)	8	14	22	27.50%
	Often (5–6 times a week)	14	10	23	28.80%
	Very Often (every day or more than 6 times)	14	10	24	30.00%
Average Duration of Stay	Less than 1 hour	1	1	2	2.50%
	one to three hours	23	21	44	55.00%
	four to six hours	13	16	29	36.30%
	six hours above	3	2	5	6.30%
Usual Activities(multiple choice)	Walking	15	12	27	21.80%
	Exercise	10	10	20	16.10%
	Sitting and resting	14	16	30	24.20%
	Chatting	13	14	27	21.80%
	Playing chess/cards	4	7	11	8.90%
	Others	9	0	9	7.30%

4.2 Descriptive statistics

By conducting descriptive statistical analysis on the data from Table 3, we found that sense of fit has an average score of 3.94, accessibility is 4.19, safety is 4.00, maintenance is 3.81, WHO-1 is 4.15, and WHO-2 is 3.99. These figures indicate that both parks perform well in several aspects, including environmental fit, accessibility, safety, maintenance, and thus, leading to high well-being scores, all of which show positive evaluations.

Table 3 Descriptive statistics of park attributes, sense of fit, and psychological well-being

Variable	Measurement Item	Morse Park		Fung Tak Park		Overall	
		Mean	SD	Mean	SD	Mean	SD
Park attributes	Accessibility	4.25	0.54	4.13	0.52	4.19	0.53
	Safety	3.90	0.59	4.10	0.59	4.00	0.59
	Maintenance	3.83	0.75	3.80	0.65	3.81	0.70
	Landscapes	3.65	0.74	3.65	0.74	3.65	0.74
	Sound	3.55	0.71	3.60	0.81	3.58	0.76
	Smells	3.45	0.68	3.58	0.81	3.51	0.75
	Seating arrangements	3.88	0.40	3.48	0.78	3.68	0.59
	Shading	3.33	0.89	3.60	0.84	3.46	0.86
	Elderly-friendly facilities	3.68	0.80	3.58	1.01	3.63	0.90
Sense of fit	Facility fit	3.60	0.81	3.48	0.88	3.54	0.84
	Environment fit	4.00	0.45	3.88	0.76	3.94	0.61
Psychological well-being	WHO-1	4.28	0.51	4.03	0.70	4.15	0.60
	WHO-2	4.08	0.66	3.90	0.63	3.99	0.64
	WHO-3	3.63	0.77	3.60	0.63	3.61	0.70
	WHO-4	3.40	0.78	3.33	0.73	3.36	0.75
	WHO-5	3.30	0.79	3.33	0.89	3.31	0.84
	Feeling connected with people	3.73	0.82	3.70	0.88	3.71	0.85
	Feeling less lonely	3.85	0.70	4.05	0.68	3.95	0.69

As shown in Table 4, the correlation analysis in Morse Park significant positive relationships: specifically, between park attributes and participants perceived FIT (r = .547, p < .001), as well as between park attributes and Psychological well-being (r = .467, p = .002). These findings suggest that improved park attributes are associated with both a stronger sense of fit and enhanced emotional experiences for users. Additionally, there was a significant positive correlation between perceived FIT and Psychological well-being (r = .378, p = .016).

For Fung Tak Park, Table 4 indicates that although the correlation between park attributes and Psychological well-being was not significant, there was a significant positive correlation between perceived FIT and Psychological well-being (r = .521, p < .001). A strong positive correlation was also observed between park attributes and perceived FIT (r = .705, p < .001). These findings indicate that park attributes and perceived FIT may positively influence visitors' Psychological well-being, with potential variations between the two parks.

Table 4 Correlation analysis results

	Morse Park(N=40)			Fung Tak Park(N=40)		
	Park attributes	Sense of fit	Psychological well-being	Park attributes	Sense of fit	Psychological well-being
Park attributes	--			--		
Sense of fit	**.547****	--		0.214	--	
Psychological well-being	**.467****	.378*	--	**.705****	**.521****	--

Notes: ** indicates significance at the 0.01 level; * indicates significance at the 0.05 level.

In Morse Park, regression analysis demonstrates, park attributes (B=0.434, p=0.037) positively predict emotional outcomes; however, after controlling for the influence of park attributes, the independent predictive effect of sense of fit on psychological well-being was no longer significant (B=0.157, p=0.314). The regression model has explanatory power (R^2=0.240, adjusted R^2=0.198, F=5.827). This outcome may suggest that the positive impact of park attributes on psychological well-being might largely encompass the explanatory power otherwise provided by sense of fit. This does not negate the intrinsic link between sense of fit and psychological well-being; rather, it suggests that in the specific context of Morse Park, improvements in the park's physical and functional attributes may largely suffice in promoting users' psychological well-being, with sense of fit not demonstrating additional independent contribution within this particular model.

Table 5 Regression analysis results in Morse Park sample

		B (Unstandardised)	Std. Error	β	t	Sig. (p)
(Constant)		1.540	0.651		2.366	0.023
Park attributes		0.434	0.200	0.371	2.168	**0.037***
Sense of fit		0.157	0.153	0.175	1.021	0.314
R^2	0.240					
Adjusted R^2	0.198					
F	**5.827***					

Notes: *** indicates significance at the 0.001 level; ** indicates significance at the 0.01 level; * indicates significance at the 0.05 level. The dependent variable is Psychological well-being.

In Fung Tak Park, regression analysis demonstrates, park attributes (B=0.551, p<.001) positively predict psychological well-being; sense of fit (B=0.254, p<.001) also significantly predicts psychological well-being. The regression model has strong explanatory power (R^2=0.641, adjusted R^2=0.622, F=33.042).

Table 6 Regression analysis results in Fung Tak Park sample

		B (Unstandardised)	Std. Error	β	t	Sig. (p)
(Constant)		0.722	0.370		1.953	0.058
Park attributes		0.551	0.089	0.622	6.172	**<.001****
Sense of fit		0.254	0.066	0.388	3.850	**<.001****
R^2	0.641					
Adjusted R^2	0.622					
F	**33.042*****					

Notes: *** indicates significance at the 0.001 level; ** indicates significance at the 0.01 level; * indicates significance at the 0.05 level. The dependent variable is Psychological well-being.

4.3 Interview interpretation

Unlike the quantitative questionnaire analysis described above, the interview provides more in-depth and rich data that can be used to complement a comprehensive picture of the impact of urban green spaces-parks on the psychological well-being of older residents. The study sites for the interview data remained Morse Park and Fung Tak Park, with a total of 25 older adults interviewed: 12 respondents in Morse Park and 13 in Fung Tak Park. Code A represents Fung Tak Park and Code B represents Morse Park. The data were translated from Cantonese to English. The corpus information was organised and thematically analysed. The results of the analysis were categorised into the following themes: (1) inadequate maintenance and lack of elderly-oriented facilities undermine park usability; (2) park facilities enable social connectivity; and (3) thermal comfort is a prerequisite for park usages. In addition, recommendations for improvement were made from the perspective of older adults.

Theme 1: Inadequate Maintenance and Lack of Elderly-Oriented Facilities Undermine Park Usability

Limitations were frequently noted in both parks. Some respondents criticised the cleanliness of surfaces (B3), insufficient toilets (B2, A11), and lack of elderly-specific facilities (B6, A7). Participants also mentioned long-standing maintenance issues such as unrepaired equipment (B5) and broken amenities (B8). The lack of diversity in facilities was especially apparent when comparing the studied park with others, as B6 mentioned "The place is big enough, but the facilities for the elderly are insufficient and very monotonous, not as diverse as Kowloon Tsai Park. This Park has not been improved for decades and only has some scattered facilities.".

Respondents called for more fitness equipment (B7, A7), soft mats to prevent injuries (A7, A8), and designated activity areas like chess zones (A6).

Theme 2: Park Facilities Enable Social Connectivity

Several respondents described facilities as both functional and socially enabling. For instance,
"I come here to exercise, there is a companion to accompany me and chat." (B8)

"I come here to exercise, ride an exercise bike, and breathe fresh air. Sometimes I chat with friends, sometimes we play together, do exercise together, and it's very happy. (B9)

"I feel happy when I come to the park. I find a seat and chat with old friends. I sit here (in the fitness area), other people see me and chat with me, and then they go to do exercise while I continue to sit here. Chatting with people is relaxing. Before other elderly folks come, I look around. When there is no one to chat with, I automatically doze off. If there are some acquaintances, I chat. Some elderly people are too lonely and there is no one to chat with at home." (A8)

Parks played a crucial role in supporting both solitude and sociability. Participants valued the park as a space where they could choose between interacting or being alone.

"It's not good to be with others all day, and it's not good to be alone. Sometimes I chat, sometimes I watch others play chess, and when I feel bored, I sit down and walk. So this park allows you to choose different social activities. Sometimes you like to be alone, and sometimes you chat with others and watch others play chess." (B2)

"In this park, I found some acquaintances to chat with. Lonely old people are like this. Walking and sitting, and then chatting. If I need to sit, there is a bench. If I like to walk, I will keep walking. If I like to find someone to chat with, I will find someone to chat with." (A1)

Seating areas enabled casual interaction, and inadequate bench availability was cited as a barrier to social exchange. Some respondents suggested enhancements that would increase the social functionality of parks.

"There are not enough benches when needed, like now, which affects chatting and communicating with people." (A5)

"It would be best if there were a bench, two more benches, and a few more tables and benches inside, so that the elderly can sit and chat. The most important thing here is to have a roof over our heads. It would be best if there were some sports equipment for the elderly too." (A12)

These features were seen not just as amenities but as means to anchor social connection in the everyday lives of older adults.

Theme 3: Thermal Comfort is a Prerequisite for Park Usages
Participants consistently emphasised the importance of thermal comfort when using park spaces. For instance,

"There are many shaded areas with trees, so it's not too hot or too shiny." (B2)

"If the sun is too hot, then I can go to a shaded place. There are trees all around." (B3)

"Now the trees are bare and cannot cover the sun. Earlier, the storm knocked down the trees, which were not replanted. We, of course, want the trees to be denser and to provide more shade." (B5)

"I stay in the pavilion when it's sunny and go outside to enjoy the sun when it's cold." (A11)

A6 proposed adding electric fans to improve airflow during hot weather, while A12 underscored the need for "a roof over our heads" to avoid direct sun exposure.

5. Discussions and Conclusions
The psychological well-being of the elderly population is a paramount concern in the context of urban development. This study investigates how the quality of urban green spaces influences elderly residents' sense of fit, thereby enhancing their leisure opportunities and psychological well-being.

Initial analyses of demographic characteristics and usage patterns in Morse Park and Fung Tak Park revealed a sticking consistency between both sites, with minimal variation in gender ratios, age groups, living situations, and self-assessed health showed . The high frequency of park visits (at least five to six times per week) and typical stays (one to three hours) underscore the embedded role of UGS in the daily lives of older adults in Hong Kong. Preferred activities, consistently identified as walking and casual social interactions with peers, further reinforce the centrality of parks as vital spaces for both recreation and informal social engagement among older urban residents, re-underscoring their importance as accessible community hubs in high-density urban settings.

Regarding the general park environment, both sites were rated highly for accessibility and safety, with maintenance and seating arrangements also garnered positive feedback. These elements are instrumental

in shaping perceived usability. As Sugiyama et al. (2010) argue, the psychological well-being of older adults is positively correlated with their perceptions of safety and the functional quality of neighborhood green spaces. Design features such as unobstructed sightlines, well-maintained walking paths, and visible staff presence can significantly reduce environmental anxiety, fostering a sense of autonomy and control beyond mere hedonic comfort. In the case of Fung Tak Park and Morse Park, regular maintenance by the Leisure and Cultural Services Department (LCSD) ensures cleanliness and functionality, contributing to consistently high ratings for environmental quality. Benches are strategically placed along pathways and within shaded zones, providing frequent opportunities for rest and enabling longer, more comfortable visits. Accessibility is another key strength. Because the parks are located within residential neighborhoods and offer several entrances, elderly residents can easily reach and enjoy these green spaces. This aligns with Hong Kong's urban planning principles that prioritise accessibility in residential zones (Planning Department HKSAR, n.d.). Well-lit environments and on-site management, combined with even, obstacle-free paths in both parks, help minimise fall risks, which is crucial for older park-goers. These findings collectively highlight the fundamental importance of well-maintained, safe, and accessible UGS as a baseline requirement for promoting older adults' well-being, particularly in compact urban areas where outdoor leisure options are scarce.

The quantitative findings presented a nuanced picture of the relationships between park attributes, sense of fit, and psychological well-being across the two parks. In Morse Park, there was a significant positive correlation between park attributes and visitors' emotional experiences, suggesting that favorable park features enhance emotional outcomes. In Fung Tak Park, perceived sense of fit was significantly associated with psychological well-being, indicating that engaging in physical activities help improve mental states. Regression analyses further supported these findings. In Morse Park, the characteristics of the park were found to have a positive impact on visitors' emotional states. It highlights how environmental features and facilities can enhance visitors' emotions. Although sense of fit was correlated with emotional outcomes, it did not emerge as a significant predictor in the regression model. Conversely, in Fung Tak Park, both the park attributes and the sense of fit were found to be significant predictors of psychological well-being. This underscores the importance of park infrastructure and opportunities for physical activity in enhancing visitors' mental health.

The findings from Morse Park revealed an interesting discrepancy. Although park attributes and sense of fit were both significantly associated with psychological well-being, the regression analysis failed to identify sense of fit as a significant predictor. This contrasts with the results from Fung Tak Park, where sense of fit emerged as a statistically significant predictor of well-being. One likely explanation lies in methodological sensitivity. Regression models, particularly with smaller sample sizes, are prone to reduced statistical power, which may obscure meaningful predictive relationships. Yet, the presence of significant correlations in Morse Park should not overshadow the substantive implications. They still point to a consistent and theoretically grounded association among park quality, perceived fit, and mental well-being. This suggests that while the strong influence of existing park attributes in Morse Park might largely encompass the explanatory power otherwise provided by sense of fit in the multivariate model, fit remains a crucial underlying component of the overall user experience and well-being pathway. It is plausible that in an environment where fundamental park attributes are already highly favorable (as suggested by the positive general ratings for Morse Park), the direct impact of these attributes on well-being becomes dominant, potentially overshadowing the additional, albeit related, contribution of a perceived fit.

Drawing on the Recreationist-Environment Fit model, our findings collectively illustrate that psychological benefits accrue when individuals perceive congruence between their leisure needs and the characteristics of their environment. This match fundamentally relies on accessible, safe, clean and well-maintained UGS, which form the bedrock of environmental supply. These high quality features enable safe mobility, facilitate meaningful activity, and reduce environmental barriers, thereby cultivating a setting that supports autonomy, ease, and comfort. Older adults who perceive their environment suitable are more likely to engage in activities aligning with their interests and abilities. These repeated positive engagements can then cumulatively foster improved psychological well-being. The quantitative findings from this study reinforce this relationship, indicating that

perceived fit may partially mediate the connection between environmental characteristics and well-being outcomes. This posits that park attributes influence psychological health in two ways: (1) directly through immediate physical conditions ; (2) indirectly through their impact on subjective perceptions of fit. This dynamic is consistent with the core propositions of the Recreationist–Environment Fit (R–E Fit) model (Tsaur et al., 2012).

Extending this mechanism further. Leisure opportunities themselves appear to operate as critical mediators within this process. Specific park attributes, such as well-maintained paths, elderly-friendly facilities, and safe environments, directly provide the necessary space and infrastructure to support various leisure activities. As engagement in these activities expands, psychological needs related to autonomy, competence, and connection are increasingly met. These meaningful experiences reinforce the perception that the park aligns with one's lifestyle and preferences. In turn, this heightened sense of environmental fit contributes to improved emotional and mental well-being. The process reflects a recursive, positive feedback loop: high-quality park attributes promote engagement in leisure, which enhances perceived fit; this improved fit fosters well-being, which then further strengthens users' positive perceptions and sustained use of the space.

Interview interpretations further complemented the quantitative findings. Participants generally appreciated accessible entrances, seating, and safe environments. However, the effectiveness of park facilities was undermined by a lack of adequate facilities for older adults and inconsistent maintenance. These limitations indicate a gap between environmental facilities and user needs, which hinders the park's ability to support sustained and meaningful engagement. The situation is particularly influential in the context of urban parks, where the quality of sports and fitness facilities is vital for older users who depend on this equipment to stay physically active (Chow, 2013; Copeland et al., 2017; Onose et al., 2020). This highlights a crucial practical implication: even generally well-regarded parks can fall short if specific age-appropriate facilities are lacking or inconsistently maintained. Such mismatches reduce the "supply" dimension in the Need–Supply Fit framework, ultimately limiting older adults' opportunities for enriching and health-promoting leisure experiences.

A salient observation from the study is the multifunctionality of specific design elements. Exercise zones, for instance, were not just places for physical activity, but also emerged as points of social convergence. This aligns with Di Bartolomeo and Papa's (2019) observation that physical activity can simultaneously support individual development and foster a sense of community. These spaces enabled users to stay active while engaging with others, illustrating how park infrastructure can meet both personal and social needs. Similarly, seating zones facilitated rest and passive observation, and when designed well, they also enabled conversation. Gehl (2010) proposed that positioning benches at a slightly open angle would allow people to choose whether to sit together or alone, thus facilitating the option for conversation. Seating areas with shade have also been proven to enhance social interactions (Wong, 2019). In addition to meeting immediate physical needs, these spatial features nurtured affective connections. In this way, the parks functioned as a flexible environment that supported both sociability and solitude. This dual functionality reflected a high degree of environmental affordance, facilitating diverse modes of engagement. Crucially, it empowered older adults to regulate their engagement based on personal mood, preference, or physical condition. The flexibility to initiate contact or remain alone contributes meaningfully to their sense of autonomy and overall well-being.

With regard to thermal comfort, the findings indicate a clear preference among older adults for parks that provide ample shaded areas. These physical conditions are a prerequisite for engaging in light physical activity, resting, or remaining in the space for even short durations. When such environmental features are absent, such as inadequate tree cover or exposure to direct sunlight, participants reported avoidance or limited engagement, indicating a clear disruption in perceived fit. The R-E Fit framework helps explain these behavioral patterns by highlighting how environmental insufficiencies inhibit the actualization of recreational intent. Rather than viewing thermal comfort as a background condition, this study reinforces its role as a decisive factor in enabling or constraining elderly park use. This aligns with previous studies that the quality of the outdoor thermal environment is considered a significant factor influencing residents' attendance and activities in open spaces (Martinelli et al., 2015; Shooshtarian et al., 2018).Thermal discomfort does not merely reduce enjoyment;

it obstructs the realization of the park's intended function as a space for leisure, relaxation, and mild exercise.
In conclusion, based on the comprehensive findings of this study, it can be clearly stated that the key attributes of urban parks: general features (accessibility, safety and maintenance), park facilities, and thermal comfort significantly enhance both the sense of R-E fit and the psychological well-being of older adults. These attributes not only directly affect their satisfaction with the park environment, but also indirectly promote their overall psychological health and life satisfaction by enhancing their leisure experience and social interaction opportunities. This study provides valuable empirical evidence for promoting age-friendly urban environments in high-density contexts, emphasising the critical role of well-designed and managed green spaces in supporting healthy and active aging.

Temporary Urbanism in Action: Theme–Neighborhood (Mis)alignment and Visitor Response in Beijing Pop-up Markets

Qingyun Luo[1*]-Wenjun Xu[1]-Mengling Jiang[1]-Anqi Xia[1]
[1] School of Architecture, Tsinghua University, China
Email:* luoqy23@mails.tsinghua.edu.cn

Abstract
Pop-up markets are increasingly deployed as temporary urban-regeneration tools, yet their capacity to deliver community benefits beyond mere commerce remains uncertain. This study mapped 447 Beijing pop-ups (Dec 2023–Nov 2024) and analysed 25 cases for market-neighbourhood fit. Fifteen-minute walking isochrones intersected Gaode POIs, land-use entropy and VIIRS night-lights; while Xiaohongshu posts provided popularity and satisfaction metrics. Theme vectors for both markets and neighbourhoods were derived via Word2Vec; their cosine similarity measured thematic alignment. Results show that while 80% markets align closely with local amenities, those with greater thematic divergence often achieve higher visitor satisfaction ($p<0.05$). Community-driven, experimentally themed pop-ups can thus act as low-risk prototypes for augmenting neighbourhood services and deepening civic engagement.

Keywords: temporary urban regeneration, pop-up market, urban informatics, neighbourhood.

1. Introduction

Temporary urbanism, commonly manifested through pop-up markets and ephemeral public space interventions, has emerged as a significant yet controversial approach in urban planning and renewal practices. Rooted in tactical urbanism, these temporary interventions are characterized by low-cost, reversible, and quickly deployable projects that allow urban stakeholders to test new functions, assess community acceptance, and respond dynamically to evolving urban challenges (Lydon & Garcia, 2015; Bertolini, 2020). Despite their operational flexibility and popularity, temporary urban projects have attracted criticism, as scholars argue they frequently become vehicles for capital-driven marketing and real estate valorization (Madanipour, 2018).

In the context of China's rapid urbanization and evolving policy landscape, the strategic role of temporary urban regeneration deserves nuanced examination (Gao & Zhang, 2024). The current trend of pop-up markets across the country offers a vivid illustration. These markets try to address issues such as the shortage of urban construction space, lack of funding for large projects, and the promotional needs for small enterprises. Recent initiatives such as China's "15-Minute Community Life Circle" and the incentives of night-time economies underline a growing institutional support for temporary, experiential urban activities. Nevertheless, the potential of these activities to transcend their commercial origins and foster meaningful community engagement and functional diversity remains under-explored.

Addressing this research gap, this study leverages urban informatics methodologies—including spatial analytics, social media sentiment analysis, and semantic modeling—to explore the interplay between pop-up market themes and the daily functional characteristics of surrounding built environments in Beijing. By systematically examining thematic alignment and divergence, this paper aims to clarify whether and how temporary market activities serve as effective instruments for tactical urbanism, fostering greater community satisfaction and resilience through experimental governance. The study period spans from December 2023 to November 2024, and it involves 447 markets for macro-level spatio-temporal analysis and 25 typical cases for in-depth thematic and sentiment analyses. Data sources include pop-up market information from WeChat public accounts, POI data from Gaode Map, and social media data from Xiaohongshu. This study further develops a methodological approach which employs Word2Vec to establish connections between urban built-environment characteristics and thematic content derived from social media, building upon earlier research by Yao et al. (2017). Our findings contribute to ongoing theoretical and practical debates by offering empirically grounded insights into how temporary urbanism principles like pop-up markets can guide the sustainable, community-responsive evolution of temporary urban initiatives.

2. Data

The empirical foundation of this study rests upon a meticulously assembled geospatial and social media dataset, designed to capture both the physical and experiential dimensions of pop-up markets in Beijing. Our spatial dataset comprises 618 pop-up market listings harvested from "Shijihui," a leading WeChat public account renowned for its exhaustive aggregation of Beijing marketplace events. To ensure comprehensive coverage and geographic precision, each listing was geocoded and cross-referenced with the 2024 point-of-interest (POI) database provided by Gaode (Amap), which offers detailed classifications for urban features such as transit nodes, retail outlets, cultural institutions, and life-service venues. Administrative boundaries and road network layers were procured from the Beijing City Lab repository, while OpenStreetMap (OSM) supplemented the street topology data to facilitate high-accuracy routing analyses. The spatial distribution of these markets is shown in Figure 1.

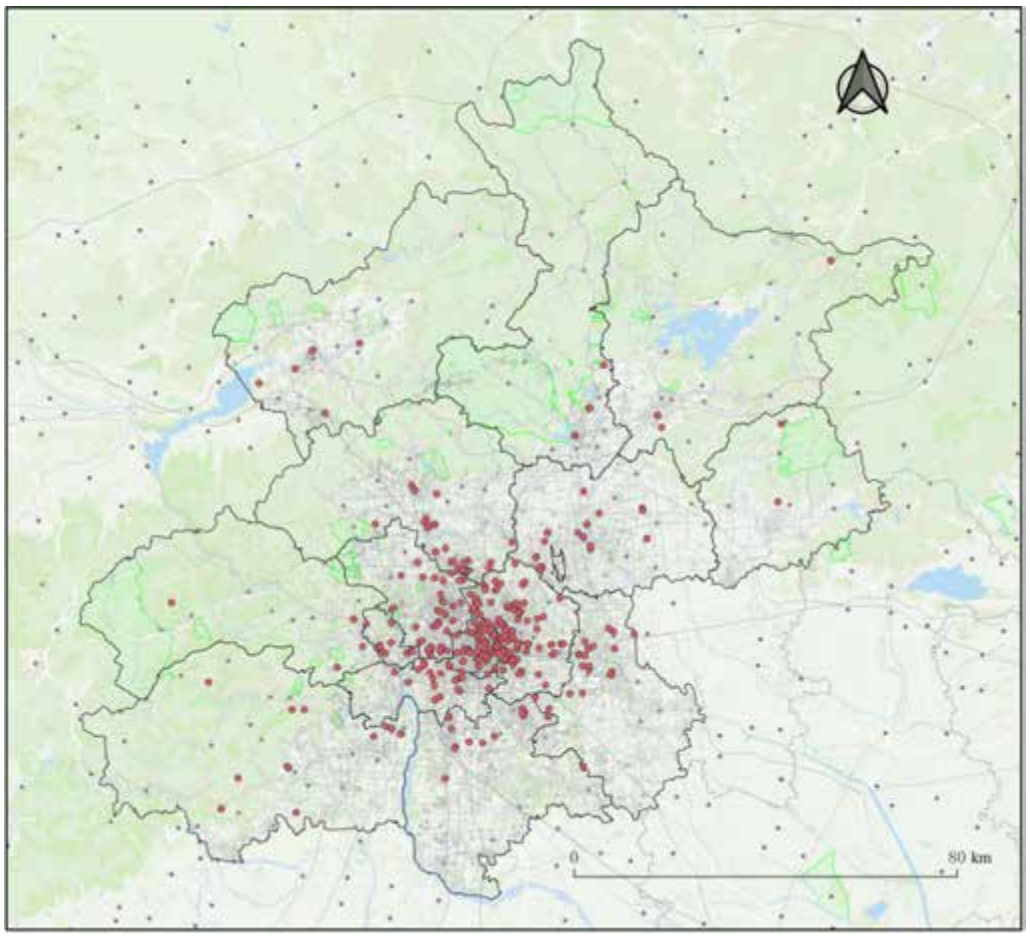

Figure 1. Pop-up markets in Beijing (2023.12-2024.11)

Recognizing the rapid evolution of urban events and to maintain analytical rigor, we confined our study period to December 1, 2023 through November 30, 2024. Markets situated outside Beijing's six core urban districts—Haidian, Chaoyang, Xicheng, Dongcheng, Fengtai, and Shijingshan—were excluded to focus on areas with advanced economic activity, data completeness, and high population densities. This spatial filtering reduced the sampling frame to 447 markets for which we have full environmental characterizations.

To capture the diversity of market typologies, we applied a keyword-based classification schema grounded in extant literature on temporary urbanism. Using descriptors such as "food," "fashion," "used goods," "art," and "comprehensive," each market was assigned to one of five categories: Food & Dining, Fashion, Used Possession, Art & Culture, and Comprehensive. We then executed a purposive sampling strategy by crawling the Xiaohongs-

hu, a popular lifestyle platform and consumer decision-making portal in China, with the query "Markets in Beijing" and manually verifying thematic relevance. From each typology, five spatially representative markets were selected, yielding a subset of 25 case markets (Figure 2) for in-depth thematic and sentiment analyses.

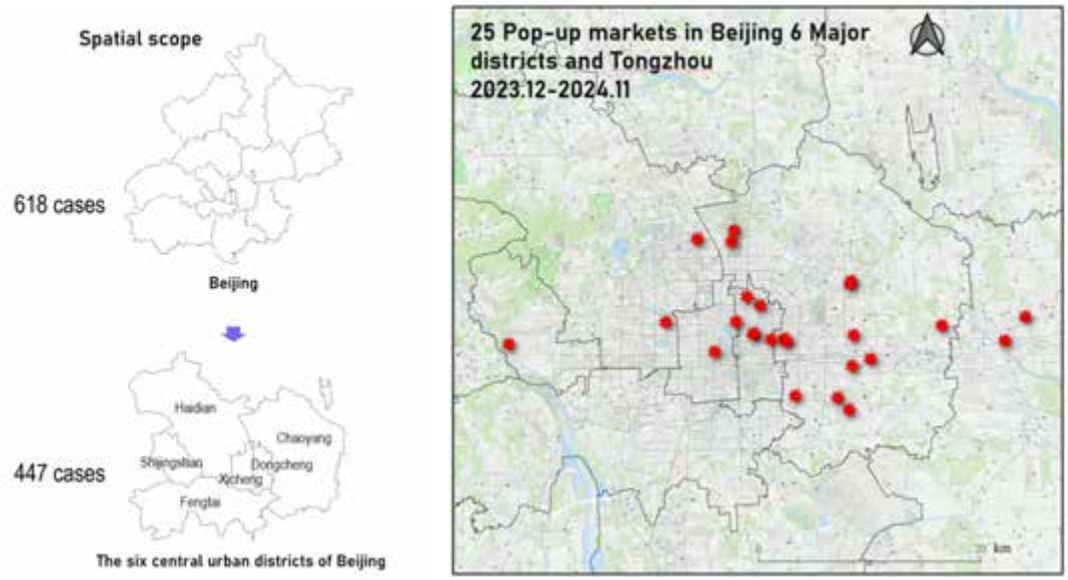

Figure 2. Schematic diagram of the screening of research subjects

Built environment metrics were calculated within a standardized 15-minute walking catchment around each market. Isochrone polygons were generated via the Mapbox API, ensuring alignment in the delineation of pedestrian accessibility zones. Within these isochrones, we extracted counts and spatial distributions of seven POI categories—subway stations, parking facilities, life services, catering venues, retail establishments, science/education/cultural institutions, and parks—using Gaode's developer API. To approximate urban vibrancy, we obtained nighttime light intensity data for the year 2023 from the NPP-VIIRS dataset maintained by NOAA and NASA by Z. Chen et al. (2020). Land use patterns were classified according to the European Urban Land Use Classification (EULUC) schema (Gong et al., 2020), providing a standardized taxonomy for comparative spatial analysis. All geospatial computations, including density metrics (e.g., facilities per square kilometer) and proximity measures (e.g., minimum walking distances to the nearest subway station), were executed in GISpro, with Kepler.gl employed for dynamic visualization of spatial layers and isochronal boundaries.

Social media data was sourced from Xiaohongshu posts associated with each of the 25 case markets. We collected metadata fields including "likes," "shares," "comments," and "collections," along with textual content and timestamps. To control for temporal sampling biases—given that older posts naturally accrue more interactions—we normalized engagement metrics by dividing the aggregate sum of interactions by the total number of posts per market. This yielded a standardized "popularity" score for comparative analysis. Sentiment analysis was performed using SnowNLP, a Python library tailored for Chinese language processing. Each comment's polarity was classified as positive or negative, and an overall "satisfaction" score was defined as the proportion of positively classified comments.

Finally, POI category proportions within each isochrone were converted into weighted semantic vectors to represent neighbourhood functional profiles. These "neighbourhood function" vectors served as the basis for our thematic alignment analysis, linking built environment attributes with pop-up market themes. Altogether, our multi-source dataset integrates spatial, social, and semantic dimensions of urban pop-up markets, forming a robust empirical backbone for subsequent methodological steps.

3.Methodology

This study employs a mixed-methods framework that synergistically combines spatial analytics, social media engagement metrics, and natural language processing to evaluate the thematic alignment between pop-up market offerings and their surrounding neighbourhood functions. Our analytic pipeline unfolds in four principal stages: spatial data assembly and pre-processing, built environment characterization, semantic embedding and similarity analysis, and statistical modeling of environment–experience relationships.

3.1 Spatial Data Assembly and Pre-processing

We began by geocoding the 618 pop-up market entries from "Shijihui" and filtering to the six core urban districts of Beijing. Markets without precise coordinates or outside the study period (Dec 2023–Nov 2024) were excluded, resulting in 447 valid cases. For each market, we generated a 15-minute pedestrian isochrone using the Mapbox API, capturing the realistic reach of on-foot visitors. POI data from Gaode was then spatially joined to these isochrones in GISpro, enabling the calculation of density (e.g., number of catering venues per square kilometer) and convenience (minimum walking distance to key services) indicators. Nighttime light intensity rasters were clipped to each isochrone and averaged to yield a proxy for local urban vibrancy. Land use classifications were overlaid using the EULUC dataset, allowing computation of land use mix indices via the Shannon entropy formula. All spatial operations adhered to a consistent coordinate reference system (WGS 84) and were validated for topology errors.

3.2 Thematic Data Extraction and Embedding

To extract market themes, we scraped the text of Xiaohongshu posts for each of the 25 case markets. Pre-processing included removal of punctuation, emojis, temporal and location markers, and high-frequency non-thematic tokens. Chinese word segmentation was conducted using Jieba, resulting in a clean corpus of thematic keywords. For each market, we identified the top 20 most frequent thematic keywords. We then trained a Word2Vec embedding model with a window size of 5 and vector dimensionality of 200 on the aggregated corpus of all market comments. Each keyword's vector was extracted and the mean across the 20 keywords yielded the "market theme" vector.

3.3 Neighbourhood Function Vector Construction

The neighbourhood characteristics around 25 case markets were analysed as follows. We translated POI category proportions within each market's 15-minute pedestrian isochrone into a semantic representation by first assigning each category a label (e.g., "Dining," "Shopping," "Science, Education & Culture," "Life Services"). Using the pretrained Word2Vec model (Figure 3), we converted each label into its vector embedding and weighted these embeddings by the category's share of total POIs. Summing these weighted vectors produced the "neighbourhood function" vector, which encapsulates the functional character of the neighbourhood surrounding each pop-up market.

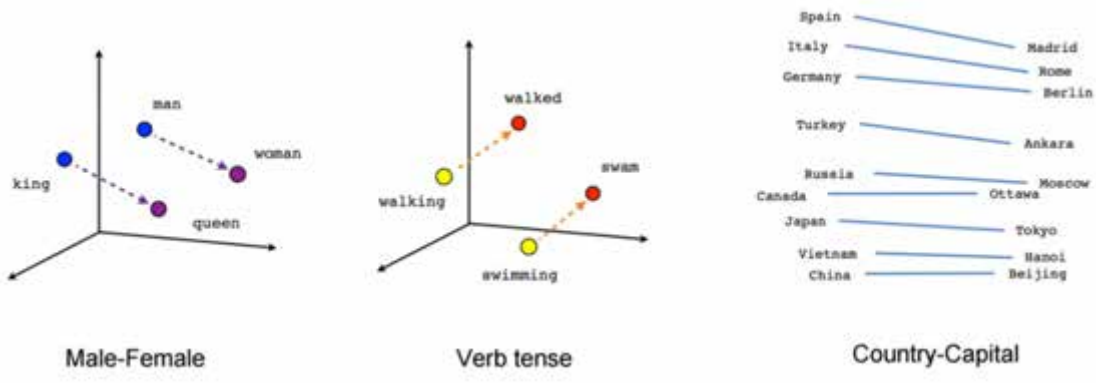

Figure 3. Schematic diagram of Word2Vec method (Ruizendaal, 2017)

3.4 Semantic Similarity and Statistical Modelling

The cosine similarity between each market's theme vector and its neighbourhood function vector served as our quantitative index of thematic alignment, with values ranging from –1 (complete mismatch) to 1 (perfect alignment). To investigate drivers of alignment and market success, we compiled a dataset combining thematic alignment indices, popularity scores (normalized social media engagement), and satisfaction scores (sentiment positivity ratios). All the case markets were divided into two groups based on the median of the alignment score: high consistency and low consistency. A t-test was then conducted on popularity and satisfaction, with $p<0.05$ indicating significant differences. Furthermore, we computed Pearson correlation coefficients to identify bivariate relationships between theme-neighbourhood alignment and the response from the public. The statistical analyses were conducted in Python (pandas, statsmodels), with significance evaluated at the 0.05 level.

By integrating geospatial methodologies, natural language processing, and statistical modeling, a holistic lens was provided for understanding how ephemeral urban events interact with their physical contexts and social perceptions. The dual focus on quantitative indices (e.g., cosine similarity, engagement metrics) and spatial visualizations ensures that our findings carry both empirical precision and practical relevance for urban planners, event organizers, and scholars interested in temporary urbanism.

4. Results

4.1 Macro-Level Spatio-temporal Patterns

All the data of markets advertised at "Shijihui" from December 2023 to November 2024 were collected and analysed, so as to present the duration of each market and the monthly distribution of all the markets throughout the year. The numerical results on the time dimensions are shown in Figure 4.

Figure 4(a). The duration of each market

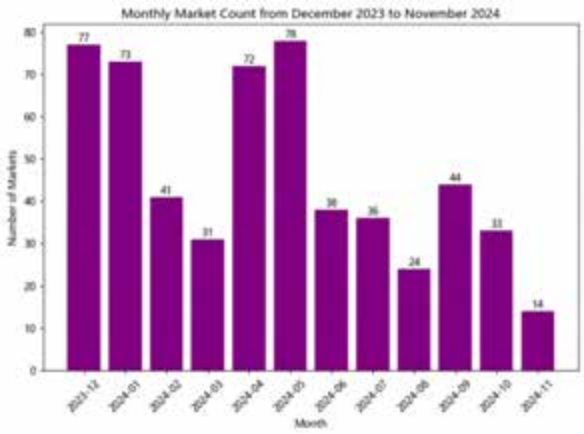

Figure 4(b). The monthly distribution of all the markets throughout the year

As is shown in the figure, markets peaked twice a year, from December to January and from April to May, with low peaks in February and August, which may be affected by the Chinese New Year in February and the summer heat in August. From further analysis of the market holding place, shopping malls are shown to be the main locations for pop-up markets, while office buildings, parks and art & creative parks are also popular venues. For the 447 market in the six main districts of Beijing, a kernel density was done. Results shown that 8 areas, including Qianmen, Longfu Temple and landmark river were concentrated places for temporary markets, as shown in Figure 5.

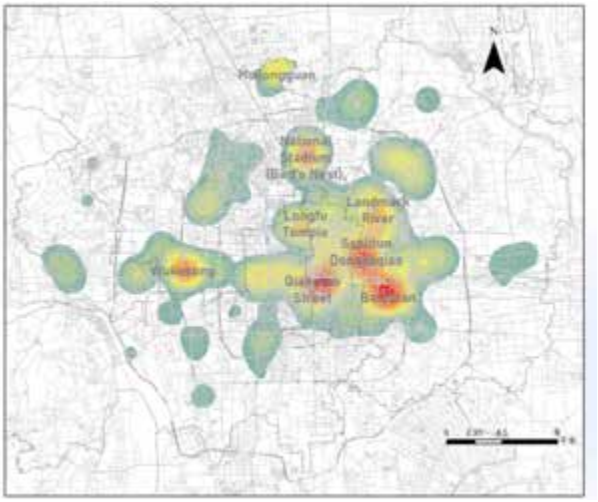

Figure 5. Kernel Density Map of Pop-up markets in Beijing 6 main districts 2023.12-2024.11

Subsequently, a preliminary investigation of the built environment surrounding all market sites was undertaken. Fifteen-minute walking isochrones for the market points were generated through the Mapbox Isochrone API, and the built environment within each isochrone was characterised along four dimensions: transportation, urban function, urban vitality and natural features. The resulting metrics were visualised with Kepler.gl. In the transportation dimension, the closest proximity to subway stations is observed for markets in Dongcheng District, Xicheng District, the western portion of Chaoyang District and the area around Olympic Forest Park, whereas parking facilities are comparatively scarce around market points situated on the northern and southern margins of Xicheng and Dongcheng Districts.

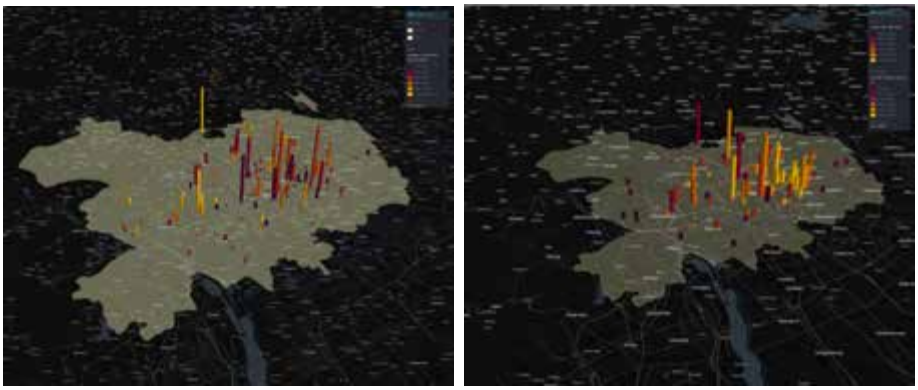

Figure 6. Walking distance to the nearest subway station (left)
Figure 7. Density of parking lots within the isochrone (right)

The markets in Chaoyang District have the most abundant surrounding life service facilities, followed by the markets near Xidan. Nightlife vitality was measured based on nighttime lighting.

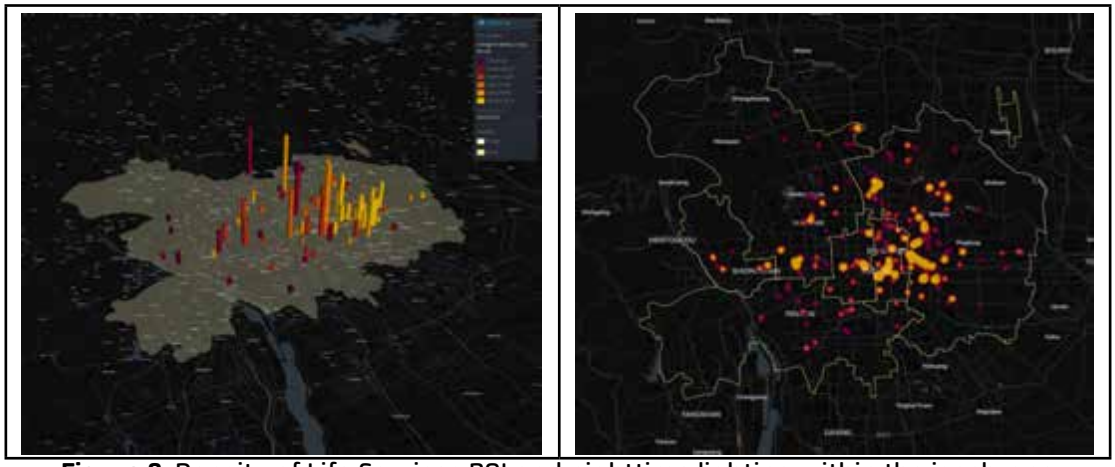

Figure 8. Density of Life Services POI and nighttime lighting within the isochrone

54% of the markets are within 1000 meters of the nearest shopping center, and there are more parks and attractions around the markets in Dongcheng, Xicheng, and Haidian Districts.

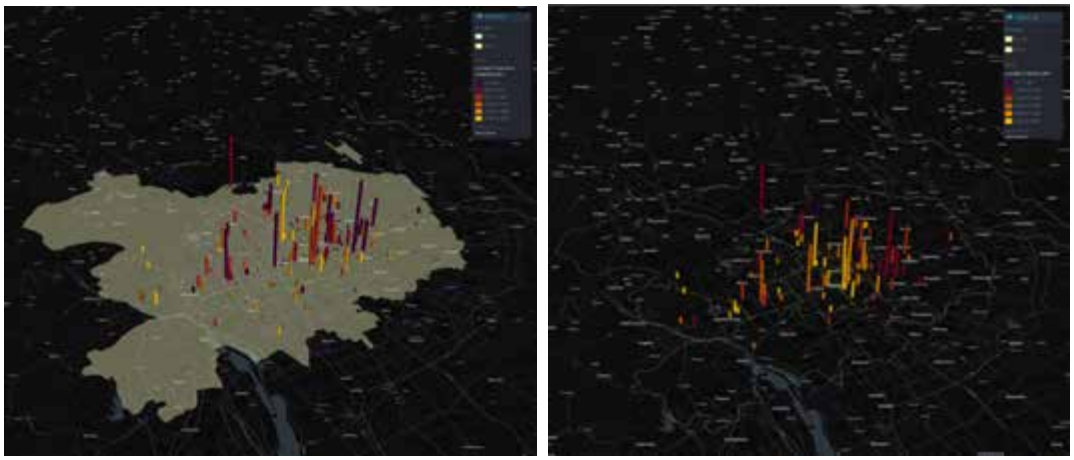

Figure 9. Walking distance to the nearest shopping center (left)
Figure 10. Density of parks within the isochrone (right)

Built-environment attributes were subjected to K-means++ clustering, and a two-cluster solution was identified as optimal. The first cluster is distinguished by higher levels of urban vitality, reflected in a greater density and diversity of facilities, whereas the second cluster is characterised by stronger integration with natural amenities, including a higher concentration of parks and scenic attractions in the immediate vicinity (Figure 11).

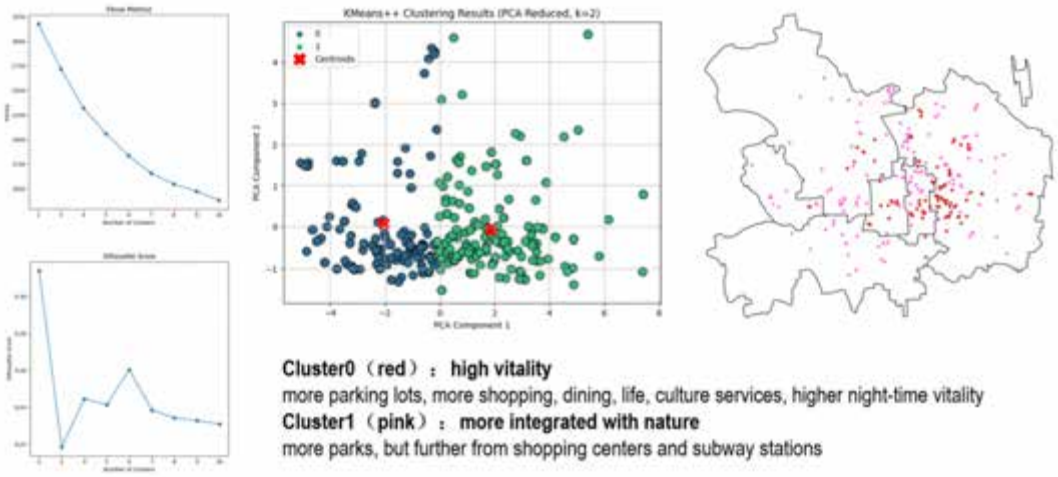

Figure 11. K-means++ Two-Cluster Solution of Market Sites by Built-Environment Attributes

4.2 Micro-Level Market–Neighbourhood Interaction Analysis

4.2.1 Theme-Neighbourhood Alignment Analysis

Table 1 summarises the thematic profile of four representative markets. For each market, the eight most frequent keywords extracted from Xiaohongshu comments are reported together with their raw counts (e.g., "Christmas 113," "Second-hand 220," "Panjiayuan 1133," "Book 638"). These terms constitute the weighted vocabulary that was embedded with Word2Vec to generate a theme vector for every market. The keyword distributions already hint at distinctive positioning: Waste Circulation Plan is dominated by "Second-hand," "Eco-friendly," "Recycling," and "Sustainability," signalling a life-style–oriented, environmental-protection theme, whereas Panjiayuan Night Market features "Night market," "Cultural objects," and "Antiques," underscoring its emphasis on culture and heritage trading. Likewise, Convex and Concave Space shows a design- and art-led orientation, while BIBF International Book Fair centres on book-related culture.

Table 1. Most frequent theme keywords of 4 example markets

Convex and Concave Space		Waste Circulation Plan		Panjiayuan Night Market		BIBF International Book Fair	
Christmas	113	Second-hand	220	Panjiayuan	1133	Book fair	638
Art	70	Eco-friendly	183	Night market	601	Books	408
Check-in	36	Recycling	145	Ghost market	334	Picture books	263
Original	28	Idle items	141	Market	278	Art	246
Jewelry	24	Life	128	Bracelet	241	Book	235
Design	24	Handmade	117	Used goods	168	Publisher	195
Shop exploration	23	Waste	108	Cultural objects	137	Reading	150
Exhibition	23	Sustainability	99	Antiques	118	Design	149

Table 2 presents the functional composition of the neighbourhoods surrounding surveyed markets, with 10 cases as examples. For each site (ID 1–25), the relative proportions of Points of Interest that fall into the four predefined categories—Life Services, Shopping, Science-Education-Culture, and Dining—are listed. The values (e.g., 0.2972 for Life Services at "Convex and Concave Space") are normalised shares that sum to one per row, and were employed as weights in the vector aggregation step when constructing neighbourhood-function theme vectors.

Table 2. Functional composition of the neighbourhoods surrounding surveyed markets

ID	Pop-up Markets	Functional composition of the surrounding neighbourhoods			
		Life Services	Shopping	Science, Education, and Culture	Dining
1	Convex and Concave Space	0.2972	0.2283	0.1764	0.2981
2	Waste Circulation Plan	0.2201	0.2975	0.0869	0.3955
3	Panjiayuan Night Market	0.2968	0.3945	0.0971	0.2116
4	NEEDFLEA	0.2758	0.3271	0.1145	0.2826
5	Dinosaur Vintage Warehouse	0.213	0.3015	0.2525	0.2326
6	Haoqi Retro Market	0.2253	0.2637	0.2857	0.2253
7	Big Doll Freak Market	0.2819	0.3343	0.1094	0.2744
8	BIBF International Book Fair	0.25	0.39	0.1197	0.2362
9	Dongpeng Ghost Market	0.2857	0.0905	0.1714	0.4524
10	Daliushu Night Market	0.2184	0.4885	0.0785	0.2146

Together, the two tables provide the weighted textual inputs required for calculating the cosine similarity between each market's theme vector and the corresponding neighbourhood-function vector, thereby quantifying theme–function alignment. Based on the cosine similarity of word vectors, the theme alignment of 25 markets is shown in Figure 12 below, with different colors representing different market categories (Art & Culture, Fashion, Food & Dining ,Used Possession, and Comprehensive).

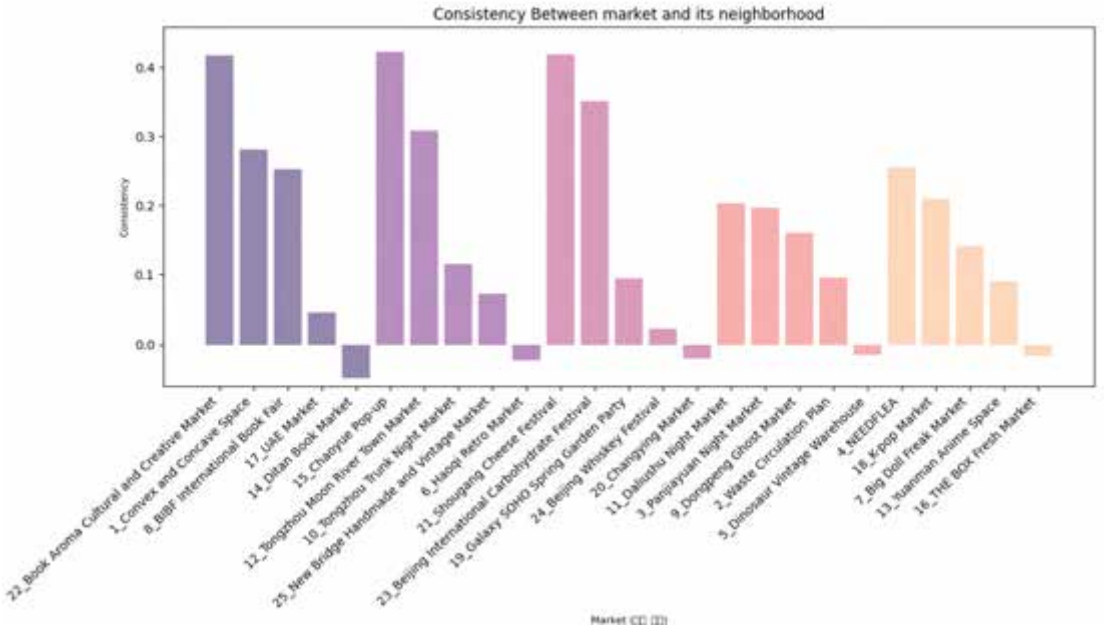

Figure 12. Alignment analysis between market and its neighbourhood

Approximately 80% of the market themes are consistent with the function themes of the surrounding neighbourhoods, while only a small portion of markets have themes that contrast with the typical functions of their neighbourhoods.

4.2.2 Market Popularity and Satisfaction Analysis

The numbers of likes, comments, and shares of 25 marketplaces are collected from Xiaohongshu. The sum of the three types of data is shown in Figure 13 (left), while each of them is shown in Figure 13 (right). We then computed a popularity score for each market:

Popularity scores = Average Likes+Average Collections+
Average Sharings+Average Comments

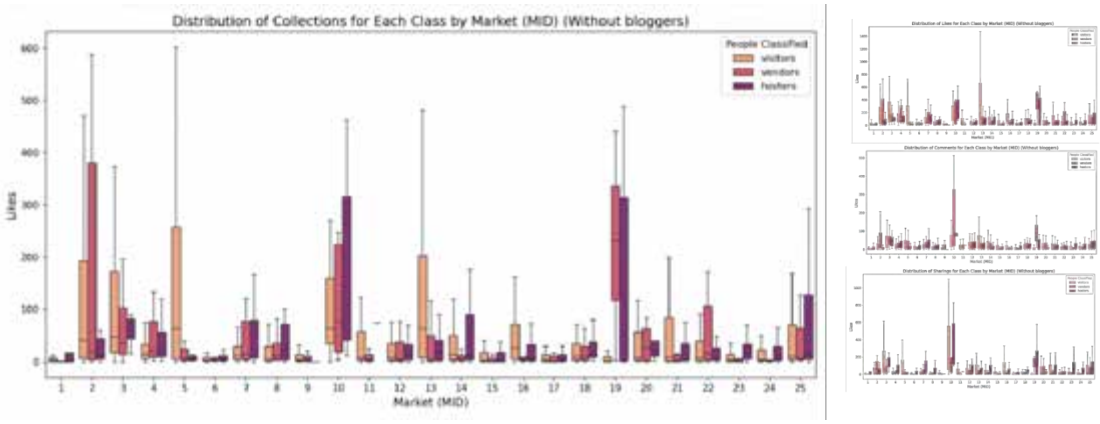

Figure 13. Numbers collected from Xiaohongshu (left) Sum data; (right) likes, comments, shares

Sentiment classification on the comments collected from Xiaohongshu was conducted, and the percentage of positive comments is shown in Figure 14 (left). Furthermore, the results of the word cloud analysis of these positive comments are presented in Figure 14 (right).

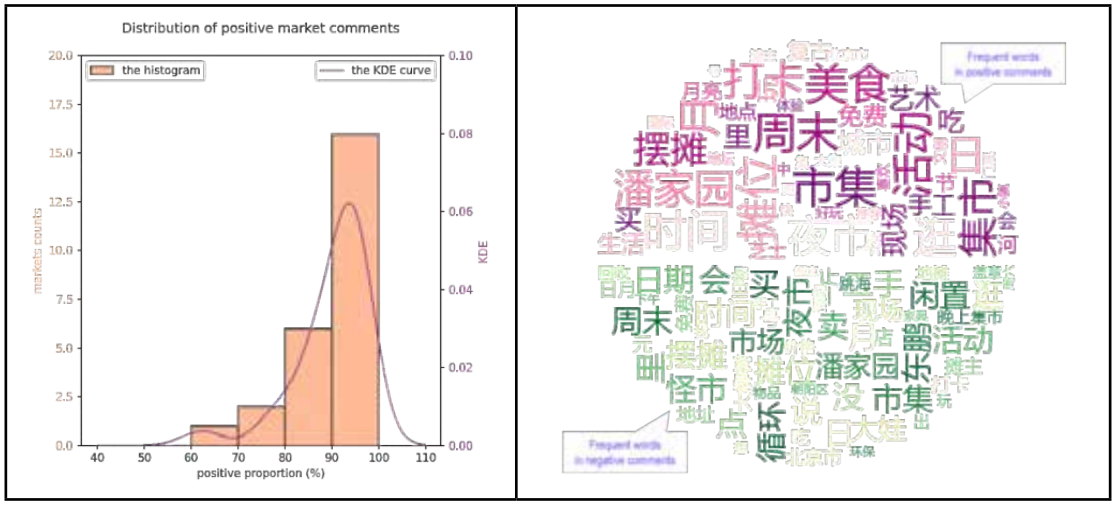

Figure 14 Positive comments analysis (left) Distribution; (right) Word cloud

Most markets have received over 80% positive feedback on social media platforms. Suggested by word-cloud, markets related to second-hand goods and non-mainstream cultures tend to face more negative feedback. This may be due to their purchase of items of poor quality, or difficulty in recognizing the sale of items from some niche cultures. The positive words in the word cloud such as "art," "food," and "events" also partially reflect the reasons why the public loves these markets.

After taking popularity and satisfaction as two criteria for evaluating market success, it can be observed that a large number of markets are in a "high satisfaction, low popularity" state, while no markets exhibit a "high popularity, low satisfaction" condition, as shown in Figure 15. In addition, the geographical distribution of these two factors is shown in Figure 16, with the size of the points representing the popularity of the markets and the color intensity indicating the satisfaction level.

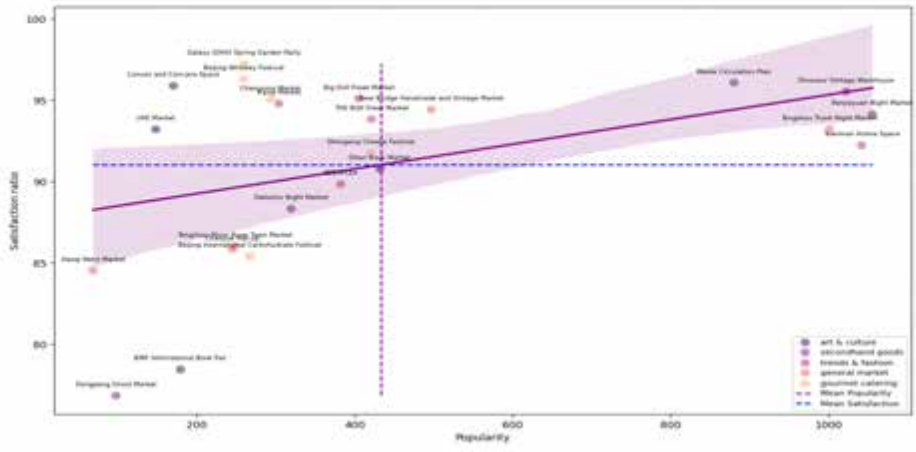

Figure 15. Popularity vs. Satisfaction: Quadrant Map of Pop-up Market Success

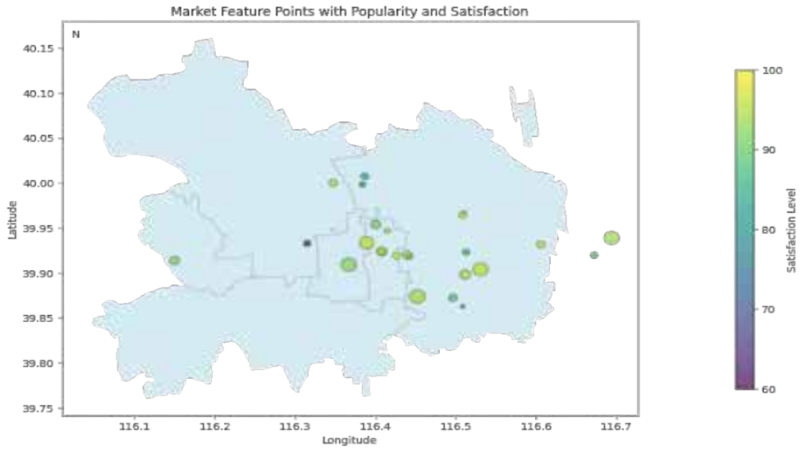

Figure 16. Geographic distribution of two factors

Generally, markets in the city center tend to be more popular, but there are also markets in Tongzhou with similarly significant influence. Furthermore, the distribution of satisfaction levels does not follow a clear geographical pattern.

4.2.3 Correlation Analysis of Alignment, Popularity and Satisfaction

By combining the theme alignment scores of the 25 markets with the two success indicators—popularity and satisfaction—the correlations among these variables can be further analysed. Markets were divided into two groups based on the median of the alignment data: high alignment and low alignment. A t-test was then conducted on popularity and satisfaction, with $p<0.05$ indicating significant differences. The results are shown in Figure 17 below.

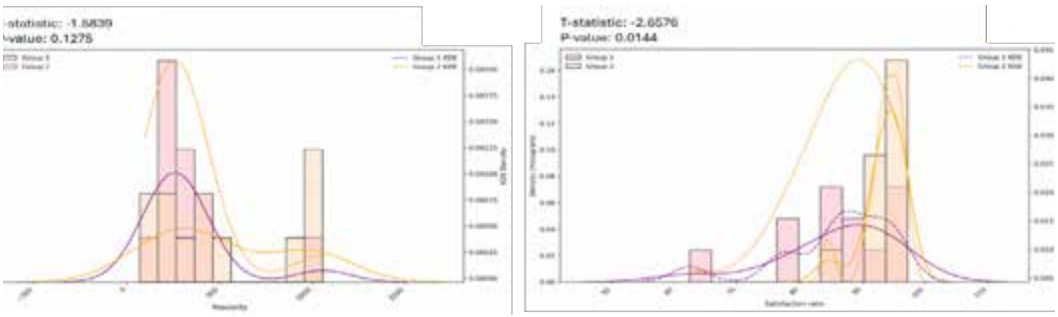

Figure 17. T-test for (left) Popularity; (right) Satisfaction

According to the t-test results, no significant difference was found in popularity between the two groups, while satisfaction showed a significant difference, suggesting that satisfaction is affected by theme alignment score.

Further regression analysis on theme alignment score and market popularity, and that on theme alignment score and market satisfaction are shown in Figure 18, 19, respectively.

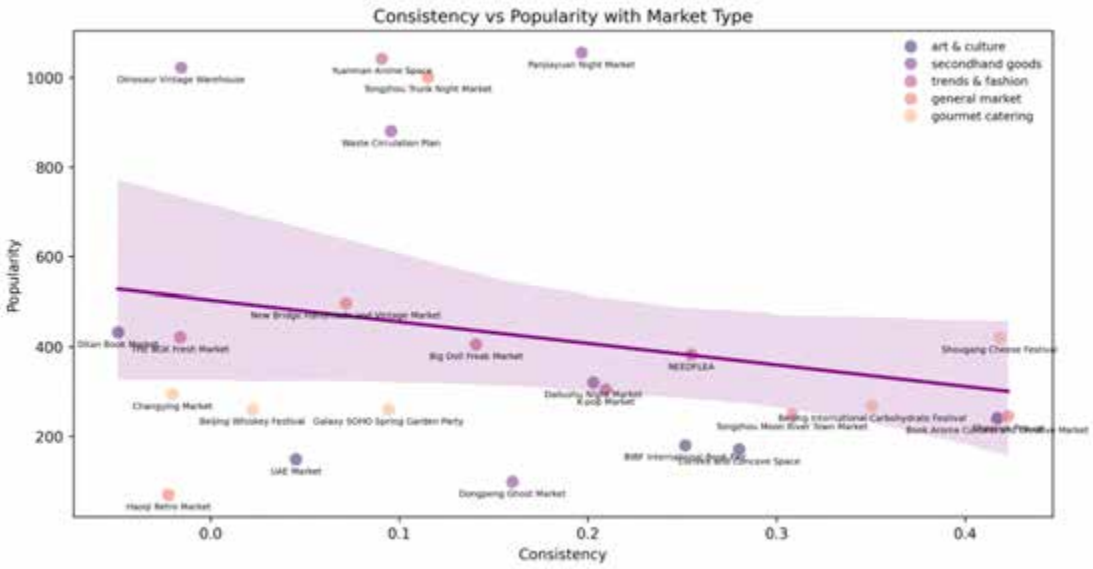

Figure 18. Regression analysis of market popularity and theme alignment

Although the popularity of the markets did not show a good regression relationship with theme alignment, a negative trend between popularity and theme alignment was still evident.

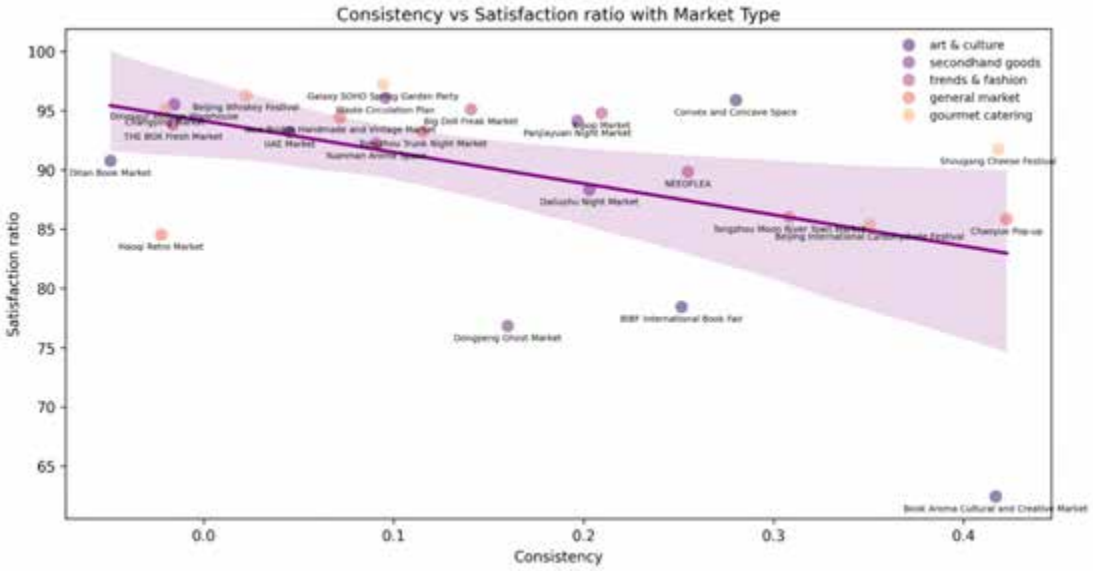

Figure 19. Regression analysis of market satisfaction and theme alignment

A linear regression was observed between satisfaction and theme alignment, indicating a linear negative correlation. This suggests that, while the market theme aligns with the neighbourhood theme in most cases, higher alignment leads to lower market satisfaction.

5. Discussion

This study employs Word2Vec to quantify the thematic alignment between urban pop-up markets and their surrounding neighbourhood functions, revealing that while many markets align closely with local amenities, those with greater thematic divergence often achieve higher visitor satisfaction. This observation invites a deeper exploration into the underlying mechanisms.

5.1 Drivers of Theme-Neighbourhood Alignment

The result of closeness between markets' themes and their neighbourhoods' function is consistent with the current market operation procedures and goals. Recent policy directives including China's "15-Minute Community Life Circle" initiative (Ministry of Housing & Urban-Rural Development, 2021) and a suite of night-time economy revitalisation programmes explicitly encourage the fast-track introduction of pop-up markets into functionally mature commercial nodes. By embedding new activities in areas with pre-existing consumer flows and complementary amenities, local governments can minimise regulatory uncertainty, while operators mitigate sunk-cost risks associated with experimental formats (Warnaby & Shi, 2018).

From the supply side, venue owners and municipal agencies exhibit risk-averse behaviour: projects whose themes match surrounding land uses are more likely to secure temporary permits within the approval cycles mandated by the post-COVID economic stimulus packages (Andres, 2021). Demand-side considerations may reinforce this tendency: compared with experimental themes with relatively high risks, market activities with the same theme as existing urban spaces can reduce the cognitive friction between brands and consumers and increase the consumption conversion rate.

Collectively, these observations suggest that institutional incentives, risk management considerations, and agglomeration economies converge to favour theme–environment alignment in contemporary Chinese pop-up practices.

5.2 Mechanisms Linking Theme Misalignment to Higher Satisfaction

Results from our Word2Vec analysis indicate that lower theme-environment alignment is positively associated with visitor satisfaction. Though this is a counter-intuitive pattern, two complementary theoretical lenses may help to explain it.

First, the "experience-economy" mechanism. Consumer-behaviour research shows that schema incongruity triggers exploratory behaviour, elevates arousal, and deepens memorability (Hirschman & Holbrook, 1982; Raju, 1980). When a pop-up market imports an unexpected theme, it breaks the cycle of habituation that dulls affective responses in routine retail settings. The effect might be amplified when organisers employ immersive staging (multisensory displays, storytelling signage) and interactive programming (hands-on workshops, live performances), thereby moving customers up Pine and Gilmore's (1999) progression of economic value from "service" to "experience". Second, the "functional-complementarity" mechanism. Many inner-city neighbourhoods exhibit mono-cultural retail ecologies. A thematically divergent market can plug latent deficits in cultural, educational, or sustainability-oriented offerings, thereby widening the local service portfolio (Bertolini, 2020) and aligning with Jacobs's (1961) argument that urban vitality thrives on mixed primary uses. This complementary injection not only satisfies unserved needs but also demonstrates, in tactical-urbanism terms, a "minimum viable product" for longer-term place upgrading (Lydon & Garcia, 2015). The resulting diversification helps improve the resilience of the overall commercial ecosystem.

Taken together, these two mechanisms help explain why theme–environment divergence, rather than harmony, can yield superior experiential outcomes in the context of urban pop-up markets.

5.3 Reframing Pop-up Markets: From Marketing Tool to Community Prototype

In the extant literature, temporary urbanism remains a contested field. On the one hand, scholars argue that short-term interventions are frequently co-opted by capital, functioning as low-cost instruments for "filling urban gaps" during periods of economic downturn and for staging future real-estate appreciation, while simultaneously diluting procedural public participation (Colomb, 2012; Douglas, 2018; Madanipour, 2018). In the North-American context in particular, the term pop-up has become almost synonymous with the commercial occupation of vacant premises to attract investors, and is therefore viewed as a potential threat to urban publicness (Baras, 2015).

Conversely, a growing body of research contends that, when framed within the logic of *incremental experimental*

governance (Bertolini, 2020), pop-up markets can act as low-risk "prototypes" for testing novel urban functions and public values. The empirical findings of the present study reinforce this view: markets whose themes diverge markedly from surrounding land-use patterns receive significantly higher visitor-satisfaction scores than markets exhibiting high thematic congruence ($p < 0.05$). This suggests that defamiliarisation and novelty can heighten motivational engagement and place attachment, offering valuable insights for the long-term enrichment of neighbourhood functions.

As discussed in § 5.1, however, pop-up markets in China face potential constraints arising from approval procedures and from the uncertain returns perceived by operators, which explains why truly complementary, "non-matching" markets themes remain scarce. We therefore advocate, drawing on the tactical-urbanism literature, that pop-up markets be reconceptualised as *minimum viable public spaces* (Lydon & Garcia, 2015; Bertolini, 2020). Experimental projects that demonstrably address community needs should receive targeted policy and financial incentives; risk should be distributed among multiple stakeholders; and real-time data monitoring combined with community co-evaluation should determine whether, and how, short-term trials are converted into permanent interventions. *The National 15-Minute Community Pilot Cases* recently issued by Ministry of Commerce of the People's Republic of China already incorporate market events in Nanjing and Wuxi as instruments for optimising neighbourhood-service layouts and enriching everyday experience, with an explicit aim to couple "quality consumption" with "service expansion." This evidences the practical feasibility of the proposed pathway. Under a regime of policy support, dedicated funding and shared risk, pop-up markets can avoid the pitfalls of neoliberal "privatised marketing tools" and instead provide quantifiable, iterative decision inputs for neighbourhood regeneration.

6. Conclusion

This study employs urban-informatics methods to capture the market events in Beijing from 2023 to 2024 over a year, summarizing their timing, aggregation, location types, and surrounding built environmental conditions. The spatial and temporal analyses highlight that flash markets are predominantly short-term events peaking in December-January and April-May, with shopping malls as their primary location. Neighbourhood characteristics shows two clusters by using K-means, with markets in Chaoyang District being notably vibrant with abundant life service facilities, and markets in other districts like Dongcheng, Xicheng, and Haidian sited in a more nature-integrated environment.

Our study further examines the relationship between markets as temporary activities and their host neighbourhoods. By applying the method of sentiment analysis and Word2Vec for content in social media platform, we explore the impact of theme alignment between market themes and the daily functional themes of the surrounding neighbourhood on the success of market events, especially for visitors' satisfaction. The results show that: 1) Themes of the markets are typically aligned with the function themes of their neighbourhoods, reflecting the general understanding of market organizers when selecting locations. 2) However, market satisfaction and popularity are negatively correlated with theme alignment. Markets with themes that differ significantly from the surrounding neighbourhood functions, which account for only 20% of the cases, received higher satisfaction ratings. 3) NLP tools, including word2vec, are effective in bridging physical and virtual spaces, especially for temporary events, considering their nature of interest-oriented and reliance on media advertisements. These conclusions may provide guidance for future research on market site selection and theme choice.

At a practical level, we have elucidated how disparities between market themes and neighbourhood functional areas can bolster market satisfaction. This insight suggests that markets might serve as a potent supplement to temporary business models within neighbourhoods. Our results demonstrate that pop-up markets—recast as minimum viable public spaces—can function as low-risk prototypes that heighten visitor engagement, test missing neighbourhood functions and generate data for long-term improvements, aligning with the existing theoretical framework of tactical urbanism. Implemented under supportive policies, shared-risk financing and real-time evaluation, such experiments can escape the pitfalls of neoliberal "privatised marketing tools" and become a scalable tool for evidence-based neighbourhood regeneration.

Integrating Energy Performance and Public Space Metrics: A Study from the Perspective of Urban Design

Mengyue Mei, Tongyu Sun
Tongji University, Shanghai, China
mengyue_mei@163.com

Abstract
Global warming necessitates energy-efficient urban design. Urban morphology critically impacts both building energy use and public space quality. While prior studies focus on typological parameters (e.g., FAR, density), block-scale energy performance also depends on contextual features like street proportions and public space ratios. This research examines how morphological variations affect energy efficiency and spatial quality by analyzing blocks with identical FAR but differing configurations. Key metrics—alignment ratio, effective street length, and street space density—are evaluated through energy simulations. Results identify specific typologies that simultaneously optimize energy performance and pedestrian experience, demonstrating the potential for integrated low-carbon, human-centric urban design. These findings provide actionable insights for early-stage planning to achieve sustainable built environments.

Keywords:public space; urban form; building energy consumption; performance driven design

Introduction

Global urban populations are projected to reach 68% by 2050, with 2.2 billion additional urban residents concentrated in Asia and Africa (United Nations Habitat, 2022). This urban expansion necessitates increased building construction, resulting in elevated energy consumption and emissions. The built environment currently represents 30% of global final energy use and 26% of energy-related emissions, according to International Energy Agency (IEA, 2022). Despite improvements in energy efficiency per square metre, total building emissions have increased by over 25% since 2000, attributable to a 65% expansion in floor area and growing electricity demand. Building electricity consumption has increased at five times the rate of power sector decarbonisation since 2000 (IEA, 2019). The Paris Agreement (2015)targets – requiring 45% emission reductions by 2030 and net-zero by 2050 – highlight the urgency of urban energy research.

Building energy analysis typically distinguishes operational energy (heating, cooling, lighting) from embodied impacts. According to data from IEA, space cooling demonstrates particular significance, with 2 billion operational air conditioning units globally, 70% of which are residential. Heating accounts for approximately 50% of building energy use worldwide. Effective strategies to reduce operational energy consumption go beyond improving the energy efficiency of heating and cooling systems. They also rely on passive, nature-based, and alternative solutions, including the enhancement of building and district design.

Building energy consumption in urban environments is influenced by multiple factors. Previous research has primarily focused on building-specific elements and parameters, such as the shape coefficient of buildings, envelope materials, and building orientation. However, buildings do not exist in isolation—they are situated within distinct neighborhood contexts, meaning their energy performance is also affected by surrounding environmental conditions. In other words, urban morphological elements equally exert significant influence on building energy consumption patterns. Delmastro et al. (2015) demonstrated that variations in urban form could account for an 11% difference in heating energy use, which increases to 16% when considering solar gain. Similarly, Silva et al. (2017), through a case study of Porto, Portugal, established that urban form could explain up to 78% of the variance in total energy consumption, including heating, cooling, and mobility. The research by Shareef and Altan (2022) demonstrated that a sinuous configuration in urban blocks could reduce building cooling loads by 4.9%.

On the other hand, urban morphological elements constitute essential components of urban design. The control of urban morphology directly and indirectly influences the creation and quality of public spaces, thereby affecting pedestrian experience. Therefore, focusing on urban morphological elements—particularly urban design indicators—can impact urban spatial quality in multiple dimensions and warrants further in-depth research.

Previous studies have explored how urban morphological elements affect building energy consumption across different climate zones, aiming to design low-carbon or even zero-energy urban blocks. However, while pursuing lower energy consumption, the external environments created by certain urban forms are often overlooked.

Crucially, under the same floor area ratio (FAR), different urban forms can produce vastly different qualities of external public spaces. These variations in public space quality profoundly influence urban users, particularly pedestrians, and have implications for spatial equity. Commonly studied urban morphological indicators—such as density, FAR, and building height—fail to fully capture the spatial characteristics of public spaces shaped by urban design.

Urban morphological elements thus exhibit a dual influence, simultaneously shaping both building energy efficiency and the quality of public spaces and pedestrian experiences. While existing research tends to examine these aspects in isolation, practical urban design necessitates an integrated approach that accounts for multiple factors. Unlike studies focusing solely on singular dimensions, this research seeks to bridge energy performance and public space contribution, with particular emphasis on the latter from an urban design—rather than purely technical—perspective.

This study adopts an urban design perspective to identify morphological indicators influencing public space quality, based on a review of urban design guidelines and practices. Three key metrics are proposed: alignment ratio, effective street length, and street space density, to better understand the relationships between building energy performance, public spaces, and urban morphological elements.

Given that total building capacity is typically predetermined in real-world urban design practice, this research conducts a comparative experiment using urban block designs with identical floor area ratios (FAR) but varying public space configurations. By analyzing energy simulation results across different design groups and their corresponding urban design elements, the study explores whether urban design approaches can balance energy efficiency with public space quality, and identifies priority morphological elements.

These findings provide valuable insights for early-stage urban design, encouraging future research to move beyond solely energy-efficient block morphology and equally consider pedestrian experience and public space quality.

Literature Review

Unlike at the building scale, the mechanisms through which block-scale urban form elements influence building energy consumption are markedly more complex. This complexity arises because block morphology not only directly affects a building's passive solar gain and heat dissipation but also indirectly alters energy performance via microclimatic modifications. Consequently, microclimatic impacts must be integral to urban form considerations.

The characterisation and selection of energy-relevant urban form elements vary across studies. Existing research predominantly focuses on four classifications: density measures, geometric measures, land use/cover measures, and typologies (Quan *et al.*, 2021). These categories emerge from systematic syntheses of prior morphological research. While the first three measure types lend themselves to quantitative data analysis, typological approaches better capture urban form complexity. Many studies therefore combine these methods or enhance typologies with context-specific indicators, enabling both relational quantification and practical application for designers.

However, synthesising energy consumption findings for individual factors reveals that most studies preclude direct cross-comparisons of singular morphological variables. Notwithstanding this limitation, our literature review identifies recurrent indicators. Table 1 collates commonly employed metrics for urban form's energy impacts.

Morphological factors in extant research can alternatively be categorised by their descriptive focus:

- Built-environment relations: Floor Area Ratio (FAR), Building Density (BD), Building Coverage Ratio (BCR)

- Non-physical spatial attributes: Open Space Ratio (OSR), obstruction angles, Sky View Factor (SVF)

Whilst both categories influence energy consumption, the second category demonstrably exerts more direct effects on public space quality and pedestrian experience.

Table 1. Morphological indicator choices of some previous research.

Year	Researchers	Location	Indicators
2016	Quan *et al.* (2016)	Shanghai, China	Building density (BD), building height (BH), floor area ratio (FAR)
2018	Javanroodi *et al.* (2018)	Tehran, Iran	Building density (BD), height to width ratio (H/W)
2019	Lima *et al.* (2019)	Maceio, Brazil	Building shape factor (BSF), building height (BH), building density (BD), building orientation (BO)
2021	Mangan *et al.* (2021)	Istanbul, Turkey	Building typology (BT), height to width ratio (H/W), number of floors (NS), building orientation (BO)
2021	Ahmadian *et al.* (2021)	London, UK	Plan depth (PD), number of floors (NS), building density (BD)
2021	Zhang and Gao (2021)	Nanjing, China	Floor area ratio (FAR), surface area ratio (SAR), sky view factor (SVF)
2023	Liu *et al.*(2023)	Jianhu, China	Building density (BD), open space ratio (OSR), shape coefficient (SC), average perimeter-area (PAR)

It is noteworthy that whilst numerous studies examine the impact of urban form at the block scale upon energy consumption, the indicators employed to describe urban form tend to prioritise characteristics of building form, frequently lacking relevant indicators from an urban design perspective. Taking density and floor area ratio (FAR) as examples, utilising merely these two indicator types to describe urban form can yield substantially divergent outcomes owing to variations in building form and layout. These differences manifest not only in the buildings themselves but also influence public space configurations shaped by building forms. Exclusive reliance upon indicators such as open space ratio may inadequately represent actual urban form whilst neglecting pedestrian experience from an urban design standpoint.

Existing urban form descriptors commonly overlook the significance of public space morphology, which holds crucial importance within urban design. Within this context, establishing how public space form influences building energy consumption becomes particularly vital. This proves especially pertinent when the design objective involves creating urban forms that must reconcile energy efficiency with the provision of human-centred, functional public spaces.

Urban design represents a principal methodology for creating and optimising urban public spaces. The urban design process incorporates elements frequently marginalised or entirely disregarded in comprehensive planning and architectural design, including building façade continuity, public space provision, street formation and articulation, alongside street density, amongst others. Consequently, research adopting an urban design perspective can meaningfully address the current knowledge gap regarding how such elements influence energy consumption.

The selection of public space morphological factors may be informed by established street design and urban design guidance. For exemplary high-quality urban spaces, urban design manuals typically furnish explicit directives and design recommendations, regularly incorporating specifications for street space morphology. For instance, the Central Melbourne Design Guide underscores that enhancing both the quantity and quality of public spaces constitutes a central urban design objective. It particularly emphasises that urban development and renewal should privilege walking as the primary transport mode.

At the urban morphology level, this is principally realised through developing laneways and pedestrian connections. The guidelines prescribe that pedestrian connections should not exceed 70 metres separation whilst maintaining minimum 6 metre width. Building volumes ought to align with streets to establish an effective street interface, except where setbacks facilitate plaza creation. The guide promotes appealing colonnades exhibiting height-to-depth ratios of 2:1. Furthermore, street walls should be of reduced height along laneways and streets narrower than 10 metres. Buildings presenting street frontages exceeding 25 metres require subdivision to introduce street façade modulation.

Concerning ground floor levels, the guidelines stipulate that no less than 80% of ground-level frontage facing streets and laneways should comprise entrances or windows, thereby ensuring active frontage. The Central Melbourne Design Guide ultimately defines average urban block length as the mean distance between opposing block sides, measured from laneways and streets.

This integrated approach highlights the necessity of incorporating public space quality considerations within urban design, guaranteeing that energy-efficient, walkable and people-focused spaces receive appropriate priority in urban planning. Correspondingly, the Shanghai Street Design Guidelines (2016) advocate that street spaces should exhibit order, comfort and pleasantness. This is attained through regulating building control lines and alignment ratios, which guarantee a coherent and continuous spatial interface. Through maintaining comprehensive consistency, these guidelines seek to establish foundations for functional spaces that sustain public life and generate walkable urban scales.

Method

To further examine the relationship between urban morphological elements and building energy performance from an urban design perspective, this study employs a set of indicators derived from urban design guidelines that characterise external building spaces. A comparative analysis is subsequently undertaken through a series of simulation experiments, with the overall research methodology and workflow illustrated in Figure 1.

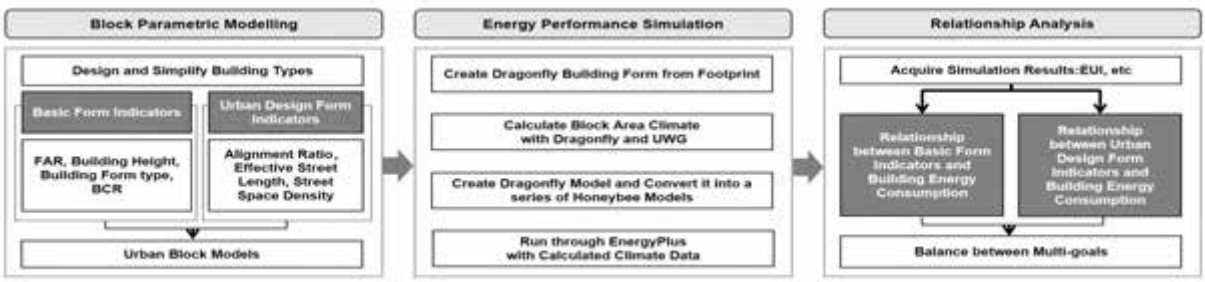

Fig. 1. Workflow of the research process with three stages.

The research comprises three principal stages: block parametric modelling, energy performance simulation, and relationship analysis. The initial stage concentrates on modelling urban forms, which establish the foundation for subsequent energy performance simulations. The results of these simulations then inform the relationship analysis conducted in the final stage.

The primary objective of the first stage involves constructing abstract urban forms and developing their parametric models. A fundamental requirement at this stage ensures all comparative forms maintain identical floor area ratio (FAR) values. This constraint is implemented for three key reasons. Firstly, within practical design processes, urban designers and architects frequently receive explicit, fixed FAR requirements during early planning stages. Secondly, variable control proves essential for isolating effects, with FAR commonly serving as a standard indicator in studies investigating urban form-energy performance relationships. Thirdly, despite FAR uniformity, urban form's inherent complexity permits significant variations in external spatial configurations, rendering these differences crucial components of design decision-making.

To maintain consistent FAR values, this study utilises a typical residential unit as a base model. The unit measures 15 metres in length, with a width of 10.5 metres and height of 3 metres. Through modifications to building heights, typologies and spatial arrangements, six distinct block models exhibiting varying external environmental characteristics are developed, as demonstrated in Figure 2.

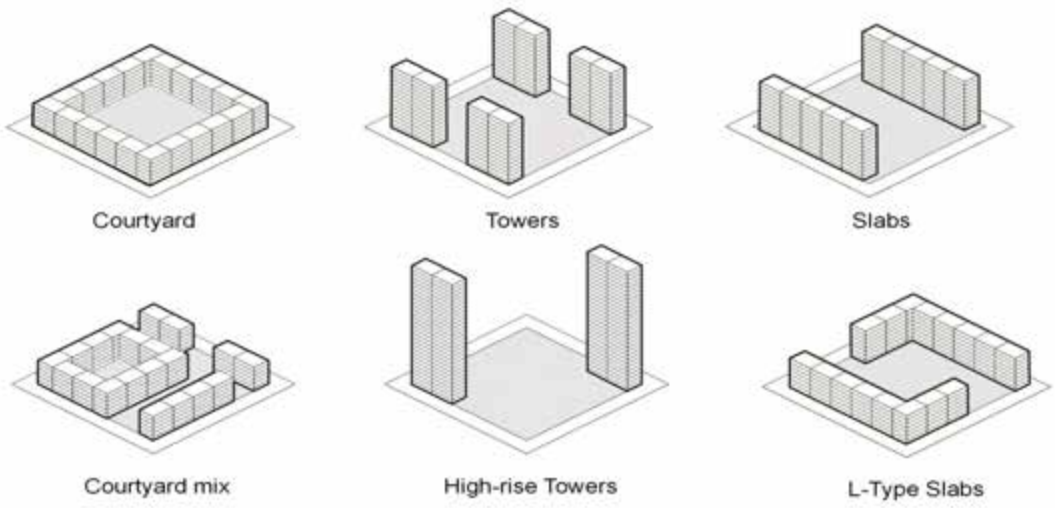

Fig. 2. Residential unit and six block form types.

Situated on identical designated sites, these block models share equivalent FAR values while differing in other fundamental form indicators, summarised in Table 2.

Table 2. Basic form indicators of six types.

No.	Form Type	Site Area	Total Building Area	Building Footprint Area	Number of Floors
C-1	Courtyard	11130.25㎡	18900㎡	3150㎡	6
C-2	Courtyard mix	11130.25㎡	18900㎡	3150㎡	6
T-1	Towers	11130.25㎡	18900㎡	1260㎡	15
T-2	High-rise Towers	11130.25㎡	18900㎡	630㎡	30
S-1	Slabs	11130.25㎡	18900㎡	1575㎡	12
S-2	L-Type Slabs	11130.25㎡	18900㎡	2520㎡	7, 8

Parametric modelling and energy performance simulations are executed based on the defined block forms. While numerous building energy simulation tools exist, determining appropriate methods and tools for block-scale analyses remains crucial. This study implements a workflow centred on Ladybug Tools (Figure 3), operating principally within Rhinoceros and Grasshopper platforms while employing EnergyPlus as the core simulation engine for energy performance analysis.

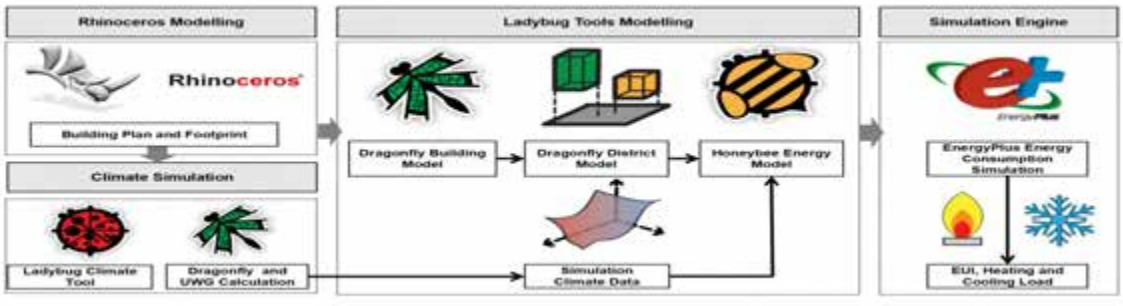

Fig. 3. Energy performance simulation workflow.

Developed by the U.S. Department of Energy, EnergyPlus provides comprehensive simulations of building thermal performance, humidity levels, airflow and lighting conditions. The software incorporates key factors including thermal conduction, air infiltration, solar radiation, lighting and HVAC system performance through its fundamental thermal balance physical model. Unlike simulation engines such as DOE-2 and DeST, EnergyPlus not only ensures thermal balance within rooms but also extends beyond linear time-invariant systems to handle surface convective heat transfer coefficients. Crawley *et al.*(2021) validated EnergyPlus's high precision in building energy consumption simulations through multiple test cases, confirming the reliability of its core algorithms.

To enhance usability, platforms including OpenStudio, DesignBuilder and Ladybug Tools have integrated the EnergyPlus engine within more accessible interfaces. The Grasshopper platform facilitates visual programming through user-friendly plugin tools, with Ladybug Tools serving as a central component. This toolkit comprises four specialised plugins: Ladybug for climate and meteorological analysis with advanced visualisation capabilities; Honeybee for energy performance and daylighting simulations; Butterfly for wind environment analysis; and Dragonfly for urban-scale microclimate and energy performance studies. The current research primarily utilises

Honeybee and Dragonfly for performance simulations.

Compared to alternative EnergyPlus-based tools like OpenStudio and DesignBuilder, Ladybug Tools offers distinct advantages. As a parametric platform, it provides superior comprehensiveness and adjustable flexibility, enabling multi-factor simulation workflows through combined use of its plugins. Consequently, researchers widely employ Ladybug Tools for studies examining solar potential, microclimate, daylighting, energy consumption and their relationships with built morphology. For instance, Rostami *et al.* (2024) applied a Ladybug Tools-UMI integrated workflow to investigate urban canyon solar potential and energy consumption under morphological influences in semi-arid regions. Furthermore, as a Grasshopper plugin, Ladybug Tools demonstrates exceptional usability within established urban design workflows, significantly reducing learning curves while facilitating performance-optimised design operations. These characteristics have led to its widespread adoption in urban morphology-energy consumption research(Feng *et al.*, 2024; Liu *et al.*, 2023; Ibrahim *et al.*,2021) justifying its selection as the primary simulation tool in this study alongside the EnergyPlus engine.

To account for local urban climate conditions, the study employs Dragonfly's integrated Urban Weather Generator (UWG), validated across multiple cities for effective urban weather data adjustment (.Bueno *et al.*, 2013). Using modified climate data, the Honeybee plugin executes EnergyPlus simulations to evaluate block configuration energy performance, generating Energy Use Intensity (EUI) and annual heating/cooling load data. The simulation methodology prioritises result reliability, workflow consistency and parametric form manipulation capacity.

The process utilises Grasshopper's parametric design platform within Rhino to define building site plans, establish volumes through floor height/count parameters, and configure daylighting via window-to-wall ratios (WWR). A Dragonfly model converts into Honeybee models for energy simulations, applying a maximum 0.35 WWR for residential buildings. All block models occupy identical urban contexts to minimise external interference, with Shanghai selected as the experimental location due to its representative ASHRAE 3A (warm and humid) climate classification.

EnergyPlus simulations incorporating Shanghai's climate parameters produce annual EUI data and monthly load outputs. Prior to energy performance comparison, the study defines four urban design form indicators (Table 3) specific to the identified typologies. These indicators focus on building-shaped external spaces, evaluating their capacity to generate sufficient, high-quality public realms.

Table 3. Urban design form indicators.

Indicator	Formula	Connection to high-quality public spaces
Alignment Ratio	$AR = \frac{\sum StreetwallLength}{\sum BuildingSetbackLineLength} * 100\%$	High AR helps to create continuous and enclosure street interfaces, thereby promoting pedestrian activity (2011).
Effective Street length	$ESL = \sum StreetwallLength$	Longer street wall length can enhance the vitality of the street attract more pedestrians to stay(Mehta, 2014).
Effective Street Space	$ESS = \sum ESL * PedestrianSpaceWidth$	Higher effective street space provides more spaces for activities (2013).
Street Space Density	$SSD = \frac{\sum Non\text{-}UrbanSpaceOccupiedByBuilding}{SiteArea} * 100\%$	Higher street space density means more accessible pedestrian spaces for vitality and more pedestrian-friendly environment (Gehl, 2003).

The study examines four key urban design indicators to evaluate block morphology:

Alignment Ratio: This measures the proportion of building street walls aligned with designated setback lines, calculated as the total building street wall length divided by the total setback line length. Urban design guidelines globally emphasise this metric as it quantifies how effectively buildings define street interfaces and contribute to coherent streetscapes.

Effective Street Length: This represents the cumulative length of building façades that actively contribute to high-quality street environments. Streets lacking continuous building interfaces typically fail to generate vibrant public spaces, making this a crucial measure of urban form quality.

Effective Street Space: This indicator calculates the total area of street space bounded by well-defined building interfaces. It measures the spatial extent of streetscapes capable of supporting diverse public activities and pedestrian interactions.

Street Space Density: A novel metric introduced in this research, defined as the ratio of non-building urban space to total site area (illustrated in Figure 4). Higher values indicate more compact, pedestrian-oriented urban configurations where public spaces are efficiently distributed within the block structure. This indicator provides a quantitative measure of urban morphology's capacity to support walkability and public space functionality.

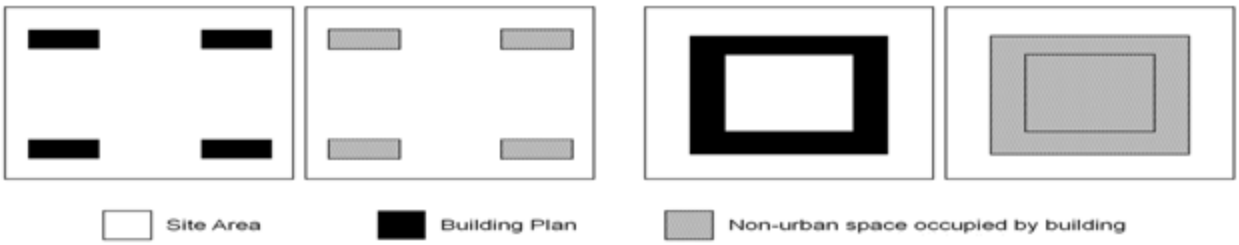

Fig. 4. Definition of street space density.

Table 4 presents the calculated values of these urban design form indicators for each block typology examined in the study. The metrics collectively provide a comprehensive framework for assessing how different urban configurations balance built form with public space quality, particularly in relation to pedestrian experience and spatial usability.

Table 4. Urban design form indicators of six types.

No.	Form Type	Effective Street length	Effective Street Space	Street Space Density	Alignment Ratio
C-1	Courtyard	342m	3820 m²	65.7%	100%
C-2	Courtyard mix	231.5m	3025 m²	65.7%	67.7%
T-1	Towers	120m	1200 m²	11.3%	35.1%
T-2	High-rise Towers	60m	600 m²	5.7%	23.7%

S-1	Slabs	150m	1500m²	14.2%	43.9%
S-2	L-Type Slabs	261m	2810m²	65.7%	76.3%

Results and Discussions

The energy performance simulation results for the six urban form types demonstrate notable variations in energy consumption patterns (Table 5). Among the tested configurations, the C-1 type achieves the lowest Energy Use Intensity (EUI), while the T-1 type exhibits the highest consumption. The Tower-type forms generally show poorer energy performance compared to both Courtyard and Slab types. Analysis of cooling and heating loads reveals C-2 as the most thermally balanced configuration, whereas S-1 displays the most significant load fluctuations, likely due to its complex morphological characteristics.

Table 5. Simulation results of six block types.

No.	Form Type	EUI	Cooling Load	Heating Load
C-1	Courtyard	167.591 KW/m²	52.496 KW/m²	43.411 KW/m²
C-2	Courtyard mix	174.148 KW/m²	53.915 KW/m²	48.267 KW/m²
T-1	Towers	182.791 KW/m²	59.248KW/m²	50.700 KW/m²
T-2	High-rise Towers	181.936 KW/m²	60.094 KW/m²	49.745 KW/m²
S-1	Slabs	170.102 KW/m²	54.854 KW/m²	42.971 KW/m²
S-2	L-Type Slabs	170.641 KW/m²	54.001 KW/m²	44.555 KW/m²

The maximum EUI difference between the highest (T-1) and lowest (C-1) performing types is 9%, indicating relatively constrained performance variations under the controlled study conditions. Notably, certain type pairs demonstrate remarkably similar energy performance, including S-1 and S-2 with nearly identical EUI values, and T-1 and T-2 showing comparable consumption patterns. These similarities presumably result from the shared experimental parameters, particularly the fixed Floor Area Ratio (FAR) and standardized environmental conditions.

When evaluating both energy performance and urban design indicators through a comprehensive ranking analysis (Figure 5), the C-1 type emerges as the optimal configuration, excelling in both energy efficiency and public space quality. In contrast, the T-2 type performs poorest overall, with T-1 following closely behind due to its high energy demands and inadequate public space provision. While S-1 and S-2 demonstrate similar energy performance, S-2 shows superior urban design outcomes through better-defined street interfaces and more generous public spaces.

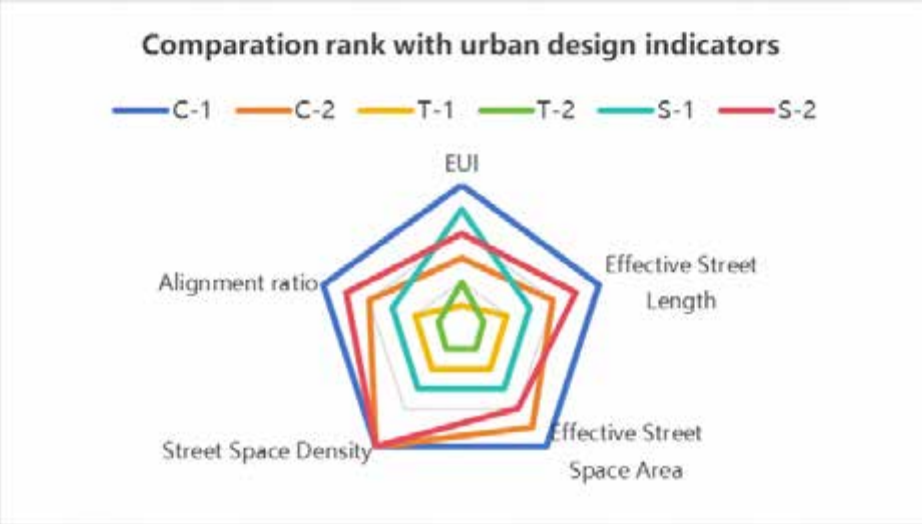

Fig. 5. Comparation rank with urban design indicators.

The comparative analysis reveals that Courtyard-type configurations achieve the best overall balance between energy efficiency and public space quality. Tower types prove least effective across all evaluation metrics, while Slab forms show intermediate performance with potential for further optimization. These findings carry important implications for urban design practice, demonstrating that equivalent FAR conditions can accommodate substantial variations in both energy performance and public space quality across different morphological types.

The study confirms that certain urban form configurations can successfully reconcile energy efficiency with high-quality public spaces, proving this dual optimization is achievable in practice. However, several limitations should be acknowledged, including the simplified morphological representations compared to real urban environments, constrained environmental parameters, focus on relative rather than absolute performance relationships, and exclusive consideration of residential functions. Despite these limitations, the findings provide valuable guidance for early-stage urban design, suggesting designers should prioritize configurations that balance energy performance with public space quality while recognizing these solutions maintain effectiveness across varying FAR conditions. The results substantiate that energy-conscious urban form selection need not compromise public space quality, offering empirical support for more holistic sustainable design approaches. Future research should address the current limitations through expanded typological variety, multifunctional analysis, and real-world validation studies.

Conclusion

Existing research on building energy performance predominantly focuses on architectural characteristics. However, in actual urban and architectural design practice, the preliminary design phase must consider not only building forms but also the configuration of external public spaces shaped by built elements - a fundamental aspect of urban experience. To achieve orderly, comfortable and sustainable urban environments, it becomes imperative to re-examine the urban morphology-energy consumption relationship through an urban design lens.

This study conducted controlled energy simulation experiments across comparative morphological typologies. The results demonstrate that urban form elements and typologies significantly influence building energy performance while exhibiting substantial variation in public space generation capacity. The C-1 typology emerged as optimal, excelling in both energy efficiency and public space provision, whereas T-type forms underperformed across both parameters. Among S-types, while energy consumption remained consistent, urban design indicators showed marked variation. These findings suggest the feasibility of identifying multi-objective

optimised morphological solutions addressable during early-stage urban design. The research provides novel perspectives and indicators to inform future scholarship and practice.

The outcomes offer practical implications for urban designers. During preliminary design phases, prioritising morphological typologies that simultaneously enhance energy performance and public space quality - with minimal FAR dependency - proves achievable. Recommended design approaches include:

When working with predetermined FAR values, designers should favour typologies combining lower energy consumption with high-quality public spaces, as exemplified by Courtyard-type configurations. Where morphological options are constrained, exploring solutions that optimally balance energy and spatial performance within given parameters becomes essential. Crucially, designers should avoid problematic typologies that yield both elevated energy demands and inadequate public space provision.

Future research should investigate larger urban blocks, incorporate diverse programme types, and establish correlations between urban design indicators and energy performance. Addressing these dimensions will facilitate the development of more precise, sustainability-focused urban design guidance. The study demonstrates that energy-conscious urban form selection need not compromise public space quality, providing empirical validation for integrated performance-based design methodologies. Subsequent work should expand typological variety and examine real-world applications to strengthen these findings

Abstract
Public spaces function as both material and symbolic environments for public life, where individuals construct and share meanings through experience. This study explores the symbolic and experiential meanings of public space by analysing user-generated content about Museum Gazhane. Drawing on 3,025 Google Maps reviews (2021–2024), it adopts a two-stage methodology: Latent Dirichlet Allocation (LDA) is used to detect thematic patterns, which are then interpreted through Critical Discourse Analysis (CDA) to reveal how narratives express social meanings. This integrative approach combines computational scalability with critical depth, enhancing both methodological rigour and interpretive nuance. Findings offer insights into how digital narratives reflect public perceptions and symbolic attachments, while highlighting the value of user-generated content for informing inclusive and responsive public space planning in contemporary cities.

1.Introduction

Public spaces are key components of urban life, enabling social interaction, cultural expression, and everyday functionality (Gehl, 1987; Jacobs, 1961; Neal, 2010). They also serve as symbolic landscapes where collective memory and urban identity are formed (Lynch, 1960; Zukin, 1995; Crilley, 1993). However, the nature of public spaces has become increasingly complex in the contemporary city. Spaces once associated with democratic ideals have been reshaped by the logic of neoliberal urban policies to enhance global competitiveness and create new images for cities (Boyer, 1993; Ercan, 2016; Madanipour, 2000, 2019). Consequently, scholars have renewed their focus on the evolving roles and typologies of public spaces. Yet dominant research approaches often emphasise specific dimensions—such as physical design (Carmona, 2010), governance models (Low & Smith, 2006; Magalhães, 2010), or user behaviours (Whyte, 1980; Shaftoe, 2008)—while underemphasising their symbolic and experiential meanings. Traditional methods such as surveys and interviews also have limitations in capturing the discursive and affective layers of spatial experience, particularly in light of sampling bias and the temporal nature of public life.

This study addresses these methodological gaps by examining digital user reviews as an alternative perspective on public space experiences. Focusing on Museum Gazhane—an industrial heritage site in Istanbul that has been adaptively reused as a cultural public space—the research aims to uncover the key themes and patterns expressed in user-generated content. Drawing on 3,025 Google Maps reviews from 2021 to 2024, the study employs Python-based text mining and Latent Dirichlet Allocation (LDA) topic modelling to analyse how users articulate their experiences, expectations, and symbolic associations.

To enhance both analytical depth and methodological robustness, the study adopts a two-stage interpretive framework. First, Latent Dirichlet Allocation is used to identify the latent thematic structure across the large corpus of user reviews. Second, these topics are subjected to close reading through the lens of Critical Discourse Analysis (CDA) (Fairclough, 2003, 2010; Van Dijk, 1993, 2003; Wodak & Meyer, 2016), enabling the exploration of how meaning, ideology, and power operate within user narratives. Combining topic modelling and discourse analysis provides a systematic yet interpretive approach that bridges the gap between scale and nuance, allowing both macro-pattern detection and context-sensitive interpretation. This integrative strategy not only increases the credibility and reliability of the findings (Jacobs & Tschötschel, 2019) but also contributes to methodological innovation in public space research by responding to the challenge of analysing large volumes of user-generated text without losing discursive richness (Törnberg & Törnberg, 2016; Mullenbach, 2022).

By analysing digital user narratives, this study provides insights into how spatial meanings are constructed through everyday experience, while offering practical implications for the design and management of public spaces in contemporary cities. The central research questions guiding this inquiry are as follows: (1) How is Museum Gazhane represented in user reviews? (2) How do these representations intersect with users' experiential relationships to the space, its historical transformation, and broader context? (3) How might such representations inform the planning, design, and governance of public spaces?

The remainder of the article is structured as follows: Section 2 presents the study's theoretical foundation, including a review of public space roles and the analytical potential of digital user data. Section 3 outlines the methodological process, including data collection, preprocessing, and data analyzing. Section 4 presents the findings of the LDA analysis, organised around five principal thematic clusters. These clusters are interpreted in relation to the sociocultural and political layers of meaning embedded in public spaces. Finally, Section 5 discusses the study's theoretical and practical contributions, reflects on its limitations, and proposes directions for future research.

2. Literature Review

This section presents the study's theoretical foundation, including a review of public space roles and the analytical potential of digital user data.

2.1 The Multifaceted Roles of Public Space

Drawing on critical urban theory, particularly Lefebvre's (1991) notion of the production of space and Massey's (2005) concept of relational space, this study conceptualises public space as a dynamic and contested terrain shaped by social relations, discourses, and everyday practices, rather than as a fixed or neutral container. According to this view, spatial meaning is continuously reconstituted through the interplay of material and symbolic dimensions. Tracing this theoretical lineage historically reveals how the meanings and functions of public spaces have evolved.

Public spaces have historically embodied shifting sociopolitical agendas, evolving from democratic Agora to commodified landscapes shaped by neoliberal urban restructuring (Mumford, 1961; Sorkin, 1992). These spaces have functioned as multilayered constructs in which social relations, cultural representations, political participation, and economic strategies are negotiated and reproduced (Lefebvre, 1991; Madanipour, 1995). Thus, public spaces are not neutral; they reflect and reproduce power relations, embedding inclusive and exclusionary logics. As Mitchell (2003) argues, the question of whose narratives are represented—and whose are erased—ultimately determines which identities are legitimised.

Building on this historical and theoretical foundation, this study conceptualises public space as a multifaceted domain and examines its meanings and lived experiences through five interrelated roles: social, physical, symbolic, political, and economic.

• **Social Role:** Public spaces are vital arenas for collective life. They enable everyday encounters and social interactions that engage people across ethnic, gender, and class lines (Madanipour, 1995; Mehta, 2014). They foster cohesion and the negotiation of difference by supporting both planned and spontaneous interactions (Jacobs, 1961; Sennett, 1971). Thus, they serve as dynamic zones where conflict and consensus coexist, reinforcing social cohesion through continuous, layered exchanges.

• **Physical Role:** Public spaces are integral to the urban fabric, linking streets, squares, and parks to ensure spatial continuity and ecological balance (Carr et al., 1992; Thompson, 1998; Ellis, 1978). The physical design of public spaces, shaped by walkability, openness, and comfort, influences not only mobility and microclimates, but also enhances psychological well-being and patterns of social engagement (Gehl, 2010; Moughtin, 1999; Whyte, 1980). Thus, public spaces serve as structural elements of the built environment and as stages for everyday social life.

• **Symbolic Role:** Public spaces serve as repositories of collective memory, cultural identity, and ideological meaning (Lefebvre, 1991; Mehta, 2023). While Lynch (1960) emphasises the role of urban form and legibility in producing shared meaning, Mitchell (2003) points out that symbolic representation often reflects dominant power structures, thereby marginalising alternative narratives. Everyday practices and shared rituals reinforce a sense of belonging, yet these spaces also become sites of contestation over cultural visibility and historical legitimacy.

• **Political Role:** Public spaces constitute vital democratic arenas characterised by the interplay of power and resistance, the negotiation of social demands, and the continual re-creation of political meanings. By facilitating encounters among strangers and elevating marginalised voices, they foster civic engagement, political expression, and collective identity formation. Their essential role in enabling both solidarity and dissent underscores their democratic necessity (Shaftoe, 2008).

• **Economic Role:** Public spaces have historically functioned as centres of commerce and urban vitality (Lofland, 1971; Thompson, 1998; Gehl, 1996). Beyond direct commercial activity, these spaces generate economic value by attracting tourism, raising property values, and enhancing urban competitiveness (Shaftoe, 2008). However, under neoliberal development, the commodification of these spaces often prioritises exchange value over public use. This exacerbates spatial inequalities and diminishes equitable access.

The interplay of these five roles—social, physical, symbolic, political, and economic—highlights the multifaceted nature of public spaces. These spaces are neither neutral nor static; rather, they serve as arenas of both cooperation and contestation, shaped by overlapping and often competing logics. This conceptual framework enables a systematic analysis of the lived, perceived, and contested meanings attributed to public spaces, and it underpins the methodological approach adopted in this study.

2.2 The Use of Digital Data in Public Space Research

In recent years, an expanding body of literature has recognised social media as valuable data sources capable of addressing the limitations of traditional field-based methods. Social media-derived data can access broader and more diverse user groups than surveys or interviews, while also capturing real-time, everyday experiences. In doing so, they illuminate the layered perceptions individuals hold about public spaces (Sim & Miller, 2019; Cheng et al., 2022). This enables researchers to explore how urban environments are experienced and interpreted through user practices and affective encounters (Liu & Xiao, 2021; Song et al., 2020).

Kaplan and Haenlein's (2010) broad definition of social media—as internet-based platforms enabling the creation and exchange of user-generated content—is adopted here. This encompasses various formats such as blogs, media-sharing sites, and online forums. Similar to traditional mass media, social media influences public perception by framing issues and events (Moscovici & Duveen, 2000). In this study, Google Maps user reviews are utilised as a form of social media data to examine public perceptions and experiences of urban space.

User reviews on platforms such as Google Maps and TripAdvisor have become prominent tools for analysing urban space. Since 2015, Google Maps has surpassed platforms like Yelp and Facebook in terms of data volume and engagement, becoming the most widely used location-based review platform globally (Munawir et al., 2019). Its accessible interface and large user base generate rich data—comprising star ratings, time-stamped narratives, and images—well suited to both quantitative and qualitative analysis.

Studies on urban parks and public spaces have highlighted the analytical value of such data in revealing usage dynamics. For instance, Song et al. (2020) used LDA topic modelling on TripAdvisor reviews of Bryant Park in New York to relate user experiences to spatial quality, offering insights for design and management. In a follow-up study, Fernandez et al. (2022) analysed seasonal variation in perceptions, demonstrating how social media data can track experiential shifts over time. Expanding this approach, Song et al. (2023) combined LDA and qualitative analysis of seven years of High Line Park reviews, illustrating how programming, history, and design influenced user experience.

Other studies have employed similar methods to assess spatial quality and satisfaction. Liu and Xiao (2021) applied text mining and sentiment analysis to Google reviews of parks in Shenzhen, identifying key physical factors—such as landscape quality and amenity diversity—through regression models. Munawir et al. (2019) examined Bandung's thematic parks to explore urban branding effects. In Jakarta, Saragih et al. (2024) used content analysis of Google reviews to identify four dimensions of inclusive design in child-friendly spaces: activity diversity, child infrastructure, environmental quality, and supporting amenities.

Digital user data also offer insight into the symbolic and emotional dimensions of public space. Wang et al. (2020) analysed eleven years of TripAdvisor reviews on the Las Vegas Strip using sentiment analysis and LDA to explore sense-of-place elements such as belonging, identity, and attachment. Similarly, Sohi et al. (2024) employed social network analysis to map perceptions of liveliness, comfort, and safety in Tehran's historic bazaar, informing urban design interventions.

Collectively, these studies demonstrate the methodological flexibility of digital user reviews in analysing spatial perception, usage patterns, satisfaction, and urban identity across scales. Their integration into planning and design offers scalable, real-time, and user-centred insights for data-informed decision-making. However, social media data are not without limitations. As voluntary content, they may lack representativeness—particularly for demographics with limited digital access, such as older adults, low-income groups, or critical voices. These biases underscore the need for reflexive, context-sensitive approaches when incorporating digital data into public space research.

A growing strand of research also highlights the value of combining computational techniques such as topic modelling with interpretive approaches like Critical Discourse Analysis (CDA). While LDA efficiently detects latent patterns across large datasets, it lacks embedded theoretical assumptions about meaning-making. CDA, in contrast, situates textual meaning within broader socio-political and ideological frameworks. The integration of these methods allows researchers to detect, interpret, and critically assess the construction of meaning in discourse, especially in domains such as identity, ideology, and hegemony (Jacobs & Tschötschel, 2019; Törnberg & Törnberg, 2016).

For instance, Jacobs and Tschötschel (2019) demonstrate how topic modelling, when used with appropriate parameters, can strengthen discourse analysis by improving transparency, scaling, and interpretive depth. Similarly, Törnberg and Törnberg (2016) show how combining LDA with CDA enables the exploration of complex ideological intersections—in their case, between Islamophobia and anti-feminism—within massive corpora of online content. Mullenbach (2022) further applies CDA to urban park discourse to reveal how elite narratives around public space planning obscure power asymmetries and environmental injustice, emphasizing the importance of reflexive and critical readings of spatial discourse.

3. Methods and materials

This study adopts a mixed-methods digital research design to examine how public perceptions, representations, and experiences of Museum Gazhane are constructed through online user-generated content. Recognising the increasing relevance of digital platforms as arenas for discourse and meaning-making, the study employs computational text analysis—specifically Latent Dirichlet Allocation (LDA) topic modelling—to uncover latent thematic structures within Google Maps reviews.

The methodological process unfolds in three interrelated stages: (1) the historical and spatial contextualisation of the study site; (2) the systematic acquisition and preprocessing of user review data; and (3) the application of LDA topic modelling to detect and interpret recurring semantic patterns.

This framework facilitates the analysis of large-scale user narratives, offering insights not only into individual experiences but also into broader sociopolitical imaginaries. Through this approach, the study addresses how users evaluate the physical and functional aspects of Gazhane, while also uncovering the symbolic, political, and

emotional meanings embedded in their digital articulations.

3.1 Study Site: Museum Gazhane

Museum Gazhane—historically known as the Hasanpaşa Gasworks—stands out as a critical case due to its transformation from an industrial heritage site into a vibrant public space, reflecting both the challenges and opportunities of preserving historical significance while addressing contemporary urban needs. It offers a unique, multifaceted, and symbolically rich example of the evolving understanding of public space in Istanbul.

The Hasanpaşa Gasworks, established in 1892, served as a vital component of the city's energy infrastructure for several decades (Göklü, 2003). Following its decommissioning in 1993, the site remained in a state of suspension for approximately thirty years. In the early 2000s, efforts to conserve and restore the Gasworks were initiated by neighbourhood-based collective movements. Over time, this initiative underwent transformation under the influence of various institutional actors.

During this period, spatial demands concerning the site centred not only on the right to access and use it, but also on the symbolic meanings shaped through representation and collective memory. The spatial discourses that emerged coalesced around themes such as public rights, cultural heritage, and communal values, significantly contributing to the redefinition of the site's public character. A comprehensive restoration project, completed by the Istanbul Metropolitan Municipality (IMM) in 2021, refunctionalised the site as a "culture- and art-oriented living space" and reintroduced it to the public under the name "Museum Gazhane."

Today, Museum Gazhane functions as a dynamic arena in which the material and symbolic dimensions of public life are continually co-constructed and renegotiated. Its evolution from a grassroots movement to a municipally led project exemplifies the interplay between community-driven efforts and institutional interventions in shaping the symbolic and experiential meanings of public spaces.

Beyond its physical presence, Gazhane's extensive digital visibility—particularly through user reviews on Google Maps—offers a valuable opportunity to investigate how everyday users perceive, interpret, and contribute to the space's evolving significance. This digitally mediated layer of engagement allows for the analysis of affective geographies, representational narratives, and spatial practices as they unfold in real time. As such, it serves as a valuable methodological interface for examining the dynamics of contemporary public space.

3.2 Data Collection and Preprocessing

Data for this study comprised 3,025 user reviews of Museum Gazhane extracted from Google Maps (2021-2024) using the Outscraper tool and Google Maps Reviews API. Automated scraping enabled efficient, large-scale data collection (Munawir et al., 2019; Song & Zhang, 2020).

Only Turkish-language reviews were retained to prioritize local user perspectives. This decision was taken to better reflect local user perceptions and provide a culturally grounded interpretation of spatial experience (Borrego & Comalat-Navarra, 2020). Due to limited advanced Turkish NLP resources, reviews were translated into English using DeepL Translate. Semantic accuracy was ensured through manual verification of a randomized sample and iterative refinement guided by a domain-specific bilingual glossary developed via comparative word frequency analysis.

Translated texts were converted into an analysable format using Python. Standard preprocessing techniques—including tokenization, stop-word removal, stemming, and lemmatization—were applied. The final preprocessed corpus consists of 92,842 words, structured to ensure coherence and interpretability for topic modelling.

3.3 Data Analysis

The analysis proceeded in two main phases: LDA topic modelling and discourse analysis. This two-stage design enabled the detection of latent thematic structures at scale, followed by their context-sensitive interpretation through qualitative techniques.

Phase 1: Topic Modelling

Following the preprocessing phase, Latent Dirichlet Allocation (LDA) was applied to uncover the latent thematic structures embedded within user reviews. LDA, a probabilistic topic modeling technique, automatically infers semantically consistent themes ("topics") from large text corpora by analyzing patterns of word co-occurrence, thereby offering a scalable yet flexible approach to textual analysis (Blei et al., 2003; Song et al., 2020). It is particularly effective for heterogeneous datasets such as user reviews, where meanings emerge from dispersed and context-dependent expressions (Song et al., 2020).

A critical step in topic modelling is identifying the optimal number of topics. The coherence score—evaluating the semantic consistency among a topic's top keywords—is widely used for this purpose, balancing computational robustness with interpretive clarity (Röder et al., 2015). In this study, multiple LDA models were tested across a range of 2 to 30 topics. The five-topic model was ultimately selected based on its highest coherence score and its ability to produce analytically distinguishable outputs.

To enhance interpretability, the model was further refined using saliency and distinctiveness metrics (Chuang et al., 2012). These helped eliminate low-density or overlapping clusters and improved thematic clarity by highlighting conceptually salient groupings of terms.

Phase 2: Interpretive Analysis and CDA Integration

The second phase involved qualitative interpretation of the five topics using a combination of computational outputs and discourse-informed reading. For each topic, word clouds were generated to visualise the most salient terms. Additionally, the top 50 user reviews with the highest probability scores per topic were selected for close textual reading.

In this phase, Critical Discourse Analysis (CDA) was adopted as a guiding interpretive framework. CDA enables researchers to explore how language constructs and reflects social meanings, ideologies, and power relations (Fairclough, 1995). In line with recent methodological advancements, topic modelling and CDA were integrated to maximise both empirical breadth and critical depth (Jacobs & Tschötschel, 2019; Törnberg & Törnberg, 2016). While topic modelling captured recurring discursive patterns across a large dataset, CDA contextualised these patterns, attending to symbolic associations, affective registers, and underlying assumptions embedded in everyday spatial narratives.

Interpretation was anchored in the conceptual framework outlined in the literature review, particularly the five foundational roles of public space—social, physical, symbolic, political, and economic. This alignment ensured that the findings were not only statistically valid but also theoretically meaningful. By mapping each topic onto these conceptual dimensions, the study bridged computational analysis with critical spatial theory to examine how users experience, represent, and evaluate Museum Gazhane.

In sum, this methodological strategy demonstrates the analytical potential of user-generated content when approached through a combined computational–qualitative lens. The integration of LDA topic modelling with discourse analysis not only enhances interpretive validity but also contributes to ongoing methodological innovation in urban studies by offering a scalable, transparent, and critically reflexive tool for investigating public space representations in digital environments.

4. Findings

Using a two-stage methodology combining Latent Dirichlet Allocation (LDA) and Critical Discourse Analysis (CDA), this study identified five thematically distinct topics within Google Maps reviews of Museum Gazhane. These topics reflect diverse user perspectives, ranging from emotional and sensory impressions to critiques of management, multifunctional uses, and symbolic meanings. Each topic is detailed in the following subsections (4.1–4.5), drawing on keyword distributions, word clouds, and close readings of representative reviews.

4.1 Symbolic and Historical Transformation

This topic reflects the transformation of Müze Gazhane from an industrial heritage site to a cultural centre and the social perception of this transformation. The higher salience of terms such as "art," "culture," "Kadıköy," "become," "centre," "gasworks," and "new" in the relevant topic demonstrates the experience of Gazhane's transformation from an industrial past to a cultural attraction centre. The higher distinctive terms in the topic, such as "culture," "restoration," "transform," "hasanpasa," "high," "gasworks," "gas," "meet," "kadikoy," "historical," and "industrial," indicates that users possess a recognition of the historical identity of the area and hold a favourable perspective on its adaptation and reuse (Figure 1).

This thematic structure underscores Gazhane's dual public character: Gazhane serves as a historical symbol of industrial heritage while also functioning as a contemporary living space that fosters art, social interaction, and cultural production. This duality is frequently emphasized by users who define the transformation as a harmonious synthesis of heritage preservation and modern functionality. The transformation of Gazhane has been met with a favourable reception by users, who regard it as a successful integration of historical preservation and contemporary urban adaptation.

Figure 1. LDA Terms for the Topic "Symbolic and Historical Transformation"- overall frequency (left), saliency (centre), and distinctiveness (right)

The social interpretation of Gazhane Museum focuses on issues related to historical significance and cultural functions as well as aesthetic values. Expressions such as "high," "quality," "successful," "breathe," and "need," which are particularly salient in word analyses, point to the high-quality urban environment offered by Gazhane and the community's need for such spaces. The repeated use of the term "quality" in the commentary indicates that Gazhane is recognized for its aesthetic values and spatial design. This contributes to the consolidation of the area's physical and psychological significance. The physical quality of the area is not limited to visual appeal; it also integrates with the spatial experience of users. For instance, assertions such as "It's a very high-quality environment" and "A culture and arts centre of European quality" demonstrate that Gazhane is evaluated not only on a local scale but also according to international standards.

The Gazhane Museum also has a strong perception in terms of local identity and public ownership. The use of keywords such as "neighborhood," "Hasanpaşa," and "Kadıköy" serves to underscore the area's intricate interconnection with its immediate environment. The Hasanpaşa neighbourhood, where Gazhane is located, represents not only the physical location of the venue but also its interaction with the neighbourhood residents and the value it adds to their lives. For instance, the assertion that "This new cultural space in Hasanpaşa has revitalized the neighbourhood" underscores the transformative impact of Gazhane on the local community. The statement, "Having such a place in the heart of Kadıköy is a great opportunity for our neighbourhood," reflects the perception of Gazhane as a public space integrated with local identity. The statements indicate that the

space has been formally accepted by its users, thereby becoming an integral component of its spatial identity. While functioning as a meeting point at the neighbourhood level, the Museum Gazhane is also regarded as a significant cultural focal point for the broader district identity of Kadıköy.

Consequently, this topic positions the Gazhane Museum as a public space where industrial heritage is preserved and reimagined with contemporary cultural functions, thereby strengthening local identity and social ownership. This topic demonstrates the Gazhane Museum's strong integration into contemporary urban life, as evidenced by its preservation of historical identity and its revitalization through cultural functions. Notably, Gazhane has become a meeting point for the local community and a powerful symbol of the evolving concept of public space in contemporary Istanbul.

4.2. Institutional Representation and Public Appreciation

This topic underscores the dual perceptions of Museum Gazhane among users: firstly, as a public-benefit transformation project, and secondly, as a means of institutional representation. Higher salience terms in topic such as "thank," "everyone," "wonderful," "contribute," "IBB," "public," "Ekrem," "city," "work," and "congratulate" reveals a strong sense of public appreciation for the adaptive reuse of the site. The basis for this appreciation is the institutional visibility of the Istanbul Metropolitan Municipality (İBB) and its mayor, Ekrem Imamoğlu. Furthermore, higher distinctive terms in topic such as "feel," "transformation," "preserve," "project," "social," "hope," and "artistic" underscores that this transformation is perceived not only as a physical intervention but also as a symbolic representation of collective hope and social progress (Figure 2).

A review of user comments pertaining to this subject indicates that Gazhane is regarded not solely as a cultural venue, but rather as a public space that is both accessible and inclusive, thereby fostering public life and promoting cultural participation. Key words such as "public," "example," "neighbourhood," "preserve," and "social" emphasize the social dimension of the transformation. Expressions such as "a public facility that enables cultural and artistic activities" and "a space that has been given to the public" highlight its role in democratizing access to art and heritage.

Figure 2. LDA Terms Distributions for the Topic "Institutional Representation and Public Appreciation"- overall frequency (left), saliency (centre), and distinctiveness (right)

However, this positive narrative also reveals a strategic framework of institutional representation. The repeated references to İBB and Ekrem Imamoğlu suggest a discursive correlation between the site's success and a particular institutional identity. The keywords "İBB," "Ekrem," "project," "work," and "contribute" establish the transformation as a municipal achievement. However, the limited visibility of grassroots actors, such as neighbourhood associations and volunteer groups, suggests a discursive asymmetry. The absence of actors such as the Gazhane Environmental Volunteers Association (*Gazhane Çevre Gönüllüleri Derneği-GÇDD*) in the key metrics further underscores this imbalance.

This tension underscores the inherently political nature of public space production. While Gazhane is presented as a space "for everyone," it simultaneously becomes a stage for hegemonic representation. This duality underscores the fact that even physically inclusive spaces may entail representational inequalities. In the case of Gazhane, this contradiction reflects the tension between institutional strategies of legitimacy and the risk of

rendering participatory practices invisible.

This thematic cluster positions Gazhane as a representational area where the performance of political legitimacy, the contestation of participation narratives, and the symbolically curated urban memory are all taking place. The site's transformation, therefore, is situated at the intersection of participatory urbanism and institutional branding. The discourse of "public benefit" suggests inclusive services; however, these often become instrumentalized through institutional narratives, which limit the visibility of grassroots actors and produce imbalances in how public space is discursively constructed. This underscores the imperative for public space production to ensure not only physical accessibility but also equitable representation through voice.

4.3 Multifunctionality and Everyday Engagement

This topic focuses on how users experience Museum Gazhane as a multifunctional public space embedded in the rhythms of everyday urban life. Higher salient terms such as "museum," "exhibition," "library," "science," "visit," "cafe," and "child" unveils the site's dual identity as a nexus for both cultural enrichment and informal social interaction. Higher distinctive terms such as "science," "climate," "cartoon," "student," "charge," and "energy" serves to underscore Gazhane's significant pedagogical function, particularly in cultivating educational engagement among children and their families (Figure 3). The distinguishing characteristic of this topic is its emphasis on programmatic diversity, functional integration, and educational content. Gazhane offers a variety of educational opportunities, including science exhibitions, library spaces, workshops, and interactive activities for children, with the aim of providing meaningful learning experiences.

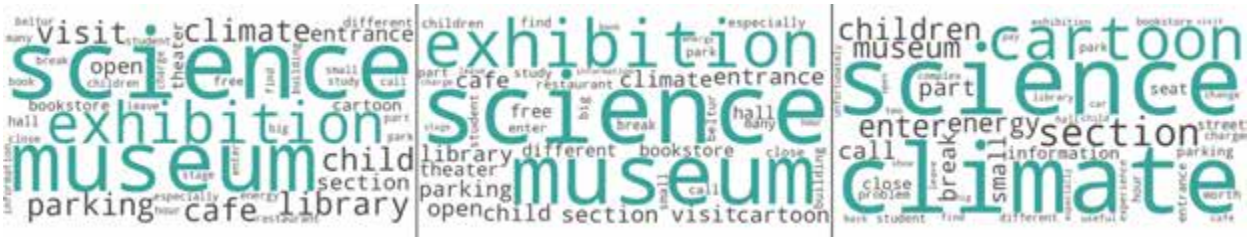

Figure 3. LDA Terms Distributions for the Topic "Multifunctionality and Everyday Engagement"- overall frequency (left), saliency (centre), and distinctiveness (right)

Concurrently, it functions as a site for casual socialization through its cafés, bookstores, and outdoor spaces, enabling users to dwell, rest, and interact. An analysis of user comments indicates that this hybrid structure has transformed Gazhane from a mere site of interest into a space that is actively inhabited and integrated into the daily routines of individuals and families. The repeated use of expressions such as "child," "student," "bookstore," and "cartoon" suggests that Gazhane is regarded as an entertaining and educational environment by younger audiences. Terms such as "library," "study," and "section" underscore the space's capacity to accommodate more deliberate, solitary forms of use, thereby establishing infrastructure for both scheduled programs and impromptu practices. This multifunctionality positions Gazhane as a hybrid spatial form that transcends the conventional visitor-site binary, becoming instead an integral and familiar element of the urban landscape.

Furthermore, the emphasis on accessibility and free entry serves to reinforce the perception of the site as a genuinely public space. The co-occurrence of terms such as "free," "accessible," and "entrance" suggests that initial user impressions are strongly positive, and that the spatial thresholds of the site promote social inclusion. Many users explicitly interpret free admission as an indication of equitable and open service provision, aligning with democratic values of access to knowledge and culture.

Within this theoretical framework, Gazhane emerges as a shared space in which the continuity of everyday life is sustained through intergenerational, multi-purpose engagement. This conception of publicness transcends the conventional boundaries of physical presence, encompassing habitual usage, accessibility, and multifaceted

functions. Gazhane's integration of cultural capital with daily urban practices offers an innovative model of contemporary public space, exemplifying the evolving logic of urban commons in the 21st-century city.

4.4 Democratic Access and Spatial Constraints

This topic reflects the dual role of Museum Gazhane as both a vibrant cultural hub and a space marked by infrastructural tensions. The success of the site in fostering artistic engagement and social interaction is counterbalanced by the challenges posed by overcrowding and spatial limitations. The Gazhane's strategic positioning of itself as a central cultural hub is further reinforced using prominent and salient terms such as "event," "concert," "activity," "free," "atmosphere," and "pleasant." However, distinctiveness metrics reveal a paradox at the heart of its popularity: while the space is celebrated as a dynamic leisure destination, its physical configuration often struggles to accommodate peak demand (Figure 4).

Gazhane's cultural offerings have been the subject of consistent praise in user comments, with users expressing appreciation for the open and inclusive nature of these offerings. The recurrence of terms such as "concert," "theatre," and "free" reflects users' appreciation of its democratizing role in expanding access to the arts. Concurrently, the lexical clusters "atmosphere," "pleasant," "good," "easy," "weekend," "fun," and "locations" serve as indicators of the site's efficacy in engendering an emotionally resonant spatial experience. These associations indicate that Gazhane is not only prized for its high-attendance events, but also for its capacity to host everyday leisure practices such as casual strolls, rest, and informal socializing.

Figure 4. LDA Terms Distributions for the Topic "Democratic Access and Spatial Constraints"- overall frequency (left), saliency (centre), and distinctiveness (right)

However, the co-occurrence of terms such as "crowded" and "tiring" alongside celebratory expressions such as "energy" and "enjoyable" reveals an underlying tension between vibrancy and comfort. While users frequently acknowledge the richness of the programming, they also often offer critiques of the logistical shortcomings that detract from their experience. These critiques posit that Gazhane's spatial design does not always align with the intensity and frequency of its event-based usage. The temporal clustering of events, particularly during weekends and evenings, exerts a significant strain on the space's carrying capacity, thereby highlighting the fragility of the existing infrastructural model. Therefore, there is an urgent need for adaptive systems.

When considered collectively, this thematic cluster positions the Museum Gazhane as an evolving urban gathering space that responds to contemporary needs for cultural enrichment, entertainment, relaxation, and self-expression. The event-oriented model under discussion here illustrates the potential of public spaces to facilitate collective enjoyment and cultural democratization. However, infrastructural constraints—including limited seating, bottlenecks, and overcrowding—also reveal the delicate balance between inclusive access and spatial comfort. In doing so, this topic foregrounds a pivotal challenge in contemporary public space design: the challenge of sustaining high levels of utilization without compromising the very experience that such utilization is intended to enhance.

4.5 Civic Provision and Commercial Use

This topic posits that Museum Gazhane functions as a hybrid public infrastructure, wherein municipal services and commercial amenities converge to create a space that extends beyond conventional cultural programming.

Gazhane has been identified as a node of everyday consumption and leisure due to the prevalence of higher salient terms in the topic, such as "Beltur," "café," "food," "affordable," "service," and "price." The presence of higher distinctive terms such as "reasonable," "tasty," "ambiance," "tea," and "beverages" serves to indicate users' appreciation of affordable prices, perceived quality, and the welcoming atmosphere (Figure 5).

Figure 5. LDA Terms Distributions for the Topic "Civic Provision and Commercial Use"- overall frequency (left), saliency (centre), and distinctiveness (right)

The lexical prominence of "Beltur", Istanbul's publicly-owned municipal enterprise, reveals Gazhane's dual identity as both a public service outlet and a managed consumption zone. The prevailing perspective often portrays cafés and restaurants situated within these locales as instrumental in extending municipal welfare, thereby facilitating more equitable access to leisure activities for the public. The presence of references to ice cream, burgers, and shops serves to underscore Gazhane's function as a social incubator. Within this context, quotidian activities such as dining, imbibing tea, or perusing merchandise can serve as catalysts for impromptu interactions and the establishment of shared practices.

The frequent co-occurrence of terms such as "perfect", "reasonable", "clean", "shop", "taste", "recommend", "staff", "belong", "municipality", and "ambiance" underscores Gazhane's perceived success in blending public service ethics with consumer satisfaction. These observations establish a foundation for exploring its potential as a model for state-led urban hospitality, wherein operational quality, pricing policy, and atmosphere are meticulously curated to foster inclusive public use. The emphasis on cleanliness, staff, and ambiance further illustrates how quotidian managerial elements contribute to the lived experience of public space.

However, several critical points emerge. A review of relevant literature reveals a paucity of indoor seating areas, service bottlenecks, and overcrowding during peak hours, particularly on weekends. These operational frictions indicate that user satisfaction is influenced not only by symbolic or aesthetic qualities, but also by the logistical and infrastructural capabilities of the space. This tension is indicative of broader concerns within the discourse on neoliberal urbanism, where public spaces are increasingly sustained by commercial revenue streams, despite efforts to maintain civic inclusivity.

Within this framework, Gazhane emerges as a hybrid public model, integrating aesthetics, comfort, and accessibility with the demands of sustainable operation. It navigates the intricate boundary between public and private spheres, between service provision and market logic. The site has been described by users as a point of social care, a meeting space, and a comfortable everyday stopover. Gazhane exemplifies an evolving understanding of publicness, one grounded not only in symbolic openness but also in the infrastructural and economic terms through which every day public life is sustained.

4.6 Summary of Key Findings

Through topic modeling and Critical Discourse Analysis, five thematic clusters were identified that reveal the multifaceted ways in which users perceive and engage with Museum Gazhane. These clusters reflect overlapping concerns ranging from symbolic transformation and multifunctionality to institutional critique and spatial constraints, demonstrating how publicness is experienced as a hybrid of social, symbolic, physical, political, and economic dimensions.

Table 1. Thematic alignment of LDA topics with the roles of public space

Thematic Cluster (LDA Topics)	Symbolic Roles			Social Roles			Physical Roles			Political Roles			Economic Roles		
Symbolic and historical transformation	■	■	■	■			■								
Institutional representation and public appreciation	■			■						■	■	■			
Multifunctionality and everyday engagement	■			■	■	■	■	■					■		
Democratic access and spatial constraints	■			■			■	■		■	■				
Civic provision and commercial use				■			■						■	■	■

Rather than mapping neatly onto singular functions, each topic intersects with multiple conceptual roles of public spaces. This multidimensionality illustrates how users' spatial meanings emerge through the interplay of design, discourse, use, and governance.

Table 1 aligns each thematic cluster with the five foundational roles of public space identified in the theoretical framework. This evaluative mapping, based on keyword saliency and interpretive readings, underscores the dialectical relationship between institutional narratives and everyday spatial experiences. It affirms that public space is continuously shaped as a negotiated, dynamic construct.

5. Conclusion

This study examined how users experience, interpret, and represent the Museum Gazhane as a contemporary public space. A two-phase methodology was used to analyse 3,025 Google Maps reviews. First, Latent Dirichlet Allocation (LDA) topic modeling was employed to identify prevalent themes. Second, critical discourse analysis (CDA) was employed to interpret these themes and reveal the social meanings, tensions, and symbolic associations embedded in user narratives.

The five thematic clusters identified—ranging from historical symbolism and institutional representation to multifunctionality and civic-commercial hybridity—reveal how users attach affective, political, and experiential meanings to the space. These representations are shaped by physical conditions and broader discursive dynamics, including municipal visibility, public participation, and market-driven governance. This approach confirms that public perception is not monolithic but rather formed through multiple—and sometimes conflicting—narratives. Representations in user reviews reflect personal encounters and socio-spatial imaginaries, demonstrating that public spaces are produced through the interplay of institutional structures and everyday experiences.

This study makes multifaceted contributions to public space research at the theoretical and methodological levels. First, it provides a comprehensive analytical framework for using user-generated digital content to analyse the experiential and symbolic meanings of public spaces. In this regard, the study proposes an innovative approach that integrates critical space theories, which posit that public spaces are constructed through discourse, with digital data analysis.

The study makes a theoretical contribution by proposing a multi-layered understanding of how public spaces are produced. It posits that user comments serve as indicators of satisfaction and as sources of representations related to abstract values, such as social memory, cultural identity, and spatial justice. The proposed theoretical framework has five dimensions representing the traditional roles of public spaces, thereby establishing a critical and applicable theoretical foundation. As illustrated in Table 1, these five dimensions are closely related to the conceptual framework of the symbolic, social, physical, political, and economic roles of public spaces. Rather than being considered separately, these roles reflect hybrid intersections that confirm the theoretical premise

that public spaces are relational and contested structures. This perspective emphasizes that the meaning of public space emerges through the interplay of institutional narratives and user experiences.

Methodologically, this study shows how combining computational and qualitative approaches can capture complex, digitally mediated spatial meanings. Integrating Latent Dirichlet Allocation (LDA) with Critical Discourse Analysis (CDA) shows how statistical pattern detection can be meaningfully enriched through context-sensitive, theoretically informed interpretation. CDA plays a central role in revealing how public spaces are constructed through discourse by users—not just described, but also symbolically and ideologically framed through everyday language. This model illustrates the potential of integrating digital methodologies with critical social sciences in public space research. Although user-generated content provides scalable, real-time insights, limitations such as digital exclusion and representational bias must be addressed through reflexive interpretation and methodological pluralism.

In practice, this study highlights the importance of incorporating user perspectives into the design, management, and repurposing of public spaces. It demonstrates the potential of an alternative data source for planning practices and offers a structured approach for its integration. Analysing users' experiences and perceptions can contribute to developing strategies that enhance spatial sustainability, social inclusion, and social belonging.

In sum, this study contributes conceptually, methodologically, and practically to the evolving field of public space research. It shows that user-generated narratives are active sites of meaning-making, not just reflections of use. Future research may expand upon this approach through longitudinal and comparative analyses, multi-platform data integration, or integration with ethnographic methods to further explore how publicness is imagined, practiced, and contested in contemporary cities.

Abstract
The demographic trend of aging is a global phenomenon, but it manifests differently across countries. Italy is one of the "oldest" countries in the world, and this phenomenon is even more pronounced in urbanized contexts. At the same time, in Italy, most people over 65 live in medium-sized cities, they continue to age at home and in their neighborhood (Aging in Place). This paper aims to present the first phase of the research funded by the Next-Generation EU initiative, titled "CASA Aging in Cities-Medium: How Housing Conditions and Urban Spaces Can Reduce or Increase Opportunities for Longevity in Health". The research develops a multiscalar and interdisciplinary analytical model to investigate how urban space influences healthy aging and neighborhood attachment, using Bergamo as a representative case of medium-sized Italian cities.

Keywords: Aging in Place, Elderly, Medium-sized City, Neighborhoods, Public Spaces

Introduction: the Role of Territory and the Spatial Dimension in Healthy Ageing

Between 2015 and 2050, the proportion of the global population aged 60 and over is expected to nearly double, increasing from 12% to 22%. By 2030, one in six people worldwide will be over the age of 60. According to recent estimates, the number of individuals in this age group will rise from 1 billion in 2020 to 1.4 billion, and is projected to reach 2.1 billion by 2050. The population aged 80 and over is also expected to triple in the same period, reaching 426 million (WHO, 2024). While global aging is a widespread phenomenon, it presents distinct patterns and challenges across different national and urban contexts.

The concepts of well-being and health are inextricably linked to the territorial dimension, and it was already in the first half of the 19th century that the role of spatial planning in contributing to the establishment of a democratic community became evident (Benevolo, 1963), particularly in addressing the public health issues posed by the emerging industrial cities. Urban planning also plays a pivotal role in this context, given the robust and intricate relationship between the built environment and the health of the elderly. The built environment encompasses factors such as community safety, accessibility to services and environmental quality, which have the capacity

to exert a substantial influence on the health outcomes of the elderly in terms of both physical and mental well-being.

A major recent study based on the UK Biobank (Argentieri et al., 2025) quantified the impact of environmental and genetic factors on the ageing, mortality and incidence of 22 age-related diseases. The study demonstrated that environmental factors have a greater influence on mortality risks than genetic factors (17% versus 2% of variation in risk of premature death can be attributed to environmental factors). Certain diseases, including cardiovascular, respiratory and hepatic pathologies, are significantly influenced by environmental factors, accounting for up to 49.4% of the observed variability. The most significant environmental factors associated with mortality include smoking, socio-economic status, physical activity, sleep quality, social isolation and air pollution. Spatial planning, therefore, plays a key role in promoting health and ageing, often overriding the contribution of genetics. This suggests that spatial planning interventions may have the potential to contribute to the prevention of disease risk, thereby facilitating healthy ageing. Additionally, the promotion of public policies that address socio-economic inequalities, promote healthy lifestyles and improve environmental conditions can have a significant impact on population health.

Italy, which is among the countries with the highest aging rates globally, is experiencing a faster demographic shift than much of Europe. This transformation is particularly evident in urban areas, where the effects of ageing are more pronounced. A considerable proportion of Italy's older population – that is to say, individuals aged 65 and over – reside in medium-sized cities and continue to age in place, remaining in their homes and communities. In such contexts, the spatial and functional organisation of urban environments exerts a substantial influence on the daily lives and health trajectories of older adults. It is crucial to recognise the pivotal role that public spaces play in either facilitating or hindering the routines, mobility, and social engagement of ageing populations.

This article presents the initial phase of an ongoing research project funded by the Next Generation EU initiative, titled CASA Aging in Cities-Medium: How Housing Conditions and Urban Spaces Can Reduce or Increase Opportunities for Longevity in Health. Specifically, the contribution delineates the theoretical and methodological approach that was used to develop a multiscalar and interdisciplinary analytical model to explore how urban spaces influence healthy ageing and the sense of neighbourhood attachment among older adults. The present research focuses on the city of Bergamo, in northern Italy, which is considered a representative case of medium-sized Italian cities. The objective of the present study is to shed light on the impact of urban structure on healthy ageing, and to examine the primary effects that high-quality urban environments have on older demographics.

The objective of the research is to understand the characteristics and effectiveness of public spaces in promoting health and social inclusion. This is achieved by integrating physical, functional, performance (in relation to climatic and environmental factors), and decision-making dimensions. The research also explores the barriers that limit the use of public spaces, such as extreme temperatures or physical obstacles. Moreover, the objective is to unveil the inherent heterogeneity amongst different neighbourhoods within a single city.

The Age-Friendly City

Healthy ageing is recognised as a global priority, as evidenced by the numerous initiatives of international bodies, e.g. The United Nations Decade of Healthy Ageing (2021-2030) (UN, 2020) emphasised the importance of the spatial dimension for the resilience of older communities, particularly in post-pandemic contexts. The Cities for All Ages project (OECD, 2025) reinforced the idea that urban infrastructure can (and should) be an ally of public health. The World Health Organisation's National Programmes for Age-Friendly Cities and Communities (WHO, 2023) also provide guidance on this topic.

The notion of age-friendly cities and communities (AFCC) was first introduced in the inaugural report published in 2007 by the World Health Organisation. The objective of the AFCC concept is to promote urban environments that encourage healthy ageing and to provide support for national programmes that are designed to create more

inclusive and all-age-friendly settings (Torku et al., 2020; Hoof, 2021). The objective of the project is to promote the well-being, health and social participation of older people, with a particular emphasis on enhancing active and independent living within their communities. The model's eight core areas of focus encompass outdoor spaces and buildings, transport, housing, social participation, respect and social inclusion, civic participation and employment, communication and information, and community support services and health. A number of studies have employed this model to assess the efficacy of initiatives implemented within specific territorial contexts. These studies have analysed urban policies and the experience of senior citizens (Perek-Białas et al., 2024; Ivan et al., 2024).

The planning of an age-friendly city is not only concerned with the elderly population; it also brings with it additional benefits, including those of pursuing sustainable urban development goals and fostering the implementation of social inclusion programmes (Han et al., 2021; Buffel et al., 2020). Furthermore, the development of smart cities as AFCC policies exploit technology and innovation (Hoof et al., 2021) is also a benefit. Concurrently, numerous challenges persist in the realisation of an age-friendly city, particularly those related to aspects of social exclusion and economic sustainability (Murtagh et al., 2021). A pertinent example of this phenomenon is the disparities observed between residing in urban and rural environments. It is an established fact that older populations tend to be more concentrated in rural areas. In addition, it is equally well-documented that rural areas tend to have lower income levels, less access to health and social services and higher levels of social isolation. These factors, it can be hypothesised, potentially contribute to the observed variations in health outcomes. A number of studies have indicated that the over 65s residing in urban areas demonstrate superior health in comparison to their counterparts residing in rural areas. The most recent Eurostat report has indicated that the over 65s residing in urban areas are believed to exhibit superior health in comparison to their counterparts residing in rural areas (Eurostat, 2023).

In the context of healthy ageing, it is also beneficial to take into consideration the changes to which the territory is subjected. Since the 1970s, and particularly in recent decades, the phenomenon of gentrification has been a subject that has attracted considerable attention. Indeed, the process of physical and socio-cultural transformation of urban neighbourhoods has been demonstrated to exert a strong influence on the elderly population (Santos et al., 2024).

Elderly People and Climate Change

The concept of 'ageing in place' must be contextualised within the most pressing global public health challenge of our time, namely climate change. It is evident that this crisis will have profound consequences for the health of the population, as it is already exerting a considerable impact on food systems, the increased spread of infectious diseases and growing risks for non-communicable diseases and mental health, rising temperatures, accessibility to certain areas, and extreme weather events (IPCC, 2022). While urbanisation has facilitated enhanced access to healthcare, it has concomitantly precipitated deteriorating air quality and the loss of green spaces. In this regard, the presence of urban greenery and Nature-Based Solutions (NBS) assumes particular significance, given their capacity to offer opportunities for physical activity, stimulate social interaction and community cohesion, and enhance the landscape. These factors have been demonstrated to exert a positive influence on mental well-being (Xu et al., 2023; Zhang et al., 2022). The aforementioned benefits are more pronounced in low-income populations, where green spaces mitigate urban heat islands and provide relief in areas with limited access to air conditioning. Urban planning that incorporates these factors has the potential to reduce inequalities and promote environmental justice, ensuring that all individuals have an equal right to robust environmental protection and to be informed and involved in decision-making processes.

Climate change has the potential to expose the elderly to a multitude of risks, including heat waves, floods, forest fires and air pollution. The impact of these risks on vulnerable populations is compounded by factors such as physical frailty, chronic diseases, social isolation and poverty (Prina et al., 2024; Hua et al., 2024; Gaugler, 2024; Dabelko-Schoeny et al., 2024; Katey & Zanu, 2024). For instance, the presence of urban green spaces has been demonstrated to play a pivotal role in the promotion of healthy ageing, offering a range of physical, mental and

social benefits that are especially pertinent for the elderly population. Individual and societal vulnerabilities have been shown to increase exposure to climate impacts, accelerating the ageing process and necessitating the integration of climate, environmental and social strategies into public policies. It is therefore crucial to promote adaptation approaches that recognise the active role of older people, not only as vulnerable individuals but also as resources for mitigation through their experience, knowledge of sustainable practices and ability to contribute to community initiatives. In this context, active ageing and climate resilience must be addressed in unison, with the involvement of older people in the construction of more inclusive, sustainable communities that are capable of coping with environmental challenges.

Walkability and its Barriers

Walkability, defined as the quality and accessibility of pedestrian environments, constitutes a vital element in the promotion of healthy ageing. For older people, walking is not only a means of transport; it is a fundamental activity that contributes to the maintenance of autonomy, physical well-being, cognitive function and social inclusion. However, the promotion of walking in old age necessitates the establishment of safe, accessible, continuous routes equipped with amenities such as benches, public toilets and green areas (He & He, 2025; Hu et al., 2025; Kim et al., 2024). A plethora of factors must be considered when assessing the walkability and appeal of a given space for older individuals. These include, but are not limited to, safety measures aimed at mitigating the risk of accidents and crime, the presence of wide pavements, the presence of street furniture, the variety of destinations along designated pathways, and the presence of aesthetically pleasing elements such as greenery. The importance of these factors in enhancing the walkability and appeal of spaces for older people has been extensively researched and documented (Appolloni & D'Alessandro, 2023; Bailey-Catalán et al., 2025; Knapskog et al., 2019).

Rising temperatures, exacerbated by climate change and the urban heat island effect (UHI), represent a significant barrier to the utilisation of public spaces by older people. As the global climate continues to warm, high temperatures have been shown to have a detrimental effect on the liveability of urban environments (Cheng et al., 2012; Alnimer et al., 2023). This is due to the fact that high temperatures can inhibit physical activity and outdoor sociability, both of which are fundamental to mental and physical well-being in old age. Excessive heat has been shown to act as an invisible barrier, with both physiological and psychological effects, which are accentuated in urban areas where temperatures can exceed those experienced in rural areas by more than 10 °C (Heisler & Brazel, 2010; Stone et al., 2010). This is due to a reduction in green areas, an increase in impermeable surfaces and anthropogenic emissions. The elderly are among the most vulnerable to the effects of heat, due to lower thermoregulatory capacity, reduced thirst perception and pre-existing chronic conditions (ASUGI, 2020; Ministry of Health & CCM, 2019).

Prolonged exposure to elevated temperatures has been demonstrated to induce a range of physiological responses, including dehydration, syncope, and heat stroke, which can result in an elevated risk of mortality (Ministry of Health & CCM, 2019; IIPH, 2022). In Italy, for instance, research has shown that the mortality rate on the hottest days can increase by up to 20.3% (IIPH, 2022). Furthermore, the impact of heat on mental health has been demonstrated to be a significant contributing factor to the prevalence of anxiety, depression and stress (IIPH, 2022).

In this context, urban design assumes a crucial role: shaded spaces, the presence of vegetation and reflective materials are effective interventions to improve pedestrian thermal comfort and make public spaces accessible even in warmer seasons (Nasrollahi et al., 2020; Jia & Wang, 2021; Huang et al., 2022). The promotion of outdoor living in temperate climates has been demonstrated to be a contributing factor to the maintenance of physical activity, social interaction and, consequently, the health of the elderly population.

Healthy Aging e Vulnerability

A key concept guiding this research is environmental vulnerability. Environmental vulnerability refers to the capacity of territories to suffer damage due to exposure to different types of stress, including environmental and social changes, and vice versa to the consequent lack of capacity to adapt to such changes. This vulnerability

is often the result of political choices and urban planning that has failed to listen to the needs of territories and populations, particularly the most fragile ones. Geographical studies have shown how such decisions contribute to significant disparities in health between different geographical areas (Anderson et al., 2025).

The concept of environmental vulnerability is multifaceted, with numerous factors contributing to its manifestation. The primary factors encompass the degree of urbanisation, as increasing populations migrate to urban areas, resulting in the loss of green spaces and elevated levels of pollution (Sheykhi, 2022). The organisation of urban space, the distribution of services, the quality of infrastructures, and the presence of green areas are not neutral elements, but rather determinants of the physical and mental health of the population, particularly the elderly (Xu et al., 2023).

Cities not only host but also shape the life experiences of older people, amplifying or reducing their risks, and to promote an improvement in quality of life during the ageing process, it is necessary to integrate health and psychological dimensions with spatial and environmental ones. From the perspective of the elderly, the issue of vulnerability has to be addressed in different ways, as a number of characteristics can be used to represent it (Channer, 2020). Low income, for example, which can be configured in terms of economic vulnerability, is a recurring factor in a number of cross-sectional studies aimed at representing the vulnerability of the elderly (Smeeding, et al., 2008; Stewart et al., 2011; Allan et al., 2011; Clarke e Gallagher, 2013). The comprehension of environmental vulnerability necessitates an investigation at multiple levels, including the examination of individual vulnerabilities (i.e. the physical and functional, the economic, and the social) as well as the environmental, institutional, and regulatory aspects.

Individual vulnerabilities encompass not only a potential decline in health, but also in mobility or cognitive abilities, as well as possible mood problems, possibly secondary to a problem of social isolation. Individual vulnerabilities are often compounded by environmental factors, leading to the perception of physical or psychological barriers in one's immediate surroundings. This can result in a sense of restriction in day-to-day activities. These factors have the potential to compromise security and independence, thereby increasing exposure to the risk of an ageing trajectory of frailty (e.g. falls, illness or isolation). As previously mentioned, economic vulnerability refers to the interaction between older people and their environment. This is characterised by a lack of financial resources, which limits the ability of older people to maintain or adapt their homes, access home care services, or meet the costs of daily living. The existence of insecure housing has a detrimental effect on the mental and physical well-being of individuals, giving rise to feelings of uncertainty and chronic anxiety. This, in turn, has a deleterious effect on the quality of life and can result in a trajectory of vulnerability to age-related frailty. Social and relational vulnerability, due to the loss of meaningful ties, withdrawal from community life or the absence of informal support networks, may need to be compensated by an AIP that has social infrastructures (community centres, transport, intergenerational initiatives) capable of supporting active ageing and, above all, of sustaining a culture aimed at promoting an assumption of responsibility by ageing individuals. As previously evidenced, the risk of social isolation and consequent feelings of loneliness can exert a detrimental effect on mental health (Nicholson, 2009).

Measuring Social Vulnerability and the Elderly Population

Vulnerability is an inherently probabilistic concept, expressing the degree to which an individual or group is exposed to harm, i.e. proximity to risk. This phenomenon does not necessarily result from a specific exposure or negative outcome; rather, it is the cumulative outcome of a combination of interdependent factors. These factors include the risk of exposure to a threat, the risk of that threat materialising, and the risk of not having adequate resources to deal with it (Schröder-Butterfill and Marianti, 2006). Consequently, elements such as variability in the probability of exposure, the scope and frequency of threats, and differing capacities to respond and adapt, contribute to varying degrees to determine both the likelihood of negative outcomes and their possible severity. The dimensions of vulnerability have the capacity to interact with each other in a compensatory manner or to reinforce each other, thereby generating different levels of vulnerability with regard to proximity to harm and its intensity. Furthermore, in specific contexts, certain of these dimensions are closely intertwined. For instance,

consider the link between exposure and threat, where it is the context itself that generates the risks and defines who is exposed to them. It is therefore the case that vulnerability is not a static attribute; rather, it is the product of individual and collective life paths. In this sense, past experiences influence the present conditions of exposure and the available "defence" strategies.

The increasing tendency of the population to reside in urban areas is often linked to manifestations of socio-economic disparity, including inequitable access to services, resources, employment prospects and educational opportunities. In this context, the configuration of urban space assumes a key role in determining the living conditions of citizens and their ability to overcome situations of deprivation, both material and social. Consequently, the mapping of social vulnerability, with particular emphasis on its spatial distribution, emerges as a core instrument to enhance comprehension of the population's characteristics and to discern the urban areas most susceptible to social, economic, environmental and epidemic hazards.

Social vulnerability is defined as a condition of deprivation across multiple levels, involving different aspects of daily life and exposing the population to risks related to natural, environmental, socioeconomic and epidemic factors (Davino et al., 2021). These factors encompass job instability, unemployment, inadequate education, substandard housing conditions, overcrowding, domestic violence, chronic diseases, addictions, insufficient access to healthcare services and disabling conditions. This is a complex concept, which requires a synthetic representation through a composite index, capable of integrating a series of elementary indicators through a multidimensional approach. The seven principal dimensions that must be given full consideration for the purpose of constructing the composite index are as follows: housing conditions, social context, social relations, education, labour market, mobility and economic well-being.

The condition of vulnerability that may accompany ageing is not a marginal phenomenon, nor is it univocal. Rather, it recalls a multiplicity of complex and interconnected dimensions, involving individual, relational and contextual aspects. Indeed, the elderly person is confronted with transformations affecting both personal resources and the social and institutional environment in which they are embedded, in a process in which fragility and resilience coexist (Schröder-Butterfill and Marianti, 2006). A plethora of studies have emphasised the central role of social relationships, health and mobility, economic resources, social participation and the quality of the living environment, such as the presence of safe and perceived pleasant neighbourhoods, in the well-being of the elderly (Gabriel and Bowling, 2004).

Vulnerability in the elderly can manifest in various forms, including the fear of premature or degrading death, the absence of adequate physical and health care, the excess or intrusiveness of care, economic disadvantage, social exclusion, loneliness, loss of autonomy, the risk of institutionalisation or homelessness (Schröder-Butterfill and Marianti, 2006). A considerable number of studies have sought to quantify social vulnerability by constructing composite indices. However, the majority of existing indices have been developed for the general population, with only a small number having been designed specifically for the elderly population (Chau et al., 2014).

How to Measure Age-Friendliness and Sustainable and Inclusive Well-Being

In recent years, the reflection on social vulnerability has broadened, moving away from the analysis of structural disadvantage or exposure to critical factors alone towards a more articulated assessment of the extent to which the urban environment favours active, autonomous and healthy ageing.

In this perspective, the studies adopt the age-friendliness paradigm, as promoted by the work of the World Health Organisation (WHO, 2015). These studies aim to assess the extent to which cities are able to respond to the specific needs of the elderly population. Consequently, the emphasis has transitioned from the mere identification of vulnerability to the evaluation of inclusivity within urban contexts. This shift in focus entails the consideration of factors such as accessibility, engagement, subjective well-being, and social cohesion. In the initial document disseminated by the WHO, a methodological framework is proposed for the assessment of urban areas' capacity to cater to the requirements of the ageing demographic. The objective of this study is twofold.

Firstly, it seeks to monitor the implementation of policies inspired by the age-friendliness paradigm. Secondly, it aims to offer a practical tool to support local governments, practitioners and communities in improving the quality of life in urban settings. The system is predicated on a structured set of core indicators, with the potential for supplementation by additional indicators, depending on the local context.

The indicators are divided into three main thematic areas: the first is the accessibility of the physical environment, which includes variables such as the presence and condition of pavements, the availability of public transport and its accessibility, the accessibility of public buildings and the cost of housing in relation to the income of the elderly. Secondly, the inclusiveness of the social environment is considered, with aspects such as participation, perceived respect, involvement in decision-making processes, economic security and access to social welfare services being taken into account. The final component pertains to the impact on the quality of life, in terms of well-being and perceived health. These three dimensions are complemented by equity indicators that detect inequalities between groups of older people according to age, gender, income, geographical area or level of education. The construction of the indicators is based on two main sources of information: local administrative data and surveys on the elderly population. The latter are also useful in capturing the subjective component, such as satisfaction with services and perception of safety. The integration of objective data and subjective perceptions is a key strength of the proposed model. The primary benefits of this approach are threefold. Firstly, it enables the comparison of areas within the same city. Secondly, it facilitates the monitoring of the evolution of age-friendliness over time. Thirdly, it identifies local criticalities.

The interest in more articulated measurement tools is not limited to vulnerability and age-friendliness but extends to the broader concept of sustainable and inclusive well-being, as demonstrated by the growing number of studies that, since the report by Sen, Stiglitz and Fitoussi (2009), have contributed to the development of multidimensional indices. These approaches seek to circumvent the limitations of conventional economic measures by incorporating social, environmental and territorial dimensions, whilst concomitantly focusing on spatial phenomena, local inequalities and interconnections between geographical areas.

The CASA Project

It is from these premises that the CASA (Aging in Cities-Medium: How Housing Conditions and Urban Spaces Can Reduce or Increase Opportunities for Longevity in Health) project was developed, a programme funded by the Next Generation EU initiative. progetto finanziato da Next Generation EU.

The CASA project is an academic initiative that aims to enhance the understanding of the multifaceted dimensions of housing and urban vulnerability in medium-sized Italian cities. A key objective of the project is to analyse the relationship between urban characteristics and the trajectories of potential ageing in senior citizens. The research adopts a case study approach, focusing on the Municipality of Bergamo as a model example. This municipality is notable for its clearly defined spatial, social and institutional characteristics, which serve as a benchmark for understanding urban dynamics. It is regarded as a prototypical “average city,” offering a useful framework for developing analytical and interpretative models that can be applied to a range of urban contexts.

The project identifies a series of socio-economic, socio-demographic and spatial indicators, both at urban and suburban (district) level, referring to the case study of Bergamo. The initial phase of the project entailed the integration of various databases, including municipal ISTAT data, hospitalisation data from the Ministry of Health, and municipal data, among others. A survey is being conducted among the elderly population residing in the municipality, with the aim of understanding the motivations and factors that have influenced their selection of living places for their ageing process. In order to analyse the settlement characteristics of the municipal context and the spatial organisation of the neighbourhoods, reference is being made, above all, to municipal and regional level databases (Open Data and the Geoportal of the Lombardy Region), given the level of detail to be guaranteed. Other national and European sources may be utilised to support and supplement the analysis. These explorations are conducted with the aim of dealing with different thematic levels (e.g. main functions of the building fabric, organisation of public spaces and equipment, mobility networks, ecological-environmental

system) both in order to recognise the characterising elements and conditions of the Municipality of Bergamo, as a city taken as an ideal type and territorial model of reference, and to identify the specific features of each district treated. In the recognition of the settlement characteristics of the spatial areas under analysis, particular attention is paid to the elements and conditions responsible for the worsening of conditions of vulnerability towards the elderly population.

In accordance with the theoretical framework delineated above, a number of key elements for analysis are identified. The factors associated with housing vulnerability can be categorised into three distinct groups: structural factors, which include characteristics such as dwelling size, age, isolation, and security; access to services, which encompasses amenities such as pharmacies, parks, meeting centres, and public transport; and the interplay between vulnerability factors and well-being, encompassing aspects such as psychophysical health and longevity. The spatial analysis is divided into two complementary elements. Firstly, the municipal focus analyses municipal data, demographic and housing-urban variability, and identifies synthetic indicators of vulnerability. Secondly, the focus at the detailed geographical unit is based on the scale of the 22 neighbourhoods of the municipality of Bergamo (Figure 1). Here, the indicators are refined, recording aspects of housing-structural type and access to services and risk conditions. As anticipated, ground temperatures (Figure 2) and ecosystem services (Figure 3) are considered at the neighbourhood scale.

The CASA project aims to achieve an in-depth understanding of the conditions and needs that older persons have in relation to the places where they live and how this relationship may determine longevity in health in average Italian cities. The result of the research will be the production of vulnerability indicators for individuals who experience ageing in their living places on a daily basis. These indicators and their relationship to health will be used to inform elderly people and policy makers with a view to proposing innovative Aging in Place policies.

Figure 1: Three analytical maps of the neighbourhood (infrastructural, settlement and environmental system). a. Infrastructure system: this map illustrates the main mobility and connection infrastructures in the neighbourhood: the main roads and connecting axes are highlighted in dark red, such as roundabouts and strategic crossroads, and the connection with the railway network and suburban roads is also highlighted, indicating the overall accessibility of the area. Infrastructure has a significant impact on the neighbourhood, creating numerous caesuras. b. Settlement system: represents the organisation of the built-up area in the neighbourhood in which densely built-up areas (residential and productive) are shown in dark grey; low-density areas (such as scattered housing or recent expansion) are in light grey. Urban voids, unbuilt areas and residual spaces are noted, which are fundamental for possible urban regeneration strategies. c. Environmental system: map dedicated to natural and environmental elements to highlight ecological corridors and linear vegetation along infrastructures, which play a relevant ecological and landscape role.

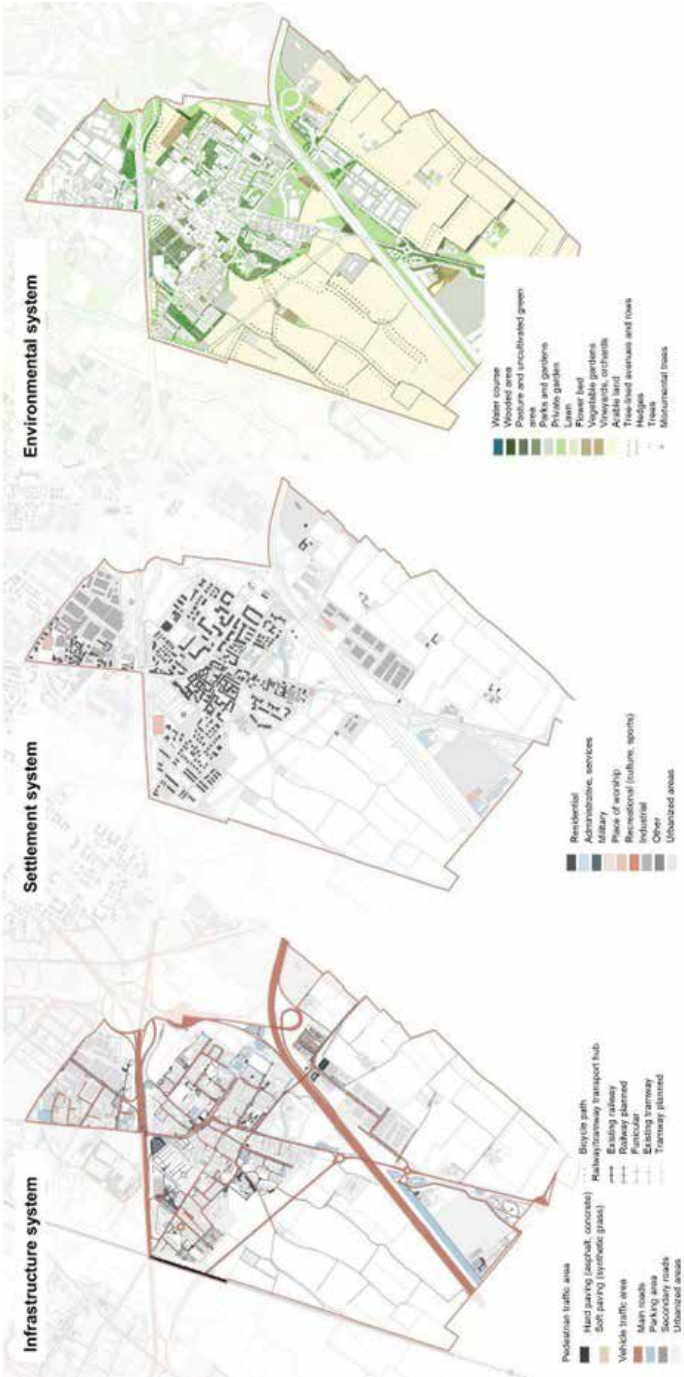

Figure 1: Three analytical maps of the neighbourhood (infrastructural, settlement and environmental system). a. Infrastructure system: this map illustrates the main mobility and connection infrastructures in the neighbourhood: the main roads and connecting axes are highlighted in dark red, such as roundabouts and strategic crossroads, and the connection with the railway network and suburban roads is also highlighted, indicating the overall accessibility of the area. Infrastructure has a significant impact on the neighbourhood, creating numerous caesuras. b. Settlement system: represents the organisation of the built-up area in the neighbourhood in which densely built-up areas (residential and productive) are shown in dark grey; low-density areas (such as scattered housing or recent expansion) are in light grey. Urban voids, unbuilt areas and residual spaces are noted, which are fundamental for possible urban regeneration strategies. c. Environmental system: map dedicated to natural and environmental elements to highlight ecological corridors and linear vegetation along infrastructures, which play a relevant ecological and landscape role.

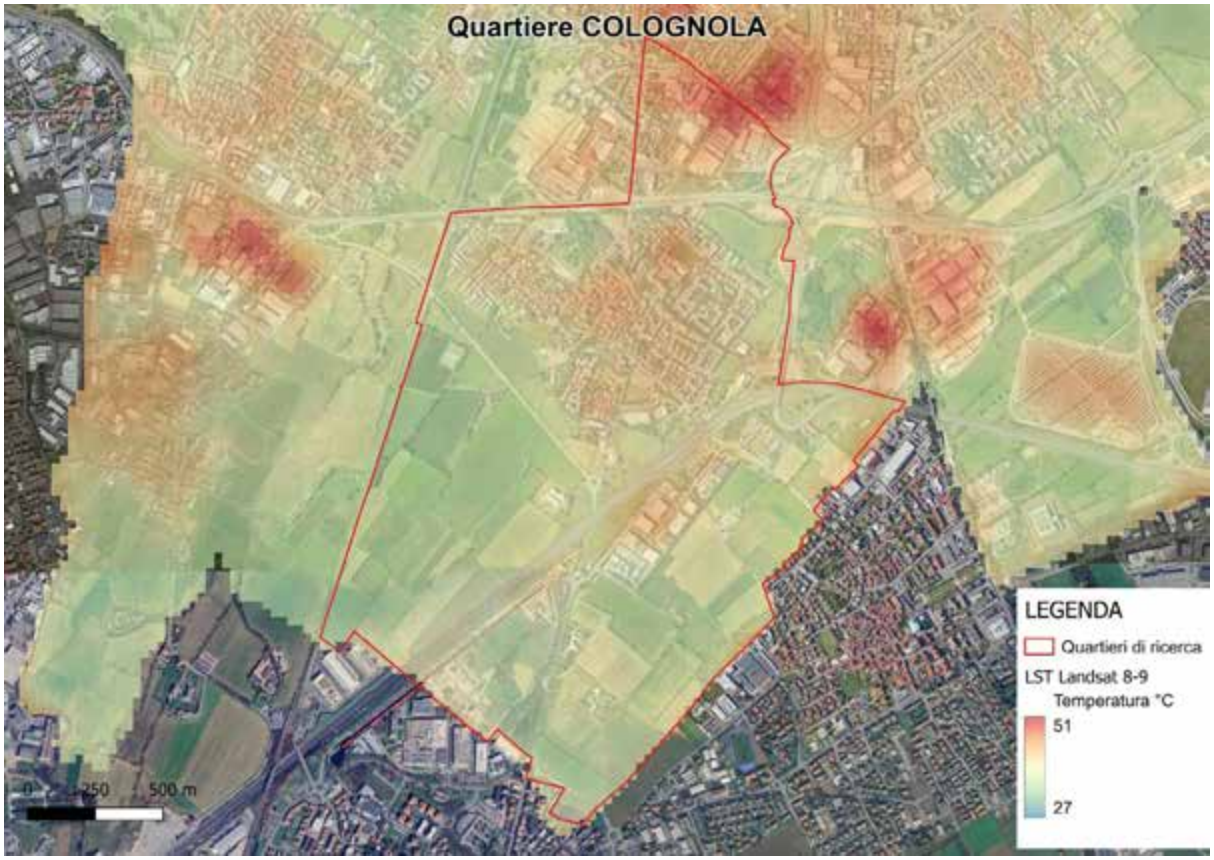

Figure 2: This map depicts the distribution of the ground surface temperature in the Colognola district: the red areas reach high temperatures (up to 51°C), typical of asphalt surfaces, industrial areas and compact urbanisation, which are subject to the heat island effect. The yellow/orange zones indicate intermediate temperatures, often associated with mixed surfaces of buildings and vegetation. The blue areas are the coolest (around 27°C), often coinciding with green areas, parks or agricultural fields. This map makes it possible to assess the critical climatic conditions in the neighbourhood and suggests the importance of mitigation measures through an increase in green areas.

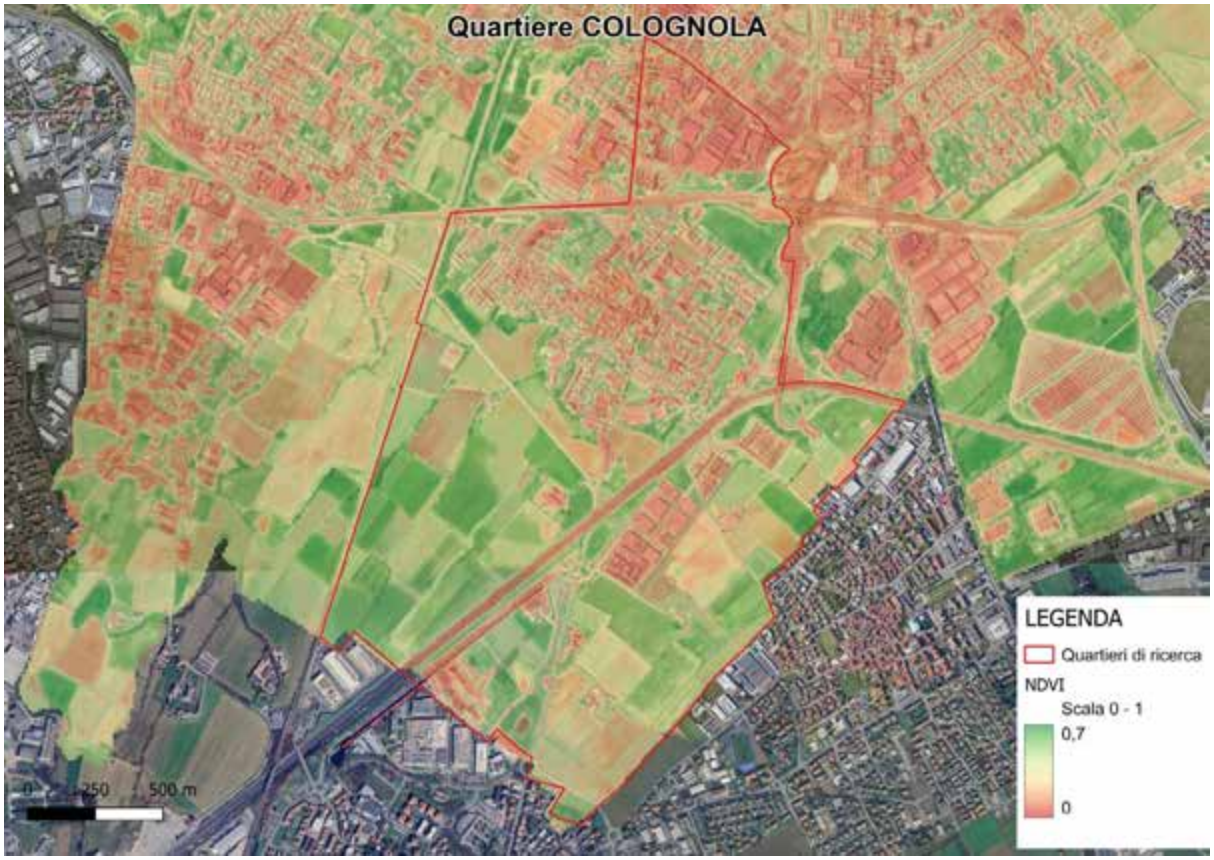

Figure 3: The map shows the vegetation vigour index in the Colognola district. The NDVI varies from 0 to 0.7, where dark green areas indicate lush and healthy vegetation, typical of parks, active agricultural areas or wooded areas; red areas show heavily urbanised or sealed areas, lacking significant vegetation (NDVI ≈ 0); intermediate shades (yellow/orange) represent medium vegetation, such as gardens, hedges or scattered trees.

Conclusion

The rapid ageing of the global population highlights the importance of urban planning and the built environment in promoting healthy ageing. Environmental factors significantly impact the health of the elderly, demonstrating the potential of spatial planning interventions to prevent disease and promote healthy ageing. Italy is experiencing rapid demographic change, particularly in cities, and the organisation of urban environments influences the daily lives and well-being of its population. Public spaces play a key role in this respect, either favouring or hindering the mobility and social engagement of elderly populations.

This paper outlines the initial stage of the CASA project, which examines how urban spaces impact healthy ageing and neighbourhood attachment in medium-sized Italian cities, using Bergamo as a case study. The research aims to understand the impact of urban structure and environments on elderly people, focusing on the effectiveness of public spaces in promoting health and social inclusion while identifying barriers to their use and recognising neighbourhood heterogeneity.

'Ageing in place' is considered in the context of climate change, which poses significant health risks for older people due to rising temperatures and extreme weather conditions. Urban greenery and nature-based solutions (NBS) are vital for encouraging physical activity, social interaction, and mental well-being, particularly in low-income areas. Walkability is vital for the independence and health of older people, yet rising temperatures and the urban heat island effect can hinder outdoor activity and social interaction. Therefore, urban design interventions are essential to improve thermal comfort and accessibility.

A key concept in this research is environmental vulnerability, which describes territories' susceptibility to environmental and social changes. This is often exacerbated by urban planning that neglects the needs of vulnerable populations, inevitably leading to inequalities. This includes individual vulnerabilities (e.g. declining health and social isolation), economic vulnerability (e.g. lack of financial resources) and social/relational vulnerability (e.g. loss of social connections), all of which can be exacerbated by environmental factors. Social vulnerability is measured using an index incorporating factors such as housing, social background, education and economic well-being.

Rather than simply identifying vulnerability, the research assesses urban inclusiveness for active, autonomous and healthy ageing, in line with the WHO's friendly age paradigm. This involves assessing accessibility, engagement, subjective well-being and social cohesion using a framework of indicators and local administrative data, supplemented by surveys of elderly people to obtain objective and subjective perceptions.

Based on these principles, the CASA project aims to gain an in-depth understanding of the conditions and needs of elderly people in relation to where they live, and how this affects their longevity and health in Italian cities. By integrating different databases and conducting surveys in Bergamo, the project identifies socio-economic, socio-demographic and spatial indicators at the urban and neighbourhood levels, focusing on factors that exacerbate vulnerability. Ultimately, the research will produce vulnerability indicators for the elderly, providing crucial information for both this demographic and policymakers to develop innovative 'ageing in place' strategies.

Public Drinking as a Transformative Practice of Placemaking

Merve Deniz TAK[a], Ayşe Burcu KISACIK[b]
Affiliation: İstanbul University, Urban and Regional Planninga,[b]
Email: mdtak@istanbul.edu.tr [a], abkisacik@istanbul.edu.tr[b]

Abstract
Global economic instability is reshaping everyday practices, with public spaces increasingly reflecting this transformation. As rising alcohol prices impact traditional forms of socializing, communities are turning to public drinking as a more affordable alternative. More than just alcohol consumption, public drinking acts as a form of placemaking, transforming streets into social hubs. This study explores the public drinking through "heterotopia" and "third place" theories, focusing on Dr. İhsan Ünlüer Street in Istanbul. Using observation method, the research investigates how the street has shifted from a space of transit to a dynamic site of gathering while also accommodating both unity and conflict.

Keywords: Public drinking, Heterotopia, Third Place, Place making

1.Introduction

Placemaking plays an important role in fostering relationships that enhance social capital and economic opportunities. The way the space is positioned, the location, the spatial attributes of space can be welcoming for new actions and eventually it constructs the place. Today, there are various theories about place, but one of the most significant focuses on maintaining social cohesion and fostering new social capital. As one of the most important examples, Ray Oldenburg published his book The Great Good Place in 1989 and stated that people have places 1. work and 2. home but beside them people also need third places to keep our sanity. As social entities, we need places to bond ourselves with others, or even nature. This third place theory became today's one of major topics in public space to remind ourselves why we need these other places.

1.1.Third Place

In the book, Oldenburg (1989) continues with defining attributes of a 3rd place. Firstly, these third places should have a neutral ground, citizens should be able to come and go whenever they wish. This publicity welcomes all groups of people in public space so the place is always open to new coincidences, and diverse groups feel relaxed to open themselves in this neutrality. Secondly, third place is a leveller. There is no barrier to enter these places like social or economic status, so the social hierarchy is not welcomed in these places. Thirdly, these places have engaging conversations, the primer activity in third place is conversation therefore creating new social bonds. The environment of these places encourages people to communicate rather than hiding in the corners. Moreover, third places are accessible and accommodating, they are open to all so there is no barrier to enter these places. Third places have regulars who make newcomers feel in a welcoming atmosphere and create more regular bonds in the community. These places' decor is warm and it stays away from making people feel like they are in a serious place like work etc. And finally, these places have a light-hearted atmosphere, encouraged with humour and playful conversations. To sum up, third places are such good options to nurture bonds in isolated society. Moreover, these places not only create social bonds but also help to increase productivity of societies by practising non-formal knowledge sharing (Fowler, n.d.).

Today, the existence of third places is more important than ever before for the ability of gathering people from different kinds of groups. Because feeling lonely is becoming a vital issue in societies with the increased usage of social media. According to a survey result from a Health Company in Australia, 41% of young people feel lonely when they see others' social media posts (Hislop, 2024). Likewise, it has been stated that social media has the potential to increase loneliness as it replaces the time devoted to social relationships in the real world (Jia et al., 2024). Addition to these effects of social media, today people are more mobile, communities are shrinking and isolation is increasing while socio-economic problems are emerging. That is why there needs to be more third places in the urban place and people tend to create their own places to relieve these damaging impacts.

In addition to these sources, UNESCO also supports the creation of third places by giving cafes as an example (Oldenburg & Christensen, 2023). Using cafes to work make them more than a place for consumption but also a place for connection, Oldenburg and Christensen claim. However, some states that the concept of third place is not valid for coffee shops since they have already evolved to a place for work (Sandiford and Divers, 2014; Ferreira et al., 2021). Moreover, if somebody wants to work in that coffee shop, proper outfits and some money to spend is mandatory, which makes coffee shops opposed to the idea of accessibility of third spaces. These debates show that third places have fluid characteristics and they overlap different usages from time to time. This function changing is actually connecting third places to another important place theory: heterotopias

1.2. Heterotopias

People want to see the ideal space they dream of in their lives, meaning they wish to reach utopias; however, by their very nature, these utopias are impossible to achieve. To avoid the opposing situations or threats of these utopias as much as possible, they have created heterotopias. Heterotopias, or "other spaces," were first mentioned by Foucault in his architecture lectures and later entered the literature through Of Other Spaces (Foucault & Miskowiec, 1989), leading to various speculations about urban space. Foucault used this term in a spatial sense, but originally, it was a term used in medicine for organs that are not in their proper place. However, after Foucault's analogical approach, heterotopias can now be seen in different fields, such as social sciences, where they are used in the context of migrants (Chambers, 2005; Göker, 2017).

Foucault explains his interest in spatial context by stating that the era he lived in had become the epoch of space. In the Middle Ages, spaces were divided only into religious and workplace settings or into urban and rural areas, whereas today, we witness simultaneous juxtapositions. According to him, these spaces derive their meanings solely from the social interactions they encompass, and based on this, he defines spaces as utopias and heterotopias. These heterotopias disrupt the continuity of everyday life, challenge uniformity, and sometimes emerge as unplanned spaces. According to Göker (2017), these spaces also demonstrate resistance against authority. This claim may not cover the definition fully when thinking about examples that Foucault gave. For example, crime stands opposite to an utopia and prisons were developed against the anti-utopian notion as the heterotopia by the authorities. So, heterotopia can be expected from every part of every culture. This brings us to the first of the six principles of a heterotopia. These principles were defined to distinct heterotopias because even though we experience them in the urban space so frequently, not every place is a heterotopia.

First principle states that heterotopia is a default attribute and every culture have its own heterotopias, which divides them as crisis heterotopias and heterotopias for deviation for primitive and modern societies. Foucault says crisis heterotopias are spaces created to manage the crisis, like exclusive, sacred or forbidden areas. He gives boarding schools for boys as an example since these schools hide the manifestations of sexual virility or honeymoons to hide “deflowering” of young women from the other part of the society. But in time, these crisis heterotopias have left their place to heterotopias for deviation with modernized society. These are places for hiding people who have deviated from the society somehow. Old age is a crisis according to him but in time it changed to a deviation and retirement houses are used to hide this deviation. Just like retirement houses, psychiatric hospitals and prisons are now places for deviation, for hiding one's from society.

Second principle states that the heterotopia can change in time with different functions according to different cultures. For example, cemeteries used to be in the centre, the sacred heart of the town but in time they were pushed out of the city and turned into other-place where people suffer their own miseries far away. As the third principle, heterotopias can juxtapose multiple incompatible places in one space and overlap them, like theatres or cinemas, places where we can see multiple scenes in one night from a box. Fourth principle of heterotopias is that they are most often linked to slices in time. These places can link ancient times with modern projects in museums or libraries, also these places can extinguish time temporarily or create new definitions of time, like festivals. Another principle of a heterotopia is they have the ability to open to penetrate and close to isolate others. To enter a prison, the person should commit a crime and need to obey the system or to enter a hospital, the person should be sick and have insurance. These are solid examples of penetration and isolation but Fouca-

ult also claims that there exist fully open heterotopias but in fact, deep down, they have invisible mechanisms that prevent everyone from penetrating the place. Everyone can get in these places but this is just an illusion for them, they have just been excluded. Lastly, heterotopias "have a function in relation to all space that remains" (Foucault & Miskowiec, 1989). Heterotopia creates two poles in the place: one is creating an illusion that exposes all remaining space, the other is creating another real space that is as perfect as our place is irregular, messy.

To sum up, both third place and heterotopia theories create revolutionary ways of seeing public space and they overlap from time to time in different places of urban areas. While both theories embrace some features of the constructed space, they indicate quite different approaches in some aspects. For example, fluid characteristics of a third place refers to heterotopia's 3rd principle, but at the same time, the welcoming nature of third places is contradictory to partly openness of heterotopias. From Foucault's examples, we see that there are numerous heterotopias and also third places, additionally, new types of them are emerging day by day with the evolving needs of society like coffee shops, even social media (Göker, 2017).

In the light of these indicators given by the literature, this study has endeavoured to search for an unobserved other-place for Istanbul. This other-place created by public drinking practices on the street has been analysed through observation and the intersections with these two theories have been examined. For this purpose, the transformation of two different streets from both shores of Istanbul into a third space has been investigated.

2. Dr.İhsan Ünlüer Street, Kadıköy

Dr. İhsan Ünlüer Street, intersecting with Kadife Street—Kadıköy's most famous drinking spot—is lined with numerous bars. However, most people purchase alcohol from a kiosk at the street's corner. Since the 2000s, rising alcohol prices and an inflationary economy have made dining and drinking out increasingly expensive in Türkiye. In response, this kiosk has become a gathering spot where middle-income adults get tipsy at a lower cost before moving on to their main venue. It has also evolved into a social hub for university students, offering an alternative space for those who cannot afford drinks in pricey bars but still create their own social capital.

Figure 1: Bars, kiosks and the flow of crowded

The observation study in this area was conducted in January between 9:30 - 10:30 PM, with the temperature at 3°C. Before arriving, it was assumed that the cold weather would keep people indoors and that the street would be empty. However, the results of the observation serve as clear evidence of how strong the third space created by Dr. İhsan Ünlüer Street truly is—the street was bustling with people.

Figure 2: People hanging on Dr.İhsan Ünlüer St. next to the kiosk

After 10:00 PM, people who bought alcohol from the kiosk spread out into distinct groups along the street. The densest crowd gathers at the opposite sidewalk of the kiosk at the entrance, and gradually gets spare further up the street. Every available space becomes a spot for socializing over drinks—even the staircases of buildings have turned into informal drinking spaces. University students, often dressed in dark colours, leather jackets, or second-hand clothing, stand in small groups. While they socialize within their circles, they also interact with others who share their broader social habitat. Sometimes people initiate conversations with strangers; sometimes groups merge due to the energy of the crowd and the social ease facilitated by alcohol. The street has become a symbolic space for these spontaneous connections.

On the night of the observation, a group of young people distributing food in memory of the late filmmaker David Lynch's death humorously reinforced this symbolism. It is no coincidence that they chose Dr. İhsan Ünlüer Street in Kadıköy for this niche act. A gathering place for avant-garde, non-mainstream, and marginal groups, this street amplifies social interactions not around a table, but on the sidewalk, driven by the courage that alcohol brings and the collective experience it fosters.

Figure 3: Food sharing in the memory of David Lynch

Young people who buy their drinks from the kiosk at the corner position themselves by leaning against the building walls. The sidewalk is designed to be level with the road, with bollards placed to distinguish the pedestrian area from the vehicle path. Despite being on the same level, these bollards seem to create a psychological sense of boundary for the groups, as their spread naturally stops at these markers.

Figure 4: Standing positions on Dr.İhsan Ünlüer street

The street accompanies multiple groups at the same time. These include individuals or small groups with 2-3 people who gather for pre-drink before heading to the main bar, standing groups of 2-5 who's next destination remains uncertain and crowded long term visitors that can be understood by their sitting on the stairs or the pavement. A key distinction emerges among these groups: their age. While this is not a surprising finding, it can be said that the primary demographic of Dr. İhsan Ünlüer Street's social habitat consists of young people aged 18–25. Although these young people are in space for a long time, they prefer to sit in a circle, closed off from the outside world, so the openness of this group is questionable. In contrast, standing groups, though often also forming a circular arrangement, remain more mobile and accessible to others. This mobility allows for temporary interactions—whether through flirtatious glances exchanged from a distance or through the chemistry of being

in a crowded (Baum & Paulus, 1987; Altay, 1999) space, where alcohol encourages temporary social bonds.

Yet, alongside this sense of collective belonging, this other-space also generates contradictions. Empty bottles are left scattered on the sidewalk, and groups sitting on staircases block the movement of residents, effectively occupying semi-public spaces and stripping locals of their everyday spatial justice. On the other hand, with the solution found by the locals, a completely different area is gradually being formed all over Kadıköy today: stairs with iron fences. These newcomers, who find a place for themselves as the others, create noise, dirt and carelessness for the locals. From this point of view, this heterotopia also evolves into a **place of conflict.**

Figure 5: stairs with iron fences

2.1. Dr. İhsan Ünlüer Street as a Third Place

These findings indicate that all gatherings in Dr.İhsan Ünlüer Street make this street a third place. Firstly, this street welcomes everyone from diverse economic and social groups, like student and middle-income pre-drinkers, and there exists no hierarchy between them. The kiosk makes the street a neutral ground for gatherings and drinking practice, which makes the street a third place as a leveller. Additionally, there is no physical barrier to enter the street. This street is accessible and accommodating for everyone (partly, due to contradicts between locals and public drinkers). It engages new conversations in a playful mood, as seen in the example of the David Lynch memorial. With the help of alcohol, most people are more welcoming than regular times here, but it should be kept in mind that people may feel more relaxed since they believe that they are with people just like them, harmless, standing just for a drink. As another evidence, this place is low profile with murals on the wall, dogs on the street, no extra effort has been made here. There is no clue of any regulated space feeling, moreover, vandalism through graffiti can be mentioned.

Apart from these, due to the methodology, it cannot be said that there are regulars in the place. Maybe bodyguards of nearby bars can be mentioned as regulars but they are not part of drinking / gathering activity. Besides, due to the methodology's limitation, information on whether they feel cosy and at home cannot be obtained. Still, other findings show that this street is highly a third place.

2.2. Dr. İhsan Ünlüer Street as a Heterotopia

The street is for accessibility at first, but in time, it becomes a gathering place temporarily with the help of alcohol. This juxtaposition is observed nearly every night in the street and in the day, everything turns into regular.

Indeed, this place shows the third principle of a heterotopia. In addition, this street might be a place for deviation for low income students who cannot find a proper place to drink which refers to the first principle of being a heterotopia. This time dependent gathering in the street may also change the perception of time especially for long standing people. The night has just started and everything will be decided according to the drinking practice, while people are having fun, time flies. For these reasons, the street shows the fourth principle of heterotopias. Lastly, this street has no barriers, everyone can enter and stand, it looks fully open but deep down, the person needs some qualifications to join this gathering. The way one dresses affects how much people are going to interact with him/her. If the person is too old, or too mainstream, it is a low possibility to feel like he/she is a part of this gathering. This reflects the fifth principle of heterotopias but when being open is the issue, this street never fully encompasses it. This partly closeness also brings new social capitals in the groups. When a girl looks at a boy who dresses just like her (with piercings and dark leather jackets), she creates her categoric knowing about him and being ready to know more about him. This prior knowledge opens up new networks and new relationships.

4. Conclusion

The initial motivation for this study came from an interest in examining the gathering dynamics of different socio-economic groups shaped by two distinct practices on either side of Istanbul: one involving alcohol purchased from a market/kiosk, and the other involving alcohol bought from a bar and consumed out on the street. On the European side (Ahmet Fetgari Street, Şişli), it was previously observed that a newly opened bar initially attracted young people and created a significant gathering space in front of it. However, after the field observations, the bar lost its popularity, and the street no longer fulfilled this gathering function. In contrast, Dr. İlhan Ünlüer Street on the Asian side has consistently maintained its character as a public and "third place" throughout all seasons. This continuity is grounded in the economic rationale behind the street-drinking practice—namely, buying the cheapest alcohol from the kiosk—which makes the space more sustainable as a site of communal activity.

Dr. İhsan Ünlüer Street has become the most famous street for public drinking in Kadıköy in recent years, thanks to its location and the convenience of the corner kiosk. With this high demand, the street has transformed into a potential space for various social gatherings. Its spatial characteristics—such as being right across from Kadıköy's well-known marginal bars like BİNA and Arka Oda, its proximity to other famous bars like Karga and Lal, and the availability of alcohol from the corner kiosk even after 10 PM—make it a frequent choice for middle-income young adults. These factors trigger group behaviour, attracting student groups who prefer not to drink in bars to gather in this space.

As a result of these gatherings, the street, originally designed for transportation, has come to serve a dual function: as a third place that fosters social interactions and as a heterotopia that disrupts conventional spatial norms. This dual identity highlights the fluidity of urban spaces. This transformation has created a public space that fosters the accumulation of social capital, which is essential for the continuity of society.

Acknowledgements

This study was conducted within the scope of the Culture and Urban Space course at İstanbul Technical University Department of Urban and Regional Planning PhD, supervised by Assoc.Prof.Dr. Eda Yücesoy. We would like to thank her for her valuable feedback and generous support throughout the process.

The Italian Integrated Water Service as a Promoter of Soil Desealing Processes

Gregorio Pezzoli
University of Bergamo
Email: gregorio.pezzoli@unibg.it

Abstract
Urban soil sealing exacerbates climate change impacts by disrupting the hydrological cycle and increasing flood risks. This paper examines how Italian Integrated Water Service Companies are promoting soil desealing to enhance urban resilience and environmental sustainability. Case studies of MM S.p.A., Gruppo CAP, and BrianzAcque in Lombardy reveal a strategic shift towards implementing Nature-based Solutions and Sustainable Urban Drainage Systems, such as depaving and bioretention areas. Regional policies, like Lombardy's hydraulic invariance principle, and national funding are crucial enablers. While promising, the limited geographical spread of these initiatives underscores the need for broader national adoption and supportive policy frameworks.

Keywords: Integrated Water Service Companies (IWSCs); Nature-based Solutions (NbS); Public spaces; Soil Desealing; Urban resilience

Introduction

The contemporary world is being impacted by the adverse consequences of climate change. The causes of this phenomenon can be attributed to the increase in anthropogenic greenhouse gas emissions (IPCC, 2023). Urban systems have been identified as both the largest generators of these climate-altering gases and the most adversely affected by them (Short & Farmer, 2021). The phenomenon of rising global temperatures, a consequence of climate change, exerts a direct influence on the hydrological cycle. The global nature of the water cycle is evident, yet the utilisation of this resource, its supply, and the associated conflicts are inherently localised phenomena (Menga, 2024). This alteration in the hydrological cycle has been shown to result in increased precipitation intensity and frequency (Trenberth, 2011), leading to flooding and periods of severe drought (Hunt & Watkiss, 2011). This dynamic results in alterations to the distribution of water between the water table and the surface, which in turn has direct consequences for erosion, runoff and water stress experienced by plants (IPCC, 2022).

The disruption of the water cycle is exacerbated by soil consumption, i.e. the expansion of infrastructure and urban areas at the expense of the natural and agricultural systems (European Commission, 2012). A considerable proportion of the soil that is consumed is also sealed. Soil sealing can be defined as the process by which soil is permanently covered by an impermeable artificial material (European Commission, 2012). The impact of soil consumption and soil sealing on water resources is multifaceted. It leads to a reduction in infiltration and increased runoff resulting in an overloading of the sewage system. Secondly, it contributes to a decline in biodiversity both above and below the soil. It also reduces the soil's capacity to store carbon and evapotranspiration. Finally, it disrupts the chemical and biological binding of microorganisms (European Commission, 2012). In 2022, Italy's soil consumption, expressed as a percentage of the total area of "usable" soil in the country, was recorded at 10.16% (SNPA, 2024).

A variety of techniques have been developed for the purpose of enhancing the management of the urban water cycle within urban systems. In particular, Nature-based Solutions (NbS) and Sustainable Urban Drainage Systems (SuDS) have been identified as playing a pivotal role. Nature-inspired solutions (NbS) are defined as interventions that offer multiple benefits with the potential to address environmental challenges (Sowińska-Świerkosza & García, 2022). In addition to economic and environmental benefits, they have the capacity to generate positive externalities from a social perspective (Haase et al., 2017; Bockarjova et al., 2022). SuDS are systems that utilise natural processes, green infrastructure and traditional infrastructure to collect, infiltrate, store, convey and treat rainwater at the location where precipitation occurs (Davis and Naumann, 2017). These natural technologies have the potential to mitigate the impacts of climate change in urban areas, including rising temperatures, flooding risks and droughts (Hobbie and Grimm, 2020). Furthermore, these interventions contribute to increasing the quantity and quality of urban public spaces.

The present contribution aims to explore the ways in which the actions and projects of Integrated Water Service Companies (IWSCs) can promote public space initiatives that enhance resilience to climate change and environmental sustainability.

The analysis will proceed according to threefold criteria. Firstly, a classification of the type of interventions implemented and their relation to other benefits in addition to urban drainage (e.g. temperature regulation, enhancement of urban biodiversity, etc.). Secondly, the identification of regional and local policies that enabled and supported the success of the projects. The final stage of the process is the evaluation of the projects' effectiveness, equity and scalability. The selection of case studies was initially based on three criteria: the strong urbanisation of the optimal territorial areas, the actual role of the IWSCs as a promoter of soil unsealing, and the geographical variety, with the objective of selecting representative cases throughout Italy. Following an initial review of the websites of all Italian companies (approximately 100), only three that were active in soil unsealing were identified, all of which were located in the Lombardy Region. The primary sources of the projects are drawn from grey literature, encompassing project data sheets, information websites, and institutional websites of integrated water service companies, municipalities, and provinces.

The Integrated Water Service (IWS)

The concept of Integrated Water Service (IWS) was born in Italy in 1994 (L. 36/1994), but is currently regulated by the Legislative Decree Environmental Regulations of 2006, which defines it as 'constituted by the set of public services of capture, adduction and distribution of water for civil uses, sewerage and wastewater treatment, and must be managed according to principles of efficiency, effectiveness and economy, in compliance with national and EU regulations' (D. lgs. 152/2006). The Integrated Water Service refers to specific territorial areas, the Optimal Territorial Areas (OTA). These areas are defined - by means of regional laws implementing Law 36/1994 - according to three parameters: (i) respect for the unity of the hydrographic basin or sub-basin or contiguous hydrographic basins; (ii) overcoming management fragmentation; (iii) achievement of adequate management size, defined on the basis of physical, demographic, technical parameters and on the basis of political-administrative subdivisions (Law 36/1994). In some regions, the subdivision follows that of the provinces, while in other cases it follows other territorial requirements. The IIS of a specific OTA is assigned to a service manager, a public or private company. However, there are cases of companies entrusted with the management of multiple OTAs. The managing company takes care of the aqueduct (collection, adduction and distribution) and sewerage (collection, conveyance and purification).

The topic of water sustainability has entered the policies of these companies. A large part of their efforts is dedicated to reducing leakages - the value of which stands at 42.4% in municipal drinking water distribution networks (ISTAT, 2024), optimising monitoring systems and raising awareness of the importance of water as an asset. A strategic shift in focus, away from their traditional core business, has recently been initiated by a number of these companies. This strategic shift is characterised by the promotion and implementation of actions with the objective of enhancing urban drainage systems, mainly on public space. These policies, aimed at achieving a harmonious city-water relationship, are implemented through a combination of conventional 'hard' engineering interventions, e.g. detention basins, and more contemporary and sustainable approaches, e.g. NBS, and SuDS.

Case studies analysis

The three cases examined, which are the only ones identified among those actively involved in sustainable urban drainage improvement measures, are the three companies MM S.p.A., Gruppo CAP and BrianzAcque. Their OTAs are part of two contiguous areas: the Metropolitan City of Milan and the province of Monza Brianza, within the region of Lombardy. It is one of the most urbanised areas in the country, so much so that it is referred to as the "Megalopoli Padana" (Turri, 2000). Within the Italian context, Lombardy stands as a notable exemplar, with a land taken that accounts for 12.19% of the region's total territory (compared to the national average of 7.16%) (ISPRA, 2024). The province of Monza Brianza has consumed 40.78% of the soil within its borders (first in Italy), while for the Metropolitan City of Milan the value stands at 31.88% (third in Italy) (ISPRA, 2024). In 2017, the Lombardy Region adopted a regulation on the principle of hydraulic invariance (R.R. 7/2017). This regulatory framework

pertains to the management of rainwater, with the objective of mitigating water runoff to conventional urban drainage systems. The principle of hydraulic invariance states that the maximum volume of stormwater runoff discharged from urbanised areas into receptors must not exceed the volume that existed prior to urbanisation. The regulation sets out standards for specific categories of building, urbanisation, and infrastructure projects. The application of the regulation has consequences for the entire regional territory, in a diversified way according to the class of criticality.

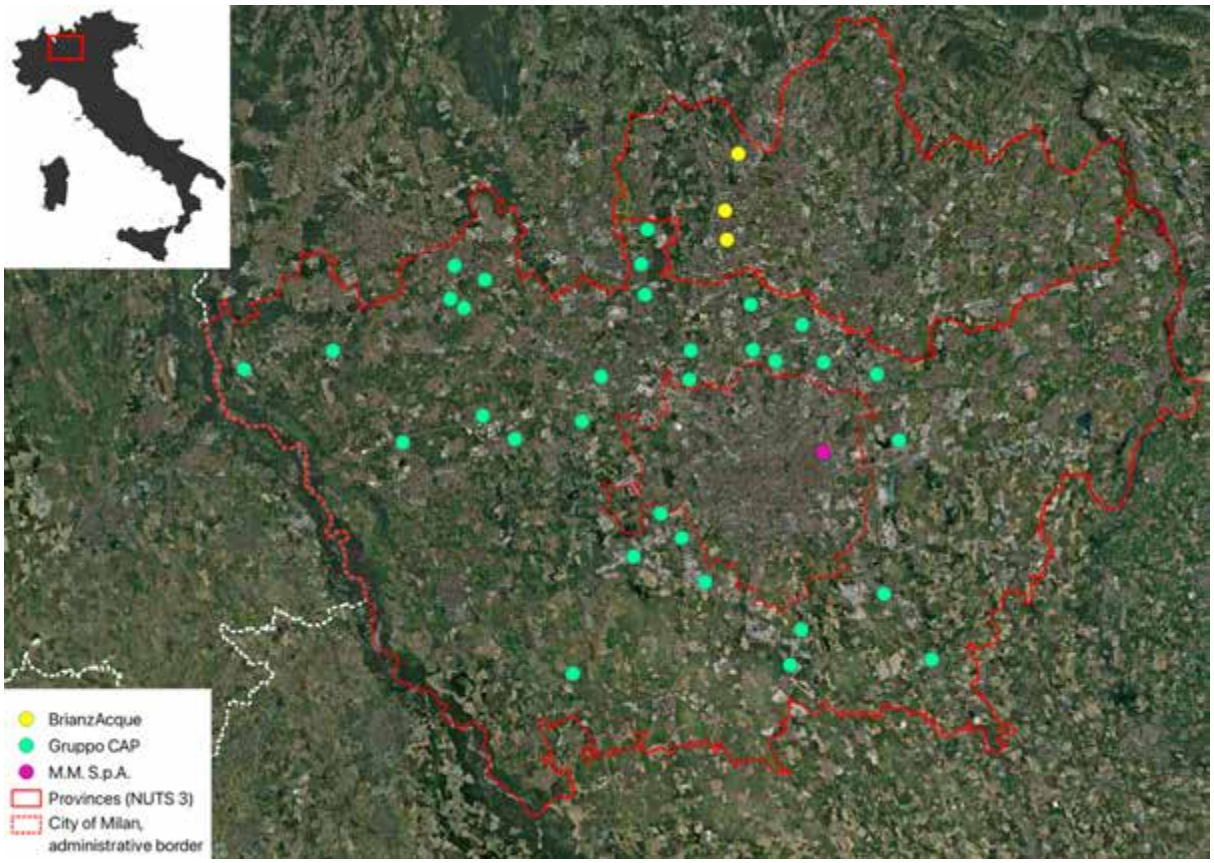

Figure 1: Location of interventions within the Milan metropolitan area. Author's elaboration.

MM S.p.A. and the Municipality of Milan

MM S.p.A. is a multiservice company operating in the fields of engineering (building and infrastructure) and the management of public residential buildings, schools, and sports facilities. It has also managed the Integrated Water Service of the Municipality of Milan since 2003.

The company has developed a first sustainable urban drainage project within the municipality of Milan, in the section of Via Pacini between Via Teodosio and Via Capranica (opened in 2023). The road segment under consideration is approximately 200 metres in length. It contains a central parterre that is free of vehicular traffic, and it is in this area that the intervention is primarily focused. The system is comprised of roadside drains equipped with overflow mechanisms that facilitate the direct conveyance of initial rainfall, which is characterised by elevated levels of pollutants, into the sewer network. Subsequent rainfall is directed towards designated bioretention areas situated within the central parterre of the road, thereby ensuring the effective management of water resources. The division of this sector into three ecological areas was based on the theoretical frequency of flooding and, consequently, the availability of water. The planting of flora was meticulously curated, with a total of approximately ten different species being selected. The implementation of automatic irrigation systems, which are connected to tanks that do not utilise potable water, is also planned to ensure resilience in the face of potential drought periods. The area had previously been used as an unregulated dirt parking area. The

intervention resulted in the creation of new pedestrian pathways, away from vehicular traffic, as well as various elements of street furniture. The construction site also intervened in the side area of the road, with an extension of pedestrian spaces and crossings. Moreover, the intervention has the potential to enhance biodiversity; however, there are concerns regarding its efficacy in mitigating temperature. The area is characterised by the presence of approximately 30-metre-high buildings and a tree-lined landscape, comprising mature, tall species. While the theoretical potential of the new vegetated parterre to contribute to a reduction in total temperatures is evident, further investigations are required to ascertain a significant effect. The objective of the initiative is to extend the pilot project by a further 700 metres.

The company is also undertaking analogous projects in the city of Milan, including those located in Via Guido da Velate and Via Paravia. It is important to note that the municipality has independently concluded additional depaving works within the city. This is indicative of an increasing awareness of the necessity to adopt mitigation and adaptation strategies, particularly within highly urbanised contexts such as Milan.

BianzAcque and the province of Monza and Brianza
BrianzAcque is the public company responsible for the management of the IWS in the province of Monza Brianza, located in the north of Milan. It is responsible for the management of 3,000 kilometres of pipelines, and its annual water supply exceeds 100 million cubic litres, serving a population of 875,000 individuals across 55 municipalities. The model utilised is one of in-house provision, with responsibility for sewerage and purification services also falling within the organisation's remit. The urban drainage interventions promoted by BrianzAcque are underpinned by a circular economy approach, with the overarching objectives of enhancing public space, reducing the risk of flooding and urban heat island phenomena. Three interventions, which were carried out and partially financed by the company, are here illustrated.

The first intervention is situated within the municipality of Cesano Maderno, which has 19,886 inhabitants (ISTAT, 2025), in the western area of the province. The intervention by BrianzAcque, which is based on tree-lined flower beds, rain gardens and drainage systems, concerns a 700-metre stretch of Corso Roma. The project encompasses the construction of 150 square metres of tree-lined pits and 900 square metres of bioretention areas. The financial outlay required for the project is €1.2 million, to be shared between the company, the municipality of Cesano Maderno, and the Lombardy Region. The objective of the project is twofold: firstly, to absorb heavy rainfall by reducing the pressure on the existing sewer network; and secondly, to create new green spaces to contribute to urban well-being.

The second project is focused on the municipality of Meda, which has 11,637 inhabitants (ISTAT, 2025) and is in the western area of the province. The project under discussion pertains to the development of a multifunctional park situated between Via degli Angeli Custodi and Via Giovanni XXIII. The project is composed of four primary interventions: the soil desealing of a parking area with the installation of permeable pavement, the transformation of an undeveloped area into an equipped and accessible park, and the creation of a bioretention area inside the new park. The project will also establish a new network for collecting white water, with the objective of directing it towards the newly developed park. In addition to the planting of 120 new trees, the intervention will enable the sustainable drainage of more than 10,000 m² and the revitalisation and opening to the public of the new park area of approximately 5,000 m². The cost of approximately €700,000 will be covered by BrianzAcque and the Lombardy Region.

The final project in the province of Monza Brianza pertains to the municipality of Boviso Masciago, which has a population of 8,245 (ISTAT, 2025). The '*Facciamo fiorire l'acqua*' (Let's make water bloom) project involves the retrofitting of 800 metres of Via Matteotti, entailing the establishment of small bioretention areas (over 50, with a cumulative surface area of 1850 m²). These areas are designed to collect rainwater and facilitate its gradual infiltration into the soil, thereby mitigating the risk of sewer overloading. The new green elements feature over 60 trees, 100 shrubs and 1700 m² of lawn. The intervention will entail the construction of a new cycle path, the reduction of the carriageway, and the imposition of a 30 km/h speed limit. The funding of over €1.3m was largely financed

by the Lombardy Region as part of the 'Lombardy Plan for Soil Protection and Mitigation of Hydrogeological Risks' project. This intervention is characterised by dual value, namely the improvement of rainwater management on site through the drainage of the sewage system. Conversely, the reduction in the speed limit, the construction of cycle tracks and the substantial increase in green areas have collectively enhanced the urban quality of the area, particularly regarding soft mobility and temperature reduction.

Gruppo CAP and the Metropolitan City of Milan

Gruppo CAP is the company that manages the integrated water service within the Metropolitan City of Milan (excluding the municipality of Milan). In a similar way to previous cases, in addition to the supply, sewerage and purification service, a series of actions aimed at improving urban water management have recently been launched. The first action was in 2018, when the 'Manual on good practices for the use of sustainable urban drainage systems' was published. The document is the result of a collaboration with the Department of Agricultural and Environmental Sciences of the University of Milan. The objective of the document is to identify innovative solutions that will mitigate flood runoff and reduce flood risk in the territory of the Metropolitan City of Milan. With regard to these solutions, the report describes their technical and economic characteristics, highlighting the importance of SuDS as an optimal solution.

The CAP Group launched the '*Milano Città Spugna*' (Milan Sponge City) project in 2021. The project entails the execution of 90 interventions across 32 municipalities. The total cost of the project is estimated to be approximately €50 million, with financing being provided through a call for tenders as part of the National Recovery and Resilience Plan. The CAP Group and the Metropolitan City of Milan submitted the application to the call for tenders 15 days after its publication. This is indicative of the company's and the territory's strategic approach to sustainable urban water management. The significant financial investment facilitates the implementation of interventions with the fundamental objectives of preventing flooding, combating soil erosion and the effects of climate change, decreasing the vulnerability of natural and socio-economic systems, and strengthening territorial resilience.

Due to the volume of data, several simplifications were implemented during the analysis of the 90 projects (table 1). Initially, projects were aggregated on a municipal basis. Consequently, traditional hydraulic engineering interventions, including storage tanks and reservoirs, were excluded from the study. The remaining interventions were classified into four categories: depaving, permeable pavement, renaturalisation, and bioretention system. However, many of the interventions can be attributed to more than one family. For instance, the intervention in Baranzate involves the renaturalisation of a brownfield site and the construction of a bioretention basin. The distinction between the initial two families - depaving and permeable pavement - is determined by the post-intervention use of the area. In the former, the removal of the pavement results in the exposure of the ground, while in the latter, the removal of the impermeable pavement is followed by the installation of a draining pavement. The bioretention family, on the other hand, encompasses all interventions, both large and small in scale, that are designed to conserve water over a period of time by means of slow release into the soil. Examples of such interventions include infiltrating and draining trenches, tree boxes and deep infiltration systems. For each intervention, the specific location (car park, park, square, street) was identified, along with the respective ownership and potential disconnection from the sewerage system.

The interventions have an average size of approximately 16,500 m2. The most compact intervention is in the municipality of San Vittore Olona and encompasses an area of 1,300 m2, incorporating drainage, paving, and infiltration wells within a brief road segment. The most extensive intervention, covering an area of 63,000 square metres within the municipality of Rho, encompasses a range of measures including the removal of paved surfaces and the disconnection of various roads and car parks from the sewerage system, all situated on municipal land. The two interventions illustrated here are also the least (260,000.00 €) and the most expensive (6,000,000.00 €). The ownership of the intervention areas is exclusively public. A total of 17 interventions have been identified, involving the disconnection of the rainwater collection system from the sewer system. The interventions on roads pertain to 10 municipalities and are predominantly focused on permeable pavements and bioretention areas. Those related to squares are 14, with interventions related to draining paving, depaving, and bioretention

areas. Parks were involved in seven municipalities through interventions involving all four families (depaving, permeable pavement, renaturation, and bioretention system). Finally, car parks were the subject of interventions in 17 municipalities, mainly through permeable pavement and bioretention systems.

Table 1: the classification of 'Milan Sponge City' projects

City	Sup. m2	Invest. (€)	Parking	Park	Square	Road	SuDS
Arluno	2.600	500,000	Yes	No	Yes	No	Permeable pavement
Assago	18.000	1,200,000	Yes	No	No	Yes	Bioretention system Permeable pavement
Baranzate	9.600	2,750,000	No	Yes	Yes	No	Renaturalization Bioretention system Permeable pavement
Bollate	24.300	1,500,000	No	No	Yes	Yes	Bioretention system Depaving
Bresso	3.400	375,000	Yes	No	No	No	Bioretention system Permeable pavement
Buscate	20.000	1,000,000	Yes	No	No	No	Bioretention system
Canegrate	13.800	925,000	Yes	No	No	No	Bioretention system Permeable pavement
Cesano Boscone	13.600	1,000,000	Yes	No	No	No	Bioretention system
Cesate	3.500	325,000	No	No	Yes	No	Bioretention system Depaving
Cinisello Balsamo	10.000	1,400,000	No	No	Yes	No	Bioretention system
Cologno Monzese	52.700	4,725,000	Yes	Yes	No	No	Bioretention system Permeable pavement Depaving
Cormano	13.800	1,425,000	No	Yes	No	No	Bioretention system
Cornaredo	5.400	1,500,000	No	No	Yes	No	Bioretention system Permeable pavement Depaving
Corsico	7.800	975,000	Yes	No	No	No	Permeable pavement
Garbagnate Milanese	30.700	1,800,000	Yes	Yes	No	No	Bioretention system Permeable pavement
Legnano	42.800	2,590,000	Yes	No	Yes	No	Permeable pavement Depaving
Marcallo con Casone	7.200	525,000	No	No	No	Yes	Bioretention system
Melegnano	3.900	450,000	No	No	Yes	No	Bioretention system
Opera	29.800	3,100,000	No	No	Yes	Yes	Bioretention system

Discussion

The present study set out with the objective of investigating the methods by which Italian IWS companies may promote public space initiatives that enhance climate change resilience and environmental sustainability, with a particular focus on soil desealing processes. The analysis was conducted through a systematic process, beginning with the classification of interventions, followed by the identification of enabling regional and local policies, and culminating in the evaluation of project effectiveness, equity, and scalability. The findings from the three case studies – MM S.p.A., Gruppo CAP, and BrianzAcque – operating within the highly urbanized Lombardy Region, demonstrate a strategic shift in the core business of these IWSCs towards sustainable urban water management and the active promotion of NbS and SuDS. The case studies reveal a clear typology of interventions, predominantly focused on depaving, permeable pavement, renaturalization, and bioretention systems.

The success and proliferation of such projects is facilitated by the presence of supportive regional and local policies. The Lombardy Region's adoption of the hydraulic invariance principle (R.R. 7/2017) represents a significant regulatory framework, mandating that stormwater runoff from urbanized areas must not exceed

pre-urbanization volumes. This regional mandate exerts a direct influence on the operational context of IWSCs, thereby encouraging the implementation of SuDS. The elevated land consumption of the target OTAs, attributable to the substantial urbanisation of Lombardy, can also be regarded as a catalyst for the initiation of sustainable urban drainage processes. Furthermore, the financing secured through national recovery and resilience plans, as evidenced by Gruppo CAP's 50 million € '*Milano Città Spugna*' project, underscores the importance of governmental support and investment in scaling these initiatives. The collaborative funding models, involving IWS companies, municipalities, and regional governments (e.g., BrianzAcque's projects), also demonstrate a shared commitment to addressing climate change impacts.

In terms of effectiveness, the projects demonstrate clear potential for mitigating the impacts of climate change. The interventions have been shown to directly address the overloading of sewage systems and the disruption of the water cycle, which is exacerbated by soil sealing. This is achieved by increasing infiltration and reducing runoff. The enhanced green spaces contribute to urban well-being and, in theory, to temperature reduction, though further investigation is sometimes needed to ascertain significant thermal effects. The emphasis on disconnecting rainwater collection systems from sewers in many of Gruppo CAP's projects highlights a direct and effective strategy for improving urban water management.

Regarding the principles of equity and scalability, the extensive implementation of these interventions across multiple municipalities, as exemplified by Gruppo CAP's '*Milano Città Spugna*' project encompassing 32 municipalities, signifies a considerable degree of scalability. The public ownership of intervention areas across all the projects analysed suggests a potential for equitable access to these enhanced public spaces and their benefits. However, a more in-depth examination of the socio-economic status of the neighbourhoods where the interventions take place, alongside monitoring of any gentrification resulting from these interventions, and the active involvement of the community in the project, would be appropriate. A further key consideration is the investigation of citizens' perceptions of the interventions, in terms of tangible improvements in quality of life, increased access to green areas, and reduced flood risk. The identification of only three IWSCs actively involved in soil desealing, all within Lombardy, suggests a geographical disparity in the adoption of such practices across Italy. While Lombardy's high soil consumption rate and pioneering regional regulation make it a natural leader, the region's limited geographical spread indicates a need for broader adoption and policy frameworks in other regions.

The strategic shift evidenced in these IWSCs signifies an awareness of their expanded role that extends beyond conventional water services. By proactively advocating for soil desealing and SuDS, these companies are transitioning towards a more comprehensive approach to urban water management, incorporating ecological and social benefits into their operations. This proactive engagement has the potential to establish IWS Companies as pivotal actors in the fields of urban climate resilience and sustainability. By shifting beyond the mere management of existing infrastructure, they are able to proactively influence and shape the urban environment.

Conclusions

The adverse impacts of climate change, particularly the disruption of the hydrological cycle, in combination with an increased consumption of soil, necessitate innovative urban management strategies. This paper has demonstrated the emerging role of Italian IWSCs as crucial promoters of soil desealing processes and Nature-based Solutions (NbS) within public spaces, thereby enhancing urban resilience and environmental sustainability. The case studies of MM S.p.A., Gruppo CAP, and BrianzAcque in Lombardy illustrate a significant and positive strategic shift in IWSCs operations. These companies are now proactively implementing a range of SuDS interventions, including depaving, permeable pavements, renaturalization, and bioretention systems. These offer multifaceted benefits beyond just urban drainage, such as improved urban biodiversity, temperature regulation, and enhanced public spaces. The success and expansion of these initiatives is strongly supported by regional policies that facilitate them, such as Lombardy's principle of hydraulic invariance, and substantial national funding mechanisms, such as the National Recovery and Resilience Plan. While the examples from Lombardy

demonstrate a promising model for addressing soil sealing and its consequences, the limited geographical spread of such proactive IWSCs across Italy highlights a significant opportunity for broader policy adoption and implementation nationwide.

In conclusion, Italian IWSCs possess the potential to be pivotal drivers in transforming urban areas into more resilient and sustainable environments. The evolution of their role, from that of service providers to that of active promoters of green infrastructure, is imperative in order to mitigate the effects of climate change, foster healthier urban ecosystems, and improve the quality of public life. Future efforts should focus on replicating these successful models across other regions in Italy and strengthening policy frameworks to encourage a widespread integration of soil desealing and NbS into urban planning and water management strategies.

Public Space as Social Infrastructure for Urban Wellbeing: Transformation and resistance in Protomagias Square, Athens under persistent austerity

Vasiliki Fragkaki
Department of Architecture, Roma Tre University
vasiliki.fragkaki@uniroma3.it

Abstract
Under ongoing multiple-crises conditions, urban transformation threatens public open spaces in Athens, Greece, with commodification, supported by persistent 'austerity urbanism' (Peck, 2012) reflecting broader patterns of uneven geographical development. This paper analyses socio-spatial dynamics in Protomagias Square at Pedion tou Areos park, examining how these interconnected spaces emerged as pivotal sites for contesting socio-spatial inequalities. The study focuses on the square's transformation since 2023, when Attiko Metro S.A. unexpectedly fenced off one-third of the public space for metro construction, storage, and office facilities, shrinking already scarce public space and constraining social life of inhabitants. Through qualitative analysis, the research demonstrates how grassroots resistance creates possibilities for democratic city-making approaches. Findings reveal how public space enclosure represents institutionalised violence against urban commons, while community mobilisation asserts alternative values prioritising care over profit and collective wellbeing over private accumulation.

Keywords: public space, spatial justice, care infrastructure, urban wellbeing

1. Introduction

Southern European cities have been severely impacted by economic austerity, climate-related events, migration flows, and socio-sanitary damages during the COVID-19 pandemic. In this multiple-crises context, public open spaces in Athens become sites of transformation and resistance under ongoing commodification, supported by persistent 'austerity urbanism' (Peck, 2012) reflecting broader patterns of uneven geographical development (Brenner et al., 2010). Since 2010, privatisation and deregulation of planning processes (Gemenetzi, 2021) have impacted public spaces whilst simultaneously catalysing forms of civic engagement and collective action for social inclusion, environmental and spatial justice.

The multiple crises affecting urban communities have created deeper discrimination and inequalities in cities. Neither state nor market policies offer solutions; indeed, substantial scholarship argues these institutions are responsible for generating such inequalities (De Angelis & Harvey, 2014). Due to this accumulation of social, economic, cultural and political crises, the concept of commons and commoning has regained wide acceptance, often incorporated ambivalently within administrative and institutional discourse. De Angelis and Harvey (2014) argue that "in general terms, the commons are social systems in which resources are shared by a community of users/producers, who also define the modes of use and production, distribution and circulation of these resources through democratic and horizontal forms of governance." However, they emphasise that these commons "exist and are produced vis-à-vis a social force, capital, that often demands their cooptation, if not enclosure."

The struggle over Protomagias Square crystallises fundamental contradictions between neoliberal urban governance and collective rights to the city. This public space, situated between Pedion tou Areos park and the former Evelpidon Military Academy complex, has become emblematic of broader processes of urban commodification operating through seemingly progressive cultural programming. Local citizens' initiatives and grassroots organised groups expose the insidious commodification and privatisation dynamics transforming the park, denouncing how private energy corporations and philanthropic foundations appropriate public spaces to advance their "sanitised" vision of urban culture whilst systematically denying permits and support to autonomous citizen-organised cultural proposals.

During crisis conditions, Protomagias Square was profoundly appropriated and transformed by users into a site of collective care, political organisation, and social reproduction essential for community survival. Since 2000, each crisis period—Olympic preparation, austerity-driven renovation, migration management, and pandemic

response—has been mobilised to advance spatial control whilst community resistance has consistently emerged to defend collective use and autonomous organisation.

The case study focuses on the latest transformation since 2023, when almost one-third of the public square was unexpectedly fenced off by Attiko Metro S.A. for construction of the new "Dikastiria" metro station (Line 4), as well as for storage and office space, further shrinking already scarce public space and disabling social life, particularly of disadvantaged inhabitants. This enclosure represents more than technical planning decisions; it constitutes "institutionalised spatial violence"—the systematic appropriation of public space undermining collective well-being whilst serving private and state interests through familiar patterns of crisis-driven privatisation.

This paper demonstrates how the defence of Protomagias Square by the local citizens' initiative '*Εμείς στο Πεδίον του Άρεως*' (We at Pedion tou Areos) represents concrete assertion of the right to the city, challenging dominant planning rationalities whilst prefiguring alternative forms of urban governance based on care, solidarity, and collective self-management. Drawing on theories of socio-spatial justice (Soja, 2010) and biopolitics (Foucault, 1978), the study contributes to understanding how public spaces shape and are shaped by daily negotiations of transformative urban changes under restrictive conditions despite facing what Madden (2022) terms "systemically induced fatigue."

2. Theoretical Framework: public space, care, and urban commons

The theoretical foundation for analysing Protomagias Square builds a coherent argument through four interconnected analytical layers: first, understanding public space as commons through commoning practices; second, examining care as both practice and infrastructure essential for urban life; third, analysing spatial justice and the right to the city as frameworks for understanding urban struggles; and fourth, contextualising contemporary enclosures within broader patterns of capitalist accumulation. This integrated approach demonstrates how public spaces function as essential infrastructure for collective life whilst revealing their vulnerability to appropriation under neoliberal urban governance.

2.1. From public space to commons: commoning as collective practice

Rather than accepting the traditional public-private binary, this study follows Harvey's (2012) insight that commons are defined by relationships where "the social group and that aspect of the environment being treated as a common shall be both collective and non-commodified." This understanding moves beyond legal ownership categories to focus on social relations and practices. Urban space and public space are shaped by social relations as products of human activity, constructing spaces for social, economic and cultural activity whilst simultaneously shaping social relations through embodied space. Harvey (2014) points out that to think of an alternative form of urbanization, it is necessary to build possibilities for an anti-capitalist turn, through recognizing the common and its potency and by starting from a convergence between the microcosm of the body and the macro space of globalization, both as arenas of enactment of the capitalist neoliberal model of production and reproduction

Stavrides (2020) advances this conceptualisation by defining commoning not simply as space-sharing but as "a set of inventive practices and imaginaries that explore the emancipatory potentialities of sharing." These practices create "life in common" through three interconnected dimensions: projective practices pointing toward possible futures, expressive practices articulating shared values, and exemplary practices demonstrating alternative social relations exceeding dominant sociality models.

2.2. Care as infrastructure and political practice

Building on this commons foundation, the analysis incorporates feminist care theory to understand how collective reproduction occurs through spatial practices. The Care Collective's (2020) definition of care as "any labour directed at maintaining or enhancing another's freedom" establishes care as fundamentally political rather than merely personal or domestic, encompassing "social capacity and activity involving the nurturing of all that is necessary for the welfare and flourishing of life."

Feminist scholars including Silvia Federici (2012), Nancy Fraser (2016), Donna Haraway (2016), and Joan Tronto (2017) reveal how capitalism systematically appropriates and commodifies care work whilst rendering it invisible. Fraser's (2016) analysis of capitalism's "crisis of care" demonstrates how social reproduction becomes a site of struggle, whilst Federici's (2012) examination of primitive accumulation shows how commons enclosure specifically targets spaces and practices of collective reproduction.

Berlant's (2016) concept of "affective infrastructure" bridges care theory and spatial analysis by revealing how spaces become "formative of collective life through their material and relational capacities." This framework illuminates "threshold spaces" and "contact points"—intermediate scales of intimacy and encounter enabling experimentation with embodied urban sociality based on care rather than commodity relations.

2.3. Spatial justice and the right to the city

The third theoretical layer establishes spatial justice as the lens through which urban struggles can be understood. Lefebvre's (2016) conceptualisation of the right to the city encompasses both access to urban space and participation in its production, establishing spatial rights as fundamentally democratic. Harvey's (2008) interpretation emphasises this right extends "far more than individual liberty to access urban resources: it is a right to change ourselves by changing the city" through collective political action.

Marcuse's (2009) critical urban theory reveals the right to the city as simultaneously "a cry and a demand"—addressing both immediate material deprivation and broader aspirations for human development. This definition connects survival needs with transformative politics, providing analytical tools for understanding how different groups mobilise spatial issues. Hence, the 'right to the city' assumes a role of resistance to neoliberal urbanism and a transformative potential toward alternative paradigms of production and reproduction of urban space.

Stavrides (2023) advances this framework by arguing that "to reclaim the right to the city means to reclaim the city as a common good, that is, to reclaim the emancipatory power of collective creativity." This understanding positions common space as both domain of urban commoning and formative factor—performed rather than permanently established, existing through sustained commoning practices.

2.4. Enclosures and contemporary capitalist accumulation

The final theoretical layer contextualises contemporary urban enclosures within broader patterns of capitalist accumulation. Drawing on Marx's understanding of primitive accumulation as ongoing rather than historically bounded, Harvey's (2005) concept of "accumulation by dispossession" reveals how "wholly new mechanisms of dispossession" operate through privatisation, commodification, financialisation, and asset manipulation in contemporary contexts.

Christophers's (2018) analysis of land privatisation processes illuminates systematic patterns of disinvestment, devaluation, and eventual private transfer—processes understood as "institutionalised spatial violence" particularly affecting marginalised communities dependent on public infrastructure. Peck's (2012) analysis of "austerity urbanism" reveals how fiscal constraints justify dismantling public services through deliberate disinvestment creating conditions subsequently used to justify privatisation.

In the Greek context, Gemenetzi's (2021) identification of systematic privatisation and planning deregulation since 2010 exemplifies what Klein (2007) terms "disaster capitalism"—exploiting crisis conditions to advance neoliberal reforms that would otherwise face political resistance.

Interpreting Protomagias Square as relational space enables understanding of socio-spatial practices of care, its material and immaterial importance for urban dwellers, especially the most vulnerable, whilst revealing how capitalism extracts value from everyday life through commodification and reconfiguration of social reproduction and its spatial expressions (Fraser, 2022).

3. The Transformation of Protomagias Square: from marginalization to care infrastructure

3.1 Historical context and crisis-driven transformation

Protomagias Square was constructed in the 1980s following urban redevelopment that moved Moustoxidi street underground, creating pedestrian space between Pedion tou Areos park and the former military complex. Prior to the COVID-19 pandemic, the square was primarily used by marginalised communities—migrants, youth, and local residents—for informal activities reflecting broader dynamics of urban marginalisation, where public spaces in central Athens were either heavily commercialised or relegated to use by excluded populations.

The historical trajectory of Pedion tou Areos park reveals systematic patterns of crisis-driven transformation illuminating broader processes of neoliberal urban governance and community resistance. The 2000-2003 period marked a critical turning point when the park became subject to an "urban renewal program" developed for the 2004 Olympic Games, initiating the first phase of systematic enclosure and control. This intervention included installation of barriers, tree cutting, spatial division into four sections, and reduction of entrances from sixteen to four—changes that provoked massive resistance and broad community opposition extending beyond immediate neighbourhood residents.

The 2008-2010 renovation, financed through 10 million euros of European and Greek public funds, represented a second phase of "sanitisation," transforming the park into a liminal space that was "no longer an open space, but not a private space either"—making the park progressively less accessible through gradual exclusion rather than immediate privatisation. The 2013 "cleansing operations" during right-wing and conservative administration exemplified how crisis discourse enables spatial violence, as authorities relocated marginalised populations to Pedion tou Areos under the banner of creating a "clean Athens," effectively using the park as a site of invisibilisation.

However, the 2015 refugee crisis revealed the park's capacity to function as essential infrastructure for collective solidarity when immigrants arriving from Aegean islands established spontaneous encampments in the absence of emergency housing solutions. This period generated positive community mobilisation despite precarious conditions, as local solidarity networks emerged alongside organised security against fascist attacks. The spatial centrality was crucial: "*many local people who were not aware of the situation of the exiles started to get involved" precisely because marginalised populations were too visible in a space located in the centre of Athens.*" (Anna, local resident, 2025)

During that year and the next one, Plateia Protomagias, became an affective space, where local inhabitants established relationships with immigrants and among them, appropriating the public space for solidarity and sharing everyday life, stories, material and immaterial elements. The processes of appropriation of that public space, among others, is understood as a process of creating spaces and conditions for life-sustaining, imagining and materialising everyday care infrastructures.

The 2018 banning of the annual autonomous and sel-organised Indie Free Festival, which had operated for thirty years without official permission, alongside the deployment of "philanthrocapitalism" (Richen and Lola, 2022) with the arrival of Onassis cultural foundation programming, intervening in the Pedion tou Areos Park by using the spaces for artistic installations, represents the most recent phase of transformation where direct state repression combines with cultural programming to neutralise autonomous organising whilst maintaining the appearance of progressive public programming.

3.2 Spatial configuration and zones of activity

Based on field observation, the square's spatial configuration enables diverse simultaneous uses through four distinct but interconnected zones facilitating different forms of collective activity and care:

The Central Open Plaza constitutes the largest area, featuring wide concrete paving appropriated for various sporting activities. This space has been regularly used by South Asian migrant communities for cricket matches,

representing cultural territorialisation that challenges dominant uses of urban space whilst creating visible presence of multicultural community life. The same area accommodates football games by local youth, children's cycling, and gatherings during political events or cultural celebrations.

The Elevated Northern Terrace sits at a higher level adjacent to the Hellenic National Defence College, accessible by wide concrete steps functioning as informal theatre seating. This elevated position provides overview of the entire square whilst creating natural gathering space for larger assemblies, political meetings, and cultural events, accommodating both formal presentations and informal socialising. Moreover, the stairs and ramps that create the various levels of the space are extensively used by youngsters for parkur.

The Platanus Grove features several old platanus trees surrounded by built-in concrete benches that have become the focal point for (mainly) Albanian migrant community's and elder peoples' daily social life. This area has been enhanced through community personal contribution in moveable furniture—plastic and wooden chairs and small tables stored nearby or left there and assembled daily to create flexible seating arrangements for domino games, meals, and extended conversations. Depending on the time, this area is used by different people, including also younger groups usually in the evening. The trees provide essential shade whilst creating a semi-defined area and distinct ambience that facilitates intimate social interaction.

The Southeastern Amphitheatre consists of a small concrete structure with tiered seating, as well as an elevated terrace connected to the amphitheatre, serving multiple functions including casual gatherings, celebrations, and political assemblies. This feature has become particularly important for grassroots political organisations seeking unmediated spaces for collective action, with architectural form enabling both speakers to address audiences and participants to engage in horizontal discussion. This space is highly used by all city dwellers, frequenting the square, especially appropriated by socio-cultural groups organizing various open and free-access events of public interest.

The "corners" along the fenced area separating the playground with the square, there is a corridor with a slightly elevated concrete wall, where informal vendor was demonstrating his products for sale. On the other side as well, right next to the southern entrance from Pedion tou Areos to Protomagias Square, there is another informal vendor, taking advantage of the spatial configuration and creating a "vendor's vitrine" to show his goods.

3.3 Public space as affective infrastructure

After the experience of 2015, Protomagias Square became once again an important point of reference for the local vulnerable and oppressed dwellers. The COVID-19 pandemic fundamentally altered the square's social dynamics when Greece imposed strict lockdown measures in March 2020, including closure of commercial socio-cultural activities and temporary restriction of access to Pedion tou Areos park. Protomagias Square emerged as one of the few remaining accessible public spaces in densely built central Athens, creating conditions for socio-spatial transformation.

The square began accommodating diverse populations across age, cultural, and class lines. Physical activities—soccer, cricket, boxing, walking, running—occupied major portions of the square, whilst social gatherings, discussions, spontaneous concerts, and political assemblies created what residents describe as "collective everyday togetherness." (Anna, local resident, 2025)

Diverse everyday practices transformed the square into infrastructure for collective care and political organisation encompassing multiple interconnected dimensions: **embodied care** through collective physical activity, such as play, parkur and dancing, essential for maintaining mental and physical health; **social care** through regular gathering patterns enabling residents to maintain connections across cultural differences; **material care** through community maintenance of shared spaces and furniture; **cultural care** facilitating intercultural encounters, music events and knowledge exchange; and **political care** encompassing assemblies and solidarity events addressing local and broader social justice issues.

4. Enclosure as institutionalised spatial violence

4.1 The mechanics of patial appropriation

Due to construction works for the new Line 4 extension of Athens Metro, "Dikastiria" Station (Government Gazette D'306/2021), part of public space in front of the Evelpidon building was occupied by Attiko Metro S.A. since 2021 as temporary construction site. The project was undertaken by the AVAX-GHELLA-ALSTOM consortium, to which 8,880 sq.m. of public "free space" where offered, whilst the contracting authority is Attiko Metro S.A., a private law legal entity established under Law 1955/1991 as a public limited company.

Figure 1. *Initial fencing of Plateia Protomagias, source: Official facebook page of the citizens' initiative, published 17 June 2023*

Since May 2023 the consortium has been trying to start the enclosure of the public space, serving for the contruction site without previous notice (Figure 1). On December 21, 2023, residents were confronted with sudden fencing of the square's largest section using concrete bases and temporary plastic mesh. As the citizens' initiative '*Εμείς στο Πεδίον του Άρεως*' (We at Pedion tou Areos) declares "HELLENIC METRO, without any public consultation and with the support of the police, proceeded to fence off the square." The enclosure relates to occupation of spaces in Protomagias Square by Attiko Metro S.A. for installation of offices, car parking and material storage spaces serving company needs. The projected duration coincides with final completion of the project, with current announced projections estimating line delivery in 2029-2030, although member of the local citizens initiative, as well as an engineer working in public infrastructures sector in Athens doubt it "considering the delays and rhythm of construction site this is quite improbable". Although the legal owner of Protomagias Square is the Municipality of Athens, its management falls under the Directorate of Parks and Groves of the Attica Region. However, Regional services were not informed about construction work commencement and fence installation, evident from their allocation of space for summer 2023 events during which Attiko Metro S.A. planned to install permanent sheet metal fencing.

As the D'306/2021 indicates the spaces to be occupied temporarily by the company to serve the construction site are the following (the topographic plan -Figure 2- is part of the official document published by the Government Gazette):

• area 1-2-3-4-1 (total area = 315 sq.m.) on Evelpidon street and Manica street intersection
• area 5-6-7-8-9-10-11-11'-17-18-19-20-21-22-23-24-5 (total area = 5.190 sq.m.) located on the intersection of Evelpidon street and Moustoksidi street
• area 11-12-13-14-15-16-17-11'-11 (total area = 3.375 sq.m.) located on the intersection of Evelpidon street and Moustoksidi street

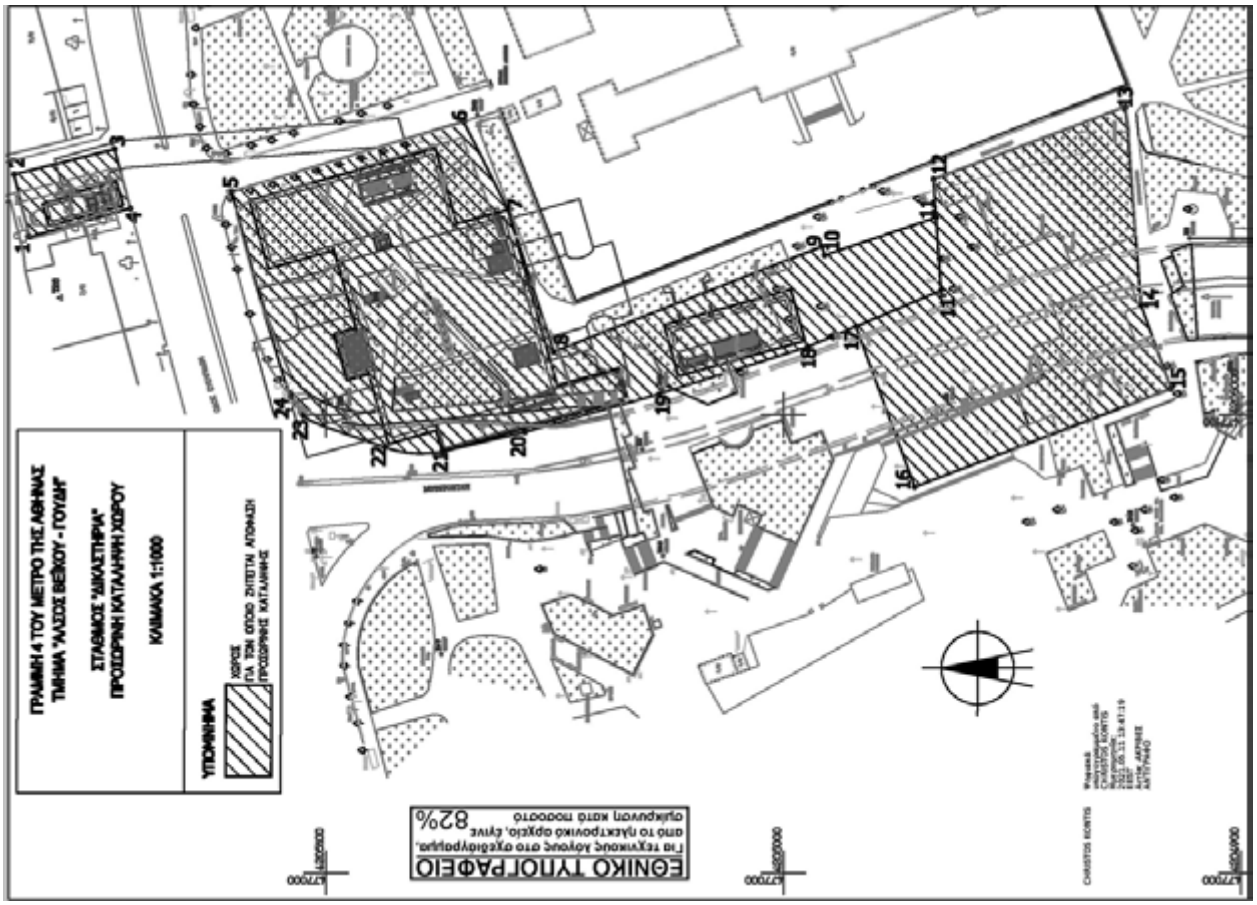

Figure 2. *Official topographic plan indicating temporary occupation for the construction site of Metro Station "Dikastiria", source: ΦΕΚ Δ' 306/01.06.2021, gov.gr*

As the initiative announces (03/04/2024), all these activities are not directly related to the construction works (excavations, etc.) of the specific metro station, they pertain to the general logistical support area for the company instead, including extensive office spaces that could have been housed in any of the many vacant office buildings in the area and beyond. The same issue for the parking, as there is an existing underground parking, serving the Court. This is evidenced by the fact that the fenced-off space is set to remain for the entire duration of the construction project, not only for the period during which works take place at the Dikastiria station. Furthermore, the contract allows for an extension of the fencing period (upon request) in case the project timeline is extended. In Figure 3 the uses in the extended enclosure are indicated: A. rebar processing area, or "ironworks", is one of the heaviest uses planned for the site. B. provision of 8 parking spaces for conventional cars, C. This passage occupies over 200 sq.m. within the fenced area of the square. However, it will not be used permanently for construction purposes; instead, it will remain vacant, merely to be opened once or twice a year to allow military vehicles to pass or park, D. offices of the contractor company 30X8m., E. storage area for materials and equipment.

The initial Environmental Impact Assessment Report provided for the occupation of more than 4,000 sq.m. beyond the original fenced area, including a section of the courtyard of the National Defense School Evelpidon, which is located above the square. After the army's reaction, that section was quickly released, and thus the Government Gazette (ΦΕΚ) for the occupation specified 3.300 sq.m. Following the mobilisations of the citizens another 1.300 sq.m. was freed, reducing the total to about 2.000 sq.m. "In each of these phases, HELLENIC METRO presented the area it intended to occupy as absolutely necessary." (initiative '*Εμείς στο Πεδίον του Άρεως*', 2024)

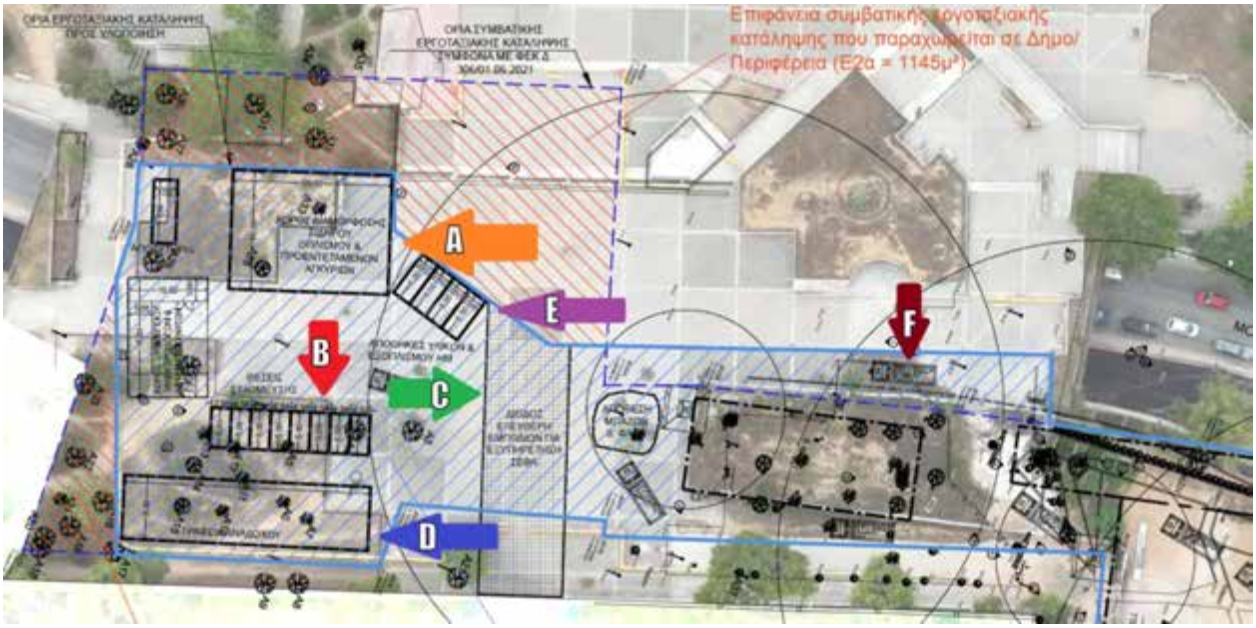

Figure 3. *Uses in the construction site, source: Environmental Impact Assessment Report, official page 'Εμείς στο Πεδίον του Άρεως', author's elaboration*

Document analysis reveals significant discrepancies between legally authorised construction areas specified in Government Gazette D'306/2021 and actual space appropriation. As published by the group '*Εμείς στο Πεδίον του Άρεως*' (2023), the plan (Figure 4) confirms the contractor consortium exceeded legal limits of enclosed area (indicated area with orange line), appropriating vital square portions, "fenced off with unaesthetic and particularly psychologically aggressive metal sheets", for non-essential uses including private vehicle parking despite available underground facilities, material storage accommodatable elsewhere, and temporaryoffice space serving corporate convenience rather than construction necessity.

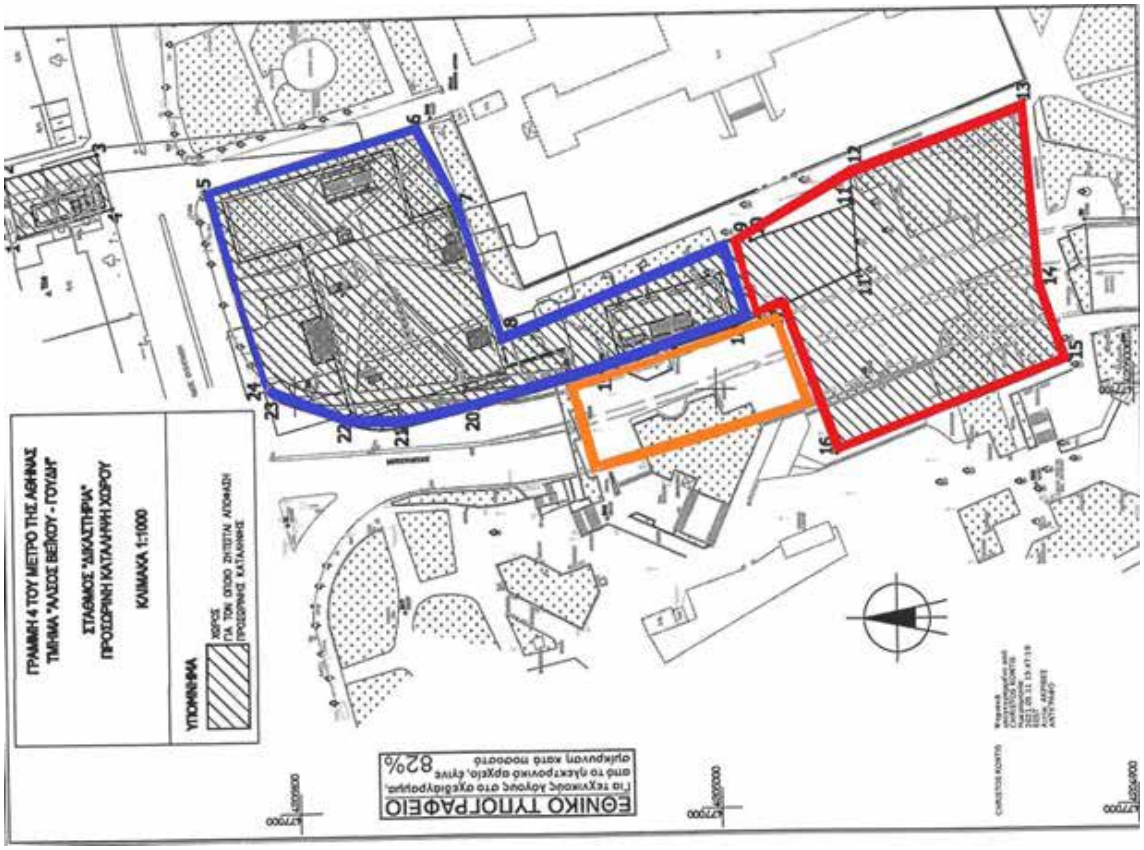

Figure 4. *Topographic plan elaborated by the citizens' initiative, showing in blue the initial construction site (since 2021), in red line the area designated in the Government Gazette (ΦΕΚ), in orange line the non-authorised enclosure established on May 2023*

Furthermore, personal field observation (Figure 5) and measurements on May 24 and 25, 2025, of the site, after the partial removal of the fence from the unauthorised enclosed area, reveal that several minor adjustments to the localization of the fence have been deployed, and the public space remaining inaccessible complies with the normative. Moreover, it is interesting to notice that if comparing the submitted plans of the architectural project, which won the public competition (second prize, by "Tense architecture network" studio) for the metro station "Dikastiria", the area of the station and the respective second entrance are limited to the plots 1-2-3-4-1 and 5-6-7-8- 20-21-22-23-24-5, which do not include the spaces of Protomagias Square.

The above process of public space appropriation illustrates how public-private partnerships enable space appropriation whilst diffusing accountability across multiple institutions, exemplifying Harvey's (2005) concept of "accumulation by dispossession" where public resources transfer to private actors through administrative mechanisms appearing as neutral technical decisions.

4.2 Legal violations and democratic exclusion

The appropriation process reveals fundamental problems in planning procedures enabling space appropriation whilst excluding community participation, representing democratic deficit by design. The selective enforcement of regulations—strict control over community uses whilst permitting corporate appropriation of public space for private parking and offices for Attiko Metro S.A. —reveals the class character of urban governance under neoliberalism. The same authorities that prohibit informal economic activities and regulate community gatherings permit systematic appropriation of public space for private commercial convenience without legal challenge or public justification.

4.3 Destabilising care networks and social infrastructure

The enclosure (even temporary) disrupted "care infrastructure"—spatial arrangements and social networks enabling collective wellbeing and mutual support during the pandemic and beyond. This destruction operated through multiple interconnected mechanisms revealing the inherently violent character of neoliberal space appropriation. The enclosure process, fencing off more public space than the legal and necessary, reveals how spatial control operates as a mechanism for broader social and political exclusion, reinforcing the democratic deficit of the local authorities and the uncaring attitude towards a common good, such as public space. The most affected urban dwellers—migrants engaging in cultural practices, political activists organizing assemblies, families using children's play areas, elders—represent populations whose presence challenges dominant narratives about appropriate uses and urban decorum (order and aesthetic) of central urban space, while their displacement "sanitises" public space for consumption by more privileged populations.

The elimination of cultural spaces displaced practices essential for community identity and social reproduction. The cricket field used by South Asian migrants was eliminated, disrupting cultural practices that had created belonging and provided visible representation of multicultural community life. Reduced open space for children's activities eliminated essential infrastructure for family life, whilst partial enclosure of the Platanus Grove disrupted access to maintained shared furniture and forced relocation of daily social activities.

The extensive fencing created blind-spots and uncomfortable spatial conditions particularly affecting women's safety through creation of narrow, dark, isolated passages between construction barriers and surrounding fencing. As residents report: "The narrow passage between the construction site fencing and the perimeter wall of the National Defence School forms a dark area with no visibility, in an urban area where attacks on women and LGBTQ+ individuals have increased." (initiative '*Εμείς στο Πεδίον του Άρεως*', 2024)

5. Resistance and democratic alternatives

5.1 Citizens' initiative organisation and democratic practice

The response to spatial appropriation by the citizens' initiative '*Εμείς στο Πεδίον του Άρεως*', along with the official and practical support of local associations, such as the Union of Secondary Education Teachers and the Association of Graduate Architects from Higher Education Institutions, demonstrates how communities can mobilise to defend spaces of historical and socio-political significance whilst asserting alternative models of democratic governance based on care, solidarity, and collective participation.

Emerging from longstanding community networks organised around park care and public space defence, the citizens' initiative represents continuity with earlier resistance to privatisation attempts whilst developing new strategies appropriate to current conditions of crisis and state retrenchment. The initiative's organisational structure reflects principles of horizontal democracy and inclusive participation, with regular assemblies held in remaining accessible areas and decision-making processes prioritising consensus over majority rule.

Membership encompasses diverse constituencies including long-term residents, recent migrants, parents with children, elderly users, political activists, and university students, reflecting the square's role as space of encounter across social and cultural differences. Actual participation of users from different backgrounds — especially those more precarious— in a horizontal process, enables intersectionality and shows how defence of public space can tighten social relations and create solidarity across difference whilst challenging dominant models of political organisation.

5.2 Strategies of resistance and rights assertion

The initiative employed multiple interconnected strategies and alternative practices to assert rights meaningful to the community, even when these conflicted with dominant legal interpretations. Their persistent presence and reaction in public space, although tiring, proved to be an effective form of action. By engaging with representatives of local authorities and the regional administration, the citizens' initiative succeeded in validating community claims regarding procedural violations and established important precedents for protecting public space from

arbitrary appropriation. Direct action and physical re-appropriation compelled the contractor consortium to reduce the originally planned fencing by 1,000 square metres, demonstrating the effectiveness of organised resistance in influencing state-corporate decisions. Public education and solidarity-building efforts further exposed the illegality of appropriation while connecting local struggles to broader issues of spatial justice and democratic participation.

Moreover, beyond the attempts to approach local and regional responsible authorities, social mobilisation, by the citizens' initiative '*Εμείς στο Πεδίον του Άρεως*', since the enclosure of the Plateia Protomagias space, was actively organised through various activities and events, informing public opinion, disseminating, reclaiming and reappropriating the right to public space. The frequent occupation of the public space with bodies, politically and socially aligned (Butler, 2018) remains the most powerful act of creating new relational space, caring for and with others for our common goods and demonstrating alternative ways of conviviality, more just and humane.

5.3 Towards alternative urban governance

Regarding the most vulnerable social groups, universal rights such as health, accessibility to water, food and adequate housing, education, an economic activity and participation to the local community life are basic aspects that should be fulfilled through an effective "local governance" (ONU, 2000), based on the decentralization of the administration and the active involvement of the people in the definition and realization of programs of socio-sanitary and financial support. While Athens has seen some efforts to improve local governance, including reforms like the Callicrates program, it still faces challenges related to centralism and the need for greater citizen participation. As Karvounis (2021) identifies "of the most important problem is the democratic deficit of the first level of local governance system" which remains highly centralised – especially after 2019 – in contrast to international trends towards more participatory and accountable local institutions.

The citizens' initiative's response demonstrates concrete alternatives to technocratic planning based on community participation, collective care, and democratic decision-making. Rather than simply opposing inappropriate development, the initiative actively demonstrates alternative approaches to space governance prioritising use value over exchange value and collective wellbeing over private profit.

These practices prefigure what Friedmann (1987) terms "radical planning" that challenges professional expertise with community knowledge whilst asserting collective rights to participate in urban development decisions. The initiative's organisational practices—horizontal decision-making, inclusive participation, consensus-building across difference—demonstrate democratic alternatives to both market mechanisms and bureaucratic hierarchy whilst suggesting possibilities for broader transformation of urban governance.

6. Conclusion: public space, care, and urban transformation

The struggle over Protomagias Square reveals public space as a critical site where fundamental questions of urban governance, social justice, and collective wellbeing are contested. The square's transformation during the immigration crisis and even more during the pandemic into essential social infrastructure demonstrates public space's capacity to function as "affective infrastructure" enabling collective navigation of crisis whilst maintaining social solidarity and political engagement across difference.

The subsequent enclosure by state authorities and private contractors represents systematic appropriation of resources essential for collective reproduction in service of private profit and administrative convenience. This appropriation operates through patterns of disinvestment, devaluation, and privatisation characteristic of austerity urbanism whilst revealing the fundamentally exclusionary character of neoliberal urban development prioritising exchange value over use value and private accumulation over collective wellbeing.

However, organised resistance by the citizens' initiative demonstrates collective capacity to challenge space appropriation whilst asserting alternative approaches to urban governance based on care, solidarity, and democratic participation. Through legal mobilisation, direct action, public education, and alternative

programming, the initiative exemplifies concrete practices of spatial justice asserting collective rights to urban space and its democratic governance whilst prefiguring possibilities for more just and collective, community-based approaches to city-making.

The case reveals how struggles over public space can illuminate and challenge broader patterns of urban inequality whilst creating possibilities for transformation based on alternative values, such as care over profit and a strong sense of conviviality. The right to the city becomes manifest through collective practices asserting these values whilst demonstrating concrete alternatives to dominant urban governance through everyday practices of care, solidarity, and democratic organisation.

The transformation of Protomagias Square during the pandemic demonstrates how public spaces can serve as essential infrastructure for collective reproduction, particularly for communities lacking adequate private space or excluded from commercialised venues. The practices of care that emerged—from informal childcare and elder support to cultural expression and political organising—demonstrate how public space can support "interdependent" rather than individualised approaches to urban life (The Care Collective, 2020).

As cities worldwide confront multiple intersecting crises, the defence of public space becomes essential for building more just and sustainable urban futures. The lessons from Protomagias Square suggest that grassroots mobilisations around spatial justice can serve as laboratories for developing alternative approaches to urban governance that centre collective care and democratic participation whilst challenging the systematic commodification of urban life under neoliberal capitalism. Such experiments in spatial democracy offer crucial insights for building urban futures based on collective wellbeing rather than private accumulation, care rather than competition, and democratic participation rather than centralised technocratic control.

Exclusion of the vulnerable from public space in the shadow of urban transformation: the case of sex workers in Istanbul's Pera

Abstract
This study examines the socio-spatial exclusion of sex workers in urban public spaces. It employs a multi-scale analysis of global frameworks and a local case study of Istanbul's Pera quarter. Building on contemporary thinkers' urban democracy and justice theories, the study reveals how urban spaces are frequently governed by majority- and authority-driven norms that marginalise vulnerable groups. Despite the global scale of the sex industry, social stigma and limited regulation perpetuate the spatial exclusion of sex workers. Using a four-step methodology ranging from international policy analysis to site-specific mapping, the study uncovers the impact of urban transformation on the displacement of sex workers in Pera. It argues for inclusive urban policies and spatial justice to ensure equitable access to public spaces for marginalised populations.

Keywords: Sex workers; Socio-spatial exclusion; Urban transformation; Public space; Istanbul

1. Introduction

Neoliberal restructuring and urban growth marginalise disadvantaged populations. This argument establishes a basis for discussions about exclusionary policies and urban justice, highlighting the challenges faced by vulnerable groups in urban areas. Along these lines, this study focuses on the exclusion of vulnerable groups from public spaces.

Before beginning the discussion, it is important to highlight the key conceptual frameworks of justice in relation to space. Henri Lefebvre (1996) argued that space is socially produced, incorporating social relations and boundaries. He also emphasised that space is both a physical entity and an area of political struggle. He considered this to be a key aspect of the concept of the 'right to the city' as a collective right. Lefebvre's concept of the right to the city supports equal participation in the production of space. Urban space is a collective asset and should not be exclusively controlled by the state or private capital. According to him, every individual, regardless of their socio-economic position, should have the right to participate in shaping their living environment.

Taking Lefebvre's definition further, David Harvey (2008) argued that the right to the city includes not only the right to access existing resources, but also the right to transform urban spaces. However, he also claimed that neoliberal urbanisation processes lead to the commodification of space, consequently causing vulnerable groups to be excluded from urban areas. This process further disadvantages vulnerable groups in terms of their well-being and socio-economic conditions. Therefore, Harvey emphasises that urban struggles should create alternative, more inclusive ways of life as an alternative to capitalist modes of production (Harvey, 2003).

Building on this, Susan Fainstein (2010) described the 'just city' approach as a set of urban planning standards that are based on democracy, diversity, and equality. Fainstein examined pragmatic planning strategies that combine Rawlsian ideas of justice with feminist perspectives. John Rawls's (1971) theory of justice has had a significant impact on urban studies. He argues that the transformation process is unfair to minorities. The relocation of

minorities comes at a significant cost. Also Rawls (1971) defended the principles of equality of opportunity and protecting the most disadvantaged groups. Although his individualistic approach to justice has been criticised for inadequately considering group identities, Rawls emphasised that institutions should be designed to protect the most vulnerable groups in order to achieve justice in society (Rawls, 2001).

Iris Marion Young's (1990) work highlights that justice is crucial for understanding the exclusion and spatial oppression experienced by marginalised groups. According to Young, injustice stems from exploitation, marginalisation, cultural imperialism and violence. Marginalised groups often experience multiple layers of socio-economic exclusion.Furthermore, economic inequalities become institutionalised as social disrespect and a lack of recognition (Honneth, 2003). This situation forces vulnerable groups to commit crimes to avoid being cleansed from urban areas, which results in their marginalisation and integration into unsafe environments. Urban transformation appears to be a solution, but it reduces the visibility of problems and creates constraints for vulnerable groups.

Subsequently, the literature argues that urban democracy and justice should encompass both distributive and recognitional aspects. This emphasizes the equitable distribution of resources and accessibility, along with social respect, cultural visibility, and participation in shaping urban life. These frameworks highlight the importance of spatial justice in understanding and reevaluating the consequences of excluding vulnerable groups from urban spaces, narratives, and visions of the future.

In contrast to discussions about the right to the city and spatial justice, Istanbul's urban policy employs neoliberal planning strategies that emphasize tourism, real estate speculation, and middle-class aesthetics. These strategies merge visibility and participation in public spaces with adherence to normative identities. As a result, vulnerable groups are excluded from urban spaces and struggle to establish a place for themselves. Against this backdrop, the study investigates the exclusion of sex workers from urban public spaces.

2. Sex work: conceptual and practical framework

Sex work exists within various sociocultural, economic, legal, moral and sexual contexts, all of which are studied by different social science disciplines. According to Dictionary.com (accessed 27 May 2025), a sex worker is someone who works in the sex industry as a prostitute, porn actress, stripper, nude model or producer of online sexual content. Another definition is 'someone who has sex to earn money and is not married' (Weitzer, 2009). The ILO also defines sex workers as individuals who exchange sexual services for money or goods.

Theory on the definition of sex work is also explored in the literature, focusing on human rights and feminist perspectives. These approaches are based on ideas about human trafficking and sex work as a profession. The definition of sex work lies between these two perspectives. Historically, it was understood as women providing sexual services to men for money; however, recent studies show that sex work is now often performed as a form of self-employment (Bernstein, 2007; Kontula, 2008).

2.1. Definition and historical overview of sex work

Although the assertion that sex work is the 'oldest profession in the world' is frequently repeated, historical records demonstrate that organised forms of prostitution existed in ancient Mesopotamia by 2400 BCE at the latest (Ringdal, 2004). Its history can be divided into four periods: 8,000–500 BCE; 530 CE to the Middle Ages; the Age of Enlightenment; and 1900 to the present day. During these periods, social and legal regulations regarding sex work varied (Ringdal, 2004).

Ancient Rome had licensing and tax regulations for sex work. However, in the Byzantine period, laws were passed that removed sex workers and brothel operators from the capital, freed slaves who had been forced into prostitution and banned sex in public baths (McGinn, 1998). During the Middle Ages, sex workers were severely punished and marginalised. In France, they were mutilated by the Roman army and labelled 'devil women' (Bullough & Bullough, 1978). Between 1350 and the 16th century, sex work in Europe became socially differentiated:

while cities such as Venice established municipal brothels, while France banned them altogether, distinguishing between elite mistresses and lower-class sex workers (Rossiaud, 1988).

In the 19th century, the Netherlands introduced prostitution regulations, but by 1910, brothels were banned as part of a moral reform movement (Van de Pol, 2011). In the early 20th century, sex work policies shifted: the U.S. imposed bans for hygiene reasons (1915), and Germany decriminalised prostitution (1927) (Roos, 2002). In the 1930s and 1940s, wartime regimes reshaped sex work: Japan established military brothels in occupied Asia (1932), while Nazi Germany re-criminalised prostitution in 1942 (Roos, 2002).

Based on the history with a high variety, today, several countries have different laws on sex work. These include banning brothels, implementing regulatory laws, legalising prostitution in specific areas, and criminalising child prostitution between the 1940s-2000s (Weitzer, 2009). Between 2000 and 2022, various countries implemented different regulations on sex work. The Netherlands and New Zealand legalised it, Germany removed its moral condemnation and introduced social insurance for sex workers. Canada criminalised the purchase of sex and Zurich imposed spatial restrictions by limiting prostitution to industrial zones (Wagenaar & Amesberger, 2013).

One considerable conclusion to derive from the analysis of this narrative is that prostitution rises during periods of social upheaval. This is followed by an uptick in epidemics and crime rates. City administrators then develop policies to address these issues, and when these prove insufficient, the cycle repeats when breaking points are reached. (Figure 1). Understanding this cycle is crucial to assessing the effectiveness of sex work policies, as well as how sex work is shaping today.

Figure 1. The cycle of sex work developing parallel to historical processes (produced by the authors)

2.2. Global forms of sex work today

As mentioned above, sex work has existed in various forms in different societies and eras. In each period, it has been examined in different socio-cultural, economic, and legal contexts. This article examines the reflection of sex work in modern society, the experiences of sex workers, and the diversity within the sector under two headings.

2.2.1. Online-based practices

The transformation of communication through technology has increasingly played a role in changing the sex industry. While one group uses technology for direct communication, another uses it to create a barrier between themselves and clients. Online-based practices can be divided into two categories: escort sex work and visual/virtual sex work.

Escort sex work

Escort sex work is commercial sexual activity done in private residences or hotel rooms, where sex workers receive money, gifts, or other material items (ILO, 2018). Unlike sex work on the street, escort work is usually independent or via agencies/digital platforms (Cunningham & Kendall, 2011; Sanders, 2005).

This type of work is embedded within the broader social, economic, and cultural dynamics of the city. From a rights-based perspective, discussions often focus on the need for legal protections, healthcare access, and support services to ensure the safety and autonomy of sex workers (Platt et al., 2018; Benoit et al., 2017). Feminist perspectives on escort sex work vary. Some argue that it can reflect sexual and economic autonomy (Nussbaum, 1998; Grant, 2014), while others view it as part of a system of exploitation and inequality (Barry, 1995; Dworkin, 1981). The varying views on this show the difficulties of interpreting consent and empowerment in the context of sex work.

Visual/virtual sex work

Digital technologies have transformed sex work, enabling new forms of interaction. Visual sex work, defined as the marketing of sexuality online, allows individuals, especially women, to create and distribute content independently via OnlyFans, Twitter, TikTok and other online spaces (Sakallı, 2018). These platforms offer greater autonomy, income potential, and safety, as workers typically operate from self-chosen environments and control their business strategies (Jones, 2020). Digital visibility also contributes to social acceptance of sex work (Blunt & Wolf, 2020).

In contrast, street-based sex work exposes workers to physical risks and social marginalisation. A rights-based approach is needed to ensure the safety, health and labour protections of street sex workers (Kinnell, 2008). While often viewed as exploitative, some feminist perspectives recognise it as a form of agency and economic self-determination (Jeffreys, 1997; O'Connell Davidson, 1998).

2.2.2. Area-based practices

Area-based sex work continues to be carried out using more traditional and familiar methods. In this context, these practices fall into two main categories: street-based and brothel-based sex work.

Street-based sex work (unregulated/informal)

Street sex work, which is often unregistered and unregulated, is defined as the provision of sexual services in public areas such as streets, parks and vehicles. It is particularly prevalent in regions where sex work is criminalised (Kurutkan, 2003). Moreover, street-based sex work, unlike escort services for high-end clients, is linked to lower-cost, more informal conditions and little social protection.

From a social rights perspective, ensuring the safety, health and dignity of street sex workers is paramount. Comprehensive, rights-based approaches emphasise the need for safe working environments, protection from violence and access to healthcare (Kinnell, 2008).

Brothel-based sex work (regulated/formal)
Brothel sex work is legally regulated prostitution where workers are registered and venues operate under specific standards. Such establishments contribute to urban economies through taxation and employment (Aalbers & Sabat, 2012). Despite this framework, sex workers often face social exclusion and restricted access to services and rights. They continue to be marginalised by social stigma and institutional discrimination, despite their legal status (WHO, 2015). From a feminist and human rights perspective, this form of sex work can regulate women's sexuality and reinforce social inequalities. Ensuring equal treatment and dismantling stigma are central to advancing their rights (Aalbers & Sabat, 2012).

Table 1 summarises the four main forms of sex work today: online-based (escort and visual/virtual) and area-based (street and brothel). Online escort work carries a medium risk of exploitation and violence, with low visibility and societal impact. Visual/virtual sex work generally carries a low risk and is considered ineffective. Area-based sex work, particularly street-based and brothel-based work, carries a higher risk of violence and has a more negative impact on society.

Table 1. Summary of the global forms of sex work today

	Type of space	Exploitation 3rd person	Violence risk	Visibility impact	Impact on society
Online-based practices					
Escort sex workers	independent operator, private property, hotel, etc.	medium	medium	low	between ineffective and negative
Visual/virtual sex work	digital platforms, mobile dating apps, social media, pornography, erotic performing arts, etc.	low	low	low	ineffective
Area-based practices					
Street-based sex work	street, car, park, cemeteries, etc.	medium to high	high	high	negative
Brothel-based sex work	brothel	high	high	medium	negative

2.3. Social and legal perspectives on sex work
As the above historical narrative analysis shows, approaches to sex work differ from society to society, depending on historical processes, legal norms and the cultural, moral, economic, and social structures that shape each society's laws and practices regarding sex work. It may be banned or regulated. Attitudes towards sex work have evolved due to crises, wars, changes in society, and value judgments, creating diverse, dynamic ideas of it.

2.3.1. Social perspectives

Marginalisation and exclusion from society make individuals vulnerable to exploitation through human trafficking. In this context, sex work can be considered within two basic frameworks: the human rights struggle of sex workers, and the anti-trafficking rights struggle of individuals victimised within the sex industry (Kilislioğlu, 2020) (Figure 2).

The relationship between sex work and human rights was placed on the global agenda after the UN Convention on Trafficking in Persons and Exploitation through Prostitution in 1949. The topic was discussed in the 1980s due to the impact of the rising feminist movement, HIV/AIDS, and related organisations such as the IOM and ILO (ILO, 2010). Documents including the 1979 CEDAW and the 1989 CRC, raised global awareness (United Nations, 1989). At the 1996 Vienna Conference, prostitution and trafficking were differentiated for the first time, emphasising that all forms of prostitution have the potential for exploitation.

Figure 2. Feminist movement: demonstration (Source: URL-1)

The 2015 "Memorandum of Understanding on Sex Work, Human Rights, and the Law" made three main demands: recognise sex work as a form of labour, end criminalisation, and support sex workers' rights to self-organise (Global Network of Sex Work Projects, 2013). Within feminist theory, discussions on sex work are divided into two main approaches. Radical feminists see sex work as a form of sexual exploitation and advocate prohibiting prostitution (Farley, 2003). Other feminist approaches recognise sex work as legitimate work and advocate for sex workers' rights, adopting a rights-based view (Figure 3).

Figure 3. Women's liberation protest (Source: URL-2)

2.3.2. Legal perspectives

Legal regulations and state policies are based on contrasting approaches that view sex work as either a form of sexual exploitation or a legitimate profession. The three main approaches of criminalisation, legalisation, and liberalisation can be analysed within four legislative models: prohibitive, preventive, regulatory, and decriminalisation (Figure 4).

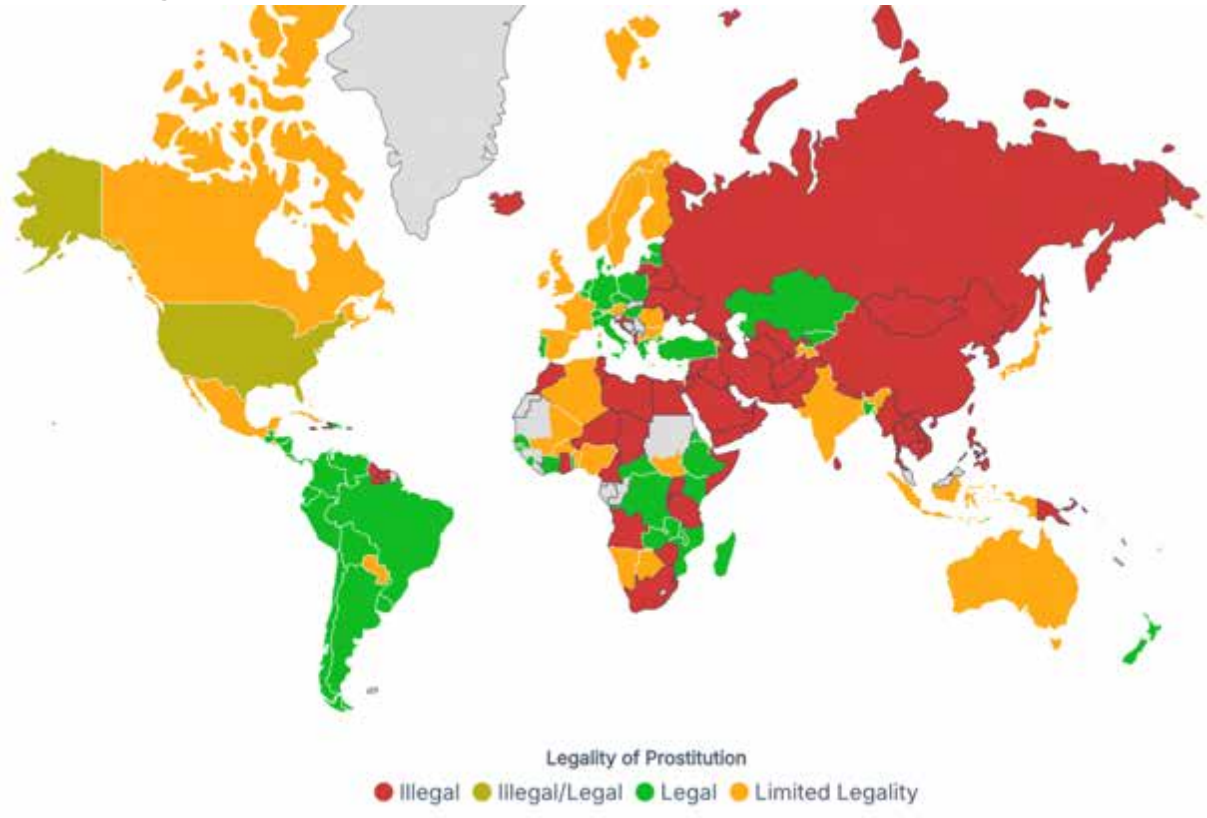

Figure 4. World prostitution policies, 2025 (Source: URL-3)

Prohibitionist model: the Swedish example

The prohibitionist model is a framework that bans all activities associated with the sex industry and penalises those involved. Its main objective is to eliminate gender inequality. Countries that apply the prohibitionist model, which appears in different parts of the world with different content within a similar framework, include the following: Iraq, Iran, Jordan, and Afghanistan in the Middle East; China, North Korea, South Korea, Thailand, Cambodia, the Philippines, Egypt, Uganda, and South Africa in Africa; and Lithuania, Albania, Croatia, and Sweden in Europe (Kilislioğlu, 2020). Here, Sweden has extensive discussion and research on the subject. Prostitution decreased due to Sweden's strict laws, but moved to hotels, restaurants, and online. This has led to unsafe working conditions and criminalisation (Dodillet & Östergren, 2011).

Abolitionist/preventive model: the Canadian example

The abolitionist model focuses on the preparation for sex work rather than the act itself, viewing it as a form of violence and exploitation. It bans advertising prostitution in public spaces, intending to reduce harm to women. Countries that implement this model include Poland, Spain, Portugal, Slovakia, Slovenia, and the Czech Republic in Europe, as well as Canada in North America (Kilislioğlu, 2020). Canada's approach aimed to remove prostitution from public, populated areas, which resulted in a visible decline. However, this shift has led to sex work becoming more hidden and isolated, increasing the risk of exploitation and violence against sex workers. (Benoit et al., 2018)

Regulatory model: the Dutch example

The regulatory model is an approach that partially legalizes and does not penalize sex work within a framework of state-set rules (Kilislioğlu, 2020). It is currently practiced in the Netherlands, Germany, Austria, Hungary, the United Kingdom, Greece, Türkiye, Belgium, Senegal, and parts of Australia and the US, including Nevada. The model's main objective is to control prostitution activities to protect public health.

The Netherlands is one of the most notable practitioners of this model. Although prostitution was technically illegal from 1911 to 2000, the government did not shut down brothels, and strict policies were not effective in fighting crime and exploitation. (Kilislioğlu, 2020). The Netherlands tried to control prostitution by creating tolerance zones, but the results have been negative. In some cases, sex workers have moved outside the tolerance zones and the zones have not fulfilled their function. While consensual prostitution is not a crime in the Netherlands, forced prostitution is (Coy, 2012).

Decriminalisation model: the New Zealand example

The decriminalisation model removes all punitive laws relating to sex work and recognises it as a voluntary profession that cannot be eradicated. New Zealand is the only country to use this model. Its purpose is to reduce social exclusion of sex workers and ensure citizens' rights within human rights (Kilislioğlu, 2020). This approach marks a shift towards recognising sex work as a rights-based profession, improving perceptions of, and the quality of life for, sex workers. However, it has also led to an increase in prostitution, with brothels now limited to four people, and raised crime rates in some areas. This has contributed to serious issues such as child exploitation, particularly in vulnerable regions. (Kilislioğlu, 2020).

3. Reflections of sex work in the Turkish context

The Red Umbrella Sexual Health and Human Rights Association (in short, Red Umbrella) in Turkey defines sex work as the exchange of sexual services for money, including porn, escorting, erotic dancing and massage. In contrast, the Turkish Language Association defines prostitution more narrowly as paid sexual intercourse that violates social norms (Red Umbrella, 2019). Historically, terms related to sex work have reflected societal marginalisation. Examples include 'prostitute', 'whore', 'rent girl' and 'sex worker'. (Açıkalın, 2013). In a narrow sense, sex work involves consensual paid sexual services without coercion.

Historically, sex work in Turkey has taken place on the urban periphery. Istanbul's development can be divided into four periods: 1600–1880, 1881–1950, 1951–2020, and the period since 2020. The legalisation of brothels in 1880 formalised sex work (Belli, 2022). Following the establishment of the Turkish Republic in 1923, legal regulations were introduced in 1926, although efforts to ban prostitution emerged in the 1930s (Wyers, 2017). After 1950, sex work grew in migrant cities, with more brothels and sex workers as consumer culture took off in the 1980s. The 1990s saw an influx of sex workers from the former Soviet Union.

The first NGOs for sex workers were established in the 2000s, and brothels closed during the COVID-19 pandemic, which started in 2020. This process was triggered by that which led to significant changes in the visibility, mobility, and working conditions of sex workers.

The global approach to sex work in Turkey is marked by diversity. State policies are shaped by regulatory models that protect the rights of working women. Some civil society organisations argue for sex workers' rights and the profession's legitimacy, while others seek to reintegrate sex workers back into society.

3.1. State attitudes and legal-administrative policies

The Ottoman Empire adopted France's prostitution regulations in 1858. The Republic of Türkiye adopted them and they were maintained until 2004. In 2004 the law was amended to prohibit prostitution and bargaining but not consensual sexual services by over-21s in private. Those who encourage, mediate, provide a place for or profit from prostitution involving children or adults are penalised under the new code.Articles on human trafficking include provisions to prevent foreigners from being exploited in the sex industry (Kilislioğlu, 2020).

A 2011 report stated that after the 2004 Penal Code, the term "general woman" referred to women who were habitual sex workers, over 21, Turkish citizens, licensed, and employed in brothels (Şimşek, 2022). The Regulation on Combating Venereal Diseases, which took effect in the same year, established responsibilities, including licensing brothels, maintaining records, inspecting prostitution establishments and preventing hidden prostitution. Additionally, the regulation includes providing support to women who do not want to engage in prostitution (Kilislioğlu, 2020).

3.2. Civil society and NGO perspectives

Red Umbrella, Kaos Gay and Lesbian Cultural Research and Solidarity Association (Kaos GL) and the Sexual Education, Treatment and Research Association (CETAD) are among Turkey's non-governmental organisations working on sex work. Red Umbrella defines sex work as a unique form of labour due to its conditions and methods. It is inappropriate to compare it with other labour, not necessarily in terms of legitimacy, but because of its unique nature (Red Umbrella Fund, n.d.). Therefore, regulatory frameworks must be developed with scientific rigour, considering the experiences and needs of sex workers. Underground environments are at high risk of exploitation and abuse without this (Demirtaş, 2021).

Kaos GL recognises sex work as legitimate labour and advocates for the rights of its workers. The organisation emphasises that this profession's individuals require rights-based support and regulations. Kaos GL critiques the concept of public morality, which fuels discrimination and criminalisation of sex workers in the media (Zengin, 2014). Sex workers, who are constantly subjected to interventions as if every one of their actions is criminal and who are portrayed as perpetrators in the media, are not criminals (Yılmaz, 2021).

CETAD, working with the Turkish Ministry of Health and funded by the European Union, promotes gender equality and human rights for sex workers through a project that focuses on respecting their rights, preventing discrimination, encouraging empathy, and getting them involved in society (CETAD, 2021). The project tackles child sex work prevention, victim rehabilitation, and sexual exploitation perpetrator prosecution. These intervention areas are considered crucial.

4. Research design and methodology

By shedding light on the realities and perceptions of this vulnerable group, this study aims to address deep-seated inequalities and advocate for social and spatial justice in the historic Pera quarter of Istanbul. One of the most well-known sex work areas of Turkey and located in central Istanbul, Pera has gone through urban transformations that affected the centuries-old sex work in the area, particularly in the last two decades.

This study uses a secondary qualitative research approach. The methodology is divided into three main phases presented in the sections below. Based on theoretical, social and legal frameworks reviewed above globally and in the Turkish context, the first phase explores the spatial dimensions of sex work within the historical development of the Pera quarter. This was achieved by examining documentaries, historical maps, and archival records. The second phase focuses on analysing urban infrastructure and transformation projects in Pera, paying particular attention to the displacement of sex workers. This phase utilised documentaries, news articles, and official records relating to urban redevelopment initiatives. The final phase synthesises the findings through a layered, CAD-based mapping exercise. This exercise visualises the intersections of sex work nodes in public spaces and urban regeneration projects, as well as the resulting processes of spatial exclusion faced by sex workers.

5. The socio-spatial transformation of sex work in Türkiye: the case of Pera

Istanbul's Beyoğlu district's sex work-related approaches were complex in the late 19th century. Linked to the port in the early Ottoman Empire, the area became a trade hub. In response, the 6th District Municipality, which includes Beyoğlu, implemented pioneering urban reforms. During this period, bachelors and prostitutes were viewed as both undesirable and an essential part of urban life. Rather than banning prostitution, authorities and elites introduced regulations to mitigate its negative consequences, importing the European and French ones.

Ottoman urban reformers considered regulating prostitution as part of their modernisation efforts in adapting to global trade. Conflicts and tensions in evolving public spaces are discussed, particularly due to impoverished women and other recent immigrants. This text examines the policies of social and administrative elites aimed at limiting prostitution's mobility and visibility in urban areas. Sex workers were indispensable to Beyoğlu's urban life, so eliminating prostitution was not considered appropriate. Instead, it was deemed important to keep prostitution out of sight in public and under administrative and medical supervision in designated areas. This was considered a step in preserving society's moral and physical cleanliness. As a result, areas within the city emerged where controlled prostitution could be practised.

Pera, in Beyoğlu, is home to many elites and marginalised people. It starts at Istiklal Street and extends to its surroundings, meeting with Yüksek Kaldırım and Galata, and then Karaköy. Pera, a Greek word meaning 'the other side', has undergone various socio-cultural, economic, and physical transformations.

5.1. Spaces of sex work

In the urban context, sex work takes place in urban spaces where it has long existed, shaped by both visibility and exclusion. These streets squeezed into the dense and layered structure of the urban fabric and stand out as contested areas where negotiations between bodily autonomy, urban governance and social norms take place.

5.1.1. Public spaces (street-based sex work)

The Pera quarter is located in the tourist and historical centre of Istanbul. For this reason, it is an attractive work area for sex workers, offering high customer potential and ease of access. Additionally, Pera's historical significance and cosmopolitan, open-minded sociological structure have increased social acceptance in the area. Due to the heavy foot traffic on the streets and avenues in and around Pera, sex workers prefer to work in this area, where there is a high customer potential. These areas are densely populated with tourists and locals, who are an important source of customers for sex workers (Erder &Kaşka, 2003).

Tarlabaşı District

After Tarlabaşı Boulevard opened in 1986, groups displaced from gentrifying neighbourhoods in Beyoğlu, such as Cihangir, Asmalımescit, and Galata, settled there (Perouse, 2011; Zengin, 2014). Changes in the 2000s as part of the Urban Transformation and Urban Renewal Project aimed to alter the region's sociological structure, but decreased social control, creating insecurity. Some displaced transgender sex workers continue to work in certain areas of Tarlabaşı due to economic hardship and because they cannot find a supportive community elsewhere. Others have moved to nearby neighbourhoods, such as Elmadağ and Kurtuluş, or to Anatolian cities. The destruction of workplaces has negatively impacted active sex workers (Şentürk, 2011) (Figure 5).

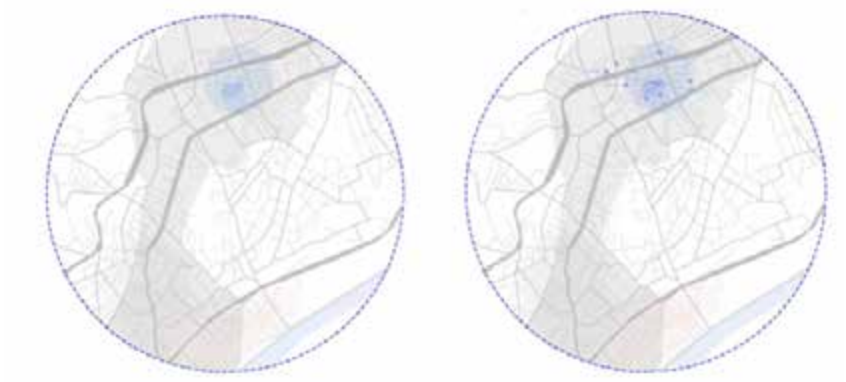
Figure 5. Changing spatial dynamics of sex work in Tarlabaşı (produced by the authors)

Küçük Bayram Street

The LGBTI+ Solidarity Association defines this area and surrounding streets have been used since 1947 (Kepenek, 2024). Police raided the area often, but trans women continued to live there. Bayram Street is a memory place for the trans+ movement in Istanbul. There were intermittent raids and attempts to stop activities, but the effective transformation movement came in 2023 with an official closure decision on the grounds of 'hanging from the window.' Some houses were sealed. The 10th Istanbul Trans Week Committee says trans women living here stated that they would not leave because unity and solidarity make them feel safe. They emphasised this with the following statement: "Trans+ people did not and will not leave despite the control mechanisms that try to make trans+ existences invisible" (Kepenek, 2024) (Figure 6).



1. A developing area where trans sex workers are concentrated 2. Police have been trying to defer them constantly with raids, currently most of the houses on this street are sealed. Most of the trans sex workers here have not left their neighbourhoods.

Figure 6. Spatial diffusion of sex work from Küçük Bayram Street (produced by the authors)

5.1.2. Private spaces (brothel-based sex work)

Brothel-based sex work occurs in more controlled and institutionalised private spaces where visibility in public spaces is limited. The Abanoz and Ziba quarters, and especially Zürafa Street, have been areas where brothels are concentrated and sex work has been spatially limited for many years in Istanbul.

Abanoz and Ziba quarters

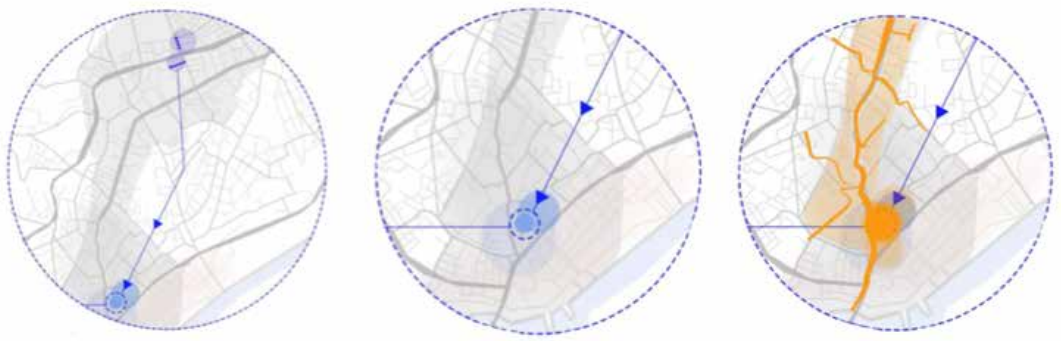
Abanoz and Ziba are among Istanbul's oldest residential areas, with a long history of trade, entertainment, and social activities. Historically, these areas were known for their brothels and street sex work (Aksoy, 1996). This made them a suitable environment for sex workers due to their visibility and security. The first brothel for foreigners living in Beyoğlu was opened in Abanoz Street in 1884. It was later moved to Zürafa Street due to social perceptions and order. Today, Abanoz Street is completely cleaned and included in commercial areas (Figure 7).

1. The first brothel area 2. Increased motivation for brothels
3. Moving the venue and female sex workers to Galata Zürafa street. Trans women continue to provide services on Ziba street

Figure 7. Transformation of Abanoz and Ziba (produced by the authors)

Zürafa Street

It is the most well-known quarter in Istanbul where the first official brothel was established. Alageyik and Yüksek Kaldırım Streets, which connect to Zürafa Street, are also part of this area. Due to its central location and ease of access, Zürafa Street has provided an ideal work area for sex workers. The buildings where the brothels are located provide both visibility and privacy, allowing customers to easily access them. The spatial structure of the area ensures that workers have a safe, economically sustainable work environment (Hubbard, 1999). The goal is to build more modern, tourist-oriented structures in the area and renovate existing structures as part of the Beyoğlu Culture Project, which is analysed in the sections below. However, the arrival of the COVID-19 pandemic has led to the closure of brothels and the spatial displacement of sex workers (Çınar, 2001) (Figure 8).



1. The first official brothel 2. Increased motivation for brothels
3. Inclusion of the place in the Beyoğlu cultural project

Figure 8. Transformation of Zürafa Street (produced by the authors)

General Evaluation

Urban areas historically identified with sex work, such as Pera, Tarlabaşı, Küçük Bayram Sokak, Abanoz and Zürafa, stand out as complex spaces where both visibility and exclusion intersect. In particular, the opening of Tarlabaşı Boulevard in 1986 and the urban renewal projects initiated afterwards transformed not only the physical but also the social structure, causing the displacement of sex workers living in the region. A similar social eviction issue occurred on Küçük Bayram Street; the trans sex work areas that had existed for many years were dispersed with the closure decisions, and this situation led to sex workers working in even more precarious conditions and in a dispersed manner. The brothels operating on Zürafa and Abanoz streets were gradually withdrawn to more isolated and suppressed areas in order to reduce public visibility. Such interventions interrupted the continuity of sex work within the city and weakened the solidarity networks of settled communities. The general map reveals how the place, rights and visibility of sex workers within the city were ignored in the planning processes (Figure 9).

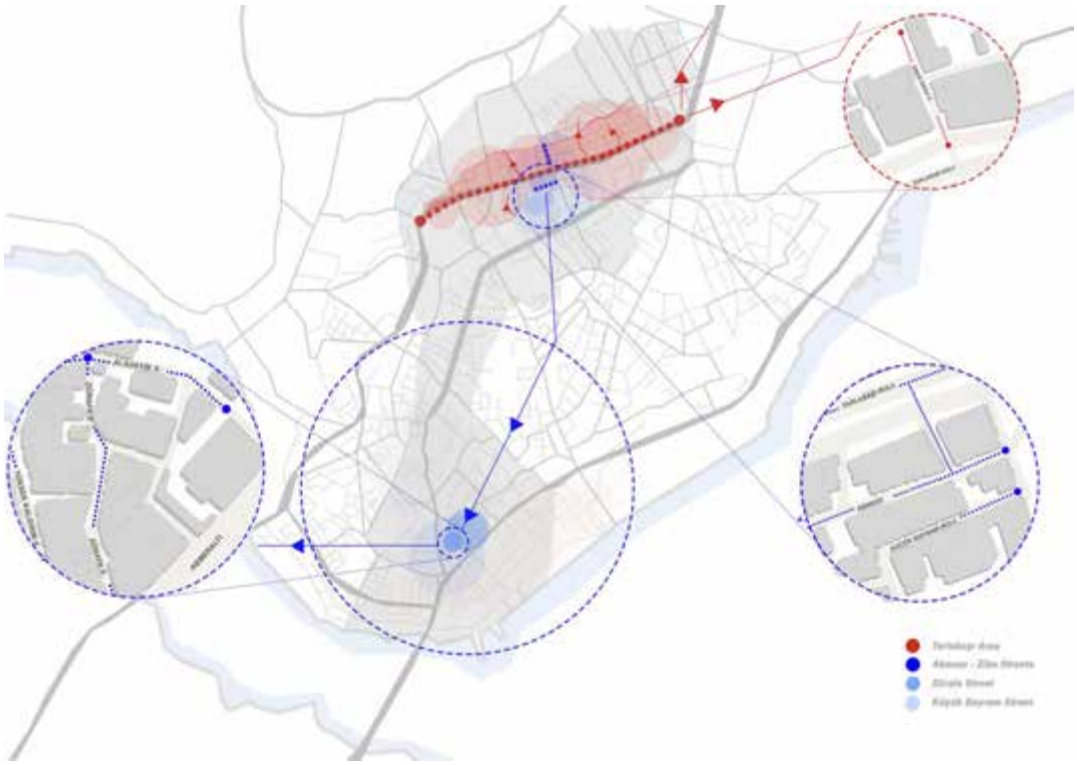


Figure 9. Displacement of sex work in Pera (produced by the authors)

5.2. Urban infrastructure and redevelopment projects affecting sex work

Tarlabaşı and Beyoğlu, located in the centre of Istanbul, are social spaces where vulnerable groups, especially sex workers, survive and build solidarity. However, successive urban interventions—including the Tarlabaşı Boulevard Project, the Tarlabaşı Renewal Project, and the Beyoğlu Cultural Road Project—have reshaped these spaces. These projects aim to transform the areas into socially homogenised urban spaces based on profiteering logic.

These projects exclude sex workers existentially, marginalise them, and displace them. Although the discourse behind these projects—security, culture, tourism, and restoration—is presented as inclusive, the projects cause the erasure of sex workers' spaces of shelter, work, and solidarity from the city centre. Thus, these projects have not only transformed spaces, but also radically limited the right to the city and public visibility of vulnerable communities.

5.2.1. The Tarlabaşı Boulevard Project

The Tarlabaşı region developed as a residential area of Pera in the 19th century. With its multicultural structure, the area hosted many groups and immigrants. However, in the 1980s, the area was defined as a 'decay zone' and targeted because its appearance was said to damage the 'image' of the city centre due to structural deterioration and socio-economic collapse (Candan & Kolluoğlu, 2008). The Istanbul Metropolitan Municipality was established by Law No. 3030, enacted in 1984. Bedrettin Dalan then took office as Istanbul's first mayor. At that time, Dalan's goal for Istanbul was to create an image of it as a 'world metropolis.' To this end, urban transformation projects were initiated (Keyder, 1999).

One of these projects was the Tarlabaşı Boulevard Project, implemented in the 1980s to improve transportation and the area. However, the project has become an ideological intervention rather than merely adding a new transportation line. It interrupted the historical and social integrity and permeability between the Tarlabaşı neighbourhood in Beyoğlu and Pera, creating a permanent separation in the urban fabric. In short, this intervention

should be evaluated not only as physical separation but also as a spatial expression of social exclusion (Figure 10).

Figure 10. Enlargement of the Tarlabaşı Boulevard in 1986-1988 (Source: URL-4)

As a result, a new 'urban gap' emerged in the Tarlabaşı-Pera region, which continues the 19th-century urban fabric. The separation has become more apparent due to the severing of passageways and construction of a high-traffic boulevard (Candan & Kolluoğlu, 2008). On an urban scale, Tarlabaşı's connection to the city centre has been cut off. The area has essentially become Pera's 'backyard,' leading to imbalances in access to social services and being ignored in planning policies (Keyder, 1999). This intervention has made low-income groups, ethnic minorities, and various marginalised communities living in Tarlabaşı even more 'invisible.' Despite being in the centre of the city, these groups have been socially pushed to the margins. Public memory has coded these neighbourhoods as 'out of order,' deepening the socio-cultural separation. Tarlabaşı Boulevard has ceased to be a tool of urban planning and has become a border where urban segregation, socio-economic exclusion, and spatial othering become concrete.

5.2.2. The Tarlabaşı Urban Renewal Project

The Tarlabaşı Urban Transformation Project is another significant example of urban intervention in the Tarlabaşı district that exacerbated social and physical segregation. Tarlabaşı is a district with a dense population of non-Muslims that has experienced demographic changes. Certain communities left the region as a result of political and social events that took place in the 1950s, and immigrants from Anatolia and other disadvantaged groups settled in their place.

In 2006, Tarlabaşı was designated a renewal area under Law No. 5366, which concerns the 'Renovation, Protection, and Revitalization of Worn-Out Historical and Cultural Immovable Assets.' Under this designation, plans were made to build luxury residences, offices, and commercial areas under the name 'Taksim360' in nine blocks of the district (Çiltaş Çatalbaş, 2022). Evacuations began in 2008, and by 2010, a large portion of the district's residents, particularly low-income and uninsured groups, had been forcibly evicted. This urban transformation has attracted high-income groups to the region, altering the economic structure and paving the way for the gentrification of the district. This situation produced a multi-layered practice of exclusion and displacement, particularly affecting long-time sex workers in Tarlabaşı. Tarlabaşı was experienced as a kind of "urban shelter" by sex workers in the region due to the solidarity networks and social relations they had established there. As the visibility of sex work has decreased, sex workers have been further criminalised, erased from the public sphere, and their advocacy for rights has weakened (Figure 11).

Figure 11. Borders of the Tarlabaşı Project (Source: URL-5)

5.2.3. The Beyoğlu Culture Route Project

The Beyoğlu Culture Route Project is a Ministry of Culture and Tourism of Türkiye initiative in Istanbul's Beyoğlu district (Kültür Yolu Festivali, 2025). It aims to create a cultural corridor from Galataport to Taksim. The structures to be restored along the route are discussed in terms of 'Beyoğlu's revival with culture' through museums, art centres, and public events. While Beyoğlu Culture Road restructures an axis covering İstiklal Avenue and the surrounding streets, it aims to remove groups that have historically existed there and often represent the 'invisible history' of the place. The public character of İstiklal Avenue, especially its nightlife, alternative culture, and gender diversity, is changing to a regulated, supervised, and 'clean' cultural area.

The area around Zürafa Street that sex workers have called home and worked in for years has been completely closed. Sex workers have lived and worked on this street for many years. However, with the project, their living spaces and social networks have been fragmented, and their economic and social security has weakened. With the increase in police presence, these areas have been taken under control with a security-oriented approach. In this context, the Culture Road Project also functions as a moral control device while reconstructing the space through culture. Sex workers are both the subject and the target of this moral regime. Thus, urban elitism and a gender regime are reproduced under the guise of 'culture'. This project is not only a cultural investment but also deeply produces spatial injustice.

5.3. A holistic spatial assessment through mapping

The spatial transformation of the streets associated with sex work in the Pera region has been shaped by large-scale urban interventions implemented in different periods, and both the physical environment and the socio-cultural structure have changed radically in this process. The mapping study visualises this transformation process and reveals how space is reproduced not only physically but also socio-politically. When the current locations of sex work areas in three different focal points (Tarlabaşı-Ziba, Zürafa and Abanoz-Küçük Bayram Streets) are examined, it is seen that these areas are shaped by strategies of oppression, eviction and exclusion. Some streets have been completely cleaned, some have continued their existence with controlled visibility, and some have become temporary shelters. As a result of all these interventions, the presence of sex workers in urban space has been systematically limited; their rights to take place in public spaces to shelter have been damaged (Figure 12).

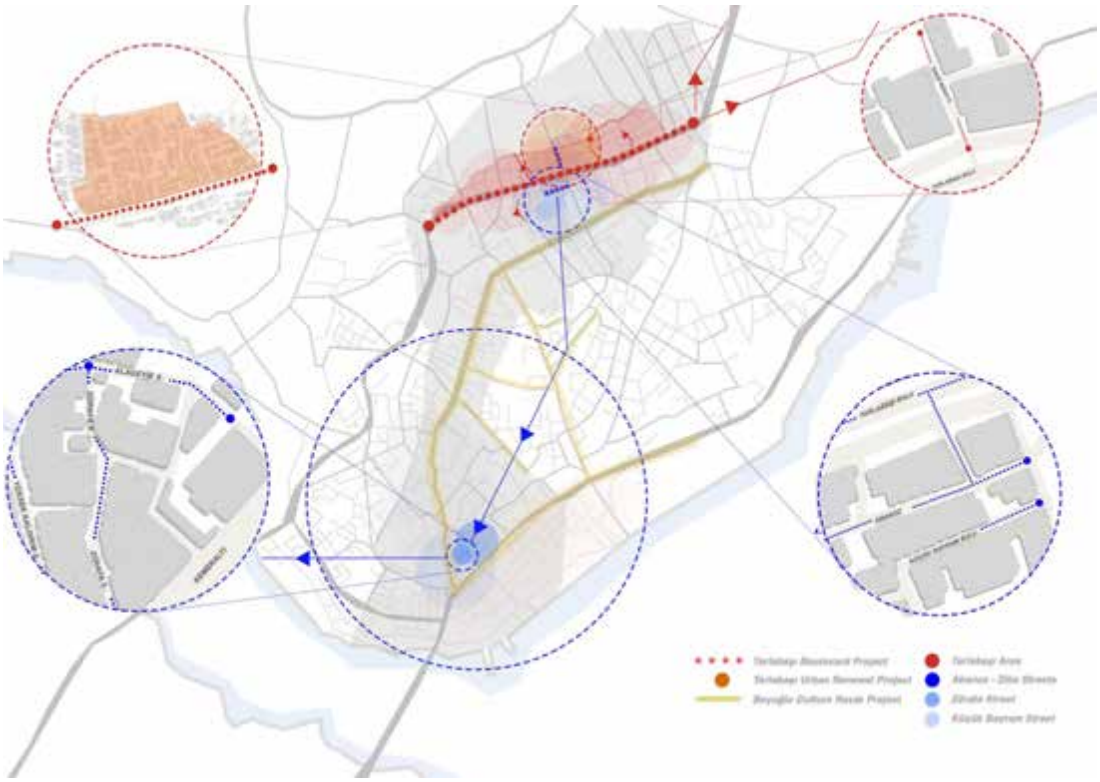

Figure 12. Spatial overlay of sex work spaces with urban redevelopment pressures (produced by the authors)

6. Concluding notes: reflections on urban transformation

Examining historical processes has revealed that prostitution increases significantly during social upheavals such as migration, war, and economic crises. This increase has led to negative consequences, including the spread of epidemic diseases and higher crime rates in cities. In response, city administrators have developed new urban policies to address these issues. However, the inadequacy of these policies has caused these breaking points to reoccur (Figure 13).

This research aims to shed light on the situation of sex workers in Türkiye, particularly those displaced due to changes in the Pera district of Beyoğlu, Istanbul. Pera, a historically diverse neighbourhood, has experienced social and economic shifts, leading to urban policies and the settlement of various ethnic and orientation groups. Emerging problems have triggered further transformations, creating a chain reaction that has shaped Pera's urban landscape.

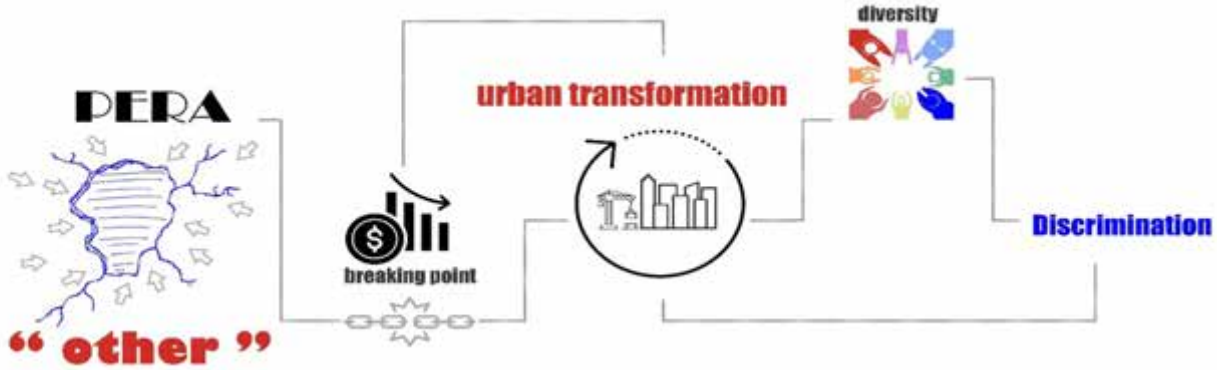

Figure 13. Abstract representation of the urban transformation story of Pera (produced by the authors)

Sex workers play an important role in the socio-cultural and economic dynamics of urban areas. However, they are seen as a problem in the public sphere and are considered one of the most fragile and disadvantaged groups in society. They are viewed as a situation that needs to be removed from city centres. The desire to 'clean up' urban centres and the prohibition and exclusion of sex work result in human rights violations, including economic hardship, lack of housing, and lack of social security for sex workers.

Consequently, efforts should be made to combat negative perceptions, ensure justice in urban transformation processes, develop and improve policy proposals, and raise awareness. This study aims to raise awareness to enable sex workers to achieve better human rights and social justice conditions and to establish a foundation for future work. The results show the gap between urban regulations and the spatial needs of sex workers in Istanbul, highlighting social equity's role in reducing systemic exclusions to encourage more inclusive practices. It thus hopes to enrich the discourse on the sustainable development of public space by advocating for the implementation of inclusive, accessible, and socially equitable spaces.

Planners and the moral power of the "unpleasant"

Ángel Aparicio
Universidad Politécnica de Madrid
angel.aparicio@upm.es

Abstract
Aesthetics are paying increasing attention to negative sensations and to individual judgements that cannot aspire to universal validity, The agreeable or pleasant, and especially its converse the unpleasant, have a considerable motivating power for action, often intertwined with ethical judgment, legitimizing action in the public sphere.

The aesthetic and ethical power of the unpleasant is illustrated by three case studies in Madrid. The first one is tactical urbanism response for street redesign (Vallecas, Arboleda street). The second one (Puerta del Sol) shows the accommodation of the public space to the pressure of touristification, to foster economic opportunities. The third case one (Green Southwest Boulevard) shows the consolidation of pre-existing power relations in response to a blighting process.

Keywords: Aesthetics, planning ethics; unpleasant; pragmatism; public space

The unpleasant as an aesthetic category

Kant paid little attention to what we now call negative aesthetic categories such as the unpleasant, the ugly or the disgusting. His most elaborated reflection on these appears in his *Critic of Judgement (1790, §48)* with an inspiring distinction between the unpleasant (which can be beautifully represented in art objects), and the disgusting (which cannot). Disgust has a sort of imposing nature which cannot be overcome, so that any object attempting to represent it cannot be dissociated with the nature of the object itself. (Kuplen, 2011). Three key features of Kantian aesthetics are positiveness (focus on beauty and the beautiful object), the disinterest of aesthetic judgments and the potential of aesthetic judgments to be universally participated, in spite of their subjective nature.

One of the first attempts to critically analyse negative aesthetic categories comes with Rosenkranz's *Ästhetik des Hässlichen* (1853). The ugly is not the mere opposite of the beautiful, but more precisely the negation of total unity and formal definitude; amorphousness or, in other words, the absence of a boundary to the outside and, internally, the absence of distinction: asymmetry and disharmony turn objects ugly.

Dewey's aesthetics turn the focus from the object to the subject or, better, to their interaction. As Dewey (1934) considers *Art as Experience*, he is placing aesthetic judgments in the humbler realm of contingent human experiences, challenging their pretence for universality and disinterest. Imagination- a human trait that can be developed through education- plays a key role in creating such experiences. For a pragmatist, there are many kinds of aesthetic experience, especially if- as Dewey did- there is no precise definition of the term or restrictions about its appropriate usage. As Shusterman, (2012) puts it, "*not all of the experiences or reactions that we call aesthetic are experiences of pleasure; not only are there bad aesthetic experiences that provide no pleasure (except by the relief of their ending), but there are also valuable aesthetic experiences that cannot be described as pleasurable*". Furthermore, aesthetic experiences can generate from everyday experiences, and are likely to merge with other human experiences, including moral ones.

Dewey's pragmatic aesthetics considerably expands the realm of aesthetic appreciation and gives room to aesthetically reflect on the ugly, the disgusting or the unpleasant (negative aesthetics), the objects and events of everyday life (everyday aesthetics), or interest and action embedded in aesthetic experiences (aesthetic engagement). Berleant develops all these dimensions with the concepts of the aesthetic field (1970), aesthetic engagement (1991), environmental aesthetics (1992) and negative aesthetics (2010). Together, they provide a

unique framework to analyse how the relationship between people and urban places (the built environment) creates an aesthetic experience prone to action.

Miller (2021) summarises the realm of negative aesthetics in Berleant (2010) as what is "*perceptually distressing, repellent, or painful, or [that which] has effects that are harmful or destructive*" and is elusive to rational criticism: "*The aesthetically negative often slips by unnoticed and eludes critical scrutiny, settling into vague discomfiture. Part of this discomfort... may result from the subtle presence of negativity or from the very failure to recognize that aesthetic negativity is indeed present*".... Berleant (2010) notes that, in the context of landscape and built environments, aesthetic negativity often takes the form of aesthetic deprivation. It is not surprising that, for Berleant (2017), the moral and the aesthetic are two dimensions along which negative aesthetics may operate.

Aesthetic engagement becomes for Berleant (2013) as the central concept of an alternative to the aesthetic disinterestedness that was central to traditional aesthetic theory. It emphasises the holistic and contextual character of aesthetic appreciation. The attention of critical scrutiny moves from the aesthetic object to the situations and the ways in which engagement arises. For Berleant, as for pragmatic aesthetics (Shusterman, 1992), aesthetic value involves experience that is somatic and not exclusively psychological.

Forsey (2016) makes a useful distinction between the various categories in negative aesthetics. The ugly- like the beautiful in Kant- has a disinterested note and an ambition for universal validity. The disgusting leads to visceral responses associated to immediate sensorial or somatic reactions that cannot be overcome. The unpleasant, however, has great motivating power together with a modesty well suited to our daily lives; it is an aesthetic category referring to physical sensations that engage our higher faculties, spurring imagination, creativeness and, ultimately, action. The fact that it does not have universalising demands does not mean that the unpleasant is completely subjective: in fact, it can be shared, eventually engaging people in acting together.

The unpleasant is for Forsey (2016) a *catalyser* of aesthetic action. Such call for action is spurred not only from the displeasure it generates, but also from our closeness to it (it forms part of our environment, and even of our everyday, which is not the case for the ugly) and from its relatively manageable size (which is not the case for the disgusting). Furthermore, the unpleasant is often morally charged as a sort of disorder, unbalance or unfairness (such as in contact with dilapidation, dirt, etc.), especially in objects or places shared with others, from our home in which we may receive friends and family to public spaces in the city. That is the intuition Saito (2001 and 2007) develops in its everyday aesthetics, looking at daily events and actions in which the human sensorial faculties are *saliently at stake*. It is also from this perspective that our judgment cannot remain purely personal, and claims some kind of minor generality, getting us involved in a- does not matter how small- community of others.

The moral and the aesthetic experience in the unpleasant

It is well known that for Wittgenstein (1923) "*ethics and aesthetics are one and the same*" (Tractatus 6.421). Appelqvist (2013) explores the sense of such identity. Aesthetics and ethics are equally transcendental and ineffable, because they both look at their respective objects (the work of art or the good life) under the same (*sub specie aeternitatis*) way of seeing, i.e., from outside. Beauty, as happiness, "*relies on the way of looking at the world*". The attitude shared by ethics and aesthetics is a feeling: "*Feeling the world as a limited whole- it is this that is mystical*" (Tractatus 6.45).

Such attitude would require the renunciation to any interest and the renunciation to seeing objects and things from the midst of them, but the latter is precisely the pragmatic understanding of the aesthetic experience and the perspective of the aesthetic engagement. By renouncing to transcendentalism and even to any pretence of universality, the pragmatic approach does not pursue any identification of aesthetics and ethics in the human experience, but this does not mean that some kind of contingent convergence is not possible. In fact, much of modern art includes some sort of ethical claims at their core, and art is eventually seen as a form of self-improvement or cultivation, for example in somaesthetics (Shusterman, 2014) or in the *art of living* pervasive in many Eastern traditions.

The unpleasant arises discomfort, as repeatedly described in works on everyday aesthetics and environmental aesthetics. It arouses our will for action and our longing for change. What is interesting is that such longing is strengthened when intertwined with some sort of ethical judgment. The combination of the feeling of the unpleasant (but not the ugly, which is contemplated without interest or engagement, nor the disgusting, which leaves us paralysed if not running away) with the feeling of the morally wrong (but not the absolutely evil, which can be seen as a particular form of the disgusting, preventing any positive action) is what emboldens the subject to presume that her judgement may have some potential of generality, and what triggers her resolution to act in the public sphere. Note that the merely *unpleasant*- as a personal judgment- hardly legitimizes such action in the public space, although it can certainly move to action in the private sphere: changing the wall colour in my room or tidying up my desk.

It is possible to find ethical considerations as a powerful leverage to trigger action out of an aesthetic experience. Note that the process moving to action is more likely to be triggered by the aesthetic experience, and that ethical considerations subsequently come to further spur the motivation for action. The urban public space is an excellent field to observe such process and the intertwining of aesthetics and ethics.

Such intertwining may be used by planners and by other urban stakeholders to gain support to their proposals for urban interventions. The subjective aesthetic experience of unpleasantness gains in generality when it is compounded with ethical motivations, enabling collective action. Micro-policies in the urban public space, like those addressing street design or mobility management, provide an excellent illustration of such intertwining of an aesthetic experience with ethical values, (1) by strengthening the claim for wider generalization of subjective judgements, and (2) by offering to those engaged in action small wins with immediate (aesthetic) satisfaction and strong ethical symbolism. Ultimately, it is the aesthetic-ethical connection which makes of the urban landscape "*markers of inclusion and exclusion in planning*" (Duncan, 2004) or "*a medium of identity formation and power relations*" (Mitchell, 1994).

Ironically, the theory and practice of planning engaging public spaces have often crystallized in a "dictatorship of the visual" in contemporary beautified cityscapes which, beyond hiding or displacing what is considered as unacceptable, introduce active practice of control over them (De Martine-Ugolotti and Genova, 2025). Modern commercial spaces, over-touristified neighbourhoods and fenced urban developments all share the traits of aesthetically led planning. Needless to say, far from begetting an aesthetic experience in the pragmatic sense, they are firmly imposed on city dwellers and visitors alike with their undisguised pretence of completeness and immobility. Such cityscapes can be not merely ugly but utterly disgusting, especially for those intertwining them with ethical considerations on power and domination. But such negative aesthetic experiences are overwhelming, unlikely to engage the wider array of people necessary to unfetter any collective action.

Current debates on the pervasive touristification of the cityscape can be read from a Deweyean perspective. For residents, familiarity, safety and identity are likely to be key traits in their everyday aesthetic experience. Such everyday traits can also trigger strong aesthetic experiences also in visitors sensitive enough to appreciate them. Aesthetically led planning, however, prefers the shortcut offered by blunt standardization of the public space for its subsequent commercialization. For residents and aesthetically aware visitors, the unpleasant moves to engagement; for massive tourism, it merely reduces commercial value.

The merely unpleasant, on the contrary, belongs to the unstable realm of the provisional; it is perceived as a temporal situation, a work-in-progress waiting- and even urgently calling- for our intervention. Therefore, it can be wishfully manipulated by planners as a way to gain momentum for subsequent collective action. One obvious example is tactical urbanism, especially within highly controversial sustainable mobility policies reallocating the street space. Whereas the negative aesthetic experience resulting from a car-dominated street or square is neutralised by daily routine and by the incremental way in which cars have conquered and transformed the cityscape, the aesthetic perception of the unpleasant by a handful of planners moves them into action, initially just to highlight with some minor painting and cheap street furniture the obvious inconsistencies of the situation.

Important to note that such tactical actions do not create a pleasant perception, very much on the contrary: the clearly provisional and unstable image tactical urbanism creates widens and generalizes an aesthetic experience that calls for subsequent action. But such call for action is not a move back to the original situation, due to the fact that now the unfairness of car-dominance has been taken to the forefront; it is that intertwining between aesthetics and ethics that make it possible to engage and move forward towards an alternative, more permanent (and expensive) design, in which the new power relations established by the tactical intervention are consolidated.

This example shows instability as one key feature of the unpleasant. If unaddressed, the unpleasant may deteriorate into the ugly (blighting). The ugly can claim universality, but it does not call as much for action as for simple cancellation, even if such cancellation is expensive in city planning. In fact, blighting has been profusely used by urban decision makers (and planners) as a strategy to subsequently claim the need to further adapt cities to cars (i.e. by increasing road capacity with expensive tunnels on the pretence of removing traffic from the surface). It is relevant to note that the aesthetic experience of ugliness, or the action for its cancellation, does not intertwine with any ethical considerations.

Planners dealing with the unpleasant: the case of street space

Cities- and particularly urban roads and streets- show how planners make use in different ways of the strength of the unpleasant to mobilize action. In some cases, they actually create the unpleasant as a way to highlight the moral inconsistency of the *statu quo* and to gain momentum for radical changes; in other cases, they provide more or less sophisticated aesthetic criticisms on the urban space, which often remain unnoticed but sometimes push decision makers to act, implementing more or less elitist projects with unexpected outcomes; in some cases, the unpleasant is left untouched by inaction, until it turns into the ugly or even the unbearably disgusting; in this case, the request for action does not come as much from planners as it does from outraged citizens or concerned decision-makers, asking planners for quick and radical change, although without challenging the causes at the root of such ugliness. The combination of the aesthetic power and ethical dimension of the public space is different in each case: respectively, with moral judgment triggering action, with aesthetic judgment claiming moral authority and with aesthetic judgment virtually ignoring moral considerations.

These approaches can be illustrated through three cases studies in Madrid, in which the planning response is ethically charged in different ways. The first case study corresponds to a tactical urbanism response provided by a street redesign in the south of Madrid (Vallecas, Arboleda street) in which power relations are first revealed and subsequently transformed. The second case study (Green Southwest Boulevard, A-5) shows a decades-long strategy of inaction leading to blighting, turning the unpleasant into the socially unbearable, and paving the way to the adoption of solutions based on the consolidation of the existing power relations in the distribution of street space. The third case study (Puerta del Sol) shows how a *beautification* attitude results in the accommodation of the public space to the pressure of touristification, changing power relations on the ethical grounds of fostering economic opportunities.

A similar itinerary is followed below in the description of each of the three interventions. After a short description, the paper examines (1) who are the actors that initially provide the judgment of unpleasantness, (2) what such actors identify with unpleasantness in the site, (3) the character of the moral considerations associated with the aesthetic judgment, (4) the actors whose interests are privileged or relegated by the aesthetic intervention and (5) the costs associated with the intervention.

Figure 1: *Tactical intervention in Arboleda Street, Vallecas District, Madrid (2019)*

Arboleda Street in Madrid provides access from one main transport hub in Vallecas District to a small University Campus, going through a blighted industrial area that has been waiting for decades the implementation of a residential development project. This semi-abandoned street served mostly as an on-street parking area for trucks and cars and induced high-speed traffic for those entering or leaving the Campus by car. The tactical action was implemented in 2018, installing (quite ugly) precast concrete barriers to expand walkways and painting an unprotected bike lane. This was well received by most street users, as well as by district residents, hoping that this would accelerate decisions about the larger regeneration project. Nevertheless, further action to consolidate the new distribution of the street space was postponed until the end of 2024, when the regeneration project for the main lot (*Tubos Borondo*, 137.074 m2, with 11.2 million of public investment) was finally launched. In accordance with such project, the final design of Arboleda street will consolidate the tactical intervention, privileging pedestrians and cyclists.

It is fair to say that the unbalanced distribution of the space in Arboleda street had remained generally unnoticed, until mobility experts and planners highlighted it through their tactical intervention, and the unpleasantness of the place was highlighted with the grey concrete barriers protecting pedestrians. In doing so, these experts and planners visualised how this "no-man's land" had been conquered by cars and trucks, not only neglecting soft modes, but actively expelled them. The aesthetic judgment was strongly intertwined with a moral judgment on the fair distribution of street space; in fact, it was even at the root of the action: the aesthetic unpleasantness was a consequence of wrong decisions in the allocation of the street space. Logically, the tactical intervention (and the subsequent regeneration project) privileges soft mode users as well as future residents, while relegating car traffic and on-street parking. The costs of the tactical intervention stayed in the tens of thousands and the public contribution to the regeneration project is 11.2 million.

Most of the surroundings of the road linking Madrid with the southwest of the country (Extremadura) and Lisbon in the outskirts of Madrid were in the past occupied by large military compounds and agricultural land.

The former were progressively abandoned since the 1980s, and the latter were replaced by high-density low-quality residential compounds since the 1950s. Urban growth, combined with the enlargement of the road to accommodate a motorway in 1968 created a progressively unattainable situation for residents.

At the end of the 1980s, as most of the military compounds had been abandoned, talks about a comprehensive regeneration plan for the whole area (named as *Operación Campamento*) proliferated, although with no tangible results. Traffic on the motorway kept growing and, in 2003, the new elected mayor announced a plan to replace the inner orbital motorway by a tunnel, including a tunnel for the 3 km of the Extremadura motorway closer to the city centre. This would not affect the area of *Operación Campamento*, but raised hopes among residents that a similar tunnel could sometime in future be built to get them rid of the motorway. Nothing happened, however, in the next decades, while residents experienced how their environment continued degrading. Demand management options to substantially reduce car traffic and traffic speed and allowing for the transformation of the motorway into a boulevard were analysed by some planners but such proposals were dismissed not only by decision makers afraid of the reaction of car users, by also by a part of the residents, encouraged by the active lobbying of the construction sector and others pushing for the tunnel option. Finally, in 2022, the project to build a 12-km long tunnel was approved, although only 3.2 km would be built in its first stage, started at the end of 2024, with a cost of € 408 million; the remaining of the 12-km tunnel will need to wait until the regeneration project of the old military sites generates enough cashflow to finance it.

Figure 2: *The A-5 in Batan neighbourhood, Madrid (2024)*

The area had been neglected for decades, since the first urban settlements started at the beginning of the XX century, in what is now known as Colonia Jardín, Batán and Lucero. Batán and Lucero already had a significant population in 1960, and shortly afterwards (1966-68), the road was enlarged and transformed into an 8-lane motorway, in some sections less than 1 meter away from residential buildings. The first buildings in Aluche, another residential development close to the motorway, appear in 1960 and the area is virtually fully consolidated at the beginning of the 1980s.

As traffic grew (and also as more pressing issues such as schools, public transport, basic equipment and parks were addressed), residents became more aware about the unpleasantness-turning-into-ugliness of their cityscape, identified the A-5 motorway as the main source of blighting, and mobilized with demonstrations

starting in the 1990s. They complained about noise, air quality, security and safety concerns, poor lighting of subway pedestrian crossing, and other nuisances linked to the motorway. For those in Madrid not living in the area, the neighbourhoods along A-5 were merely a no-man's land in the outskirts of the capital, very much an unnoticed place. If addressed in the 1990s or in the 2000s, the residents' concerns could still have been addressed with simple traffic and demand management measures to progressively reduce the number of cars and encouraging their users to try the alternative bus, metro and commuter train lines, but when this was tried, in 2018, it was probably too late. By then, the construction coalition had successfully created an alternative vision, replacing the motorway section by a long tunnel, as had been done 15 years ago with most of the inner orbital motorway. In spite of such strong opposition, the municipality introduced a traffic management scheme reducing speeds and capacity, but a change in the municipal leadership resulted in the removal of the concept after only 4 months of operation.

The aesthetic judgment associated to the unpleasant initially referred to the poor living conditions created by the motorway in already socially stressed neighbourhoods.

Surprisingly, as a way to strengthen the claim for the tunnel project, car users were also considered to be treated unfairly should traffic conditions be restricted. This resulted in planners developing a solution primarily addressing car users' interests (a tunnel with similar capacity to the existing motorway) and residents getting rid of the perceived nuisances. The project was named as the Green Southwest Boulevard. What is debatable is whether the resulting green corridor above the tunnel will be able to generate the sort of dynamics and liveability than the transformation of the motorway into a boulevard was expected to launch. Obviously, the costs for the taxpayer skyrocketed to the hundreds of million. The instability leading to radical action, in spite of high costs, grew incrementally due to the inaction of planners and decision makers.

The recent reform of Puerta del Sol can be seen as a good example of the adaptation of the public space to touristification. It could be said that virtually any mayor in Madrid has tried to leave its footprint in Puerta del Sol. A busy (if not messy) irregular crossroads of eleven streets, which took the form of a rectangular square in the XVI century and was transformed into its now characteristic semi-elliptical layout surrounded by homogenous 30-m high white façades in 1860. Since then, multiple reforms adapted this space to the claims of the day: leaving space first to trams and later to cars, setting, displacing or removing fountains and sculptures, placing or removing vegetation and trees... In 2009, after long and costly works to establish a major underground transport hub (including metro and commuter railway lines) and to dedicate most of the space to pedestrians, some thought that the time for reforms was over. And yet... only a four years later, the regional association of architects successfully lobbied the municipality to launch an international competition to redesign the site, on the basis that *Puerta del Sol* was lacking a well-balanced visual image.

Disorder was, therefore, in the essence of the unpleasantness felt by these professional body. No moral considerations were made here, beyond the certainty that "Madrid deserved better". Surprisingly for a call focused on aesthetical considerations, the obvious point that the landmarks located in this square were little more than a bunch of kitsch objects lacking artistic merit was not mentioned at any time by either those asking for action or those participating in the contest. The winning project (subsequently subject to some minor changes at the final implementation stage) provides a clean space, better suited for an occasional visit than for recurrent stand-byers, by rearranging its traditional landmarks. Although not implemented until now, the winning project also intended to replace the main entrance to the underground public transport hub with a more *discreet* one, as if it were better to hide the daily lives of citizens to allow tourists and visitors to enjoy a clean cityscape. The new layout implicitly relegated daily local passers-by and the few remaining residents in the vicinity of the square, while fostering its iconic value for occasional visitors and singular events. No significant changes in mobility behaviour were expected, as the site was already almost fully pedestrianized, although it could be argued that locals would probably prefer to avoid the site and use alternative routes instead of crossing such a space. Tax-payers footed a bill than reached € 12 million. Unpleasantness in this case seems to generate from elitist professional criticism (and ambition to intervene in a highly symbolic space) that allies with the ambition of

decision makers to intervene in such spaces; in fact, this has been a traditional mechanism in the history of urban planning and the source for the creation of both, revered public spaces and wasteful arrangements, the one destined to survive for generations, the latter just waiting for the next politician to convene another international contest.

Figure 3: *Tiding up Puerta del Sol, Madrid (2024)*

Conclusions

The unpleasant can be understood as a key aesthetic category, in spite of lacking the Kantian traits of positiveness, disinterest and universality. In fact, the absence of these traits is what can turn the unpleasant- and more generally *negative aesthetics*- into a leverage for action in planning. For turning into action, the aesthetic judgment of the unpleasant is often intertwined with moral judgments, although in different ways. For example, planners in tactical urbanism often challenge consolidate power relations in the public space and aim at rebalancing them, provisionally with visually unpleasant arrangements to gain legitimacy for such rebalancing as a way to build up the consensus to consolidate the new power relations with more permanent and costly designs. Planners in traffic engineering may prioritise the consolidation of pre-existing power relations, generally favouring car traffic, and use the unpleasant and inaction towards its deterioration as a way to gain support for costly infrastructure solutions preserving car hegemony. Planners following the city beautification tradition may use unpleasantness as a label to use in elitist aesthetic criticism of existing public spaces, to influence decision makers and undertake dubious public space reforms on the ground of fostering economic development opportunities. This has been illustrated by three case studies in Madrid.

Besides showing different ways of identifying the unpleasant to make of it a force for change, the three case studies also show other differences. First, in the different relevance they give to everyday experiences, characterised by the prioritisation they give to certain actors compared to others: Everyday experiences become the focus for planners when residents or daily passers-by are put at the centre. This is pretty much the case in *Vallecas* and much the contrary in *Puerta del Sol* (where the casual experience of tourists or attendants to events is clearly privileged). The third case study (the A-5 motorway) stands somewhere in the middle: residents are given a brand new public space in what used to be a major barrier and a source of nuisance and blight, but planners have not cared much about the residents' everyday practices and how these practices may be affected by the new design; there is not much clue about whether everyday life will go on without making much use of the renovated space or will change in unforeseen ways, for good or bad.

Another difference revealed by the three case studies, closely linked to the ethical dimension, refers to the ambition for transformation of dominance and submission relationships. In the three case studies, mobility and public space distribution are at the centre of the intended actions, although with quite diverse sensitivities. In Vallecas, space reallocation is at the centre of the tactical action and of the subsequent permanent intervention it intends to kick off; therefore, there is a significant change in the dominance relationships, changing priorities from cars and trucks to pedestrians and cyclists. In the A-5 motorway, there is a similar push for change, although with a significant difference: residents and pedestrians (as well as ,eventually, public transport users) are expected to benefit, but without compromising the conditions of car traffic; in fact, the intervention can be better understood as a way to protect the mobility privileges of car users at a moment in which they could be challenged by residents and other actors in the public space. In Sol, the pedestrians-cars relationship had already stopped to be relevant many years ago, and conflicts were now growing between different kinds of pedestrians: close-by residents, daily passers-by, tourists, and occasional attendants of flagship events, with these two already establishing their dominance; the intervention obviously takes sides in their favour.

The case studies also show how the social (and the planners') toleration to the unpleasant is quite different depending on the parts of the city under scrutiny. Central public spaces have historically been the most sensitive places to the criticism of mainstream planners as well as urban designers that see intervention in these areas as an opportunity to gain social prestige. On the contrary, the no-man's land in the outskirts of cities is likely to remain unnoticed for decades, and even when they receive the attention of advocacy planners or the living conditions attain the unbearable sparkling the protests of residents, the planning bureaucracy and decision makers are slow to react. Interestingly, once they receive the attention of a wider group of stakeholders, such places may be perceived by developers and infrastructure contractors as an investment opportunity provided the political and social pressure forces decision makers to poured tax-payers' money in expensive infrastructural solutions, like the A-5 tunnels analysed above, and they actively engage in establishing coalitions to push for such expensive solutions. In short, planners actively participate in the social construction of the unpleasant, although in different ways, and such differences show how planners align with different urban development agendas.

Email: anja.pejovic@polito.it, riccardo.pollo@polito.it

Abstract
Car-centric urban planning has marginalised the social dimension of the streets and continues to cause various environmental and health issues. Cities have been developing strategies to address those challenges, transforming streets into public spaces that encourage active mobility. However, these efforts often lack participatory processes and heat mitigation strategies, both considered essential in such interventions. This paper proposes a methodology to address those issues, combining citizen science-based methods, such as thermal walks, and technical and administrative expertise. The four-phase participatory framework encompasses citizen engagement, data analysis, co-design of adaptation scenarios and their evaluation, combining the lived experience with the scientific knowledge and administrative considerations. The proposed approach provides inclusive and context-sensitive adaptation scenarios, enhancing both community acceptance and heat stress mitigation.

Keywords: Street transformation; Microclimate; Thermal comfort; Citizen science; Participation

1. Introduction

Most cities today are dependent on motorised transportation and the use of private cars. The role of the street has become predominantly to maximise transportation efficiency, disregarding its social dimension and placing people on the margins of public spaces (Ravazzoli and Torricelli 2017). The car-centric urban planning has caused various issues related to environmental pollution, energy consumption and inactive lifestyles (Nieuwenhuijsen and Khreis 2016; Mueller et al. 2020). To address these challenges, urban planning has recently prioritised a more sustainable, compact development characterised by higher density and diversity and shorter distances (Giles-Corti et al. 2016; Nieuwenhuijsen 2021). However, while this resulted in a decrease in CO_2 emissions and an increase in sustainable mobility opportunities, new issues arose from compact city planning that have detrimental impacts on human health. These include exposure to extreme heat, air and noise pollution, as well as a higher density of motorised traffic (Mueller et al. 2017; Khomenko et al. 2021; Nieuwenhuijsen 2021). In recent years, diverse strategies have increasingly been developed to respond to these problems, focusing on the redevelopment of streets and public spaces and promoting active mobility, in order to create more liveable, human-centred spaces. Reclaiming the spaces dedicated to motorised vehicles allows the transformation of the street function to an open public space that generates different aspects of urban life, affecting the quality of urban spaces, social interaction, physical activity, economic and environmental factors. These strategies vary from single street transformations to more complex urban models such as Superblocks in Barcelona or Low Traffic Neighbourhoods in London. They mainly involve the reduction of motorised traffic, a measure that often faces resistance from residents, making these strategies a controversial topic. Experiences from already implemented strategies strongly highlight the need for the inclusion of citizens in the development of such plans and interventions (Cruz and Paulino 2020; Lunetto et al. 2023; Vásquez et al. 2024). Participatory approaches enable integration of the needs and perspectives of the citizens in decision-making, leading to higher acceptance and usability of public spaces. Citizen engagement in the development of these interventions ensures their alignment with the community's requirements, while addressing the issues of urban development and climate change (Rodriguez and Komendantova 2022; Sondou et al. 2025).

On the other hand, these transformations could help mitigate the heat stress of pedestrians while promoting liveable streets and active mobility (Nieuwenhuijsen 2021). However, there is very limited evidence of thermal comfort considerations in such interventions, often considering the improvements in qualitative terms, without quantifying the actual impacts. This indicates a gap between the research on the issues of thermal comfort and heat mitigation and its implementation in urban planning.

Recognising the importance of the presented issues and their interconnections, this study focuses on the development of a methodology that integrates public participation and heat mitigation into street transformation processes aimed at promoting active mobility.

2. Methodology development

Due to the need to integrate participative processes and thermal comfort into street redesign plans, we propose a participatory framework that brings together citizens, experts and public administration. The framework adopts citizen science-based thermal walks, focusing on dynamic thermal comfort, to assess and measure thermal experience, with the aim of co-designing the adaptation scenarios. The process consists of four distinctive phases that follow after the need for intervention has been identified (Fig. 1).

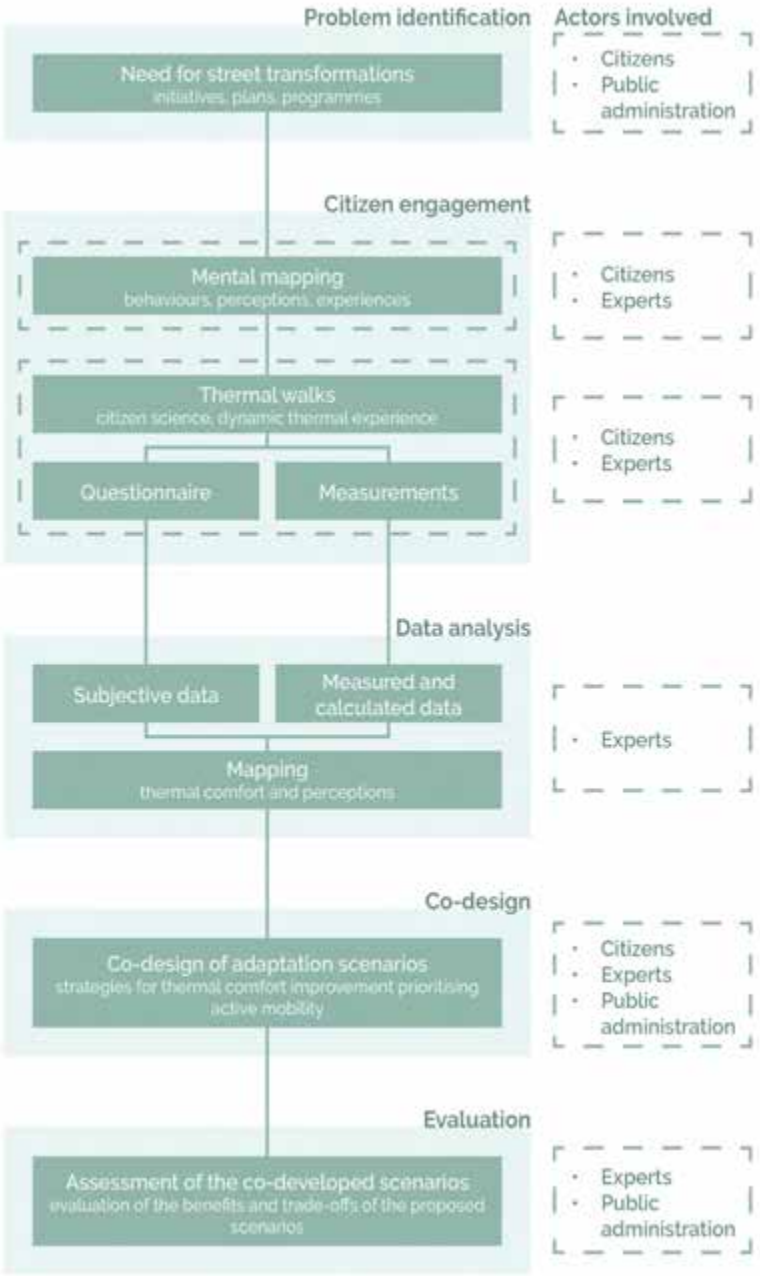

Figure 1. Phases of the proposed framework.

2.1 Citizen engagement

The phase of citizen engagement consists of two main activities – mental mapping and thermal walks. These activities have been used in the literature to examine both subjective thermal perceptions (Moderow et al. 2023; Květoňová et al. 2024) and to investigate dynamic thermal experiences (Vasilikou and Nikolopoulou 2020; Xie et al. 2022). Citizen engagement, especially thermal walks activities, is based on a citizen science approach. Citizen science has increasingly been utilised and studied as a method of empowerment, promoting behavioural change and collective action, while simultaneously increasing knowledge and awareness of the public and crowdsourcing data for research purposes (Sardo et al. 2024). This citizen science approach has been applied in various projects and studies, including microclimate research (Květoňová et al. 2024) and sustainable mobility (Sardo et al. 2024), highlighting the importance of citizen involvement in co-designing projects and policies. Incorporating citizen participation into street redesign processes could promote more inclusive, context-sensitive and scientifically informed urban planning practices.

2.1.1 Mental mapping

Mental or cognitive maps have been used to study people's perceptions of thermal comfort in urban environments, expanding the insights obtained using solely quantitative approaches. This qualitative method captures subjective experiences and behavioural adaptations, drawing on people's experiences to identify hotspots, cool areas, comfortable and uncomfortable spaces (Lenzholzer 2010; Lehnert et al. 2023; Moderow et al. 2023). As such, it serves as a valuable tool in participatory planning and climate adaptation, facilitating public engagement and co-creation (Foshag et al. 2020; Moderow et al. 2023). Cognitive maps emphasise the psychological and contextual aspects of thermal perception, which might differ from the objective data gathered through measurements or remote sensing (Květoňová et al. 2024). One limitation of this method is its tendency to focus on easily accessible or more frequented locations, potentially neglecting peripheral or less familiar areas (Květoňová et al. 2024). Nonetheless, this approach could be interpreted as a means of identifying locations with higher levels of public interest or activity, supporting prioritisation of possible intervention areas based on actual use rather than solely on objective data. Mental maps, combined with quantitative methods, could be instrumental in exploring differences between thermal expectations and thermal sensation and real thermal conditions, enhancing public participation in climate adaptation.

2.1.2 Thermal walks

Studies on microclimate conditions in urban areas often rely on static measurements and models to investigate thermal comfort (Ravnikar et al. 2023; Zhao et al. 2024). However, the static tools fail to account for diverse conditions experienced by humans while traversing urban spaces (Zhao et al. 2024). Dynamic thermal experience is based on different factors, including continuously changing environments (Lau et al. 2019; Zhao et al. 2024), psychological responses (Wang et al. 2022; Zhao et al. 2024), psychological responses (Vasilikou and Nikolopoulou 2020; Dzyuban et al. 2022; Jia et al. 2022; Mohite and Surawar 2024), thermal history and sequence of exposure (Nakayoshi et al. 2014; Xie et al. 2022; Zhao et al. 2024), alliesthesia (Dzyuban et al. 2022; Li et al. 2023; Zhao et al. 2024) and environmental variations (Lau et al. 2019; Lee et al. 2020; Dzyuban et al. 2022; Jia et al. 2022; Li et al. 2024; Mohite and Surawar 2024). To capture these different factors, recent studies have been using the thermal walks method, involving participants in assessing subjective perceptions along routes accompanied by mobile microclimate measuring devices, emphasising the importance of thermal perceptions and sensations for overall thermal comfort (Nakayoshi et al. 2014; Vasilikou and Nikolopoulou 2020; Dzyuban et al. 2022; Xie et al. 2022; Květoňová et al. 2024; Mohite and Surawar 2024). Studies employing thermal walks vary in their methodology, including the number of walks, instruments used and the duration of the study, based on their aims, type of study and availability of participants. Typically, thermal walks studies involve 10-15 participants (Vasilikou and Nikolopoulou 2020; Dzyuban et al. 2022; Květoňová et al. 2024; Mohite and Surawar 2024). Nevertheless, while some studies conduct only a single walk per participant (Dzyuban et al. 2022; Květoňová et al. 2024), others adopt a longitudinal approach with repeated walks across two seasons and multiple times of day (Vasilikou and Nikolopoulou 2020; Mohite and Surawar 2024). Most studies focused on the hottest period of the year, while longer ones considered both cold and warm weather. These methodological differences lead to significant variations in the amount of collected data, ranging from tens to hundreds of measurements and questionnaires.

Citizen science-oriented thermal walks, proposed in this study, have a twofold objective - to collect dynamic thermal experience data and to help raise citizens' awareness of the excessive heat issues and the potential of adaptation strategies, in terms of both the structural modifications, e.g. green infrastructure or changes in materials, and behavioural changes. The walks consist of two main activities, participatory microclimate measurements and a thermal perceptions questionnaire. During the walks, the citizens carry out the measurements using portable devices. Devices used in citizen science projects and experiments with similar aims are mainly low-cost mobile weather stations, measuring essential parameters such as air temperature and relative humidity (Kulkarni et al. 2022; Peña-Rodríguez et al. 2022; Hohenegger et al. 2023; Loglisci et al. 2024). These parameters mainly suffice the objectives of such studies, allowing the collection of the data needed for a better understanding of the weather conditions. However, to ensure the validity and precision of the collected data, additional measurements should be performed using professional equipment, e.g. a professional stationary weather station. The mobile measurements performed by the citizens allow real-time interpretation of the measured values and parameters, enhancing understanding and further raising their awareness of the heat-related issues in the urban areas.

The assessment of the people's perceptions is a fundamental component of the thermal walks. Subjective thermal experience is mainly examined through questionnaires and surveys based on the standards such as ISO 10551:2019 (International Organization for Standardization 2019) and ASHRAE Standard 55 (American Society of Heating 2023). The questionnaire includes personal data such as age, gender, weight, height and clothing information of the participants, in order to better understand the metabolic rates and clothing insulation, which are critical in thermal comfort investigations. To investigate the dynamic thermal experience, the questionnaire should include questions on thermal sensation, comfort and preference in different points of the walk, accounting for variations between different urban configurations and exposure (Vasilikou and Nikolopoulou 2020; Dzyuban et al. 2022; Xie et al. 2022; Mohite and Surawar 2024). Additionally, comparing instantaneous sensations at each point with the whole-trip experience would provide a more comprehensive understanding of the thermal experience during the walks (Zhao et al. 2024).

2.2 Data analysis

The analysis of the data collected through mental mapping and thermal walks follows different steps.

The data collected by the mobile measurement devices should be validated against that collected by the weather station on-site, to ensure their accuracy and reliability. Firstly, the raw sensor data needs to be pre-processed to remove statistical outliers before further analysis is performed (Schilt et al. 2023).

The methods commonly used for data validation between the measurement devices involve statistical validation methods and calibration techniques. Statistical metrics include Pearson and Spearman correlation coefficients, Mean Absolute Error (MAE), Root Mean Square Error (RMSE), sensor bias and regression analysis (Kureshi et al. 2022; Rivera et al. 2023; Schilt et al. 2023). Linear regression and machine learning methods are often used to calibrate low-cost sensors against reference data (Yamamoto et al. 2017; Kureshi et al. 2022).

Data collected from the thermal walks and the weather station could be used for the numerical simulation of thermal conditions. The simulations are often performed using computational fluid dynamics (CFD) software, e.g. ENVI-met, Ansys Fluent, or energy balance models (EBM), such as RayMan, SOLWEIG. These models mainly enable the spatial distribution of the weather parameters, including the calculation of thermal comfort indices such as Physiological Equivalent Temperature (PET), Universal Thermal Climate Index (UTCI) and others. Data obtained from the simulations should be further analysed and validated against the measurements. Methods commonly used for validating simulation performance are based on statistical approaches and metrics, e.g. RMSE, MAE, Mean Bias Error (MBE) (Peng et al. 2023; De Quadros et al. 2024).

Finally, the outputs of the questionnaire could be compared to the measured and simulated data to highlight possible differences between subjective perceptions and objective data. The data could be further analysed to evaluate different factors affecting the judgement of the participants. Scientific literature often employs

statistical analysis methods such as Spearman's correlation (Dzyuban et al. 2022), Pearson's correlation (Ma et al. 2021), path analysis (Chan et al. 2017; Peng et al. 2019; Ma et al. 2021) to understand the relationship between different variables.

The analysed data should be mapped to enable spatial visualisation of the data in different layers, facilitating the further steps of the process.

2.3 Co-design

Co-design is a collaborative approach that unites citizens, experts and public administration in the process of developing street transformation plans based on the knowledge and lived experience. This method gives voice to the community members, empowering them to shape innovative and contextually relevant outcomes and solutions (Echaniz et al. 2022). The importance of this approach is becoming increasingly recognised in urban interventions where the success depends on social acceptance and usability (Lunetto et al. 2023; Vásquez et al. 2024).

This phase involves all relevant stakeholders and community representatives to ensure inclusivity and integration of local values while taking into account technical knowledge and administrative considerations provided by experts and public authorities. The co-design workshops are based on the data and experience collected through citizen science experiments and mapping activities. The workshops are structured in four consecutive sections:

1. Presentation of findings and elaborated data from the previous activities and discussion, allowing all participants to share their personal experiences and insights.

2. Identification of priority areas and challenges for the interventions.

3. Conceptualisation of the possible scenarios and strategies addressing both heat-related issues and active mobility.

4. Refinement of the scenarios with the expert feedback and administrative constraints.

The outcome of the co-design phase is a set of street transformation scenarios that form the base for the evaluation and policy considerations in the following phase.

2.4 Evaluation

The evaluation phase is a crucial component aimed at critically assessing the co-designed adaptation scenarios from technical and socio-environmental perspectives. The scenarios are evaluated not only for thermal comfort improvements, but in a broader framework of benefits and trade-offs that include environmental, economic, social, health and mobility impacts, ensuring feasibility and effectiveness of the solutions. The multicriteria framework reflects the multifunctional nature of street spaces, highlighting the complexity of urban transformations. Due to the need to integrate the previously mentioned aspects and the stakeholder views and opinions, a multicriteria decision analysis (MCDA) approach is adopted. MCDA is a systematic methodology that combines different input factors with the considerations of stakeholders to compare and rank different project options (Huang et al. 2011).

The framework of different impacts is based on different indicators, depending on the types of strategies and interventions in the scenarios. Potential indicators and assessment methods are presented in Table 1.

Table 1. Framework of different impacts, potential indicators and assessment methods.

Impacts	Potential indicators
Environmental	Thermal comfort improvement Biodiversity benefits Air pollution reduction Noise pollution reduction
Economic	Cost of implementation Maintenance costs Impacts on property values Impacts on local businesses' activity
Social	Use of space Inclusivity Accessibility Safety
Health	Physical activity levels Mental health benefits Reduction in heat and air pollution exposure
Mobility	Changes in mobility flows and modes Changes in traffic speed and volume

3. Discussion

The participatory methodology developed in this study integrates thermal comfort considerations and participative processes into the development of street transformation plans. The four-phase framework is based on a holistic approach to urban adaptation, bridging the gap between scientific research, decision-making and local experience.

One of the strengths of this methodology is the combination of qualitative and quantitative approaches. Through citizen science-based thermal walks and participatory mapping, the process captures both subjective thermal experience and objective microclimate conditions. This approach helps translate and reflect the lived experience of the citizens in the design processes, fostering a bottom-up approach. The co-design phase involves citizens, experts and public authorities in the development of adaptation scenarios, enhancing the sense of ownership and legitimacy, essential for the acceptance and long-term success of the projects (Echaniz et al. 2022; Lunetto et al. 2023). The framework is further strengthened by adopting a multicriteria decision analysis approach to evaluate the co-developed scenarios. The comprehensive assessment encompassing environmental, economic, social, health and mobility dimensions, as well as stakeholders' perspectives, highlights various benefits and trade-offs of the solutions while supporting transparency in decision-making (Huang et al. 2011).

Despite its strengths, the methodology has several limitations. Firstly, the reliability of citizen-collected data can vary, especially when using low-cost devices. The framework addresses this issue through validation with professional equipment and calibration, however, the potential for error remains (Kureshi et al. 2022; Schilt et al. 2023). Secondly, a common challenge of participatory processes is ensuring inclusivity and broad participation. Citizen science activities primarily attract individuals already engaged in similar activities or with specific interests, potentially leading to underrepresentation of less vocal or marginalised groups (Květoňová et al. 2024).

The methodology provides opportunities for further research and practice in several ways. Longitudinal studies could use citizen-led thermal walks as a method to assess the impacts of the adaptation strategies after the implementation, enhancing and fostering participatory approaches long-term. Additionally, citizen engagement could be facilitated through the development or integration of digital tools, such as mapping platforms or apps for data collection, thereby enabling the accessibility of the data. Finally, the methodology could be tested across

different contexts, such as diverse climates or socio-economic environments, in comparative studies to help refine it and test its adaptability.

4. Conclusion

The contemporary street designs still prioritise motorised transport infrastructure, neglecting their potential as liveable public spaces. This study proposed a participatory methodology for integrating citizen engagement and thermal comfort considerations into street redesign processes aimed at promoting and encouraging active mobility, addressing the gap between research and its application in urban adaptation plans and strategies. By combining citizen science-based thermal walks, mental mapping, co-design and multicriteria evaluation, the framework unites technical and administrative expertise with lived experience, providing inclusive and context-sensitive adaptation scenarios.

The proposed approach addresses two significant gaps in current urban planning practice – the lack of thermal comfort considerations and the need for citizen participation in decision-making. By involving citizens directly in data collection and scenario development, the framework enhances the scientific basis of interventions while increasing public awareness, sense of ownership and acceptance. The methodology is further strengthened through multicriteria evaluation, assessing environmental, economic, social, health and mobility dimensions, accounting for benefits and trade-offs of each scenario.

While the methodology demonstrates significant potential for creating more liveable and people-centred open spaces, several limitations remain, mainly regarding the inclusivity of participatory processes and technical challenges of data analysis and evaluation. Future work will focus on testing and refining the methodology on a case study of Turin, within the Interreg Alpine Space project COMMONAIR.

Finally, this approach provides the foundation for more inclusive and adaptive urban street transformations. The framework fosters a replicable process that promotes rethinking of the streets as healthier and people-centred public spaces.

Reclaiming or excluding?
The evolution of waterfront redevelopment and public space in Genoa

Necdet Ayik
Department of Architecture and Urban Studies, Politecnico di Milano
necdet.ayik@polimi.it

Abstract
This research revolves around how the waterfront redevelopment paradigm has chronologically shifted and its direct impact on public grounds. Increased influence of the market, changing involvement weights of stakeholders, the underlying rationale for waterfront regeneration, and their reflection on the hinterland's spatial and programmatic development of the waterfront projects from the emergence of the phenomenon to the current timespan are discussed by addressing back to the main idea of the "reclaiming waterfronts for the public". This issue is comparatively examined in terms of the redevelopment process of Genoa's urban waterfront to evaluate the public nature of the transformed spaces, from the Porto Antico's regeneration to the ongoing Waterfront di Levante redevelopment project.

Keywords: Urban waterfront redevelopment, publicness, public space

1. Introduction

Waterfronts have long been recognised as an essential component of a city's identity, and they have become heavily influential for cities' economic, social, and environmental improvement. Historically, these areas have created an expanded surface for the interaction of different urban actors and functions, where everyday activities intertwine with the maritime operations. However, the intense spatial occupation of port infrastructure has significantly disrupted this open nature of waterfronts, once enabling fluid interaction between the water and the city. Maritime activities that revolve around the industrial, trade, and transportation functions suppressed the ordinary utilisation that led to the rupture of public life and urban waterfronts.

Following the mid-20th century, the traditional maritime activities experienced a notable decline that decreased spatial needs for maritime operations (Kostopoulou, 2013; Taufen and Yocom, 2021). Particularly, the progress in the naval technologies that require advanced technical infrastructure and the introduction of containerisation to the maritime transportation resulted in the relocation of ports outside the perimeters of the urban areas (Kokot, 2008). While forming the contemporary port infrastructure, the inner-city waterfronts and historical port areas became *"ghost districts"* suffering from industrial structures, refineries, wastes, and pollutants (Hein, 2016). As a result of this circumstance, waterfronts became vacant spaces inside the city. This phenomenon spread to port cities worldwide, signalling the beginning of waterfront rehabilitation projects. In other words, urban planning projects have focused on waterfront restructuring, also referred to in the literature as waterfront *"redevelopment"*, *"regeneration"*, *"revitalisation"*, *"renaissance"*, or *"rehabilitation"* with the primary goal of converting underutilised or abandoned port and industrial areas into vibrant, mixed-use districts that integrate residential, commercial, recreational, and cultural amenities (Kostopoulou, 2013).

Beyond the initial port models that focused on the port development such as "anyport" by Bird (1963), Hoyle (1989) introduced the model of "*Stages in the evolution of port-city interrelationship*" that included *"redevelopment of waterfront"* as a stage in between 1970s-1990s when urban renewal is situated in the original core. Hoyle (2000) expanded the model by introducing the next stage, *"renewal of port/city links,"* from the 1980s, where he emphasised the spatial integration/new connections between port and city via the influence of globalisation and intermodalism, and how port roles are transformed. Subsequently, Schubert (2008) summarised the typical trajectory waterfront regeneration in different stages: initial derelict and disuse of former ports, the relocation of ports outside of urban centres, idle areas and buildings in the former port areas, visioining the potentials of waterfront for reallocation, implementation and re-functioning the area by introduction of new urban/ architectural program and revitalisation. It remarks on the importance of waterfront redevelopment as a crucial

step while examining the port-city relationship.

The early examples of waterfront redevelopment emerged in the North American context, particularly through well-known and highly influential projects that shaped subsequent initiatives. As cities such as Baltimore, Boston, and San Francisco became widespread, waterfront redevelopment projects also gained interest in Europe and later spread to Australia and Asia (Hoyle, 2000). Furthermore, the earlier projects' substantial impact also influenced how the waterfront redevelopment projects would be realised in the upcoming decades, especially with similar urban programs, design approaches, and planning strategies, widely considered in the literature as "*Baltimore syndrome*". The early waterfront redevelopment initiatives primarily aimed to recontextualise the underutilised port areas by introducing various urban functions, including predominantly residential, commercial, recreational, and cultural, mixed-use purposes for reclaiming the edge of the city (Breen & Rigby, 1996). Urban waterfronts have undergone a paradigm shift, moving from being centres of production and transition to spaces mainly focused on consumption and experiences.

Starting from the beginning of the 21st century till the current timeframe in waterfront redevelopment projects points to another important milestone. Alongside the common challenges of urban regeneration under neoliberal policies (Harvey, 2002), the most recent instances of waterfront redevelopment initiatives reflect the significant influence of market pressure and dominance over the primary goals observed in the earlier stages (Bassett, Griffiths and Smith, 2002; Pinto and Kondolf, 2020). In many waterfront redevelopments, the orientation shifted towards economic development to attract investment. Gradually, this augmented influence of the private sector in the current period led to a prioritisation of economic returns over broader community interests, resulting in the development of waterfront spaces that primarily cater to affluent residents, tourists, and consumers (Oakley, 2009; Cheung and Tang, 2015; Avni and Teschner, 2019). These have affected the involvement of private and public sectors, governance, and funding models, which are fundamentally related to waterfront redevelopment projects' spatial, social, and economic outcomes.

The commodification of waterfront spaces has given rise to concerns regarding the accessibility and inclusivity of these areas for all segments of society (Chan, 2020). Especially the discussions around the community ownership and public access rights (Sairinen and Kumpulainen, 2006; Huang et al., 2007; Attia and Ibrahim, 2017) have been the topic of planning conflicts in the waterfront redevelopment projects. Even though waterfronts have been widely considered and experienced as collective areas of the cities, as urban commons (Iovino, 2016), the role of a community in the course of transformation has been overlooked (Cheung and Tang, 2015; Iovino, 2018). This illustrates the significance of examining the public space and the dimensions of publicness in the scope of waterfront regeneration processes to understand shifting paradigms and dynamics for evaluating increased capital pressure and its spatial and programmatic reflections. Such assessment offers insight into the extent to which these spaces serve the needs and interests of the public, promote social equity, and contribute to the overall quality of urban life, and how the assessment could offer insight into the social equity and contribute to the overall development of the urban waterfront and the city.

This paper examines the shifting dynamics in the waterfront redevelopment under the influence of economic priorities and commodification of space, which necessitates an examination of the notion of publicness and the qualities of public space in the context urban waterfronts to understand better the social, spatial, and programmatic implications of waterfront regeneration in the longitudinal term dating back from the first applications till the ongoing projects. Genoa Waterfront is a prime case study investigating these transformations and examining challenges and opportunities associated with balancing economic development and public interests. The issue is assessed through the lens of publicness and the dimensions of publicness to provide a comprehensive analysis of the waterfront redevelopments in different terms but in the same context, as well as their impact on public spaces created and considered in the hinterland of the waterfronts. While investigating the inter-generational implementations, particular attention is given to the narrative, actors, and stakeholders, the process of the projects, and the physical, social, and programmatic outcomes in the selected case study to draw broader conclusions about the nature of waterfront redevelopment and public space.

2. Scope and Context

Genoa's case study was selected because of the multi-layered trajectory of waterfront redevelopment initiatives. The context displays rich examples of different governance and management strategies and the economic infrastructure, representing various public-led and private-led redevelopment schemes. Furthermore, interventions realised in different periods also allowed for the longitudinal study. The temporal scope of the project spans from the Genoa Urban Regulatory Plan in the 1980s to the current time. Similarly, the spatial scope of the project includes Porto Antico, Darsena, Ponte Parodi and the eastern section of Genoa's waterfront in the boundaries of Waterfront di Levante redevelopment -Genoa's former fair area (see Figure 1).

Figure 1: Genoa's waterfront in the spatial scope of the research, edited by the author over the satellite image from Google Earth (February 2025)

This study is grounded in the qualitative framework for examining the contested evolution of Genoa's urban waterfront. The analysis was conducted by reviewing archival documents, policy analysis, interpretive mapping, and spatial assessment based on the ownership, management, accessibility and inclusivity model to investigate the dimensions of publicness more deeply and reveal the patterns of the paradigmatic shift. A wide range of sources, including urban plans (starting from 1980), port plans, design proposals, competition entries, municipal documents, secondary literature and news articles, have been consulted to contextualise the research. Moreover, the mapping process of the different timeframes and diagrammatic representation has been completed via digitalisation of the historic orthophotographies and maps using GIS tools.

3. The Evolution of Genoa's Urban Waterfront Redevelopment

3.1. The Prologue

The emergence of the first waterfront redevelopment attempts can be traced back to *"Il Piano Regolatore Generale della Città di Genova (PRG) 1980"*, which can be regarded as the initial blueprint for the transformation of Genoa's waterfront. This regulatory plan framework followed the municipal approval in 1976 and its subsequent

ratification by the regional authorities in 1980. Considering the neglected waterfronts of the city, Darsena was identified as a place for introducing various urban functions alongside the maritime functions in the city's historic port. The plan aimed to facilitate technological areas, sports areas, and educational activities in the port area (Gastaldi, 2010). This master plan was followed by the "*Studio organico d'insieme del Centro storico*" studies in 1983 by the municipality, with the emphasis on the recovery of the port and the increased interest in the connection of the historic city with its waterfront (Gastaldi, 2010).

Simultaneously, the municipality of Genoa appointed six different architects in the different sections of the waterfront, and the architect Renzo Piano's engagement in the regeneration of the Molo district in the scope of 2.2 hectares of urban area (Tasso, 2015) marked a significant turning point for the urban waterfront of Genoa. Central interventions revolved around the two important topics: recovery of the Molo district and the newly introduced service hub; furthermore, the design included the large square at Via Turati by re-locating the street in subterranean level and introducing three main buildings longitudinal towards the sea that house hotel and conference centre at the docks (Tasso, 2015; Gastaldi and Camerin, 2020). However, the project has not been implemented due to the lack of a financial plan, the issue of scale, and operational struggles (Gastaldi and Camerin, 2020). In summary, this period can be considered the starting point in identifying the waterfront's potential.

3.2. Early Initiatives and Porto Antico Redevelopment

The rest of the 1980s witnessed a growing awareness of the necessity to revitalise the city's waterfront areas, and two different initiatives came to the fore in the historic port. Genoese entrepreneurs introduced the first set of proposals for redeveloping the historic port into a tourist port that accommodates marina and touristic functions. The second set of initiatives was promoted by public administrations, highlighting the creation of a large exhibition area for the Genoa Expo 92' and the enhancement of port activities; even though the primary plans for the exhibition were to locate the exhibition areas outside of the city centre perimeters or introduction of a platform on the sea (Gastaldi and Camerin, 2020). Moreover, it is important to note that both proposed projects shared the exact location and were developed in the same timeframe at the initial stage.

These entrepreneurial plans started with the Newport project designed by P. Gambacciani in 1984, and the project scope included the areas of the historic port from Darsena to Magazzini del Cotone, where Renzo Piano's first proposal was also located. The key element of the project was the programmatic conversion of the docks and elongation of the docks towards the sea that form the marina. The project's program aimed to enhance commercial identity in the historic port by introducing a marina, a hotel, a shopping centre, and entertainment facilities heavily influenced by North American instances (Tasso, 2015). The first scheme was followed by the updated version of the project in 1986, which was predominantly concerned with the economic parameters of the project. The revision was proposed to include reduced boat capacity in the marina, a multifunctional building with a conference centre in Ponte Spinola, and restoration of the Magazzini del Cotone. Although the project had not been realised in the exact location, this created a groundwork for the upcoming development of the Marina Porto Antico at the beginning of the 1990s. The main decision in terms of relocating this development plan arose from the administration's intention to allocate the area for the Expo'92, following the decisions suggested in the "*Triporto*" commission, which was composed of members from regional, municipal, and port authorities in 1986 and later approved in 1988. The tourist port project has been realised in the Ponte Morosini-Ponte Spinola area, accommodating the initially proposed similar functions such as hotel, residences, and commercial services, and designed with a complex connection of piers and four interconnected buildings during the period spanning from 1991 to 1995. The project has been realised with private investment alongside the limited contribution of public funds.

However, at the same year, private bodies and investors suggested the "Portman Project" consist of the famous cone with 262 meter high designed to accommodate hotel functions, the artificial island in the heart of the Porto Antico served as a triangular base for the cone and designed in four different levels with commercial, tertiary, touristic functions. In the following period, due to the increased criticism of the public and concerns regarding the conflict it represents with the port and city plans, the plan was rejected and not realised.

Along with Newport and Portman's project proposals, public initiatives were being discussed for the Molo Vecchio and Magazzini del Cotone area for the international exposition of Genoa in 1992. As mentioned following the approval of the plan that includes the decisions in the commission, situating the exhibition areas in "*Porto Antico*" -the historic port of Genoa- was a result of Renzo Piano's preliminary studies and the proposal of "*Via San Lorenzo al Mare*" connecting the city to the sea in 1984 (Gastaldi, 2010; Gastaldi and Camerin, 2020). The project was designed by considering the San Lorenzo street elongation towards the sea as a new pier to create the central axis from the historic centre to the city's old port with newly introduced commercial and public functions. The project evolved further by changing the axis from via San Lorenzo to via Ponte Reale, modest filling in the docks, and adaptive reuse strategies for the historic warehouse of the "*Magazzini del Cotone*" to house the exposition in 1985. During this period, the officials visited Baltimore to analyse the port redevelopment. They were particularly inspired by the aquarium as a typology for future intervention in the historic port of Genoa (Tasso, 2015). Following the updates of the project in 1987 and the delivery-approval period in 1989, the design of the project was completed with the adaptive reuse of the Magazzini del Cotone as an exhibition centre and conference facility, the construction of the aquarium, and the introduction of commercial activities to the area. Moreover, the total intervention area was 90.000 square meters by considering the transformation of the existing volumes and new structures; the main functions were defined as exhibition spaces for the Expo, conference centre, commercial facilities, aquarium, cinema, and service spaces (Renzo Piano Foundation, n.d). The project has been completed with a public-private partnership, with a predominant share of funding provided by public authorities by the consortium between the Municipality of Genoa, the Liguria Region, and the Genoa Chamber of Commerce under Porto Antico SpA.

Simultaneously, minor interventions were also completed in the Darsena area by the Faculty of Economics's construction and the Maritime Station's renovation at the beginning of the 1990s.

3.3. Strategic Shifts and Unrealised Visions

The designation of Genoa to host the G8 Summit influenced the city's overall development in 2001. The construction of the Biosphere as the last addition to the historic port of Genoa coincided with the time of the event, again designed by Renzo Piano. In the same year, Ponte Parodi was opened for the architectural design competition to evaluate the possibilities for the under-utilised area in the historic port. The competition aimed to redefine the relationship between the city and the port by regenerating the Ponte Parodi area (Ferrari, 2008). The competition was organised by Porto Antico SpA and resulted in the selection of the UNStudio's proposal. The project was designed with a mixed-use approach, including spaces for leisure, culture, commerce, and entertainment, designed like a public square that is formed from a series of surfaces expanding towards the sea and covers the dock area with a total of 23.000 square meters of intervention; however, the project has not been realised because of the planning and financial issues.

The Darsena area, the land-side of Ponte Parodi, has also been undergoing considerations for redevelopment. The Darsena redevelopment project was approved in 2001, as part of the broader Porto Antico plan, to improve the accessibility and attractiveness of the area in the scope of the regeneration plan, thanks to the designation of Genoa as European Capital of Culture in 2004 (Ferrari, 2008). The total intervention covered more than 10.000 square meters of area and involved constructing new buildings, renovating existing structures, and demolishing the selected structures. The most prominent intervention within the project's scope was the Museum of the Sea, designed by Guillermo Vázquez Consuegra, completed in 2004. Among the other interventions, commercial, service, and office spaces have been introduced to the area with private investment.

Another important work in this era, Affresco, designed by Renzo Piano, reconsidered the entire Genoa waterfront in 2004. Piano's design includes several interventions, the most notable of which is constructing an artificial island in front of the city to house the airport and the continuous seafront promenade for enhancing the connection of the waterfront with the city (Ferrari, 2008). The following part of the proposal included new waterfront solutions for maritime and civil functions. This ambitious master plan with a broad vision of waterfront-city connections has gone through two further modifications in the following each year: the second version proposed the

relocation of the airport even further than the previous position towards to sea, the third version enhanced the urban functions in the waterfront over maritime-related program (Gastaldi, 2010). Due to the estimated budget of the project and lack of financial groundwork, the master plan has not been implemented.

3.4. The Blueprint and the Rise of Waterfront di Levante

Following the Affresco proposal, Renzo Piano prepared another master plan, the Blueprint, which focused entirely on the eastern section of the city's waterfront from Porta Siberia to Punta Vagno in 2014. The initial plan proposed the construction of a new navigable canal near the ancient city walls, adjacent to the raised road, obtained through excavating portions of the existing quays and demolishing some abandoned buildings (Rosasco and Lombardini, 2020). The final version of the master plan highlighted ten important considerations that had been discussed during the project phase, and it included a new urban park, improving the connections between the city and the sea, and introducing new residential, commercial, and recreational facilities to the area (Gastaldi and Camerin, 2020). The Blueprint guidelines evolved as a design competition by Genoese local authorities for the municipality-owned areas, predominantly focused on the marina as a former fair area on the city's east coast. However, despite more than seventy international participants, the competition resulted in no selection of the winning proposal in 2016. Nevertheless, Piano's initial design -the Blueprint- was rethought and adopted for the former fair area that created the framework of the project.

The "Waterfront di Levante" project emerged as the following phase of the Blueprint masterplan, spurred by the competition's outcome and the city's evolving urban dynamics (Rosasco and Lombardini, 2020). This updated iteration maintained the core concept of integrating water into the urban fabric, albeit with a reduced building footprint. The project was once again appointed to the Renzo Piano Building Workshop, which further developed the scheme and proposed an integrated approach for the regeneration of the area by addressing the need for open public spaces, improving accessibility, enhancing the marine environment, and creating new economic opportunities (Moretti et al., 2019).

The integration of private investment into the project was coordinated by SPIM SpA, a publicly owned municipal company. Its primary function was to promote the sale and assess proposals related to publicly owned land. The demolition of the existing structures in the former fair area -Pavilion C, Office Building, Pavilion M, Pavilion D-, and excavation for the proposed canal appointed to the developer as additional tasks besides the area's overall development (SPIM Genova, 2018). It has also been stressed that Pavillion B, designed by Jean Nouvel and completed in 2009, was excluded from the sale and the public funds to be allocated for the reorganisation of the transportation infrastructure, demolition of the former NIRA, excavation for the main canal entrance and completion of the urban park that was mentioned at that time as a possible intervention for the upcoming period (SPIM Genova, 2018). Following the sale of the fair area with the conditions outlined, the involvement of private capital makes approximately three-fourths of the redevelopment budget, and the rest of the approximately one-fourth would be covered by the various public investment programmes planned within a legislative term. Overall, this process seems founded chiefly on speculation and the privatisation of public areas: tenders for the concession and/or sale of state property will be issued, risking depleting the public bodies' role (Moretti et al., 2019).

The master plan program includes developing residential, commercial, and cultural facilities and public spaces designed primarily to attract residents and visitors. The project is composed of five different functional lots that include the restoration of the existing sport hall for hosting the indoor sport activities in the first lot, the hotel and student housing approximately 8,900 m^2 in the second lot, residences approximately 15,500 m^2 in the third lot, offices approximately 10,000 m^2 in the fourth lot, and the fifth lot got characterised with the linear urban park nearly covers 16,500 m^2 area; the total intervention area was defined as approximately 115,000 m^2 (Comune di Genova, 2021).

4. Discussion

Genoa's waterfront transformation from the first implementations until now highlights the challenges of balancing urban waterfront enhancement with the preservation of publicness and assurance of public benefits, particularly considering the shifting dynamics between the involvement of public and private sectors. This shift reframes the norm of waterfront redevelopment that started as a waterfront renaissance that aimed to reclaim the waterfronts for the city and resulted in the form of privately developed and managed waterfronts. Therefore, the central concern revolves around who these spaces are for and to what extent they are truly public.

4.1. Narrative and Process

The redevelopment process of Genoa's urban waterfront unfolds a long and complex narrative. The earlier instances in the scope of Porto Antico redevelopment were primarily catalysed by the international exhibition Expo 1992, aimed to promote the activities that respond to the growing tourism demands, overall enhancement of the city's image, improvement of the waterfront usage, and connection of the waterfront with the city. It has been conceived not only as a singular project, but as part of a broader urban regeneration strategy, designed to elevate the city's historic centre and the waterfront. These interventions focused mainly on reclaiming former industrial and port areas for public use. Alongside the waterfront's functional transformation, the port heritage's integration and recovery to host the new functions have formed a maritime collective memory. Therefore, the discourse was centred around the urban reconnection and civic recovery of the port as an integral part of Genoa's urban identity.

The following process encompasses the broader vision of redeveloping Genoa's urban waterfront. The emergence of several master planning initiatives, such as Affresco and Blueprint, primarily reveals the intention for growing interest in the transformation of the overall urban waterfront, from the water towards the land, harmonised with the large-scale interventions. They remained unrealised mainly due to financial constraints.

The Waterfront di Levante initiative illustrates the increasing economisation of the redevelopment narrative in the present era. The main objective is to attract private capital, as evidenced by the increasing emphasis on revenue generation. The outcome is a hybrid narrative that rhetorically emphasises public benefit and connectivity, while spatial outcomes increasingly align with the priorities of private capital and real estate markets.

4.2. Governance, Management, and Actors

Genoa's waterfront redevelopment trajectory illustrates a significant transition from state-led initiatives to complex arrangements involving public-private partnerships, private developers, and semi-autonomous bodies. Initially, local, regional, and port authorities were in charge of planning and funding in the form of public-private partnerships. Yet, the dominance of the investment was mainly over the public, and in carrying out the projects. This term reveals redevelopment attempts in favour of public functions, creating accessible waterfronts and enhancing the maritime heritage with public-oriented approaches. Over time, as priorities shifted towards attracting private investment and promoting economic growth, the public benefits were overlooked, and the primary concern was creating a real estate market in the waterfront. The change can be observed from the state-led Porto Antico redevelopment program to the property-led strategy of the Waterfront di Levante project, even though the initiations of both projects introduced by the public authorities, augmented involvement of the private capital deeply affected, especially the process of transformation and the results. Moreover, rather than creating a balanced relationship between public and private funds, the decision to privatise the process also illustrates the changing vision into an asset management strategy.

The repeated engagement of Renzo Piano as a prime actor for drawing a vision and designing the interventions in the urban waterfront redevelopment plans and projects demonstrates the important role of architecture while re-shaping the contemporary scene in Genoa's waterfront. While the involvement of international firms signals ambitions to create high-profile waterfronts, it also implies the potential risk of homogenising architectural and urban design, potentially marginalising local or regional specificities. However, as a local to the same geography, Renzo Piano contributes a lot to the process of identity-making and maintaining the sense of place in Genoa's

waterfront redevelopment in the redevelopment process of Porto Antico. On the other hand, the Waterfront di Levante project reveals patterns more similar to those in global instances by introducing the high-end design and lacking sensitivity to the existing context. Furthermore, this technocratic approach that dominates recent projects appears to be a retreat from broader civic engagement.

4.3. Contextual Considerations

The contextual considerations start from the selection of the intervention site. The distinct relationships established by the redevelopment of the Porto Antico project, located in the historic port area, were achieved by being part of the broader regeneration plan from both sides of the historic centre and the historic port. A contextually sensitive and spatially integrative approach could be traced from the approach that waterfront was not treated as an isolated intervention, but as a catalyst for the broader revitalisation of the historic urban core, which had suffered from long-term physical and socio-economic decline. The project fosters a dynamic relationship, extending the publicness of the city's historic centre towards the waterfront. This has been achieved by establishing a strong connection between the city's public infrastructure and the public areas introduced within the intervention site to maximise continuity between the waterfront and its hinterland. Intervention partially engages with the urban context constrained to specific parts of the inner urban fabric and responds to the needs of the limited surrounding area (see Figure 2). The project thus exemplifies a market-led regeneration paradigm in which the pursuit of economic optimisation supersedes the imperative for social and territorial cohesion.

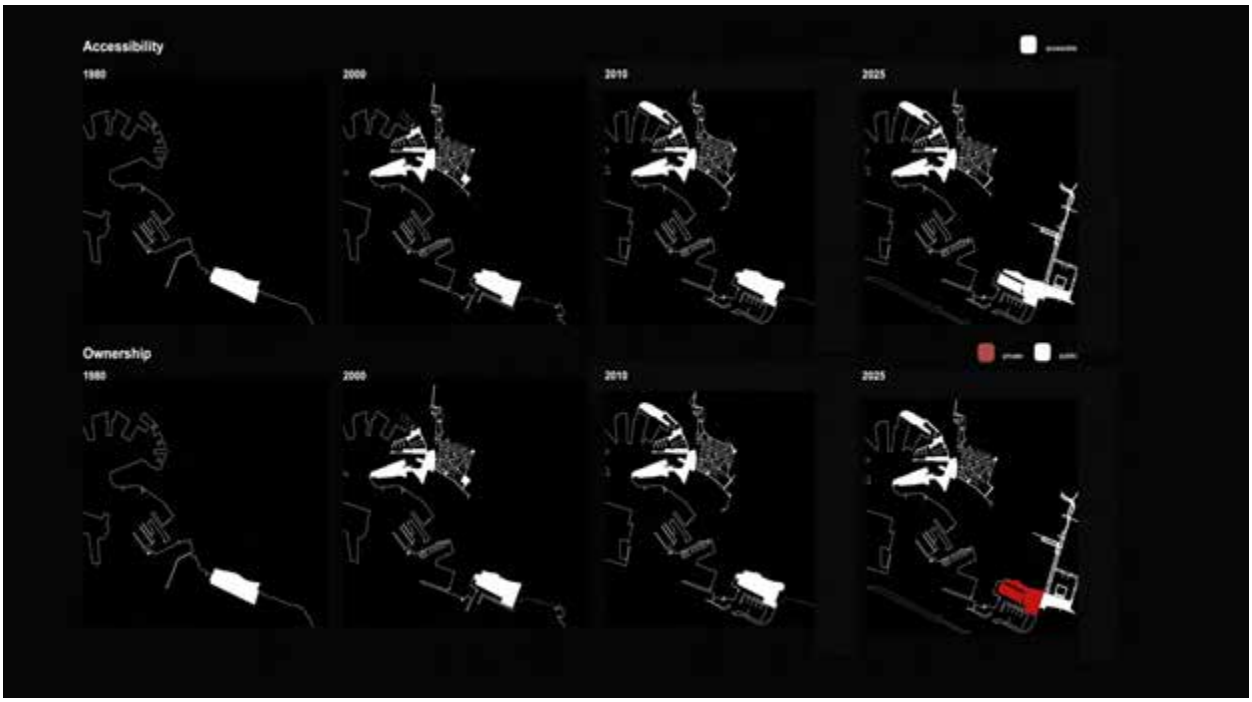

Figure 2: Spatio-temporal shift in Genoa's urban waterfront public ground in terms of accessibility (above), and ownership (below)

4.4. Spatial and Programmatic Outcomes

The physical outcomes of the earlier period applications, realised predominantly with the Porto Antico redevelopment project, were defined by a series of newly constructed or renovated public spaces, including promenades, parks, and cultural amenities. The spatial logic of these interventions generally prioritised public access and connectivity, aiming to create spaces of encounter that broad segments of the population could freely access. The design decision of including the mixture of renovation of the existing historic buildings, harmonised by the new structures that accommodate new typologies and functions, and the arrangement of these components

in the public realm contributed to the success of the early redevelopments on Genoa's waterfront. On the other hand, even though the program was centred on public functions, it is essential to underscore the criticality of the event-led nature of the project, which brings further questions regarding sustaining public engagement in the long term by their limited capacity to generate durable patterns of integration. This reflects a broader tendency characteristic of waterfront redevelopment during that period, leisure-oriented programming, and the prevailing "port-out, city-in" approach (Tommarchi, 2025), which was often questionable regarding the depth and permanence of public engagement.

However, as exemplified by the Waterfront di Levante project, the spatial and programmatic logic is powerfully shaped by commercial imperatives, emphasising attracting private investment and an exclusive user profile. With the introduction of the retail and residential functions, the access and use of spaces are implicitly regulated by market mechanisms. The spatial enclosure and exclusion through high-end residential enclaves, controlled access zones, and commercial programming that privileges affluent users represent the prominent issues in the waterfront redevelopment implementations during late neoliberalism—not only in the architecture of the built environment but also in the carefully curated image of the waterfront as a space of consumption and leisure, further reinforcing the patterns of socio-spatial segregation (see Figure 3).

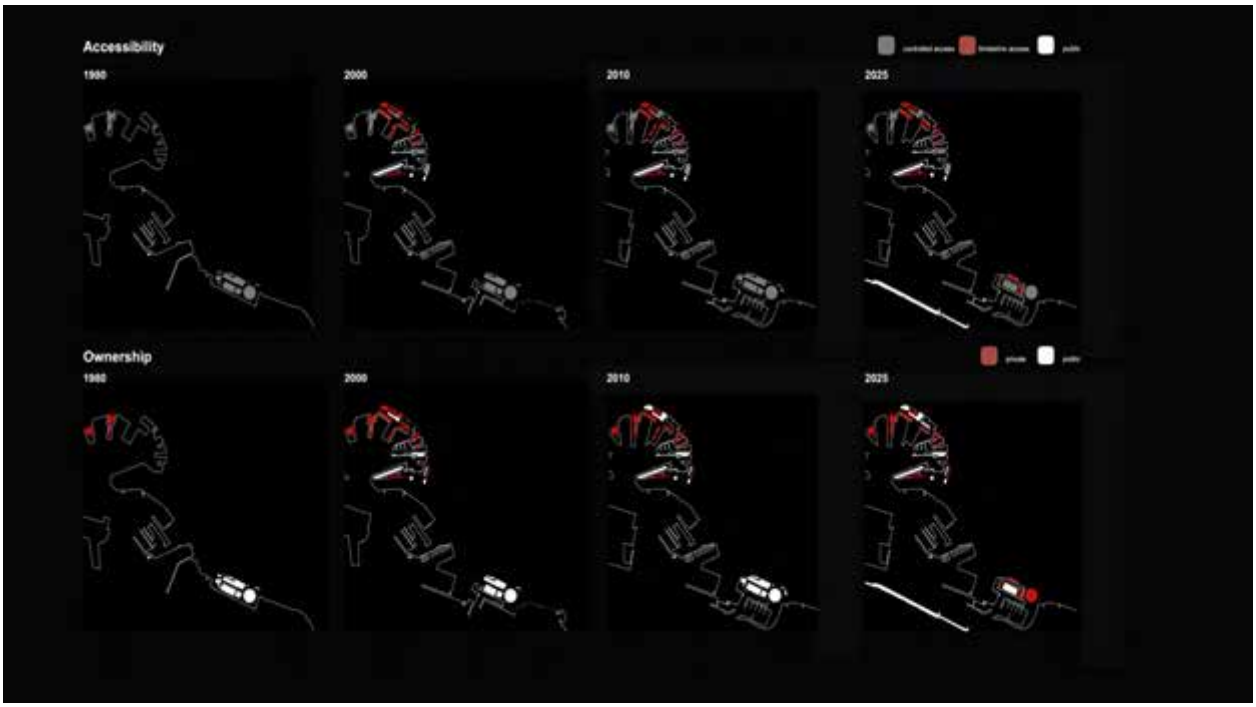

Figure 3: Spatio-temporal change in the built environment in the scope of waterfront redevelopment projects in terms of accessibility (above), and ownership (below)

5. Conclusion

Renzo Piano defines the process of the Waterfront di Levante project by referring to his former project of Porto Antico, and emphasising that Genoa once again "re-conquers the sea" (Minella, 2023). However, the process and results do not reveal similar patterns or attempt to address similar concerns as they were in the initial phases. Prioritising urban reconnection and public engagement with the waterfront has been replaced with market dynamics that eventually lead to spatial and social segregation of waterfronts from urban life and public actors. Therefore, the main motto of the waterfront redevelopment programs was identified with the attempts to reclaim the waterfront for the city and reshape it according to the developer's priorities. All in all, this reveals the dramatic shift in the paradigm of waterfront redevelopment.

The case of Genoa's waterfront reveals how the objectives of such initiatives have transformed in the near history, raising concern over the publicness of the waterfront, and the growing issue of spatial and social exclusion. Even though the recency of the project limits further impact studies in the current timeframe, it sheds light on this global trend of enclaving the waterfronts via exclusive spaces and selected user profiles, illustrating how the phenomenon of waterfront redevelopment has shifted from a public-oriented direction to the opposite.

Abstract
The visual quality of streets is an important factor that determines the attractiveness of public spaces. Studies conducted on this subject emphasize the effect of environmental perception and aesthetic evaluation on people and street views. One of the elements that increase the visual quality of streets is the green texture, the seasonal change of trees on streets is also an important component of environmental perception and aesthetic evaluation. Therefore, in order to understand the visual quality of streets, a mixed approach should be adopted that includes not only objective evaluations of physical features but also subjective perceptions of people. The aim of this study is to question the relationship between measurable design qualities (diversity/complexity, green area density, openness ratio, closedness ratio, facade density, and light/shadow effect) that affect visual quality through street views and perceived aesthetic appreciation, taking into account the seasonal changes of street trees.

Keywords: Public space, street trees, visual quality, seasonal differences

1.Introduction

It is stated in the literature that visual quality is an important element of urban design. In particular, it is emphasized that the design elements on the streets and their effects on visual quality should be measured quantitatively. This evaluation should be made in order to contribute to making effective urban design decisions and creating high-quality streets and avenues (Ye et al., 2019, Demir and Gürel, 2024).

However, visual quality is an abstract concept and is usually associated with physical features. However, it is not possible to fully understand people's general perception based on physical features alone. Therefore, when evaluating the physical elements of a space, it is necessary to take into account people's perceptual experiences.

Lothian (1999) suggests a mixed approach where both objective and subjective paradigms are used together to evaluate the visual quality of the natural and built environment. The objective approach views quality as an intrinsic property of the environment, while the subjective approach assumes that quality is a value based on the perception of the observer (Lothian, 1999; Tveit, 2009). Qualitative methods used to evaluate visual quality include surveys, interview techniques, case, and behavioral studies, and aesthetic preference questionnaires. Quantitative methods include approaches such as fractal geometry, visual statistical analysis, the golden ratio, correlation methods, content analysis, Brunswik's lens model, entropy, artificial intelligence, spatial index, and fuzzy logic theory.

In order to develop and improve the visual quality of streets, it is first necessary to determine the elements that affect the visual quality of the streets (Tekel, 2021). Research shows that determining these elements has a significant impact on people's perception and use of the urban environment.

There are many variables and design qualities that affect the visual quality of the built environment. While some of these qualities are measurable, some cannot be. In this research, a query was made on measurable design principles and criteria. The aesthetic evaluation on the streets was examined on the measurable design qualities that affect visual quality, such as diversity/complexity, green area density, openness ratio, closedness ratio,

facade density, and light/shadow effect.

Streets are important public spaces of daily life. The presence of green areas in these spaces is an important factor that increases visual quality (Cooper et al., 2013). Studies suggest that seasonal differences in green areas are an important component of environmental perception and aesthetic evaluation (Junge et al., 2015). Landscape physiognomy can vary greatly depending on seasonal changes, which can affect people's perceptions and preferences. However, few studies have taken seasonal dynamics into account (Palang et al., 2007; Stobbelaar and Hendriks, 2007; Junge et al., 2015).

In the literature, it is stated that comparative studies on visual quality through street images are limited according to different seasons (Palang et al., 2007; Stobbelaar and Hendriks, 2007; Junge et al., 2015). In this study, a detailed literature review was conducted with the keyword "seasonal differences". The total number of sources reached in the WoS (Web of Science) database is 131. The shortcomings in these studies limit our full understanding of how human perception and aesthetic preferences are affected by different seasons. However, it is stated that comparative studies conducted according to different seasons provide important information about how they affect people's perceptions and aesthetic preferences (Zhao et al., 2017; Kuper, 2020).

This study aims to identify design elements that increase aesthetic appreciation on the streets and to understand how these elements are affected by seasonal changes. It also aims to provide a basis for better understanding the impact of seasonal factors on visual quality and aesthetic perception and to develop more effective strategies in public space design.

2.Materials and Methods

This study aims to question the relationship between measurable design attributes (diversity/complexity, green area density, openness ratio, closedness ratio, facade density, and light/shadow effect) affecting visual quality through street views, taking into account seasonal changes in street trees, and perceived aesthetic appreciation. Thus, a mixed approach was adopted, including objective evaluations addressing physical characteristics and subjective evaluations considering aesthetic appreciation in order to identify design elements that increase aesthetic appreciation in streets.

In this context, the method followed in the study was designed in three stages. In the first stage, the study area was determined. Data collection was carried out by taking photographs in the field study. For the photography, first of all, sample streets were determined within the study area and photo shooting points were created.

The study area was determined as Mebusevleri Neighborhood, one of the original neighborhoods of Ankara during the Republican Period, which attracts attention with its tree texture on its streets. All original streets within the neighborhood were included in the sample, and 9 shooting points were determined to reflect these differences from the streets with differences in terms of structure and tree texture. A database was created by taking photos in the winter and summer periods at the created photo shooting points. Impartiality was observed while taking photos from the research area, and no tendency that could affect the participants was shown. In the study conducted by Jiang et al. (2017), it was stated that eye-level photography is widely used by designers, planners, and researchers in obtaining information about green areas and examining human reactions in real environments. In this study, the photos were taken at eye level and from the very center of the streets where the shots were taken.

In the second stage, measurable design qualities that determine the visual quality of the streets (diversity/complexity, green area density, openness ratio, closedness ratio, facade density, and light/shadow effect) and the measurement methods of these qualities were determined. In this context, the photographs obtained were analyzed using fractal and image statistical analysis methods (HarFa v5.5 and Photoshop). Diversity/complexity was analyzed using fractal analysis method; image statistical analysis was used for the analysis of other design

qualities. In addition, the aesthetic appreciation assessment of the sample streets was carried out using the photo-survey method conducted on the obtained photographs. Table 1 presents information on the demographic characteristics of 150 volunteer students who participated in the survey conducted via Google Forms.

Tablo 1. Demographic characteristics of participants

Variable	Category	n	%
Gender	Female	118	78,66
	Male	32	21,33
Department	Architecture	53	35,33
	Urban and Regional Planning	97	64,66
Academic Year	1st year undergraduate	17	11,33
	2nd year undergraduate	16	10,66
	3rd year undergraduate	26	17,33
	4th year undergraduate	57	37,99
	Master's degree	17	11,33
	PhD degree	17	11,33
Total number of participants: 150			

As seen in Table 2, the necessary procedures were applied to the photographs to be used in the analysis.

Table 2. Stages of preparation of street images for analysis.

1. Street images are deleted in PhotoShop software, such as cars, people and clouds.	2. The resolution of the street images was kept constant at 672 × 1200 pixels.	3. The color of the street images was removed and the images were used in grayscale for analysis.	4. For the fractal analysis of street images, black and white images were used.

In the third stage, the relationship between seasonal differences and measurable design attributes affecting visual quality and aesthetic appreciation was statistically analyzed using SPSS program. It was tested with Spearman correlation analysis and measurable design attributes according to seasonal differences were compared using Mann-Whitney U test.

2.1. Fractal analysis

Fractal analysis, which is frequently used in analyzing visual complexity in built environments, provides effective results with morphological measurements (Işınkaralar and Varol, 2023, p.2). Fractal dimension, which is the basic statistical parameter in fractal analysis, measures the ability of a pattern to fill the gaps and therefore the level of complexity. The more complex the pattern, the higher the fractal dimension. The value obtained varies between 0 and 2 (Işınkaralar, 2023).

The complexity of a place depends on the diversity of the physical environment, especially the number and types of buildings, architectural diversity/complexity and ornamentation, landscape elements, street furniture, signs, and human activity (Ewing et al., 2006). In the study of Cooper and Oskrochi (2010), a positive relationship was found between fractal dimension levels and visual diversity/complexity levels. According to the research of Yılmaz (2021), areas with a fractal dimension value of approximately 2 represent complex and rich urban spaces, while areas with a value of approximately 1 represent less complex regions.

In this study, the diversity/complexity values of the sample streets were calculated using the HarFa 5.5 program. According to the study, the fractal dimension values of the street images in the winter season varied between 1.3152 and 1.7758. In the summer season, the fractal dimension values of the street images varied between 1.3473 and 1.7176. The fractal dimension values of the sample street images selected from the study area calculated in different seasons are given in Table 3.

Table 3. Diversity /Complexity analysis of example ımages

Mebusevleri Neighbourhood		
	Winter	Summer
Şerefli St.		
1	BW FD=1,5954	BW FD=1,5127
Ören St.		
2	BW FD=1,6477	BW FD=1,5213

2.2.Image statistical analysis

In this study, measurable design attributes such as green area density, openness ratio, closedness ratio, facade density, and light/shadow effect were analyzed on photographs obtained by image statistical analysis method.

Green area density

Green spaces provide many benefits, such as inspiring an individual's visual aesthetic perception of streetscapes, increasing outdoor time, and preventing stress and negative psychological symptoms (Chen., 2021). The restorative potential of nature has been theoretically and empirically associated with a strong affinity and aesthetic preference for natural environments (Ibarra et al., 2017).

Existing research shows that most studies on the measurement of street trees focus on the "amount of greenery", whereas the assessment of aesthetic qualities is neglected due to methodological shortcomings (Hu et al., 2022).

Figure 1. Green area density (Demir & Gürel, 2024)

In this study, the green area density of sample streets was calculated using the Histogram command in Photoshop software using the Image Statistical Analysis (GIA) method. The total number of green area pixels in the street images was proportional to the total number of pixels in the street images. In the winter season, the green area density of the sample street images varied between 24.54 and 43.53. In the summer season, the green area density of the sample street images varied between 37.38 and 65.12. The green area density values of the sample street images selected from the study area are given in Table 4.

Table 4. Green area density of example ımages (Original, 2024)

Mebuseyleri Neighborhood			
		Winter	Summer
Şerefli St.	1	41.31	65.12
Ören St.	2	36,77	55,82

Openness ratio

Openness refers to the portion of the sky that can be seen from a vantage point, and the height and alignment of building facades directly affect this openness. For example, setbacks create a broad horizon, while dense clusters of tall buildings divide the sky into narrow visual areas.

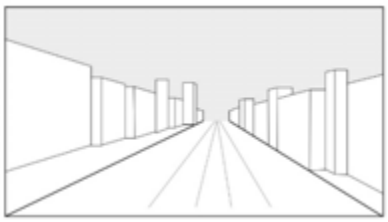

Figure 2. Openness (Demir & Gürel, 2024)

The openness ratio of the sample streets was calculated using the Histogram command in Photoshop software using the Image Statistical Analysis (ISA) method. The total number of visible sky pixels in the street images was proportional to the total number of pixels in the street images. In the winter season, the openness ratio of the sample street images varied between 28.96 and 37.24. In the summer season, the openness ratio of the sample street images varied between 0.7 and 33.05. The openness ratio values calculated for the sample street images selected from the study area in different seasons are given in Table 5.

Table 5. Openness ratio of example ımages (Original, 2024)

Mebusevleri Neighborhood			
		Winter	Summer
Şerefli St.			
1		32.13	5.92
Ören St.			
2		31,79	0,7

Closedness ratio

Closedness refers to the space created by buildings and is related to people's perception of spatial confinement. A well-closed street increases the sense of security and provides more opportunities for physical activities. Therefore, closedness is considered an important feature in street designs.

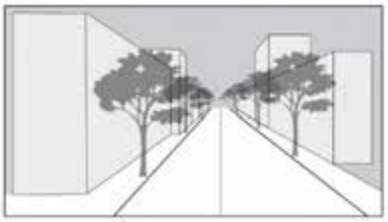

Figure 3. Closedness (Demir & Gürel, 2024)

The closedness ratio of sample streets was calculated using the Histogram command in Photoshop software using the Image Statistical Analysis (ISA) method. The closedness ratio in street images is the ratio of the total number of pixels of visible building facades to the total number of road pixels in street images. In winter, the closedness ratio of sample street images varies between 1.89 and 62.39. In summer, the closedness ratio of sample street images varies between 1.41 and 26.56. The closedness ratio values calculated for sample street images selected from the study area in different seasons are given in Table 6.

Table 6. Closedness ratio of example ımages (Original, 2024)

Mebusevleri Neighborhood	Winter	Summer
Şerefli St.		
1	35,42	7,67
Ören St.		
2	62,39	10,6

Facade density

Studies on street photographs show that measurable design elements such as facade density and the presence of landscape elements play an important role among the factors that determine the aesthetic quality of the street. The facade density of the streets is among the critical elements that determine the characteristics of the space and the integrity of the street wall (Akbaba, 2022).

Figure 4. Facade density (Demir & Gürel, 2024)

The facade density of the sample streets was calculated using the Histogram command in Photoshop software using the Image Statistical Analysis (GIA) method. The facade density in the street images is the ratio of the total number of pixels of the visible building facades to the total number of pixels in the street images. In the winter season, the facade density of the sample street images varies between 0.82 and 19.98. In the summer season, the facade density of the sample street images varies between 0.71 and 7.7. The facade density values calculated for the sample street images selected from the study area in different seasons are given in Table 7.

Table 7. Facade Density of Example Images (Original, 2024)

Mebusevleri Neighborhood	Winter	Summer
Şerefli St.		
1	12,23	2,36
Ören St.		
2	19,98	4,24

Light / Shadow effect

The effect of light and shadow (contrast) in street images is related to the amount of detail in the image (Kalavı, 2021). According to literature research, light and shadow deeply affect the perceived beauty of street scenes. Properly arranged landscapes and structures, when used in harmony with natural light sources, increase the aesthetic value of the landscape. The correct use of shadows increases the perception of depth and size, increasing visual appeal. Shadows in cities often leave important impressions on individuals. Shadows and light can transform the depth and atmosphere of an area. Street greenery and tree shadows affect thermal comfort and are advocated for the creation of pleasant urban environments. (Demir, 2024)

Figure 5. Light/Shadow effect (Demir & Gürel, 2024)

The light/shadow effect of the sample street images, namely the contrast ratio, was calculated using the Histogram and Luminosity commands in Photoshop software using the Image Statistical Analysis (GIA) method (Table 5.6). According to the table, the light/shadow effect of the sample street images in the winter season varies between 64.17 and 85.78. In the summer season, the light/shadow effect of the sample street images varies between 52.47 and 89.97. The light/shadow effect values calculated for the sample street images selected from the study area in different seasons are given in Table 8.

Table 8. Light/Shadow effect of example ımages (Original, 2024)

Mebusevleri Neighborhood				
	Winter		Summer	
Şerefli St.				1	72.31		85.10	
Ören St.				2	71,72		89,97	

Conclusion

Seasonal change of green areas on streets is an important component of landscape perception and aesthetic evaluation in studies on visual quality (Junge et al., 2015). In this context, when the relationship between seasonal differences on streets and aesthetic appreciation values is questioned, it is seen that the summer and winter season averages of the variables are different from each other. It is observed that the aesthetic appreciation average of the summer period is greater than the aesthetic appreciation average of the winter period. When the values of measurable design qualities are evaluated together with aesthetic appreciation, it can be said that when the values of diversity/complexity, green area density, closedness ratio, facade density, and light/shadow effect are high, aesthetic appreciation increases, whereas when the openness value is high, aesthetic appreciation decreases.

• Cooper and Oskrochi (2010) found a positive relationship between fractal dimension levels and visual diversity/complexity levels. In this study, when the relationship between diversity/complexity level (fractal dimension) and aesthetic appreciation was examined with Spearman's Rank Correlation Coefficient analysis, there was no statistically significant relationship between aesthetic appreciation and fractal dimension for the winter season. Similarly, no significant relationship was found between aesthetic appreciation and fractal dimension for the summer season. When the diversity/complexity level in street images in the sample was examined according to seasonal differences, it was shown that there was no statistically significant difference between fractal dimension levels.

• When the green area density is examined, it is observed that the green area density of street images is higher in summer than in winter. According to the correlation analysis, there is no significant relationship between aesthetic appreciation and green area density in winter. However, a positive and significant relationship was found between aesthetic appreciation and green area density in summer. In addition, the comparison of green area density according to seasonal differences was made with the Mann-Whitney U test and the obtained significance value was determined as 0.002 ($P<0.05$). These results show that seasonal changes have a significant effect on green area density.

• When the openness ratio is examined, the openness ratio of street images is lower in summer than in winter. In the correlation analysis, there is no statistically significant relationship between aesthetic appreciation (winter) and openness ratio (winter). Similarly, no statistically significant relationship was found between aesthetic appreciation (summer) and openness ratio (summer). Comparison of openness ratio according to seasonal

differences was made with Mann-Whitney U test and the obtained significance value was determined as 0.002 (P<0.05). This result shows that seasonal changes have a significant effect on the openness ratio. It was observed that the openness ratio was higher in winter.

• When the closedness ratio is examined, it is shown that the closedness ratio of street images is higher in summer than in winter. According to the correlation analysis, there is a positive and statistically significant relationship between the aesthetic appreciation (winter) value and the closedness ratio (winter). However, there is no statistically significant relationship between the aesthetic appreciation (summer) value and the closedness ratio (summer). The significance value obtained as a result of the Mann-Whitney U test conducted to examine the closedness ratio according to seasonal differences was determined as 0.038 (P<0.05). This result shows that there is a significant difference between the closedness ratio depending on seasonal changes. According to the rank average values, it is observed that the closedness ratio is higher in winter than in summer.

• When facade density is examined, it is shown that facade density of street images is lower in summer than in winter. According to the correlation analysis, there is a positive and statistically significant relationship between the aesthetic appreciation (winter) value and facade density (winter). In other words, there is a strong and significant relationship between the aesthetic appreciation values in street images and the facade density in winter. However, there is no statistically significant relationship between the aesthetic appreciation (summer) value and facade density (summer). The significance value obtained as a result of the Mann-Whitney U test conducted to examine the facade density according to seasonal differences was calculated as 0.019. This result shows that the facade density in winter is significantly higher than in summer.

• According to the correlation analysis conducted to examine the relationship between the Light / Shadow effect and aesthetic appreciation, there is no statistically significant relationship between the aesthetic appreciation (winter) value and the light / shadow effect (winter) and between the aesthetic appreciation (summer) value and the light / shadow effect (summer). The significance value obtained as a result of the Mann-Whitney U test conducted to examine the Light / Shadow effect according to seasonal differences was determined as 0.627. This result shows that there is no significant difference between the light / shadow effect level depending on seasonal changes.

As a result, it has been determined that seasonal changes in street trees may affect individuals' evaluation of the visual quality of streets and may lead to differences in measurable design attributes that shape perceptual differences.

Email:2230105@tongji.edu.cn

Abstract
Under the guiding principle of "People-Oriented Urban Development," public space has become a core focus of urban development in China. As major cities enter a stage of stock-based urban regeneration – emphasized repeatedly at the national level, notably in the 2025 State Council meeting – the potential of under-bridge spaces as public space assets in megacities has garnered significant attention. However, formal regeneration approaches often face prolonged implementation cycles due to complex land rights and the involvement of multiple management departments. In contrast, the informal use of under-bridge spaces (e.g., temporary markets, sports grounds) is widespread yet understudied in large Chinese cities. Based on co-production theory and adopting a socio-spatial perspective, this study investigates multiple cases of informal under-bridge space utilization in Guangzhou, a representative Chinese megacity. The research aims to systematically summarize the core characteristics of such informal use (such as spatial adaptability, actor diversity, and functional dynamics) and reveal the interaction mechanisms among diverse actors in the informal production of space. The findings offer theoretical insights and practical references for overcoming the challenges of formal regeneration and exploring more inclusive and adaptive governance models for under-bridge spaces in megacities within the context of urban renewal.

Keywords: Urban Regeneration; Under-bridge Space; Public Space; Co-production; Informal Use

1 Introduction

The Report of the 20th National Congress of the Communist Party of China emphasises the principle that "a people-centered city is built by and for the people." This signals a paradigm shift in China's urban development philosophy—from incremental, expansion-oriented growth to connotative, human-centered development (Shen, 2019). In this transition, the construction of urban public spaces increasingly responds to citizens' diverse needs. However, central districts of major cities often suffer from inadequate public space supply, spatial mismatch between supply and demand, and significant challenges in spatial supplementation.

In this context, elevated expressways, as critical infrastructures in megacities, have drawn attention in recent urban regeneration initiatives, particularly for the potential reuse of space beneath the overpasses. For instance, the Shanghai Urban Regeneration Action Plan (2023–2025) identifies five major regeneration tasks. Under the third task—"Optimisation of Public Space Facilities"—it proposes upgrading the quality of under-elevated spaces to create high-quality urban public environments (Shanghai Municipal Government, 2023).

Existing domestic research primarily focuses on the formal uses and planning strategies of space beneath elevated roads (Huang, 2019). However, the share of under-elevated spaces that are suitable for formal redevelopment remains limited. Moreover, the formal transformation of such spaces is constrained by complex multi-agency governance, dynamic urban policy adjustments, ambiguous land tenure in certain areas, and potential interference with traffic systems. These challenges result in a rigid and narrowly applicable formal planning framework, with prolonged implementation cycles.

In contrast, the informal uses of under-elevated spaces in megacities can potentially compensate for the limitations of formal redevelopment. Yet, theoretical frameworks for understanding such informal utilisation remain underdeveloped in China. Little attention has been paid to the spatial characteristics, governance mechanisms, and user preferences associated with informal practices in these spaces.

This study seeks to address this gap by drawing on the theory of co-production to examine informal uses of multiple under-elevated spaces in Guangzhou. Adopting a social-spatial negotiation perspective, the paper aims to identify informal use characteristics, spatial structures, and user preferences, thereby contributing

strategic recommendations for revitalising these underutilised spaces within the broader context of urban stock regeneration.

2 Literature Review: Informal Use of Under-Elevated Spaces from the Perspective of Co-Production Theory

2.1 Current Research on the Informal Use of Space Beneath Elevated Roads

International scholarship on the informal use of under-elevated spaces emerged relatively early, with numerous studies affirming the positive effects of such practices under certain conditions. Some scholars argue that temporary uses of space represent innovative and experimental solutions, capable of breathing new life into abandoned facilities while preserving their historical, cultural, and environmental values (Galdini, 2020). These practices, by reassigning function and meaning to otherwise disused areas, contribute strategically to holistic urban regeneration processes (Galdini, 2020).

Research has also highlighted that informal uses of space beneath elevated highways can foster spatial integration between both sides of an overpass. Akinci (2016), for example, points out that while elevated highways fragment urban fabric, the spaces beneath them retain a certain urbanity. Informal everyday activities conducted by local residents under these structures can serve as symbolic and functional urban bridges.

International studies on urban informality primarily examine various forms of informal socio-economic activities, with a focus on their causes, governance models, and impacts. This body of literature also analyses the spatial characteristics of informality across different scales (Guo, 2023).

In contrast, domestic research has largely concentrated on **formal uses** of under-elevated spaces. Informal uses are typically discussed within typological analyses that highlight their **negative effects** and propose regulatory strategies (Liu, 2017). Research on urban informality in China has focused predominantly on the distribution and governance of informal economic activities—such as street vending—within urban villages, sidewalks, and streets. Recent studies have gradually begun to acknowledge the role of informal spatial practices in **complementing formal planning**, exploring governance models under different sociospatial structures (Guo, 2023).

In sum, both domestic and international literature have long recognised the relevance of informal space use in urban regeneration. However, in China, such research remains relatively nascent, particularly with respect to **theoretical understandings** and **spatial characterisation** of informal uses beneath elevated highways.

2.2 Informal Use of Under-Elevated Spaces from the Perspective of Co-Production Theory

The concept of **co-production** was first proposed by economist **Elinor Ostrom** in the 1970s to describe the active participation of citizens in the delivery of public goods and services (Albrechts, 2012). The theory emphasises the collaborative and direct involvement of both public administrators and citizens in managing public spaces, particularly under conditions where state capacity is limited. It proposes that such collaboration often constitutes **an optimal model for spatial regeneration**.

Some scholars argue that urban informality should be taken more seriously during spatial planning processes (Joshi, 2004). Others suggest that informal practices can facilitate co-production between governments and local communities, enhancing public engagement in space-making. The **spatial negotiation** among multiple actors over the informal use of urban spaces, in this view, constitutes a form of co-production in itself (Song, 2016).

Informal use may also serve to **rebalance unequal power relations** between space managers and users by enabling more equitable access to spatial resources (Song, 2016). In the domestic context, scholars have pointed out that informal uses foster **organic spatial growth**, promoting diversity in population structure, spatial morphology, and landscape form (Liu, 2017). Accordingly, how to institutionalise and regulate informal uses without stifling their vitality has become a central concern in contemporary urban planning.

In practice, many international cases of under-elevated space reuse exemplify co-production through **multi-stakeholder participation**. For example, New York City's *High Line Park*—initiated by the non-profit "Friends of the High Line"—transformed an abandoned elevated railway into a celebrated public space. Although the structure was initially slated for demolition due to complaints about unmanaged space below, planners and community members began experimenting with its use and negotiated with government agencies. Since opening in 2009, the park has become one of New York's major tourist attractions and a catalyst for the revitalisation of Manhattan's West Side.

In China, some scholars have also highlighted that the bottom-up adaptation and value redefinition of under-elevated spaces—through user-initiated modifications and cross-sector collaboration—can be viewed as a process of co-production (Li, 2023).

This study investigates **three long-established, functionally stable** cases of informal use beneath elevated highways in Guangzhou. Drawing on co-production theory and employing the **Actor-Network Theory (ANT)** as an analytical lens, it aims to identify the spatial characteristics, usage patterns, and governance logics that underpin the informal reuse of these spaces.

2.3 Informal Use of Under-Elevated Spaces from the Perspective of Co-Production Theory

The concept of **co-production**—also referred to as "collaborative production"—was first introduced in the 1970s by economist **Elinor Ostrom**. It emphasises the active involvement of citizens in the creation and delivery of public goods and services that directly affect their lives (Albrechts, 2012). Ostrom's formulation of co-production underscores the joint and direct participation of public administrators and ordinary citizens in service provision, particularly in the governance of public spaces. Co-production is widely recognised as a potentially optimal approach to spatial renewal, especially in contexts where public authority is weak or fragmented. Some scholars have further argued that informal spatial uses should be taken more seriously during spatial planning processes (Joshi, 2004).

In theoretical research, international studies suggest that informal uses of space can facilitate co-production between governments and communities, thereby activating public participation. The negotiation processes among various actors over informal spatial uses can themselves be understood as **forms of spatial co-production** (Song, 2016). Informal uses may also serve to moderate inequalities in **spatial agency** and **resource access** between space managers and users (Song, 2016). In the domestic context, researchers have observed that informal spatial practices can foster **organic spatial growth**, characterised by functional mix, contextual adaptation, and morphological diversity in population, spatial form, and landscape (Liu, 2017). As a result, the challenge of how to **institutionalise and guide** the orderly development of informal spatial practices has become a key issue in the field of urban planning.

In practice, many international examples of under-elevated space revitalisation have adopted co-production mechanisms involving **multiple stakeholders**. These collaborative efforts often aim to address the scarcity and misalignment of community public spaces. A prominent example is the **High Line Park** in New York City, initiated by the non-profit organisation *Friends of the High Line*. Originally an elevated railway decommissioned in 1980, the structure faced widespread complaints due to unmanaged and underutilised space beneath the tracks. Although there were calls for demolition, local planners began experimenting with new uses and engaged in sustained negotiations with government actors. This process eventually led to the preservation and transformation of the structure into a unique elevated urban park. Since its opening in 2009, the High Line has become one of New York's most popular tourist destinations and has played a pivotal role in revitalising the West Side of Manhattan.

Similar reflections have emerged in Chinese scholarship. For example, Li Zhigang (2023) argues that the spontaneous use, modification, and subsequent renegotiation of space beneath elevated roads represent a **process of multi-actor co-production**. In this study, we examine three long-established and functionally stable cases of informal use beneath elevated highways in Guangzhou. Through the lens of **co-production theory** and

employing **Actor-Network Theory (ANT)** as a methodological framework, we analyse patterns of spatial utilisation and extract key characteristics of informal practices under elevated infrastructure.

3 Empirical Study on Informal Uses of Under-Elevated Spaces in Guangzhou

3.1 Research Scope and Methodology

This study investigates three cases of informal use beneath elevated roads in Guangzhou:

(1) the space beneath the Dongsha Bridge at the intersection with Xixiang Third Road, located at the urban–rural fringe; (2) the underpass space of the Nansha Port Expressway intersecting Xiaozhou East Road; and (3) the ramp space between Yanjiang West Road and Shamei Third Street (Figure 1).
The study adopts a two-scale spatial analysis framework:

① At the neighbourhood scale, we analyse the five-minute pedestrian catchment surrounding each site, focusing on pedestrian flow patterns, land use types, and associated socio-spatial characteristics. ② At the micro-scale, we examine the under-elevated spaces themselves, identifying their physical configurations, patterns of informal use, and associated user groups.

Findings are further interpreted through the lens of **co-production theory**, summarising the typology of informal spatial practices and governance logics involved.

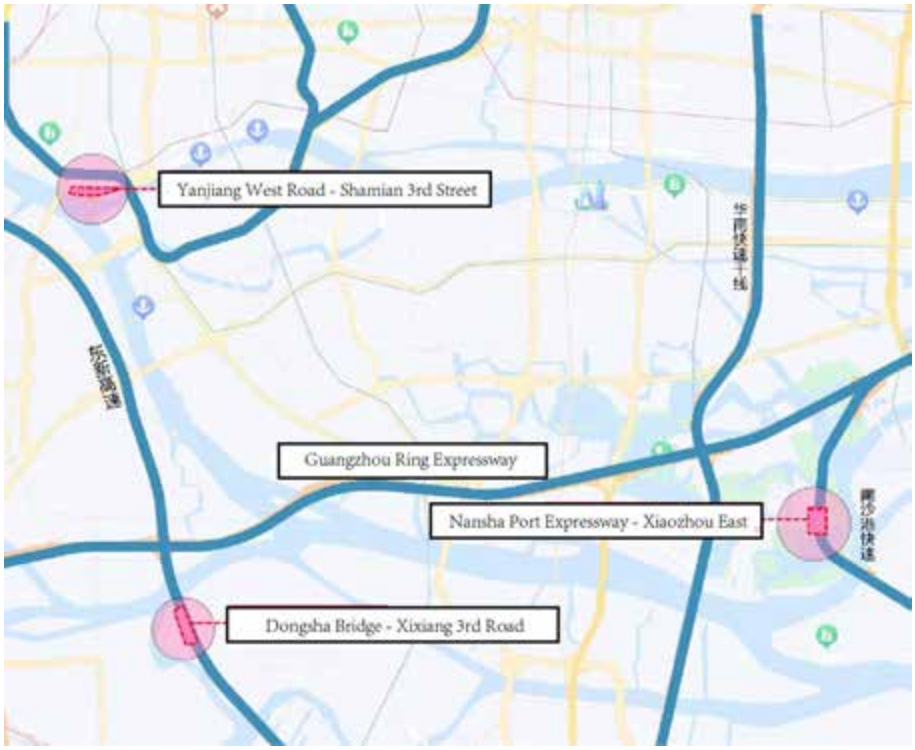

Figure 1 Location map of case study sites: under-elevated spaces in Guangzhou.
Base map source: Baidu Maps; diagram created by the author.

3.2 Nansha Port Expressway – Xiaozhou East Road

3.2.1 Spatial Context and Use Characteristics

The under-elevated space at the intersection of the Nansha Port Expressway and Xiaozhou East Road lies within the Xiaozhou Village Art District. The road bisects the space beneath the overpass into two distinct functional zones (Figure 3):

To the north: a self-organised fruit market initiated by village residents;

To the south: informal artist studios.

These functions are closely linked to the surrounding spatial structure, especially Xiaozhou Village and the nearby Guangzhou Academy of Fine Arts (Figure 2).

Figure 2 Contextual spatial analysis of selected case site.
Base map source: Baidu Maps; diagram created by the author.

Land use analysis within the five-minute pedestrian catchment (Figure 3) reveals a mix of village housing, woodland, and urban green space. Xiaozhou East Road, a minor road, provides the primary access. On-site observations indicate low vehicular traffic and a pedestrian-friendly environment.

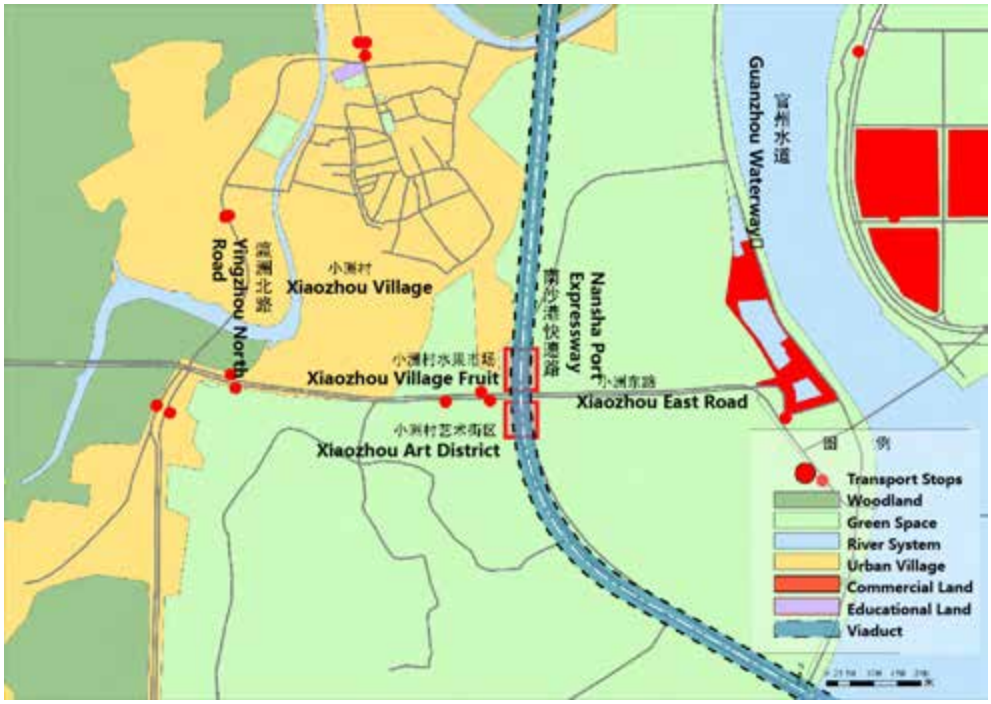

Figure 3 Five-minute walking catchment and land use analysis around the Nansha Port Expressway–Xiaozhou East Road underpass.
Diagram created by the author

The space accommodates two primary types of informal use: fruit vending, which functions as a **consumption-oriented activity**, and artistic production, which constitutes a **culturally embedded use** (Figure 4). These uses have emerged in a self-organised manner and coexist within the same under-elevated zone, creating a unique spatial synergy between everyday livelihood needs and creative practices. The primary user groups include local village residents, fruit vendors, art students preparing for university entrance exams), and young artists affiliated with the nearby Guangzhou Academy of Fine Arts.

Field investigations and interviews revealed that both the fruit market and the artist studios have existed continuously for more than one year and have become routinised components of the local spatial ecology. The site operates on a **full-day temporal cycle**, with peak activity periods observed during early morning (around 6:00 a.m., when vendors set up stalls) and again from late afternoon to early morning, when both vending and artistic activities intensify.

The fruit market is composed of **lightweight, collapsible stalls and mobile furnishings**, allowing vendors to adapt to changing space conditions and respond flexibly to demand and weather. Most of the infrastructure is semi-permanent but easily removable, which reflects the provisional nature of informal commercial activity. On the other hand, the artist studios take the form of **prefabricated panel structures or temporary cabins**, often built with plywood, plastic sheets, or reused materials. These units provide enclosed working environments for sketching, painting, and storage.

Together, these uses reflect **a multi-functional, informally co-produced urban microspace**. The spatial configuration not only satisfies practical needs such as daily food provision and low-cost workspace but also activates the underutilised overpass area with a blend of social and cultural vibrancy. This case illustrates how informality can serve as a tool for spatial optimisation in the context of megacity regeneration and space scarcity.

Figure 4 Top: Xiaozhou Village fruit market; Bottom: Xiaozhou Village art district. *Photographs taken by the author.*

3.2.2 Informal Use as Co-Produced Space

This site exemplifies a relatively complex and dynamic process of spatial production, resulting in a **functionally stable and socially embedded informal configuration**. Located adjacent to Guangzhou University Town but lying outside its formal administrative boundaries, Xiaozhou Village benefits from a unique **regulatory grey zone**. This peripheral positioning allows for greater spatial flexibility and tolerance of informality, as local administrative authorities tend to adopt a more lenient or non-interventionist approach. Such an environment enables organic spatial appropriation and adaptive reuse, indirectly facilitating long-term spatial stability beneath the overpass.

Several key conditions converge to support this stability. First, the area's **relatively low land rent** and **proximity to public transportation nodes** make it an attractive location for young artists, art students, and migrant vendors alike. The village lies only three kilometers from the Guangzhou Academy of Fine Arts, and its accessibility by bus and bike further strengthens its functional ties with the art school. As a result, a **local creative ecosystem** has gradually taken shape. According to field interviews, there are currently **dozens of intensive art training centers** (commonly known as) operating within the village, offering short-term residency, portfolio coaching, and art tutoring services.

The under-elevated fruit market on the north side of the road responds not only to the **everyday consumption needs** of village residents and art students but also plays a **supplementary role in the local art economy**. Fruit

is a recurring subject in foundational art education—particularly in sketching and still-life drawing exercises—which transforms the market into both a consumption space and a symbolic component of the **productive artistic environment**. This co-functionality of consumption and education creates **layered meaning and utility** within the space.

Meanwhile, on the south side of the overpass, the presence of self-built studios, temporary structures, and creative clusters illustrates a bottom-up formation of an **informal cultural district**. These spaces are typically constructed using prefabricated materials, reclaimed wood, or modular panels, and are highly adaptable to changing user needs. Artists, art students, and even part-time instructors from the Academy make use of these spaces for drawing, teaching, exhibiting, and even small-scale commercial work.

Crucially, this spatial arrangement is **not the result of a formal plan** but rather a **co-produced urban microenvironment** formed through the alignment of diverse actor needs—residents, artists, vendors, students, and local governance actors. Each party contributes to the spatial logic through their ongoing use, maintenance, and negotiation. The elevated infrastructure itself—often regarded as residual or dead space—is thus transformed into a **productive, multifunctional, and socially cohesive zone**.

In summary, the Xiaozhou Village case demonstrates how **spatial informality, artistic economies, and everyday consumption can intersect through co-production**, producing a hybrid and resilient public space that challenges the binaries of formal/informal and planned/spontaneous in contemporary urban theory (Figure 5).

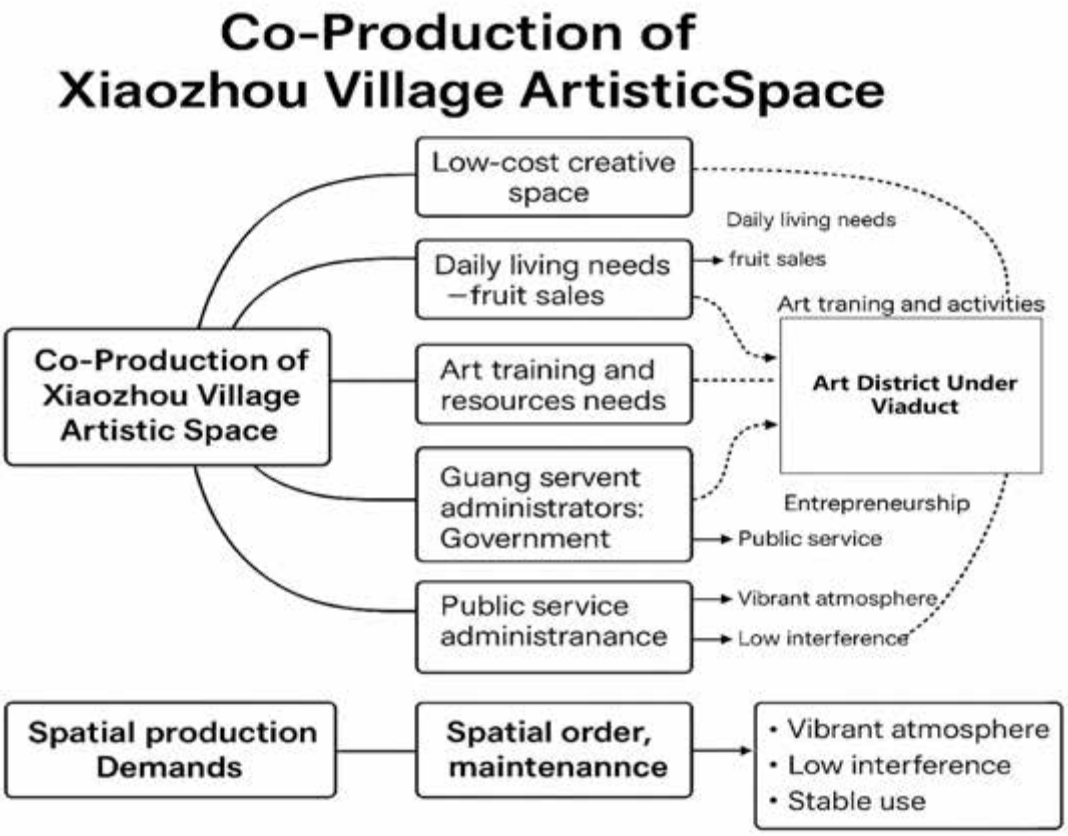

Figure 5 Characteristics of informal use under the Nansha Port Expressway–Xiaozhou East Road overpass. *Diagram created by the author.*

3.3 Dongsha Bridge – Xixiang Third Road

3.3.1 Spatial Context and Use Characteristics

This case involves the under-elevated space beneath Dongsha Bridge at its junction with Xixiang Third Road. A self-organised farmer's market has emerged beneath the structure (Figure 6).

- The eastern side is dominated by rural homesteads ();
- The western side consists of second-class residential land (R2 zoning).

Land use in the five-minute walking radius includes a mix of rural and urban housing, as well as cultivated farmland.

The bridge's clearance reaches approximately 20 metres, providing a rare, sheltered public space. The space's openness and shading qualities are especially valued in the local village context.

Additionally, moderate commuter flows from nearby roads and surrounding residents create a consistent demand for agricultural produce. Informal vending activities have emerged spontaneously over time. Restaurants along the roadside also occasionally encroach into the under-elevated area.

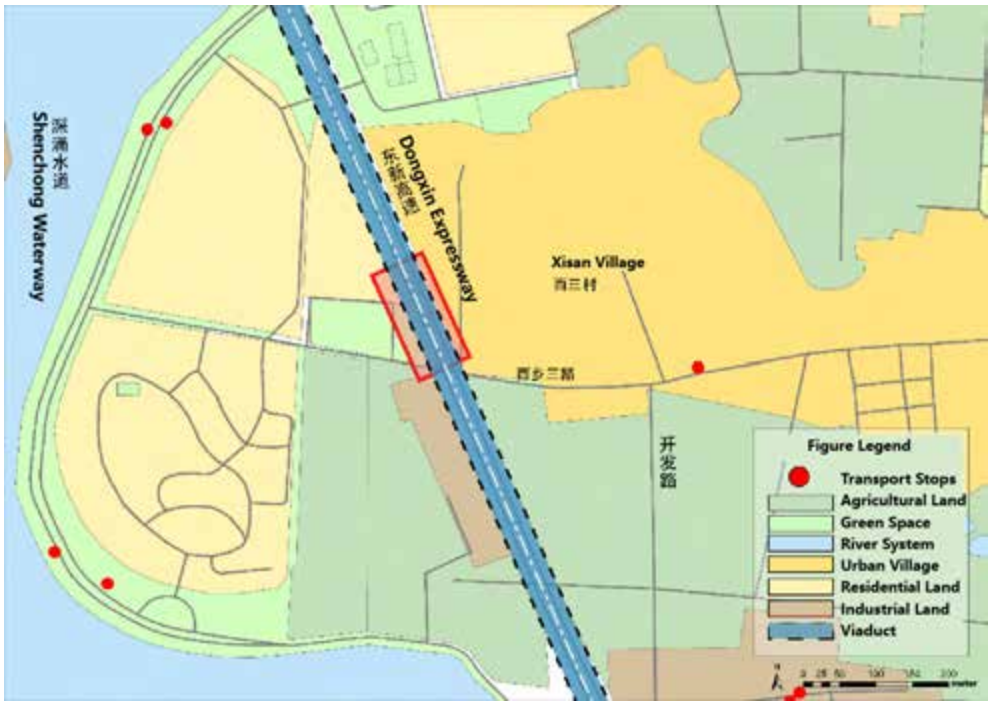

Figure 6 Land use analysis within a five-minute walking radius around the Dongsha Bridge–Xixiang Third Road underpass.
Diagram created by the author,

Figure 7 Informal use of space beneath the Dongsha Bridge–Xixiang Third Road overpass.
Diagram created by the author.

3.3.2 Informal Farmers' Market as Co-Produced Space
In this case, the rural residents of Xisan Village act as the primary initiators of informal spatial use beneath the Dongsha Bridge. Their need to sell surplus agricultural products—often grown in nearby peri-urban plots—naturally intersects with the everyday consumption patterns of passing commuters, local shopkeepers, and nearby residents. This **spatial and economic intersection** has facilitated the spontaneous emergence of an informal farmers' market beneath the elevated infrastructure.

Over time, through repeated transactions and habitual occupation, a **stable, trust-based relationship** has formed between vendors and consumers. The spatial regularity of the market—its specific time windows and physical configuration—has become part of the local socio-spatial rhythm. The elevated bridge structure provides critical environmental affordances: shade from sunlight, shelter from rainfall, and a relatively noise-buffered, open-air environment that does not impede vehicle circulation.

Importantly, the site is characterised by **low vehicular traffic flow and high pedestrian accessibility**, which supports the safe coexistence of informal economic activities and surrounding circulation systems. This case demonstrates how informal markets are not merely the result of economic necessity but are **co-produced through spatial affordances, social routines, and adaptive use of urban residue**. It underscores the planning potential of recognising informal practices as integral components of everyday urban systems.

3.4 Yanjiang West Road – Shamei Third Street
3.4.1 Spatial Context and Use Characteristics
Located on Shamian Island, a protected historical district and renowned tourist destination in Guangzhou, this site consists of a strip of under-elevated leisure space with informal seating and a bar (Figure 9).

The local street network is composed of narrow pedestrian-friendly roads, with walking as the primary mode of transport.

The elevated road above is currently decommissioned, allowing the space below to be fully appropriated for public use.

Visitors to Shamian often complete a loop around the island and stop at the riverside for rest. The underpass area provides essential shade and shelter from intense sunlight. It also hosts performances by local bar musicians, and a bar operates beneath the structure during evening hours.

The government has since incorporated this vibrant underpass space into its planning framework, designating it as a **"high-decibel vitality park"** within the Shamian Park system.

Figure 8 Indicative land use diagram of the ramp underpass at Yanjiang West Road, Shamian Island.}
Diagram created by the author.

Figure 9 Informal activities beneath the Yanjiang West Road–Shamei Third Street overpass. *Photograph taken by the author.*

3.4.2 Informal Recreation as Co-Produced Space

This case illustrates a **multi-actor co-production process** that has gradually stabilised into a vibrant leisure-oriented informal public space beneath the elevated ramp at Shamian Island. The key stakeholders involved can be categorised into three functional groups:

(1) **Space users**, including local elderly residents and domestic or international tourists, who regularly occupy the area for rest and socialisation;
(2) **Space beneficiaries**, particularly bar owners and informal performance groups (e.g., musicians and small bands), who generate cultural and commercial value through spatial use; and
(3) **Space managers**, namely local government departments and park authorities, who adopt a facilitative yet non-intrusive regulatory stance.

The **primary spatial functions** observed in this setting include passive recreation, live music performance, and outdoor food and beverage services. Informal usage patterns typically manifest during evenings and weekends, with actors deploying **movable furniture**, such as tables, chairs, sound equipment, and improvised stages. These temporary spatial interventions occur in response to fluctuating user demand and weather conditions, showcasing a high degree of **spatial adaptability**.

Notably, the local government's regulatory approach is **permissive but observant**. Rather than dismantling or formalising the space, officials have recognised the social and economic vitality generated by informal use. In some instances, they have gone further by incorporating the area into local spatial plans—designating it as a **"high-decibel vitality zone"** that tolerates noise, foot traffic, and spontaneous gatherings.

This governance flexibility has allowed informal space production to **move beyond precarity**, achieving temporal consistency and social acceptance. It also reflects a broader shift in urban governance paradigms—from formal control to **collaborative stewardship of public space**. By enabling spontaneous, low-cost cultural activity to thrive, this case offers a model for how informality and leisure can **coexist within heritage-sensitive, high-value urban environments**, enriching both local identity and the everyday public realm (see Figure 10).

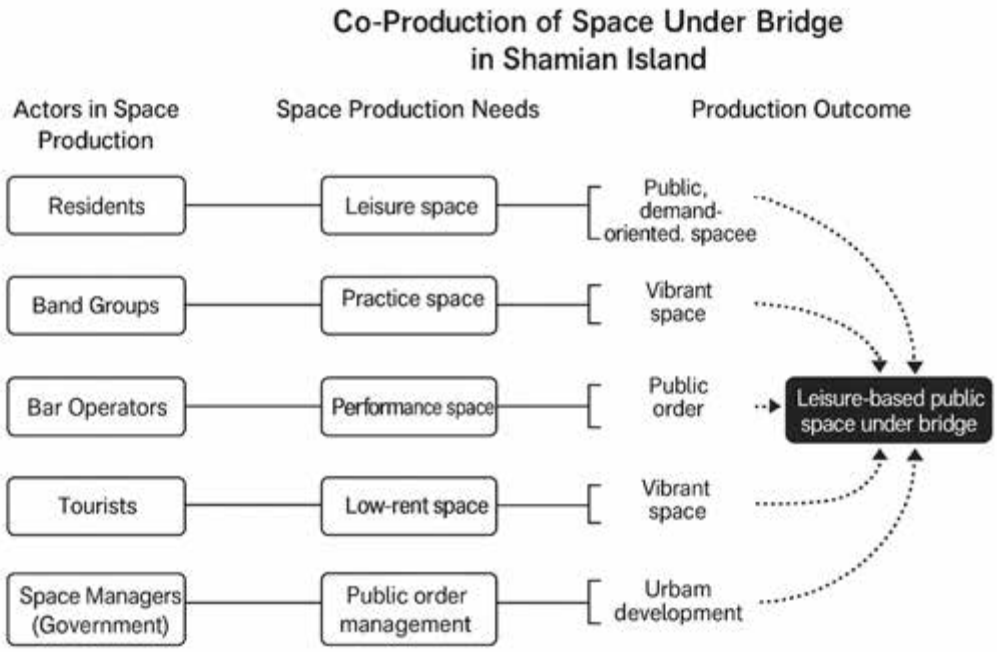

Figure 10 Characteristics of informal use beneath the ramp underpass on Shamian Island.
Diagram created by the author.

4 Insights into Informal Uses of Under-Elevated Spaces in Megacities under Stock-Oriented Urban Regeneration
4.1 Spatial Conditions that Support Overflow Functions from Adjacent Land Uses
Beyond the aforementioned three cases, this study extends the spatial analysis to several other sites across Guangzhou. Findings suggest that relatively stable, long-term informal public spaces beneath elevated highways generally exhibit the following spatial characteristics:

First, land uses on both sides of the overpass typically include **public activity-oriented functions**, with the under-elevated space absorbing overflow public uses. For example, in the Xiaozhou Village case, the art-related land uses west of the overpass—comprising art education industries and proximity to the Guangzhou Academy of

Fine Arts (within 2 km)—feed directly into the underpass art district.

Second, all cases are located within five-minute walking distances from **residential land**, whether in urban core areas or peripheral zones. This implies that continuous residential activity and strong public demand form the social basis for informal space activation, indicating the **necessity of community presence** to sustain use.

Third, suitable under-elevated spaces are generally **safe, calm, and pedestrian-friendly**. In all analysed cases, the relevant spaces are either beneath minor roads or entirely disconnected from vehicular traffic, forming semi-enclosed and stable environments. In the subtropical Lingnan climate, such covered yet ventilated spaces function similarly to traditional **arcades (骑楼)**—offering shade, rain protection, and fulfilling basic outdoor rest and gathering needs.

4.2 Formation of Stable Informal Uses Requires Multi-Stakeholder Spatial Production and Negotiation
The establishment of stable informal public spaces beneath elevated roads inevitably requires **multi-actor coordination**. Therefore, a communicable planning context becomes a prerequisite. The development process often involves four progressive stages:

Problematisation Stage:
Citizens or grassroots users must articulate spatial use needs from the bottom up, or managers must identify latent public functions of the space, initiating informal space formation.
Proposal and Resource Allocation:
Stakeholders collaboratively define the spatial product, identify beneficiaries, and clarify the nature of participation and resource inputs. Interests are negotiated, and actors are empowered to proceed.
Policy Formation Stage:
Based on site surveys and user engagement, public managers coordinate with other actors to formulate directional policies or decisions to support space production.
Maintenance Stage:
Long-term effectiveness of spatial governance must be ensured. Sustained support for spatial producers and responsiveness to evolving needs are essential to preserving stakeholder motivation and action continuity.

A relatively stable informal space emerges only when these stages are successfully completed. The formation mechanism can be summarised by four critical factors:

Top-down institutional design, where enabling policy environments are crafted by the government;
Active participation of community residents as spatial producers;
Supportive spatial production factors, such as nearby universities (e.g., the Guangzhou Academy of Fine Arts), artist communities, and vocational training demands;
Grassroots leadership and collaboration, including resident support and participation by students, artists, and vendors.

4.3 Long-Term Informal Use Relies on Stable Actor Networks
Whether initiated by institutional design, policy incentives, production conditions, or economic interests, **the formation of stable under-elevated informal public spaces requires a robust actor-network**. Key characteristics of such networks are:

Recurring spatial needs from producers, leading to the articulation of spatial use issues. For example, in the Shamian Island case, a senior citizens' band rehearses daily at a fixed time, and the audience that gathers around them further reinforces public demand for informal use.

Consistent and communicative relationships between public managers and spatial users. Effective governance depends on iterative dialogue and responsiveness across different production stages.

These factors help foster **networked co-production**, where the government, community organisations, social groups, and active users form a collaborative ecosystem for public space use.

5 Conclusion

In the context of China's rapid urbanisation, elevated highways have served as a key spatial instrument to support the functional expansion of megacities. However, the majority of under-elevated spaces remain **inactive and underutilised**. With increasing pressure for spatial intensification and rising public expectations for high-quality urban spaces, the potential of underpass spaces for adaptive reuse is becoming more evident.

Nevertheless, current informal uses are largely **sporadic and uncoordinated**, occurring in isolated pockets. There is still a pressing need to construct **scalable and replicable models of flexible spatial governance**. Such models should allow for formal recognition, support, and guidance of grassroots-driven informal practices within the broader framework of **People-Oriented Urbanism (人民城市).**

6. Discussion

This study explored the informal utilisation of under-elevated spaces in Guangzhou through the lens of co-production theory, using three representative cases—Xiaozhou Village, Dongsha Bridge, and Shamian Island. The findings provide critical insights into how spontaneous, actor-driven uses can evolve into functionally stable public spaces. Here, we reflect on the broader theoretical and practical implications of the research.

6.1 Rethinking Informality as a Strategic Layer of Urban Public Space

Conventional urban planning tends to regard informality as a disorderly or transitional phenomenon. However, our findings suggest that in the context of spatial scarcity and rigid institutional frameworks, informal uses can fill important spatial, social, and economic gaps. The analysed cases demonstrate that informal uses under elevated infrastructure are not merely adaptive; they are co-constructed by overlapping needs, negotiations, and routines across multiple stakeholders. Such bottom-up practices can be viewed as **strategic layers** of urban functionality rather than marginal exceptions.

6.2 Co-production as a Mediating Mechanism for Space Governance

Through Actor-Network Theory (ANT), we identified that the co-production of under-elevated informal spaces involves iterative interactions among residents, artists, vendors, tourists, and public managers. This reveals that governance of urban space need not be exclusively top-down; rather, it can emerge through negotiation, adaptation, and shared responsibility. In particular, the local government's flexible management style—by tolerating or even facilitating such uses—can stabilise informal activities without formalising them entirely. This suggests an **institutional space for negotiated informality** that may be more resilient than rigid spatial interventions.

6.3 From Fragmented Practice to Typological Recognition

Despite their ad hoc origins, the three case studies exhibit recurring spatial typologies:

Creative-cultural spaces (e.g., Xiaozhou Village),
Informal vending and micro-economies (e.g., Dongsha Bridge),
Leisure-based activation (e.g., Shamian Island).

Each typology reflects not only spatial conditions (e.g., shade, access, enclosure) but also **relational configurations** among actors. Recognising these patterns offers a potential pathway to shift from fragmented interventions to **typological recognition and planning integration**. Future urban design frameworks could include under-elevated zones as experimental zones for semi-formal co-production, especially in high-density contexts.

6.4 Limitations and Further Research

This study is limited to three qualitative case studies within one metropolitan context. Although the co-production framework proved effective in interpreting spatial and social dynamics, further research could:
Extend comparative analysis to other Chinese megacities or global south contexts;
Incorporate quantitative assessments of spatial performance and user behaviour;

Explore legal and planning instruments for formal–informal hybrid governance models.

Note

[1] Informal Use:
In this paper, "informal use" refers to urban spatial activities that arise spontaneously and contingently, without explicit official planning control or formal authority intervention.

[2] Urban Residual Space :
In *The Death and Life of Great American Cities* (1961), Jane Jacobs questioned conventional urban renewal models and introduced the concept of urban residual spaces, such as "urban dead zones" and "dead corners." In this study, residual space primarily refers to linear spatial remnants generated during urban development processes that remain underutilised.

[3] Co-production:
Co-production (also referred to as "collaborative production") is a key concept proposed by economist Elinor Ostrom in the 1970s. It emphasises that citizens can play an active role in the production of public goods and services that significantly affect their lives (Albrechts, 2012). This concept is extended in this study to frame the informal use of space.

Acknowledgements

This research was supported by the National Natural Science Foundation of China (General Program), Project Title: *Spatial Impacts and Mechanisms of Cross-Boundary Activities in Metropolitan Areas from the Perspective of Manifold Interaction* (No. 5227083004).

The author(s) would like to express sincere thanks to local participants in Xiaozhou Village, Dongsha, and Shamian Island for their time, trust, and insights during the fieldwork. Special appreciation is extended to the planning officials and community managers who provided valuable information and access to under-elevated spaces.

Abstract
Urban parks in Costa Rica, though limited in number, are widely frequented and have gained importance since the COVID-19 pandemic, with over half of visitors reporting increased use. This study investigates perceptions of metropolitan parks as spaces of well-being after the pandemic. Data were gathered in 2024 through walking interviews in the country's three largest metropolitan parks, differentiated by age groups, and analysed using thematic and geospatial methods. Findings reveal that parks are deeply valued for recreation, social interaction, and emotional support, especially among older adults and active users. However, concerns persist about safety and deteriorating infrastructure due to underfunding. The study underscores urban parks' vital role in fostering resilience, social connection, and collective well-being in post-pandemic urban life.

Keywords: post pandemic, urban parks, parks reappreciation, Costa Rica.

Introduction

During the COVID-19 pandemic, urban parks played a crucial role in supporting overall well-being and maintaining social connections, even amidst physical distancing measures (Powers, Pitas and Mowen, 2022). These green spaces offered a vital outlet for physical activity, stress relief, and safe social interaction during an unprecedented global health crisis. However, the extent to which parks can fulfil these roles effectively depends significantly on the quality of their infrastructure. Well-designed, accessible, and well-maintained facilities are essential for enhancing user experiences and encouraging frequent visitation. Moreover, diverse and inclusive infrastructure can support a wide range of recreational, social, and cultural activities, thereby meeting the varied needs of different community groups (Heckert and Bristowe, 2021).

Urban parks in Costa Rica are scarce but widely used by people of all ages. Following the COVID-19 pandemic, more than 50% of visitors to the country's main metropolitan parks reported an increase in their visitation frequency (Barrantes-Chaves, Centeno-Mora and Cruz-Zúñiga, 2024; Barrantes-Chaves, Cruz-Zúñiga and Centeno-Mora, 2024). This paper explores how their visitors perceived those places as agents of well-being, both before and after the pandemic, this is done through georeferenced walks with park's users (Evans and Jones, 2011; Barrantes-Chaves, 2025). The findings suggest that urban parks are highly valued for recreation and social interaction, particularly by older adults and individuals engaging in outdoor sports. Participants reflected on their experiences before and after COVID-19, highlighting how they have come to reappreciate these spaces. Key themes that emerged included social interaction, infrastructure, and available facilities. However, concerns were raised regarding safety and the deterioration of park infrastructure due to insufficient funding, which has negatively impacted services and amenities.

Both adults and older adults expressed their challenges and expectations for the future, emphasizing how urban parks have helped them navigate the social and emotional effects of the pandemic. These spaces have facilitated the creation of new support networks and reinforced their role as essential resources for collective well-being.

COVID-19 and Urban parks as space for hope.

Certain design features are especially important for specific groups of park users, particularly when it comes to encouraging walking and regular use. For instance, older adults often have specific needs that must be considered in park design. Key elements such as gentle slopes, shaded areas provided by tree cover, smooth and stable walking surfaces, and easy, direct access from parking lots are critical to ensuring comfort, safety, and accessibility for this demographic (Paudel *et al.*, 2023). When these features are thoughtfully incorporated, parks become more inclusive and supportive of active aging and overall public health.

Wong (2009) argues that older adults tend to use parks more intensively than other age groups, highlighting the important role these spaces play in their daily routines and overall well-being. However, accessibility remains a key factor in their usage patterns. Zhang et al. (2022) found that older adults generally prefer not to walk more than 15 minutes to reach a park, indicating that proximity is crucial in determining whether they will actually make use of these public spaces. This suggests that urban planning efforts should prioritise the equitable distribution of parks within walkable distances, particularly in neighbourhoods with a high proportion of older residents.

Internal accessibility within parks is equally essential, particularly for older adults and individuals with limited mobility. Ensuring that paths, facilities, and recreational areas are easily navigable can significantly enhance the usability and inclusiveness of these spaces. Initiatives aimed at improving accessibility often focus on upgrading infrastructure and providing services that accommodate people with disabilities, such as smooth pathways, ramps, accessible restrooms, and seating areas (Pivetta *et al.*, 2020).As a result, the emphasis on accessibility has driven continuous improvements in park design and management. These enhancements not only promote greater inclusivity but also contribute positively to public health and quality of life, especially for vulnerable populations (Santana-Santana, Peña-Alonso and Pérez-Chacón Espino, 2020). Importantly, when public spaces are designed with the needs of older adults, children, and people with limited mobility in mind, they ultimately benefit everyone. Universal design principles create environments that are safer, more comfortable, and more welcoming for all users, regardless of age or ability.

While the need for improved infrastructure in parks is undeniable—particularly to enhance accessibility and inclusivity—it's important that such developments are thoughtfully planned and not result in the overbuilding of unnecessary structures. Excessive or poorly integrated infrastructure can detract from the natural character of green spaces and reduce their appeal. In fact, research has shown that many park users, often express a strong preference for walking through natural environments such as forests and wooded areas (Matasov *et al.*, 2023), where the experience of tranquillity and contact with nature is prioritized over built features. Therefore, park design should strike a careful balance between providing essential amenities and preserving the natural landscape to support users' psychological well-being and desire for authentic outdoor experiences.

Although existing research has recognised the importance of urban parks during the COVID-19 pandemic, few studies have captured the evolving emotional, social, and functional perceptions of park users in the post-pandemic context, particularly through in-situ (Zhang and Li, 2023), qualitative, and geospatial methods in underrepresented regions like Central America. Even fewer have focused on how older adults and vulnerable groups articulate aspirations, perceived safety, and accessibility barriers, all of which are essential for inclusive urban policy and design.

In this regard, this article aims to explore how urban parks in Costa Rica have been reappreciated as essential spaces for social interaction, emotional resilience, and public well-being in the aftermath of the COVID-19 pandemic. By analysing georeferenced walking interviews conducted with adult and older adult users in the country's three main metropolitan parks, the study seeks to uncover how different age and gender groups perceive these spaces, the challenges they encounter, particularly in terms of safety and infrastructure, and the aspirations they hold for more inclusive and accessible urban environments.

Methods

Data were collected through walking interviews conducted in 2024 across Costa Rica's three largest metropolitan parks. In each location, two separate walks were undertaken—one with participants under the age of 65 and another with participants aged 65 and above. These walks were tracked using Global Positioning System (GPS) devices and synchronised with audio recordings to accurately document spatial and verbal data.

The walking interview recordings were transcribed and subsequently analysed using thematic analysis, following the methodological framework proposed by Braun and Clarke (2006). The identified themes were coding and then georeferenced using Geographic Information Systems (GIS) to spatially represent participants' experiences and perceptions within the park environments.

In addition, each participant was provided with a printed map of the respective park and a set of colour-coded stickers representing different levels of fear. Participants were asked to place these stickers on the map to indicate areas where they felt varying degrees of safety or vulnerability. This process generated a series of visual data outputs, including maps illustrating the intensity of fear and others depicting a broader spectrum of emotional responses experienced throughout the parks.

The participants were regular users of the three metropolitan parks included in the study. Recruitment was carried out through collaboration with park administrative staff and local community organisations, including organised user groups and neighbourhood associations.

Administrative officers played a crucial role in identifying frequent visitors and initiating contact with potential participants. Established community networks further supported the recruitment process by ensuring diverse representation across age groups and user experiences. Each walking interview consisted of groups ranging from five to fifteen participants. This approach allowed for the inclusion of individuals with varying degrees of familiarity and engagement with the park spaces, thereby enhancing the richness and depth of the data collected.

Results and discussion

Table 1 presents a breakdown of comments by gender (Women and Men), age (Older adults and adults) and sentiment (Positive, Neutral, Negative), categorised by thematic areas related to a park. For example, the category General Aspirations (GA) reflects desires for the park's future and potential improvements. Infrastructure (IN) refers to its physical features, while Interaction with the park mainly relates to activities taking place within it. Maintenance (M) concerns keeping the park in good condition. The Pandemic (P) category includes memories of COVID-19 and the park's role during that time. Perception of safety (PS) captures feelings related to crime and how vulnerable people feel in the park. Lastly, Perception of the environment (PE) involves the experience of moving through the park and includes elements such as vegetation, built structures, sounds, and the overall atmosphere.

Table 1. Summary of comments within the three analysed parks.

Category	Positive comments (N=282)		Neutral comments (N=558)		Negative comments (N=486)	
	Women	Men	Women	Men	Women	Men
General Aspirations (AG)						
Older Adults	2.66%	0.00%	5.26%	1.39%	1.36%	1.39%
Adults	2.66%	2.13%	4.68%	0.46%	2.73%	0.46%
Infrastructure (IN)						
Older Adults	19.15%	11.70%	9.65%	18.98%	25.45%	18.98%
Adults	2.66%	10.64%	9.06%	15.74%	15.00%	15.74%
Interaction with the Park (IP)						
Older Adults	7.98%	1.06%	15.50%	1.85%	3.64%	1.85%
Adults	7.98%	3.19%	14.33%	6.94%	4.09%	6.94%
Maintenance (M)						
Older Adults	5.85%	2.13%	2.63%	2.78%	3.64%	2.78%
Adults	0.53%	3.19%	1.17%	3.70%	5.45%	3.70%
Pandemic (P)						
Older Adults	0.53%	0.00%	7.31%	0.00%	0.91%	0.00%
Adults	2.13%	2.13%	2.92%	0.00%	0.45%	0.00%
Perception of Safety (PS)						
Older Adults	12.77%	10.64%	10.53%	30.09%	22.73%	30.09%
Adults	9.57%	18.09%	6.43%	12.50%	7.73%	12.50%
Perception of the Environment (PE)						
Older Adults	19.68%	15.96%	5.26%	3.70%	3.64%	3.70%
Adults	5.85%	19.15%	5.26%	1.85%	3.18%	1.85%
Total	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%

General Aspirations

Within this category, women contributed a higher proportion of positive and neutral comments than men. The theme centres on aspirations and visions for the future of the park, including proposed interventions aimed at improving its attractiveness and functionality. One female participant, for instance, expressed a desire to repurpose underutilised areas, suggesting their transformation through aesthetic enhancements:

"If a space like this is not going to be used, gardens can be created — something with greater visual beauty."

This perspective invites broader reflection on the adaptive potential of public spaces and the importance of responsive design in addressing the changing needs of communities. It also highlights the need to consider the interplay between aesthetic, recreational, and social dimensions in urban planning. The proposal to enhance visual appeal through the creation of gardens not only responds to concerns about underuse but also underscores the role of beauty and environmental quality in shaping public experience and promoting well-being. In this regard, it is crucial to incorporate infrastructure that is adaptable to diverse user needs, along with improved safety measures — including the reduction of concealed or poorly visible areas and the provision of comprehensive facilities with integrated support services. (Zhang et al., 2022).

Infrastructure and maintenance

Infrastructure was one of the most frequently discussed topics, generating both positive and negative feedback. Within this category, older women shared more positive comments than any other demographic group. In contrast, adult women under 65 offered fewer positive remarks compared to men in the same age range.

A recurring complaint focused on one of the free-entry parks (La Sabana), where users must pay to use the toilets while parking remains free. One adult female participant remarked:

"The toilet over there next to La Sabana charges a fee, and it makes much more sense to charge for parking than for the toilet, as using the toilet is a physiological necessity — not everyone will have the money to pay for it."

Charging for toilet access can disproportionately affect vulnerable populations — such as low-income individuals and children — who may not be able to afford the fee. It also reflects urban policy choices that appear to prioritize car users over pedestrians and public health.

Another frequent concern involved the poor condition of pavements and footpaths. One older male participant commented on this issue during a visit to La Paz Park in August 2024:

"These pavements are a disaster. You should see how people fall and trip. They had done just some patchwork repairs..."

This highlights ongoing issues with accessibility and safety — particularly for older adults, who have become some of the most frequent park visitors since the pandemic (Barrantes-Chaves, Cruz-Zúñiga and Centeno-Mora, 2024). For many in this group, the park serves as an important space for socialising and maintaining physical and mental well-being. However, damaged or poorly maintained walkways can pose a serious risk of falls and injuries, undermining the park's role as a safe and welcoming environment. Addressing these issues is essential to ensure the space remains inclusive and secure for all users, especially older adults.

Conversely, well-designed park pathways can significantly encourage physical activity among older adults. As one older male participant observed during a visit to La Sabana Park in September 2024:

"Very nice for people who ride bicycles or who want to come and run among the trees."

This positive remark underscores the value of well-maintained infrastructure in promoting active lifestyles and meaningful contact with nature. His appreciation suggests that the park supports inclusive recreational activities — such as cycling and running — within a natural setting that enhances the overall experience.

Regarding maintenance, older women tend to express more positive comments compared to other age groups. In contrast, women under 65 are more likely to offer negative feedback than other participant groups. This difference may reflect varying expectations or experiences with park upkeep across age demographics.

For example, one older female participant praised recent improvements, saying:

"They installed that over there — that basketball court was just newly built, very nice. That one as well. Look at the condition of this soccer field. Everything is lovely. Over there, look — the maintenance is excellent. Just look at the grass."

Her remarks highlight an appreciation for visible efforts to maintain and upgrade park facilities. This positive feedback suggests that good maintenance resonates strongly with some visitors, particularly older women, who may value well-kept spaces for recreation and socialising. Research has highlighted the disproportionate impact of the pandemic on older adults; however, there remains a lack of public policies that promote inclusive design and the development of age-friendly cities (Buffel et al.,2023).

Interaction with the Park and Perception of the environment

In terms of social interaction, women—both under and over the age of 65—tended to express more positive views about the park as a space for connection and shared experiences than their male counterparts. One adult woman in La Sabana described:

"These are free, accessible entertainment spaces where you do not have to pay an entry fee or do a lot to enjoy yourself. You can even bring your own food. You can have a good time — even if there are concerts, you can listen from outside if your group is not going in. There is plenty to do: play sports, eat, watch, talk."

She highlights how these parks are intentionally inclusive, offering a welcoming environment for people of all socioeconomic backgrounds. She emphasises their appeal as spaces for casual, low-pressure recreation, where people can participate in communal activities or simply enjoy the atmosphere—even without engaging directly in formal events like concerts. This perspective underscores the importance of informal, spontaneous social interactions, especially for individuals or families with limited financial resources.

Men also expressed positive views about the parks, particularly in relation to their role as communal gathering spaces. One older male participant at El Este Park remarked:

"We celebrate birthdays and weddings here..."

This comment highlights the park's function as a vital and inclusive setting for family and community celebrations. Figures 1 and 2 illustrate various views of the park, including the designated area used for weddings and other social events. The images reflect a forested and tranquil environment conducive to relaxation and connection. For older adults in particular, such accessible public spaces are essential for sustaining social bonds and commemorating significant life milestones. These parks thus operate not only as recreational environments but also as meaningful venues for collective memory, identity, and intergenerational engagement.

Figure 1 and **2**. Views from El Este park.

Another significant aspect of public space design is the incorporation of natural elements—such as water—which can enhance both social interaction and emotional well-being. In this context, an older female participant reflected during the walking interview in El Este Park in July 2024:

"I love it, the river sounds so beautiful."

This comment illustrates the profound impact of sensory experiences in public spaces. Elements such as the sound of flowing water, the presence of greenery, and an overall sense of tranquillity contribute to feelings of peace, joy, and connectedness to the natural environment. For many older adults, these features offer a soothing retreat from urban stressors and play a vital role in promoting psychological well-being. Such observations suggest that aesthetic and sensory dimensions can be just as important as physical infrastructure in shaping meaningful and enjoyable experiences in public parks. This supports existing research indicating that natural settings may, in some cases, hold greater significance than built amenities (Matasov *et al.*, 2023).

However, in parks where lakes form a central part of the landscape, user perspectives are more divided. While some individuals value these features as untouched natural spaces, others express a desire for them to serve a

more recreational purpose. One older male participant, speaking about the lake in La Paz Park, during the walking interview in August 2024, stated:

"It's nice, but what's missing is recreation — recreational activities, little boats or something like that."

His response reflects an appreciation for the lake's aesthetic qualities while simultaneously identifying a lack of opportunities for active engagement. The suggestion to incorporate amenities such as small boats indicates a desire for age-appropriate, interactive features that move beyond passive enjoyment. This underscores the importance of recreational infrastructure that supports light physical activity, social participation, and meaningful interaction — all of which are crucial to promoting healthy ageing and fostering inclusive community environments. Figures 3 and 4 provide visual representations of the lakes referenced in his comments. As depicted, there is a noticeable absence of leisure-oriented activities surrounding these water bodies. However, it is also important to acknowledge that environmental factors—such as water contamination—may limit the feasibility of direct human interaction with natural features. In this regard, planning policies that incorporate community participation are crucial for guiding future administrative decisions about the park. For example, decisions concerning the management of the lakes could lead to public dissatisfaction if not properly addressed, as a lack of community engagement has been shown to negatively impact park usage (Kyriakidis et al.,2023).

Figure 3 and **4**. Lakes from La Paz Park.

Taken together, these insights suggest that successful public spaces for older adults should strike a balance between calm, sensory-rich environments and opportunities for gentle recreation and interpersonal connection. Designing spaces that support both contemplation and active engagement may better meet the diverse needs of older populations and foster more inclusive, age-friendly public environments.

Perceived Safety

Fear of crime remains a persistent concern among both men and women. Negative perceptions regarding safety were more frequently expressed than positive ones, particularly in parks with free public access. For instance, an older man in La Paz stated:

"Well, it's just that I don't come at night. If I did, it would feel really unsafe. Of course, at night it becomes dangerous — after 7 p.m., this place is not safe."

This comment illustrates a perceived temporal shift in the safety of public spaces, where environments are considered acceptable during daylight hours but become threatening after dark. The interviewee draws a clear boundary: the space is usable by day but effectively off-limits at night. This perception underscores the significance of lighting, surveillance, and active community presence in shaping the experience of public spaces across different times of day. Figures 5 and 6 illustrate participants' perceptions of safety in La Paz Park during daytime (Figure 5) and nighttime hours (Figure 6). The comparison clearly indicates a heightened fear of crime

after dark, particularly in areas located farther from the main streets, where visibility and public presence are reduced.

Figure 5. Map illustrating the intensity of perceived fear during day as reported by users during walks-along in La Paz Park, conducted in August 2024.

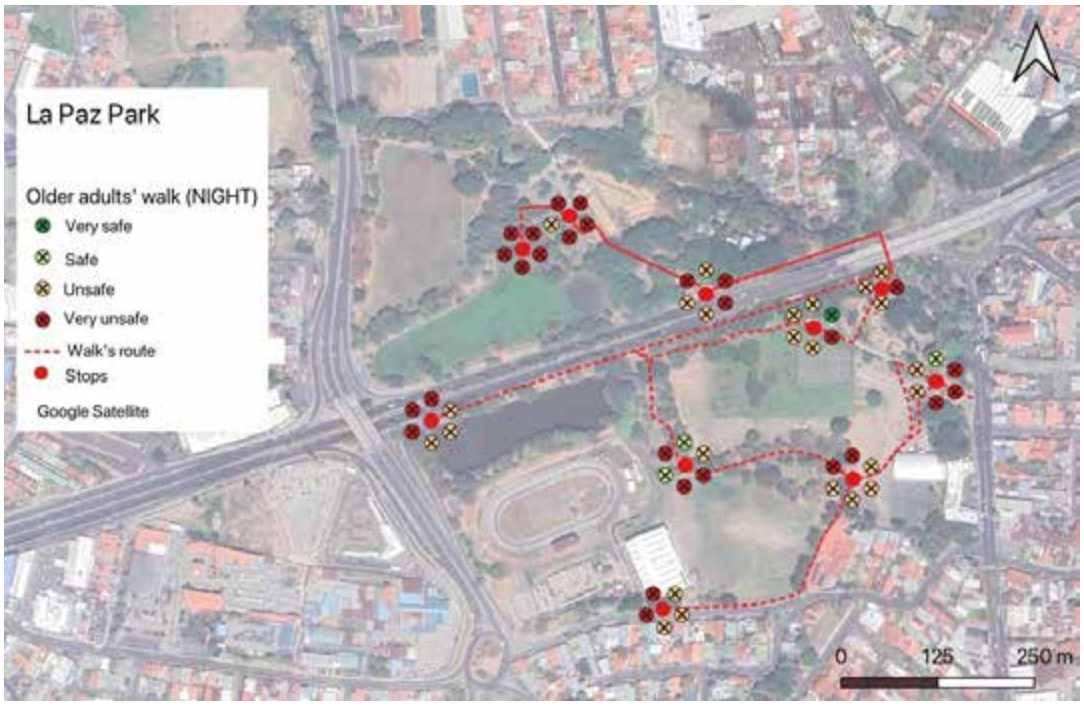

Figure 6. Map illustrating the intensity of perceived fear during night as reported by users during walks-along in La Paz Park, conducted in August 2024.

Despite concerns related to safety during nighttime hours, certain elements were identified as mitigating these fears. During a walking interview conducted in La Sabana Park in September 2024, an adult female participant observed:

"Just the fact that you see the police nearby already makes you feel a bit safer. Also, there are always lots of children around, which makes the environment feel more friendly — and because it's close to the street."

This reflection suggests that visible indicators of oversight—such as police presence—can reduce anxiety and enhance the perceived security of a space. The presence of children is highlighted as a further reassuring factor, symbolising normalcy, vitality, and a family-friendly environment. Such humanising features contribute to an emotional sense of safety beyond mere physical protection. The reference to proximity to the street introduces the idea that openness and integration into the urban fabric—rather than isolation or enclosure—foster greater comfort and perceived accessibility. In this regard, prior research within the Costa Rican context has demonstrated that the normalisation of gating contributes to a feedback loop that reinforces fear of crime, thereby intensifying perceptions of insecurity in the surrounding areas (Barrantes-Chaves, 2024).

Similarly, another woman interviewed in El Este Park expressed:

"I feel that it feels safe because... well, first of all, there are people who work here, and also there are structures around, so you kind of feel surrounded by things that give you the sense that if something were to happen, there would be support."

Here, safety is associated with the visible presence of workers and structural features within the park. These individuals may function as informal stewards or guardians, whose presence implies oversight and the potential for assistance if needed. Moreover, the respondent points to the psychological impact of the built environment: being "surrounded by things" conveys a sense of enclosure, familiarity, and orientation. Such spatial features enhance perceived safety by reducing feelings of exposure and isolation, instead offering cues of support and surveillance.

Overall, these findings underline the critical role of intentional design, visible care, and social presence in cultivating a sense of safety in public spaces. The physical and social composition of these environments significantly shapes users' emotional and psychological experiences, particularly in relation to fear, comfort, and belonging.

Pandemic Impacts on Public Space Use

During the COVID-19 pandemic in Costa Rica, many public parks were either entirely closed or only partially accessible due to lockdown restrictions. For families in vulnerable communities, these parks functioned as essential green spaces—effectively their only access to nature—yet became inaccessible under public health measures. Reflecting on this experience, an older male participant at La Paz Park recounted:

"Well, I used to come to the park during the pandemic, and the police made me leave. I told them, 'Look, there's no one around — I need to breathe, get some fresh air.' They said to me, 'You cannot, do it around the neighbourhood instead,' and I responded, 'No, because I have a broken ankle and the pavement and asphalt hurt me too much. I need to do it on the grass.'"

This testimony reveals the tensions between pandemic-era public health enforcement and the specific needs of individuals, particularly those with mobility issues or chronic health conditions. The speaker's account underscores how uniform, top-down regulations—though well-intentioned—can unintentionally marginalise vulnerable populations. The reference to the physical pain caused by hard surfaces highlights the role of design and materiality in shaping accessibility. Parks, typically associated with health, recovery, and inclusion, were paradoxically rendered off-limits during a period when their therapeutic value may have been most urgently needed. This example emphasises the importance of empathy and flexibility in urban governance, particularly

in times of crisis.

However, the pandemic also led to some lasting, positive behavioural shifts. Two women interviewed in separate parks offered reflections on changes in public space use:

A female adult in La Sabana noted:

"What I think is that during the pandemic people had more time to dedicate to physical activity, and after the pandemic they kept that routine. So, there are more people exercising now than before the pandemic."

Similarly, a female adult in El Este observed a dramatic increase in visitation:

"Definitely. Much more. But, I mean, what can I say? About 300% more. After the pandemic."

These comments point to a durable transformation in the way public spaces are valued and used. The first highlights the role of the pandemic in catalysing new health-related behaviours, particularly physical exercise, which in many cases have persisted beyond the period of lockdown. This supports broader arguments about the importance of habit formation and access to supportive environments for long-term public health outcomes. The second, with its emphatic estimation of a "300%" increase in visitation, reflects a renewed public appreciation for parks as vital spaces of recreation, wellbeing, and social interaction, this aligns with previous research indicating that, following the COVID-19 pandemic, there has been an increased appreciation of urban parks. (Soares and Brasil, 2020; Wu et al., 2023).

Taken together, these narratives illustrate how the pandemic redefined public parks—not merely as sites of leisure but as critical urban infrastructure supporting physical, mental, and emotional resilience. The growing reliance on such spaces has, in turn, generated increased expectations that they remain open, inclusive, and well-maintained in order to meet heightened and sustained public demand.

Conclusions

The findings from this study highlight the multifaceted roles that urban parks play in the lives of diverse user groups, particularly older adults and women. Participants' aspirations for the future of these spaces underscore a desire for more responsive and inclusive urban design — one that balances aesthetic enhancements with functional utility. The recurring call to transform underused areas into visually appealing gardens, for instance, reflects broader public interest in making parks both more beautiful and more inviting. These visions suggest that public spaces should not be static but adaptive, evolving with community needs and expectations, and incorporating both sensory experiences and recreational functions.

Infrastructure and maintenance emerged as both enablers and barriers to inclusive park usage. While older women tended to express greater satisfaction with maintenance efforts, inconsistencies in infrastructure — particularly the condition of walkways and the policy of charging for toilet access — reveal underlying inequities. These issues disproportionately affect vulnerable users, such as older adults, people with mobility challenges, and low-income visitors. Conversely, positive feedback regarding well-maintained amenities, such as cycling paths and sports courts, suggests that quality infrastructure can significantly enhance engagement and well-being. The differential experiences across age and gender groups further illustrate how park infrastructure and maintenance are not neutral but have socially differentiated impacts that must be considered in future planning.

Finally, the COVID-19 pandemic reshaped the public's relationship with green spaces, illuminating both their essential function and the limitations of current governance frameworks. While restrictions rendered parks inaccessible for many, the crisis also fostered long-term behavioural shifts, including increased rates of exercise and park visitation. These changes reaffirm the vital status of parks as everyday public infrastructure supporting physical, mental, and social resilience. As expectations for access, safety, and quality rise, it is imperative for

urban policy to integrate inclusive, health-promoting, and flexible design strategies that recognise public spaces not merely as recreational luxuries, but as foundational components of equitable, age-friendly cities.

Acknowledgements
We extend our sincere gratitude to the University of Costa Rica for supporting this research through the Women in Research Support Fund (*Fondo de Apoyo a la Mujer en Investigación*). We are also deeply thankful to the community leaders, park administrators, research participants, and research assistants whose invaluable contributions and collaboration made this study possible.

Visual Perception of Universal Design Interventions for World Heritage Sites: Case of Istanbul Historic Peninsula

Buse Ceren Ener

erhankurtarir@gmail.com

Abstract
Universal Design is defined with seven principles for enhancement of inclusivity for various fields of design. Some enhancements are especially aimed to be visibly highly noticeable, so they can be used intuitively, self-directing the audience with added visibility and attention. However, when it comes to urban heritage sites visual unity and coherence brings heritage value. Therefore, potentially the addition of highly visible indicators might be contradicting with the idea of the nature of interventions. Core tension of this study is the conflicting nature between inclusive urban design applications and conservation policies for World Heritage Sites where minimum intervention aimed. In-depth interviews with users of public spaces in Historic Peninsula Istanbul conducted, results will be discussed to reach parameters for universal design tools for heritage sites.

Keywords: Inclusivity, Public Space, World Heritage Sites, Accessibility, Universal Design

Introduction

Universal Design refers to designing environments and services to be usable by all people to the greatest extent possible. In the context of World Heritage Sites (WHS) protected under UNESCO's World Heritage Convention applying UD principles means making historical urban environments inclusive for people with disabilities, the elderly, and other disadvantaged groups. Yet this must be done sensitively so as not to compromise heritage integrity or authenticity (WHC, 2025) defined as Outstanding Universal Value. The Historic Peninsula of Istanbul, consists of four districts that covered the WHS (Topkapı Archaeological Park, Süleymaniye District, Zeyrek District, and City Walls) selected as the case study area since the sites are both home for millions of residents plus millions of tourists visiting every year. Historic core with its narrow-cobbled streets and dense tourism make accessibility a challenging question itself as well as universal design. "Should demands for access for all be ignored to satisfy calls for heritage conservation, or vice versa?" is the core question and efforts for new approaches recognise that both goals may coexist (McClelland, 2022).

Scope and Aim

This paper studies how universal design principles can be applied in urban design, management and planning for World Heritage sites to enhance inclusivity without losing the heritage integrity. Istanbul's Historic Peninsula selected as a case study area and the study aims to find out the visual perception of inclusivity interventions in physical space and how public spaces in historic urban districts can be modified with respect to the parameters that the study will explore. The study investigates the research question of Is it possible and if so how it is possible to integrate inclusive design to urban heritage sites especially World heritage sites so that the outstanding universal value would not be comprimised? Literature review starts with bibliometric analysis with searching keywords world heritage sites and inclusive design in both Scopus and Web of Sciece platforms. The sources found are briefly referd part of the literature review and the methodology is conducted in accordance with the priliminary research. Methodology of the study is consisting of two parts where methodwise extensive and intensive research approaches for social sciences reseach by Sayer (2010) is adopted and withing that procedings paper the intensive research part is conducted and the first part resullts are given place. In-depth interviews are conducted with a small group of participants as the intensive research where the extensive research approach is planned as the second part of the further studies as a more integrative and comprehensive approach. Core

argument is shaping around the fact that with universal design it is possible designing environments usable by all people, for people with disabilities, the elderly, families with children and so on while respecting historic character. Special attention is given to visual perception tools such as interpretive signage, tactile maps, guided transitions, and multi-sensory wayfinding, discussing how they can be adapted in heritage contexts. After the in-depth interview is decoded and analyed the main themes will be listed to construct the parameters for inclusive design in heritage areas. Historic urban areas such as the zones mentioned part of Istanbul's Historic Peninsula are complex urban settings to bring together public and stakeholder engagement together for public good and also another question of ethics of the subject embedded at the core of the world heritage as the words meanings trying transfer the messege of the site is not just a property of a country or a specific city yet they belong to all human-kind; even the ones who are not born yet.

Focusing on the core conflicts mentioned above study aims to find how to enhance the visual perception of the inclusive design indicators for a public space with an urban heritage value; especially for the World Heritage Sites without causing disturbance on the value of the site?". While maintaining the main emphasis on universal design principles, how can site-specific urban design solutions can apply and how they will be perceived by the users of public space is the scope of this research. After the case study finally the results and conclusion aim to discuss and find out the possible parameters for universal design tools specifically of heritage sites.

Literature Review

Urban heritage conservation and accessibility are traditionally seen as separate goals, but growing consensus questions otherwise as mentioned. Universal design extends beyond basic accessibility standards; it is an inclusive philosophy is changing the heritege preservation perspectives as well. For 2030 Unesco and WHC is determining strategices for cultural inclusion as well as sustainability and accessibility. Capacity building is another important part highligthed under the inclusivity framework for heritage conservation in real life practices (UNESCO WHC, 2025).

Importantly, UD is distinguished from merely meeting minimum accessibility codes. While accessibility often focuses on enabling people with disabilities to use a place (usually via specialized features like ramps or lifts), UD assumes the primary design solution accommodates everyone. In other words, where accessibility might add a separate solution, The inclusive design approach means that installations (e.g. elevator, ramp, signage) benefit not only disabled persons but all users, thus investing in universal access yields broad social and economic benefits (Darcy, 2006).

Applying UD in heritage sites raises concerns about preserving authenticity and integrity. International charters that heritage places should retain their historical fabric, which can conflict with modern interventions. However, recent thinking suggests that inclusion is part of sustainability and continuity of heritage. UNESCO and ICOMOS support integrating disabled access into cultural heritage as part of living heritage preservation. For example, UNESCO's "Making Culture Accessible" initiative notes that cultural heritage sites should be experienced by all and that existing infrastructure should be adapted for both disabled and non-disabled. (UNESCO WHC, 2025) A Norwegian government report on heritage and universal design likewise asserts that everyone "expects to be able to experience monuments and sites in an equal manner" and encourages local solutions that balance access with conservation (Norvegian Ministry of Environment et al, 2010) This affirming with thoughtful design, inclusivity can be built into heritage environments without undermining their values.

On the other-hand the application itself is also a challenge even if the aim is constituting this basis of awareness of inclusive design. Urban heritage areas present specific challenges: they often have uneven terrain, narrow streets, cobblestones, stairs, and tightly spaced buildings. Diken and Onur (2022) observe that streets and public spaces in historic city sites seldom incorporate UD principles due to "topographic problems and inadequacies in existing traditional areas" Integrated approaches – such as pedestrianizing streets, improving pavements, and designing public furniture accessibly – are recognized as part of sustainable urban heritage management.

Heritage sites are mostly sites that are unfamiliar to many visitors being there the fisth time in their lives. Therfore wayfinding is one of the key concepts of visual perseption related to space. Visual perception tools such as signage, maps, digital media guide visitors through complex historic environments. Adapting these tools universally means considering diverse sensory and cognitive needs.

Traditional signage at heritage sites must balance readability with aesthetics. To serve all visitors, interpretive signs should use high-contrast, large fonts on plain backgrounds, avoiding visual clutter. Importantly, signs can include tactile elements and Braille. Multisensory tools are other important concept of visual perseption of the inclusivity tools as the would be integrated to the actual physical site. Multisensory features do not compromise heritage imagery; rather, they enrich engagement. A heritage site could pilot such an accessible sign in a courtyard or entrance area to enhance inclusivity. Even digital displays (e.g. touchscreen kiosks) can follow principles of universal design as they should have audio output, haptic feedback, and simple interfaces compliant with universal design standards.

As mentioned above orientation in a heritage district can be challenging due to irregular layouts. At this point the Tactile (3D) surfaces or maps placed at key nodes can visually impaired visitors. These maps generally use raised contours and textures for buildings and terrain, often accompanied by Braille labels. They must be located at accessible height and located at logical transitions (e.g. station exits, major squares). For universal design, the same map should be usable by all: e.g., a map with clear pictograms and text can serve general visitors, while the raised features serve visually impaired users as referring to Equality principle of universal design.

İnalhan and Ergeneoğlu (2010) define disabled customer's market is an important niche market for the tourism industry. "A Disabled person's willingness to travel may vary according to their hearing, speaking, seeing, or orthopedic disabilities. Therefore, people's disabilities should be considered when designing indoor" (Kahraman, 2019, p.5). In a historic site, moving from one space to another (e.g. from street to building interior, or between elevations) can be disorienting if not handled well. Universal design advocates "same route" access, meaning everyone should follow the same circulation path. For example, a grand museum entrance should have a ramp integrated alongside steps, rather than a hidden side entrance. At Hagia Sophia or Topkapı Palace, this could mean designing unobtrusive ramps at entrances so that wheelchair users and those with strollers enter through the main gate. Similarly, textured paving or gentle level changes can signal transitions between public squares and building forecourts. "All users follow the same routes through the site" and that primary entrances should have no step (National Park Service, 2025). Lighting and subtle wayfinding markers (e.g. distinct floor patterns) can guide visitors smoothly without altering historic thresholds.

Methodology and Case Study

As the study uses a qualitative review of relevant literature, policy documents, and case reports, supplemented by illustrative examples from Istanbul's Historic Peninsula; both white literature and grey literature; to construct the foundation of the in-depth interview questions the visual perseption, world heritage sites and inclusive design are taken as key themes. Key sources include academic studies on accessibility, UNESCO guidelines and decisions, engineering and design reports on the Istanbul Historic Peninsula. The discussion is organised thematically: first reviewing universal design concepts in heritage contexts, then examining visual perception and wayfinding adaptations, and finally analyzing Istanbul-specific challenges and practices. This approach highlights both theoretical guidance and concrete urban design interventions.

Figure 1 Istanbul Historic Peninsula World Heritage Site Zones. (WHC, UNESCO, 2025 retrieved from https://whc.unesco.org/en/list/356/maps/)

Istanbul's Historic Peninsula faces typical constraints of a layered heritage environment: ancient Byzantine walls, Ottoman mosques and palaces, mixed-use bazaars, and a labyrinthine street network. These physical conditions, plus heavy tourism, create both barriers and catalysts for universal design. Over recent decades, local planners have pursued projects that implicitly apply universal design and inclusivity principles, starting with integration of public transportation, pedestrianisation, enhanced wayfinding systems and maybe last but not the least important one as the social inclusion indicators.

Public transportation is one of the major determinents of accessibility and inclusivity as the ramps and related assistive layout is missing in most of the public transit stops and stations (Evcil, 2009). This might bring the thought of most people with disability do not feel welcomed or do not feel they have the chance to join city life and leave their homes. Pedestrianisation is another aspect of accessibility studies, on contrasting levels; with groups supporting the idea or opposing to this particularly. Between years 2005–2012 Istanbul undertook major pedestrianization in the Peninsula. Streets were repaved with smooth granite, obstacles removed, and service corridors As a result, bollards, curbs and barriers that once hindered wheelchairs were gradually. Many people opposed to the projects as the retail sectors are mostly negatively effected by those kind of physical interventions (Öztaş and Akı, 2014).

Results and Discussion

The study adopts two partile method combinin extensive and intensive resarch methods as Sayer (2010) defines. This part of the study focusing on the background of the subject and tries to understand the mechanisms and

perception, awareness and social structure behind inclusivity on site. As a part of this intensive approach the Google Earth street view tool is used for the digital documentation of the physical structure and its change through time. For example a related image is given at Hagia Sophia adjacent street between 2023-2024 there had been an implementation on the pavements with high contrast level yellow pavement lines paninted on the street to draw extra attention to the level differences on the road and pedestrianised area (Please see figure 2 and figure 3).

Indepth interviews showed that 5 particepents all mentioned the tactile pavements and yellow lines used for visual impairments yet did not notice the info desks or other supportive indicators. The emphasis is mostly on the visually impaired and the wheelchaire users when disabilies are concerned. Neuro-diversity is totally neglected none of the participants know the topics and its relationship to the inclusivity or universal design.

Figure 2 Additional Attention Yellow Path is added at 2023 and 2024 in Sultanahmet District (Photo produced by Buse Ceren Ener using the digital source Google Earth)

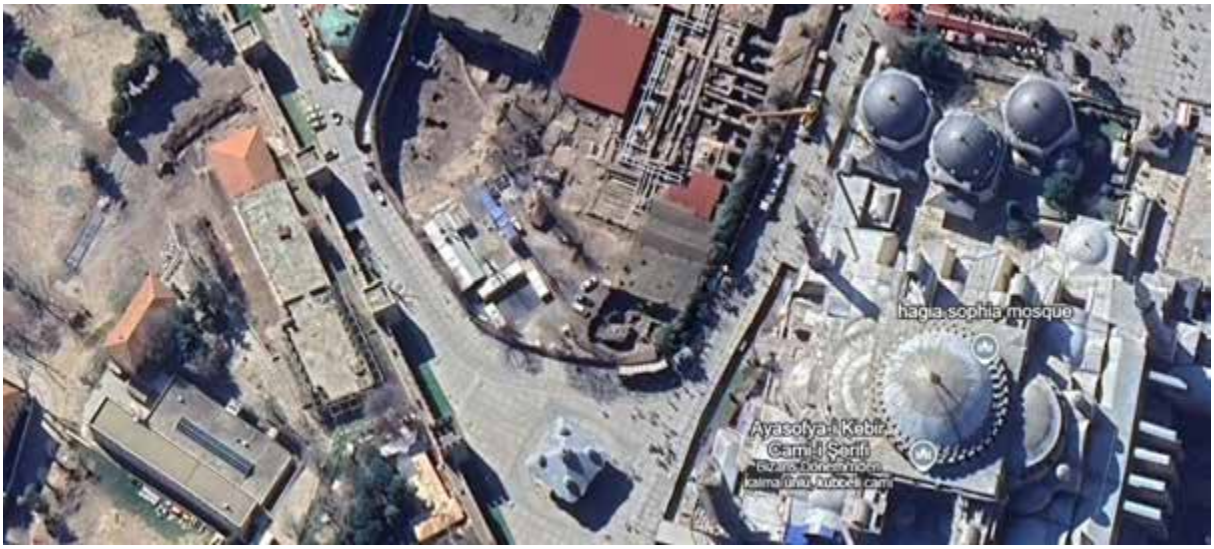

Figure 3 Additional Attention Yellow Path is added at shown near Hagia Sophia, years 2023 and 2024 in Sultanahmet District (Photo produced by Buse Ceren Ener using the digital source of Google Earth)

Conclusion

This study can be taken as a priliminary study, a first step towards an extended further researches on the site. Its importance lies at the future attributes where future social inclusion and capasity building is on the agenda. To sum up all this, it should be underlined again that UNESCO World Heritage status imposes strict conservation regulations that often require heritage authority approval for any physical interventions, including accessibility features, to ensure they are reversible and visually unobtrusive. As this applies all world heritage sites the case study area Istanbul is particularly difficult to be approached as the metropole has over 15 million residents and numerous visitors. Institutional coordination is another major challenge, as overlapping responsibilities between municipal, district, and national agencies can delay universal design (UD) projects. Should also adress the main limitation is that since İstanbul is a very complex case to study it is difficult to take visual perception as an indepentent attribute.

Socially and economically, universal design presents clear benefits: it enhances tourism by expanding accessibility for international visitors while also improving quality of life for residents, including the elderly and pregnant women. Evidence from other heritage cities shows that accessible environments contribute to increased tourism satisfaction, dwell time, and spending in heritage zones.

Universal design offers a path to greater inclusivity at heritage sites like Istanbul's Historic Peninsula while upholding conservation goals. The principles of UD – equitable use, perceptible information, tolerance for error, etc. – can be applied in urban heritage planning to create spaces and tools that welcome all visitors. Key strategies include designing shared accessible routes, deploying multisensory interpretive media, and carefully integrating access features into historic contexts (UNESCo, 2025). Although challenges exist (physical constraints, regulatory complexity, institutional coordination), the opportunities are significant: enhanced visitor experience, compliance with human rights frameworks, and alignment with sustainable development goals. Future efforts should focus on comprehensive management plans that explicitly incorporate universal design, continued stakeholder engagement, and pilot projects showcasing innovative wayfinding technologies. By doing so, Istanbul can become a model for how World Heritage Cities. "Disability ought to be regarded as an instance of diversity, not as a limitation" says Falt and Manocha, (2019) addressing India's perspective as many other countries that now opening inclusivity universal design and heritage horizons, for further studies and geographies.

TOURISM

Mass Tourism in Malia: Towards a Decolonial Model for the Lassithi Plateau

Konstantina Nikoletta Karasarini
KU Leuven
Email: konstantinakarasarini@gmail.com

ABSTRACT
This paper explores how mass tourism operates as a neo-colonial mechanism in the Malia region of Crete, and whether degrowth can serve as a decolonial alternative for the Lassithi Plateau tourism development, located 20km away. Combining desk and action research, the study investigates how tourism-driven urbanisation, cultural commodification, and extractive infrastructure perpetuate economic and spatial inequalities. In contrast, the Lassithi Plateau showcases that cultural background, agricultural activity, and community agency offer fertile ground for a degrowth-based tourism model. Based on local findings and international case studies, this research examines whether a community-led framework could comprise a viable alternative for future tourism development. Despite structural challenges, degrowth tourism emerges as a strategy for restoring cultural identity, reclaiming autonomy, and resisting capitalist extraction in tourism-dependent regions.

KEYWORDS: Mass tourism, Neo-Colonial, Degrowth, Community, Cultural Landscape

INTRODUCTION

Tourism has been a vital part of the Greek economy since 1930, shaping its cultural identity and contributing to economic development (Karvounis, 2021). Post-war years saw significant growth in the tourism domain with US investments through the Marshall program[1] , establishing a tourism industry aligned with Western Standards. The GNTO[2] organisation in 1951 marked the beginning of a systematic development contributing to economic reform and modernisation of the state (Tournikiotis and Monemvasitou, 2012).

The inflow of foreign currency significantly influenced the Greek economy's exchange rate and contributed to its stability (Karvounis, 2021). This affected the cultural interpretation of Greece, aiming to attract high-income tourists. Ancient Greek civilisation and local traditions were selectively integrated with the expectations of modern living standards, forming a "new cultural identity" (Tournikiotis and Monemvasitou, 2012). Moreover, constructing a "touristic brand", commodifying on landscape and planetary commons, the sun and the sea, exposed the Greek periphery, particularly the islands and areas with valuable natural beauty, to tourism development (Tournikiotis and Monemvasitou, 2012). The gradual tourism-led urbanisation transformed the landscape, especially from the 1970s, when mass tourism emerged, until its exaggeration in the 1990s (Andriotis, 2001).

Today, the legacy of early tourism strategies is still visible in Crete, where tourism remains a dominant economic force. The region of Malia has been exposed to tourism investments, intensive urbanisation of coastal areas, appropriation and privatisation of the landscape, and the commodification of culture. Traditionally based on agriculture and fishing, its local economy shifted to the tertiary sector, and mass tourism significantly shaped its cultural landscape (Andriotis, 2001).

In contrast, the Lassithi Plateau, 20 km south of Malia, remains an untouched area of natural beauty, with the economy still rooted in agriculture. Mass tourism in the late 1970s prompted internal migration from the Plateau to emerging tourist hubs along the island's northern coast, particularly in Malia (Terkenli and Bellas, 2007), impacting its cultural landscape. The Plateau, formerly known for its traditional windmills and agricultural life, is experiencing socioeconomic degradation and demographic reduction. The gap between the two regions is widening due to the coastal zone development, underscoring the need for sustainable and balanced growth in alternative tourist models.

1 The US provided economic aid to Western Europe post-war, with Greece being notably influenced by Truman's 1947 governance, bringing the country under western influence (Beckmann, 2012).
2 Greece's National Tourism Organisation.

This research aims to investigate how mass tourism functions as a neo-colonial mechanism in the case of Malia and whether Degrowth could operate as a Decolonial practice, suggesting an alternative tourism model for the case of the Lassithi Plateau. The research questions to frame are the following.

1. How does mass tourism operate as a neo-colonial mechanism, and how does it affect the spatial and cultural transformation in the Malia region?
2. What are the further implications for the cultural landscape in the Lassithi Plateau?
3. Could a tourism model based on degrowth principles offer a decolonial alternative for the Lassithi Plateau's future tourism development?

METHODOLOGY

This research employs a qualitative and interpretive methodology that combines desk research, field-based action research, and comparative case study analysis. The desk research component involved an extensive review of academic literature, statistical reports, and policy documents related to tourism development in Greece, spatial planning in Crete, and theoretical frameworks of neocolonialism and degrowth. This established the historical and conceptual context of the study and informed the critical reading of institutional strategies and tourism narratives.

The choice of Malia's case, based primarily on desk research, was necessary to understand how mass tourism dynamics impacted the Lassithi Plateau's socio-economic structure and cultural landscape over the years.

The action research occurred in the Lassithi Plateau through a two-week field visit organised within the programs of MaULP[3] and IMSDP[4] of KU Leuven. During the fieldwork, our team, comprised of 13 students, young researchers, and two supervisors, conducted semi-structured interviews, unofficial conversations, and ethnographic observation, participating in local events. Residents, farmers, craftspeople, and representatives of community associations and local authorities became part of the research. The time was limited, but the findings were valuable. The interviews were not formally coded but were treated as narrative and contextual material. They contributed to comprehending locals' perspectives and interpretations of the Plateau's cultural landscape, its transformation, the historical importance of the windmills, and their vision or concerns about tourism and development. Through a careful reading process highlighting repeated concepts, values, and tensions, these local narratives were thematically interpreted, providing findings about locals' future tourism vision and windmills' role.

This interpretative approach prioritised the lived experience and the community voice, serving as a decolonial praxis (Mignolo and Walsh, 2018) in which the lived experience adds essential value to the research. Our interaction with locals let us better understand the dynamics of the place and the community. This aided in exposing the rooted cultural logic and collective memory that formed the Plateau's identity and potential, and comprehending the locals' vision for their place.

Moreover, two case studies from Ecuador, where Indigenous communities have implemented degrowth-aligned tourism models that emphasise community ownership, environmental stewardship, and cultural regeneration, were also examined using a comparative lens. This comprehensive framework for evaluating other development models and these scenarios critically examines the potential and limits of using comparable models in the context of Crete.

The methodological elements offer a multi-layered understanding of tourism's political, cultural, and spatial aspects. They enable a grounded analysis of how local communities in Crete might resist extractive tourism through culturally embedded and environmentally conscious development models.

MASS TOURISM AND DEGROWTH

How does mass tourism function as a neocolonial mechanism, impacting spatially and culturally the Malia region? Neocolonialism refers to continuing colonial power dynamics through indirect economic, cultural, and spatial control (Childs and Williams, 1997). As a globalised industry, mass tourism often perpetuates these dynamics by fostering economic dependency, commodifying local cultures, and reshaping physical spaces to serve external interests (Butcher, 2020). Degrowth arises as a critique of the neocolonial practice in mass tourism, aiming to explore a decolonial alternative for future tourism development in the Lassithi Plateau.

Mass tourism as a Neocolonial Mechanism in Shaping Space and Culture

Historically, tourism has been utilised by imperial forces to maintain power, modernise economies, and legitimise colonialism in former colonies. Mass tourism, developed by a small elite in industrialised countries, was celebrated for granting access to leisure activities to the working class (Butcher, 2020). This phenomenon has expanded globally since the 1960s, driven by transnational corporations, fostering labor exploitation, cultural commercialisation, and spatial inequalities (Williams, 2012; Butcher, 2020; Linehan, Clark and Xie, 2020).

Spatially, mass tourism reflects colonial urban segregation by privatising and commodifying planetary commons, intensifying urban expansion, and internal migration (King, 1976, 1989; Karvounis, 2021). While culturally, mass tourism incorporates Orientalist[5] narratives by romanticising and commodifying local cultures, and shaping identities through Eurocentric standards and capitalist consumption culture (Childs and Williams, 1997; Mason, 2006; Baylis, Smith and Owens, 2023). Thus, mass tourism functions as a contemporary tool of neocolonialism, sustaining imperialist values of control, exploitation, and profit extraction (Karvounis, 2021).

Mass tourism, a neocolonial phenomenon, significantly impacts space and culture by introducing a new cultural service-based economy based on foreign and domestic private investments, capitalist consumption culture, and global trends. In 2023, the economy of Crete Island depended on tourism to the extent of 70%, while it accounted for 26% of the annual revenue distribution of international incoming tourism (Ikkos and Koutsos, 2024).

The Malia region has experienced rapid growth, with the coastal area now dominated by large-scale resorts and medium-scale hotels (Figure 1). This has changed radically its cultural landscape, renegotiating its place identity to align with mass tourism's leisure and consumption culture. Malia has become a popular destination for young tourists, promoting capitalist consumption and global lifestyle trends. However, the tension between traditional values and Western culture is evident, with local cultural distinctiveness often being overshadowed by urban lifestyle or commercialised traditions (Terkenli and Bellas, 2007). The commodification of natural landscapes, historical sites, and religious architecture superficially interprets the place's history and culture, highlighting the mutual influence of space and culture.

5 Edward Said's concept of Orientalism influenced post-colonial space and culture by portraying the "Orient" as inferior, legitimising imperialist policies, and reinforcing Western self-perceptions, thereby distorting traditional cultures (Childs and Williams, 1997; Baylis, Smith and Owens, 2023).

Figure 1: Large and Medium Scale Hotels and Resorts in Malia (Hersonissos and Malia Tourism Development [Mp4], 2025)

Degrowth as a Decolonial Tourism Practice

Decolonial theory aims to expose the colonial roots of mass tourism and its impact on Western societies and culture. It advocates for placing life in the center of thinking and practice, enforcing local communities' ways of living, detached from the internalised colonial roots (Mignolo and Walsh, 2018).

Degrowth critiques extractivism's logic, the economy-centered development, and incorporates decolonial perspectives by supporting a collective shift toward post-capitalist paradigms. It prioritises well-being, ecological balance, and community autonomy over economic accumulation. The concept of "growth" is not demonized. Redistributing "growth" would allow less developed regions to evolve and overdeveloped ones to decelerate, bridging the gap between them. It suggests different political and economic structures where top-down and bottom-up initiatives complement each other (Fletcher et al., 2019).

As Latouche argues Western economic expansion, driven by extractive industries like mass tourism, negatively impacts cultural landscapes and suppresses local communities (Latouche, 2004). Decolonial features of degrowth emphasise reducing economic reliance on extractive industries like mass tourism. It suggests a collective tourism model focusing on steady, qualitative development within a post-extractive economy that measures growth in community resilience, autonomy, environmental balance, intercultural exchange, and not in GDP (Chassagne and Everingham, 2019). Thus, a "communing tourism" model involving community-driven governance through cooperatives and associations could promote a low environmental footprint, sustainable production and consumption patterns, and equal redistribution of goods and costs within the community (Fletcher et al., 2019).

Malia's cultural landscape has been dominated by mass tourism, though degrowth offers a potential alternative. It re-conceptualises tourism as a beneficial tool for local communities, preventing colonisation of pure regions like the Lassithi Plateau. This approach emphasises environmental preservation, cultural integrity, and community empowerment as key to a future decolonial tourism.

MASS TOURISM MECHANISM IN MALIA

The Greek periphery transitioned towards tourism development in the 1970s due to its reliance on the tertiary sector and growing demand for Western European holidays and leisure activities (Andriotis, 2001). The mass tourism model standardised package holidays, making the Mediterranean coast and islands attractive destinations (Butcher, 2020). Despite facing infrastructure, transportation, and connectivity challenges (Buhalis, 1999), Crete remains an attractive international tourist destination (Figure 2), consistently ranking first in global tourism revenue until 2023 (Insete, 2021).

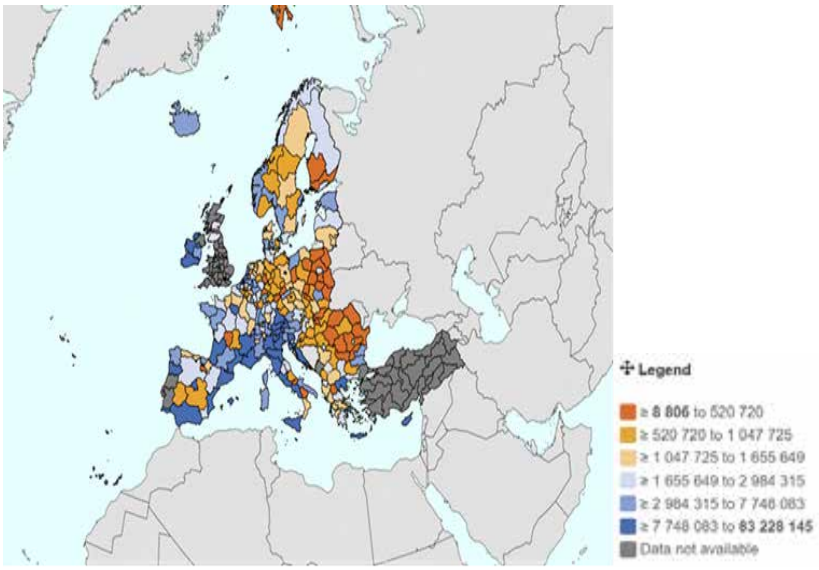

Figure 2: Foreign Overnight Stays in 2023 (Eurostat, 2025)

Tourism-Led Development and Spatial Transformation

Tourism growth in Crete has led to significant infrastructural projects, altering the island's socioeconomic trajectory and landscape. The economy heavily relies on tourism, attracting public and private investment in infrastructure to accommodate visitor flows and stimulate market activity (Andriotis, 2001).

The northern part of Crete (Figure 3), facing the European mainland, has become a focal point for such investments, including the BOAK highway, the Heraklion port, and the Heraklion New Airport (Figure 4) (Andriotis, 2001). That spatially impacted Malia Starting in the 1970s, it underwent a rapid spatial reconfiguration that grew more intense in the 1980s and 1990s. The accompanying urban expansion was catalyzed by infrastructural connectivity and tourism growth. As illustrated in cartographic materials, construction gradually concentrated along coastal zones and road networks, progressing steadily in subsequent decades (Figures 5 and 6).

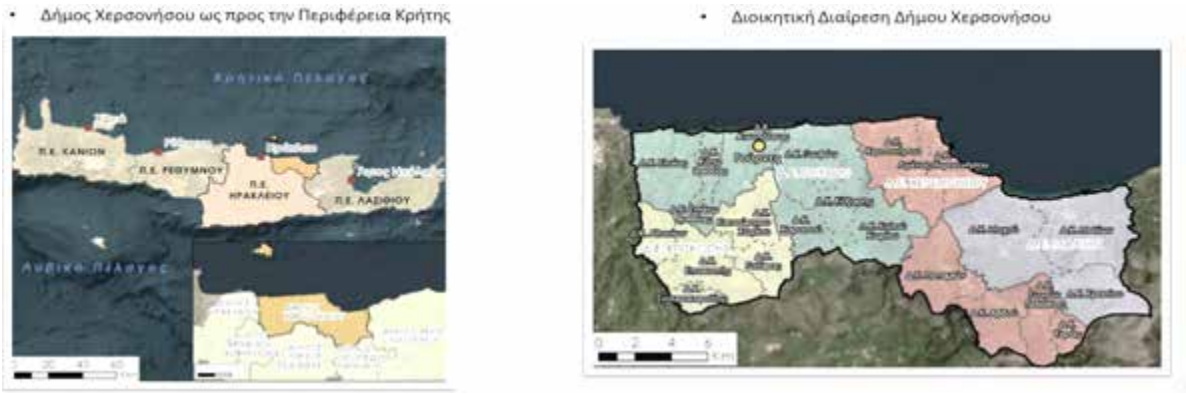

Figure 3: Location of the Malia region in Crete (Ministry for the Environment and Energy and Technical Chamber of Greece, 2024)

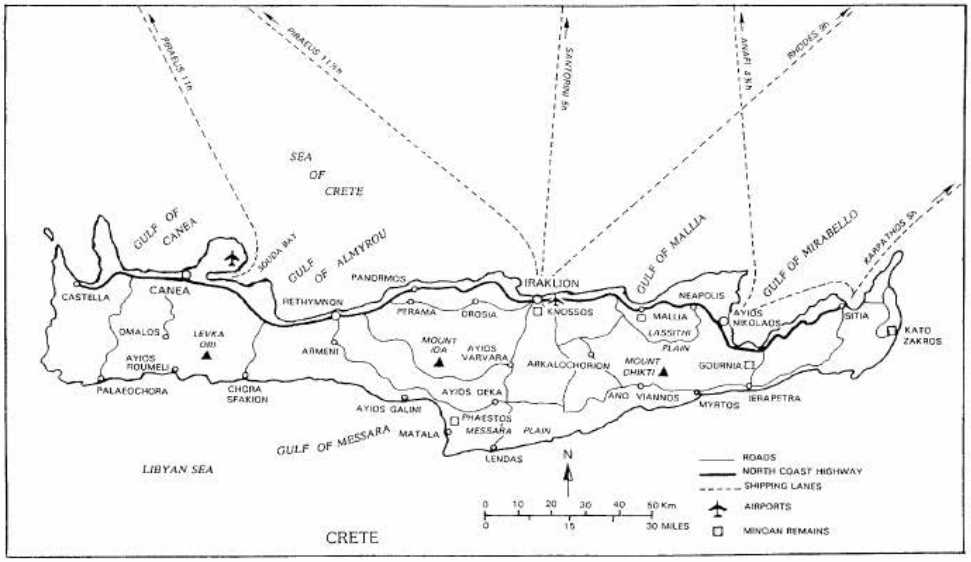

Figure 4 Map of Crete

Figure 4: Large-Scale Infrastructure Projects in the Northern part of Crete (Andriotis, 2001)

The construction of an international airport in Kastelli, is expected to accelerate development and connect Crete's northern and southern areas. The airport, strategically located at the boundary of the Heraklion and Lassithi regions (Figure 5), is the second largest in Greece (Herakion International Airport, 2025). Such public-private infrastructure development projects reveal deeper economic dependencies, reinforcing neocolonial dynamics through indirect economic control (Buhalis, 1999). This is also indicated in the airport company's ownership, which is distributed among shareholders, including the Hellenic Republic (45.9%), GEK TERNA Kastelli S.M.S.A. (32.5%), and GMR Airports Greece S.M.S.A. (21.6%) (Heraklion International Airport 2025), with the GEK Terna Group contributing as well 55% to the BOAK highway extension in Crete (GEK Terna, 2018). It is thus questionable who these projects serve, and what criteria guide their design and implementation.

Figure 5: New Airport in Kastelli and its proximity from Malia and the Lassithi Plateau (Google Maps, 2019)

Tourism-led investments have significantly reshaped the built environment in Malia, with the first hotel built in the 1960s near the coast (Figure 6) (Explore Crete, 2014). Today, it hosts numerous all-inclusive hotels and resorts

(Figure 7), several held by domestic and foreign parties. Smaller family-run lodgings continue to exist inland, exhibiting various levels of tourism growth. Crete has consistently attracted domestic and foreign investment, particularly in high-end tourism facilities, maintaining strong market performance. Despite mass tourism's critique of seasonal limitations, Crete continues to be portrayed as a resilient market for tourism growth (Gov, 2024).

Figure 6: Malia Coastal Urban Expansion in 1966 (Hellenic Military Geographical Service, 1966)

Figure 7: Malia Coastal Urban Expansion in 2024 (Google Maps, 2019)

In 2024, the Heraklion prefecture had 509 registered hotel units, 373 of which are located in the municipality of Hersonissos (Ministry for the Environment and Energy and Technical Chamber of Greece, 2024). While the total number of accommodations on the island has grown by only 5% over the past decade, a 68% increase in 5-star hotels (Figure 8) indicates a clear trend toward luxury and all-inclusive development (Hellenic Chamber of Hotels, 2024). Although luxury tourism may appear distinct from mass tourism, its scale and capacity contribute to a high-volume, high-impact tourism consumption model.

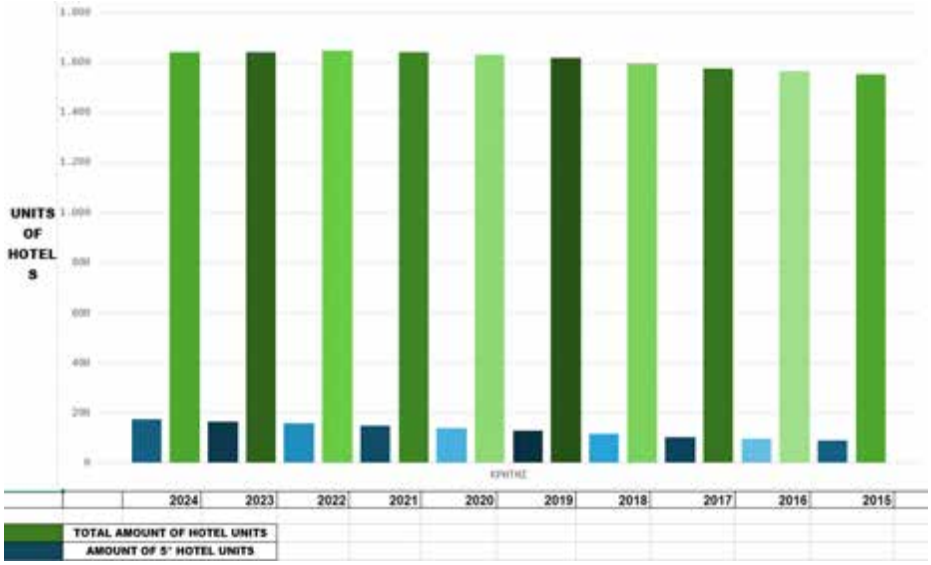

Figure 8: Total amount of Hotel Units & 5 Star Hotel Units in Crete (2015-2024) (Hellenic Chamber of Hotels, 2024)

The lack of early strategic planning allowed economy-driven tourism expansion. The spatial impact of investments increased the market interest, structuring urban growth accordingly. In the 1970s, national planning policies focused on economic gains through coastal development and construction incentives, such as grants and tax breaks (Andriotis, 2001). In the 1990s environmental considerations were introduced, but tourism investment continued in facility upgrades (Andriotis, 2001; Mason, 2006). These policies reflected centralised decision-making, detached from local community dynamics and rooted in monetised conceptions of growth.

Moreover, transitioning to the tertiary sector set tourism as a central pillar. Policies in the mid-1970s encouraged small-scale construction and hospitality enterprises, leading to internal migration of the rural population to profitable coastal zones like Malia (Andriotis, 2001). According to locals of the Lassithi Plateau, many families relocated to Malia to capitalise on land ownership and invest in tourism-related businesses. By the 1990s, nearly 40% of Crete's population was employed in the tourism sector (Andriotis, 2001), reflecting a broader rural-to-urban demographic shift (Figure 9) (Kotzamanis and Androulaki, no date).

Figure 9: Rural & Urban Population Transformation in Greece (Kotzamanis and Androulaki, no date)

Contemporary tourism planning acknowledges past overdevelopment while promoting new strategies for diversification models. The current Strategic Planning and Operational Program for Crete and the Local Urban Plan of Hersonissos emphasise alternatives, such as agro-tourism and mountain tourism, integrating natural and cultural assets to extend the tourism season year-round. However, they include strategies, continuing supporting large-scale investments, prioritising the upgrade or creation of 3, 4, and 5-star hotel units, and encouraging land uses related to leisure, cultural parks, and marinas (Figure 10) (Gov, 2024; Ministry for the Environment and Energy and Technical Chamber of Greece, 2024).

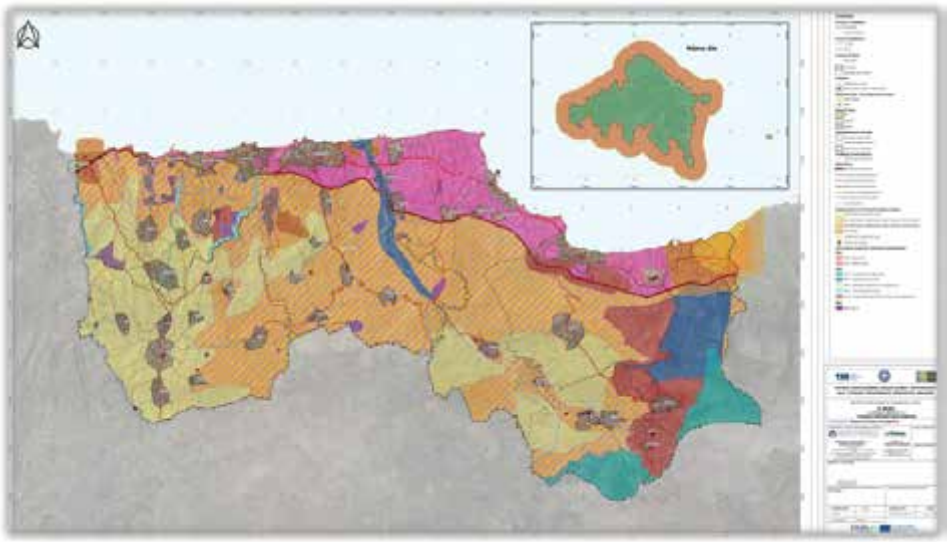

Figure 10: Tourism Development Zone, Intense Intervention Scenario. (Ministry for the Environment and Energy and Technical Chamber of Greece, 2024)

Therefore, tourism and infrastructure development in Malia reveal a spatial landscape significantly influenced by investment, policy, and market-driven demands. This sustains a tourism model still rooted in patterns of exclusivity, dependency, and unequal growth, even with strategic planning changes towards alternatives.

Tourism Labor Force and Social Dynamics Impact

Crete heavily depends on the tourism industry, embracing the imperatives of economy-led growth, perpetuating spatial and cultural inequalities. Culture is understood as the agent (Smith, 2013), the mediator that transforms space in response to the needs of local society (King, 1976). Thus, in the case of Malia, culture subsequently adapted to serve these demands.

Malia's tourism follows market dynamics, fostering a capitalist consumption culture. The local population and seasonal workers form the labour force that supports this system (Williams, 2012; Linehan, Clark and Xie, 2020). Demographic trends and the seasonal fluctuations in the population of the Hersonissos municipality underscore the role of tourism. In 2021, the permanent population numbered 27,220, characterised by a strong youth presence and a high proportion of two- and single-member households, most employed as wage or salary earners. During the same year, the seasonal population, including visitors, seasonal workers, and permanent residents, reached 59,699, doubling the local population (Ministry for the Environment and Energy and Technical Chamber of Greece, 2024).

This disparity reveals a service-based, seasonal economy where employment is precarious and tightly bound to mass production and consumption, increasing competition and raising concerns about working conditions (Andriotis, 2003). The region's 18.7% permanent population, primarily European immigrants, indicates a mobile labour force, concentrating predominantly in Malia and Hersonissos (Ministry for the Environment and Energy and Technical Chamber of Greece, 2024).

While the tourism industry generates employment opportunities, it imposes a capitalist-oriented work culture that profoundly affects the lives of the permanent population. Seasonality introduces distinct temporal rhythms, rising to two parallel realities (Terkenli, 2005). During the tourist season, places and people become commodified. Economic dependency intensifies livelihood risk throughout the year, reinforcing pressure to meet tourists' expectations and demands. This opportunistic work culture fosters impermanence, weakens local ties, and contributes to a fragmented sense of community and place.

Staged Authenticity and Capitalist Consumption Culture in Malia

Beyond its labor dynamics, tourism promotes a narrative of cultural authenticity. Local traditions, cuisine, landscapes, and heritage are commodified for tourists. Local culture becomes a curated product, projecting simplified, often romanticised versions of history and identity (Linehan, Clark and Xie, 2020).

The representation of Greece to foreign visitors has been tied to its ancient civilisation. Archaeological sites have been preserved and marketed since the beginning of systematic tourism development, forming a central element of the national identity (Tournikiotis and Monemvasitou, 2012). In Malia, the Minoan civilisation remains a major tourist attraction. According to the Strategic Planning & Operational Program for the Region of Crete 2024–2028 (Gov, 2024), Crete is described as:

"...a fusion of cultures such as the Minoan, Byzantine, Roman...which, combined with its landscapes and recreational opportunities, is often chosen by tourists...as a destination of cultural interest and holidays."

Another cultural representation that mass tourism promotes is linked to the commercialisation of the planetary commons. Regional authorities' survey confirms that visitors widely perceive Crete as a destination of "Sun–Sea–Relaxation" (Gov, 2024), which is reinforced by the promotion of all-inclusive hotels and resorts along the Malia

coastline. Current tourism development plans do not challenge this triptych; they propose strategies to extend the tourist season throughout the year. The plan states:

"The Region of Crete is aware that the 'Sun and Sea' model will remain dominant... However, the uniqueness, and diversity of the destination 'Crete' is a 'treasure', and if we reintroduce it to the world, we will gain forever."

Therefore, the Strategic Planning & Operational Program for the Region of Crete 2024–2028 suggests the "Brand Equity" strategy, aiming to promote a "new" cultural value in tourism, which taps into localised "brands" of each area's unique characteristics and products. It targets "qualitative" tourism and private investment to enhance competitiveness, diversity, and innovation (Gov, 2024). The represented culture is designed to appeal to the ideal tourist, whose preferences guide how place identity is framed and marketed to drive economic growth. Authenticity is constructed through experiences tailored to visitor expectations and reproduced by local industry actors. Thus, profit becomes a principle (Childs and Williams, 1997), and cultural expression is subordinated to marketability.

Mass tourism introduces as well a new cultural identity rooted in capitalist consumption, modernity, and Eurocentrism[6]. In the post-war period, the GNTO employed modernity as a tool of "civilisation" for local populations (Tournikiotis and Monemvasitou, 2012). Today, it is reflected in consumerism and the adoption of globalised lifestyle standards.

Malia comprises a popular international youth tourism destination known for its nightlife, drug use, clubbing, and sex tourism. Foreign and Greek tour operators promote these experiences, targeting specific tourist groups. A micro-network of local business operators guides tourists to select venues and organises high-attendance events (Party Hard Travel, 2024). The often-accompanying violent behavior places considerable pressure on the local community (Terkenli and Bellas, 2007). Alternative package tours that market "adventurous" experiences, such as safari day trips to natural areas like the Lassithi Plateau, also raise concerns. The landscape and surrounding villages become spectacles for the tourist gaze, with little regard for the local community's lived reality or meaningful engagement with the place.

The Strategic Plan for Tourism Development in Crete (2024–2028) acknowledges the importance of tourist profiles, aiming to attract visitors from Europe, the USA, China, and Israel with higher educational and socio-economic backgrounds. These groups are perceived as more receptive to personalised, alternative tourism models such as agrotourism (Gov, 2024). Thus, even if the plan proposes a hybrid tourism system, incorporating alternative models to extend the tourist season, it does not address the structural issues of mass tourism, merely commodifying culture, landscape, and resources.

THE CULTURAL LANDSCAPE OF THE LASSITHI PLATEAU

The Lassithi Plateau, located 20 km south of Malia, is part of NATURA 2000 preservation since 1997 (Natura 2000, 2025), with an economy still rooted in agriculture. Situated at an altitude of 820–870 meters, it is surrounded by 11 villages (Figure 11) (General Secretariat for Spatial Planning & Urban Environment, 2024) arranged in a circular formation. It is known for its unique cultural landscape, which is historically tied to the 1950s, when 10,000 windmills on the plateau indicated the intense agricultural activity of the period (Demelis, 2017).

6 Eurocentrism is the belief that Europe serves as the primary reference point for understanding world history, civilisation, and human progress, often evaluating other societies based on their European models (Baylis, Smith and Owens, 2023).

Figure 11: Lassithi Plateau Map (Google Maps, 2019)

These windmills were an inventive industrial accomplishment based on a design created by Emmanuel Papadakis, a carpenter from the village of Psychro. His concept significantly enhanced the irrigation water pumping operation compared to the traditional Venetian water systems. The windmills (Figure 12) supported the growth of a self-sufficient local economy, based on vegetable production, while strengthening the community's ties to the land and developing a shared cultural identity ingrained in the local memory (Zaimakis et al., 2022).

Figure 12: Lassithi Plateau Windmills (National Index of Intangible Cultural Heritage, 2025)

The locals describe this period as a milestone in their communal life. At that time, livelihood was rooted in land cultivation and farming, with nearly every family in the surrounding villages owning a plot of agricultural land. The last windmill technician of Tzermiado village mentioned that families would contact him to build a windmill on their land, which typically took up to three days. While local artisans handled technical maintenance, each family was responsible for the daily operation of the windmills (Local No 1 and Local No2, 2025).

This shared responsibility fostered a collective consciousness, reflected in social interactions and the spatial

practices of the community. For example, when wind conditions were strong, neighbors would furl the sails of vulnerable windmills, even if they did not own them. They added as well that people cooperated closely, often sharing labor and agricultural products. (Local No 1 and Local No2, 2025). They mention:

"Back then, we didn't have extra labour hands. We cooperated, helping each other with agricultural work..."

Spatially, plots of land were not fenced, which endures today, symbolising deep mutual trust and a strong sense of place cultivated through communal living (Local No 1 and Local No2, 2025).

The community's well-being, self-sufficiency, and locally rooted economy, centered on family needs, cooperative use of windmills, and a collective sense of belonging, illustrate context-specific practices adapted to local conditions. These practices align with the principles of degrowth, which emphasise ecological sustainability and social cohesion (Kallis, Varvarousis and Petridis, 2022).

Impacts of Development Dynamics on the Lassithi Plateau's Cultural Landscape

The installation of the electrical grid in the 1960s, the introduction of new technologies, the rise of mass tourism along Crete's northern coast in the 1970s–1990s, and increasing urbanisation during the same period contributed to the transformation of the Lassithi Plateau's cultural landscape.

Depopulation was the first significant consequence, affecting the cultural agents of the landscape. Larger villages such as Tzermiado and Agios Georgios absorbed populations from smaller settlements, but both have experienced over 40%—50% depopulation since the 1960s (Figure 13). A few villages, such as Psychro and Kaminaki, indicated slight increases in active population due to their proximity to the tourist attraction of Dikteon Cave, but this was not sustained (Zaimakis et al., 2022).

The evolution of the population of the Plateau over time (1900-2011)

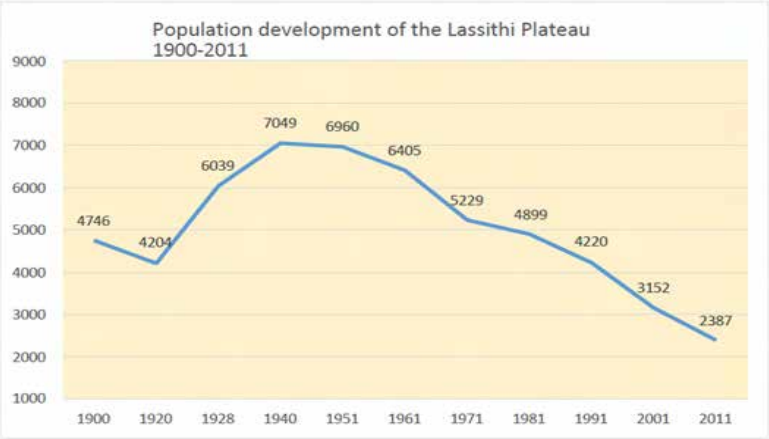

Figure 13: The Evolution of the Lassithi Plateau's population (1900-2011) (Zaimakis et al., 2022)

According to the 2021 census (ELSTAT, 2021), the Lassithi Plateau has 2,438 people, slightly increased from 2011 (ELSTAT, 2021). It has the highest employment rate among its economically active population (92%) despite having the lowest population density in the region (18/km²) (Zaimakis et al., 2022). This highlights a paradox: a productive core persists despite aging and population loss, especially in agriculture and tourism.

The second major shift came in 1965, when high-power water pumps replaced traditional windmills (Figure 14) (Demelis, 2017). The initial strong community relationships, maintained by a sustainable, circular system, were upset by the simultaneous collapse of windmills and population.

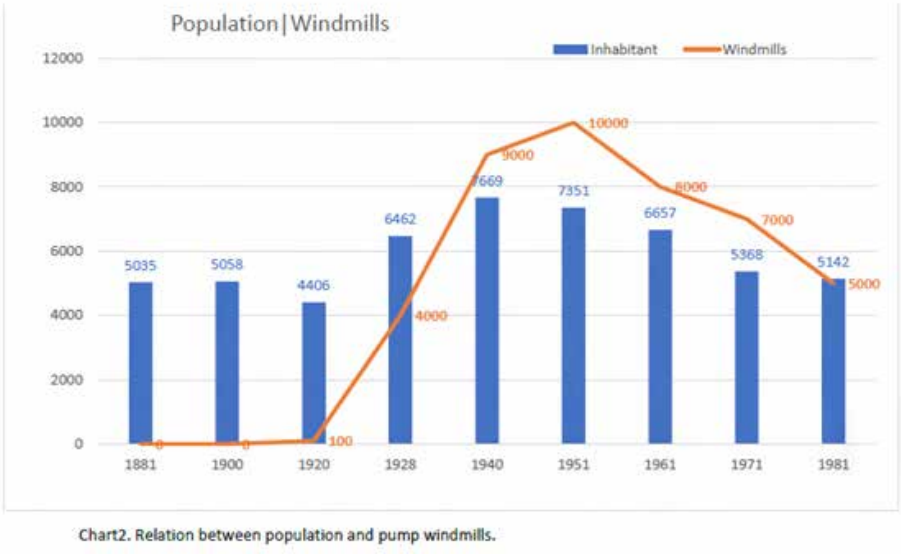

Figure 14: The Relation between Population and Windmill Transformation (Demelis, 2017)

Today, half the permanent population is economically inactive, while the active labour force is evenly split between the primary and tertiary sectors (Figure 15). However, the principles of agricultural work have changed. According to the farmers' union representative, depopulation and aging have led to the accumulation of land in the hands of a few full-time farmers. As he puts it:

"At least the plain is cultivated. Because if it's not rented, it'll be empty within a year."

Economic profitability is essential, and adopting modern irrigation technologies helps reduce costs and boost productivity.

"Being on an island increases costs for both farmers and stockbreeders... but product prices don't increase accordingly... but still, our products are worthwhile, so they sell" (Interview No.9, 2025).

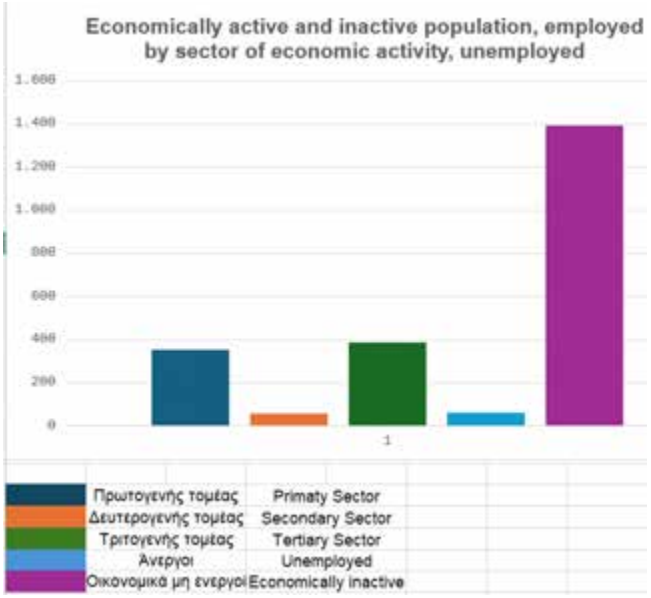

Figure 15: Economically Active and Inactive Population by Economic Sector (ELSTAT, 2021)

Few windmills remain, and most are in poor condition. According to a local mechanical engineer, only 150 have been restored to serve as tourism attractions and are no longer functional (Interview No.2, 2025; Interview No.9, 2025). The once vibrant cultural landscape of the Plateau has been reshaped by modernisation and economic growth, reflecting a detached relationship with the land (Figure 16).

Nevertheless, based on observations during the action research, the agent of culture is still present. Community ties remain visible through events and festivals organised by cultural associations and the municipality, the existence of an agricultural cooperative, and even informal gatherings at village cafés (kafenia). Most of the residents address depopulation as a significant challenge for the future. While some express hope that young people will return, others acknowledge outmigration as necessary due to limited employment opportunities and services.

Figure 16: Lassithi Plateau 2025 (Research Group's Own)

This raises questions: Are current tourism strategies sufficient to revitalise the area? And what role can the windmills play in this?

Tourism Development Strategies and Challenges in the Lassithi Plateau

The Strategic Planning & Operational Programme for Crete 2024-2028 aims to extend the tourism season by promoting alternative tourism forms based on site-specific characteristics and local products. These alternatives emphasise agro-tourism and eco-tourism, under a globally competitive tourism market branding "CRETE" (Gov, 2024).

For the Lassithi region specifically, the proposed strategies include (Karagiannis and Centre for Technological Research of Crete, 2024):

- Attracting investment for agrotourism development
- Supporting the primary sector by certifying and promoting local products within the tourism industry
- Promoting and protecting traditional settlements and fostering self-sustaining tourism centers
- Utilising areas of outstanding natural beauty
- Protecting forests and creating recreational parks for ecotourism

While expanding the tourism industry toward alternative models could benefit local employment and population retention, the current strategy remains profit-oriented, prioritising the needs and experiences of tourists. A revealing example is the phrase: "If the locals don't have a good time, the visitors won't have a good time either" (Gov, 2024). This framing subtly positions locals as a means to enhance the tourist experience, reducing their well-being to a functional index of visitor satisfaction.

Further evidence of the emphasis on growth is seen in references to large-scale infrastructure projects scheduled for completion between 2027 and 2030. The only concern noted is the potential for an "unpleasant image" of the island during the construction phase, mitigated by assurances that the infrastructure will match that of the tourists' home countries (Gov, 2024).

The SWOT Analysis included in the Strategic Plan for Crete 2024–2028 (Gov, 2024) highlights several structural weaknesses and threats accordingly:

- "Spatial over-concentration – Inadequate institutional and regulatory framework – Vulnerability of the Cretan landscape – Vulnerability of the tourism product – Fragmented actions and initiatives"
- "Deterioration of tourism resources – Exceeding carrying capacity and overtourism – Climate change – Rising costs – Abandonment – Weakening of the countryside"

At a policy level, the New Special Spatial Framework for Tourism 2024 lacks an overall development strategy and fails to address spatial over-concentration in line with carrying capacity indicators. Environmental priorities and landscape protection are also underestimated, considering promoting large-scale hospitality infrastructure in sensitive zones, such as islets or small islands. Moreover, supporting significant investments in small-scale regions redirects financial inflows away from the local economy and dismisses the long-term impacts on landscape, culture, and community (Spilanis, 2024).

The tourism development approach faces challenges due to misalignment between central and regional authorities. Lassithi Plateau's proximity to the Kastelli airport poses risks to capital-driven tourism dynamics. The lack of site-specific strategies and an adequate policy framework raises concerns about tourism's impact on local communities and landscapes. Considering that permission to install large-scale wind turbines in the Lassithi Plateau, a Natura 2000 zone, has already been approved, indicating no prevention towards extractivist processes (INSIST, 2018), increases the concerns about future development plans.

.

Regarding the windmills and their contribution to tourism development, local authorities and residents highlight their significant role in attracting visitors. They have shaped a distinct cultural identity, remaining deeply embedded in the collective memory of the local population. The iconic "postcard" image of the Plateau from the 1960s reinforces the community's vision for reviving the area as a thematic cultural park.

Local interviewees say restoring traditional windmills can rebuild the cultural landscape and revive local identity. This is perceived as an optimistic scenario for the future development of the villages. The municipality supports a model of slow tourism, with the proposed thematic park showcasing aspects of traditional agricultural life and windmill operation (Interview No.4, 2025; Interview No.6, 2025; Interview No.8, 2025; Interview No.9, 2025). A local stated (Interview No.9, 2025):

"The windmills are the identity of the Plateau...I would like to see the Plateau revitalised, with twice as many people living here. People from Heraklion who own property in the area should return and invest in it, maybe develop a windmill park for tourists, with cafés and taverns, so that visitors say: 'I'm going to the Plateau to stay, relax, and have a good time.'"

Although restoration efforts have occurred in the past, the lack of funding, specialised technicians, and ongoing maintenance has prevented them from continuing (Interview No.2, 2025). A complete restoration of the roughly

1,000 windmills on the Plateau could support an application for inclusion in UNESCO's list of Intangible Cultural Heritage. Such recognition would help protect the area from unregulated tourism expansion and encourage sustainable development strategies centered on environmental, cultural, and landscape preservation (World, 2018).

The tourism industry presents potential development, but the lack of a clear policy framework and profit-driven strategies prioritise tourist needs over local community well-being. Despite windmill restoration and possible UNESCO recognition, the process risks romanticising and modifying the cultural landscape for tourism purposes, highlighting the need for a reconceptualised tourism development model.

DEGROWTH AS A DECOLONIAL ALTERNATIVE FOR TOURISM DEVELOPMENT IN THE LASSITHI PLATEAU

Since tourism operates within an extractive capitalist system, suggesting alternatives to mass tourism is questionable regarding their contribution to a sustainable development model. Considering the landscape transformation of Malia and the upcoming risk for Lassithi Plateau due to the new airport or the wind turbines project, degrowth tourism could prevent these implementations and benefit the community, as happened in the following cases in Ecuador.

Degrowth Tourism: Indigenous Cases in Ecuador

Degrowth suggests a post-extractive economy prioritising community resilience and well-being, environmental balance, and intercultural exchange (Chassagne and Everingham, 2019). This system could better absorb tourism alternatives. Two Ecuadorian cases demonstrate how Indigenous communities utilise tourism to boost their local economy and prevent the construction of large-scale infrastructure projects that could harm nature and the environment.

Cotacachi canton[7], an ecological reserve in the UNESCO Biosphere Reserve, has implemented a tourism model based on an "anti-growth" concept to counter large-scale mining activities and protect nature and community well-being. The initiative includes eco-tourism and agro-tourism alternatives, empowering the community. The local government supports micro-scale enterprises and ensures development meets community needs. Planning strategies include strengthening ecotourism networks, cultural exchange, promoting reforestation, and environmental education. This case demonstrates how top-down and bottom-up mechanisms can promote tourism for economic and social development.
(Chassagne and Everingham, 2019).

The Añangu community in the Napo River implemented a tourism model called "Community-Owned Tourism" (COT) in 2007, which aimed to reclaim full ownership after financial mismanagement with cooperative NGO's. The COT aimed to limit migration, retain youth through tourism education, and provide employment opportunities tailored to local values. Tourism also helped redefine local culture through community-curated experiences, while revenues from tourism funded conservation efforts and small-scale renewable energy projects. Decision-making was done through monthly assemblies with equal participation, communal rules, and work parties to ensure collective responsibility (Renkert, 2019).

Both cases reveal tourism's benefits to local communities, advocating for their needs and preserving environmental values. Profit becomes a means rather than a goal, supporting projects that contribute to local autonomy.

Reconceptualising Tourism in the Lassithi Plateau

Despite contextual differences between the Lassithi Plateau and the case studies, several local elements form a fertile ground for a degrowth-oriented tourism model. These include:

7 The subdivision of a country based on political or administrative factors.

- Historically rooted culture of sharing is still evident among locals
- Strong sense of place
- Slow pace of life
- Collective action through the villages' Cultural Associations, the Farmers' Union, and the Lassithi Mountaineering Club
- Community self-sufficiency, grounded in land fertility and local production
- Desire to reclaim and preserve the cultural landscape
- Locals' desire for youth return

Drawing on the Plateau's natural beauty, agricultural activity, and lifestyle, tailored models of agro-tourism and eco-tourism could be developed in line with degrowth principles. A community-led cooperative could manage tourism locally, ensuring that decisions prioritise community well-being. This cooperative would represent local interests in dialogue with municipal or regional authorities, mediating an autonomous and bottom-up governance.

Collaboration between this cooperative and existing local groups, such as the Cultural Associations, the Farmers' Union, and the Lassithi Mountaineering Club, could strengthen community empowerment. This would encourage participatory governance and collective agency by uniting these actors within a self-sustaining system. Such an initiative could promote cultural exchange, local food products, and ceramics, thereby supporting the local economy. Considering the environmental advocacy of the Mountaineering Club, an active voice against industrial renewable energy developments[8] (Interview No.8, 2025), educational activities alongside organised hiking trails could be developed to raise environmental awareness among residents and visitors.

Regarding rebuilding the Plateau's cultural landscape and identity, a local mechanical engineer suggests that updated versions of traditional windmills could be reintroduced to pump underground water, a plentiful resource in the area (Interview No.2, 2025). Integrating this water system into the agricultural sector would revive the cultural landscape, serve the local economy through autonomous food production and consumption systems, and aid tourism by attracting visitors.

Collaboration with top-down governance structures is also crucial. As Vourdoubas argues, the active participation of local authorities, businesses, residents, and tourists is necessary to balance economic activity with sustainability. At the policy level, he advocates for eco-taxes, caps on tourist numbers to maintain sustainable levels, and restrictions on hotel development. Furthermore, a shift from quantity to quality in tourism could be incentivised through support to local tourism agents promoting eco-friendly models that encourage longer stays and higher visitor spending (Vourdoubas, 2025).

Thus, the Lassithi Plateau provides a promising context for a degrowth-tourism approach, enhancing the local economy and reclaiming community autonomy. Nonetheless, significant challenges must be acknowledged. As Buch-Hansen and Nesterova highlight, transitioning toward degrowth requires transformation across four interconnected planes[9]: material interactions with nature, social interactions, societal structures, and inner being. Implementing initiatives that challenge deeply rooted capitalist and individualistic structures is complex and demands personal commitment and a shared vision within the community. Degrowth, in practice, necessitates combining of bottom-up action and supportive eco-social policies (Buch-Hansen and Nesterova, 2023). Moreover, it remains a philosophical ideal rather than a widely adopted policy practice. The lack of detailed policy frameworks, concrete implementation strategies, and multi-scalar governance mechanisms presents significant ob-

8 Large-scale renewable energy resources.

9 Four planes emphasise the importance of reducing waste and pollution, promoting empathy and respect in social interactions, reducing competition and inequality, and personal transformation towards self-transcendence (Buch-Hansen and Nesterova, 2023).

.

stacles to a systemic transition (Fitzpatrick, Parrique and Cosme, 2022).

Consequently, the degrowth tourism model offers a promising vision, but its implementation remains uncertain. Rethinking tourism through a degrowth lens could offer locally beneficial mechanisms resisting extractivism and empowering communities for greater autonomy.

DISCUSSION

The study examines the relationship between tourism, space, and culture in Malia, revealing that mass tourism operates as a neo-colonial mechanism, reshaping the landscape and influencing local identity. The Lassithi Plateau, on the other hand, retains context-specific elements that align with degrowth principles, such as collective memory, sense of place, sharing culture, ecological awareness, and a slower pace of life. This presents a fertile ground for participatory governance, cultural resilience, and autonomy, encouraging the reconceptualisation of an economically viable and socially and environmentally recovering tourism model.

However, structural barriers exist, as current policy frameworks focus on attracting private investment and increasing tourist numbers. International case studies from Ecuador show that degrowth-inspired tourism is feasible and successful when rooted in community governance and supported by inclusive state policies. Thus, while the Lassithi Plateau faces challenges, it holds unique potential for embracing degrowth in tourism, reimagining development from the perspective of community well-being and ecological integrity.

CONCLUSIONS

The research suggests a decolonial approach to tourism, contrasting the neo-colonial mass tourism model in Malia. The Lassithi Plateau presents an opportunity for degrowth tourism, but challenges like lack of coherent policy and capitalist culture hinder its implementation. Combining community-driven initiatives with top-down policy frameworks could challenge extractivist models and promote community autonomy, offering a hopeful alternative to profit-driven tourism development.

AKNOWLEDGEMENTS

I would like to express my gratitude to the research group for sharing this unique experience during action research in the Lassithi Plateau and for their valuable feedback throughout the research process. I am also deeply thankful to the local community for welcoming and supporting us and letting us see their place through their eyes.

Exploring the genuine flavours of Tehran's cafes: a postmodern destination for tourism

Maryam Farash Khiabani
Urbanism, University of Art, Tehran, Iran
Maryamkhiabani86@gmail.com

Abstract
Globalisation and multiculturalism have significant impacts on food culture worldwide. Iran, with its diverse climate and local cuisine, has a rich variety of cooking styles. However, the situation is different in major bustling cities like Tehran; fast-food and routine restaurants that serve the same foods are primarily ordinary, and some traditional foods are also served. Meanwhile, some Western-style restaurants serve the most popular international foods. Here, some cafes play a different role as a third place.

This research aims to explore the role of Tehran's cafes in promoting and expanding Iranian local cuisine as a tourism destination. It was conducted using a qualitative approach, incorporating ethnography, and involved 22 locations with their users at the centre of Tehran city.

The research outcome reveals that in recent years, some of these cafés have profoundly impacted the introduction of local and traditional Iranian foods and beverages to tourists and new generations, while also serving as a reminder to elders. Some 'home cafés' symbolise the connection between yesterday and modern life: a postmodern destination. The main themes derived from the study portray these places as authentic, friendly, aesthetic, and creative, with a cultural vibe, highlighting the lost aspects of the city and the importance of cafés in preserving our past.

Keywords: gastronomy tourism, postmodernism, café culture, third place, conservation

1. Introduction

Food occupies a crucial position in local communities, cultural identities, and daily life. The use of regional and natural ingredients, distinct cooking styles, and even the choice of cutlery are central to this culinary tradition. However, international brands and cooking methods, particularly fast food, have become increasingly prevalent even in small towns worldwide. These modern influences, along with the global proliferation of food brands, often overshadow traditional local cuisines. In response, some communities are striving to reconnect with their culinary roots by reimagining traditional styles and creating welcoming spaces for diverse groups. These semi-public venues aim to foster connections that extend beyond routine conversations, addressing the limitations often found in fully public spaces. They also contribute to reviving the often-overlooked histories and cultures of the area, fostering a sense of belonging. As Ray Oldenburg describes, such places can evoke a sensation of being both at home and away from home, which he refers to as a "third place." Today, the necessity of these social spaces is increasingly recognised.

Even when the COVID-19 lockdowns commenced, a reporter from Boston inquired whether we believed third places would return. We responded confidently with a "Yes!" as we understood that online meetings and virtual happy hours could never substitute for in-person interactions (https://unesco.org). The swift rebound from COVID-19 indicates that the tourism market and industry, as well as many governments at various levels, have not yet acknowledged the importance of redirecting tourism growth (Butler, 2024). Herein, the vital role of these spaces, not merely as venues to serve specific items, but as social hubs, is evident in our currently isolated societies. Some of these spaces are not only welcoming to the locals but also cater to contemporary tourists.

This transition stems from recent changes in tourism concepts and cultural developments in our contemporary era. We are moving beyond traditional or even modern definitions of our needs, social lives, tourism, and other aspects of human experience. These encompass interdisciplinary terms that reflect current diversity and provide practical ideas for navigating daily life in this age of variety. This research aims to explore the current land-

scape of tourism and the role of one of the prominent examples of third places—cafés—in shaping gastronomy tourism in central Tehran, the capital of Iran. As the country's pioneering modern city, Tehran is witnessing new trends and diverse demands that seek to respond to its dynamic atmosphere.

1. The Era of Diversity: Postmodernism

Postmodernism is a set of conditions that currently influence all aspects of contemporary life, and whether we like it or not, it will continue to have this impact (Ward, 1997: 304). Although postmodernism emerged from various architectural movements and theorists in this field, Jean-François Lyotard is one of its most essential philosophers. He rejects the authoritarian view of history and society, which he refers to as meta-narratives (Lyotard, 1984). In his view, if we want to summarise the term postmodern as much as possible, it can be defined as a distrust of meta-narratives. For Lyotard and other intellectuals concerned with the ideal of freedom, only small narratives (Petits récits) and the proliferation of meanings are compelling in the postmodern era. Lyotard's postmodern mission is to oppose totalitarianism and totalising ideologies and to avoid the longing for unity (Nesbitt, 1997: 63-66).

Over the last two decades, instead of critical writers on modern urbanism directly engaging with postmodern texts, the emphasis on the effects of the modern approach to urbanism and the criticisms directed at it has led to the creation of works that explore the relationship between the city and its inhabitants, striving to create spaces that encourage greater public presence. One notable example of these works is Michael Sorkin's Twenty Minutes in Manhattan (2009), which, influenced by Jane Jacobs, describes the author's walks in Manhattan. He believes that modernity, influenced by science, has consistently faced ethical challenges and attributes the excessive focus on functionalism to this issue. In the writings of Jan Gehl (1987, 2010, 2013), the prevalence of car-centric spaces, resulting from modernist urban planning, is critiqued, highlighting the importance of pedestrians and urbanism that prioritises people.

One of the primary characteristics of postmodern urbanism is contextualism, which encompasses historical, physical, social, and public culture, in contrast to modern urbanism, which relies on a break from the past (Ellin, 1999: 185). Meanwhile, figures such as Jacobs, Mumford, Lynch, and others emphasised the importance of understanding the reality of the contemporary city. In contrast to the rupture of modernity, they also examined the matter of historical continuity within urban spaces. Another significant work from this period is Jonathan Raban's book, Soft City, published in 1974. Harvey describes this work as follows: "Soft City, written at that time, is a presumptive text that should not be interpreted as anti-modern; rather, it serves as a vital acknowledgement of the arrival of the postmodern era" (Harvey, 1990: 6). In this text, Raban provides a unique portrayal of life in his city, London. According to Harvey, Soft City outlines the concept of the postmodern city, and its depiction of urban life reflects the inherent and conditional aspects of becoming postmodern (Stevenson, 2014).

A part of this perspective relates to the evolving concept of the city. In the postmodern cultural context, the city, according to Castells (1989), has become a "collective organisation of consumption." Here, a duality emerges where the boundary between an alternative culture opposing the dominant culture, in its criticism of tradition or consumerism, can itself reproduce another pattern of consumption. In this pattern, even "simplicity" as a value becomes a commodity, which is often available only to a limited group. This notion recalls the saying, "I'm not rich enough to live simply," or the English proverb, "I'm not rich enough to buy cheap things," both of which emphasise the importance of quality over quantity. This perspective values and upholds high-quality, durable goods from the past. A lifestyle is celebrated and perpetuated in which "tradition" is revived through nostalgia; shops selling nostalgic items and spaces become popular, and the representation of everything is both marketable and priced. The closer the represented commodity is to its original form, while discarding the unpleasant aspects of tradition, the more it becomes accepted. Consequently, cultural items that revitalise traditions to meet current needs and lifestyles, rather than opulent spaces, are increasingly appealing due to their simplicity and are in demand among certain groups of people, primarily because of a growing awareness of climate challenges. After considering the effects of modernity and the use of machinery, along with the increase in air pollution, even some city dwellers are striving to reduce their carbon footprint by dining out less at restaurants and opting for

fast food alternatives, choosing to cycle and utilise public transport, prioritising their health, thereby transforming their everyday lifestyle. This shift also affects visits to other spaces and tourism cultures.

In terms of tourism, postmodern tourism is another term that warrants specific research (see Pecheniuk & Kiziun, 2022). Still, it can be briefly described as an open approach to different cultures, embracing pluralism, relativity, and diversity (Uriely, 1997). This approach utilises new methods to collect information about destinations and devises innovative journeys and paths rather than traditional ones. This reflects the growing tendency to seek individualised services and remain in small-scale enterprises (Ateljevic & Doorne, 2000). In this context, postmodern tourism encompasses specialised experiences, the rising attraction of nostalgia and heritage tourism, the growth of nature-focused tourism, the emergence of simulated tourism environments, and a variety of tourist experiences and motivations (Uriely, 1997). Post-tourists primarily consist of middle-class individuals who view oppositional travel as a valuable cultural experience and seek to differentiate themselves from conventional, modern, and mass tourists (Dujmović & Vitasović, 2015). In this study, the emphasis is on "postmodernism" as a "condition" and its impact on tourism destinations, approaches and the "cultural turn", as cultural scholars have mentioned (Jameson, 1998; Alexander, 1988) and not precisely on "postmodern tourism" as a specific term. One of the main changes in tourism definitions in the postmodern condition is the consideration of new categories and the importance of culture. One of them is food, cuisine, or gastronomic tourism, which is primarily characterised by its cultural aspects.

2. Gastronomy tourism

Gastronomy tourism centres on travel experiences focused on food and related activities. This form of tourism encompasses authentic, traditional, and innovative culinary experiences, including visits to local producers, attendance at food festivals, and participation in cooking courses (https://www.unwto.org/glossary-tourism-terms). Nowadays, tourism is facing various challenges, including climate change and environmental issues; thus, traditional concepts of tourism are no longer sufficient. Most approaches aim to make tourism more sustainable; consequently, new movements and activities are emerging. One aspect is that they pay greater attention to details and tourism businesses. Food and cuisine have always been inseparable from tourism. This is why "Gastronomy tourism", as a professional term in the tourism sector, is on the rise. Many international organisations are providing data on these perspectives, such as the United Nations tourism ambassadors for Sustainable Tourism, who come from diverse fields, including sport, entertainment, business, gastronomy, and more. As leaders in their respective fields, they volunteer their time and voices to amplify the message of tourism for sustainable development and equal opportunity. In recent years, the number of ambassadors has continued to grow, reflecting the sector's significance and diversity (https://www.unwto.org/un-tourism-ambassadors). Considering gastronomy as one of the tourist attractions, it is not solely about the dishes served, but also about the place and the people who are the hosts. From east to west, numerous efforts are made to create a positive impression for patrons as they enter, even if they are merely visiting for a meal. This experience is realised when all elements align—from the physical environment to the tastes and aromas, the hosts' behaviour, and the lasting memories formed in that space. That is why every detail matters here: the designs, plates, cutlery—everything, as if one is a guest in a thoughtfully prepared welcoming home (Figure 1).

Figure 1. A sample of a home café in Moscow, serving traditional foods and desserts with homely cutlery and décor (photo from the author's archive, June 2018)

One of the well-known examples of gastronomy and tourism in Iran is Rasht, which has been recognised as a Creative City[1] of Gastronomy by UNESCO since 2015. The Heritage Museum emphasises the importance of traditional cultural expressions, such as crafts, folk art, and gastronomy, with a particular focus on the distinctive cooking techniques that use Gamaj clay pots. Gastronomy plays a vital role in fostering community ties and facilitating intercultural and intergenerational conversations, while also serving as a significant catalyst for sustainable connections between urban and rural areas and promoting economic growth. To support this initiative, the city offers long-term loans designed to assist farmers. Furthermore, Rasht offers numerous workshops and vocational training opportunities in gastronomy, highlighting the sustainable production and consumption of nutritious food (https://www.unesco.org/en/creative-cities/rasht). As a Creative City of Gastronomy, Rasht aims to establish a local food museum to preserve and showcase traditional Guilanese food products and recipes, highlighting the region's indigenous culinary heritage.

Figure 2. Rasht's local foods (https://Isna.ir)

1 . For further reading on this concept, refer to "The Rise of the Creative Class" by Richard Florida.

The remarkable thing is that some of these spaces transcend mere establishments for food and drink; they serve as a creative central hub for gathering, experiencing, chatting, and fostering a sense of belonging. They are welcoming and enjoyable places for newcomers and locals alike. Over the years, sociologists and urban scholars have studied these spaces and proposed a new term to describe them, emphasising their characteristics. In the following, the concept of "third place" is described as one that can connect gastronomy tourism and urban studies within the cultural context.

3. Third place

While people in a bustling city spend time commuting and are occupied with work, some welcoming places open their doors to visitors, catering to the desires of both citizens and newcomers alike. A simple place to relax, chat with others, unwind from a hectic day, and enjoy the tastes and smells. Somewhere away from home, yet with the feeling of being at home. As urban sociologist Ray Oldenburg described, these places are the great and good places, the "third place".

He describes seven features for the third place, which include the following items (Oldenburg, 1991; Carmona, 2007):

1. As a Leveller, 2. Conversation is the primary activity. 3. Accessibility and accommodation. 4. The regulars. 5. A low profile. 6. The mood is playful. 7. A home away from home. This is a place that is generally inclusive and open to the public, with no official criteria for exclusive membership. People often select their companions, friends, and acquaintances from those who are socially akin to their class. The finest characteristic of a third place is conversation. Lively, exciting, and engaging talk, accompanied by smiles, winks, handshakes, pats on the back, and various gestures, serves as an initial indicator of the joy of being in a third place. This enthusiasm is maintained and sustained through enjoyable and entertaining conversations.

Third places that provide the best and most comprehensive services are those where people can go at any time of day or night, confident they will encounter familiar faces or someone to converse with. In fact, for anyone wishing to visit a third place, accessibility, location, and the time of use are highly important. A third place, as a physical space, is often straightforward. These venues, with simple decorations and comfortable, homely, informal furnishings, promote equality among all and foster numerous social interactions. Part of this lack of pretence also encompasses clothing; patrons do not come here to change or dress up as they might at home, but rather attend as they are. The overall atmosphere of a third place is not serious. It is characterised by enjoyment and harmony, with the motivation to continue being together. Therefore, anxiety and dissatisfaction have no place in such environments. Finally, while there may be distinctions between a home, defined as the centre of family life and a social unit formed by collective living, and a third place, the third characteristic of a home as "a loving environment" aligns well with most third places. Psychologically and in terms of the emotional support it offers, a third place closely resembles a good home. These places serve as venues for meeting, connection, and socialising. People typically visit locations that resonate with their self-image, self-concept, and social values. When individuals encounter a place that supports their social values, it is classified as a type of "meaningful" third place (Sugiyama et al., 2015, cited in Joo, 2020: 337).

Many third places are viewed as facilitators for fostering relationships through formal or informal activities, providing a physical space for building communities within society and enhancing social cohesion (Cabras & Mount, 2017: 72). These locations aim to offer meaningful design that resonates with users who understand and appreciate these values. This is how the interactions formed in these spaces enable one customer to influence another. The shared values and sense of loyalty among the patrons of these places reinforce the feeling of a common purpose in cultivating this community, bringing people closer together (Meshram & O'Cass, 2018).

Oldenburg's examples of third places include public spaces such as parks and plazas, as well as commercial spaces like cafés and pubs. This concept has also been applied to other semi-public places, including libraries, markets, chain restaurants, and even virtual spaces (Dolley, 2020: 3). Additionally, various studies from around

the world have examined other examples of the third place in their respective countries (Wohl, 2016; Dolley, 2020; Farash Khiabani & Shahabian, 2019). Many of these studies demonstrate that the connections formed in third places enhance relationships within neighbourhoods and various social groups, reduce loneliness and isolation, and foster a sense of security and belonging (Dolley, 2020: 3).

4. Methodology and background

Among the various research methods, this study employs a qualitative approach grounded in Creswell's five-category classification (Creswell, 2007). Of these five qualitative methods, this research selects ethnography as its approach. This research design facilitates broader investigations of individuals in diverse societies at both the city level and on smaller scales. As a qualitative approach, it centres on the stories shared by participants (Pardo & Prato, 2018: 38). In the urban context, urban ethnography emerged as a research method within the sociology department at the University of Chicago (Ocejo, 2013: 4-5).

It is essential to consider several key points during the ethnographic process. Time and its management are among the most critical factors, as the risk of inconclusive research is prevalent in ethnographic studies. Therefore, a specific timeframe should be established for this study. One of the most critical considerations in applying ethnographic methods is how to conduct the study from the outset to the conclusion. Thus, the process of implementing the method and the relationship with the ethnographer must be taken into account. A defining characteristic of the ethnographer is their long-term presence in the research context. In this study, considering that the researcher has been a frequent user and actively engaged in the studied spaces for over 10 years, spending considerable time in these environments and having served as a manager of one of these spaces for several years, along with previous studies conducted about these spaces, provides a strong foundation for familiarity with the places and their patrons. Following this, the research process is well-designed and illustrated in Figure 3.

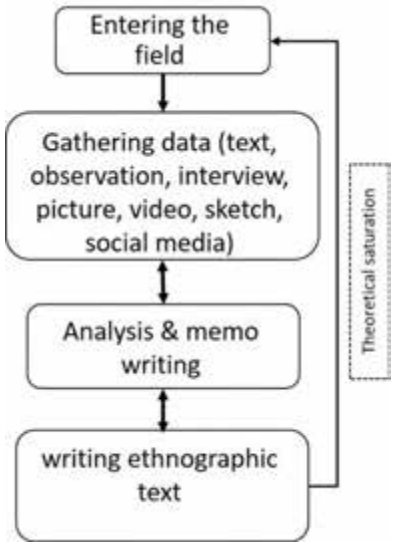

Figure 3. The process of applying the ethnographic approach (Farash Khiabani, 2021)

In applying the method within the cultural context of Tehran's central area, alongside the researcher's deliberate observations, 22 semi-structured, in-depth interviews were conducted. It is essential to note that the conditions and interviews carried out during the research process prompted the researcher to utilise snowball sampling, also known as network sampling or chain referral sampling. This method entails introducing the next member or case after establishing a connection with one of the initial cases (samples) (Blaikie & Priest, 2018). The process of data analysis and coding in this research is depicted in Figure 4. Moreover, all diverse outputs of ethnographic work, despite their differences, involve producing text that includes ethnographic analysis not only as a cognitive activity but also as a form of writing (Hammersley & Atkinson, 2007: 190). Thus, generating an ethnographic text is a key outcome of this research, which details the situation and functions of the studied locations.

• Interpreting and contextualising findings

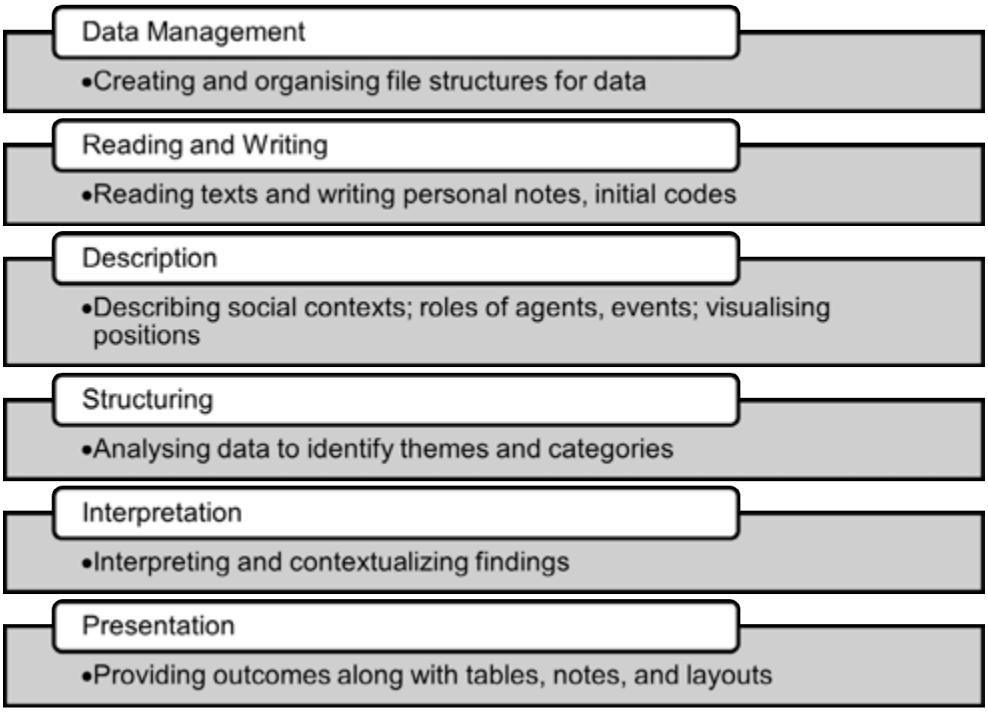

Figure 4. Data analysis and presentation based on the ethnographic research (based on Creswell, 2007).

Before exploring the contemporary cafés in Tehran, it may be beneficial to review various activities in cafes, their significance as tourist attractions, and their potential for future studies based on texts as this journey unfolds.

4.1. The potential of cafes

In the book 'The Starbucks Experience', the concept of the 'third place' is frequently referenced. While this book discusses the experience of this globally renowned coffee brand, the various store experiences worldwide affirm the brand's role as a third place from the author's perspective. Not only are the managers aware of this, but many customers across the globe also view these stores as their second home or the third place after home and work. Essentially, people enter environments where they feel personally valued and respected, fostering meaningful connections. Everything the coffee shop does is geared towards ensuring customers have a positive and perhaps joyful experience, whether it involves purchasing a quality drink or a food item. This third place must cultivate warmth and unique intimacy that set it apart from the first two places where most people reside, namely home and workplace (Michelli, 2006: 29). This is the very point that Christopher Alexander emphasises in his early sketches for the design of Lintz Café. He views the building as a place for ordinary people to rest. Every room, porch, and window is thoughtfully selected to create a comfortable environment—a place where each individual can feel completely at home (Alexander, 1981: 22).

Lintz Café is nestled in nature, embodying a distinctive identity shaped by its local surroundings. Referring to identity as the 'spirit', it is believed that the designer does not need to assign an abstract, intrinsic spirit to a place to create coherent meaning. In describing this place, Schulz considers the study of a locale as an examination of the events and occurrences that transpire there; thus, a collection of happenings, shapes, colours, smells, and textures forms the character or identity of a place. He establishes a connection between architecture, place, and cultural identity, asserting that the experience of being in a place is an experience of perceiving its meaning (Norberg-Schulz, 2000). These descriptions of certain well-known Western cafés serve as an introduction to high-

light their importance as essential and notable attractions. In the following, Tehran's cafés and their potential are viewed as inviting spaces for various groups.

4.2. Tehran's cafes

In numerous studies, Tehran is examined as a representation of political and social power (Farash Khiabani, 2021). The citizens of Tehran, possessing various forms of economic, social, and cultural capital, exhibit a significant degree of social control. A large portion of the country's population, comprising students or individuals with a university education and thus capable of influencing the masses, resides in this city. Cultural diversity and varying lifestyles should also be taken into account, as they contribute to the social fabric of this city. Conversely, Tehran's status as the capital and its centralist policies have fostered the multiculturalism of society, with the process of modernity being adopted here earlier than in other parts of Iran. In recent years, the renovation of old houses and shops for new commercial purposes has gained momentum, particularly in central Tehran. Recognising the value of these spaces and the interest from various artistic and cultural groups has significantly influenced this trend. The relationship between this perspective and the tourism sector is evident, as similar spaces can be found in cities such as Rasht, Isfahan, and Shiraz. These cities are part of an active tourism network rich in nostalgic signifiers and elements of Iranian identity, from architecture to cuisine. Tehran, along with the creation of small cultural spaces, presents imaginative and often fantastical representations of each of these cities.

In the history of this city, as the host of Iranian modern cafés (Figure 5), these establishments became venues for intellectuals and their gatherings. The modernisation process enabled women to visit cafés, transforming them into spaces that were no longer exclusively for men (Farash Khiabani & Goldar, 2024; Shahri, 1992)

Figure 5. Loghanteh Café, the symbol of Iranian modern Café, was located in the central district of Tehran during the Pahlavi period, as documented by the author from the Loghanteh Café Museum's archives in Tehran.

Tehran's cafés serve as valuable social hubs for local communities and are among the most popular tourist spots in Iran; however, they are unfortunately overlooked by the government. Despite this neglect, these venues, cherished by their patrons and supported by the private sector, have the potential to act as urban catalysts. By changing our perspective on them and recognising their capabilities, they can have a significant impact on the community. Since the 2010s, cafés have emerged as key symbols of contemporary culture, often maintaining a strong connection to historical identity with the aid of social media. Elements such as the cafés' interior and exterior design, including furniture, cutlery, and cuisine, significantly influence the business and are vital for attracting customers. The Digital Revolution has eliminated barriers, allowing cafés to cater to a broader audience beyond just students or specific social classes; they now accommodate families and people of various ages and backgrounds (Farash Khiabani & Goldar, 2024).

In Tehran, traditional Iranian buildings feature inward-facing courtyards, various rooms, porches, and balconies that protect against street noise, ensuring privacy and tranquillity. Cafés, galleries, bookstores, and mixed cultural spaces opening in old mansions represent new concepts that primarily change function without altering

the core elements of the original design and all building spaces during the reuse process. The narrative of space is equally significant. Some have been designed or created by renowned artists (such as the No. 14 gallery, by Nezam Ameri, a student and colleague of Frank Lloyd Wright), while others have left a lasting impression in users' minds. Regrettably, some of these spaces are losing their identity due to government mismanagement, and the private sector has been increasingly active in recent decades. By repurposing these locations as cafés or cultural hubs, a vibrant tourism movement is emerging in the central area of Tehran (Figure 6).

Figure 6. Reconstruction of a house and reusing it as a café (a sample of home-café) in the centre of Tehran by traditional and authentic Iranian items (photo by the author, April 2025)

One of the main special features of these places is their menu, which serves traditional Iranian foods and drinks. More so than typical restaurants, they offer local dishes from various regions of Iran, spanning from the north to the south (Figure 7). They celebrate the value of local or seemingly simple foods, such as Ab-Dugh-Khiar, Panir-Bureshte, and Baghali-ghatogh from Northern Iran, Bandari sandwich from the south, and Gheime-nesar from the centre, among others. Even some of the items that serve both cold and hot drinks are traditional Iranian items that are not easily found in other countries.

Figure 7. Panir boreshteh and Mirzaghasemi, Northern Iranian traditional foods, served in one of the central home-cafes in Tehran (Photo by the author, May 2025)

5. Discussion

This study's examination of Tehran's contemporary cafes reveals a tourism destination that emphasises a specific type of tourism: gastronomy. This cultural aspect serves as one of the attractions of these spaces, showcasing all their cutlery, accessories, furniture, and more (Figure 8). These destinations offer opportunities for postmodern tourism, thanks to their diverse attractions, including local interactions, historical sites, varied tourist demographics, authentic experiences, nostalgia, and small-scale businesses. By analysing customers' and visitors' perceptions of Tehran's contemporary cafes, particularly home cafes, over the past decade on social media (primarily through Instagram in Iran), we aim to uncover insights into the destination's image, including any shifts from traditional or luxury restaurants to a friendly, cosy, homely experience.

The account given by the sample interviewee about their experience at one of the locations during a semi-structured interview is as follows:

(A one-hour conversation with a 35-year-old woman):

"Whenever I have free time between my activities and since there's no chance to go home, the best option is to visit a café, enjoy a comforting drink or meal, read a book, have an engaging experience, and pass the time until my next task. The cosy atmosphere of this café makes it feel less formal than a restaurant. I love the aroma of coffee, traditional foods, and the rows of books nearby. Those who arrive here typically seek culture, a sense of familiarity, and a friendly atmosphere. Although my home is on the north side of the city (Pasdaran), I travel to the city centre for work, to visit cafés, and to socialise. This area is more my hangout spot; I feel a stronger connection with the people here. Music has also influenced my attraction to this environment; it is calming".

Figure 8. The collection of traditional kitchen items in Khaneye 1308 Café in Tehran (photo from the author's archive, January 2022)

Even during special periods like Ramazan, some café menus have changed to serve traditional items, regardless of whether one is fasting or not; these fresh and nostalgic offerings can capture customers' attention (Figure 9).

Figure 9. Persian Eftar in a café, special foods for Ramazan (Sangak bread, cheese, date, zoorbia bamie, soup and a cup of tea) (Photo by the author, April 2025)

5.1. Coding process

It is important to note that in qualitative research, the researcher employs classification-based reasoning alongside intuitive and implicit interpretations to identify findings that appear similar or evoke a sense of likeness, allowing for their grouping (Saldana, 2013: 14). Thus, the coding process can be tailored to align with the specific needs of the study (Ibid: 102). Table 1 illustrates the coding process employed in this research, as described in the methodology section, which facilitates the emergence of categories and themes, ultimately culminating in a

textual description of the cafés studied, along with the cultural context that develops within them.

One of the key features of the third type of spaces examined is the potential for dialogue and interaction within these environments. Cafés lead the way in this aspect. They have successfully attracted a diverse clientele across various age groups. Notably, those cafés situated in historic houses with open spaces and courtyards have managed to maintain a vibrant atmosphere and enjoy greater popularity compared to others that lack such elements. Beyond facilitating conversations among acquaintances, these spaces also promote interactions with strangers, fostering the formation of new connections. Social tables, individual and co-working areas, social tables, and conversations following meetings all provide opportunities for interaction among individuals who may not know each other. These venues create an environment conducive to familiarity and dialogue around shared interests. They play a significant role in shaping identity, while also being influenced by the identities of their users. This reciprocal relationship is highly effective in the development and evolution of these spaces.

Table 1. A sample of the coding process

Initial Coding	Categories	Themes
Chatting	Conversation	Authenticity
Conversation		
Friendly space	Entertaining and nice	Aesthetic
Laughter and happiness	Enjoy, Openness	
Calm environment	Peaceful	Friendly
Serene atmosphere		
Cozy place		
Free costume	Safety	Creativity
No unwelcome gazes or disparaging remarks in contrast to other public or semi-public spaces	Freedom	
Acting freely, without any authority	No judgement	Cultural vibe
Different groups	Variety, Diversity	
Easy to get by public transport or on foot	Accessibility	
Nostalgic items: cutlery, cups, plates, furniture,	Nostalgia	
Original tastes and smells	Originality	
Traditional and folk music	Genuineness	
Homy styles and smells	Identity	
Well-designed (building, furniture, cutlery, etc.)	Creativity Beauty	
Close to the essence of nature in the area, such as having a yard, flowers, and ponds	Natural and fresh	

Many of the dishes served in these cafés showcase authentic recipes from various Iranian regions, often presented in traditional settings. The café format lends validation to their authenticity. Furthermore, the inclusion of a selection of Iranian cold and hot beverages, crafted from herbal extracts, enhances the cafés' menus, making them exceptional, genuine, and diverse. These offerings are seldom found in luxury restaurants, allowing tourists to experience the authentic flavours of Iran. The cafés create a remarkable environment for new generations to connect with their cultural heritage while catering to contemporary needs, establishing them as post-modern destinations. The primary themes identified through the coding process characterise these venues as authentic, aesthetically mindful, creative, and friendly, all wrapped in a vibrant cultural atmosphere.

5.2. The ethnographic text

Elaboration and description of the study's findings, along with drafting the text, are considered critical stages in the ethnographic research process. In this method, the ethnographer, much like a writer, must craft a compelling narrative. The author's preferences and skills greatly influence the language and style employed in the writing. This text can take various forms, including a tale, description, analysis, interpretation, or thematic narration (Creswell & Poth, 2018: 442-443). While the primary draft of the text arising from this research is extensive, a sample paragraph summarising the key findings is provided below:

In today's Tehran, many downtown cafés have transformed into more than just establishments along the street; they have become homes away from home. These cafés seamlessly blend various activities, evolving into vibrant social and cultural hubs. They host exhibitions, sell cultural and artistic products, and provide spaces for dialogue and connection, offering a cosy and inviting atmosphere. These venues embody a particular way of life, serving not only a diverse selection of food and drinks but also functioning as platforms for interaction and conversation.

Several of these cafes are situated in historic buildings that resonate with Iranian identity, where the atmosphere, music, furniture, and decorations highlight traditional Iranian elements. Others are strikingly modern, embodying Tehran's contemporary character. Despite their visual disparities, all these establishments strive to be vibrant gathering places for socialising, storytelling, and the affirmation or reconstruction of cultural identity. Additionally, each cafe caters to its specific audience.

A notable aspect of these cafes is their function as places for a brief respite and relaxation. A primary reason for their widespread popularity is the prevailing sense of simplicity and intimacy within their atmosphere. From the exterior façade to the interior design, furnishings, details, and even the staff's attitude, there is an aura of authenticity and modesty. Luxurious or ostentatious elements have no place here. These characteristics contribute to making these spaces feel more like "homes." As a result, the food culture in these cafes often embodies a sense of homeliness and reflects local values.

Traditional Iranian beverages, including herbal syrups and native distillates from various regions, are favoured over sodas and modern drinks. Alongside international cuisines, local dishes from different Iranian ethnic groups are served, enriching the menu. Iranian stews and even forgotten recipes, which are seldom found in restaurants, play a crucial role in enhancing the dining experience. Older patrons visit these establishments to relive nostalgic memories and enjoy flavours that evoke their childhood homes, reminiscent of their grandmothers' cooking. Meanwhile, younger generations seek to connect with a bygone era, immersing themselves in the food and ambience of neglected spaces as they craft their own Iranian identity within a vibrant modern city, essentially searching for a piece of home.

In today's world, these cafés go beyond being simple establishments for dining and refreshments; they embody a "third place"—an enriching experience that few other venues can provide. These spaces offer a harmonious blend of colours, aromas, and flavours, set against an authentic backdrop enriched by the depth of Iranian culture, lending a greater significance to the experience.

6. Conclusion

Over the past two decades, cafés have become one of the main attractions and tourist destinations in the heart of Tehran. The recognition of the importance of Iranian vernacular architecture has spurred a movement to renovate historic buildings into vibrant cultural spaces and cafés. This repurposing of heritage homes not only helps in preserving the city's historical elements—both tangible and intangible—but also enriches the urban landscape. The flourishing economy has fuelled the aspirations of these café ventures, transforming them into sought-after locales.

These inviting venues offer a unique ambience that feels like home, allowing patrons to escape the chaos of the city. Visitors can engage with their surroundings, participate in informal activities and conversations, and connect with a diverse range of social groups. Cafés provide a sanctuary from modern loneliness, fostering a sense of security and belonging within the community. Notably, it is not just the architecture and physical features that attract visitors; the food, tableware, décor, and intricate details of culinary traditions are also celebrated, nurturing a deep appreciation and respect for the culture.

For many, these cafés evoke a sense of nostalgia, reminding them of the traditional Iranian image of old brick houses surrounded by lush gardens filled with fresh food and beverages. For newer generations, they symbolise a sense of meaning, identity and belonging to a setting that contrasts with their previous environments. While many cafés have devoted patrons, they also foster a welcoming atmosphere for newcomers. The establishments in historic Tehran serve a crucial function as tourist attractions, having evolved to accommodate contemporary demands in culinary offerings and cuisine. This adaptability not only enhances the cultural landscape but also fosters an environment that is both vibrant and inviting. By blending innovation with authenticity, these venues create a rich and immersive experience for visitors, thereby contributing significantly to the city's unique cultural identity.

Abstract

The tourism-driven revitalisation of traditional villages has become a significant pathway to achieving historical and cultural heritage preservation and promoting rural revitalisation in the new era. Among these efforts, constructing the regional characteristics of the built environment in villages is a critical aspect of revitalisation. Tourists' emotional perceptions during their spatial experiences in tourism villages serve as an important evaluation metric for the localization characteristics of the space. This study investigates the correlation mechanisms between 13 spatial elements—such as spatial organization, morphology, and interface—and tourists' emotional types and intensity preferences based on the distribution characteristics of tourists' emotional perceptions in the street spaces of tourism villages. Facial expression images of tourists in different village streets were collected via smartphone photography, and a deep learning model, YOLOv5, was trained using a manually labeled dataset to recognize and quantify four types of emotions: smile, surprise, calm, and negative emotions. To enhance recognition accuracy, the model's performance was improved using techniques such as RGB value adjustment, flipping, and augmentation. Subsequently, a multiple regression analysis was conducted to identify the street space elements influencing tourists' emotional perceptions. The results indicate that the proposed model optimization methods effectively identified tourists' emotions under various scenarios with high accuracy. Regression analysis revealed that spatial segmentation factors of streets had a regression coefficient of 0.184, making it a key factor affecting tourists' perceptions. The findings identified five typical street space elements that positively influence tourists' emotions. Based on these results, recommendations for optimizing street space to enhance tourists' perceptions were proposed, offering support for improving street space tourism experiences and promoting the sustainable development of traditional villages.

Keywords: Facial expression perception; Deep learning; Alley space; Tourist Emotions; Yuan Family Village

1. Introduction

With the rapid development of tourism, the revitalisation of traditional village tourism has become an important way to preserve historical and cultural heritage and promote rural revitalisation. In this process, the construction of village built environment with regional characteristics is an important link. The emotional perception of tourists in the physical space experience of tourism villages has received increasing attention from researchers as an important indicator for evaluating spatial regionalisation characteristics. Since the 1960s, with a rethinking of modern urban planning dominated by functional zoning, there has been a growing emphasis on diverse and vibrant urban spaces [1]. Vibrant cities and streets enhance the happiness of residents and social cohesion[2] Urban street vitality has become an important indicator for assessing the attractiveness and potential of urban neighbourhoods for sustainable development[3] . Many design theories have been proposed to create a vibrant urban street space and a growing body of methodological and empirical research has been conducted on the role of relevant physical environment variables, such as street interface continuity, greening ratio, ground floor interface transparency, and commercial density, in fostering street activities and vitality[4]. It is postulated that AI may also be employed in the monitoring of human activities in urban settings. For instance, Yamadaetal. employed Deep Learning to assess the impression of a city, while Liuetal. utilised machine learning to construct buildings dedicated to the evaluation of the quality of maintenance management. Furthermore, technologies for the monitoring of shop-goers using cameras installed in shops are becoming increasingly feasible[5]. Existing research has mostly focused on the economic and socio-cultural impacts of tourism, with less attention paid to tourists' emotional responses in specific spaces. However, emotional perception, as a core component of tourists' experience, Not only affects tourists' overall impression of a tourist village, but also directly relates to their satisfaction and willingness to return. Therefore, it is of great theoretical and practical significance to explore the association mechanisms between the spatial organisation, morphology, and interface of streets and lanes and tourists' emotional types and intensity preferences.

2. Materials and Methods

2.1 Materials

Yuanjia Village, situated in Liquan County, Xianyang City, Shaanxi Province, is one of the second batch of traditional villages included in the list of traditional villages in China. It is a natural village with a long history in the Guanzhong area of Shaanxi Province(Figure 1). The location and layout of Yuanjia Village are centred on the base of the village, with a landscape pattern that reflects the traditional Chinese landscape pattern of "Facing the sunny side and backing the shady side, backed by mountains and facing water" This was a pattern that is typical of the Guanzhong area, and it was one that Yuanjiacun has better preserved and continued. The village was surrounded by mountains and by blue water. Secondly, Yuanjia Village was a popular tourist destination. As of 2023, the number of tourists visiting Yuanjia Village annually exceeded 8 million, with the village's annual tourism output value exceeding RMB 1.2 billion. [6]making it one of the villages with the highest number of annual visitors in the Shaanxi region. Based on the annual increase in tourist visitation and tourism revenue, Yuanjia Village was one of the traditionally successful villages in tourism transformation. The substantial number of tourists provided universality and data credibility for sampling to simulate and test tourist perceptions.

Therefore, the research focused on six typical streets within the core scenic area of Yuanjia Village (as shown in Figure 1): namely, Ancestral Hall Street (CT=248m), Muslim Quarter Street (HM=156m), Snack Street (XC=428m), Sanqin Ancient Street (SQ=704m), Academy Street (SY=413m), and Kangzhuang Old Street (KZ=383m).

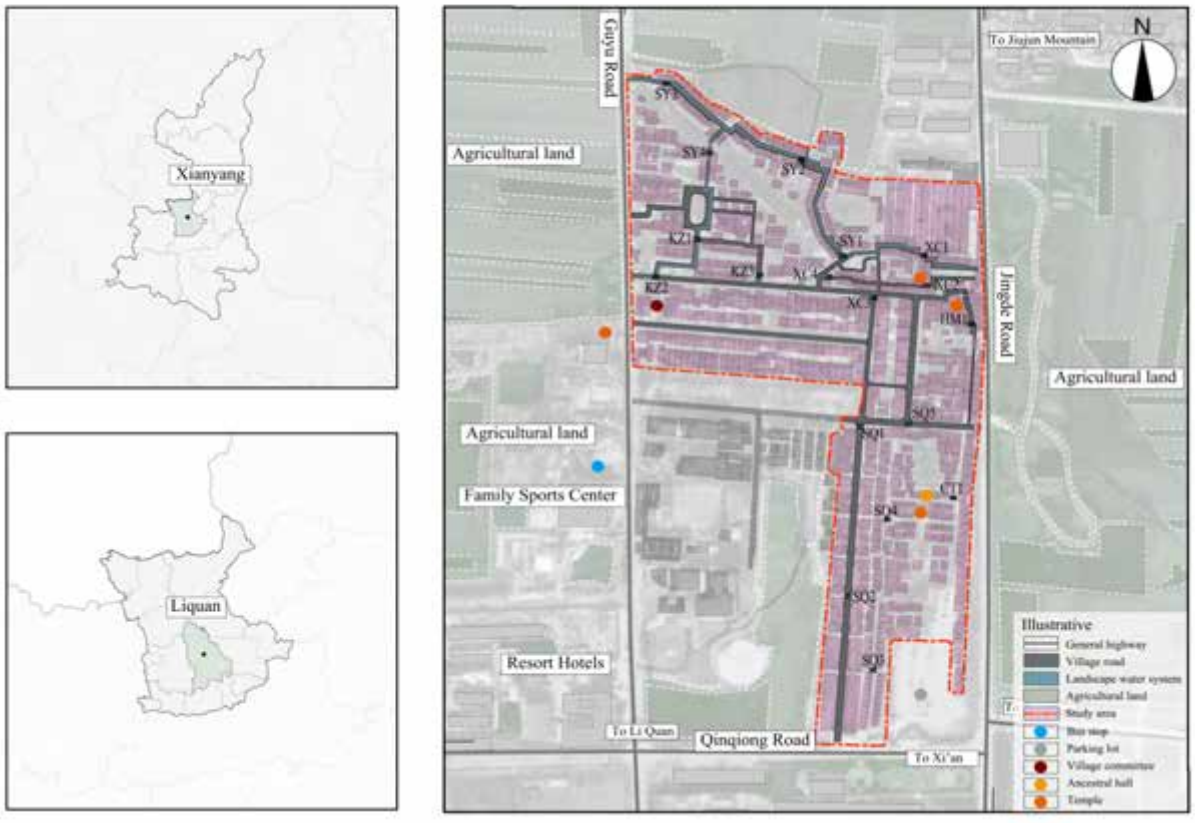

Figure 1 Location and Layout Plan of Yuanjia Village

2.2 Methods

Building upon previous studies, this paper proposes an improved YOLOv5 recognition model and pathway designed to more accurately and comprehensively capture facial information from photographs. Furthermore, it correlates optimised subjective perception values of tourist emotions with built environment contexts. Through multiple regression analysis, the study aims to explore the impact of the optimised approach on facial expressions and emotions of tourists in spatial environments.

2.2.1 Facial expression recognition based on YOLOv5

YOLO, as a mature algorithm in the field of deep learning, has demonstrated superior performance and practical feasibility in numerous domains and real-world applications. The facial expression analysis component of this study drew inspiration from the research of Shungo Noji[7], Liu[8], leveraging deep learning algorithms. By training deep learning models with real-world photos of different time periods and age groups, the study aimed to enhance the accuracy of facial expression recognition for specific populations in a designated area (where the images were collected). Furthermore, in subsequent experiments, the study hypothesized smile rates among different populations at various locations. In this study, the YOLOv5 model was employed (The YOLO-v5 model, which is based on a real-time object detection algorithm). The YOLO network was optimised to minimise the loss function as the training objective to achieve object detection. The YOLO network consisted of convolutional layers specifically designed for object detection tasks and included three key modules as illustrated in Figure 1: 1. Backbone network: This module was used to extract generic feature representations and served as a high-performance classifier network. 2. Neck network. The three convolutional networks collaborated to produce the final output of object detection results. In this training session, we employed common data processing techniques such as Shungo Noji. This included adjustments to the data such as angle rotation, flipping, and slight changes in colour and brightness to achieve more robust results. The model was pretrained using the COCO dataset and further fine-tuned and trained using a proprietary dataset. The proprietary dataset used in this experiment consisted of 1006 images collected in the autumn of 2023, with a resolution of 3840 x 2160 pixels. 85% of these images were used as the training dataset, and 15% were used as the test dataset to validate the efficiency and accuracy of the model.

In this experiment, the processed dataset underwent various data augmentation techniques, including colour variations, image flipping, and image overlays. Mild colour adjustments were applied, encompassing changes in brightness, contrast, and saturation to simulate different lighting conditions, thereby enhancing the model's adaptability to various lighting environments. Additionally, horizontal and vertical flipping of images was performed to help the model better handle variations in object orientations and improve its recognition capability. Through image overlays, we merged two or more images to create more complex scenes. This method helped the model learn how to accurately identify and locate objects amidst complex backgrounds and multiple object occlusions. These data augmentation techniques effectively increased the diversity and complexity of the training data, significantly boosting the model's robustness and generalization ability. This enhancement allows the model to more accurately detect and classify target objects in practical application scenarios of this experiment.

Emotions including Smile, Lugh, Neutral, and Negative Emotion were identified and quantified to determine the facial expression recognition across various street locations. This process culminated in calculating the subjective smile rate (E) for different streets by integrating the total number of recognized expressions, as detailed in the formula.(1):

$$E=(\sum Smile + \sum Lugh)/(\sum Smile + \sum Lugh + \sum Neutral + \sum Negative\ Emotion)$$

2.2.2 Selection and calculation methods of influencing factors

This study drew inspiration from previous research on measurement systems for street and lane indices[9[10], and integrated with the spatial characteristics of Yuanjiacun's streets and lanes, established an index system influencing tourists' emotional perception. These influencing factors were categorized into three aspects: spatial form, spatial function, and spatial interface (Figure 2).

Primary indicator	Secondary indicators	Description	Labeled Name	Assignment Description
Street scale and form	Scale of streets	Width	KD	/
		Ratio of street height to width	GKB	Average building height on both sides/street width
	Street of morphology	Relationship of Streets to Landforms	JX	Responding to the terrain
		Ground Level Elevation	DMTS	Whether the height difference between the transition space and the street space is significant
	Transition space	Space Separation	KJFG	Significant height difference between transitional space and street space
Street floor characteristics		Façade Setbacks/Extensions	LMHT/WY	Separation of spaces from the street through parapets, low walls, planters
	Permeability	Longitudinal Subgrade	ZSDM	ground-floor openings/extension to interior
		Longitudinal cross roads	ZXJCDL	Vertical alleyway entrance at ground-floor
	Curvature	Straight bottom elevation	PZDCLM	Vertical projection of ground-floor elevation is straight
		Curvature Curvilinear ground-floor	QZDCLM	ground-floor façade is clearly angled, projecting or recessed
Lane space function	Type of business	Six business types: hotel, food, shopping, attractions, entertainment, and public services	F	Assign values 1-6
	Business density	Density of commercial POI points per 10m street buffer zone	FD	FD=?POI_num/Road_length
	Business mixing degree	Street mix (diversity) is the mix of vitality-related POIs in the Street buffer.	FH	FH(X) = -?P(xi)logP(xi) (i=1,2,..n)

Figure 2 Classification and Assignment of Street Space Element Data

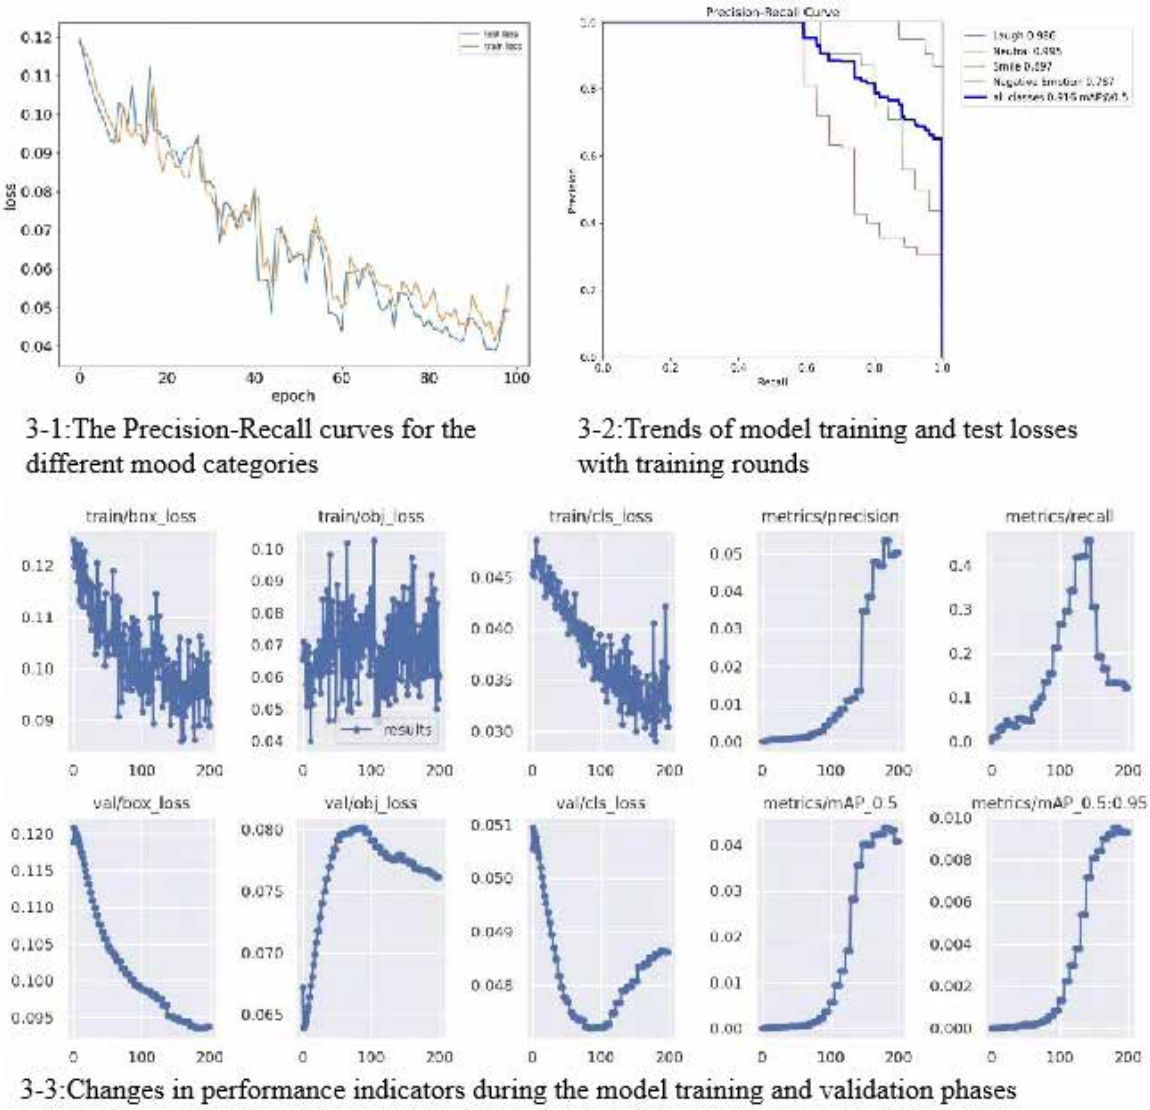
3. Discussion

3.1 A more efficient method for facial expression recognition

This study utilized Anaconda3 to construct the environment, ensuring stability and independence during model training and execution. Additionally, labelImg Python scripts were employed for manual annotation, and annotations were cross-checked by fellow research lab members to guarantee dataset accuracy. The implementation was based on the PyTorch framework, and training and testing were conducted on a single NVIDIA RTX A5000 GPU. To optimize the network, we utilized stochastic gradient descent (SGD) optimizer with a learning rate of 0.01 and momentum of 0.9.

To overcome challenges such as a small private dataset, significant outdoor lighting variations, and complex backgrounds, data augmentation techniques were employed. These included deformation, adjusting RGB values, flipping, and overlaying methods to enhance model robustness by augmenting the dataset. In terms of model performance metrics analysis, we achieved relatively high average precision (AP) values, indicating stable performance on the test data. The deep blue line in Figure 1 represents the average of the four classification results. Through multiple validations, AP values consistently exceeded 0.9, meeting the experiment's precision requirements (Figure 3-1). Additionally, Figure 3-2 illustrates the loss values during the training process. The experiment utilized test loss X and Y axes to monitor performance changes, aiming for minimal validation loss. As shown in the graph, with increasing epochs, the loss gradually decreased, indicating effective training.

In conclusion, graphical representations of AP values and loss values demonstrated expected progress in model training. Significant improvements in classification accuracy and continuous reduction in loss values validate the effectiveness of our approach.



3-1:The Precision-Recall curves for the different mood categories

3-2:Trends of model training and test losses with training rounds

3-3:Changes in performance indicators during the model training and validation phases

Figure 3 Detection of Tourist Facial Expressions Using Recognition Models

The graph depicted various performance metrics of our model during the training and validation phases (Figure 3-3). The horizontal axis represented training epochs, while the vertical axes indicated loss values and performance metrics. The graph was divided into two rows: the upper row illustrated performance on the training data, and the lower row showed performance on the validation data. Throughout the training process, both train/box_loss and train/cls_loss steadily decreased as training epochs progressed, indicating ongoing improvements in bounding box prediction and classification accuracy. Despite fluctuations, train/obj_loss exhibited an overall decreasing trend, signifying a reduction in object detection loss. Precision (metrics/precision) and recall (metrics/recall) on the training data demonstrated noticeable upward trends, underscoring enhanced precision and comprehensiveness in detection and classification tasks. During validation, significant declines were observed in both val/box_loss and val/cls_loss, further confirming the model's efficacy during training. However, val/obj_loss initially showed a minor increase followed by a decline, suggesting potential early-stage overfitting. Average precision on the validation set (metrics/mAP_0.5 and metrics/mAP_0.5:0.95) progressively improved, particularly within stricter threshold ranges (0.5 to 0.95), indicating consistent performance across diverse evaluation criteria and effective detection of various data types. In summary, these findings from the graphical representations underscored the anticipated advancements in model training, with enhancements observed across both training and validation metrics over successive epochs, validating the efficacy and resilience of our methodology.

Although there remained scope to enhance accuracy in recognizing negative emotions, this was attributed to the limited number of data samples for negative emotions and the imbalance in quantities across different data types. Overall, these metric fluctuations reflected effective training of our model and a steady improvement in performance. Despite fluctuations during training, the model consistently demonstrated strong learning capability and adaptability on both training and validation data, suggesting its potential for achieving favorable outcomes in practical applications ()
